Hilbert's tenth problem

David Hilbert, in the 10th of the list of 23 problems he published after a famous lecture in 1900, asked his audience to find a method that would answer all such questions.

Hilbert's tenth problem (H10)

Find an algorithm that solves the following problem:

input: *a multivariable polynomial $f(x_1, \dots, x_n)$ with integer coefficients*

output: *YES or NO, according to whether there exist integers a_1, a_2, \dots, a_n such that $f(a_1, \dots, a_n) = 0$.*

More generally, one could ask for an algorithm for solving a **system** of polynomial equations, but this would be equivalent, since

$$f_1 = \dots = f_m = 0 \iff f_1^2 + \dots + f_m^2 = 0.$$

Theorem (Davis–Putnam–Robinson 1961 + Matiyasevich 1970)

No such algorithm exists!

In fact they proved something stronger...

Family of polynomial equations

$$\begin{array}{rcl} & & \vdots \\ x_1^2 + x_2^2 + x_3^2 + x_4^2 & = & -2 \quad \text{NO} \\ x_1^2 + x_2^2 + x_3^2 + x_4^2 & = & -1 \quad \text{NO} \\ x_1^2 + x_2^2 + x_3^2 + x_4^2 & = & 0 \quad \text{YES} \\ x_1^2 + x_2^2 + x_3^2 + x_4^2 & = & 1 \quad \text{YES} \\ x_1^2 + x_2^2 + x_3^2 + x_4^2 & = & 2 \quad \text{YES} \\ & & \vdots \end{array}$$

The set of $a \in \mathbb{Z}$ such that

$$x_1^2 + x_2^2 + x_3^2 + x_4^2 = a$$

has a solution in integers is

$$\{0, 1, 2, \dots\} =: \mathbb{N}$$

Bjorn Poonen

Definition

$A \subseteq \mathbb{Z}$ is **diophantine** if there exists

$$p(t, \vec{x}) \in \mathbb{Z}[t, x_1, \dots, x_m]$$

such that

$$A = \{ a \in \mathbb{Z} : p(a, \vec{x}) = 0 \text{ has a solution } \vec{x} \in \mathbb{Z}^m \}.$$

Example

The subset $\mathbb{N} := \{0, 1, 2, \dots\}$ of \mathbb{Z} is diophantine,
since for $a \in \mathbb{Z}$,

$$a \in \mathbb{N} \iff (\exists x_1, x_2, x_3, x_4 \in \mathbb{Z}) x_1^2 + x_2^2 + x_3^2 + x_4^2 - a = 0.$$

Definition

$A \subseteq \mathbb{Z}$ is **listable** if there is a Turing machine such that A is the set of integers that it prints out when left running forever.

Example

The set of integers expressible as a sum of three cubes is listable.

(Print out $x^3 + y^3 + z^3$ for all $|x|, |y|, |z| \leq 10$, then print out $x^3 + y^3 + z^3$ for $|x|, |y|, |z| \leq 100$, and so on.)

Halting problem

Can one write a *debugger* to solve the **halting problem**?

input: program p and natural number x

output: YES if p on input x eventually halts,
NO if it enters an infinite loop.

Theorem (Turing 1936)

No such debugger exists; the halting problem is unsolvable.

Sketch of proof:

Enumerate all programs. If we had a debugger, we could use it to write a new program H such that for every $x \in \mathbb{N}$,
 H on input x halts \iff program x on input x does *not* halt.

Taking $x = H$, we find a contradiction:

H on input H halts $\iff H$ on input H does not halt. \square

Negative answer to H10

What Davis-Putnam-Robinson-Matiyasevich really proved is:

DPRM theorem: Diophantine \iff listable

(They showed that the theory of diophantine equations is rich enough to simulate any computer!)

The DPRM theorem implies a negative answer to H10:

- The unsolvability of the halting problem provides a listable set for which no algorithm can decide membership.
- So there exists a *diophantine* set for which no algorithm can decide membership.
- Thus H10 has a negative answer.

“Diophantine \iff listable”

has applications beyond the negative answer to H10:

- Prime-producing polynomials
- Diophantine statement of the Riemann hypothesis

The set of primes equals the set of positive values assumed by the 26-variable polynomial

$$\begin{aligned}
 & (k + 2)\{1 - ([wz + h + j - q]^2 \\
 & \quad + [(gk + 2g + k + 1)(h + j) + h - z]^2 \\
 & \quad + [16(k + 1)^3(k + 2)(n + 1)^2 + 1 - f^2]^2 \\
 & \quad + [2n + p + q + z - e]^2 + [e^3(e + 2)(a + 1)^2 + 1 - o^2]^2 \\
 & \quad + [(a^2 - 1)y^2 + 1 - x^2]^2 + [16r^2y^4(a^2 - 1) + 1 - u^2]^2 \\
 & \quad + [((a + u^2(u^2 - a))^2 - 1)(n + 4dy)^2 + 1 - (x + cu)^2]^2 \\
 & \quad \quad + [(a^2 - 1)l^2 + 1 - m^2]^2 \\
 & \quad \quad + [ai + k + 1 - l - i]^2 + [n + l + v - y]^2 \\
 & \quad + [p + l(a - n - 1) + b(2an + 2a - n^2 - 2n - 2) - m]^2 \\
 & \quad + [q + y(a - p - 1) + s(2ap + 2a - p^2 - 2p - 2) - x]^2 \\
 & \quad \quad + [z + p\ell(a - p) + t(2ap - p^2 - 1) - pm]^2\}
 \end{aligned}$$

as the variables range over nonnegative integers

Riemann zeta function

The series

$$\zeta(s) := \frac{1}{1^s} + \frac{1}{2^s} + \frac{1}{3^s} + \dots$$

converges for real numbers $s > 1$.

But $\zeta(s) \rightarrow \infty$ as $s \rightarrow 1$ from the right.

- Within \mathbb{R} , there is no way to extend $\zeta(s)$ to an analytic function across 1 to define it to the left of 1.
- But in \mathbb{C} , one can go *around* 1, to get values like

$$\zeta(-1) = -\frac{1}{12}.$$

Some people pretend that this means that

$$1 + 2 + 3 + \dots = -\frac{1}{12}.$$

Riemann hypothesis

Riemann hypothesis (from 1859, still not proved)

All zeros of $\zeta(s)$ except for $-2, -4, -6, \dots$ satisfy $\text{Re}(s) = 1/2$.

The DPRM theorem gives an explicit polynomial equation that has a solution in integers if and only if the Riemann hypothesis is *false*.

Construction of this polynomial equation.

- One can write a computer program that, when left running forever, will detect a counterexample to the Riemann hypothesis if one exists.
- Simulate this program with a diophantine equation. □

H10 over rings of integers

Given a number field k , its **ring of integers** is

$$\mathcal{O}_k := \{\alpha \in k : f(\alpha) = 0 \text{ for some monic } f \in \mathbb{Z}[x]\}.$$

Example

If $k = \mathbb{Q}(i) = \{a + bi : a, b \in \mathbb{Q}\}$, then $\mathcal{O}_k = \mathbb{Z}[i]$.

Conjecture

H10/ \mathcal{O}_k has a negative answer for every number field k .

Question

Why can't we just replace \mathbb{Z} by \mathcal{O}_k in the proof of DPRM?

Answer:

- For the **Pell equation** $T: x^2 - dy^2 = 1$ (where $d \in \mathbb{Z}_{>0}$ is a fixed non-square), $\text{rank } T(\mathbb{Z}) = 1$.
- For most number fields k , it is impossible to find tori T such that the needed conditions on $\text{rank } T(\mathcal{O}_k)$ hold.

On the other hand, there exist other algebraic groups. . .

Hilbert's tenth problem over \mathbb{Q}

Undecidability in
number theory

Bjorn Poonen

Question

*Is there an algorithm to decide whether a multivariable polynomial equation has a solution in **rational numbers**?*

The answer is not known!

- If \mathbb{Z} is **diophantine over \mathbb{Q}** , then the negative answer for \mathbb{Z} implies a negative answer for \mathbb{Q} .
- But there is a conjecture that implies that \mathbb{Z} is *not* diophantine over \mathbb{Q} :

Conjecture (Mazur 1992)

For any polynomial equation $f(x_1, \dots, x_n) = 0$ with rational coefficients, if S is the set of rational solutions, then the closure of S in \mathbb{R}^n has at most finitely many connected components.

Related problems

H10 over \mathcal{O}_k
H10 over \mathbb{Q}
First-order sentences
Subrings of \mathbb{Q}
Status of knowledge

- H10 is about truth of **positive existential sentences**

$$(\exists x_1 \exists x_2 \cdots \exists x_n) p(x_1, \dots, x_n) = 0.$$

- Harder problem: Find an algorithm to decide the truth of arbitrary **first-order sentences**, in which any number of bound quantifiers \exists and \forall are permitted, e.g.,

$$(\exists x)(\forall y)(\exists z)(\exists w) (x \cdot z + 3 = y^2) \vee \neg(z = x + w).$$

If variables range over **integers**, this is undecidable (since it is harder than the original H10).

But what if variables range over **rational numbers**?

Theorem (Robinson 1949, P. 2007, Koenigsmann 2016)

The set \mathbb{Z} equals the set of $t \in \mathbb{Q}$ such that

$$\begin{aligned}
 & (\forall a, b)(\exists x_1, x_2, x_3, x_4, y_2, y_3, y_4) \\
 & (a + x_1^2 + x_2^2 + x_3^2 + x_4^2)(b + x_1^2 + x_2^2 + x_3^2 + x_4^2) \\
 & \cdot \left[(x_1^2 - ax_2^2 - bx_3^2 + abx_4^2 - 1)^2 \right. \\
 & \left. + ((t - 2x_1)^2 - 4ay_2^2 - 4by_3^2 + 4aby_4^2 - 4)^2 \right] = 0
 \end{aligned}$$

is true, when the variables range over rational numbers.

Corollary (Robinson 1949)

There is no algorithm to decide the truth of a first-order sentence over \mathbb{Q} .

Building on these ideas, Koenigsmann (2016) proved also that the complement $\mathbb{Q} - \mathbb{Z}$ is diophantine over \mathbb{Q} .

This was generalized to number fields by Jennifer Park.

Subrings of \mathbb{Q}

There are rings between \mathbb{Z} and \mathbb{Q} :

Example

$$\mathbb{Z}[1/2] := \left\{ \frac{a}{2^m} : a \in \mathbb{Z}, m \geq 0 \right\}$$

Example

$$\mathbb{Z}[1/2, 1/3] := \left\{ \frac{a}{2^m 3^n} : a \in \mathbb{Z}, m, n \geq 0 \right\}$$

In general, if $S \subseteq \mathcal{P} := \{\text{all primes}\}$, one can define

$$\begin{aligned} \mathbb{Z}[S^{-1}] &= \text{the subring of } \mathbb{Q} \text{ generated by } p^{-1} \text{ for all } p \in S \\ &= \left\{ \frac{a}{d} : a \in \mathbb{Z}, d \text{ is a product of powers of primes in } S \right\} \end{aligned}$$

Proposition

Every subring of \mathbb{Q} is of the form $\mathbb{Z}[S^{-1}]$ for a unique S .
