## 18. Lecture 15: Vector bundles and $K^0_c(X)$ Wednesday, 8 October

We start with an involution which is a finite rank perturbation of  $\gamma_1$ ,  $\gamma_1 + a$ ,  $\Pi_k a = a \Pi_k = a$ . Thus, restricting to  $\mathbb{C}^2 \otimes \Pi_k$  which we can identify with any other 2k-dimensional vector space we have an involution

(18.1) 
$$I = I_+ - I_- \text{ acting on } \mathbb{C}^2 \otimes \operatorname{Ran}(\Pi_k) \equiv \mathbb{C}^{2k}.$$

Then consider a further slice  $\mathbb{C}^2 \otimes (\Pi_{3k} - \Pi_k)$ . Here we can identify  $\operatorname{Ran}(\Pi_{3k} - \Pi_k)$  with  $\mathbb{C}^{2k}$  and so write the restriction of  $\gamma_1 \otimes \operatorname{Id}$  as

(18.2) 
$$\gamma_1 \otimes (I_+ + I_-).$$

So the part of the involution in  $\mathbb{C}^2 \otimes \operatorname{Ran}(\Pi_{3k})$  is

(18.3) 
$$(I_{+}(x) - I_{-}(x)) \oplus E_{+} \otimes (I_{+} + I_{-}) \oplus -E_{-} \otimes (\Pi_{3k} - \Pi_{k}),$$

$$E_{+} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad E_{-} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

Now, the  $I_{-}$  part of the first block can be rotated rotated with the  $I_{-}$  part of the second block and thus there is an homotopy leading from (18.2) to

(18.4) 
$$(I_+(x) + I_-(x)) \oplus E_+ \otimes (I_+ - I_-) \oplus -E_- \otimes (\Pi_{3k} - \Pi_k)$$
$$= (E_+ + E_-) \oplus \Pi_k + E_+ \otimes (I_+ - I_-) \oplus -E_- \otimes (\Pi_{3k} - \Pi_k)$$

This computation proves:-

**Lemma 21.** Any  $f \in \mathcal{C}^{\infty}_{c}(X; \mathcal{H}^{-\infty}_{iso}(\mathbb{R}^{d})$  is homotopic through such maps to one of the form

(18.5) 
$$\tilde{f}(x) = \gamma_1 \otimes (\operatorname{Id} - \Pi_{3k}) + \begin{pmatrix} I(x) & 0\\ 0 & -\operatorname{Id} \end{pmatrix} \otimes (\Pi_{3k} - \Pi_k) + \begin{pmatrix} \operatorname{Id} & 0\\ 0 & \operatorname{Id} \end{pmatrix} \otimes \Pi_k$$

where I(x) is a smooth family of involutions acting on the 2k-dimensional space which is the range of  $\Pi_{3k} - \Pi_k$ .

In consequence  $\tilde{f}$  commutes with  $\gamma_1$  and has positive and negative projections of the form

(18.6) 
$$f_{+}(x) = E_{+} \otimes (\mathrm{Id} - \Pi_{3k} + I_{+} + \Pi_{k}) + E_{-} \otimes \Pi_{k}$$
$$\tilde{f}_{-}(x) = E_{-} \otimes (\mathrm{Id} - \Pi_{k}) + E_{+} \otimes I_{-},$$

which therefore commute (with each other of course and) with  $E_+$  and  $E_-$ . One really might as well write this in the more symmetric form

(18.7)  

$$\begin{aligned}
\tilde{f}_{+}(x) &= E_{+} \otimes (\mathrm{Id} - P^{-}(x)) + E_{-} \otimes (P^{+}(x)), \\
\tilde{f}_{-}(x) &= E_{-} \otimes (\mathrm{Id} - P^{+}(x)) + E_{+} \otimes (P^{-}(x)), \\
\Pi_{l} P^{\pm} &= P^{\pm} \Pi_{l} = (P^{\pm})^{2} \text{ and } P^{+} P^{-} = P^{-} P^{+} = 0
\end{aligned}$$

where l = 3k. Then (18.6) shows that we can take  $P^+ = \Pi_k$ ,  $k \leq l$ ; by considering -I it follows similarly that one can arrange by homotopy that  $P^- = \Pi_k$  instead. Note that it follows from (18.7) that (18.8)

$$\operatorname{ind}(\hat{f}(x)) = \frac{1}{2}\operatorname{tr}\left((E_{-} + E_{+}) \otimes P^{+}(x) - (E_{+} + E_{-}) \otimes P^{-}(x)\right) = \operatorname{rank}(P^{+}) - \operatorname{rank}(P^{-}).$$

## BKLY08

This gives us the basic relationship between vector bundles and smooth families of involutions, namely  $P^+ \ominus P^-$  is a 'superbundle' – the formal difference of two bundles – which also determines the element of  $\mathrm{K}^0_{\mathrm{c}}(X)$  fixed by  $\tilde{f}$ . Said a different way, the space  $\mathcal{H}^{-\infty}_{\mathrm{iso}}(\mathbb{R}^k)$  of involutions itself has an involution

acting on it, namely

(18.9) 
$$\mathcal{H}_{\rm iso}^{-\infty}(\mathbb{R}^k) \ni \gamma_1 + a \longmapsto \gamma_1(\gamma_1 + a)\gamma_1 \in \mathcal{H}_{\rm iso}^{-\infty}(\mathbb{R}^k)$$

This is however 'trivial' as far as homotopy is concerned. Namely

**Lemma 22.** Any map  $f \in \mathcal{C}^{\infty}_{c}(X; \mathcal{H}^{-\infty}_{iso}(\mathbb{R}^{k}))$  is homotopic to some

(18.10) 
$$\tilde{f} \in \mathcal{C}_c^{\infty}(X; \mathcal{H}_{iso}^{-\infty}(\mathbb{R}^k)) \text{ satisfying}$$
$$\gamma_1 \tilde{f}(x) = \tilde{f}(x)\gamma_1 \text{ and } a = \Pi_k a = a\Pi_k$$

for some k.

Proof by Jesse and Paul, not proofread yet. First suppose that

$$f_i: X \to \mathcal{H}_{iso}^{-\infty}(\mathbb{R}^d), \ i = 0, 1,$$

are maps with  $f_1 \sim f_2$ . Then there is a map

$$\begin{array}{rcl} : \left[0,1\right] \times X & \rightarrow & \mathcal{H}_{iso}^{-\infty}\left(\mathbb{R}^d\right) \\ F(0,x) & = & f_0(x) \\ F(1,x) & = & f_1(x) \end{array}$$

f By the above lemma, there is a homotopy from F to a map  $\widetilde{F}$  so that  $\widetilde{F}$  has a decomposition

$$\widetilde{F}(t,x) = E_+ \otimes \left( Id - 2P_-(t,x) \right) - E_- \otimes \left( Id - 2P_+(t,x) \right),$$

and that furthermore  $P_{-}$  can be chosen so that  $P_{-} \equiv \pi_{k}$  for some big k, so in particular  $P_{-}(0,x) = P_{-}(1,x)$ . It follows that the  $P_{+}(t,\cdot)$  define isomorphic bundles for all t by an open and closed argument (openness is always true, and the closed part follows from the constancy of the rank.)

For the converse, suppose we have an equivalence of bundles

(18.11) 
$$P^0_- \oplus P^1_+ \oplus S = P^1_- \oplus P^0_+ \oplus S = \mathbb{C}^l,$$

over a space X. Then we choose an identification of  $\mathbb{C}^l$  with a subspace of  $\mathcal{S}(\mathbb{R}^d)$ so that  $\pi_l$  is projection thereon, and define

$$f^i = E_+ \otimes \left( Id - 2P_-^i \right) - E_- \otimes \left( Id - 2P_+^i \right)$$

for i = 0, 1. The lemma then follows by using (18.11) and rotating blocks as follows.

$$\begin{split} f^{0} &= E_{+} \otimes \left( Id - 2P_{-}^{0} \right) - E_{-} \otimes \left( Id - 2P_{+}^{0} \right) \\ &= E_{+} \otimes \left( (Id - 2P_{-}^{0})\pi_{l} \right) - E_{-} \otimes \left( (Id - 2P_{+}^{0})\pi_{l} \right) \\ &+ E_{+} \otimes \left( (Id - 2P_{-}^{0})(Id - \pi_{l}) \right) - E_{-} \otimes \left( (Id - 2P_{+}^{0})(Id - \pi_{l}) \right), \end{split}$$

so just deal with the middle line, so that we only consider  $f^0 (E_+ \otimes \pi_k + E_- \otimes \pi_k)$ , which is

$$= E_+ \otimes (Id_{\mathbb{C}^l} - 2P_-^0) - E_- \otimes (id_{\mathbb{C}^l} - 2P_+^0) \\ = E_+ \otimes (P_+^1 + S - P_-^0) - E_- \otimes (P_-^1 + S - P_+^0)$$

Everything here is in blocks, so you can rotate the two S's into one another, which switches their signs. This and another substitution gives

$$= E_{+} \otimes (P_{+}^{1} - S - P_{-}^{0}) - E_{-} \otimes (P_{-}^{1} - S - P_{+}^{0})$$
  
$$= E_{+} \otimes (2P_{+}^{1} - Id_{\mathbb{C}^{l}}) - E_{-} \otimes (2P_{-}^{1} - Id_{\mathbb{C}^{l}})$$
  
$$= E_{+} \otimes (Id_{\mathbb{C}^{l}} - 2P_{-}^{1}) - E_{-} \otimes (Id_{\mathbb{C}^{l}} - 2P_{+}^{1})$$

Adding this back to the part we ignored gives the homotopy we wanted.

This is a direct consequence of Lemma 21.

**Proposition 16.** Any map  $\tilde{f} \in \mathcal{C}^{\infty}_{c}(X; \mathcal{H}^{-\infty}_{iso}(\mathbb{R}^{k}))$  satisfying (18.10) is of the form (18.7) and two such maps  $\tilde{f}_{i}$  are homotopy if and only if there is a vector bundle S over X which is identified with  $\mathbb{C}^{p}$  outside a compact set and a bundle isomorphism

(18.12) 
$$\operatorname{Ran}(P_1^+) \oplus \operatorname{Ran}(P_2^-) \oplus S \longrightarrow \operatorname{Ran}(P_2^+) \oplus \operatorname{Ran}(P_1^-) \oplus S$$

which is the natural identification outside a compact set; here the ranges of the projections are considered as vector bundles over X.

Proof.

The adiabatic Bott element constructed ealier

(18.13) 
$$B = \gamma_1 \otimes \operatorname{Id} + D, \ D \in \Psi_{\operatorname{sl}\,\operatorname{iso}}^{-\infty}(\mathbb{R}; \mathbb{C}^2)$$

is an involution,  $B^2 = \text{Id}$ , and satisfies

(18.14) 
$$\sigma_{\rm sl}(B) = \gamma_1 \otimes \operatorname{Id} + \delta(t,\tau) = b(t,\tau)$$
$$R(B) = \gamma_1 \otimes (\operatorname{Id} - \Pi_1) + \operatorname{Id} \otimes \Pi_1 \in M(2,\mathbb{C}) + \Psi_{\rm iso}^{-\infty}(\mathbb{R};\mathbb{C}^2)$$

which is (18.7) with  $P^- = 0$ ,  $P^+ = \Pi_1$ , l = 1.

Completion of proof of Proposition 15. To prove the even semiclassical lifting property we can take an element in the form (18.7). Consider

(18.15) 
$$\ddot{B} = \gamma_1 \otimes (\mathrm{Id} - P^+(x) - P^-(x)) + B \otimes P^+(x) - B \otimes P^-(x)$$
$$\in \mathcal{C}^{\infty}_c(X; M(2, \mathbb{C}) + \Psi^{-\infty}_{\mathrm{ad}, \mathrm{iso}}(\mathbb{R} : \mathbb{R}^k).$$

I think this quantizes to the right thing and so proves the surjectivity of R in (17.15). Injectivity follows using Atiyah's rotation again.

Now, let me consider the clutching constructions. Perhaps I will take the time to do this carefully, for the moment I have just written these down and am hoping for the best!

First, from even to odd. There is an actual map

(18.16) 
$$\operatorname{cl}_{\operatorname{eo}} : \mathcal{H}_{\operatorname{iso}}^{-\infty}(\mathbb{R}^{k}) \ni I = \gamma_{1} + a \mapsto$$
  
 $\left( \cos(\Theta(t)) - i \sin(\Theta(t))\gamma_{1} \right) \left( \cos(\Theta(t)) + i \sin(\Theta(t))I \right)$   
 $= \operatorname{Id} + i \sin(\Theta(t)) \left( \cos(\Theta(t)) - i \sin(\Theta(t))\gamma_{1} \right) a \in G_{\operatorname{sus,iso}}^{-\infty}(\mathbb{R}^{k}; \mathbb{C}^{2}).$ 

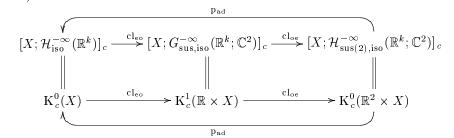

BKLY08

Here  $\Theta \in \mathcal{C}^{\infty}(\mathbb{R})$  is non-decreasing, vanishes for t sufficiently negative and is equal to  $\pi$  for t positive. Similarly, from odd to even

$$(18.17) \quad \operatorname{cl}_{\operatorname{oe}} : G_{\operatorname{iso}}^{-\infty}(\mathbb{R}^{k}) \ni g \longmapsto$$

$$I(t) = \begin{cases} \begin{pmatrix} \cos(\Theta(t)) & \sin(\Theta(t))g \\ \sin(\Theta(t))g^{-1} & -\cos(\Theta(t)) \end{pmatrix} & t \leq 0 \\ \\ \cos(2\pi - \Theta(-t)) & \sin(2\pi - \Theta(-t)) \\ \sin(2\pi - \Theta(-t)) & -\cos(2\pi - \Theta(-t)) \end{pmatrix} & t > 0 \end{cases}$$

**Proposition 17.** The clutching maps in (18.16) and (18.17) induce isomorphisms in K-theory giving commutative diagrams for any manifold X: (18.18)

and
