# THE UNITARY DUAL

$G$  : real reductive group ( $GL(n, \mathbb{R}), Sp(2n, \mathbb{R}), E_8(\textit{split})$ )

Problem: compute the **Unitary Dual**  $\widehat{G}$  of  $G$ : the irreducible, norm-preserving representations of  $G$  on a Hilbert space (up to isomorphism)

Hermann Weyl (1920s)

Not known in general. Some cases which are known:

Compact groups (Weyl)

$SL(2, \mathbb{R})$  (Bargmann 1947)

$GL(n, \mathbb{R}), GL(n, \mathbb{C}), GL(n, \mathbb{H})$  (Vogan, 1986)

Complex classical groups (Barbasch 1989)

$G_2$  (Vogan, 1994)

The answer is known to be very complicated in many cases.

# ATLAS OF LIE GROUPS AND REPRESENTATIONS

## THEOREM (VOGAN, 1980S)

For any given group  $G$  *there exists* a finite algorithm to compute  $\widehat{G}$

Question: is this result of more than theoretical interest? In other words, can this algorithm be made explicit, and implemented on a computer?

[Atlas of Lie Groups and Representations](#) (2002): take this question seriously. . .

Also:

- many other questions in representation theory.
- Software for the mathematical community
- I only really understand something if I can implement it on a computer

## $(\mathfrak{g}, K)$ -MODULES

Harish-Chandra reformulated the question algebraically in terms of  $(\mathfrak{g}, K)$ -modules.

$\mathfrak{g}_0 = \text{Lie}(G)$ ,  $\mathfrak{g} = \mathfrak{g}_0 \otimes \mathbb{C}$ ,  $K$  : maximal compact subgroup of  $G$ .

An admissible  $(\mathfrak{g}, K)$ -module is an algebraic representation  $(\pi, V)$  of  $\mathfrak{g}$  and (compatibly)  $K$ . The **admissible dual** is known (Langlands/Knapp/Zuckerman/Vogan).

We say  $(\pi, V)$  (irreducible) is **Hermitian** if it preserves a non-degenerate invariant Hermitian form  $\langle \cdot, \cdot \rangle$  on  $V$ :

$$\begin{aligned}\langle \pi(X)v, w \rangle + \langle v, \pi(X)w \rangle &= 0 \quad (X \in \mathfrak{g}_0) \\ \langle \pi(k)v, \pi(k)w \rangle &= \langle v, w \rangle \quad (k \in K)\end{aligned}$$

We say  $(\pi, V)$  is **unitary** if this form is positive definite.

## THEOREM (HARISH-CHANDRA)

$$\widehat{G} \xrightarrow{1-1} \{(\pi, V) \text{ irreducible unitary}\} / \sim \text{ equivalence}$$

The groups:  $G(\mathbb{C})$  is a connected, complex reductive group; with real points  $G = G(\mathbb{R})$

## THEOREM (ATLAS)

*Suppose  $\pi$  is an irreducible admissible  $(\mathfrak{g}, K)$ -module. There is an explicit, computable algorithm to compute the signature of the invariant Hermitian form on  $V$ , and in particular to determine if  $\pi$  is unitary.*

This algorithm has been implemented in the ATLAS software.

# SIGNATURES OF HERMITIAN FORMS

The notion that an invariant Hermitian form on an infinite dimensional vector space is **positive definite** is well defined.

However, what does it mean to compute the **signature** of a Hermitian form  $\langle , \rangle$  on  $(\pi, V)$ ?

$$\pi|_K \simeq \sum_{\mu \in \widehat{K}} \text{mult}_\pi(\mu) \mu \quad (\text{mult}_\pi(\mu) \in \mathbb{Z}_{\geq 0})$$

This sum is orthogonal with respect to  $\langle , \rangle$ . On the  $\mu$   $K$ -isotypic component:

$$\langle , \rangle \text{ is } \begin{cases} \text{positive definite on} & p \text{ copies of } \mu \\ \text{negative definite on} & q \text{ copies of } \mu \end{cases}$$

$$(p + q = \text{mult}_\pi(\mu)).$$

Record this information:

## DEFINITION

$$\mathbb{W} = \mathbb{Z}[s] \quad (s^2 = 1)$$

$$\text{sig}_\pi : \widehat{K} \rightarrow \mathbb{W} : \text{sig}_\pi(\mu) = p + qs$$

$$(\pi, \langle, \rangle) = \sum_{\mu \in \widehat{K}} \text{sig}_\pi(\mu) \mu$$

$\text{sig}_\pi$  is a refinement of the  $\text{mult}_\pi$ :

$$\text{sig}_\pi(\mu)|_{s=1} = p + q = \text{mult}_\pi(\mu) \quad (\mu \in \widehat{K})$$

## THEOREM (VOGAN)

Suppose  $\pi$  is an irreducible admissible representation. Then there are *finitely many* irreducible tempered representations  $\pi_i$ , and  $w_i \in \mathbb{W}$  such that

$$\text{sig}_\pi = \sum_{i=1}^n w_i \text{mult}_{\pi_i}$$

$\pi$  is unitary if and only if  $w_i \in \mathbb{Z}$  for all  $i$ , or  $w_i \in s\mathbb{Z}$  for all  $i$ .

In other words the  $\text{sig}_\pi$  functions are in the finite  $\mathbb{W}$ -span of the  $\text{mult}_{\pi_i}$  functions. Or:

$$\text{sig}_\pi(\mu) = \sum_{i=1}^n \text{mult}_{\pi_i}(\mu) w_i$$

Tempered implies unitary.

The functions  $\text{mult}_{\pi_i}$  are “known”.

ATLAS computes  $\text{mult}_\pi$  for any  $\pi$  (tempered or not; this is a long story in itself)

# EXISTENCE AND UNIQUENESS OF HERMITIAN FORMS

Question: suppose  $(\pi, V)$  is an irreducible admissible representation.

- Does it have an invariant Hermitian form?
- If so, it is canonical up to sign?

Answers: No, and No (i.e. not always)

From now on: restrict to case of real infinitesimal character ( $\lambda \in X^* \otimes \mathbb{R}$ ).  
There is a natural reduction to this case (Vogan  $\leftrightarrow$  Knapp).

Knapp and Zuckerman (1986) computed the “Hermitian” dual.

## **THEOREM (ATLAS)**

*Let  $\theta$  be the Cartan involution of  $\mathfrak{g}$ . Then  $\pi$  is Hermitian if and only if  $\pi^\theta \simeq \pi$ .*

*In particular: every representation of an equal rank group is Hermitian.*

(Reminder: real infinitesimal character)

# THE C-FORM

**Example:**  $G = SL(2, \mathbb{R})$ , principal series with odd  $K$ -types  $\leftrightarrow 2\mathbb{Z} + 1$ , infinitesimal character  $0 < \nu < 1$ :

$\langle , \rangle$  has **opposite signs** on the two lowest  $K$ -types  $\pm 1$ .

Recall:

$$\langle \pi(X)v, w \rangle + \langle v, \pi(X)w \rangle = 0 \quad (X \in \mathfrak{g}_0)$$

Want  $X \in \mathfrak{g}$ :

$$\langle \pi(X)v, w \rangle + \langle v, \pi(\sigma(X))w \rangle = 0 \quad (X \in \mathfrak{g})$$

where  $\sigma$  is anti-holomorphic, and  $\mathfrak{g}_0 = \mathfrak{g}^\sigma$ .

# THE C-FORM

So: while in small examples it is possible to compute these  $w_i$ , it is not possible to formulate a general algorithm for them.

Here is the key idea to resolve this: use a modification of the invariant form.

## DEFINITION

A  $c$ -form on  $(\pi, V)$  is a Hermitian form satisfying:

$$\langle \pi(X)v, w \rangle_c + \langle v, \pi(\sigma_c(X))w \rangle_c = 0 \quad (X \in \mathfrak{g})$$

Here  $\sigma_c$  is the **compact** real form of  $\mathfrak{g}$ :  $\sigma_c \sigma = \sigma \sigma_c$ , and  $G(\mathbb{C})^{\sigma_c}$  is the compact form of  $G(\mathbb{C})$ .

## DEFINITION

$\text{sig}_\pi^c(\mu) = p + qs$  according to the signature  $(p, q)$  of the  $c$ -form on the  $\mu$ -isotypic subspace.

# THE C-FORM

Recall it isn't possible to formulate a precise algorithm to compute  $\text{sig}_\pi$ .

## THEOREM (ATLAS - LIFE IS BEAUTIFUL)

*Suppose  $(\pi, V)$  is irreducible, with real infinitesimal character.*

- $\langle \cdot, \cdot \rangle_c$  exists
- $\langle \cdot, \cdot \rangle_c$  is canonical (positive on all lowest  $K$ -types)
- There is an explicit formula relating  $\langle \cdot, \cdot \rangle_c$  and  $\langle \cdot, \cdot \rangle$ .

So it is at least possible to formulate an algorithm to compute  $\text{sig}_\pi^c$ , and therefore  $\text{sig}_\pi$ .

We want a formula for

$$\text{sig}_\pi^c = \sum_{i=1}^n w_i^c \text{mult}_{\pi_i} \quad (\pi_i \text{ tempered})$$

and a way to go from  $\text{sig}_\pi^c$  to  $\text{sig}_\pi$ .

# THE ATLAS ALGORITHM: MAIN STEP

Each irreducible representation  $\pi$  is the unique irreducible quotient of a standard module

$$I(P, \sigma, \nu)$$

$P = MAN$  is a real parabolic subgroup

$\sigma$  is a discrete series of  $M$

and  $\nu \in \mathfrak{a}^* \simeq \mathbb{C}^n$

Real infinitesimal character:  $\nu \in \mathbb{R}^n$ .

Tempered:  $\nu = 0$ .

## KEY STEP: DEFORMATION

$I(\nu) = I(P, \sigma, \nu)$ : all realized on the same vector space  $V$ .

Write the Hermitian form  $\langle, \rangle_\nu$  on  $I(\nu)$ .

Deform  $\nu$  to 0:  $\langle, \rangle_\nu$  only changes at (finitely many) reducibility points.

At a reducibility point  $\nu_0$  we have the Jantzen filtration.

Basic principle:

$\langle, \rangle_{\nu_0+\epsilon}$  and  $\langle, \rangle_{\nu_0-\epsilon}$  differ on **odd levels of the Jantzen filtration**.

(Essentially:  $f(x) = x^n$  changes sign at 0 if and only if  $n$  is odd.)

So: deform  $\nu$  to 0; keep track of the sign changes

At  $\nu = 0$  the representation is tempered, and all signs are positive.

# ATLAS ALGORITHM FOR THE SIGNATURE OF THE C-FORM

Deformation (see Astérisque/arXiv):

$$\begin{aligned} \text{sig}^c(I((1 + \epsilon)\nu)) &= \text{sig}^c(I((1 - \epsilon)\nu)) + \\ & (1 - s) \sum_{\substack{\phi, \tau \\ \phi < \tau < \gamma \\ \ell(\gamma) - \ell(\tau) \text{ odd}}} s^{(\ell_0(\gamma) - \ell_0(\tau))/2} P_{\phi, \tau}(s) Q_{\tau, \gamma}(s) \text{sig}^c(I(\phi)) \end{aligned}$$

$P, Q$  : the Kazhdan-Lusztig-Vogan polynomials  $\in \mathbb{Z}[q]$ .

Applied recursively:  $\nu \rightarrow 0$  (tempered), this gives a computable formula

$$\text{sig}^c(I) = \sum_{i=1}^n w_i^c \cdot \text{mult}_{\pi_i} \quad (\pi_i \text{ tempered})$$

# ATLAS ALGORITHM FOR THE SIGNATURE OF THE C-FORM

Furthermore: you can express an irreducible representation  $\pi$  (with its form) as a linear combination of standard representations to give a formula for  $\text{sig}_\pi^c$ .

Finally the  $c$ -form and the ordinary form are related in the equal rank case by:

$$\langle v, w \rangle = \zeta_\pi \langle \pi(x)v, w \rangle_c$$

where  $\zeta_\pi$  is a fixed root of unity and  $x \in K, x^2 \in Z(G)$ .

Most significant thing swept under the rug: in the unequal rank case we need an **extended group**  $K \rtimes \delta$  with  $\delta^2 = 1$ , and  $x \in K\delta$ . This requires the **twisted** Kazhdan-Lusztig-Vogan polynomials studied by Lusztig and Vogan (2014).

## APPLICATION: UNIPOTENT REPRESENTATIONS

Let's consider the most interesting unitary representations.

$$\Gamma = \text{Gal}(\mathbb{C}/\mathbb{R})$$

$G$  : connected reductive algebraic group, defined over  $\mathbb{R}$

$${}^{\vee}G^{\Gamma} = G^{\vee} \rtimes \Gamma$$

$$\begin{array}{ccc} \Psi : \text{SL}(2, \mathbb{C}) \times \Gamma & \longrightarrow & {}^{\vee}G^{\Gamma} \\ & \searrow & \swarrow \\ & \Gamma & \end{array}$$

This is a **unipotent Arthur parameter**

### CONJECTURE (ARTHUR - 1983)

Associated to  $\Psi$  is a finite set  $\Pi(\Psi)$  of irreducible "unipotent" representations.

# APPLICATION: UNIPOTENT REPRESENTATIONS

Arthur gave some properties these packets should have, including:

- 1  $\Pi(\Psi)$  contains a certain L-packet  $\Pi(\phi_\psi)$
- 2 The representations in  $\Pi(\psi)$  have infinitesimal character  $\lambda_\psi = d\Psi(\text{diag}(\frac{1}{2}, -\frac{1}{2}))$
- 3 The span of the distribution characters  $\{\theta_\pi \mid \pi \in \Pi(\Psi)\}$  contains a stable character.
- 4 The representations in  $\Pi(\Psi)$  are unitary.

Arthur conjectured that the (global) unipotent representations are the building blocks for general automorphic representations.

Locally: the unipotent representation of real groups are expected to be the **building blocks** of the unitary dual.

# WHAT IS A UNIPOTENT REPRESENTATION/PACKET?

Arthur did not give a definition of what unipotent representations should actually be.

The terms **unipotent representation/packet** have come to mean many different things, over  $\mathbb{R}$ , and over local and global fields (Barbasch and others), and are not precisely defined in full generality (see Vogan's Orange book for more on this).<sup>a</sup>

Here we only discuss  $\mathbb{R}$ , and well defined notions of **Arthur unipotent** (aka **Special unipotent**) representations/packets.

These were originally defined by Barbasch and Vogan [1986] for complex groups, and Adams/Barbasch/Vogan [1992] for real groups.

# WEAK UNIPOTENT ARTHUR PACKETS

It is natural to ignore the restriction to  $\Gamma$ :

## DEFINITION

Suppose  $\mathcal{O}^\vee \subset G^\vee$  is a unipotent orbit. The weak Arthur packet associated to  $\mathcal{O}^\vee$  is

$$\Pi(\mathcal{O}^\vee) = \bigcup_{\substack{\Psi: \mathrm{SL}(2, \mathbb{C}) \times \Gamma \rightarrow {}^\vee G^\Gamma \\ \Psi|_{\mathrm{SL}(2, \mathbb{C})} \leftrightarrow \mathcal{O}^\vee}} \Pi(\Psi)$$

It turns out it is easier to describe weak Arthur packets  $\Pi(\mathcal{O}^\vee)$ .

# WEAK ARTHUR PACKETS

We now apply the definition of  $\Pi(\Psi)$  [ABV 1992] to compute  $\Pi(\mathcal{O}^\vee)$ . This becomes essentially [BV 1986] and has the following simple form.

## THEOREM

*The weak Arthur packet  $\Pi(\mathcal{O}^\vee)$  consists of the irreducible representations  $\pi$  of  $G$  satisfying:*

- 1 The infinitesimal character of  $\pi$  is  $\lambda_{\mathcal{O}^\vee}$
- 2  $AV(\text{Ann}(\pi)) = \overline{d\mathcal{O}^\vee}$

Ingredients:

$d$  is Spaltenstein/Barbasch/Vogan duality:  $\text{Unip}(G^\vee) \rightarrow \text{Unip}(G)$

$\text{Ann}(\pi)$  is the annihilator of  $\pi$  in  $\mathcal{U}(\mathfrak{g})$

$AV(\text{Ann}(\pi))$  is the associated variety of  $\text{Ann}(\pi)$ : the closure of a complex unipotent orbit  $\mathcal{O}$  of  $G$ .

# UNIPOTENT REPRESENTATIONS

## DEFINITION

The unipotent representations  $\Pi_u(G)$  of  $G$  are the union of the weak Arthur packets.

$$\Pi_{\text{Unip}}(G) = \bigcup_{\mathcal{O}^\vee \in \text{Unip}(G^\vee)} \Pi(\mathcal{O}^\vee)$$

Remark: Honest Arthur packets has a similar definition, but involving the finer invariant  $AV(\pi)$  in place of  $AV(\text{Ann}(\pi))$ .

# UNIPOTENT REPRESENTATIONS IN ATLAS

## THEOREM

*There is an explicit algorithm to compute each weak Arthur packet  $\Pi(\mathcal{O}^\vee)$ , and therefore  $\Pi_{Unip}(G)$ .*

This algorithm has been implemented in the ATLAS software: given  $G$  and  $\mathcal{O}^\vee$ , we compute an explicit list of Langlands parameters of the representations in  $\Pi_G(\mathcal{O}^\vee)$ .

# UNIPOTENT REPRESENTATIONS IN ATLAS

Ingredients:

- Unipotent orbits  $\{\mathcal{O}^\vee\}$  in  $G^\vee$
- $S(\mathcal{O}^\vee) = \text{Cent}_{G^\vee}(\psi)$  (a disconnected reductive group)
- Action of the Weyl group on the Grothendieck group  $Gr$  of virtual  $(\mathfrak{g}, K)$ -modules
- The Kazhdan-Lusztig-Vogan polynomials
- The cell decomposition of  $Gr$
- Special representation of each cell
- Duality of nilpotent orbits
- Springer correspondence (\*)  
(\* ) Only the Springer correspondence requires tables: everything else is computed *de novo* for an arbitrary reductive group.

# UNITARITY

Every unipotent representation of  $GL(n, \mathbb{R})$  or  $GL(n, \mathbb{C})$  is unitary.

If  $G = SO(n)$  or  $Sp(2n)$  (split) Jim Arthur has shown that every unipotent representation is unitary (any local field).

## **THEOREM (ATLAS-STEPHEN D. MILLER/JOE HUNDLEY)**

*Every unipotent representation of a real exceptional group is unitary, with the possible exception of 4 representations of  $E_8$  (split).*

# UNITARITY

Sketch:

Miller and Hundley have shown that some of the unipotent representations of split groups can be realized as  $L^2$ -residues of Eisenstein series, and are therefore unitary.

If  $\mathcal{O}^\vee$  is not distinguished (it intersects a proper Levi subgroup  $L^\vee$ ), then  $\Pi_G(\mathcal{O}^\vee)$  can be obtained by unitary (or cohomological) induction from  $\Pi_L(\mathcal{O}_L^\vee)$  ( $L$  is a real (or  $\theta$ -stable) Levi factor of  $G$ ).

The ATLAS software can determine if each  $\pi$  is unitary. **However:** for some representations of  $E_8$  this is not possible due to time and/or memory limitations.

The unitarity of many unipotent representations can be checked by several of these methods.

# CONJECTURE I

Each Arthur packet comes with a map

$$\tau : \Pi(\Psi) \rightarrow \mathcal{R}(\mathcal{S}_\Psi)$$

where  $(\mathcal{S}_\Psi$  is the component group of  $\text{Cent}_{G^\vee}(\Psi)$ ):

$$\mathcal{S}_\Psi = \mathcal{S}_\Psi / \mathcal{S}_\Psi^0$$

$\mathcal{R}$  is the finite dimensional representations (not necessarily irreducible)

## CONJECTURE

For  $\Psi$  a unipotent parameter  $\tau$  is a *bijection*

$$\Pi(\Psi) \xleftrightarrow{1-1} \widehat{\mathcal{S}}_\Psi$$

This is known to be false for more general (non-unipotent) Arthur packets

We know of no counterexamples to the Conjecture.

## CONJECTURE II: TEMPERED UNIPOTENT ARTHUR PACKETS

Question: When does  $\Pi(\mathcal{O}^\vee)$  consist entirely of tempered representations?

Very roughly: never, since the whole point of the  $SL(2, \mathbb{C})$  factor is to account for non-tempered representations.

Roughly: If  $\Psi|_{SL(2, \mathbb{C})} = 1$

### PROPOSITION

1) If  $G$  is split then  $\Pi(\mathcal{O}^\vee)$  is nonempty for all  $\mathcal{O}^\vee$ .

2) Let  $\mathcal{O}^\vee = \{0\}$ . Then  $\Pi(\mathcal{O}^\vee)$  is nonempty if and only if  $G$  is quasisplit. In this case

$$\Pi(\Psi) = \{\pi \mid \text{infinitesimal character of } \pi = 0\}$$

and these representations are all tempered.

(See the talk by Lucas Mason-Brown, in this seminar on May 29, for more on 2).

## CONJECTURE II: TEMPERED UNIPOTENT ARTHUR PACKETS

### CONJECTURE

$\Pi(\mathcal{O}^\vee)$  consists entirely of tempered representations if and only if  $\mathcal{O}^\vee$  is the *minimal* orbit for  $G$  such that  $\Pi(\mathcal{O}^\vee)$  is nonempty.

This is true for  $G$  quasisplit (previous Proposition), or compact (duh), and for all real forms of exceptional groups (case-by-case).
