Dynamic Systems

Introduction

Definitions

Dynamic System

a system whose state changes over time, like the system of differential equations

$$\dot{x_1} = f_1(x_1, x_2)$$

$$\dot{x_2} = f_2(x_1, x_2)$$

Fixed Point

a point that is maped to itself by the function, or where for some $x^* = (x_1^*, x_2^*)$: $\dot{x_1} = f_1(\mathbf{x^*}) = 0$

$$\dot{x_2} = f_2(\mathbf{x^*}) = 0$$

Now we have λe^{λt}v = e^{λt}Av, or λv = Av, so v is and eigenvector of A, with eigenvalue λ

Dynamic Systems

Linear Systems

Solving Linear Systems

- Expressing linear systems as $\dot{\mathbf{x}} = \mathbf{A}\mathbf{x}$ is very useful
- First look for solutions that stay on a straight line, some vector \mathbf{v} , leading to a solution $\mathbf{x} = \mathbf{e}^{\lambda t} \mathbf{v}$, going through a fixed point
- Now we have λe^{λt}v = e^{λt}Av, or λv = Av, so v is and eigenvector of A, with eigenvalue λ
- If this is a 2 dimensional system, then often there are two eigenvalues and two eigenvectors, so the solutions are of the form $\mathbf{x} = \mathbf{c_1} \mathbf{e}^{\lambda_1 \mathbf{t}} \mathbf{v_1} + \mathbf{c_2} \mathbf{e}^{\lambda_2 \mathbf{t}} \mathbf{v_2}$.

Dynamic Systems

Linear Systems

Eigenvalues and Solutions

• The eigenvalues determine the behavior of the solution at the fixed point

Dynamic Systems

Linear Systems

Eigenvalues and Solutions

- The eigenvalues determine the behavior of the solution at the fixed point
 - Linear systems are well behaved, so the behavior at fixed points determines the behavior elsewhere

▲ロト ▲帰ト ▲ヨト ▲ヨト 三回日 のの⊙

Dynamic Systems

Linear Systems

Eigenvalues and Solutions

- The eigenvalues determine the behavior of the solution at the fixed point
 - Linear systems are well behaved, so the behavior at fixed points determines the behavior elsewhere
- Real eigenvalues: both positive, both negative, or one of each in 2D case:

▲ロト ▲冊ト ▲ヨト ▲ヨト 三回日 ろんで

Dynamic Systems

Non-Linear Systems

Solving Non-Linear Systems

• Analytically solving nonlinear systems is almost impossible

(日)

Dynamic Systems

Non-Linear Systems

Solving Non-Linear Systems

- Analytically solving nonlinear systems is almost impossible
- But there is hope! We can analyze nonlinear systems about their fixed points using linearization

Dynamic Systems

Non-Linear Systems

Solving Non-Linear Systems

- Analytically solving nonlinear systems is almost impossible
- But there is hope! We can analyze nonlinear systems about their fixed points using linearization
- Systems are approximated near fixed point using the Jacobian matrix

$$\begin{pmatrix} \frac{\partial f}{\partial x} & \frac{\partial f}{\partial y} \\ \frac{\partial g}{\partial x} & \frac{\partial g}{\partial y} \end{pmatrix}$$

Dynamic Systems

Non-Linear Systems

Solving Non-Linear Systems

• These approximations are analyzed like with linear systems

Dynamic Systems

Non-Linear Systems

Example of Solving a Non-Linear System

• Consider a system describing the population growth of rabbits and sheep

$$\dot{x} = x(3 - x - 2y)$$
$$\dot{y} = y(2 - x - y)$$

Figure: Analysis of the fixed points, and approximation of the solution

Dynamic Systems

Non-Linear Systems

Chaos and what makes non-linear systems difficult

- Small changes in initial conditions lead to very different results
- The Lorenz Equations:

$$\dot{x} = \sigma(y - x)$$
$$\dot{y} = rx - y - xz$$
$$\dot{z} = xy - bz$$

Figure: xz plane view of one trajectory

- General Triangles

Example

Figure: Approximate flow of a triangle under discrete curve shortening flow

◆□> <□> <=> <=> <=> <=> <=> <=> <=>

Definitions

Curvature

In a discrete curve, the curvature k(x) at point x is defined as $\pi - \alpha$, where α is the interior angle at x.

Normal vectors

The normal vector $\vec{n}(x)$ or \vec{n}_x at point x is defined as the outward-facing unit vector in the direction of the angle bisector of the angle at x.

Differential equation

We define the motion of a point x with this differential equation:

$$\frac{dx}{dt} = -k(x)\vec{n}(x)$$

- General Triangles

Here is how we will define the isosceles triangle:

Figure: Equilateral Triangle

Finding
$$\frac{dx}{dt}$$
 and $\frac{d\alpha}{dt}$

 Finding the linear approximation of the triangle after small time ε, points A', B', C'

• Get differential equations using
$$\frac{df(t)}{dt} = \lim_{\epsilon \to 0} \frac{f(t+\epsilon) - f(t)}{\epsilon}$$

• $\frac{dx}{dt} = -\frac{\pi + \alpha}{2} \sin \frac{\pi + \alpha}{4} + \cos \frac{\alpha}{2} (\alpha - \pi)$
• $\frac{d\alpha}{dt} = \frac{1}{\cos \alpha} \frac{d \sin \alpha}{dt} = \lim_{\epsilon \to 0} \frac{\sin \alpha' - \sin \alpha}{\epsilon} \text{ for } \alpha' = \angle A'B'C'$
• $\frac{d\alpha}{dt} = \frac{\frac{1}{\sqrt{2}} (\pi + \alpha)(\sin \frac{\alpha}{4} - \cos \frac{\alpha}{4}) + 2\sin \frac{\alpha}{2} (\pi - \alpha)}{x}$

Summary

Dynamic Systems

- Linear systems can be solved using eigenvalues and eigenvectors
- Non-linear systems can generally not be solved directly, but their behavior can be found with linear approximations

Discrete Curve Shortening Flow

- Isosceles triangles with top angle $\geq \frac{\pi}{3}$ go to points
- All other triangles go to line segments
- Not yet proven
 - Two of the angles of any scalene triangle go to $\frac{\pi}{2}$
 - The angles go to their endpoint before c goes to 0
