Symmetric Polynomials

Definition (symmetric polynomial)

A *symmetric polynomial* is a polynomial in n variables that remains the same under any permutation of its n variables.

Symmetric Polynomials

Definition (symmetric polynomial)

A *symmetric polynomial* is a polynomial in n variables that remains the same under any permutation of its n variables.

Examples:

- $x_1x_2 \dots x_n$
- $x_1x_2^2 + x_1^2x_2 + x_2x_3^2 + x_2^2x_3 + x_3x_1^2 + x_3^2x_1$
- Not symmetric: $x_1x_2^2 + x_2x_3^2 + x_3x_1^2$

Monomial Symmetric Polynomials

Definition (partition)

A *partition* is a finite nonincreasing sequence of nonnegative integers. If λ is a partition, its elements are denoted $\lambda_1 \geq \lambda_2 \geq \dots$

Example: $(4, 3, 3, 1, 0)$

Monomial Symmetric Polynomials

Definition (partition)

A *partition* is a finite nonincreasing sequence of nonnegative integers. If λ is a partition, its elements are denoted $\lambda_1 \geq \lambda_2 \geq \dots$

Example: $(4, 3, 3, 1, 0)$

Definition (monomial symmetric polynomial)

If λ is a partition of length n , then $m_\lambda(x_1, x_2, \dots, x_n)$ is the symmetric polynomial that is the sum of all **distinct** terms that result from permuting the variables in $x_1^{\lambda_1} x_2^{\lambda_2} \dots x_n^{\lambda_n}$.

Monomial Symmetric Polynomials

Definition (monomial symmetric polynomial)

If λ is a partition of length n , then $m_\lambda(x_1, x_2, \dots, x_n)$ is the symmetric polynomial that is the sum of all **distinct** terms that result from permuting the variables in $x_1^{\lambda_1} x_2^{\lambda_2} \dots x_n^{\lambda_n}$.

Examples:

- $m_{(4,2,1)}(x_1, x_2, x_3) = x_1^4 x_2^2 x_3 + x_1^4 x_2 x_3^2 + x_1^2 x_2^4 x_3 + x_1^2 x_2 x_3^4 + x_1 x_2^4 x_3^2 + x_1 x_2^2 x_3^4$
- $m_{(2,2,0)}(x_1, x_2, x_3) = x_1^2 x_2^2 + x_1^2 x_3^2 + x_2^2 x_3^2$
- $m_{(1,1,1)}(x_1, x_2, x_3) = x_1 x_2 x_3$

These polynomials form a basis of all symmetric polynomials.

Hall-Littlewood Polynomials

Definition (Hall-Littlewood polynomial)

For a constant t and a partition λ , the *Hall-Littlewood polynomial* is given by:

$$P_{\lambda}(x_1, \dots, x_n; t) = \text{const}_{\lambda}(t) \sum_{\sigma \in S_n} \sigma \left(\prod_{1 \leq i \leq n} x_i^{\lambda_i} \prod_{1 \leq i < j \leq n} \frac{x_i - tx_j}{x_i - x_j} \right)$$

where S_n is the set of permutations of the variables x_i .

Hall-Littlewood Polynomials

Definition (Hall-Littlewood polynomial)

For a constant t and a partition λ , the *Hall-Littlewood polynomial* is given by:

$$P_{\lambda}(x_1, \dots, x_n; t) = \text{const}_{\lambda}(t) \sum_{\sigma \in S_n} \sigma \left(\prod_{1 \leq i \leq n} x_i^{\lambda_i} \prod_{1 \leq i < j \leq n} \frac{x_i - tx_j}{x_i - x_j} \right)$$

where S_n is the set of permutations of the variables x_i .

- $t = 1$ gives the monomial symmetric polynomials.
- $t = 0$ gives the Schur polynomials, another important basis of symmetric polynomials.

Path Ensembles

$$\lambda = (4, 3, 3, 1, 0)$$

This is a *type- A path ensemble* with end state λ with n paths, where n is the length of λ .

Path Ensembles

$$\lambda = (4, 3, 3, 1, 0)$$

This is a *type- A path ensemble with end state λ* with n paths, where n is the length of λ .

- Paths may only go right and down and cannot intersect.
- Paths enter at the left and exit at the bottom.
- Only one horizontal path may enter or exit each tile.
- The number of paths exiting the bottom in column i is the number of instances of i in λ .
- Each tile is associated with a variable x_i , and each tile in a row is associated with the same variable.

Path Ensembles

$$\lambda = (4, 3, 3, 1, 0)$$

Path Ensembles

Each tile is assigned a *weight*, depending on the paths that enter and exit it and the variable x associated with it (t is, again, a constant):

 m x  $m + 1$ x  $m - 1$ $1 - t^m$  m

1

The weight of a path ensemble is the product of the weights of all its tiles.

Path Ensembles and Hall-Littlewood Polynomials

Theorem (Tsilevich)

For a partition λ , the sum of the weights of all type-A path ensembles with end state λ , divided by $\prod_{1 \leq i \leq n} x_i$, is the Hall-Littlewood polynomial:

$$\text{const}_\lambda(t) \sum_{\sigma \in S_n} \sigma \left(\prod_{1 \leq i \leq n} x_i^{\lambda_i} \prod_{1 \leq i < j \leq n} \frac{x_i - tx_j}{x_i - x_j} \right)$$

Type- BC Path Ensembles

$$\lambda = (4, 3, 1)$$

This is a *type- BC path ensemble with end state λ* .

- The construction is similar to type- A path ensembles, but there are twice as many rows, with tiles associated with the variable x_i or x_i^{-1} .
- At the left, exactly one path enters in each pair of rows with variables x_i and x_i^{-1} .
- Weights are the same, but with an additional weight of $-t$ each time a path enters in the row associated with x_i^{-1} .
- (The model is simplified slightly here for brevity.)

Type-BC Hall-Littlewood Polynomials

Theorem (Wheeler, Zinn-Justin)

The sum of the weights of all type-BC path ensembles with end state λ , divided by $\prod_{1 \leq i \leq n} (x_i - tx_i^{-1})$, is the type-BC Hall-Littlewood polynomial:

$$\text{const}_\lambda(t) \sum_{\omega \in S_n \rtimes \{\pm 1\}^n} \omega \left(\prod_{1 \leq i \leq n} \frac{x_i^{\lambda_i}}{1 - x_i^{-2}} \prod_{1 \leq i < j \leq n} \frac{(x_i - tx_j)(x_i x_j - t)}{(x_i - x_j)(x_i x_j - 1)} \right)$$

where $S_n \rtimes \{\pm 1\}^n$ is similar to the set of permutations of the variables, except that it can take x_i to either x_j or x_j^{-1} .

Generalized Weights

Generalized weights are defined with an additional constant parameter s (they give normal weights when $s = 0$):

m

$$\frac{x-st^m}{1-sx}$$

$m + 1$

$$\frac{(1-s^2t^m)x}{1-sx}$$

$m - 1$

$$\frac{1-t^m}{1-sx}$$

m

$$\frac{1-st^m x}{1-sx}$$

Problem

Theorem (Borodin)

The sum of the generalized weights of all type-A path ensembles with end state λ , divided by $\prod_{1 \leq i \leq n} x_i$, is:

$$\text{const}_\lambda(t, s) \sum_{\sigma \in S_n} \sigma \left(\prod_{1 \leq i \leq n} \frac{((x_i - s)/(1 - sx_i))^{\lambda_i}}{1 - sx_i} \prod_{1 \leq i < j \leq n} \frac{x_i - tx_j}{x_i - x_j} \right).$$

Problem

Theorem (Borodin)

The sum of the generalized weights of all type- A path ensembles with end state λ , divided by $\prod_{1 \leq i \leq n} x_i$, is:

$$\text{const}_\lambda(t, s) \sum_{\sigma \in S_n} \sigma \left(\prod_{1 \leq i \leq n} \frac{((x_i - s)/(1 - sx_i))^{\lambda_i}}{1 - sx_i} \prod_{1 \leq i < j \leq n} \frac{x_i - tx_j}{x_i - x_j} \right).$$

Question (Borodin)

How do we similarly generalize type- BC Hall-Littlewood polynomials?

Our Result

Theorem

The sum of the generalized weights of all type-BC path ensembles with end state λ , divided by $\prod_{1 \leq i \leq n} (x_i - tx_i^{-1})$, is:

$$\text{const}_\lambda(t, s) \sum_{\omega \in S_n \times \{\pm 1\}^n} \omega \left(\prod_{1 \leq i \leq n} \frac{((x_i - s)/(1 - sx_i))^{\lambda_i}}{(1 - x_i^{-2})(1 - sx_i)} \prod_{1 \leq i < j \leq n} \frac{(x_i - tx_j)(x_i x_j - t)}{(x_i - x_j)(x_i x_j - 1)} \right).$$

Further Research

- Type- BC polynomials have a *dual* formed by slightly modifying the weights. What is the corresponding dual of generalized type- BC polynomials?

Further Research

- Type- BC polynomials have a *dual* formed by slightly modifying the weights. What is the corresponding dual of generalized type- BC polynomials?
- Borodin defined *skew* generalized type- A Hall-Littlewood polynomials by allowing paths to enter at the top. Is there an analog for type- BC Hall-Littlewood polynomials?

Further Research
