Skyscraper Project

version: January 12, 2023

Compiler: HAO PENG(彭淏)
hao_peng@mit.edu

Peking University
Massachusetts Institute of Technology

Preface

What is this? : At first, this is a note containing subtle or important materials I encountered while studying. I started this project in the fall of my third undergraduate year(October 2019) in Peking University, noticing that I have a poor memory and consistently forget what I thought I have already learned. So it came to me that I can compile all the proofs of theorems I cannot recall that is hard and subtle yet appearing over and over again. But gradually it turns out I want to make it as comprehensive as possible.

I constantly add stuff to this note, and I regularly put them online. You can find the newest version released at https://math.mit.edu/~hao_peng/skyscraper.pdf. Don't be surprised to find many sections containing only titles, and the symbol "**?**" means "further work required here". If you find errors or have suggestions, please feel free to email me.

Constitutions: The following are principles of the structure of this note, but the current version is far from it. They serve as ultimate goals.

- This note should be self-contained.
- Notations should be consistent throughout the whole note.
- Propositions should be put in the (sub)section of the most advanced term appeared in the statement, or as a corollary.
- Logical order is not necessary, but vicious circles are intolerable. Although it should also be properly ordered logically in the sense that if every notion appearing is referred to its definition, the ordering has the least number of reverse cross-references(i.e. referring to definitions after it) under admissible permutation, where admissible permutation means a permutation that preserves the tree structure of this note(i.e. the tree of chapter-section-subsection-$\cdots$ ordering).
- Theories should be stated at the most generality. There's no need to give proofs for the special case but clarify the deduction from the general case, unless it is needed in the proof of the general case, then state it as a lemma.
- When facing multiple proofs, only the most elegant and essential proof should be recorded.
- References should be traced to the original author and his specific paper.
- Each section should contain less than 30 pages. Each chapter should contain less than 20 sections.

Writing Styles: The following are writing standards of this note. Main references are [CMOS] and [Poo]. Notice some rules of [Poo] remain to be discussed.

- Use less words and more math symbols and equations, and use plain English, so that even those who don't speak English can understand without much effort.
- Use proper cases for names of people.
- A proposition is a proven mathematical sentence.
- A theorem is a proposition of notable importance.

- A lemma is a proposition whose importance is derived from the theorem or proposition it aims to prove.
- A corollary is a proposition whose proof readily follows from its corresponding proposition or theorem.
- A conjecture is a proposition whose proof(or disproof/proof of independence) is unknown yet.
- The naming of lemmas/propositions/theorems/conjectures by multiple authors follows the lexicographical order, except for historical followup works. Authors of the same paper is connected by "-" symbol, and authors of different papers are separated by a "/" symbol.

Tips: This is hardly a *readable* note. I use it as a dictionary. It only contains materials that I'm interested in and many proofs are still missing. Hopefully I can complete them all as time goes by. The main reason why I have to latex all these materials together is that I need tons of cross-references. So I believe it's the best way to read this book digitally, and it's good to know how to go forwards and backwards between hyper-references on your computer. For example, on a MacOS system, the default shortcuts are ⌘+[, ⌘+] for Preview and ⌥+←, ⌥+→ for Foxit Reader. Foxit Reader is stable when handling a large file.

Acknowledgement: Sincere thanks to Yi Tian(田翊) for answering my questions when I was learning algebraic geometry and p-adic geometry in year 2020 when I was in Peking University. His help is fundamental. Thanks to Zhiyu Zhang(张志宇) for giving me directions on mathematical study and advices on mathematical life in year 2022 when I was in MIT.

There is already a great online book [Sta] maintained by de Jong that covers considerably much of the Algebraic Geometry part of this note. I haven't finish reading it but I reordered the materials that I learnt and kept track of it in my own way. I sometimes used different paths to optimize the proof. The idea to compile this note was inspired by [Sta]. One different feature of this note compared to [Sta] is that I want to make every proof as optimal and as general as possible(See Constitutions above). Any suggestion to optimize proofs or generalize statements is strongly encouraged.

The writing style of this note is imitating and influenced by various literature, including beautiful writings of J. S. Milne, especially [Mil17][Mil17d] and [Mil08], monographs of J. Lurie, especially [Lur09] and [Lur11], and also de Jong's magnificent [Sta].

"And they said, Go to, let us build us a city and a tower, whose top may reach unto heaven; and let us make us a name, lest we be scattered abroad upon the face of the whole earth."
–Genesis 11:1-9

Table of Contents

1 Mathematical Logic and Foundations

1.1 Mathematical Logic

Cf.[Logic for mathematicians, Hamilton], [Axiomatic Set Theory] and [Mathematical Logic, Mendelson].

1 Philosophical Issue

Following [The World as Will and representation, Schopenhauer], the world is a representation of my thought(Vorstellung) of will(Wille). Even this book is just a representation of my thoughts at certain moment.

One representation of will is the ability to reason.

Logic is the analysis of methods of reasoning. It is interested in the form rather than the content of the argument.

The systematic formalization and cataloguing of valid methods of reasoning are a main task of logicians.

Another representation of will is the ability to express and comprehend. I will assume that

The goal of **mathematics** is to express logic in a comprehensible way.

If the work used mathematical techniques or if it is primarily denoted to the study of mathematical reasoning, then it may be called **mathematical logic**.

We will assume the will have some ability to write this book:

- The will can discern lexicographical order.

2 Peano's Postulates for Natural Numbers

After settling Philosophical Issue, I can start expressing now. In fact, I already started when I am explaining philosophical issue to you.

the Primordial Systems

Def. (1.1.2.1) [the Primordial Languages]. The **primordial language** $\mathcal{L}_0$ consists of

- **free variable symbols** a, b, c, d, m, n.
- **bound variable symbols** x, y, z, w.
- **constant variable symbol** 0.
- **function symbols** $S, +, \cdot,$
- **predicate symbols** $=$.
- **punctuations symbols** "(", "…". ")".

- **connective symbols** $\neg$ and $\implies$.
- **quantifier symbol** $\forall$.

Def. (1.1.2.2) [the (Blank)Peano Arithmetic system]. The (blank)**Peano arithmetic system** PA consists of the following data:

- the primordial language $\mathcal{L}$(1.1.2.1).
- A procedure called a **grammer** to specify which thing are called **well-formed formulas** or wffs:
  - There is a procedure to specify which things are called **terms**:
    * 0 and free variable symbols are terms.
    * If t, s are terms, then $S(t), (t + s), t \cdot s$ are terms.
  - There is a procedure to specify which things are called **atomic formulas**: If t, s are terms, then $t = s$ is an atomic formula.
  - The procedure to determine wffs:
    * Atomic formulas are wffs.
    * if φ, ψ are wffs and x is a bound variable not appearing in φ, then $\neg\varphi, (\varphi \implies \psi), (\forall x)\varphi(x/a)$ are wffs, where $\varphi(x/a)$ is obtained from φ by replacing each occurrence of some free variable a by a bound variable x that doesn't appear in φ.
- A procedure to specify which well-formed formulas are called **axioms**: The following are axioms:
  - Logical Axioms: If φ, ψ, η are wffs,
    * $(\varphi \implies (\psi \implies \varphi))$.
    * $((\varphi \implies (\psi \implies \eta)) \implies ((\varphi \implies \psi) \implies (\varphi \implies \eta)))$.
    * $((\neg\varphi \implies \neg\psi) \implies (\psi \implies \varphi))$.
    * $(\varphi \implies (\psi \implies \varphi))$.
    * $(\varphi \implies (\psi \implies \eta)) \implies ((\varphi \implies \psi) \implies (\varphi \implies \eta))$.
    * $((\neg\varphi \implies \neg\psi) \implies (\psi \implies \varphi))$.
    * $((\forall x)\varphi \implies \varphi(a/x))$ where $\varphi(a/x)$ is obtained from φ by replacing each occurrence of the bound variable x in $\varphi(x)$ by the free variable a.
    * $((\forall x)(\varphi \implies \psi) \implies (\varphi \implies (\forall x)\psi))$, if the free variable a in φ which are quantifying with x doesn't appear.
    * (Modus Ponuns or MP)$\varphi \wedge (\varphi \implies \psi) \to \psi$.
    * (Generalizations)$\varphi \to (\forall x)\varphi(x/a)$, where x is a bound variable symbol that doesn't appear in φ, and $\varphi(a/x)$ is obtained from φ by replacing each occurrence of some free variable a by x.
  - Non-Logical Axioms: If a, b, c are any free variables, x, y, z are any bound variables and φ a wff., then
    * $(a = b) \implies ((a = c) \implies (b = c))$.
    * $(a = b) \implies (S(a) = S(b))$.
    * $\neg(0 = S(a))$.
    * $(S(a) = S(b)) \implies (a = b)$.

  * $(a+0)=a$.
  * $a+S(b)=S(a+b)$.
  * $a\cdot 0=0$.
  * $a\cdot S(b)=a\cdot b+b$.
  * (Principle of mathematical induction) $\varphi(0/a) \implies ((\forall x)(\varphi(x/a) \implies \varphi(S(x)/a)) \implies (\forall x)\varphi(x))$.

terms in the Peano arithmetic system will be called **natural numbers**.

Remark (1.1.2.3) [Metaphysical Issue].

- From now any definition/proposition/rem we make should be regarded as wffs in a formal sufficiently high order system containing the blank PA system(1.1.2.2) and the class system to be defined in(1.1.3.2) and we can quantify over any other systems. In other words, I assume will can comprehend everything in this book. Such a language is called a **metasystem** for it. The symbols in this metalanguage is called a **metavariable**.
- I assume it has an axiom which is a stronger form of the mathematical induction(1.1.2.2)(i.e. Induction can apply to properties of classes).
- If you don't agree with the axioms and assumptions I made so far, you should close this file and leave right now.

Meta Def. (1.1.2.4) [Abbreviations]. An **abbreviation** is the introduction of a new term.

In a metasystem, we use a symbol $\varphi \triangleq \psi$ to mean "we enlarge the original system to include the term φ and include the axiom $(\varphi \iff \psi)$. in fact, this metasystem is a conservative extension.**?**

A **definition** is an introduction of a new symbol or new abbreviation.

Whenever we substitute abbreviates, we will use $\overset{\text{subst}}{\iff}$.

Remark (1.1.2.5). Notice abbreviations is a metasymbol, and they are introduced to save space. It should be clear that all statements or proofs in the extended system can be converted back to its 'primitive form', and the appearance of abbreviations are be totally removed.

Remark (1.1.2.6) [Logical Issue]. Pedantically, by our construction of our mathematical system, in order for propositions to be defined in a lower order system, we should have defined symbols exclusively each time we enlarge the system, and never say something like "let n be a natural number, $n+1>0$", because this is not a wff. In stead, we should write $(\forall n)(n+1>0)$, because this is a wff. in Peano's system PA, and n is born to be representing a natural number, i.e. a symbol in the system PA.

But in practice, it is annoying to do so, so we will be more tolerant on this kind of usage. Just remember always this kind of sentence can be formalized.

3 Class System(ZF)

Def. (1.1.3.1). In fact this theory is a theory that lies between ZF and NBG. I think it is better to just change everything to NBG**?**

Def. (1.1.3.2) [Class System]. The **class system** ZF is a formal system(1.1.4.2) with

- Language: A first order language(1.1.6.1) with
  - Free variable symbols:

    * $0, a_0$ are free variable symbols.
    * For any natural number n, if a_n is a free variable symbol, then a_{n+1} is also a free variable symbol.
  - Bound variable symbols:
    * $x(0)$ is a bound variable symbol.
    * For any natural number n, if x_n is a bound variable symbol, then x_{n+1} is also a bound variable symbol.
  - Predicate symbol: $\in, =$.
  - Punctuation symbols: "(", ")", "...", "," and "{", "}", "|", ":".
  - Connective symbols: $\neg$ and $\to$.
  - Quantifier symbol: $\forall$.
- Grammar:
  - A procedure to specify wffs:
    * If a, b are free variable, then $a \in b$ is a wff..
    * If φ, ψ are wffs, a, b are free variables and x is a bound variable, then

$$(a \in \{x|\psi(x/a)\}), \quad (\{x|\psi(x/a)\} \in b), \quad (\{x|\varphi(x/a)\} \in \{x|\psi(x/b)\})$$

      are wffs, where $\psi(x/a)$(resp. $\varphi(x/b)$) is obtained from ψ(resp. φ) by replacing a free variable a(resp. b) by a bound variable x that doesn't appear in ψ(resp. φ).
    * If φ, ψ are wffs, then $\neg\varphi$ and $\varphi \to \psi$ are wffs.
    * If φ is a wff. and x is a bound variable, then $(\forall x)\varphi(x/a)$ is a wff.
  - A procedure to specify terms:
    * Variables are terms.
    * If φ is a wff., then $\{x|\varphi\}$ is a term, called a **class**.
- Axioms:
  - Logical Axioms: If φ, ψ, η are wffs,
    * $(\varphi \implies (\psi \implies \varphi))$.
    * $((\varphi \implies (\psi \implies \eta)) \implies ((\varphi \implies \psi) \implies (\varphi \implies \eta)))$.
    * $((\neg\varphi \implies \neg\psi) \implies (\psi \implies \varphi))$.
    * $((\forall x)\varphi \implies \varphi(a/x))$ where $\varphi(a/x)$ is obtained from φ by replacing each occurrence of the bound variable x in $\varphi(x)$ by the free variable a.
    * $((\forall x)(\varphi \implies \psi) \implies (\varphi \implies (\forall x)\psi))$, if the free variable a in φ which are quantifying with x doesn't appear.
    * (Modus Ponuns or MP)$\varphi \wedge (\varphi \implies \psi) \to \psi$.
    * (Generalizations)$\varphi \to (\forall x)\varphi(x/a)$, where x is a bound variable symbol that doesn't appear in φ, and $\varphi(a/x)$ is obtained from φ by replacing each occurrence of some free variable a by x.
  - Non-logical axioms: If φ, ψ are wffs, then

    C1: $(a \in \{x|\varphi\}) \iff \varphi(a/x)$, where $\varphi(a/x)$ is φ with all occurrence of x replaced by a.

C2: $(\{x|\varphi(x)\} \in a) \iff ((\exists y)((y \in a) \wedge (\forall z)((z \in y) \iff \varphi(z/x))))$, where $\varphi(z/x)$ is φ with all occurrence of x replaced by z.

C3: $(\{x|\varphi(x)\} \in \{x|\psi\}) \iff ((\exists y)(\psi(y/x) \wedge (\forall z)((z \in y) \iff \varphi(z/x))))$, where $\varphi(z/x)$ is φ with all occurrence of x replaced by z and $\psi(y/x)$ is ψ with all occurrence of x replaced by y.

C4: (Equality)$(a = b) \iff (\forall x)((x \in a) \iff (x \in b))$.

C5: (Axiom of Extensionality)(1.1.3.3).

C6: (Axiom of Pairing)(1.1.3.20).

C7: (Axiom of Union)(1.1.3.26).

C8: (Axiom of Power Set)(1.1.3.30).

C9: (Axiom Schema of Replacement)(1.1.3.31).

C10: (Axiom of Regularity/Foundation)(1.1.3.40).

C11: (Axiom of Infinity)?.

Equalities

Axiom (1.1.3.3) [Axiom of Extensionality]. $((a = b) \wedge (a \in c)) \to (b \in c))$.

Meta Thm. (1.1.3.4) [Reduce Class to Sets]. For any wff φ in the class system, there exists a wff φ^* in the set system s.t. φ is deducible from φ^* and φ^* is deducible from φ.(1.1.5.1)?

Proof: Use induction.? □

Remark (1.1.3.5). This tells us that the extension from set system to class system is conservative.?

Def. (1.1.3.6).

- If φ is a wffs, define $\{x : \varphi\} \triangleq \{x|\varphi\}$.
- If A, B are classes, then define $A \notin B \triangleq \neg(A \in B)$.
- If A is a class and φ is a wff., define $(\forall x \in a)\varphi \triangleq (\forall x)(x \in a)(\wedge\varphi)$

Meta Thm. (1.1.3.7). The set system**??** is a subsystem(1.1.5.4) of the class system(1.1.3.2). Moreover, every term in set system is a term in the class system.

Def. (1.1.3.8) [Equality between Classes]. If A, B are classes, then

$$A = B \triangleq (\forall x)((x \in A) \iff (x \in B)), \quad A \neq B \triangleq \neg(A = B)$$

Meta Thm. (1.1.3.9). If A, B, C are classes, then

- $(A = B) \iff (\exists x)((x = A) \wedge (x \in B))$.
- $(A = A)$.
- $(A = B) \to (B = A)$.
- $(A = B) \wedge (B = C) \to (A = C)$.

Proof: Cf.[Axiomatic Set Theory]P13. □

Meta Thm. (1.1.3.10). $(a = b) \to (\varphi(a/x) \iff \varphi(b/x))$, where $\varphi(a/x)$ is constructed from φ by replacing every free occurrence of x by a.

Proof: Cf.[Axiomatic Set Theory, P8]. The proof used induction on the number of logical symbols in φ.? □

Thm. (1.1.3.11) [Every Set is a Class]. $a = \{x|x \in a\}$.

Proof: This follows from axiom (C2) and the fact $(\forall x)((x \in a) \iff (x \in a))$. □

Def. (1.1.3.12) [Set Predicate]. If A is a class, $\mathscr{M}(A) \triangleq (\exists x)(x = A)$.

Prop. (1.1.3.13). $\mathscr{M}(a)$.

Proof: $a = a$. □

Meta Thm. (1.1.3.14). If A is a class, then $(A \in \{x|\varphi(x)\}) \iff (\mathscr{M}(A) \wedge \varphi(A))$.

Proof: Use induction on A? □

Thm. (1.1.3.15) [Russell's Paradox]. Define $\mathrm{Ru} \triangleq \{x|x \notin x\}$. Then $\neg\mathscr{M}(\mathrm{Ru})$.

Proof: By considering the wff. $\varphi : x \notin x$, it follows from(1.1.3.14) that

$$(\mathscr{M}(\mathrm{Ru}) \wedge (\mathrm{Ru} \notin \mathrm{Ru})) \to (\mathrm{Ru} \in \{x|x \notin x\}) \overset{\text{subst}}{\iff} (\mathrm{Ru} \in \mathrm{Ru})$$

so

$$\mathscr{M}(\mathrm{Ru}) \to ((\mathrm{Ru} \notin \mathrm{Ru}) \to (\mathrm{Ru} \in \mathrm{Ru})).$$

so

$$\mathscr{M}(\mathrm{Ru}) \to (\mathrm{Ru} \in \mathrm{Ru}).$$

Then by axiom (C3),

$$(\mathrm{Ru} \in \mathrm{Ru}) \to ((\exists y)(\psi(y/x) \wedge (\forall z)((z \in y) \iff z \notin z)))$$

which is false. So $\neg\mathscr{M}(\mathrm{Ru})$. □

Def. (1.1.3.16) [Definable Sets]. If φ is a wff., then we say that $\{x|\varphi(x)\}$ is a **definable set** if $\mathscr{M}(\{x|\varphi(x)\})$.

<u>**Properties of Classes**</u>

Def. (1.1.3.17) [Pairs and Ordered Pairs].

- $\{a, b\} \triangleq \{x|(x = a) \vee (x = b)\}$.
- $\{a\} \triangleq \{a, a\}$.
- $(a, b) \triangleq \{x|(x = \{a\}) \vee (x = \{a, b\})\}$.
- $a_n \triangleq (a, n)$.(notice n is a natural number).

Meta Def. (1.1.3.18) [MultiPairs]. For any free variable a_0 and a natural number n, define a term $\{a_1, \ldots, a_n\}$. For any bound variable x_0, define a bound term $\{x_1, \ldots, x_n\}$.

Prop. (1.1.3.19).

- $(c \in \{a,b\}) \iff ((c = a) \vee (c = b))$.
- $(c \in \{a\}) \iff (c = a)$.
- $(c \in (a,b)) \iff ((c = \{a\}) \vee (c = \{a,b\}))$.
- $(\{a\} = \{b\}) \iff (a = b)$.
- $(\{a\} = \{b,c\}) \iff ((a = b) \wedge (b = c))$.
- $((a,b) = (c,d)) \iff ((a = c) \wedge (b = d))$.
- $((\forall x)((a \in x) \to (b \in x))) \to (a = b)$.

Axiom (1.1.3.20) [Axiom of Pairing]. $\mathscr{M}(\{a,b\})$.

Cor. (1.1.3.21). $\mathscr{M}((a,b))$.

Meta Thm. (1.1.3.22) [Objects of Classes are Sets]. For classes A, B, $(A \in B) \to \mathscr{M}(A)$.

Def. (1.1.3.23) [Unions]. For classes A, B, define

- $A \cup B \triangleq \{x | (x \in A) \vee (x \in B)\}$.
- $A \cap B \triangleq \{x | (x \in A) \wedge (x \in B)\}$.
- For a class A, define $\cup(A) \triangleq \{x | (\exists y)((x \in y) \wedge (y \in A))\}$.

Prop. (1.1.3.24). $(a \cup b) = \cup(\{a,b\})$.

Proof: Cf.[Axiomatic Set Theory, P16]. □

Prop. (1.1.3.25).

- $(a \in (b \cup \{b\})) \iff (a \in b) \vee (a = b)$.
- $A \cup B = B \cup B$.
- $A \cap B = B \cap A$.
- $(A \cup B) \cup C = A \cup (B \cup C)$.
- $(A \cap B) \cap C = A \cap (B \cap C)$.
- $A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$.
- $A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$.

Proof: □

Axiom (1.1.3.26) [Axioms of Union]. $\mathscr{M}(\cup(a))$.

Cor. (1.1.3.27). $\mathscr{M}(a \cup b)$.

Proof: □

Def. (1.1.3.28) [Subclasses]. For classes A, B, define

- $A \subset B \triangleq (\forall x)((x \in A) \to (x \in B))$.
- $A \subsetneq B \triangleq ((A \subset B) \wedge (A \neq B))$.

Def. (1.1.3.29) [Power Sets]. $\mathscr{P}(a) \triangleq \{x | x \subset a\}$, called the **power set** of a.

Axiom (1.1.3.30) [Axiom of Power Set]. $\mathscr{M}(\mathscr{P}(a))$.

Axiom (1.1.3.31) [Axiom Schema of Replacement]. For each wffs φ, there is an axiom

$$((\forall x)(\forall y)(\forall z)((\varphi(x/a,y/b)\wedge\varphi(x/a,z/b))\rightarrow(y=z))\rightarrow\mathscr{M}(\{y|(\exists x\in a)\varphi(x/a,y/b)\})).$$

Meta Cor. (1.1.3.32). For any class A, $\mathscr{M}(a\cap A)$.

Proof: Cf.[Axiomatic Set Theory, P20]. □

Def. (1.1.3.33) [Setminus]. For classes A,B, define $A\setminus B\triangleq\{x|(x\in A)\wedge(x\notin B)\}$.

Meta Thm. (1.1.3.34). If A is a class, then $\mathscr{M}(a\setminus A)$.

Proof: $\mathscr{M}(a\setminus A)\overset{\text{subst}}{\iff}\mathscr{M}(\{x\in a|x\notin A\})$ is a theorem by(1.1.3.32). □

Def. (1.1.3.35) [Empty Class]. $0\triangleq\{x|x\notin x\}$.

Prop. (1.1.3.36). $a\setminus a=0$.

Proof: $a\setminus a\overset{\text{subst}}{\iff}\{x|(x\in a)\wedge(x\notin a)\}=\{x|x\notin x\}$**?** □

Cor. (1.1.3.37) [Empty Set]. $\mathscr{M}(0)$.

Prop. (1.1.3.38).

- $(\forall x)(x\notin 0)$.
- $(a\neq 0)\iff(\exists x)(x\in a)$.

Proof: 1: $(\forall x)(x=x)$.
2: By axiom (Equality),

$$(a\neq 0)\iff(\exists x)((x\in 0)\wedge(x\notin a))\vee((x\in a)\wedge(x\notin 0)).$$

Then it follows from item1 that $(a\neq 0)\iff(\exists x)(x\in a)$. □

Meta Def. (1.1.3.39). We define $\{a_1\in a_2\in\ldots\in a_n\}$ as in(1.1.5.3).**?**

Axiom (1.1.3.40) [Axiom of Regularity(Foundation)]. $(a\neq 0)\rightarrow(\exists x\in a)((x\cap a)=0)$.

Cor. (1.1.3.41). $(a\notin a)$.

Proof: If $(a\in a)$, then $\{a\}\neq 0$ by(1.1.3.38), and unwinding the definition**?**,

$$(\forall x)((x\in\{a\})\rightarrow(x\cap\{a\})\neq 0),$$

contradicting axiom of regularity(1.1.3.40). □

Meta Cor. (1.1.3.42). For any natural number $n>0$, $\neg(a_1\in a_2\in\ldots\in a_n\in a_1)$.

Proof: If $(a_1\in a_2\in\ldots\in a_n\in a_1)$, then $\{a_1,\ldots,a_n\}\neq 0$ by(1.1.3.38), and

$$(\forall x)((x\in\{a_1,\ldots,a_n\})\rightarrow(x\cap\{a_1,\ldots,a_n\})\neq 0),$$

contradicting axiom of regularity(1.1.3.40). □

Prop. (1.1.3.43) [von.Neumann Universe]. Define $\mathscr{V} \triangleq \{x|x = x\}$, then $\neg\mathscr{M}(\mathscr{V})$. And in fact $\mathscr{V} = \mathrm{Ru}$(1.1.3.15).

Proof: Since $\mathscr{V} = \mathscr{V}$, if $\mathscr{M}(V)$, then $V \in V$, by(1.1.3.14), then this together with $\mathscr{M}(V)$ contradicts(1.1.3.41) after unwinding definition**?**. (Notice that metathm(1.1.3.14) is a wff. when restricted to V).

For the last assertion,**?** □

Meta Thm. (1.1.3.44). For classes A, B,

- $0 \subset A$.
- $A \subset \mathscr{V}$.
- $(\forall x)(x \notin A) \to (A = 0)$.
- $(A \subset a) \to \mathscr{M}(A)$.
- $\mathscr{M}(A) \to \mathscr{M}(A \cap B)$.
- $A \notin A$.

Meta Thm. (1.1.3.45) [Strong Regularity]. The axiom of regularity(1.1.3.40) implies a stronger form of regularity: For any class A,

$$(A \neq 0) \to (\exists x \in A)((x \cap a) = 0).$$

Proof: Cf.[Axiomatic Set Theory]P80. □

Meta Cor. (1.1.3.46). For any class A,

$$(\forall x)(x \subset A) \to (x \in A)) \to (A = \mathscr{V})$$

(In words, if every set a has a property(a wff. φ) whenever every element of a has this property, then every set has this property.)

Proof: If $(\forall x)(x \subset A) \to (x \in A))$, denote $B = V \setminus A$, if $B \neq 0$, then by strong regularity(1.1.3.45),

$$(\exists a)((a \in B) \wedge (a \cap B) = 0).$$

So

$$(\forall y)((y \in a) \to (y \notin B)).$$

But $y \in V$, so

$$(\forall y)((y \in a) \to (y \notin A)).$$

And then $a \subset A$, and the hypothesis on A implies $a \in A$, contradicting the fact $a \in B$. So $A = V$, by(1.1.3.44). □

Meta Cor. (1.1.3.47) [Inclusion Induction]. There are no infinite descending $\in$-chains of sets.

Proof: The property $\mathscr{P}$ of not having infinite descending $\in$-chain is a wff., so $A = \{x|\mathscr{P}(x)\}$ is a class. And it can be shown $(a \subset A) \to (a \in A)$. Thus by(1.1.3.46), $A = \mathrm{Ru}$, so every set has no infinite descending $\in$-chains. □

4 Languages

Def. (1.1.4.1) [Languages]. A **language** $\mathcal{L}$ is a set of symbols. There may be subsets of symbols such as free symbols, bound symbols, function symbols, logical symbols, etc..

Remark (1.1.4.2) [Formal System]. A **formal system** L consists of the following data:

- A language L(1.1.4.1), or equivalently, a set of symbols.
- A set of **well-formed formulas** or wffs.
- A set of **axioms**.

Remark (1.1.4.3) [Class System as a Metasystem]. Notice for any language or system, the class system is a metasystem of it. So we can formalize talking about everything about this system in the class system, like consistency, completeness...

Given a formal system L, we will typically use metavariables a, b, c, x, y, z whose domain is the collection of symbols in L, and use metavariables φ, ψ, η to describe wffs in L.

Meta Thm. (1.1.4.4). The primordial language $\mathscr{L}_0$(1.1.2.1) is a language(1.1.4.1). In fact a first order language to be defined in(1.1.6.1). The class system $\mathscr{L}_C$ is a formal system(1.1.4.2). (i.e. they are sets).

Remark (1.1.4.5). Until now I settled all the logical issues, but remember I made several assumptions that is metaphysical and cannot be settled by logic or math:

- There is a representation of will called the primordial language(1.1.2.1),
- There is a "talking system" that is a representation of will that can describe all other systems can enables the presence of this book(1.1.2.3).

5 Formal Propositional Calculus

Meta Def. (1.1.5.1) [Deductions]. Let L be a formal system(1.1.4.2), a **proof** is a finite sequence of wffs s.t. every wffs appearing is either an axiom or a wedge of two wffs before it.

A **theorem** in L is a wffs that is deducible from an axiom η of L. A proof(resp. theorem/defi) in the metasystem is called a **metaproof**(resp. **metatheorem**/defi).

Meta Def. (1.1.5.2) [Multiple Deduction]. Let L be a formal system and ψ a wff. in L, then for any natural number $n > 0$ and any $\{\eta_1, \ldots, \eta_n\}$(1.1.3.18), then introduce metaterms

$$\{\eta_1\} \vdash_L \psi, \quad \{\eta_1, \eta_2\} \vdash_L \psi, \quad \{\eta_1, \ldots, \eta_n\} \vdash_L \psi$$

and metaaxioms:

$$\{\eta_1\} \vdash_L \psi \triangleq \vdash_L (\eta_1 \to \psi).$$

$$\{\eta_1, \ldots, \eta_{n+1}\} \vdash_L \psi \triangleq \{\eta_1, \ldots, \eta_n\} \vdash_L (\eta_{n+1} \to \psi)$$

It reads: ψ is **deducible form η_1 to η_n**.

Remark (1.1.5.3). This definition of multiple deduction shows that we have the ability to handle multiple definition involving "...". But due to limit of space, we will not do so again, and leave it to the future to formalize it.**?**

Meta Def. (1.1.5.4) [Subsystem]. A formal system L is called a **subsystem** of another formal system L' or L' is an **extension system** of L if:

- There is a procedure to assign a wff. in L' for each wff. in L such that
  - Every proof in L is assigned to a proof in L'.
  - Every axiom in L is a theorem in L'.

Propositional Calculus

Def. (1.1.5.5) [Formal System of Propositional Calculus]. The formal system(1.1.4.2) of **propositional calculus** $\mathscr{L}$ is defined by the following:

- Symbols:
  - A procedure to specify which things are **variable symbols**.
  - **punctuation symbols** "(", ")".
  - **connective symbols**: $\neg, \implies$.
- Grammer:
  - Symbols are wffs.
  - If φ, ψ are wffs, then $\neg\varphi$ and $(\varphi \implies \psi)$ are wffs.
- Axioms: If φ, ψ, η are wffs, then the following are axioms:
  L1: $(\varphi \implies (\psi \implies \varphi))$.
  L2: $((\varphi \implies (\psi \implies \eta)) \implies ((\varphi \implies \psi) \implies (\varphi \implies \eta)))$.
  L3: $((\neg\varphi \implies \neg\psi) \implies (\psi \implies \varphi))$.
  L4: (Modus Ponuns or MP)If φ, ψ are wffs, then $\varphi \wedge (\varphi \to \psi) \to \psi$.

From now on, this system is the foundation of the book, and every language follows will contain $\mathscr{L}$.

Def. (1.1.5.6) [Logical Abbreviations]. For wffs φ, ψ,

- $(\varphi \vee \psi) \triangleq (\neg\varphi \implies \psi)$,
- $(\varphi \wedge \psi) \triangleq \neg(\varphi \implies \neg\psi)$,
- $(\varphi \iff \psi) \triangleq \neg((\varphi \implies \psi) \implies \neg(\psi \implies \varphi))$,
- $[\triangleq \{$,
- $] \triangleq \}$.

Meta Thm. (1.1.5.7). let L be a language and φ, ψ, η be wffs in L

- Axioms of L are theorems in L.
- $\{(\varphi \implies \psi), (\psi \implies \eta)\} \vdash_L (\varphi \implies \psi)$.
- $\vdash_L (\neg\psi \implies (\psi \implies \varphi))$.
- $\vdash_L ((\neg\varphi \implies \varphi) \implies \varphi)$.

Proof: Cf.[Hamilton, Chap2]. □

Meta Thm. (1.1.5.8) [Deduction Theorem]. Let φ, ψ be wffs in L,

- If $\Gamma \cup \{\varphi\} \vdash_L \psi$, then $\Gamma \vdash_L (\varphi \implies \psi)$.
- If $\Gamma \vdash_L (\varphi \implies \psi)$, then $\Gamma \cup \{\varphi\} \vdash_L \psi$.

Proof: Cf.[Hamilton, P32].? □

Adequacy Theorem for $\mathscr{L}$

6 First Order Systems

Formal Predicate Calculus

Def. (1.1.6.1) [First Order Languages]. A **first order language** L is a language(1.1.4.1) with

- a set of **bound variable symbols**.
- a set of **free variable symbols**.
- a set of **constant symbols**.
- a set of **predicate(relation) symbols**.
- a set of **functions symbols**.
- the **punctuations symbols** "(", ")" and ",".
- the **connective symbols** $\neg$ and $\implies$.
- the **quantifier symbol** $\forall$.

Def. (1.1.6.2) [Formal System of Predicate Calculus]. Given a first order language L(1.1.6.1), we can define a formal system(1.1.4.2) of **predicate calculus** $\mathscr{K}_L$ as follows:

- Symbols: symbols in L.
- Grammar:
  - There is a countable set of **terms**:
    - Constant symbols and free variable symbols are terms.
    - For any natural number n, If f^n is a function symbol, and for any $m < n$, t_m is a term, then $f(t_1,\ldots,t_{n_f})$ is a term.
  - There is a set of **atomic formulas**: If R^k is a predicate symbol and $t_1,\ldots,t_k$ are terms, then $R^k(t_1,\ldots,t_k)$ are atomic formulas.
  - There is a countable set of wffs:
    - Atomic formulas are wffs.
    - if φ,ψ are wffs and x is a bound variable not appearing in φ, then $\neg\varphi, (\varphi \implies \psi), (\forall x)\varphi(x/a)$ are wffs, where $\varphi(x/a)$ is obtained from φ by replacing each occurrence of some free variable a by a bound variable x that doesn't appear in φ.
- Axioms: If φ,ψ,η are wffs in $\mathscr{K}_L$ and x is a variable, then There the following countably many axioms:

  K1: $(\varphi \implies (\psi \implies \varphi))$.

  K2: $((\varphi \implies (\psi \implies \eta)) \implies ((\varphi \implies \psi) \implies (\varphi \implies \eta)))$.

  K3: $((\neg\varphi \implies \neg\psi) \implies (\psi \implies \varphi))$.

  K4: $((\forall x)\varphi \implies \varphi(a/x))$ where $\varphi(a/x)$ is obtained from φ by replacing each occurrence of the bound variable x in $\varphi(x)$ by the free variable a.

  K5: $((\forall x)(\varphi \implies \psi) \implies (\varphi \implies (\forall x)\psi))$, if the free variable a in φ which are quantifying with x doesn't appear.

  K6: (Modus Ponuns or MP)$\varphi \wedge (\varphi \implies \psi) \to \psi$.

K7: (Generalizations)$\varphi \to (\forall x)\varphi(x/a)$, where x is a bound variable symbol that doesn't appear in φ, and $\varphi(a/x)$ is obtained from φ by replacing each occurrence of some free variable a by x.

Meta Def. (1.1.6.3). A **sentence** is a formula without free variables.
A **theory** is a set of sentences in a language $\mathcal{L}$.

Meta Thm. (1.1.6.4) [Tautologies are Theorems]. if φ is a wff. in a language L and it is a tautology?, then φ is a theorem(1.1.5.1) of $\mathscr{K}_L$(1.1.6.2).

Proof: Cf.[Hamilton]P72. □

Meta Thm. (1.1.6.5)[Soundness Theorem for $\mathscr{K}_L$]. If φ is a wff. in a language L and $\vdash_{\mathscr{K}_L} \varphi$, then φ is locally valid?,

Proof: Cf.[Hamilton]P74. □

Meta Cor. (1.1.6.6)[Consistence for $\mathscr{K}_L$]. $\mathscr{K}_L$ is consistent.

Proof: Cf.[Hamilton]P74. □

Meta Cor. (1.1.6.7). For any wffs φ, ψ, η of L,

$$\{(\varphi \implies \psi), (\psi \implies \eta)\} \vdash_{\mathscr{K}_L} (\varphi \implies \eta)$$

Proof: Cf.[Hamilton]P76. □

Adequacy Theorem for $\mathscr{K}_L$

Def. (1.1.6.8).

Satisfaction and Truth

See[Hamilton].

7 Models and Examples of Systems

Def. (1.1.7.1) [(Mathematical) Languages]. A **mathematical language** $\mathcal{L}$ is a first order language(1.1.6.1) given by the following data:

- A set $\mathcal{F}$ of **function symbols**.
- A set $\mathcal{R}$ of **relations symbols**.
- A set $\mathcal{C}$ of **constant symbols**.

Function symbols, relations symbols, constant symbols consists of all symbols in $\mathcal{L}$. For simplicity, we call a mathematical language simply a language.

Def. (1.1.7.2)[Languages].

- $\mathcal{L}_r$ is defined to be the language of rings.
- $\mathcal{L}_{or}$ is defined to be the language of ordered rings.

Def. (1.1.7.3)[Theories].

- ACF is defined to be the theory of alg.closed fields, w.r.t $\mathcal{L}_r$.

- ACF_p is defined to be the theory of alg.closed fields of char$p$.
- DAG is defined to be the theory of non-trivial torsion-free divisible Abelian groups, w.r.t. $\mathcal{L}_r$.
- DLO is the theory of dense linear orders without endpoints.
- $ODAG$ is the theory of nontrivial divisible Abelian groups.
- RCF is the theory of real closed fields w.r.t $\mathcal{L}_{or}$.

8 Computability

Prop. (1.1.8.1) [Turing Machine]. For the ring structure of $\mathbb{N}$, there is a $\mathcal{L}$-formula $\varphi(e, x, s)$ that $\mathbb{N} \models T(e, x, s)$ iff the Turing machine coded with e halts on input x within s steps. So the set of **halting computation** is definable by the formula: $\exists s\varphi(e, x, s)$.

Proof: Cf.[Models of Peano Arithmetic Kaye]. □

Def. (1.1.8.2) [Recursively Enumerable Sets]. A subset $S \subset \mathbb{N}$ is called **recursively enumerable** iff there is an algorithm that the set of input numbers that halts is exactly S. Equivalently, a recursively enumerable set is a set that there is an algorithm that 'enumerates' the members of S.

Prop. (1.1.8.3) [Hilbert's 10-th Problem]. For any recursively enumerable set(1.1.8.2) $A \subset \mathbb{N}^n$, there is a polynomial $P(\underline{X}^n, \underline{Y}^m)$ that

$$A = \{\underline{X} \in \mathbb{N}^n : \mathbb{N} \models \exists y_1 \exists y_2 \ldots, \exists y_m p(\underline{X}, \underline{Y}) = 0\}$$

Proof: Cf.[M. Davis, J. Matijasevi ˇc, and J. Robinson, Hilbert's 10th Problem. Diophantine equations: Positive aspects of a negative solution, in Mathematical Developments from Hilbert's Problems, F. Browder, ed., American Mathematical Societ, Providence, RI, 1976.] □

1.2 Set Theory

Main references are [?], [Model Theory Marker], [Axiomatic Set Theory], [Hamilton],

Notation (1.2.0.1).

- Use notations from Mathematical Logic.
- We build theories based on the class system(1.1.3.2).
- As in(1.1.2.3), all propositions are regarded as theorems in a system that is an extension of all other systems defined in this book, in particular it is an extension of the blank PA system(1.1.2.2) and the class system $\mathscr{L}_C$(1.1.3.2).
- We will rebuild PA system and NBG/ZF set theory, so the logic section will no longer be cited other than this section.**?**

1 Von.Neumann-Bernays-Gödel Set Theory(NBG)

Def. (1.2.1.1) [Inductive Sets]. A set I is called **inductive** if $0 = \varnothing \in I$ and if $n \in I$, then $n+1 \in I$, where $n + 1 = S(n)$ the successor.

Axiom (1.2.1.2) [Axiom of infinity]. An inductive set(1.2.1.1) exists.

Def. (1.2.1.3) [Set of Natural Numbers]. The **set of natural numbers** $\mathbb{N}$ is defined to be

$$\mathbb{N} = \{x \in I_0 | x \in I \text{ for all inductive set } I\},$$

where I_0 is an inductive set given by(1.2.1.2). Elements of $\mathbb{N}$ are called **natural numbers**.

Cor. (1.2.1.4) [Inductive Principle]. If $P(x)$ is a property that $P(0)$, and $P(n)$ implies $P(n + 1)$, then $P(n)$ for each natural number n.

Proof: By definition $B = \{n \in \mathbb{N} | P(n)\}$ is an inductive set, so $\mathbb{N} \subset B$. □

Prop. (1.2.1.5). $\mathbb{N}$(1.2.1.3) is a linearly ordered set.

Proof: Cf.[Set Theory Jech P43]. □

Cor. (1.2.1.6) [Inductive Principle Second Version]. If $P(x)$ is a property that $P(0)$, and $P(k)$ holds for all $k < n$ implies $P(n)$, then $P(n)$ for each natural number n.

Proof: Use induction principle(1.2.1.4) for the property $Q(n) : P(k)$ for all $k < n$. Then $Q(n)$ implies $Q(n + 1)$. □

2 Relations and Functions

Def. (1.2.2.1) [Products]. For classes A, B, $A \times B$ is the class

$$\{x | (\exists y \in A)(\exists z \in B)(x = (y, z))\},$$

called the **product of A and B**.

Prop. (1.2.2.2). $\mathscr{M}(a \times b)$.

Proof: Cf.[Axiomatic Set theory]P23. □

Def. (1.2.2.3). Inductively define**?** class terms

- $A^1 \triangleq A$,
- $A^{n+1} \triangleq A^n \times A$,
- $A^{-1} \triangleq \{(x,y)|(y,x) \in A\}$.

And define

Def. (1.2.2.4) [Relations and Functions]. Define the following predicates:

- $\mathrm{Rel}(A) \triangleq A \subset V^2$.
-

Def. (1.2.2.5) [Bijections].

Def. (1.2.2.6) [Finite and Infinite Sets]. For $n \in \mathbb{N}$ and a set X, we say X has n elements iff there is a bijection from n to X. We say X is finite if it has n elements for some $n \in \mathbb{N}$, and infinite otherwise.

3 Orderings

Def. (1.2.3.1) [Ordering]. A **partial ordering** on a set A is a relation $<$ on A, or equivalently a subset $C \subset A \times A$ that

- For no $x \in A$, $x < x$ holds.
- If $x < y$ and $y < z$, then $x < z$.

It is called a **total ordering** if moreover it satisfies

- For every $x, y \in A$ that $x \neq y$, either $x < y$ or $y < x$.

A **poset** is just a partially ordered set.

Def. (1.2.3.2) [Reverse Ordering]. The **reverse ordering** A^{op} of an ordered set A is the same set A with the ordering reversed.

Def. (1.2.3.3) [Cofinality]. The **cofinality** of or a poset (i.e partially ordered set) α is the is the smallest cardinality δ of a cofinal subset of α.

Def. (1.2.3.4) [κ-Filtered Poset]. For a cardinal κ, a poset is called **κ-filtered** if for any subset unbounded from above has cardinality$\geq \kappa$.

Def. (1.2.3.5) [Directed Set]. A **directed set** is a poset that 3-filtered and non-empty.

Def. (1.2.3.6). In a poset P, two element p, q are called **compatible** if there is an $r \in P$ that $r < p, r < q$.

Def. (1.2.3.7) [κ-Chain Condition]. For a cardinal κ, a poset P is said to satisfy the **κ-chain condition** if for any subset $A \subset P$ that elements of A are pairwise incompatible(1.2.3.6), then $|A| \leq \kappa$.

Total Ordering

Def. (1.2.3.8) [Well-Ordering]. A **linear ordering** is just a total ordering.

A linear ordering is called a **well-ordering** if every nonempty subset has a minimal element.

Def. (1.2.3.9) [Lexicographical Ordering]. If given a family of linearly ordered set A_i indexed by a well-ordered set I, then there is a linear ordering on $\prod_I A_i$, where $(f_i) < (g_i)$ iff $(f_i) \neq (g_i)$ and for the minimal i_0(well-ordering used) that $f_{i_0} \neq g_{i_0}$, $f_{i_0} < g_{i_0}$. It is called the **lexicographical ordering**.

Def. (1.2.3.10). An ordered set X is called **dense** iff for each $a < b$, there is a x that $a < x < b$.

Def. (1.2.3.11) [Least Upper Bound]. An ordered set A is said to have the **least upper bound property** if any subset $A_0 \subset A$ bounded above has a least upper bound. It is said to satisfy the **greatest lower bound property** if A^{op} satisfies the least upper bound property.

Prop. (1.2.3.12) [Cantor]. Any two ordered set that is countable, dense and has no endpoints are isomorphic. In particular, any of these is isomorphic to the set of rational numbers $\mathbb{Q}$.

Proof: We will built the isomorphism by extending partial embeddings. Let $a_0, \ldots, a_n, \ldots$ be an ordering of A, $b_0, \ldots, b_n, \ldots$ be an ordering of B, and we can alternatively extend mapping on a_n and b_n, as A, B are complete without endpoints. Then we get an isomorphism of A and B. □

Cor. (1.2.3.13). Any countable linearly ordered set can be mapped isomorphically into $\mathbb{Q}$.

Def. (1.2.3.14). A **initial segment** of an ordered set W is the ordered set $W[a] = \{x \in W | x < a\}$.

Lemma (1.2.3.15). If W is a well-ordered set, then any increasing function $f : W \to W$ satisfies $f(x) \geq x$.

Proof: If the set $\{x | f(x) < x\}$ is not empty, then it has a minimal element a, then $f(f(a)) < f(a)$, contradiction. □

Cor. (1.2.3.16). A well-ordered set cannot be isomorphic to an initial segment of itself, and an automorphism of a well-ordered set must be identity.

Proof: Use the above lemma(1.2.3.15), if it is isomorphic to $W[a]$, then $f(a) < a$, contradiction. For any automorphism, $f(x) \geq x, f^-(x) \geq x$, so $f(x) = x$. □

Prop. (1.2.3.17) [Comparison of Well-Orderings]. A cut of a well-ordered set is well-ordered. And for any two well-ordered sets W_1, W_2, either they are isomorphic, or one of them is isomorphic to a initial segment of another.

Proof: The three cases are mutually exclusive by(1.2.3.16), So it suffices to show one of them holds.

Define a set $f = \{(x, y) \in W \times W | W_1[x] \cong W_2[y]\}$. (1.2.3.16) shows f is injective and monotone in both coordinates. Now we want to prove that if the domain of f is not all W_1, then it is an initial segment, and the image is all W_2, this will finish the proof.

It is clearly an initial segment $W_1[a]$ because it is well-ordered and if $h : W_1[x] \cong W_2[y]$ and $x' < x$, then $h : W_1[x'] \cong W_2[h(y)]$. If the image is not all of W_2, then similarly the image of f is an initial segment of W_2, $= W_2[b]$. But this means $W_1[a] \cong W_2[b]$, so a, b is also in the domain(image), which is a contradiction. □

Complete Linear Ordering

Def. (1.2.3.18) [Complete Ordering]. A **cut** of an ordered set X consists of two disjoint nonempty subsets $A \cup B = X$ that $a < b$ for any $a \in A, b \in B$.

It is called a **Dedekind cut** if A doesn't has a maximal element. It is called a **gap** if A doesn't have a maximal element and B doesn't have a minimal element.

An ordered set is called **complete** if there are no gaps.

Prop. (1.2.3.19). Any complete ordered set R has the least upper bound property and greatest lower bound property.

Proof: Consider the cut $A = \{x | x < a$ for some element in $T\}, B = \mathbb{R} - A$, if T is bounded above, B is not empty, so this is truly a cut, and A doesn't has a maximal element, because if $x < a \in \mathbb{R}$, then $x < \frac{x+a}{2} < a$. So by completeness of R, B has a minimal element, that is, the supremum of A exists. Similarly for the case A bounded from below. □

Prop. (1.2.3.20)[Completion of Ordering]. There is an obvious ordering on the set C of all Dedekind cuts of X, and X embeds into C by $b \mapsto \{x | x < b\} \cup \{x | x \geq b\}$.

C is complete and has no endpoints, P is dense in C, which is called a **completion** of P.

Proof: Cf.[Set Theory Jech P88]. □

Prop. (1.2.3.21) [Real Numbers]. $\mathbb{Q}$ has a unique completion ordering $\mathbb{R}$, called the **set of real numbers**. $\mathbb{R}$ is not countable.

Proof: $\mathbb{R}$ is a dense linear ordering without endpoints, so by(1.2.3.12) if it is countable then it is isomorphic to $\mathbb{Q}$, but this is not possible because $\mathbb{Q}$ is not complete. □

Prop. (1.2.3.22). $|P(\mathbb{N})| = |2^{\mathbb{N}}| = |\mathbb{R}|$, which is denoted by $2^{\aleph_0}$. By(1.2.3.21), $\aleph_0 < 2^{\aleph_0}$.

Proof: The first equality is by(1.2.7.4). Now by the construction of $\mathbb{R}$, it can be embedded into $P(\mathbb{N})$, so $|\mathbb{R}| \leq |P(\mathbb{Q})| = |P(\mathbb{N})|$. Conversely, $|2^{\mathbb{N}}| \leq |\mathbb{R}|$ by decimal representation, so they are equal by bernstein(1.2.6.1). □

4 Ordinals

Def. (1.2.4.1) [Ordinal Numbers]. A set is called **transitive** iff each element of T is a subset of T. A set α is called a **ordinal number** iff α is transitive and well-ordered by inclusion.

Prop. (1.2.4.2). If α is an ordinal, then $S(\alpha) = \alpha \cup \{\alpha\}$ is also an ordinal, obviously. Thus any natural number is an ordinal by definition.

An ordinal is called a **successor ordinal** iff $\alpha = S(\beta)$ for some β, and a **limit ordinal** otherwise.

Lemma (1.2.4.3).

1. If α is an ordinal, then $\alpha \notin \alpha$.
2. Every element of an ordinal is an ordinal.
3. If ordinals $\alpha \subsetneq \beta$, then $\alpha \in \beta$. That is, for ordinals, $\subsetneq$ is the same as $\in$.

Proof:

1. If $\alpha \in \alpha$, then contradiction to the fact $\in$ is a ordering(1.2.4.1).

2. To show $x \in \alpha$ is transitive, it suffices to show that if $u \in v \in x$, then $u \in x$, because then v is a subset of x. But this follows from the fact $\in$ is an ordering. And because $x \subset \alpha$, the inclusion of x is the restriction of inclusion in α, so it is a well-ordering.
3. Consider $\beta - \alpha$, it has a minimal element γ. Notice $\gamma \subset \alpha$, because otherwise there is an element of $\beta - \alpha$ smaller than γ, by definition(1.2.4.1).
   Now we show $\gamma = \alpha$, then it will follow that $\alpha \in \beta$. For this, if $\delta \in \alpha$ and $\delta \notin \gamma$, then $\gamma \in \delta$ or $\gamma = \delta$. But then this implies that $\delta \in \alpha$ because α is an ordinal, contradicting the fact $\gamma \in \beta - \alpha$.

□

Prop. (1.2.4.4) [Ordinal is Well-Ordered]. Define the ordering of ordinal by $\alpha < \beta$ iff $\alpha \in \beta$. The ordering of ordinals is a total ordering and is a well-ordering.

Proof: If $\alpha\beta \in \gamma$, then $\alpha \in \gamma$ because γ is transitive. If $\alpha \in \beta \in \alpha$, then $\alpha \in \alpha$, contradicting(1.2.4.3).

Given any two ordinals, $\alpha \cap \beta$ is also an ordinal by definition. If $\alpha \cap \beta = \beta$ or α, then $\alpha \subset \beta$, hence $\alpha \in \beta$ by(1.2.4.3). If $\alpha \cap \beta \subsetneq \alpha$ and $\alpha \cap \beta \subsetneq \beta$, then $\alpha \cap \beta \in \alpha \cap \beta$, contradiction.

Well-ordering: Given a set of ordinals, take $\alpha \in A$ and consider the set $\alpha \cap A$. If $\alpha \cap A = \varnothing$, then α is minimal in A, because otherwise some $\beta \in \alpha \cap A$. If $\alpha \cap A \neq \varnothing$, then it has a minimal element β in the inclusion because α is an ordinal. Then β is the minimal element of A. □

Cor. (1.2.4.5) [Supremum Ordinal]. Any set of ordinals has a supremum ordinal, it is just $\cup_{\alpha \in X}\alpha$.

Proof: Firstly $\cup_{\alpha \in X}\alpha$ is transitive and it is well-ordered(for each subset $A \subset X$, choose an $\alpha \in X$ that $\alpha \cap A \neq 0$, then the minimal element of $\alpha \cap A$ is just the minimal element of A.) so it is an ordinal.

Now if $\alpha \in X$, then $\alpha \subset \cup X$, so $\alpha \leq \cup X$ by(1.2.4.3). And if $\alpha \in \gamma$ for some ordinal γ, then $\cup X \subset \gamma$. So $\cup X$ is truly the supremum. □

Cor. (1.2.4.6). For any set X of ordinals, there is an ordinal α that is not in X, just choose $S(\cup X)$.

Prop. (1.2.4.7). Every well-ordered set is isomorphic to a unique ordinal.

So we can regard an ordinal as an equivalence class of isomorphic well-ordered sets.

Proof: Cf.[Set Theory Jech P111]. □

Cor. (1.2.4.8) [Cardinal as Initial Ordinal]. The axiom of choice together with(1.2.4.4) asserts that every cardinal has a unique smallest ordinal, called the **initial ordinal**. So we can identify cardinal number α as an ordinal that is the initial ordinal ω_α of α. Anyway, cardinal number is fewer than ordinal numbers.

The first infinite cardinal number(or the first initial ordinal) is denoted by ω or $\aleph_0$.

Prop. (1.2.4.9) [Transfinite Induction/Recursion]. If a property defined for the set of ordinals satisfies:

1. $P(0)$.
2. $P(\alpha + 1)$ if $P(\alpha)$.
3. $P(\lambda)$ if $P(\beta)$ for all $\beta < \lambda$.

then P is true for all ordinals.

Transfinite recursion:

Proof: □

Ordinal Arithmetic

Cf.[Set Theory Jech Chap5.5].

Def. (1.2.4.10). We use infinite recursion to define **addition of ordinals** as

- $\beta + 0 = \beta$
- $\beta + (\alpha + 1) = (\beta + \alpha) + 1$, where $\alpha + 1$ is the successor of α.
- $\beta + \alpha = \sup\{\beta + \gamma | \gamma < \alpha\}$ for a limit ordinal α.

The **multiplication of ordinals** and **exponentiation of ordinals** are defined similarly.

Remark (1.2.4.11) [Cardinal and Ordinal Arithmetics]. Note that the ordinal arithmetics may be smaller than the ordinal sum of the corresponding initial ordinal(1.2.4.8), because operations of initial ordinals may not be initial, the deeper reason is that the cardinal case, we can rearrange the order to get a smaller ordinal.

Prop. (1.2.4.12). The addition and multiplication of ordinals are of the order type of $\alpha \coprod \beta$ in adjunction order and $\alpha \times \beta$ in lexicographical order respectively, Cf.[Set Theory Jech P120,122]

Cantor Normal Form

Prop. (1.2.4.13) [Cantor Normal Form]. Any ordinal α can be expressed uniquely as the form $\alpha = \sum_{i<n} \omega^{\beta_i}$, where $\beta_0 \geq \beta_1 \geq \ldots \beta_{n-1}$ are ordinals.

Proof: Cf.[Jech Set Theory P124]. □

Prop. (1.2.4.14) [Goodstein Sequence]. The **weak Goodstein sequence** is a sequence that m_2 is any positive integer, m_{k+1} is m_k written in k-basis and replacing the base by $k+1$, and then minus 1.

The **Goodstein sequence** is a is a sequence that m_2 is any positive integer, m_{k+1} is m_k written in k-basis and even the exponents in k-basis and and replacing the base by $k+1$, and then minus 1.

Then for each Goodstein sequence and weak Goodstein sequence, it reaches 1 in a finite number of times.

Proof: Let $m_k = \sum k^{a_i} b_i$, then let the ordinal $\alpha_k = \sum \omega^{a_i} b_i$. Then it is clear that $\alpha_2 > \alpha_3 > \ldots$. But if the weak Goodstein sequence doesn't terminate, we constructed a descending sequence of ordinals that doesn't terminate, contradiction(choose a minimal element).

Similarly for Goodstein sequences, just replace every base k by ω. □

5 The Axiom of Choice

Def. (1.2.5.1) [Choice Functions]. Let S be a system of sets, a function g defined on S is called a **choice function** iff $g(X) \in X$ for each $X \in S$.

Axiom (1.2.5.2) [the Axiom of Choice, Zermelo1904]. Any system of sets has a choice function.

Thm. (1.2.5.3) [Zermelo1904]. The following are equivalent:

1. the axiom of choice.
2. (the well-ordering principle)Every set can be well-ordered.
3. (Zorn's lemma)If every chain in a partially ordered sets has a upper bound, then the partially ordered set has a maximal element.

Proof: $2 \to 1$: If A is well-ordered, then $P(A)$ clearly has a choice function, that is the minimal element of a set.

$1 \to 2$: Use transfinite recursion, Cf.[Set Theory Jech P137].

$2 \to 3, 3 \to 2$: Cf.[Set Theory Jech P142]. □

Prop. (1.2.5.4). Every infinite set X has a countable subset, if the axiom of choice holds.

Proof: Choose a well-ordering of it(1.2.5.3), then it is an infinite ordinal. Then the initial segment of the first ordinal $X[\omega]$ is a countable subset. □

Prop. (1.2.5.5). For every infinite set S, there exists a unique aleph $\aleph_\alpha$ that $|S| = \aleph_\alpha$.

Proof: choose a well-ordering of S(1.2.5.3), then it is an infinite ordinal, and it has the same cardinality as an initial cardinal by(1.2.4.8), thus the result. □

Cor. (1.2.5.6). For any sets A and B, either $|A| \le |B|$ or $|B| \le |A|$.

Proof: Because the ordinal is totally ordered(1.2.4.4). □

6 Cardinals

Thm. (1.2.6.1) [Cantor-Schröder-Bernstein]. If there is an injection from A to B and an injection from B to A, then there is a bijection from A to B. Thus the ordering of the cardinal is well-defined.

So we can denote $\#A \le \#B$ iff there is an injection from A to B. Then if $\#A \le \#B$ and $\#B \le \#A$, then $\#A = \#B$. In particular, this is a well-defined order relation.

Proof: It $f : A \to B$, $g : B \to A$ be injection, then use the above lemma(1.2.6.2) for $g \circ f(A) \subset g(B) \subset A$. □

Lemma (1.2.6.2). If $A_1 \subset B \subset A$ with $\#A = \#A_1$, then $\#A = \#B$.

Proof: Let f be a bijection from A to A_1. Define inductively $A_{n+1} = f(A_n), B_{n+1} = f(B_n)$. Then $A_{n+1} \subset B_n \subset A_n$. Let $C_n = A_n - B_n$, $C = \cup C_n$, then $f(C_n) = C_{n+1}$, so $f(C) = \cup_{i>0} C_i$.

Now define $g : A \to B = f(x)$ on C and x on $A \backslash C$, then it is a bijection from A to B. □

Def. (1.2.6.3) [Cardinal Numbers]. A **cardinal number** is an equivalence class of sets, where equivalence is given by bijections. it is used to describe the 'size' of a set.

It is by the axiom of choice that any two cardinal number can be compared.?

Denote $\aleph_0 = \#\mathbb{N}$(1.2.1.3).

Peano Arithmetics

Countable and Uncountable Sets

Def. (1.2.6.4) [Countable Sets]. A set is called **countable** iff it has the cardinality of $\aleph_0$(1.2.6.3). It is called a **finite set** if it has the cardinality of n for some natural number $n \in \mathbb{N}$. It is called an **uncountable set** iff it is not countable or finite. It is called an **at most countable set** if it is finite or countable.

Prop. (1.2.6.5). The subset or image of an at most countable set is at most countable.

Proof: □

Prop. (1.2.6.6). The product of two at most countable sets is at most countable. (Use diagonal enumerating).

Proof: □

Prop. (1.2.6.7). A countable union of almost countable subsets is almost countable.

Proof: It suffices to prove the countable case, the rest follows from(1.2.6.5). For this, choose an enumerating $a_n(k)$ for each A_n, the $\cup A_n$ is the image of $\mathbb{N}\times\mathbb{N}:(n,k)\mapsto a_n(k)$. Then it is countable by(1.2.6.6). □

Prop. (1.2.6.8). The set of finite sequences and hence the set of finite subsets of a countable set is countable.

Proof: The desired set equals $\cup_k A^k$, which is countable by(1.2.6.6) and(1.2.6.7). □

7 Cardinal Arithmetics

Def. (1.2.7.1). The **sum**, **multiplication** and **exponentiation** of two ordinal is the cardinality of the set $A\coprod B$, $A\times B$ or A^B respectively.

It is easily verified to be associative and commutative, just as usual operations.

Prop. (1.2.7.2). $\aleph_0\times\aleph_0=\aleph_0$ by(1.2.6.6). And $\kappa\times\kappa=\kappa$ for any infinite cardinal, if one uses the axiom of choice by(1.2.8.3).

Prop. (1.2.7.3). The image of a set X has cardinals no more than X, if axiom of choice holds.

Proof: Use axiom of choice to choose an element from each inverse image $f^{-1}(\{x\})$, then it is an injection from $f(X)$ to X. □

Prop. (1.2.7.4) [Cantor]. $\#P(X)=2^{\#X}$, and $\#X<\#\mathcal{P}(X)$.

Proof: The first is obvious, for the second, the function $x\to\{x\}$ is an injection of X into $P(X)$. And there are no mapping from X onto $P(X)$, because if f is one, the consider $S=\{x|x\notin f(x)\}$, then S is not in the range of f, because if $f(z)=S$, then $z\in S$ iff $z\notin S$, contradiction. □

Prop. (1.2.7.5) [Cardinality Arithmetic of $\aleph_0$]. For cardinality arithmetics involving $\aleph_0$, Cf.[Set Theory Jech P98].

Proof: □

Prop. (1.2.7.6). if $|B|=2^{\aleph_0}$ and $|A|\leq\aleph_0$, then $|B-A|=2^{\aleph_0}$. In fact, $|B-A|=|B|$ for any $|A|<|B|$, if one uses the axiom of choice.

Proof: By(1.2.7.5), we can assume $B=\mathbb{R}\times\mathbb{R}$, then project A onto the coordinate axis, then $\pi(A)$ has cardinality$\leq\aleph_0$, so there is a $x_0\notin\pi(A)$, so $x_0\times\mathbb{R}\subset B-A$, so $|B-A|=2^{\aleph}$.

For the general case, ? □

Conj. (1.2.7.7) [The Continuum Hypothesis, Cantor1878]. There is no cardinal κ that $\aleph_0<\kappa<2^{\aleph_0}$.

Notice $2^{\aleph_0}\geq\aleph_1$ by Cantor's theorem(1.2.7.4), and this hypothesis is equivalent to $2^{\aleph_0}=\aleph_1$.

Proof: □

For Infinite operation of Cardinal Arithmetics, Cf.[**?**]Chap9.

8 Alephs

Prop. (1.2.8.1). For any set A, there is a least ordinal that is not equipotent to any subset of A, called the **Hartogs number** of A. This is clearly an initial ordinal.

Proof: By axiom schema of replacement, any well-ordered subsets of A is equipotent to an ordinal, and also by axiom schema of replacement, there is a set H that for any well-ordering of subsets of A in $P(A\times A)$, this ordered sets is equipotent to a $\alpha\in H$. Then use(1.2.4.6) to find a minimal ordinal that is not equipotent to any subset of A. In fact, this is just $h(A)=\{\alpha\in H|\alpha \text{ equipotent to some subset of A}\}$. □

Def. (1.2.8.2)[Aleph]. The **alephs** for ordinal numbers are defined recursively: $\aleph_0=\omega$, $\aleph_{\alpha+1}=h(\aleph_\alpha)$, and $\aleph_\alpha=\sup\{\aleph_\beta|\beta<\alpha\}$ for a limit ordinal α. By definition $\alpha_\alpha<\aleph_\beta$ when $\alpha<\beta$.

Then $\aleph_\alpha$ are all infinite initial ordinal numbers, and any infinite ordinal number is of the form $\aleph_\alpha$ for some ordinal α. So natural numbers together with alephs are just all the cardinal numbers.

Notice: to avoid confusion, when do arithmetic of ordinal numbers, $\aleph_\alpha$ is written as ω_α.

Proof: Use transfinite induction on α. The only nontrivial case is when α is a limit ordinal, where if $\gamma<\aleph_\alpha$ and $|\gamma|=|\aleph_\alpha|$, then there is a $\beta<\alpha$ that $\gamma\le\aleph_\beta$ by definition, so $|\aleph_\alpha|<|\gamma|\le|\aleph_\beta|<|\aleph_\alpha|$ as $\aleph_\beta$ is an initial ordinal.

To prove that any infinite initial ordinal is an aleph, first notice that $\alpha<\aleph_\alpha$ by a simple transfinite induction. So we may use transfinite induction on the following assertion for α: if $\Omega<\aleph_\alpha$, then there is a $\gamma<\alpha$ that $\Omega=\aleph_\gamma$. For this, $\alpha=0$ is trivially true, if $\alpha=\beta+1$, then $\Omega<h(\aleph_\alpha)$ implies that $|\Omega|<|\aleph_\alpha|$ by definition. Because Ω is initial, $\Omega=\aleph_\beta$ or $\Omega<\aleph_\beta$, so by induction hypothesis it is true. If α is a limit ordinal, then $\Omega<\omega_\beta$ for some $\beta<\alpha$, so also by induction hypothesis it is true. □

Aleph Arithmetics

Prop. (1.2.8.3). $\aleph_\alpha\cdot\aleph_\alpha=\aleph_\alpha$.

Proof: Cf.[Set Theory Jech P134]. □

Cor. (1.2.8.4). $\aleph_\alpha\cdot\aleph_\beta=\aleph_\beta$ for $\alpha\le\beta$, and $n\cdot\aleph_\beta=\aleph_\beta$.

So $\aleph_\alpha+\aleph_\beta=\aleph_\beta$ for $\alpha\le\beta$, and $n+\aleph_\beta=\aleph_\beta$.

9 Natural Numbers and Real Numbers

Prop. (1.2.9.1). $\mathbb{R}$ is the unique ordered field in which every non=empty bounded set has a least upper bound.

Proof: □

Prop. (1.2.9.2). $(\mathbb{N},<)$(1.2.1.5) is a well-ordered set.

Proof: □

Example (1.2.9.3)[Examples of Countable Sets].

- $\mathbb{Z}$.
- $\mathbb{Q}$.

Arithmetic of Real numbers

Prop. (1.2.9.4). The set of real numbers $\mathbb{R}$(1.2.3.21) can be endowed with a field structure, making it an ordered field.

Proof: Cf.[Set Theory Jech P175]. □

Prop. (1.2.9.5). $\mathbb{R}$ satisfies the least upper bound hypothesis.

Proof: □

10 Filters and Ultrafilters

Def. (1.2.10.1) [Filter]. For a poset P, a **filter** on P is a subset F that

- If $p < q$ and $p \in F$, then $q \in F$.
- If $p, q \in F$, then there is an $r \in F$ that $r < p, r < q$.

Def. (1.2.10.2) [Filter on Sets]. Let S be a non-empty set, a **filter** on S is a filter F on $\mathcal{P}(S)$ that $\varnothing \notin F$.

an **ideal** on S is a collection F of subsets of S that:

- $\varnothing \in F$ and $S \notin F$.
- If $X, Y \in F$, then $X \cup Y \in F$.
- If $X \in F, X \supset Y$, then $Y \in F$.

An ideal is just the dual(complement) of a filter.

Def. (1.2.10.3) [Finite intersection property]. A family of subsets of a set is said to have the **finite intersection property** if any finite collection of elements of this family is non-empty.

Lemma (1.2.10.4). let G be a collection of subsets of S that has the finite intersection property(1.2.10.3), then there is a smallest filter F that $G \subset F$. It is just the collection of subsets of S that contain some finite intersection set of elements of G.

Def. (1.2.10.5) [Ultrafilter]. An **ultrafilter** is a filter F that for every subset X, $X \in F$ iff $S - X \notin F$. A **prime ideal** is an ideal that for every subset X, $X \in F$ iff $S - X \notin F$.

A ultrafilter is equivalent to a maximal filter. And it is equivalent to a $\{0, 1\}$-valued finitely additive measure on S.

Proof: If F is an ultrafilter, then it is maximal, because any larger filter will have some $X, S - X$, thus has $\varnothing$, contradiction.

Conversely, if F is maximal filter but not ultra, then there is a X that $X \notin F$, $S - X \notin F$. Let $G = F \cup \{X\}$, then any finite intersection of elements of G is not empty: $X_1 \cap \ldots \cap X_n \cap X \neq 0$ otherwise $S - X \in F$. So there is a filter containing G by(1.2.10.4), contradiction. □

Prop. (1.2.10.6) [Pushforward of Filters]. If $\mathcal{F}$ is a(n) (ultra)filter on X and $f : X \to Y$ is a function, then $f_*(\mathcal{F}) = \{A \subset Y | f^{-1}(A) \in \mathcal{F}\}$ is a(n) (ultra)filter on X, called the **pushforward filter** of $\mathcal{F}$.

Prop. (1.2.10.7). For an ultrafilter $\mathcal{F}$ on X , if $U_i \notin \mathcal{F}$, then $\sum_{i=1}^{n} U_i \notin \mathcal{F}$.

Proof: As $X - U_i \in \mathcal{F}$, there intersection are in $\mathcal{F}$, so its complement is not in $\mathcal{F}$. □

Prop. (1.2.10.8). Any filter can be extended to an ultrafilter(maximal filter), if the axiom of choice is used.

Proof: Use Zorn's lemma(1.2.5.3). It suffices to prove that a union of a chain of filters is a filter, which is trvial. □

Cor. (1.2.10.9). Non-principal ultrafilter exists on any infinite set. And in fact, any non-principal ultrafilter contains all the cofinite sets.

For any non-principle ultrafilter, it cannot contains a single pt $\{x\}$, so it contains every cofinite set.

Proof: Consider any ultrafilter containing the filter of cofinite sets of S, then it is non-principal. □

Def. (1.2.10.10) [κ-Completeness]. Let κ be an uncountable cardinal, then a field F on a set S is called **κ-complete** if for every cardinal $\lambda < \kappa$, if $X_\alpha \in F$ for every $\alpha < \lambda$, then $\cap_{\alpha<\lambda} X_\alpha \in F$.

An $\aleph_1$-complete filter is also called a σ-complete filter.

Closed unbounded and Stationary Set

11 Models

Cf.[Axiomatic Set Theory]P12.

Def. (1.2.11.1).

Absoluteness

12 Large Cardinals

Def. (1.2.12.1) [Abstract Measures]. Let S be a non-empty set, then an **abstract measure** on S is a non-trivial probabilistic measure μ on the measurable space $(S, \mathscr{P}(S))$ that $\mu(\{a\}) = 0$ for any $a \in S$.

Def. (1.2.12.2) [Regular Cardinal]. A cardinal is called **regular** if it is not a sum of λ cardinals κ_i that $\lambda < \kappa$ and $\kappa_i < \kappa$.

Def. (1.2.12.3)[Strong Limit]. A cardinal κ is called a **strong limit** if $2^\lambda < \kappa$ for any $\lambda < \kappa$(1.2.12.3).

Def. (1.2.12.4)[Strongly Inaccessible Cardinal]. A cardinal κ is called **strongly inaccessible(SI)** if it is regular(1.2.12.2) and is a strongly limit.

Def. (1.2.12.5) [Weakly Inaccessible Cardinal]. A cardinal κ is called **weakly inaccessible** if it is regular and is a limit cardinal.

Prop. (1.2.12.6) [Measure and CH]. If there exists an abstract measure on $2^{\aleph_0}$, then the Continuum Hypothesis(1.2.7.7) fails.

Proof: Cf.[**?**]P242. □

Prop. (1.2.12.7). If there is a measure on a set S, then some cardinal $\kappa \leq |S|$ is weakly inaccessible.

Proof: Cf.[**?**]P243. □

Prop. (1.2.12.8). Let μ be a $\{0,1\}$-valued measure on S, then $U = \{X \subset S | \mu(X) = 1\}$ is a non-principal σ-complete ultrafilter of S

Prop. (1.2.12.9) [Stanislaw-Ulam Dichotomy]. If there exists a measure on some set, then either there exists a $\{0,1\}$-valued measure on some set, or there exists a measure on $2^{\aleph_0}$.

Proof: Cf.[**?**]P245. □

Def. (1.2.12.10) [Measurable Cardinals]. A **measurable cardinal** is an uncountable cardinal κ on which there exists a non-principal κ-complete ultrafilter.

Prop. (1.2.12.11). A measurable cardinal is strongly inaccessible.

Proof: Cf.[**?**]P247. □

13 Gödel Model

14 Silver Machine

15 Forcing

Def. (1.2.15.1) [Dense Subset]. In a poset P, a subset $D \subset P$ is called **dense** if for any $p \in P$, there is a $q \in D$ that $q < p$. If $\mathcal{D}$ is a collection of dense subsets of P, a filter $G \subset P$ is called **$\mathcal{D}$-generic** if $D \cap G \neq \varnothing$ for all $D \subset \mathcal{D}$.

Prop. (1.2.15.2). If $\mathcal{D}$ is a countable collection of dense subsets of P, then there is a $\mathcal{D}$-generic filter G.

Proof: Let $\mathcal{D} = \{D_1, \ldots, D_n, \ldots\}$. Choose $p_0 \in P$, and consecutively choose $p_n \leq p_{n-1}$ that $p_n \in D_n$, and define $G = \{q | q \geq p_n \text{ for some } n\}$. □

Axiom (1.2.15.3) [Martin's Axiom]. If P is a partially ordered set satisfying the countable chain condition(1.2.3.7), and D is a collection of dense subsets of P with $|D| < 2^{\aleph_0}$, then there is a D-generic filter on P.

16 Determinacy

17 Stationary Set

1.3 Combinatorial Set Theory

Def. (1.3.0.1) [Notations]. For a set S, let $[S]^r$ be the set of subsets of S of order r. Let κ, λ be cardinals, we write $\kappa \to (\lambda)^r_s$ as a shorthand for: for any set S with $|S| = \kappa$ and every partition of $[S]^r$ into s classes, there exists a subset $H \subset S$ that $[H]^r$ is in the same class, and $|H| \geq \lambda$.

Prop. (1.3.0.2) [Ramsey's Theorem]. For any positive natural number r, s if we color the r-subsets of a set with cardinality $\aleph_0$ into s families, then there is a subset of cardinal $\aleph_0$ that all its r-subsets are colored the same.

Cor. (1.3.0.3). Every infinite linearly ordered set contains a subset isomorphic to $(\mathbb{N}, <)$ or $(\mathbb{N}, >)$.

Proof: Choose a well ordering of it. Then consider this new ordering and the original ordering. Then there is an infinite set that is compatible with the original ordering, or converse. Then its initial segment of order type ω_0 satisfies the requirement. □

Def. (1.3.0.4) [Weakly Compact Cardinals]. An **weakly compact cardinal** is an uncountable cardinal κ that $\kappa \to (\kappa)^r_s$(1.3.0.1) for any $r, s \in \mathbb{Z}_+$.

Prop. (1.3.0.5). Weakly compact cardinals are strongly inaccessible.

Proof: Cf.[**?**]P224. □

Trees

Def. (1.3.0.6). A **tree** is a partial ordered set T that there is a minimal element r and for each x, $\{y \in T | y < x\}$ is finite and linearly ordered.

A tree is called **of finite branched** for each x, there is a finite set $\{y_1, \ldots, y_r\}$ is T that $y_i > x$ and if $z > x$, then $z \geq y_i$ for some i.

Def. (1.3.0.7) [Height]. For any node x, $\{y \in T | y < x\}$ is a well-ordered set, which is isomorphic to an ordinal by(1.2.4.7), it is called the **height** of x. T_α denotes the set of all nodes of T of order α. The least α that $T_\alpha \neq \varnothing$ is called the **height** of T.

A **branch** is a maximal chain in T, its **length** is its ordinal. The length is always smaller than the height of the tree. If it equals the height of the tree, it is called **cofinal**.

Def. (1.3.0.8). A **subtree** is a subset T' of T that if $x \in T', y < x$, then $x \in T'$.

An **antichain** of a tree T is a subset $A \subset T$ that any two elements in A are incomparable.

Def. (1.3.0.9). A **path** through T is a morphism of ordering from ω to T.

Lemma (1.3.0.10) [König's Lemma]. If T is an infinite finite branching tree, then there is a path through T.

Proof: Use recursion to choose for each n an element that has infinite successors. □

Def. (1.3.0.11). An **Aronszajn tree** is a tree of height κ and all its level sets are at most countable, but has no branches of length κ.

Prop. (1.3.0.12). An **Aronszajn tree** of height ω_1 exists.

Proof: Cf.[Set Theory Jech P228]. □

1 Finite Sets

Thm. (1.3.1.1) [Dirichlet's Box Principle].

Proof: □

Ramsey's Theory

Prop. (1.3.1.2) [Finite Ramsey's Theorem]. For any $\alpha, k, n_1, \ldots, n_k \in \mathbb{Z}_+, n_i \geq \alpha$, there exists a minimal $R(\alpha, k; n_i) \in \mathbb{Z}_+$ s.t. if we divide the α-subsets of a set with cardinality $R(\alpha, k; n_i)$ into k groups $C_1, \ldots, C_k$, then there is some $1 \leq i \leq k$ and a subset S of cardinality n_i s.t. all the α-subset of S is in C_i. Moreover,

$$R(\alpha, k; n_i) \leq R(\alpha - 1, k; m_j = R(\alpha, k; n_1, \ldots, n_{j-1}, n_j - 1, n_{j+1}, \ldots, n_k)) + 1.$$

Proof: We use double induction on (α, k) in lexicographical order. If $\alpha = 1$, clearly $R(1, k; n_i) = \sum_{i=1}^k (n_i - 1) + 1$. And if $k = 1$, then $R(\alpha, 1; n_1) = n_1$.

Suppose $\alpha > 1, k > 1$, if some $n_i = \alpha$, then $R(\alpha, k; n_i) = R(\alpha, k-1; n_1, \ldots, \widehat{n_i}, \ldots, n_k)$, thus we are reduced to smaller k. So we can assume that $n_i > \alpha$ for each i. In this case, we prove that

$$R(\alpha, k; n_i) \leq R(\alpha - 1, k; m_j = R(\alpha, k; n_1, \ldots, n_{j-1}, n_j - 1, n_{j+1}, \ldots, n_k)) + 1.$$

And this will finish the induction process.

To prove this, notice that if we have a set X with cardinality equal to the RHS, and let $x \in X$, then we can divide the $(\alpha - 1)$ subsets of $X \setminus \{x\}$ into k groups $C'_1, \ldots, C'_k$ s.t. an $(\alpha - 1)$-set S has cardinality $\alpha - 1$ belongs to C'_i iff $S \cup \{x\}$ belongs to C_i. Then by definition, there exists some i and some subset Y of $X \setminus \{x\}$ of cardinality $R(\alpha, k; n_1, \ldots, n_{i-1}, n_i - 1, n_{i+1}, \ldots, n_k)$ s.t. all $(\alpha - 1)$-subset of Y belongs to C'_i. Then by definition, there either exists some $j \neq i$ and some subset Z_1 of Y of cardinality n_j s.t. all the α-subset of Z_1 is in C_j, in which case the assertion is satisfied; or exists some subset Z_2 of Y of cardinality $n_i - 1$ s.t. all the α-subset of Z_2 is in C_i. Then $Z_2 \cup \{x\}$ satisfies the assertion. □

Prop. (1.3.1.3) [Szekeres]. For any $a, b \in \mathbb{Z}_{\geq 2}$, $R(2; a, b) \leq \binom{a+b-2}{a-1}$.

Proof: Use induction on $a + b$: If $a = 2$ or $b = 2$, this is easy. And for $a, b \geq 3$, by(1.3.1.2),

$$R(2; a, b) \leq R(2; a-1, b) + R(2; a, b-1) \leq \binom{a+b-3}{a-2} + \binom{a+b-3}{a-1} = \binom{a+b-2}{a-1}$$

□

Prop. (1.3.1.4) [Erdös]. For $k \in \mathbb{Z}_{\geq 3}$,

$$2^{k/2} < R(2; k, k) \leq \binom{2k-2}{k-1} < 4^{k-1}.$$

Proof: If $N < 2^{k/2}$, then the number of different graphs of N vertices equals $2^{N(N-2)/2}$, and the number of different graphs containing a complete k-graph is less than

$$\binom{N}{k} 2^{N(N-1)/2 - k(k-1)/2} < \frac{N^k}{k!} 2^{N(N-1)/2 - k(k-1)/2} < \frac{2^{N(N-1)/2}}{2},$$

because $2^{\frac{k}{2}+1} < k!$ for $k \geq 3$. So there exists a graph G that neither G and its complement graph G' contains a complete k-graph. Thus $2^{k/2} < R(2; k, k)$.

The second inequality follows form(1.3.1.3). □

Intersection Theorems

Prop. (1.3.1.5) [Sperner]. For $n \in \mathbb{Z}_+$, any system $\{S_1, \ldots, S_v\}$ of subsets of $[n]_+$ s.t. no set S_i contains another S_j, then $v \le \binom{m}{\lfloor m/2 \rfloor}$.

Proof: □

Prop. (1.3.1.6) [Erdös-Ko-Rado]. For $k, n \in \mathbb{Z}_+, n \ge 2k$, any system $\mathcal{S} = \{S_1, \ldots, S_v\}$ of subsets of $[n]_+$ s.t. $\#S_i = k$ for each i, and $S_i \cap S_j \ne \varnothing$ for any $1 \le i, j \le v$, then $v \le \binom{n-1}{k-1}$. The equality can be achieved when all S_i contains 1.

Proof: Use counting by twice method: For any permutation σ of $[n]_+$, let $A_s^\sigma = \{\sigma(s), \sigma(s+1), \ldots, \sigma(s+k-1)\}$(where addition is modulo n), then it can be seen easily that among the subsets $\{A_1^\sigma, \ldots, A_n^\sigma\}$, at most k of them are contained in $\mathcal{S}$. Thus by counting twice,

$$\frac{\#\mathcal{S}}{\binom{n}{k}} \le \frac{k}{n},$$

which implies $\#\mathcal{S} \le \frac{k}{n}\binom{n}{k} = \binom{n-1}{k-1}$. □

1.4 Homotopy Type Theory

1.5 Model Theory

References are [Model Theory Marker]. The exercises of [Model Theory Marker] are important.

Notation (1.5.0.1).

- Use notations defined in Set Theory.
- All propositions from now are wffs in class theory(or with choice or large cardinal), so there are no metatheorems.

1 Set Models

Basics

Def. (1.5.1.1) [Structures]. Given a mathematical language $\mathcal{L}$(1.1.7.1), an **$\mathcal{L}$-structure** on a set M is an assignment for each constant symbol c an element $c^M \in M$, for each function symbol f of arity n a function $f^M : M^n \to M$, and for each relation symbol R of arity m a subset $R^M \subset M^m$. These c^M, f^M, R^M are called **interpretations** of $\mathcal{L}$.

And there is a natural definition of morphisms of $\mathcal{L}$-structures, and an injective morphism of $\mathcal{L}$-structures is called an embedding or a **structure extension**.

Def. (1.5.1.2) [Satisfaction]. Let φ be a formula with free variables $\overline{v} = (v_{i_1} \ldots, v_{i_m})$, then we inductively define $\mathcal{M} \models \varphi(\overline{a})$ as follows:

- If φ is $t_1 = t_2$ where t_1, t_2 are terms, then $\mathcal{M} \models \varphi(\overline{a})$ if $\sqcup_1^{\mathcal{M}}(\overline{a}) = t_2^{\mathcal{M}}(\overline{a})$.
- If φ is $R(t_1, \ldots, t_n)$, then $\mathcal{M} \models \varphi(\overline{a})$ if $(t_1^{\mathcal{M}}(\overline{a}), \ldots, t_n^{\mathcal{M}}(\overline{a})) \in R^{\mathcal{M}}$.
- If φ is $\neg\psi$, then $\mathcal{M} \models \varphi(\overline{a})$ if $\mathcal{M} \not\models \psi(\overline{a})$.
- If φ is $\psi \wedge \theta$, then $\mathcal{M} \models \varphi(\overline{a})$ if $\mathcal{M} \models \psi(\overline{a})$ and $\mathcal{M} \models \theta(\overline{a})$.
- If φ is $\exists v_j \psi(\overline{v}, v_j)$, then $\mathcal{M} \models \varphi(\overline{a})$ is there is a $b \in M$ that $\mathcal{M} \models \psi(\overline{a}, b)$.

and we say M **satisfies** $\varphi(\overline{a})$, or $\varphi(\overline{a})$ is true in M. Notice if there is no free variables, $\varphi(\overline{a})$ just writes φ.

Def. (1.5.1.3) [Mathematical $\mathcal{L}$-Theory]. Let $\mathcal{L}$ be a mathematical language, then a (mathematical)**$\mathcal{L}$-theory** is a consistent extension of $\mathscr{K}_{\mathcal{L}}$(1.1.6.2).

Def. (1.5.1.4) [Models]. If T is an $\mathcal{L}$-theory and M a set with $\mathcal{L}$-structure satisfying all theorems $\varphi \in T$, then M is called a **model** of T, and writes $M \models T$.

A theory T is called **satisfiable** iff there is a model $\mathcal{M}$ for T.

A set of $\mathcal{L}$-structures $\mathcal{K}$ is called an **elementary class** iff there is an $\mathcal{L}$-theory T that $\mathcal{K} = \{\mathcal{M} | \mathcal{M} \models T\}$.

Given a $\mathcal{L}$-structure on M, the **theory of** M is the set of all sentences true in M.

Two $\mathcal{L}$-structures $\mathcal{M}$ and $\mathcal{N}$ are called **elementary equivalent**, denoted by $\mathcal{M} \equiv \mathcal{N}$, if for all $\mathcal{L}$-sentences φ, $\mathcal{M} \models \varphi \iff \mathcal{N} \models \varphi$.

Prop. (1.5.1.5). If T is a mathematical $\mathcal{L}$-theory given by axioms, and every axiom of M is a set with $\mathcal{L}$-structure satisfying every axiom, then $\mathcal{M}$ is a model of T.

Proof: This follows from induction on the length of the proof of a theorem. □

Prop. (1.5.1.6). A mathematical $\mathcal{L}$-theory is consistent iff it has a model.

Proof: Cf.[Hamilton]P91+98.**?** □

Prop. (1.5.1.7) [Quantifier-Free Formulae]. Suppose $\mathcal{M}$ is a substructure of $\mathcal{N}$ and $\overline{a}$ is a tuple in $\mathcal{M}$. If $\varphi(\overline{v})$ is a quantifier-free formula, then $\mathcal{M} \models \varphi(\overline{a})$ iff $\mathcal{N} \models \varphi(\overline{a})$.

Proof: Cf.[Model Theory P11]. □

Prop. (1.5.1.8). If $\mathcal{L}$-structures $\mathcal{M} \cong \mathcal{N}$, then $\mathcal{M}$ is elementarily equivalent to $\mathcal{N}$.

Proof: This seemingly trivial proposition still needs proof, and the proof uses induction, just as that of(1.5.1.7). □

Def. (1.5.1.9) [Logical Consequence]. Let T be an $\mathcal{L}$-theory and φ an $\mathcal{L}$-sentence, then φ is called a **logical consequence** of $\mathcal{T}$, writes $T \models \varphi$, if for any $\mathcal{L}$-structure $\mathcal{M}$ that $\mathcal{M} \models T$, $\mathcal{M} \models \varphi$.

Definable Sets and Interpretability

Def. (1.5.1.10). Let $\mathcal{M}$ be an $\mathcal{L}$-structure, a subset X of $\mathcal{M}^n$ is called **definable** iff there is an $\mathcal{L}$-formula $\varphi(v_1, \ldots, v_n, w_1, \ldots, w_m)$ and a tuple $\overline{b} \in \mathcal{M}^m$ that $X = \{\overline{a} \in M^n : \mathcal{M} \models \varphi(\overline{a}, \overline{b})\}$. Moreover if $A \subset M$, X is called **A-definable** iff $y_i \in A$.

Prop. (1.5.1.11) [Examples of Definable Sets]. The definability of some sets are often nontrivial, using many number theories. For example, Cf.[Marker P20].

Prop. (1.5.1.12). There is an inductive characterization of definable sets, Cf.[Marker P22].

Prop. (1.5.1.13). If $\mathcal{M}$ is an $\mathcal{L}$-structure, If $X \subset \mathcal{M}^n$ is A-definable, then very $\mathcal{L}$-automorphism of $\mathcal{M}$ that fixes A pointwise will fixes X setwise.

Proof: For an automorphism τ of $\mathcal{M}$, $\mathcal{M} \models \varphi(\overline{b}, \overline{a})$ iff $\mathcal{M} \models \varphi(\tau(\overline{b}), \tau(\overline{a})) = \varphi(\tau(\overline{b}), \overline{a})$. □

Cor. (1.5.1.14). $\mathbb{R}$ is not definable in $\mathbb{C}$.

Proof: If $\mathbb{R}$ is definable, it is definable over a finite set $A \subset \mathbb{C}$, Let r, s be algebraically independent over $\mathbb{A}$ and $r \in \mathbb{R}, s \notin \mathbb{R}$. This can be done, otherwise $\mathbb{C}$ or $\mathbb{R}$ is finite transcendental over $\mathbb{Q}$, then $|\mathbb{C}| = |\mathbb{Q}|$(2.2.6.3), which is impossible by(1.2.3.21). Then there is an automorphism σ of $\mathbb{C}$ fixing A that $\sigma(r) = s$, so $\mathbb{R}$ is not definable by(1.5.1.13). □

Def. (1.5.1.15) [Definably Interpretability]. An $\mathcal{L}_0$-structure $\mathcal{N}$ is called **definably interpreted** in an $\mathcal{L}$-structure $\mathcal{M}$ if there is a definable set $X \subset \mathcal{M}^n$ that we can interpret the symbols of $\mathcal{L}_0$ as definable subsets and functions of X and the resulting $\mathcal{L}_0$-structure is isomorphic to $\mathcal{N}$.

The usual example is that the group structure of $GL_2(K)$ is definably interpreted in the ring structure of a field.

Def. (1.5.1.16) [Interpretability and Quotient Construction]. An $\mathcal{L}_0$-structure $\mathcal{N}$ is called **interpretable** in an $\mathcal{L}$-structure $\mathcal{M}$ iff there is a definable set $X \in \mathcal{M}^n$ and a definable equivalence relation E on X, that we can interpret the symbols of $\mathcal{L}_0$ as definable subsets and functions of X/E and the resulting $\mathcal{L}_0$-structure is isomorphic to $\mathcal{N}$.

The usual example is that the set structure of a projective space is interpretable in the ring structure of a field.

Prop. (1.5.1.17). Any structure for a countable language can be interpreted in a graph.

Proof:

□

2 Basic Techniques

Def. (1.5.2.1) [Definitions for Theories]. A theory T is said to have the **witness property** iff whenever $\varphi(v)$ is an $\mathcal{L}$-formula with one free variable v, there is a constant symbol c that $T \models (\exists v\varphi(v) \to \varphi(c))$.

A theory T is called **maximal** iff for any $\mathcal{L}$-sentence, either $\varphi \in T$ or $\neg\varphi \in T$.

A theory T is called **complete** iff for any $\mathcal{L}$-sentence, either $T \models \varphi$ or $T \models \neg\varphi$.

Def. (1.5.2.2) [Consistent Theory]. A theory T is called **inconsistent** if there is a sentence φ that $T \vdash \varphi \wedge \neg\varphi$, otherwise it is called **consistent**.

Def. (1.5.2.3) [Recursiveness and Decidablility]. A language $\mathcal{L}$ is called **recursive** iff there is an algorithm that decides whether a sequence of symbols is an $\mathcal{L}$-formula.

An $\mathcal{L}$-theory T is called **recursive** iff there is an algorithm that decides whether a given $\mathcal{L}$-sentence is in T.

An $\mathcal{L}$-theory T is called **decidable** iff there is an algorithm that decides whether a given φ satisfies $T \models \varphi$.

Prop. (1.5.2.4). If $\mathcal{L}$ is a recursive language and T is a recursive $\mathcal{L}$-structure, then $\{\varphi | T \vdash \varphi\}$ is recursively enumerable.

Proof: There is a computable listing $\sigma_1, \ldots, \sigma_n \ldots$ of all the finite sequences of $\mathcal{L}$-formulas, because $\mathcal{L}$ is recursive. Then we can check at each stage iff σ_i is a proof of φ. This involves checking if each formula is in T(checkable because T is recursive) or it is a simple consequences of formulae before it, and finally check the last formula is φ. If σ_i is a proof of φ, then halt, otherwise go on to check σ_{i+1}. □

Prop. (1.5.2.5). The halting computation set is not computable.

Proof: Cf.[Mathematical Logic Shoenfield]**?**. □

Cor. (1.5.2.6). The full theory $Th(\mathbb{N})$ of the ring structure of $\mathbb{N}$ is undecidable.

Proof: If such an algorithm exists, then we can use it to compute whether the sentence

$$\varphi(e, x) = \exists s T(\underbrace{1 + \ldots + 1}_{e-\text{times}}, \underbrace{1 + \ldots + 1}_{x-\text{times}}, s)$$

is computable. Then this will contradicts the fact that halting computation set is not computable(1.5.2.5). □

Prop. (1.5.2.7) [Gödel's Completeness Theorem]. Let T be an $\mathcal{L}$-theory and φ is an $\mathcal{L}$-sentence, then $T \models \varphi$ iff $T \vdash \varphi$.

Proof: **?** □

Cor. (1.5.2.8) [Consistent and Satisfiable]. A theory T is consistent iff it is satisfiable.

Proof: If T is satisfiable, then it is clearly consistent, and if T is not satisfiable, then there are no models for T, so $T \models \varphi \wedge \neg\varphi$ by definition, so $T \vdash \varphi \wedge \neg\varphi$ by Gödel's completeness theorem. □

Cor. (1.5.2.9) [Lemma on Constants]. Suppose $T \vdash \varphi(\bar{c})$ and $\bar{c}$ is a tuple of constants not appearing in T, then $T \vdash \forall x\varphi(x)$.

Proof: We use the Gödel's completeness theorem(1.5.2.7), and notice this theorem is obviously true for $\vdash$ replaced by $\models$. Notice we can add the constants to $\mathcal{L}$, thus $\varphi(\bar{c})$ has no free variables. □

Ultraproducts of Theories

Def. (1.5.2.10) [Ultraproducts of Theories]. If $M_i, i \in I$ is a collection of $\mathcal{L}$-structures and $\mathcal{F}$ is an ultrafilter on I, then the **ultraproduct** $\prod_I M_i/\mathcal{F}$ of M_i is a $\mathcal{L}$-structure defined as:

- The underlying set $M = \prod M_i/\sim$, where $(a_i) \sim (b_i)$ iff $\{i \in I | a_i = b_i\} \in \mathcal{F}$, which is an equivalent relation.
- If c is a constant symbol, then $c^M = (c^{M_i})$.
- If f is a function symbol, then $f^M([a_{i1}], \ldots, [a_{in}]) = [f^{M_i}(a_{i1}, \ldots, a_{in})]$.
- If R is a relation symbol, then $([a_{i1}], \ldots, [a_{in}]) \in R^M$ iff $\{i \in I | (a_{i1}, \ldots, a_{in}) \in R^{M_i}\} \in \mathcal{F}$.

Prop. (1.5.2.11) [Los Theorem]. Let $M_i, i \in I$ be $\mathcal{L}$-structures and $\mathcal{F}$ be an ultrafilter on I. Let $\varphi(\overline{x})$ be a first-order logic formula in the free variables $\overline{x}$, and let $\overline{[(a_i)]}$ be a tuple of elements from $\prod_I M_i/\mathcal{F}$, then

$$\prod_I M_i/\mathcal{F} \models \varphi(\overline{[(a_i)]}) \iff \{i \in I | M_i \models \varphi_i(\overline{a_i})\} \in \mathcal{F}.$$

Proof: The proof is by induction, which is routine, Cf.[Model Theory for Algebra and Algebraic Geometry, P22]. ☐

Cor. (1.5.2.12). An ultraproduct of models for a theory T is also a model for T.

Cor. (1.5.2.13) [Non-Standard Model for Th($\mathbb{R}$)]. Consider $\mathbb{R}$ in the language $\mathcal{L}_r$, where L_r is the language of rings, (i.e., the ring structure), let $\mathcal{F}$ be a non-principle ultrafilter on $\mathbb{N}$(1.2.10.9), and consider the ultraproduct $\mathcal{R} = \prod_{i \in \mathbb{N}} \mathbb{R}/\mathcal{F}$, which is called an **ultrapower** of $\mathbb{R}$.

Notice each factor satisfies $Th(\mathbb{R})$, so $\mathcal{R}$ also satisfies $Th(\mathbb{R})$.

Cor. (1.5.2.14). Using ultraproduct construction, we can find a field of characteristic 0 that has exactly one algebraic extension in each degree.

Proof: Just use the field model $\mathbb{F}_p$ for all p and construct their ultraproduct w.r.t. a non-principal ultrafilter. ☐

Prop. (1.5.2.15) [Keiler-Shelah Theorem]. Two $\mathcal{L}$-structures $\mathcal{M}$ and $\mathcal{N}$ are elementary equivalent iff there is an index set I and an ultrafilter $\mathcal{F}$ on I that $\prod_I M/\mathcal{F} \cong \prod_I N/\mathcal{F}$.

Proof: Cf.[C. C. Chang and H. J. Keisler, Model Theory 6.1.15]. ☐

Compactness Theorem and Henkin Construction

Lemma (1.5.2.16). Suppose T is a maximal and finitely satisfiable $\mathcal{L}$-theory with the witness property, then T is satisfiable. In fact, T has κ constant symbols, then there is a model $\mathcal{M} \models T$ that $|\mathcal{M}| \leq \kappa$.

Proof: Cf.[Marker, P35]. ☐

Lemma (1.5.2.17). Let $\mathcal{L}$ be a finitely satisfiable $\mathcal{L}$-theory, then there is a language $\mathcal{L} \subset \mathcal{L}^*$ and a $T \subset T^*$ a finitely satisfiable $\mathcal{L}^*$-theory that any $\mathcal{L}^*$-theory extending T^* has the witness property. And we can choose $|\mathcal{L}^*| = |\mathcal{L}| + \aleph_0$.

Proof: We first show there is a language $\mathcal{L} \subset \mathcal{L}_1$ and a finitely satisfiable $\mathcal{L}_1$-theory $T \subset T_1$ that witnesses all $\mathcal{L}$-formulae: We add a constant symbol c_φ for each $\mathcal{L}$-formula φ, and add sentences $(\exists v\varphi(v)) \to \varphi(c_\varphi)$ to T, then this T_1 is finitely satisfiable, because for any finite subset Δ of T_1, only f.m. constant symbols appear, and we have a model $\mathcal{M}$ for $\Delta \cap T$, thus we can interpret c_φ as the element a that $\mathcal{M} \models \varphi(a)$, if $\mathcal{M} \models \exists v\varphi(v)$. Now we can inductively define L_n, T_n, and consider their union, then this satisfies the desired conditions. And the cardinality is also clear. □

Lemma (1.5.2.18). If T is a finitely satisfiable $\mathcal{L}$-theory, then there is a maximal(1.5.2.1) finitely satisfiable $\mathcal{L}$-theory $\mathcal{L} \subset \mathcal{L}'$.

Proof: it is easy to construct a maximal satisfiable $\mathcal{L}$-theory, and it is truly maximal in sense of(1.5.2.1): for any sentence φ, if $T \cup \varphi$ is not finitely satisfiable, then there is a finite set $\Delta \subset T$ that $\Delta \models \neg\varphi$. Then we claim $T \cup \neg$ is finitely satisfiable: for another finite set Σ, because $\Delta \cup \Sigma$ is finitely satisfiable and $\Delta \models \neg\varphi$, $\Sigma \cup \neg\varphi$ is satisfiable. □

Prop. (1.5.2.19) [Strong Compactness Theorem]. If T is a finitely satisfiable $\mathcal{L}$-theory and κ is an infinite cardinal that $\kappa > |\mathcal{L}|$, then there is a model of T of cardinality at most κ.

Proof: By(1.5.2.17), we get a desired language $\mathcal{L}^*$ of cardinality$\leq \kappa$, and a theory $\mathcal{T}^*$, and by(1.5.2.18), we can assume T^* is maximal and finitely satisfiable, and it has the witness property. Then(1.5.2.16) says there is a model of cardinality$\leq \kappa$. □

Cor. (1.5.2.20) [Compactness Theorem]. A theory T is satisfiable iff every finite subset of T is satisfiable.

Remark (1.5.2.21). Notice the compactness theorem is also a consequence of the completeness theorem(1.5.2.7): if T is not satisfiable, then it is not consistent by(1.5.2.8). Let σ be a proof of a contradiction in T, then σ consists of f.m. sentences in T, which consists of a finite unsatisfiable subset T_0 of T.

It is clear provable using ultrafilters: If there is a family of structures $\{M_\Delta\}$ indexed by the collection of all finite subsets of T, with $M_\Delta \models \Delta$ for all $\Delta \in I$ where I is the set of all finite subsets of T.

Then we want to find an ultrafilter $\mathcal{F}$ on I that for all $\varphi \in T$, $\{\Delta | M_\Delta \models \varphi\} \in \mathcal{F}$, then we can use Leo's theorem(1.5.2.11) to show that $\prod_I M_\Delta/\mathcal{F}$ is a model for all $\varphi \in T$. Now in fact we make pick a ultrafilter over the filter generated by all the $A_\varphi = \{\Delta | \varphi \in \Delta\}$, because $M_\Delta \models \Delta$. In fact, this is the case because A_φ has the finite intersection property trivially.

Cor. (1.5.2.22). If $T \models \varphi$, then $\Delta \models \varphi$ for some finite $\Delta \subset T$.

Proof: If not, then $\Delta \cup \{\neg\varphi\}$ is satisfiable for all finite $\Delta \subset T$, so $T \cup \{\neg\varphi\}$ is finitely satisfiable, thus satisfiable by compactness theorem, but this cannot be true because $T \models \varphi$. □

Cor. (1.5.2.23) [Torsion Elements]. Let $\mathcal{L}$ be a language containing $\{\cdot, e\}$, the language of groups, and T is a theory extending the theory of groups, let $\varphi(v)$ be an $\mathcal{L}$-formula. If for any n there is a $G_n \models T$ and G_n has an element of finite order greater than n, then there is an $\mathcal{L}$-structure G that $G \models T$ and G has an element of infinite order.

In particular, there is no formula that defines the torsion elements in any models for T.

Proof: Consider a new language $\mathcal{L}^* = \mathcal{L} \cup \{c\}$, and T^* an $\mathcal{L}^*$-theory that

$$T^* = T \cup \{\varphi(c)\} \cup \{\neg(\underbrace{c \cdots c \ldots c}_{n-\text{times}} = e)\},$$

then the theory T^* is finitely satisfiable by hypothesis, so T^* is satisfiable by compactness theorem. □

Cor. (1.5.2.24) [Element Larger than All Natural Number]. Consider $\mathcal{L}$ the language of ordered rings, let $\mathrm{Th}(\mathbb{N})$ be the theory of $\mathbb{N}$, then there is an $\mathcal{L}$-structure $\mathcal{M}$ that $\mathcal{M} \models \mathrm{Th}(\mathbb{N})$ and $\mathcal{M}$ has an element that is larger than every natural number.

Proof: The same proof as that of(1.5.2.23), but use

$$T^* = \mathrm{Th}(\mathbb{N}) \cup \{\underbrace{1 + \ldots + 1}_{n-\text{times}} < c\}$$

□

Prop. (1.5.2.25) [Model of a Given Cardinality]. If T is an $\mathcal{L}$-theory with infinite models, then if κ is an infinite cardinal that $\kappa \geq |\mathcal{L}|$, then there is a model of T of cardinality κ.

Proof: Let $\mathcal{L}^* = \mathcal{L} \cup \{c_\alpha : \alpha < \kappa\}$, where c_α are pairwise different new constants, and T^* be the $\mathcal{L}^*$ theory $T \cup \{c_\alpha \neq c_\beta, \alpha < \beta < \kappa\}$, then any model for T^* must has cardinality$\geq \kappa$. But then we use strong compactness theore(1.5.2.19), it suffices to show T^* is finitely satisfiable: for any finite $\Delta \subset T^*$, there are only f.m. new constant symbols, thus we can use the infinite model $\mathcal{M}$ to interpret the constant symbols randomly, thus we are done. □

Complete Theories

Def. (1.5.2.26). Let κ be an infinite cardinal and T is a theory with models of size κ. T is called **κ-categorical** iff any two models of T of cardinality κ are isomorphic.

Prop. (1.5.2.27). The theory of torsion-free divisible Abelian groups is κ-categorical for all $\kappa > \aleph_0$.

Proof: A torsion-free Abelian group is just a vector space over $\mathbb{Q}$. Thus the conclusion is trivial, just notice for a cardinal $\kappa > \aleph_0$, a vector space of dimension κ has cardinality κ. □

Prop. (1.5.2.28) [Vaught's Test]. Let T be a satisfiable theory with no finite models, if L is κ-categorical for some $\kappa \geq |\mathcal{L}|$, then T is complete.

Proof: If there is a sentence φ that $T \not\models \varphi$ and $T \not\models \neg\varphi$, so $T_0 = T \cup \{\varphi\}$ and $T_1 = T \cup \{\neg\varphi\}$ is satisfiable. They both have infinite models by hypothesis, so by(1.5.2.25) there are models of cardinal κ for T_0 and T_1, but they cannot be isomorphic, contradiction. So T is complete. □

Prop. (1.5.2.29) [Recurve Complete Satisfiable is Decidable]. If T is a recursive complete satisfiable theory in a recursive language $\mathcal{L}$, then T is decidable.

Proof: Because T is satisfiable, The set of all φ that $\mathcal{M} \models \varphi$ and the set of all φ that $\mathcal{M} \models \neg\varphi$ are disjoint, and their sum is the set of all sentences by completeness. By Gödel's completeness theorem, this is equivalent to $\mathcal{M} \vdash \varphi$ or $\mathcal{M} \vdash \neg\varphi$. Then by(1.5.2.4), they are both enumerable, so it is decidable by definition. □

Up and Down(of Cardinality)

Def. (1.5.2.30) [Elementary Embedding]. An $\mathcal{L}$-structure embedding $j : \mathcal{M} \to \mathcal{N}$ is called an **elementary embedding**, denoted by $\mathcal{M} \prec \mathcal{N}$, if for any $\mathcal{L}$-formula φ,

$$\mathcal{M} \models \varphi(\overline{a}) \iff \mathcal{N} \models \varphi(j(\overline{a})).$$

Notice that one way implication is sufficient, because we can use negation.

Isomorphisms are elementary embeddings by(1.5.1.8).

Def. (1.5.2.31) [Diagrams]. Let $\mathcal{M}$ be an $\mathcal{L}$-structure, then we can add to $\mathcal{L}$ constant symbols for each element of M, and the class $Diag(M)$ of **atomic diagrams** of M is sentences of the form $\varphi(m_1, \ldots, m_n)$, where φ is an atomic $\mathcal{L}$-formula or the negation of an atomic $\mathcal{L}$-formula, and $\mathcal{M} \models \varphi(m_1, \ldots, m_n)$. And the class $Diag_{el}(M)$ of **elementary diagrams** of M is sentences of the form $\varphi(m_1, \ldots, m_n)$ where φ is an $\mathcal{L}$-formula that $\mathcal{M} \models \varphi(m_1, \ldots, m_n)$.

Prop. (1.5.2.32) [Diagrams and Embedding]. The diagram and elementary diagram is very important in constructing embeddings of theories: Let $\mathcal{N}$ be an $\mathcal{L}_M$-structure, then:

- If $\mathcal{N} \models Diag(M)$, there is an $\mathcal{L}$-embedding $\mathcal{M} \subset \mathcal{N}$.
- If $\mathcal{N} \models Diag_{el}(M)$, there is an elementary $\mathcal{L}$-embedding $\mathcal{M} \prec \mathcal{N}$.

Prop. (1.5.2.33) [Upward Löwenheim-Skolem Theorem]. Let $\mathcal{M}$ be an infinite $\mathcal{L}$-structure and κ be an infinite cardinal that $\kappa \geq |\mathcal{M}| + |\mathcal{L}|$, then there is an $\mathcal{L}$-structure $\mathcal{N}$ of cardinality κ that $\mathcal{M}$ embeds into $\mathcal{N}$.

Proof: $Diag_{el}(M)$ is clearly satisfiable, so by(1.5.2.25), there is an $\mathcal{L}^*$-model $\mathcal{N}$ of cardinality κ that $\mathcal{N} \models Diag_{el}(M)$. Then clearly $\mathcal{M} \prec \mathcal{N}$. □

Prop. (1.5.2.34) [Tarski-Vaught Test]. A substructure $\mathcal{M}$ of a structure $\mathcal{N}$ is an elementary substructure iff for any formula $\varphi(v, \overline{w})$ and $\overline{a} \in M$, if there is $b \in N$ that $\mathcal{N} \models \varphi(b, \overline{a})$, then there is a $c \in M$ that $\mathcal{N} \models \varphi(c, \overline{a})$.

Proof: Cf.[Marker P45].? □

Prop. (1.5.2.35) [(Downward)Löwenheim-Skolem Theorem]. Suppose $\mathcal{M}$ is an $\mathcal{L}$-structure and $X \subset \mathcal{M}$, then there is a elementary submodel $\mathcal{N}$ that $X \subset \mathcal{N}$ and $|\mathcal{N}| \leq |X| + |\mathcal{L}| + \aleph_0$.

Proof: Cf.[Marker P46]. □

Def. (1.5.2.36) [Universal Sentences]. A **universal sentence** is a sentence of the form $\forall v \varphi(v)$, where φ is quantifier-free.

For a theory T, denote by $T_\forall$ the set of all of the universal sentences φ that $T \models \varphi$.

A $\mathcal{L}$-theory T is said to have a **universal aximatization** iff there is a set of universal $\mathcal{L}$-sentences Γ that $\mathcal{M} \models T$ iff $\mathcal{M} \models \Gamma$.

Prop. (1.5.2.37) [Universal Axiomation]. An $\mathcal{L}$-theory T has a universal axiomatization iff for any $\mathcal{N} \subset \mathcal{M}$, if $\mathcal{M} \models T$, then $\mathcal{N} \models T$.

Proof: Cf.[Marker P47]. □

Prop. (1.5.2.38) [Universal Consequences]. If T is an $\mathcal{L}$-theory, then $\mathcal{A} \models T_\forall$ iff there is an $\mathcal{M} \models T$ that $\mathcal{A} \subset \mathcal{M}$.

Proof: If $\mathcal{A} \subset \mathcal{M}$, then $\mathcal{A} \models T_\forall$, by(1.5.2.37). Conversely, if $\mathcal{A} \models T_\forall$, then consider $Diag(\mathcal{A})$, then it suffices to show $Diag(\mathcal{A})$ is satisfiable. If it is not, then by compactness theorem(1.5.2.20) there is a finite set that is not satisfiable, and the part coming from diagrams of M can be expressed by a single formula $\chi(\overline{a})$, where χ is quantifier-free, $\overline{a} \in M$, $\mathcal{M} \models \chi(\overline{a})$, and we are saying that $T \cup \{\chi(\overline{a})\}$ is not satisfiable, then $T \models \neg\chi(\overline{a})$.

Now $T \models \forall\overline{x}\neg\varphi(\overline{x})$ as $\mathcal{L}$-theory because $\overline{a}$ can be designated arbitrarily, but this sentence is in $T_\forall$, thus $\mathcal{M} \models \forall\overline{x}\neg\varphi(\overline{x})$, in particular, $\mathcal{M} \models \neg\varphi(\overline{a})$, contradiction. □

Prop. (1.5.2.39) [Elementary Chain]. If $\mathcal{M}_i$ is a chain of $\mathcal{L}$-structures that $\mathcal{M}_i \prec \mathcal{M}_j$ for any $i < j$, then we can define there union $\mathcal{M} = \cup M_i$. Then $\mathcal{M}$ is an elementary extension of each $\mathcal{M}_i$.

Proof: Use induction on formulas to show that

$$\mathcal{M}_i \models \varphi(\overline{a_i}) \iff \mathcal{M} \models \varphi(\overline{a_i}),$$

for all $\mathcal{L}$-formulas φ. This is true for quantifier-free formula by(1.5.1.7), and if this is true for φ, ψ, then this is true for $\neg\varphi$ and $\varphi \wedge \psi$. For the sentence $\varphi = \exists v\psi(v, \overline{w})$, if $\mathcal{M}_i \models \psi(b, \overline{a})$ for some b, then so does $\mathcal{M}$. Conversely, if $\mathcal{M} \models \psi(b, \overline{a})$ for some b, then $b \in \mathcal{M}_j$ for some j, then $\mathcal{M}_j \models \varphi$, by the condition, $\mathcal{M}_i \models \varphi$ also. □

Back and Forth Argument

Cf.[Marker Chap2.4]. Some deep ideas are involved.

Prop. (1.5.2.40) [Cantor]. The theory DLO(1.1.7.3) is $\aleph_0$-categorical and complete.

Proof: It is $\aleph_0$-categorical by(1.2.3.12), and it is complete, by Vaught's test(1.5.2.28), as it has no finite models. □

3 Quantifier Elimination

Def. (1.5.3.1) [Quantifier Elimination]. A theory is said to have **quantifier elimination** if for each formula $\varphi(\overline{v})$, there is a quantifier free ψ that $T \models \forall\overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v}))$.

Lemma (1.5.3.2). Suppose $\mathcal{L}$ contains a constant symbol c, T is an $\mathcal{L}$-theory, and $\varphi(\overline{a})$ is an $\mathcal{L}$-formula, then the following are equivalent:

- There is a quantifier-free $\mathcal{L}$-formula $\psi(\overline{v})$ that $T \models \forall\overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v}))$.
- If $\mathcal{M}, \mathcal{N}$ are models of T, and $\mathcal{A}$ is an $\mathcal{L}$-structure that $\mathcal{A} \subset \mathcal{M} \cap \mathcal{N}$, then for all $\overline{a} \in \mathcal{A}$, $\mathcal{N} \models \varphi(\overline{a}) \iff \mathcal{M} \models \varphi(\overline{a})$.

Proof: $1 \to 2$ is clear, because a quantifier-free formula $\psi(\overline{a})$ is preserved under substructure by(1.5.1.7).

$2 \to 1$, Cf.[Marker, P74].**?** □

Lemma (1.5.3.3). Let T be an $\mathcal{L}$-theory that for any quantifier-free $\mathcal{L}$-formula $\theta(\overline{v}, w)$, there is a quantifier-free formula $\psi(\overline{v})$ that $T \models \forall\overline{v}(\exists w\theta(\overline{v}, w) \leftrightarrow \psi(\overline{v}))$, then T has quantifier elimination.

Proof: We want to show for each formula $\varphi(\overline{a})$, there is a quantifier-free formula $\psi(\overline{a})$ that $T \models \forall\overline{v}(\varphi(\overline{a}) \leftrightarrow \psi(\overline{v}))$, and we use induction on the complexity of φ.

If φ is quantifier-free, this is trivial. If $\varphi = \neg\theta_0$ or $\varphi = \theta_0 \wedge \theta_1$, then we are easily done. If $\psi(\overline{v}) = \exists w\theta(\overline{v}, w)$, and $T \models \forall\overline{v}(\theta(\overline{v}, w) \leftrightarrow \psi_0(\overline{v}, w))$, then $T \models \forall\overline{v}(\varphi(\overline{v}) \leftrightarrow \exists w\psi_0(\overline{v}, w))$. But the assumption shows there is a quantifier-free ψ that $T \models \forall\overline{v}(\exists w\psi_0(\overline{v}, w) \leftrightarrow \psi(\overline{v}))$, and then $T \models \forall\overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v}))$. □

Prop. (1.5.3.4) [Criterion for Quantifier Elimination]. Combining(1.5.3.2) and(1.5.3.3), we get: If T is an $\mathcal{L}$-theory that for all quantifier-free formula $\varphi(\overline{v}, w)$ and models $\mathcal{M}, \mathcal{N} \models T$, and $\mathcal{A} \subset M \cap N, \overline{a} \in A$, and if there is $b \in M$ that $\mathcal{M} \models \varphi(\overline{a}, b)$ will implie there is $c \in \mathcal{N}$ that $\mathcal{N} \models \varphi(\overline{a}, c)$, then T is quantifier-free.

Def. (1.5.3.5) [Algebraically Prime Models]. A theory T is said to have **algebraically prime models** if for any $\mathcal{A} \models T_\forall$(1.5.2.36), there is a $\mathcal{M} \models T$ and an embedding $i : \mathcal{A} \subset \mathcal{M}$ that for any other $\mathcal{N} \models T$, any embedding $j : \mathcal{A} \to \mathcal{N}$ factors through i.

Def. (1.5.3.6) [Simply Closed Model]. If $\mathcal{M}, \mathcal{N}$ are models of T, and $\mathcal{M} \subset \mathcal{N}$, then $\mathcal{M}$ is called **simply closed** in $\mathcal{N}$, denoted by $\mathcal{M} \prec_s \mathcal{N}$, iff for any quantifier-free formula $\varphi(\overline{a}, w)$ and $\overline{a} \in \mathcal{M}^n$, if $\mathcal{N} \models \exists w \varphi(\overline{a}, w)$, then so does $\mathcal{M}$.

Prop. (1.5.3.7) [Quantifier Elimination Test]. If T is an $\mathcal{L}$-theory that has algebraically prime models, and any inclusion of models for T is simply closed, then T has quantifier elimination.

Proof: This is an immediate consequence of(1.5.3.4). □

Def. (1.5.3.8) [Model Complete]. An $\mathcal{L}$-theory T is called **model complete** if $\mathcal{M} \prec \mathcal{N}$ whenever $\mathcal{M} \subset \mathcal{N}$. A complete theoy is clearly model complete.

Prop. (1.5.3.9). If T has quantifier elimination, then T is model complete.

Proof: If $\mathcal{M} \subset \mathcal{N}$, let $\varphi(\overline{a})$ be an $\mathcal{L}$-formula, and $\overline{a} \in \mathcal{M}$, then there is a quantifier-free formula $\psi(\overline{v})$ that $T \models \forall \overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v}))$. By(1.5.1.7), the formula $\psi(\overline{a})$ passes between $\mathcal{M}$ and $\mathcal{N}$, so

$$\mathcal{M} \models \varphi(\overline{a}) \iff \mathcal{M} \models \psi(\overline{a}) \iff \mathcal{N} \models \psi(\overline{a}) \iff \mathcal{N} \models \varphi(\overline{a}).$$

□

Prop. (1.5.3.10) [Minimal Model and Completeness]. If T is model-complete and there is a minimal model $\mathcal{M}_0$ that $\mathcal{M}_0$ embeds into every model of T, then T is complete.

Proof: Clearly any model is elementary equivalent to $\mathcal{M}_0$, thus clearly T is complete. □

Prop. (1.5.3.11) [Eliminating Algorithm]. Let T be a decidable theory with quantifier elimination, then there is an algorithm to find the elimination ψ of a given formula φ.

Proof: We just need to find a quantifier-free ψ that $T \models \forall \overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v}))$. This an effective search because T is decidable, and we can eventually find ψ because T has quantifier elimination. □

Examples of Quantifier Elimination

Prop. (1.5.3.12). The theory DLO(1.1.7.3) has quantifier elimination.

Proof: Cf.[Marker P72]. □

Lemma (1.5.3.13). DAG(1.1.7.3) has algebraically prime models.

Proof: This is just the alg.closure of the quotient field of an integral domain. □

Prop. (1.5.3.14). DAG has quantifier elimination.

Proof: We use(1.5.3.7) By**??** DAG has algebraically prime models, thus it suffices to show any inclusion of models for DAG(1.1.7.3) is simply closed: For any torsion-free divisible Abelian groups $H \subset G$, $\varphi(\overline{a}, w)$ quantifier-free, $\overline{a} \in H, b \in G$ that $G \models \varphi(\overline{a}, w)$. Then φ is a disjunction of conjunctions of atomic or negated atomic formulas, and we need to prove $H \models \varphi(\overline{a}, w)$.

So we may assume φ is conjunction of atomic formulas and negated atomic formuals:

$$\varphi(\overline{a}, w) \leftrightarrow \bigwedge(g_i + m_i w = 0) \wedge \bigwedge(h_i + m_i' w \neq 0).$$

If any $m_i \neq 0$, then $b \in H$. If all $m_i = 0$, then there are only f.m. constraints, and there is $b' \in H$ that $H \models \varphi(\overline{a}, b')$ because H is infinite. □

Cor. (1.5.3.15). The theory DAG is complete, by(1.5.3.10), as $(\mathbb{Q}, +, 0)$ embeds in every model of DAG, and(1.5.3.14)(1.5.3.9).

Prop. (1.5.3.16). The theory $ODAG$ is a complete theory with quantifier elimination. In particular, any ordered divisible Abelian group is elementarily equivalent to $(\mathbb{Q}, +, <)$, by completeness.

Proof: Cf.[Marker, P80]. □

Prop. (1.5.3.17) [Presburger Arithmetic]. Presburger arithmetic is a complete decidable theory with quantifier elimination in the language $\mathcal{L}^*$.

Proof: Cf.[Marker, P84]**?**. □

<u>**Strongly Minimal Theory**</u>

Def. (1.5.3.18) [Strongly Minimal Theory]. A theory T is called **strongly minimal** iff for any $\mathcal{M} \models T$, every definable subset of $\mathcal{M}$ is either finite or cofinite.

Prop. (1.5.3.19). DAG(1.1.7.3) is strongly minimal.

Proof: Cf.[Marker P78]. □

4 Alg.Closed Fields

Lemma (1.5.4.1). ACF_p(1.1.7.3) is κ-categorical for all uncountable cardinal κ.

Proof: Because two alg.closed field of the same transcendental degree over the base field is isomorphic**??**. The conclusion follows as an alg.closed field of transcendence degree κ has cardinality $\kappa + \aleph_0$. □

Prop. (1.5.4.2). The theory ACF_p is complete, by(1.5.4.1) and(1.5.2.28).

Cor. (1.5.4.3). ACF_p is decidable, in particular, Th($\mathbb{C}$), the first-order theory of the fields of complex numbers, is decidable.

Proof: ACF_p is complete by(1.5.4.1) and(1.5.2.28), it is clearly recursive, and it is clearly satisfiable, so use(1.5.2.29). □

Prop. (1.5.4.4) [First order Lefschetz Principle]. Let φ be a sentence in the language of rings, the following are equivalent:

1. φ is true in $\mathbb{C}$.

2. φ is true in every(some) alg.closed field of char 0.
3. For p large/there exists arbitrary large p, φ is true in any alg.closed field of char p.

Proof: 1, 2 are equivalent because ACF_p is complete(1.5.4.2) and use Gödel's completeness theorem. If 2 is true, then $ACT_0 \models \varphi$, so by(1.5.2.22), then some $\Delta \models \varphi$. So for p sufficiently large, $ACF_p \models \Delta$, so $ACF_p \models \varphi$ for p large.

If $ACF_0 \not\models \varphi$, then $ACF_0 \models \neg\varphi$ by completeness(1.5.4.2), so by above argument, $ACF_p \models \neg\varphi$ for p large, contradiction. □

Cor. (1.5.4.5) [Ax]. Any injective polynomial map from $\mathbb{C}^n$ to $\mathbb{C}^n$ is surjective.

Proof: By Lefschetz principle(1.5.4.4), it suffices to show this for $(\mathbb{F}_p)^{alg}$ for p large. If this is not true, then choose the coefficients of the coordinate map of f, and the coordinates of an element that is not in the image, then the subfield k they generated is algebraic over $\mathbb{F}_p$, so it is finite, and clearly f is also surjective on k^n, contradiction. □

Cor. (1.5.4.6). Let $K \subset L$ be alg.closed fields, and V, W be varieties defined over K, and f is a polynomial isomorphism of V and W over L, then there is a polynomial isomorphism of V and W over K.

Proof: Let f have degree d. Then we can write a formula Ψ saying that there is an embedding of K into $\mathcal{M}$ and there is a polynomial bijection of V and W over $\mathcal{M}$, then $L \models \Psi$, and because ACF is complete(1.5.4.2), $K \models \Psi$, too. Thus there is also an isomorphism over K. □

Prop. (1.5.4.7). $ACF_\forall$ is the theory of integral domains.

Proof: Clearly a ring is a subring of an alg.closed field iff it is an integral domain, so the result follows from(1.5.2.38). □

Prop. (1.5.4.8). ACF has qualifier elimination.

Proof: Use(1.5.3.5), clearly it has algebraically prime models(1.5.4.7), and we need to check simply closedness.

For this, If $K \subset L$, notice that a quantifier-free formula φ is just a conjunction of some polynomial functions and negation of polynomial functions, with their coefficients in K. If there are some polynomial, then the solution b of φ in L is algebraic over K, thus in K because K is alg.closed. Now if it is just negations of polynomials, then clearly φ is true in K for some $c \in K$, because K is alg.closed thus infinite. □

Cor. (1.5.4.9). ACF is model-complete, by(1.5.3.9).

Lemma (1.5.4.10). Let K be a field, then the subsets of K^n defined by atomic formulas are exactly Zariski closed subsets. And a subset of K^n that is quantifier-definable iff it is a Boolean combination of Zariski closed subsets(constructible). (Clear).

Prop. (1.5.4.11). ACF is strongly minimal.

Proof: Because by quantifier elimination(1.5.4.8), every definable set is a finite Boolean combination of sets of the form $V(p) = 0$, where $p \in K[X]$, but $V(p)$ is either finite or all of K. □

Elimination of Imaginaries in Alg.Closed Fields

Def. (1.5.4.12) [Algebraicity]. Let $\mathcal{M}$ be an $\mathcal{L}$-structure and $A \subset M$, then for $b \in M$, $b \in acl(A)$ if there is a formula $\varphi(x, \overline{y})$ and $\overline{a} \in A$ that $\mathcal{M} \models \varphi(b, \overline{a})$, and $\{x \in M | \mathcal{M} \models \varphi(x, \overline{a})\}$ is finite.

Def. (1.5.4.13)[Algebraicity over Equivalence Class]. Let $\mathcal{M}$ be an $\mathcal{L}$-structure and E a definable equivalence relation on M^n, then we say a element $c \in M$ is algebraic over $\overline{a}/E, b_1, \ldots, b_m$ if there is a formula $\varphi(c, \overline{y}, \overline{z})$ that

- $\mathcal{M} \models \varphi(c, \overline{a}, \overline{b})$.
- If $\overline{a}E\overline{a}'$, then $\mathcal{M} \models \varphi(c, \overline{a}, \overline{b}) \leftrightarrow \varphi(c, \overline{a}', \overline{b})$.
- $\{x | \mathcal{M} \models \varphi(x, \overline{a}, \overline{b})\}$ is finite.

And a sequence $\overline{c}$ is called algebraic over $a/E, b_1, \ldots, b_m$ iff each coordinate is.

Lemma (1.5.4.14). Suppose $\overline{c}$ is algebraic over $\overline{a}/E, \overline{d}, \overline{b}$, and $\overline{b}$ is algebraic over $\overline{a}/E, \overline{d}$, then $\overline{c}$ is also algebraic over $\overline{a}/E, \overline{d}$.

Proof: Cf.[Marker, P92]. □

Lemma (1.5.4.15). Suppose K is an alg.closed field and E is a definable equivalence relation on K^n, and $\psi(\overline{x}, \overline{y}, \overline{d})$ defines E. If $\overline{a} \in K^n$, then there is a $\overline{c} \in K^n$ algebraic over $\overline{a}/E, \overline{d}$ s.t. $\overline{c}E\overline{a}$.

Proof: Cf.[Marker, P92].**?** □

Prop. (1.5.4.16) [Elimination of Imaginaries]. Let K be an alg.closed field, $A \subset K$, and E is an A-definable equivalence relation on K^n, then for some l there is an A-definable function $f : K^n \to K^l$ that $\overline{x}E\overline{y}$ iff $f(\overline{x}) = f(\overline{y})$.

Proof: Cf.[Marker, P92]. □

5 Real-Closed Fields

Prop. (1.5.5.1). The class of real-closed fields is an elementary class(1.5.1.4) of $\mathcal{L}_r$-structures.

Proof: The real-closed fields are axiomatized by:

- Axioms for fields.
- For each $n \geq 1$, the sentence $\forall x_1 \ldots \forall x_n (x_1^2 + \ldots + x_n^2 + 1 \neq 0)$.
- $\forall x \exists y (y^2 = x \vee y^2 + x = 0)$.
- For each $n \geq 0$, the sentence $\forall x_1 \ldots \forall x_n \exists y (y^{2n+1} + \sum_{i=0}^{2n} x_i y^i = 0)$.

These truly axiomatize real-closed fields, by(2.2.9.7). □

Prop. (1.5.5.2). Let F be a real-closed field, then the definable sets in F^n w.r.t the $\mathcal{L}_{or}$ is also definable w.r.t. $\mathcal{L}_r$.

Proof: Because we can replace all instances $t_i < t_j$ by $\exists v (v \neq 0 \wedge t_i + v^2 = t_j)$. □

Prop. (1.5.5.3). $RCF_\forall$ is the theory of ordered integral domains(easy).

Cor. (1.5.5.4). RCF has algebraically prime models.

Proof: Let D be an ordered domain, and let R be a real closure of the fraction field of D compatible with the ordering of D. Let F be another real-closed field extension of D, then let K be the algebraic closure of the fraction field of D in F, then K is a real-closed field by(2.2.9.7), then by(2.2.9.12) there is an isomorphism of $R \cong K$ extending $D \to K$, thus embeds R into F extending $D \to F$. $\square$

Prop. (1.5.5.5). RCF has quantifier elimination (w.r.t. $\mathcal{L}_{or}$).

Proof: Use(1.5.3.5), it has algebraically prime models by(1.5.5.4), and we need to check simply closedness: Let $F \subset K$ be RCFs, $\varphi(v, \overline{w})$ be a quantifier-free formula and let $\overline{a} \in F, b \in K$ that $K \models \varphi(b, \overline{a})$. Then there are polynomials that

$$\varphi(v, \overline{a}) \leftrightarrow (\bigwedge p_i(v) = 0 \wedge \bigwedge q_i(v) > 0).$$

If any $p_i \neq 0$, then b is algebraic over F, but then $b \in F$ because F is real-closed. So we may assume $\varphi(v, \overline{a}) \leftrightarrow \wedge q_i(v) > 0$. Then because $q_i(b) > 0$ and q_i has f.m. zeros, by intermediate property(2.2.9.9), we can find a nbhd of b that is interval with endpoints in F that $q_i > 0$, and because F is dense(char0), there is an element b' that $F \models \varphi(b', \overline{a})$. $\square$

Cor. (1.5.5.6). RCF is complete and decidable. Thus it is just the theory of $(\mathbb{R}, +, \cdot, <)$, and it is decidable.

Proof: It is model-complete by(1.5.3.9), and it has a minimal model that is the field $\mathbb{R}_{alg}$ of algebraic numbers in $\mathbb{R}$, then it is complete by(1.5.3.10). It is decidable by(1.5.2.29). $\square$

Prop. (1.5.5.7) [RCF is o-Minimal]. The theory RCF(1.1.7.3) is o-minimal.

Proof: Because RCF has quantifier elimination, every definable set of a real-closed field R is semialgebraic, thus it is clearly a disjoint union of intervals and points. $\square$

Semialgebraic Sets

Def. (1.5.5.8) [Semialgebraic Sets]. Let F be an ordered field, then $X \subset F^m$ is called **semi-algebraic** if there it is a Boolean combination of sets of the form $\{\overline{x} | p(\overline{x}) > 0\}$, where $p(\overline{X}) \subset F[\overline{X}]$.

Prop. (1.5.5.9) [Tarski-Seidenberg Theorem]. If F is a real-closed field, the semialgebriac sets are closed under projection.

Proof: This is because quantifier elimination(1.5.5.5) implies semialgebraic sets are just definable sets, and the projection of a definable set is also definable. $\square$

Cor. (1.5.5.10). The composite of two semialgebraic functions are semialgebraic.

Prop. (1.5.5.11) [Closure of Semialgerbaic Sets]. Let F be a real-closed field and $A \subset F^n$ be semialgebraic, then the closure of A in the Euclidean topology is also semialgebraic.

Proof: The closure of A is defined by

$$\{\overline{x} | \forall \varepsilon > 0, \exists \overline{y} \in A, d(\overline{x}, \overline{y}) < \varepsilon\}.$$

Thus it is definable, and thus semialgebraic by quantifier elimination(1.5.5.5). $\square$

Prop. (1.5.5.12). Let F be a real-closed field and $X \subset F^n$ be closed and bounded, f be a continuous semialgebraic function, then $f(X)$ is closed and bounded.

Proof: If F is $\mathbb{R}$, then this follows from(3.3.5.2) that X is compact hence the image is also compact hence closed and bounded. As we can formulate a sentence asserting the conclusion. Thus the theorem follows as RCF is complete(1.5.5.6). □

Lemma (1.5.5.13). For R a real-closed field and $f : R \to R$ semialgebraic, then for any interval U there is an element x that f is continuous at x.

Proof: It suffices to prove for $R = \mathbb{R}$ by completeness of RCF. If there is an interval that f has finite range, then the inverse image of some point b is infinite, but also definable, so by o-minimality contains an interval that f is constant, hence continuous.

Otherwise, we inductively choose a chain of intervals: $V_0 = U$, and the image of V_n is definable thus contains an interval of length at most $1/n$, by o-minimality and our assumption. Now for the same reason the inverse image of this interval contains an interval, called V_{n+1}, s.t. $\overline{V_{n+1}} \subset V_n$, then $\cap V_n = \cap \overline{V}_n \neq \varphi$ because $\mathbb{R}$ is locally compact. For any $x \in V$, it is easy to see f is continuous at x. □

Prop. (1.5.5.14). For R a real-closed field and $f : R \to R$ semialgebraic, then f is discontinuous only at f.m. points.

Proof: The discontinuous points of f is definable by

$$D = \{x | F \models \exists \varepsilon > 0 \forall \delta > 0 \exists y |x - y| < \delta \wedge |f(x) - f(y)| > \varepsilon\},$$

thus it is a finite union of intervals and points, by o-minimality(1.5.5.7), but it must be f.m. points, by(1.5.5.13). □

Def. (1.5.5.15). We can naturally define the notion of **definably connected** and **definably arcwise connected** sets in R^n.

Def. (1.5.5.16) [Cells]. For an real-closed field F, we inductively define n-cells:

- $X \subset F^n$ is a 0-cell if it is a single point.
- If $X \subset F^m$ is an n-cell and $f : X \to F$ is a continuous definable function, then $Y = \{(\overline{x}, f(\overline{x})) | \overline{x} \in X\}$ is an n-cell.
- If $X \subset F^m$ is an n-cell and f, g are either continuous functions from X to F or constants $\pm\infty$, then $Y = \{(\overline{x}, y) | \overline{x} \in X \wedge f(\overline{x}) < y < g(\overline{x})\}$ is an $n+1$-cell.

Prop. (1.5.5.17) [Uniform Bounding]. Let $X \subset F^{m+1}$ be semialgebraic, then there is a natural number N that if $\overline{a} \in F^n$ and $X_{\overline{a}} = \{y | (\overline{a}, y) \in X\}$ is finite, then $|X_{\overline{a}}| < N$.

Proof: First notice $X_{\overline{a}}$ is definable, thus by o-minimality, $\{\overline{a} || X_{\overline{a}}| < \infty\}$ is definable, thus we may assume these are all of X.

Now let Γ be the theory

$$RCF + Diag(F) + \{\exists y_1, y_2, \ldots, y_m [\bigwedge_{i<j} y_i \neq y_j \wedge \bigwedge y_i \in X_{\overline{c}}]\}$$

where $m \in \mathbb{N}$, and $c_1, \ldots, c_n$ are new constants. (Notice $y_i \in X_{\overline{c}}$ is a sentence).

Then Γ is not satisfiable, because otherwise there is an embedding $F \subset K$, and by model completeness $F \prec K$, thus there is no $\overline{a}$ that $X_{\overline{a}}$ is infinite, because it is definable, contradiction.

Then by compactness theorem, there is some f.m. sentences of Γ that is unsatisfiable, thus the conclusion follows. □

Prop. (1.5.5.18) [Cell Decomposition]. Let F be a real-closed field, then any semialgebraic set $X \subset F^m$ is a finite disjoint union of cells.

Proof: Cf.[Marker, P103]. □

6 O-Minimal Structures

Cf.[O-Minimal Structures].

Def. (1.5.6.1) [O-Minimal Structure]. An ordered structure is called o-**minimal** if any definable set is a finite union of intervals with endpoints in $M \cup \{\pm\infty\}$ and points.

Def. (1.5.6.2) [General O-Minimal Expansions]. A structure expanding the real-closed field R is a collection $\mathcal{S} = (\mathcal{S}^n)$, where $\mathcal{S}^n$ is a family of subsets of R^n, that

- Algebraic subsets are in $\mathcal{S}$.
- Each $\mathcal{S}^n$ is a Boolean subalgebra of the powerset of R^n.
- $\mathcal{S}$ is stable under Cartesian product and projection.

And $\mathcal{S}^n$ are called the **definable subsets** of R^n. And this structure is called o-**minimal** if moreover each subset in $\mathcal{S}^1$ is a finite unions of intervals and points.

2 Algebras

2.1 Group Theory

Main References are [Finite Groups, Issac], [Lan05] and [代数学引论，丁石孙].

1 Notations

Notation (2.1.1.1).

- Use notations defined in **??**.

2 Magmas

Def. (2.1.2.1) [Binary Operators]. A **binary operator** on a set X is a map $\circ : X \times X \to X$.

Def. (2.1.2.2) [Unital Operator]. A **unital binary operator** on a set X is a map $\circ : X \times X \to X$ that has a left and right identity element $1_\circ$.

Prop. (2.1.2.3) [Associative Operators]. An **associative operator** on a set X is an operator $\circ : X \times X \to X$ s.t. $(x \circ y) \circ z = x \circ (y \circ z)$ for any $x, y, z \in X$.

Def. (2.1.2.4) [Magma]. A **magma** is a set X with a binary operator $\circ : X \times X \to X$. A **unital magma** is a magma that the operator is unital. It is called **Abelian** if $x \circ y = y \circ x$ for any $x, y \in X$.

Prop. (2.1.2.5) [Eckmann-Hilton argument]. If $\circ$ and $\otimes$ are two unital binary operators on a set that commute with each other: $(a \otimes b) \circ (c \otimes d) = (a \circ c) \otimes (b \circ d)$, then they are equal and in fact commutative and associative.

Proof: Firstly the units coincide, because

$$1_\circ = 1_\circ \circ 1_\circ = (1_\otimes \otimes 1_\circ) \circ (1_\circ \otimes 1_\otimes) = (1_\otimes \circ 1_\circ) \otimes (1_\circ \circ 1_\otimes) = 1_\otimes \otimes 1_\otimes = 1_\otimes.$$

Next

$$a \circ b = (1 \otimes a) \circ (b \otimes 1) = (1 \circ b) \otimes (a \circ 1) = b \otimes a = (b \circ 1) \otimes (1 \circ a) = (b \otimes 1) \circ (1 \otimes a) = b \circ a.$$

Thus $\circ$ and $\otimes$ coincide and are commutative. Finally for associativity:

$$(a \otimes b) \otimes c = (a \otimes b) \otimes (1 \otimes c) = (a \otimes 1) \otimes (b \otimes c) = a \otimes (b \otimes c).$$

$\square$

Def. (2.1.2.6) [Monoid]. A **monoid** is an associative unital magma $(X, \circ)$.

3 Groups

Def. (2.1.3.1) [Groups, Cayley1854]. ?, The category of Groups is denoted by $\mathcal{G}\text{rp}$.

Def. (2.1.3.2) [Generators]. Let $G \in \mathcal{G}\text{rp}$ and $S \subset G$, then S is said to be a **set of generator** for G if the only subgroup of G containing S is G.

Def. (2.1.3.3) [Normal Subgroups]. A **normal subgroup** of a group G is a subgroup N that if $x \in G$, then $x^{-1}Nx = N$.

Def. (2.1.3.4) [Simple Groups]. A **simple group** is a group that has no normal subgroups.

Def. (2.1.3.5) [Finitely Generated Group]. A group G is called finitely generated if there is a finite subset S that the only subgroup containing S is G itself.

Def. (2.1.3.6) [Product Subgroups]. Let G be a group and N, H be subgroups such that N is normal in G, then $NH = \{x \in G | x = nh, n \in N, h \in H\}$ is a subgroup of G, called the **product subgroup**.

Def. (2.1.3.7) [Coset]. Let G be a group and H a subgroup. Consider the equivalence relation on G s.t. $x \sim y$ iff $x = yh$ for some $h \in H$, then the equivalence classes is denoted by G/H, called the **right coset** of H in G. And G acts on this set by left translation.

Similarly we can define **left coset** $H\backslash G$ of H in G.

Moreover, if H is normal in G, then this set is a group with structure given by $\tau H \cdot \sigma H = \tau\sigma H$, called the **quotient group** structure. It satisfies the universal property that any group homomorphism $\varphi : G \to G'$ s.t. $\varphi(H) = e$ factors through G/H uniquely.

Prop. (2.1.3.8) [Fundamental Isomorphisms]. Let G be a group and N, H be subgroups such that N is normal in G, then

- there is a natural isomorphism $G/NH \cong (G/N)/(H/H \cap N)$ as sets, and if H is also normal, this is an isomorphism of groups.
- there is a natural isomorphism of groups: $H/N \cap H \cong NH/N$.

Proof: 1:

2: Consider the natural isomorphism $N \mapsto NH/H : n \mapsto nH$, then it is a group homomorphism, and the kernel is $N \cap H$, thus we are done. □

Cor. (2.1.3.9). if H_1, H_2 are subgroups of a group G that has finite indexes, then $H_1 \cap H_2$ also has finite index in G.

Proof: By fundamental isomorphism(2.1.3.8), $H_1/H_1 \cap H_2 \cong H_1H_2/H_2 \subset G/H_2$, so $H_1 \cap H_2$ has finite index in H_1, so by transitivity of indexes, $H_1 \cap H_2$ has finite index in G. □

Def. (2.1.3.10) [Index of Subgroup]. The **index of a subgroup** H in a group G is defined to be the number of the left coset G/H, if it is finite. Now if H has finite index in G, then $|G/H| = |H\backslash G|$.

Proof: Because for any system of representative a_i for the left coset G/H, a_i^{-1} is a representative for the right coset $H\backslash G$, and vise versa. □

Prop. (2.1.3.11). If a finite group G has an automorphism α that $\alpha^2 = \text{id}$ and α has no fixed point other than e, then G is an Abelian group of odd order.

Proof: G is clearly of odd order. Consider the map $g \mapsto \alpha(g)g^{-1}$, then it is injective, hence it is also surjective, and consider $\alpha(\alpha(g)g^{-1}) = g\alpha(g)^{-1} = (\alpha(g)g^{-1})^{-1}$, thus $\alpha(h) = h^{-1}$ for all $h \in G$, thus clearly G is Abelian. □

Prop. (2.1.3.12). If H is a subgroup of a finite group G, then $G \neq \cup g^{-1}Hg$.

Proof: There are at most $|G/H|$ different summands in the right hand side, so it doesn't have enough elements. □

Prop. (2.1.3.13). If G is a f.g. group(2.1.3.5) and H is a group of finite index in G, then H is f.g.

Proof: Suppose G has generators g_i, we may add their inverses to it, and let $Ht_1, \ldots, Ht_m$ are all the right cosets with $t_1 = 1$, then there are h_{ij} that $t_i g_j = h_{ij} t_{k_{ij}}$, then we claim H is generated by h_{ij}.

For this, consider any $h = \prod g_{i_r}$, then $g_1 = h_{1i_r} t_{k_{1i_r}}$, and we can do this from left to right. Now $h = \prod h_{i_s j_s} t_o$, then t_o must by 1, and we are done. □

Prop. (2.1.3.14). Let $\varphi : G \to H$ be a map of sets between groups s.t. $\#\mathrm{Im}(\varphi) = \infty$, and for each $g \in G$, there is a set $S(g) \in H$ that $\varphi(h)\varphi(g) = \varphi(hg)$ for any h s.t. $\varphi(h) \notin S(g)$, then φ is a homomorphism.

Proof: For $g, h \in G$, take f s.t. $\varphi(f) \notin S(g) \cup \varphi(g)^{-1}S(h) \cup \{\varphi(gh)\}$. Then

$$\varphi(f)\varphi(g)\varphi(h) = \varphi(fg)\varphi(h) = \varphi(fgh) = \varphi(f)\varphi(gh),$$

thus $\varphi(g)\varphi(h) = \varphi(gh)$. □

4 Abelian Groups

Remark (2.1.4.1). An Abelian group is the same as a module over $\mathbb{Z}$. Thus the theory of commutative algebra applies in this case. The category of Abelian groups is denoted by $\mathcal{A}\mathrm{b}$. The category of finite Abelian groups are denoted by $\mathcal{A}\mathrm{b}^{\mathrm{fin}}$.

Prop. (2.1.4.2) [Abelianization]. There is a functor from the category of Abelian semi-groups to the category of Abelian groups that is left adjoint to the forgetful functor, called the **Abelianization**.

Proof: Define A' to be the quotient

$$\bigoplus_{(a,b)\in A^2} \mathbb{Z} \to \bigoplus_{x\in A} \mathbb{Z} \to A' \to 0,$$

where $1_{(a,b)}$ is mapped to $1_a + 1_b - 1_{a+b}$. Then it can be seen this satisfies the universal property and it is functorial in A. □

Prop. (2.1.4.3) [Classifying F.g. Abelian Groups]. Any finitely generated Abelian group is of the form

$$\mathbb{Z}^r \bigoplus_{p_i \text{ primes}} \oplus_{j\leq n_i} \mathbb{Z}/(p_i^{a_{i,j}})$$

Proof: As $\mathbb{Z}$ is PID, the classifying theorem follows immediately from(2.2.4.21): □

Prop. (2.1.4.4) [Baer-Specker Group]. The group $\prod^{\mathbb{N}}\mathbb{Z}$ is called the **Baer-Specker group**. Then the natural homomorphism

$$\mathrm{Hom}(\prod^{\mathbb{N}}\mathbb{Z},\mathbb{Z})\to\prod^{\mathbb{N}}\mathbb{Z}$$

is injective with image $\bigoplus^{\mathbb{N}}\mathbb{Z}$.. In particular, by countability argument, $\prod^{\mathbb{N}}\mathbb{Z}$ is not a free group(4.3.1.5). Moreover, any infinite direct product of $\mathbb{Z}$ is not free, because otherwise the subgroup $\prod^{\mathbb{N}}\mathbb{Z}$ would be free.

Proof: The natural homomorphism is the composite?

$$\mathrm{Hom}(\prod^{\mathbb{N}}\mathbb{Z},Z)\xrightarrow{\varepsilon^*}\mathrm{Hom}(\#^{\mathbb{N}}\mathbb{Z},\mathbb{Z})\xrightarrow{\eta}\prod^{\mathbb{N}}\mathbb{Z}.$$

Thus the assertion follows from(2.1.6.6) and(2.1.6.5). □

Remark (2.1.4.5). This can be proven in other ways, like using condensed mathematics?.

Forms on Abelian Groups

Def. (2.1.4.6) [Quadratic Forms]. For $A\in\mathcal{A}b$, a function $d:A\to\mathbb{R}$ is called a **quadratic form** if

- $d(\alpha)=d(-\alpha)$ for any $\alpha\in A$.
- The form $B_d:A\times A\to\mathbb{R}$: $(\alpha,\beta)\mapsto[d(\alpha+\beta)-d(\alpha)-d(\beta)]/2$ is bilinear.

It is called **positive semi-definite** if moreover $d(\alpha)\geq 0$. And **positive-definite** if moreover $d(\alpha)=0\iff\alpha=0$.

Prop. (2.1.4.7) [Cauchy-Schwartz]. Let A be an Abelian group and d a positive semi-definite quadratic form over A, then

$$|d(\alpha-\beta)-d(\alpha)-d(\beta)|\leq 2\sqrt{d(\alpha)d(\beta)}.$$

Proof: Consider the bilinear form B_d, then

$$0\leq d(m\alpha-n\beta)=m^2d(\alpha)+n^2d(\beta)-2mnB_d(\alpha,\beta).$$

This is true for any $m,n\in\mathbb{Z}$, thus the discriminant $B_d(\alpha,\beta)^2\leq d(\alpha)d(\beta)$. □

Prop. (2.1.4.8). If M,N are Abelian groups and d is a quadratic form on $M\times N$ s.t. $d(0\times N)=d(M\times 0)=0$, then d is bilinear in both M and N.

Proof: The bilinear form associated to d satisfies $B_d((a,0),(0,b))=d(a,b)$, thus it is clear d is bilinear in M and N. □

Def. (2.1.4.9) [Polarization]. Let Γ be an Abelian group and $h:\Gamma\to\mathbb{R}$ is a function, then the r-th **polarization function** $P_r(h):\Gamma^r\to\mathbb{R}$ is defined to be

$$P_r(h)(x_1,\ldots,x_r)=\frac{1}{r!}\sum_{I\subset\{1,\ldots,r\}}(-1)^{r-\#I}(\sum_{i\in I}x_i).$$

Lemma (2.1.4.10).

- Let $\tau_a(h)(x)=h(a+x)-h(x)$, then $\tau_a\tau_b=\tau_{a+b}-\tau_a-\tau_b$.

- $P_r(h)(x_1,\dots,x_r) = \tau_{x_1}\tau_{x_2}\dots\tau_{x_r}(h)(0) = \tau_{x_2}\dots\tau_{x_r}(h)(x_1)$.
- If $A_r \in \mathrm{Sym}^r\Gamma^\vee$, let $\Delta A_r : \Gamma : \mathbb{R} : \Delta A_r(x) = \frac{1}{r!}A_r(x,\dots,x)$, then $\tau_a \Delta A_r(x) = \sum_{1\le s<r}\Delta A_s$, where $A_s \in \mathrm{Sym}^s\Gamma^\vee$, and $A_{r-1}(x_1,\dots,x_{r-1}) = A_r(x_1,\dots,x_{r-1},a)$.
- If $A_r \in \mathrm{Sym}^r\Gamma^\vee$, $P_r(\Delta A_r)(x_1,\dots,x_n) = A_r(x_1,\dots,x_r)$ and $P_s(\Delta A_r) = 0$ for $s > r$.

Prop. (2.1.4.11). There is a natural isomorphism of additive groups

$$\bigoplus_{j=0}^{r-1}\mathrm{Sym}^j\Gamma^\vee \cong \{h:\Gamma\to\mathbb{R}|P_r(h)=0\} : (A_0,\dots,A_{r-1}) \mapsto \sum_{i=0}^{r-1}\Delta A_i.$$

Proof: This is an injective map by(2.1.4.10), and for any h that $P_r(h)=0$, By(2.1.4.10) item1, this means $A_{r-1} = P_{r-1}(h) \in \mathrm{Sym}^{r-1}\Gamma^r$. Let $h' = h - \Delta A_{r-1}$, then(2.1.4.10) item4 shows $P_{r-1}(h') = 0$, thus we can use induction to show $h' = \sum_{i=1}^{r-2}\Delta A_i$, thus $h = \sum_{i=1}^{r-1}\Delta A_i$. □

Prop. (2.1.4.12). Let Γ be an Abelian group, for functions $h_1,h_2 : \Gamma\to\mathbb{R}$, let $h_1 = h_2 + O(1)$ denote the fact that $|h_1 - h_2|$ is bounded on Γ. Then there is a natural isomorphism of additive groups:

$$\bigoplus_{j=0}^{r-1}\mathrm{Sym}^j\Gamma^\vee \cong \{h:\Gamma\to\mathbb{R}|P_r(h)=O(1)\}/O(1) : (A_0,\dots,A_{r-1}) \mapsto h(x) = A_0 + A_1(x) + \dots A_{r-1}(x,\dots,x).$$

Proof: The map is injective by(2.1.4.11). To show surjectivity:

By hypothesis and(2.1.4.10), there exists $C>0$ s.t.

$$|P_{r-1}h(x_0+x_1,x_2,\dots,x_{r-1}) - P_{r-1}h(x_0,x_2,\dots,x_{r-1}) - P_{r-1}h(x_1,x_2,\dots,x_{r-1})| \le C.$$

So

$$|P_{r-1}h(2^N x_1,x_2,\dots,x_{r-1}) - 2P_{r-1}h(2^{N-1}x_1,x_2,\dots,x_{r-1})| \le C$$

for any N, and by iterating,

$$|P_{r-1}h(2^N x_1,2^N x_2,\dots,x_{r-1}) - 2^{r-1}P_{r-1}h(2^{N-1}x_1,2^{N-1}x_2,\dots,2^{N-1}x_{r-1})| \le (2^{r-1}-1)C.$$

$$|\frac{P_{r-1}h(2^N x_1,2^N x_2,\dots,x_{r-1})}{2^{N(r-1)}} - \frac{P_{r-1}h(2^{N-1}x_1,2^{N-1}x_2,\dots,2^{N-1}x_{r-1})}{2^{(N-1)(r-1)}}| \le \frac{2^{r-1}-1}{2^{N(r-1)}}C.$$

Thus

$$A_{r-1}(x_1,\dots,x_{r-1}) = \lim_{N\to\infty}\frac{P_{r-1}h(2^N x_1,2^N x_2,\dots,x_{r-1})}{2^{N(r-1)}}$$

exists, and it is clear that $A_{r-1}\in\mathrm{Sym}^{r-1}\Gamma^\vee$ and $A_{r-1}(x_1,\dots,x_{r-1}) - P_{r-1}h(x_1,\dots,x_{r-1}) \le 2^{r-1}C$. Let $h' = h - \Delta A_{r-1}$, then $P_{r-1}h' = P_{r-1}h - A_{r-1} = O(1)$, thus we can use induction to show $h' = \sum_{i=1}^{r-2}\Delta A_i + O(1)$, thus $h = \sum_{i=1}^{r-1}\Delta A_i + O(1)$. □

Cor. (2.1.4.13). Let Γ be an Abelian group and $h:\Gamma\to\mathbb{R}$ be a function on an Abelian group Γ that

$$h(\sum_{i=1}^{3}x_i) = \sum_{1\le i<j\le 3}h(x_i+x_j) - \sum_{i=1}^{3}h(x_i) + O(1),$$

then there exists a unique symmetric bilinear pairing b on Γ and l a homomorphism $\Gamma\to\mathbb{R}$, that

$$h(x) = \frac{1}{2}b(x,x) + l(x) + O(1).$$

Prop. (2.1.4.14). Let M be an Abelian group and $b : M \times M \to \mathbb{R}$ is a bilinear form on M that $\mathrm{rad}(B) = 0$, so b defines a bilinear form on $B_{\overline{R}} : M \otimes_{\mathbb{Z}} \mathbb{R}$. Then $b_{\mathbb{R}}$ is positive-definite iff for any f.g. subgroup M' of M and $C > 0$, $\{x \in M' | B(x, x) \leq C\}$ is finite.

Proof: We may assume M is f.g.. As M/M_{tor} is torsion-free, it is a lattice in $M_{\mathbb{R}}$(12.2.3.32). Assume $b_{\mathbb{R}}$ is positive-definite, then it defines a topology on $M_{\mathbb{R}}$, then $\{x \in M' | b_{\mathbb{R}}(x, x) \leq C\}$ is finite because it is a compact discrete set.

Conversely, if $\{x \in M' | b(x, x) \leq C\}$ is finite and $b_{\mathbb{R}}$ is not positive-definite, then it is at least semi-positive definite. If $b_{\mathbb{R}}(y, y) = 0$, then by Cauchy-Schwartz inequality(2.1.4.7), y is in the radical of $b_{\mathbb{R}}$. By hypothesis $y \notin M_{\mathbb{Q}}$.

Now choose a basis $e_1, \ldots, e_n$ of M, for any $n > 1$, there is a $y_n \in M$ s.t. $y_n - ny \in S = \{\sum \alpha_i e_i | 0 \leq \alpha \leq 1\}$, and

$$b_{\mathbb{R}}(y_n, y_n) = b_{\mathbb{R}}(y_n - ny, y_n - ny)$$

is bounded by the maximal value of $b_{\mathbb{R}}$ on S. These y_n are all different because $y \notin M_{\mathbb{Q}}$, thus contradicting the hypothesis. □

Prop. (2.1.4.15). Let $M \in \mathcal{A}b$ s.t. $\# M/nM < \infty$ for some $n \geq 2$ and there is a positive semi-definite symmetric bilinear form B on M s.t. $\{x \in M | B(x, x) \leq C\}$ is finite for any $C > 0$, then M is f.g..

Proof: Choose a set of generators $\{x_i\}$ for M/nM. Now there is a constant C that whenever $(x, x) \geq C$,

$$(x - x_i, x - x_i) < 2(x, x), \forall i,$$

because by Cauchy-Schwartz inequality(2.1.4.7), $(x - x_i, x - x_i)$ is similar to (x, x) when (x, x) is large.

Now let $\Gamma = \{x_1, \ldots, x_s\} \cup \{x \in \Gamma | (x, x) < C\}$. Then Γ is finite by hypothesis. We prove Γ generates M: Consider the infimum C_0 of (x, x) that x is not generated by M, then there is a x that $C_0 \leq (x, x) < 2C_0$. Obviously $C_0 \geq C$. Let $x = x_i + ny$ for some $x_i \in \Gamma, y \in M$, then

$$(y, y) = \frac{1}{n^2}(x - x_i, x - x_i) < \frac{2}{n^2}(x, x) \leq \frac{1}{2}(x, x) < C_0.$$

Thus by minimality of C_0, $y \in \Gamma$, thus $x \in \Gamma$. □

Def. (2.1.4.16) [Lagrangian Decomposition]. Let A be a f.g. Abelian group and $\Gamma : A \times A \to \mathbb{Q}/\mathbb{Z}$ is a bilinear alternating non-degenerate pairing, then a **Lagrangian decomposition** of A is an Abelian subgroup $B \subset A$ s.t. $\Gamma|_B = 0$, called an **isotropic subgroup** of A, such that $A \cong B \oplus \widehat{B}$, and Γ is given by

$$\Gamma((x, \chi), (y, \psi)) = \chi(y)\psi(x)^{-1}.$$

Prop. (2.1.4.17). Let A be a f.g. Abelian group and $\Gamma : A \times A \to \mathbb{Q}/\mathbb{Z}$ is a bilinear alternating non-degenerate pairing, then A admits a Lagrangian decomposition.

In particular, if $\# A < \infty$, then $\# A \in (\mathbb{Z}_+)^2$.

Proof: Because A is f.g., take x, y in A s.t. $\Gamma(x, y)$ has the maximal denominator, then it is easy to see that for any $z \in A$, $z - ax - by \in \mathrm{span}(x, y)^{\perp}$ for some $a, b \in \mathbb{Z}$, so $A = \mathrm{span}(a, b) \oplus \mathrm{span}(a, b)^{\perp}$, and we can use induction. □

Finite Abelian Groups

Prop. (2.1.4.18)[Characterizing Finite Cyclic Groups]. Let $G \in \mathcal{A}\mathrm{b}^{\mathrm{fin}}$ that $\#\{x \in G | x^d = 1\} \leq d$ for any $d \geq 1$, then G is cyclic.

Proof: Consider the subset G_d of elements of order d, if it is non-empty, choose $y \in G_d$, then $\#\langle y \rangle = d$, thus $\langle y \rangle = \{x \in G | x^d = 1\}$, which means $\# G_d \leq \varphi(d)$. Then $|G| = \sum_{d|n} \# G_d \leq \sum_{d|n} \varphi(d) = n$. Thus $G_n \neq \varnothing$, which means G is cyclic. □

Cor. (2.1.4.19). For $k \in \texttt{Field}$, any finite subgroup of $k^\times$ is cyclic.

Cor. (2.1.4.20) [Primitive roots modulo q]. For $p \in \mathbf{P}$ and $q \in p^{\mathbb{Z}_+}$, $\mathbb{F}_q^\times$ is cyclic, i.e. $\mathbb{F}_q^\times \cong \langle \sigma \rangle$. Any such generator σ is called a **primitive root modulo** p.

5 Automorphism Groups

Def. (2.1.5.1) [Automorphisms Groups]. Let $G \in \mathcal{G}\mathrm{rp}$, the set of automorphism of G is a group, denoted by $\mathrm{Aut}(G)$.

Then for any $g \in G$, there is an automorphism $C_g \in \mathrm{Aut}(G) = \mathrm{Hom}(G, G) : x \mapsto gxg^{-1}$. And the mapping $G \to \mathrm{Aut}(G) : g \mapsto C_g$ is a group homomorphism. All automorphisms of G of the form are called **inner automorphisms** of G. The group of inner automorphisms of G is denoted by $\mathrm{Inn}(G)$. Automorphisms that are not inner are called **outer automorphisms**.

Prop. (2.1.5.2). Any group of order> 2 have at least 2 automorphisms.

Proof: Assume the contrary, consider its inner automorphism, then it is Abelian, and then multiplying by p for p large prime is not identity, Then $\#G|(p-1)$ for such G. Now it is clear $|G| = 2$, because otherwise we can choose $p \equiv 2 (\mathrm{mod}\ \#G)$. □

Def. (2.1.5.3) [Automorphic Complete Groups]. An **automorphic-complete group** is a group whose automorphisms are all inner.

Prop. (2.1.5.4). S_n is the automorphism group of A_n for $n = 5$ or $n \geq 7$.

Proof: □

Prop. (2.1.5.5). If G is a non-Abelian simple group, then $\mathrm{Aut}(G)$ is a complete group.

Prop. (2.1.5.6). S_n are complete groups except for S_6.

Proof: S_n is the automorphism group of A_n for $n = 5$ or $n \geq 7$ by(2.1.5.4), thus it is complete by(2.1.5.5). □

Prop. (2.1.5.7) [Wielandt]. If G is a finite group with trivial center, then the sequence

$$G < \mathrm{Aut}(G) < \mathrm{Aut}(\mathrm{Aut}(G)) < \dots$$

must terminate in finite steps.

Proof: □

6 Free Groups and Presentations

Def. (2.1.6.1) [Free Groups]. There is a **free group** functor $\mathrm{F}:\mathcal{S}\mathrm{et}\to\mathcal{G}\mathrm{rp}$ that is left adjoint to the forgetful functor.

The image of the set $[n-1]$ is denoted by F_n.

Proof: For the existence of F, Cf.[Lan05]P66.**?** □

Prop. (2.1.6.2) [Nielsen-Schreier]. A subgroup H of a free group G is a free group. Moreover, a subgroup H of finite index m in F_n is isomorphic to $\mathrm{F}_{1+m(n-1)}$.

Proof: A free group is the fundamental group of a graph X which is a wedge sum of circles, and there is a covering $X_H\to X$ the $\pi_1(X_H)=H$ by(3.14.1.28). And if H is of index m in a free group G, $X_H\to X$ has degree m by(23.1.1.5). Now (23.1.1.5) shows $H=\pi_1(X_H)$ is a free group, and the final assertion follows by comparing two ways of counting Euler number χ. □

Prop. (2.1.6.3). Use the same method as in(2.1.6.2), we can determine all the subgroups of index 2 in F_2.

Proof: **?** □

Def. (2.1.6.4) [Earring Group]. For any $n\in\mathbb{Z}_+$, there are group homomorphisms $\mathrm{F}_n\to\mathrm{F}_{n-1}$ corresponding to the map of sets

$$[n-1]\to\mathrm{F}_{n-1}:i\mapsto\begin{cases}[i] & ,i\le n-2\\ 1 & ,i=n-1\end{cases}.$$

The **Earring group** $\#^{\mathbb{N}}\mathbb{Z}$ is defined to be the subgroup of

$$\varprojlim_{n\in\mathbb{N}}\mathrm{F}_n$$

consisting of elements $(w_0,w_1,\ldots,w_n,\ldots)$ s.t. if each w_n is a reduced word, then for any $k\in\mathbb{Z}_+$, the number of $[k]^{\pm}$ appearing in w_n stablizes.

Prop. (2.1.6.5). The natural homomorphism

$$\eta:\mathrm{Hom}(\#^{\mathbb{N}}\mathbb{Z},\mathbb{Z})\to\prod^{\mathbb{N}}\mathbb{Z}$$

is injective with image $\oplus^{\mathbb{N}}\mathbb{Z}$.

Proof: Cf.https://wildtopology.com/2014/05/09/the-hawaiian-earring-group-is-not-free-part-i/. □

Prop. (2.1.6.6). There is a natural group homomorphism $\varepsilon:\#^{\mathbb{N}}\mathbb{Z}\to\prod^{\mathbb{N}}\mathbb{Z}$ that is surjective.

Proof: The k-th coordinate of this map is given by omitting all the elements that is not $[k]$. It is clearly surjective. □

Prop. (2.1.6.7) [Smith]. $\#^{\mathbb{N}}\mathbb{Z}$ is not a free group.

Proof: Cf.https://wildtopology.com/2014/05/09/the-hawaiian-earring-group-is-not-free-part-i/. □

List of Presentations of Important Groups

Prop. (2.1.6.8). Let F be a field, then $SL(2,F)$ has a representation as:

$$\langle t(y), n(z), w_1\rangle, \quad y\in F^*, z\in F$$

quotient the relations:

$$t(y_1)t(y_2)=t(y_1y_2), \quad n(z_1)n(z_2)=n(z_1+z_2), \quad t(y)n(z)t(y)^{-1}=n(y^2z), \quad w_1t(y)w_1=t(-y^{-1}).$$

$$w_1n(z)w_1=t(-z^{-1})n(-z)w_1n(-z^{-1}), z\in F^*,$$

And the isomorphism is given by Φ:

$$t(y)\mapsto\begin{bmatrix} y & \\ & y^{-1}\end{bmatrix}, \quad n(z)\mapsto\begin{bmatrix}1 & z\\ & 1\end{bmatrix}, \quad w_1\mapsto\begin{bmatrix} & 1\\ -1 & \end{bmatrix}.$$

Proof: The map vanishes on the relations is direct calculation. An inverse of Φ is constructed by

$$\Psi(\begin{bmatrix}a & b\\ c & d\end{bmatrix})=\begin{cases} n(a/c)t(-c^{-1})w_1n(d/c) & c\neq 0\\ t(a)n(b/a) & c=0\end{cases}$$

The verification of the inverse is verified by direct calculation. □

Prop. (2.1.6.9). Let F be a field, then $SL(2,F)$ is generated by $N(F)$ and any element in $SL(F)\backslash N(F)$.

Proof: Take this element in $G(F)\backslash B(F)$, left and right multiplying by elements in $N(F)$, we see it contains some $\begin{bmatrix} & -a^{-1}\\ a & \end{bmatrix}$, then it contains $\begin{bmatrix} & -a^{-1}\\ a & \end{bmatrix}^{-1}N(F)\begin{bmatrix} & -a^{-1}\\ a & \end{bmatrix}=\begin{bmatrix}1 & \\ * & 1\end{bmatrix}$. Then it contains $N(F)\begin{bmatrix} & -a^{-1}\\ a & \end{bmatrix}=\begin{bmatrix} * & -a^{-1}\\ a & \end{bmatrix}$. Left multiplying by $\begin{bmatrix}1 & \\ * & 1\end{bmatrix}$ and right multiplying by $N(F)$, we see it contains all diagonal matrices in $SL(2,F)$. So it contains $\begin{bmatrix} & -1\\ 1 & \end{bmatrix}$, thus contains $SL(2,F)$, by Bruhat decomposition. □

Prop. (2.1.6.10). $SL(2,\mathbb{Z})$ is generated by $S=\begin{bmatrix} & -1\\ 1 & \end{bmatrix}, T=\begin{bmatrix}1 & 1\\ & 1\end{bmatrix}$ with relations

$$S^4=1, \quad (ST)^3=S^2$$

.

Proof: [Serre, Trees, P81]. □

Cor. (2.1.6.11) [Modular Group]. $PSL_2(\mathbb{Z})=SL_2(\mathbb{Z})/\{\pm 1\}$ is generated by $S=\begin{bmatrix} & -1\\ 1 & \end{bmatrix}, T=\begin{bmatrix}1 & 1\\ & 1\end{bmatrix}$ with relations

$$S^2=1, \quad (ST)^3=1.$$

Prop. (2.1.6.12) [Braid Group]. The **Braid group** B_n, defined by $B_n = \pi_1(\mathbb{C}^n\backslash \bigoplus\{z_i = z_j\}/S^n)$ has a presentation by $b_i, i = 1, \ldots, n-1$ and relations

- if $|i-j| \geq 2$, then $b_i b_j = b_j b_i$.
- $b_i b_{i+1} b_i = b_{i+1} b_i b_{i+1}$.

Proof: □

Cor. (2.1.6.13) [Pure braids]. Due to the covering map $\mathbb{C}^n\backslash \bigoplus\{z_i = z_j\} \to \mathbb{C}^n\backslash \bigoplus\{z_i = z_j\}/S^n$ with fiber S^n, there is a map $B_n \to S_n$ which is easily seen to be surjective and with kernel $P_n = \pi_1(\mathbb{C}^n\backslash \bigoplus\{z_i = z_j\})$, called the group of **pure braids**.

Prop. (2.1.6.14). There is a group homomorphism $B_3 \to PSL_2(\mathbb{Z})$ that maps $a = \sigma_1\sigma_2\sigma_1$ to S and $b = \sigma_1\sigma_2$ to T. The kernel of this map is the group generated by $c = a^2 = b^3$.

7 Sylow Theory

Prop. (2.1.7.1) [Class Equation]. For a finite group G, if $G_x = C((x))$, then

$$|G| = |C(G)| + \sum |G|/|G_x|$$

where the summation is over non-trivial conjugate classes of G.

Proof: Consider the left action of G on itself, and calculate elements. □

Cor. (2.1.7.2) [p-Groups are Solvable]. if G is a p-group, then G has a non-trivial center. In particular, any p-group is solvable.

Cor. (2.1.7.3). If $p||G|$, then G has an element of order p.

Proof: Follows from Sylow theory and any p-group has a non-trivial center. □

Lemma (2.1.7.4). For any p-group G acting on a finite set X, $|X| \equiv X^G \mod p$.(trivial).

Prop. (2.1.7.5) [Sylow Theorem, Sylow1872]. For a finite group of order $|G| = p^k m$.

- There is a Sylow p-group.
- For a Sylow p-subgroup, any p-subgroup is contained in a conjugate of P. In particular, any two Sylow p-subgroups are conjugate.
- the number of Sylow p-groups n_p satisfies: $n_p | m, n_p \equiv 1 \mod p$.

Proof: 1: Use induction, let $Z = C(G)$, if $p||Z|$, then Z contains a cyclic group of order p. Choose a p-Sylow subgroup of G/C, then its inverse image in G is a p-Sylow subgroup. If Z is prime to p, consider the conjugate action of G on $G - Z$, then some conjugacy class has order prime to p, by(2.1.7.4), then the stablizer H of this class satisfies $[G : H]$ is prime to p. Thus H contains a p-Sylow subgroup by induction.

2: If Q is a p-subgroup, then Q acts on G/P by left translation, so it has a fixed element by(2.1.7.4), $QxP = xP$ for some x, thus $Q \subset xPx^{-1}$.

3: $n_p|m$ by considering the conjugate action of P on the set of conjugates of P, then as in the proof of item2, P is the only fixed element, so $n_p \equiv 1 \mod p$ by(2.1.7.4). □

Lemma (2.1.7.6). If G has a sylow subgroup H that $|G/H|!$ is not divisible by $|G|$, then G is not simple.

Proof: Consider the conjugate action of G on the conjugacy classes of H, then it is a group homomorphism of G into a subgroup of $S_{|G/H|}$, but the hypothesis shows that it is not injective, thus the kernel is non-trivial normal. □

Prop. (2.1.7.7) [Frattini Argument]. If G is a finite subgroup, N is normal in G and P is a Sylow subgroup of N, then $NN_G(P) = G$.

Proof: For any element $g \in G$, consider $g^{-1}Pg \subset N$ is a Sylow subgroup of N, thus by Sylow theorem(2.1.7.5), there is a $n \in N$ that $g^{-1}Pg = n^{-1}Pn$, thus $gn^{-1} \in N_G(P)$, thus $g \in NN_G(P)$. □

8 Split Extension

Prop. (2.1.8.1)[Cyclic Central Extension Split]. If there is an exact sequence $0 \to Z \to G \to C \to 0$ where $Z \subset C(G)$ and C is cyclic, then G is Abelian.

Proof: This is because we can choose an inverse image of a generator of C. □

Prop. (2.1.8.2) [Schur-Zassenhaus]. An exact sequence of finite groups $0 \to A \to E \to G \to 0$ must split when $|A|$ and $|G|$ are relatively prime.

Proof: □

Prop. (2.1.8.3). Let $\alpha, \beta : G \to \mathrm{Aut}(H)$ be two actions of G on H, then theirs semiproduct sequences

$$1 \to H \to G \ltimes H \to G \to 1$$

are isomorphic iff α, β are equivalent modulo $\mathrm{Inn}(H)$.

9 Subnormality

Def. (2.1.9.1) [Normal Series]. A **subnormal series** of a group G is a descending chain of groups:

$$G = G_0 \rhd G_1 \rhd \ldots \rhd G_r = \{e\}$$

that G_{k+1} is normal in G_k. It is called a **composite series** iff each G_k/G_{k+1} is simple.

Lemma (2.1.9.2) [Butterfly Lemma]. Let H_1, H_2 be subgroups of a group G, N_1, N_2 are normal subgroups of H_1 and H_2, then there is a canonical isomorphism of groups:

$$N_1(H_1 \cap H_2)/N_1(H_1 \cap N_2) \cong N_2(H_2 \cap H_1)/N_2(H_2 \cap N_1).$$

Proof: Cf.[Lan05]P20. □

Prop. (2.1.9.3) [Schreier]. Any two subnormal series of a group G have a common refinement.

Proof: □

Cor. (2.1.9.4) [Jordan-Hölder]. For any two composition series $G = G_0 \rhd G_1 \rhd \ldots \rhd G_r = \{e\}$, $G = G'_0 \rhd G'_1 \rhd \ldots \rhd G'_{r'} = \{e\}$, there $r = r'$, and there exists a permutation $\sigma \in S_{r-1}$ s.t. $G_i/G_{i+1} \cong G'_{\sigma(i)}/G'_{\sigma(i)+1}$.

Def. (2.1.9.5) [Central Series]. A **central series** of a group G is an ascending chain of groups:

$$\{e\} = Z_0 < G_1 < \ldots < G_r = G$$

that Z_{k+1}/Z_k is in the center of G/Z_k.

Prop. (2.1.9.6). A group is

- solvable iff it has a normal series that G_i/G_{i+1} is Abelian.
- nilpotent iff it has an upper central series.

Proof: □

Def. (2.1.9.7) [Supersolvable Groups]. A group G is called a **supersolvable group** iff it has a normal series that G_i/G_{i+1} is cyclic.

If G is finite, this notion is equivalent to solvable.

Lemma (2.1.9.8) [p-Group is Nilpotent]. Any p-group is nilpotent.

Proof: Using induction by(2.1.7.2), we see it has a central series, thus nilpotent(2.1.9.6). □

Prop. (2.1.9.9) [Nilpotent Finite Groups]. If G is a finite group, then the following are equivalent:

- G is nilpotent.
- $N_G(H) > H$ for every proper subgroup $H < G$.
- Every maximal subgroup of G is normal.
- Every Sylow subgroup of G is normal.
- G is a direct product of its non-trivial Sylow subgroups.

Proof: $1 \to 2$: Choose a central series Z_n, let $Z_n \subset H$ and $Z_{n+1} \not\subset H$, then $[Z_{n+1}, H] \subset [Z_{n+1}, G] \subset Z_n \subset H$, thus $Z_{n+1} \subset N_G(H)$.

$2 \to 3, 4 \to 5$: trivial.

$3 \to 4$ For any p-Sylow subgroup G, if $N_G(P)$ is proper subgroup, then it is contained in some maximal subgroup M, and M is normal, thus by Frattini argument(2.1.7.7), $G = N_G(P)M = M$, contradiction.

$5 \to 1$: By lemma(2.1.9.8). □

Prop. (2.1.9.10) [Jordan-Horder]. For a finite group G, any two of its composite series has the same length, then the quotient groups G_k/G_{k+1} are in bijection with each other as sets.

Proof: Cf.[代数学引论 P89]. □

Prop. (2.1.9.11) [Minimal Normal Subgroup]. The minimal normal subgroup N of a finite group G is a direct product of simple groups L^n.

Proof: Let N_1 be a maximal normal subgroup of N, then N/N_1 is simple, and let N_i be the conjugates of N_1 in G, then they are all maximal normal subgroup of N. the simple groups N/N_i are mutually isomorphic, and $\cap N_i = 1$ by the minimality of N.

Now we use induction to prove $N/N_1 \cap \ldots \cap N_i$ is isomorphic to a product of N/N_1, which will finish the proof.

Now assume $N_1 \cap \ldots \cap N_{i-1} \not\subset N_i$, then $(N_1 \cap \ldots \cap N_{i-1})N_i = N$, and notice

$$N/N_1 \cap \ldots \cap N_i \cong N_1 \cap \ldots \cap N_{i-1}/N_1 \cap \ldots \cap N_i \times N_i/N_1 \cap \ldots \cap N_i \cong N/N_i \times N/N_1 \cap \ldots \cap N_{i-1}.$$

□

Prop. (2.1.9.12). If a finite group $|G| = \prod p_i$, where p_i are different primes that $\prod p_i$ and $\prod(p_i - 1)$ are coprime, then G is cyclic.

Proof: We prove all the Sylow groups are normal. Choose the maximal Sylow group A_n, then it is normal by Sylow theorem, and other Sylow groups act by conjugation is trivial(consider the center(2.1.7.2), then the center of the quotient, and so on), hence A_n is in the center. Now consider the quotient, by induction it is cyclic, hence this is a central extension of a cyclic group, hence G is Abelian(2.1.8.1), so cyclic. □

Prop. (2.1.9.13). If G is a finite group and p is the minimal prime number of $|G|$, then all subgroups N of G of index p is normal.

Proof: Consider the left action of G on G/H, then the kernel is $\cap a^{-1}Ha$, which is the maximal normal subgroup contained in H. Now this is group homomorphism of G into S_p, thus it has kernel at lest $|G|/p$, so the kernel equals H, showing H is normal. □

Prop. (2.1.9.14) [Burnside's Theorem]. If p, q are primes, then any finite groups of order $p^a q^b$ is solvable.

Proof: Cf.[Serre Linear representations of finite groups, P65]. □

Prop. (2.1.9.15) [Thompson]. A finite group is not solvable iff there exist non-trivial elements x, y, z of coprime orders a, b, c that $xy = z$.

Prop. (2.1.9.16) [Feit-Thompson]. All finite groups that has odd order is solvable.

Proof: □

10 Commutators

Def. (2.1.10.1) [Notation].

- $[a, b] = a^{-1}b^{-1}ab$.
- $x^y = y^{-1}xy$.

Prop. (2.1.10.2) [Commutator relations]. .

Def. (2.1.10.3) [Metabelian Groups]. A **metabelian** group is a group G that G' is Abelian.

Prop. (2.1.10.4). If $G = AB$ where A, B are Abelian, then $[G, G] = [A, B]$ and G is metabelian.

Proof: The first one is easy to verify, the second because if we let $b^{a_1} = a_2b_2$, $a^{b_1} = b_3a_3$, then

$$[a, b]^{a_1b_1} = [a, b^{a_1}]^{b_1} = [a, b_2]^{b_1} = [a^{b_1}, b_2] = [a_3, b_2]$$

and similarly, $[a, b]^{b_1a_1} = [a_3, b_2]$, so we have $[a, b]$ commutes with $[b_1^{-1}, a_1^{-1}]$, which shows $[A, B]$ is Abelian. □

Prop. (2.1.10.5). If G is a metabelian finite group, then the transfer of $Ver : G \to G'$ is trivial map.

11 Transfer

12 Permutation Groups

Lemma (2.1.12.1). If $n \geq 3$, then any proper normal subgroup of A_n has index divisible by 3.

Proof: Otherwise consider $n = |G/H|$, then every p-power is in H. But then an element c of order 3 is in H, because $c = c^{3k+1} = (c^{-1})^{3k+2}$ for any k. But A_n is generated by 3-Cycles. □

Lemma (2.1.12.2). A_5 is simple.

Proof: By(2.1.12.1), any proper normal subgroup H has order dividing 20. H cannot contain a 5-cycle, because a 5-cycle has □

Prop. (2.1.12.3). A_n is simple for $n \geq 5$.

Proof: Cf.[代数学引论 P66]. □

13 Classification of Finite Groups

Thm. (2.1.13.1) [Classification of Finite Simple Groups]. Every finite simple group is one of the following:

- $\mathbb{Z}/(p)$.
- A_n.
- 16 infinite family of finite groups of Lie type.
- 26 exceptional groups, called **sporadic simple groups**.

Proof: A full list is inhttps://brauer.maths.qmul.ac.uk/Atlas/v3/? □

Prop. (2.1.13.2) [Monster Group]. The largest sporadic simple group is called the **Monster group** $\mathbb{M}$.

$$\#\mathbb{M} = 2^{46} \cdot 3^{20} \cdot 5^9 \cdot 7^6 \cdot 11^2 \cdot 13^3 \cdot 17 \cdot 19 \cdot 23 \cdot 29 \cdot 31 \cdot 41 \cdot 47 \cdot 59 \cdot 71.$$

Proof: □

Prop. (2.1.13.3) [Happy Family]. There are 20 sporadic groups appearing as a subquotient of $\mathbb{M}$, and they form a set called the **happy family**. The remaining 6 groups are known as the **pariah groups**, including the **Lyons group**, **Janko groups** J_1, J_3, J_4, **Rudvalis group** and the **O'Nan group** $\mathbb{O}\mathbb{N}$.

Prop. (2.1.13.4) [Baby Monster Group]. The second largest sporadic simple group is called the **baby Monster group** $\mathbb{B}$.

Def. (2.1.13.5) [O'Nan Group].

Prop. (2.1.13.6). The O'Nan group has size

$$\#\mathbb{O}\mathbb{N} = 2^9 \cdot 3^4 \cdot 5 \cdot 7^3 \cdot 11 \cdot 19 \cdot 31.$$

Prop. (2.1.13.7) [Classification of Small Groups].

1. A group G of prime order p or order p^2 is Abelian.

2. A group G of order $p^a q^b$ that it has q^b p-Sylow subgroups, then its q-Sylow subgroup is normal thus it is not simple.
3. A non-Abelian group G of order 6 is isomorphic to S_3.
4. Any non-Abelian group of order 8 is isomorphic to D_4 or quadratic numbers Q.
5. A group of order smaller than 60 is solvable.
6. Any simple group G of order 60 is isomorphic to A_5.
7. A group of order 148 is not simple, by(2.1.7.6) applied to the 37-Sylow subgroup.
8. A group of order 150 is not simple, by(2.1.7.6) applied to the 5-Sylow subgroup.

Proof:

1. Because G has non-trivial center Z by(2.1.7.2), if $Z = G$, then it is Abelian, otherwise the $|Z| = p$, and the quotient G/Z is cyclic, thus G is Abelian by(2.1.8.1).
2. Calculating elements.
3. Consider its normal 3-Sylow group, then the quotient is cyclic thus G is semi-product which must by S_3 when non-Abelian.
4.
5.
6. Consider G has 6 5-Sylow groups, thus there are 24 elements of order 5.
   G has 4 or 10 3-Sylow subgroups, if it have 4 3-Sylow subgroups, then the normalizer contains a 5-Sylow subgroup, so we have a subgroup of order 15, which must by $\mathbb{Z}/15$, so it contains a normal 5-Sylow subgroup, which shows there are at most $60/15 = 4$ 5-Sylow subgroups, contradiction.
   So we have 10 3-Sylow subgroups, which shows there are at most 15 elements of order 2 or 4. So we have 3 or 5 2-Sylow subgroups. If it is 3, then we can do the same as that for 3-Sylow to construct a 20-order group and reach contradiction.
   So now it have 5 2-Sylow subgroups, and then we consider the conjugate action on Sylow subgroups, which is transitive, so it has trivial kernel, and $G \hookrightarrow S_5$. Now $G = [G, G] \subset [S_5, S_5] = A_5$.

□

Prop. (2.1.13.8). There is a group that is group that $a^3 = 1$ for any $a \in G$, but is not Abelian. It is the uni-upper-triangular matrices in $M_3(\mathbb{F}_3)$.

14 Profinite Groups

Basic references are [Neukirch Cohomology of Number Fields], [Serre Galois Cohomology] [Profinite Groups Zalesskii] and [Shatz Profinite Groups, Arithmetic and Geometry].

Def. (2.1.14.1)[Profinite Groups]. A **profinite group** is a topological group that is an inverse limit of finite discrete groups.

Lemma (2.1.14.2). For a compact totally disconnected group G, any nbhd U of e contains a normal open subgroup.

Proof: U contains a precompact nbhd of e, then by(3.11.1.24), U contains an open subgroup V, so by(3.11.1.6), there is a nbhd V' of e that $xV'x^{-1} \subset V$ for all $x \in G$, this says $\cap x^{-1}Vx$ is open, so it is an open normal subgroup. □

Prop. (2.1.14.3) [Profinite Compact and Totally Disconnected]. A profinite group is the same thing as a totally disconnected, compact Hausdorff topological group. In particular, $G \cong \varprojlim G/U$ where U runs over all open normal subgroups of G.

Proof: One way is because $\lim G_i$ is a closed subgroup of $\prod G_i$ which by Tychonoff's theorem is compact.

Conversely, by(2.1.14.2), G has a basis of e consisting of normal open subgroups, and by(3.11.1.23), the intersection of open normal subgroups is $\{e\}$. For any open normal subgroup N of G, G/N is compact discrete hence finite, the map $G \to \varprojlim G/N$ is continuous and has dense image, but G is compact and the right is Hausdorff, so the image is closed, hence it is surjective. It is injective because $\cap N = \{e\}$. Hence $G \cong \varprojlim G/N$. □

Cor. (2.1.14.4). A closed subgroup of a profinite group is profinite, and a quotient group is profinite.

A direct product of profinite groups are profinite, and so the inverse limit profinite groups are profinite, as it is a closed subgroup of a direct product.

Proof: The closed subgroup is totally disconnected by(3.3.1.26).

To show the quotient group is totally disconnected, by(3.11.1.23), it suffice to prove H is intersection of compact open nbhds in G/H. If $x \notin H$, then there is an open subgroup U disjoint from xH by(3.11.1.7), so it is closed hence compact. So UH is a compact nbhd of H in G/H that doesn't contains xH, hence the result. □

Cor. (2.1.14.5). A closed subgroup of a profinite group is a intersection of open normal subgroups of G containing it, as G/H is profinite and as in the proof of(2.1.14.3), H is the intersection of open normal subgroups of G/H.

Prop. (2.1.14.6). For $G \in \mathcal{P}\mathrm{rof}$, if U_α is the system of open normal subgroups of G, and H is a closed subgroup of G, then there is a natural isomorphism of topological groups

$$H \cong \varprojlim H/H \cap U_\alpha,$$

and if H is normal, then there is a natural isomorphism of topological groups

$$G/H \cong \varprojlim G/HU_\alpha.$$

Proof: Cf.[Central Simple Algebras]P113.? □

Prop. (2.1.14.7). Any infinite profinite groups is uncountable.

Proof: [Profinite Groups Zalesskii]Prop2.3.1. □

Prop. (2.1.14.8). The category of profinite Abelian groups is Pontryagin dual to the category of torsion abelian group. (not that hard to verify).

Proof: □

Pro-p-Groups

Def. (2.1.14.9) [Surnatural Number]. To consider indexes of closed subgroups of a profinite group, the notion of surnatural numbers are needed. A **surnatural number** is a formal product $\prod_p p^{n_p}$, $n_p \in \mathbb{N} \cup \{0, \infty\}$.

For a closed subgroup H of a profinite group G, $[G : H]$ is defined to be the least common multiple of $[G/U : H/H \cap U]$ where U goes over all open normal subgroups of G. This also equals the least common multiple of $[G : V]$ for V open containing H(because for any such V, there is an open normal subgroup U that $HU \subset V$(3.11.1.6)).

Prop. (2.1.14.10). The index is compatible with composition and quotient: $[G : K] = [G : H][H : K]$ and $[G : H] = [G/K : H/K]$ for K closed normal in G.

$[G : H]$ is finite iff H is open. For a decreasing family of closed subgroups H_i of G, $[G : \cap H_i]$ equals the least common multiple of $[G : H_i]$.

Proof: $[G/U : K/K \cap U] = [G/U : H/H \cap U][H/H \cap U : K/K \cap U] | [G : H][H : K]$, giving one way of inequality. For the converse, Cf.[Etale Cohomology Fulei P150]. The quotient case is trivial.

If $[G : H]$ is finite, then For the final assertion, notice for a open subgroup V, $G - V$ is compact, so $\cap H_i \subset V$ iff $\cap H_i \subset V$ for some i. □

Def. (2.1.14.11) [Pro-p-Group]. A profinite group G is called a **pro-p-group** iff $[G : 1]$ is a power of p.

Given a profinite group, a closed subgroup H is called **Sylow pro-p-subgroup** of G if H is pro-p and $[G : H]$ is prime to p.

Proof: □

Prop. (2.1.14.12). A profinite group G is a pro-p-group iff it is an inverse limit of finite p-groups. In particular, any finite quotient of a pro-p-group is a p-group.

Proof: □

Prop. (2.1.14.13) [Sylow Pro-p-Group Exists].

Proof:

□

Prop. (2.1.14.14). Any pro-p subgroup H of G is contained in a Sylow p-subgroup of G, and any two Sylow p-subgroups are conjugate. And a surjective morphism of profinite groups maps a pro-p group to a pro-p group.

Proof: For any open normal subgroup U of G, let I_U be the sets of all Sylow groups of G/U containing $H/H \cap U$, then the map $G/VG/U$ maps I_V to I_U, and I_U is finite nonempty by Sylow theory. So the inverse limit of I_U is nonempty, and let (P_U) be such an element, and $P = \varprojlim_U P_U$, then P is a pro-p subgroup of G, and $[G : P]$ equals the least common multiple of $[G/U : P_U]$, which is prime to p, so it is a Sylow p-group. Similarly, for two Sylow-p subgroup, we consider A_U the set of all $x \in G/U$ that $x^{-1}(PU/U)x = P'U/U$, then there is a inverse element x, and $x^{-1}Px = P'$.

If $G' = G/N$, then $[G/N : PN/N] = [G : PN] | [G : P]$ is prime to p, and $[PN/N : 1] = [P : P \cap N] | [P : 1]$ is a power of p, so PN/N is Sylow-p in G'. □

Prop. (2.1.14.15). For a pro-p group G, any nonzero simple p-torsion G-module is isomorphic to $\mathbb{Z}/p\mathbb{Z}$ with trivial G-action.

Proof: The action of G on A factors through a finite quotient group which is a p-group, by**??**, $A^G \neq 0$, so $A = A^G$, then A must be $\mathbb{Z}/p\mathbb{Z}$. □

2.2 Abstract Algebra

References are [Lan05], [Rom07] and [Finite Groups Issac].

This section differs from sections on Commutative Algebras because it contains more basic, but maybe non-commutative properties. This section differs from sections on Group Theory because it concerns objects with more structure than a group.

Notation (2.2.0.1).

- Use notations defined in Group Theory.

1 Rings

Basics

Def. (2.2.1.1) [Rings]. A **ring** is an Abelian group $(R, +)$ together with a multiplication map

$$\times : R \times R \to R$$

s.t.

- $(R, \times)$ is a monoid.
- For any $x, y, z \in R$,
$$x(y+z) = xy + xz, \quad z(x+y) = zx + zy$$

A **commutative ring** is a ring that the multiplication is commutative. The category of rings is denoted by $\mathcal{R}\mathrm{ing}$, the category of commutative rings is denoted by $\mathcal{CR}\mathrm{ing}$.

Def. (2.2.1.2). $R \in \mathcal{R}\mathrm{ing}$ is called

- a **simple ring** iff it has no non-trivial two-sided ideals.
- a **domain** or an **integral ring** iff whenever $ab = 0$, $a = 0$ or $b = 0$.
- **reduced** iff it has no non-zero nilpotent element.
- **Dedekind-finite** iff for any $a, b \in R$, $ab = 1 \Rightarrow ba = 1$.

Def. (2.2.1.3) [Fields]. A **field** is a commutative ring that every non-zero element has an inverse. The category of fields is denoted by `Field`.

Prop. (2.2.1.4) [Characteristic]. For $R \neq 0 \in \mathcal{R}\mathrm{ing}$, there exists at most one $p \in \mathbf{P}$ s.t. $p \cdot 1 = 0 \in k$. If such a p exists, denote $\mathrm{char}\, k = p$, otherwise denote $\mathrm{char}\, k = 0$.

Prop. (2.2.1.5). If $1 - ab$ is left(right) invertible in a unital ring R, then so is $1 - ba$, and

$$(1-ba)^{-1} = 1 + b(1-ab)^{-1}a.$$

Proof: Direct Calculation. □

Prop. (2.2.1.6) [Kaplansky]. If a has a right inverse by no left inverse in a ring, then a has infinitely many right inverses.

Proof: If $ab = 1$, then in fact $b + (1-ba)a^n$ are right inverses for a for any $n \geq 0$, and they are distinct, because if $b + (1-ba)a^n = b + (1-ba)a^m$, then $(1-ba)a^n = (1-ba)a^m$. And by multiplying b on the right, we get $(1-ba)a^{n-m} = 1 - ba$, so $((1-ba)a^{n-m-1} + b)a = 1$. □

Division Rings

Def. (2.2.1.7) [Division Rings]. A **skew field**(or **division ring**) is a unital ring that every non-zero element is invertible (but may not be commutative).

Prop. (2.2.1.8) [Wedderburn]. A finite division ring D is a field.

Proof: Use the class equation for the invertible elements of D, if it is not isomorphic, consider the center $Z(D)$ of D, let $|Z(D)| = z$, then it is a field, and any other centralizer can be seen as a vector space over $Z(D)$, let it of dimension k, then $z^n - 1 = z - 1 + \sum \frac{z^n-1}{z^{k_i}-1}$. But then let Ψ_n be the cyclotomic polynomial of degree n, then $\Psi_n(z)$ divides $z - 1$. But this is not true, as it is bigger. □

Prop. (2.2.1.9). If D is a f.d. division algebra over $\mathbb{R}$, then it is isomorphic to $\mathbb{R}, \mathbb{C}$ or $\mathbb{H}$.

Proof: Cf.[Advanced Linear Algebra P466]. □

Prop. (2.2.1.10). Let $k \in \texttt{Field}, k = \overline{k}$, then any division ring A over k with dimension$< \#k$ is isomorphic to k.

In particular, a division ring A of at most countable dimension over $\mathbb{C}$ is isomorphic to $\mathbb{C}$.

Proof: Notice it suffices to find an eigenvalue of $\varphi\cdot : A \to A$ for each $\varphi \in A$. But $\{(\varphi - a)^{-1}\}$ is a uncountable set of elements of A, so some $\sum a_i(\varphi - c_i)^{-1} = 0$, spanning the expression, we see $\prod_k(\varphi - \mu_k) = 0$, so some $\varphi - \mu_k = 0$, contradiction. □

Prop. (2.2.1.11) [Hua Equation]. In a division ring D, if $a, b \neq 0$ and $ab \neq 1$, then

$$a - (a^{-1} + (b^{-1} - a)^{-1})^{-1} = aba$$

Proof: suffices to show

$$1 = (1 - ab)a(a^{-1} + (b^{-1} - a)^{-1}) = (1 - ab)(1 + a(b^{-1} - a)^{-1}).$$

But this is equal to

$$(1 - ab)(1 - (b^{-1} - a)(b^{-1} - a)^{-1} + b^{-1}(b^{-1} - a)^{-1}) = (1 - ab)(1 - ab)^{-1} = 1.$$

□

Remark (2.2.1.12). For more about division rings, see Finite Semisimple k-Algebras and Brauer-Grothendieck Groups.

Others

Prop. (2.2.1.13). If $R \in \mathcal{R}\text{ing}$, $\#R = p^2$, then R is commutative.

Proof: Consider the center of R, it is non-trivial because**?**. □

Prop. (2.2.1.14). Let A, A' be k-algebras and B, B' subalgebras of A, A' with centralizers C, C', then the centralizer of $B \otimes_k B' \subset A \otimes_k A'$ is $C \otimes_k C'$.

Proof: It suffices to show that $C \otimes_k A' \cap A \otimes_k C' = C \otimes_k C'$, which is clear because they are flat over k. □

2 Polynomials

Prop. (2.2.2.1)[Descartes's Rule of Sign]. Let $p(x) = a_0x^{b_0}+a_1x^{b_1}+\cdots+a_nx^{b_n}$ be a real polynomial with nonzero a_i, where $A_0 < B_1 < \cdots < b_n$, then the number of positive roots of $p(x)$ has the same parity with the number of consecutive changes of signs of $(a_k)_{k=0,\ldots,n}$.

Proof: Lemma: when $a_0a_n > 0$, the number of positive roots are even and when $a_0a_n < 0$, it is odd. This is seen by consider $p(0)$ and $p(\infty)$.

Then we consider the derivative p' and use induction. Denote the number of changing sign by $v(p)$ and the number of positive roots by $z(p)$, then if $z_0a_1 > 0$, then $v(p) = v(p')$ and $z(p) \equiv z(p') \mod 2$. Then we have $z(p) \equiv v(p) \mod 2$ and middle value theorem shows that $z(p') \leq z(p) - 1$, hence by induction and parity argument, we have $v(p) \geq z(p)$.

If $a_0a_1 < 0$, then the same method shows that $v(p) = v(p') + 1 \geq z(p') + 1 \geq z(p')$ and the have the same parity by the lemma. □

Prop. (2.2.2.2) [Lagrange Interpolation]. if K is a field, a_i are $n+1$ elements of K, b_i are $n+1$ elements of K, then there is a unique polynomial f of degree no greater than n that $f(a_i) = b_i$.

Proof: The polynomial in search is

$$f(x) = \sum \prod_{j\neq i} b_i \frac{x-a_j}{a_i-a_j}.$$

It is a polynomial of degree smaller than $n+1$, and it satisfies the hypothesis. And clearly there is at most one such polynomial, otherwise their difference has $n+1$ zeros. □

Cor. (2.2.2.3). If $f(x) = a_nx^n + \ldots + a_0$, then for any $n+1$ different integers $a_0, \ldots, a_n$, there exists some $|f(a_i)| \geq \frac{n!}{2^n}|a_n|$.

Proof: Use Lagrange interpolation and consider the leading coefficient. □

Prop. (2.2.2.4). If a degree n polynomial p satisfies $p(n) = 2^n$ for $n = 0, 1, \ldots, n$, then $p(n+1) = 2^{n+1} - 1$.

Proof: The polynomial in search is $p(x) = \sum_{k=0}^n \binom{x}{k}$. □

Prop. (2.2.2.5) [Combinatorial Nullstellensatz]. If F is a field and $f \in F[X_1, \ldots, X_n]$ is a polynomial. Let $S_1, \ldots S_n$ be nonempty finite subsets of F and $g_i = \prod_{s\in S_i}(x_i - s)$, then if f vanishes at the common zeros of g_i, then there are polynomials $h_i \in F[X_1, \ldots, X_n]$ that $\deg h_i \leq \deg F - \deg g_i$ and $g = \sum h_i g_i$.

Proof: The proof is very simple, just replace terms of f by lower degree terms, using equation of g_i, then we get a polynomial that has degree in x_i smaller than $|S_i|$ and vanish on $S_1 \times \ldots \times S_n$, so it must be 0, as easily checked. □

Cor. (2.2.2.6)[Combinatorial Nullstellensatz]. If F is a field and $f \in F[X_1, \ldots, X_n]$ is a polynomial of degree n, if $\prod X_i^{t_i}$ is a highest degree term of f and S_i are arbitrary subsets of F that $|S_i| > t_i$, then there are some $s_i \in S_i$ that $f(s_1, \ldots, s_n) \neq 0$.

Proof: May assume $|S_i| = t_i + 1$. By combinatorial Nullstellensatz(2.2.2.5), if no such s_i exist, then there are h_i that $f = \sum h_i \prod_{s\in S_i}(x_i - s)$, but the term $\prod X_i^{t_i}$ needs to appear, so it must by some term of h_i times $x_i^{t_i+1}$, which is a contradiction. □

Remark (2.2.2.7). For many combinatorial applications of the combinatorial nullstellensatz, Cf.[Combinatorial Nullstellensatz].

Irreducibility

Prop. (2.2.2.8). If $f = a_n x^n + \ldots + a_1 x + p \in \mathbb{Z}[X]$ satisfies p is a prime and $\sum |a_i| < p$, then f is irreducible in p.

Proof: The ideal is that all of its roots has norm bigger than 1, because otherwise $p = |\sum a_k x^k| \leq \sum |a_k| < p$, contradiction. So if now $f = gh$, then g, h all have roots with norm greater than 1, in particular it has constant coefficients norm greater than 1, which is a contradiction because p is a prime. □

Resultants

Def. (2.2.2.9) [Resultants]. Let $R \in \mathcal{CR}\mathrm{ing}$, the **resultant** $\mathrm{res}(A, B)$ of two polynomials $A, B \in R[X]$ of degree d, e respectively is the determinant of the linear map

$$W_e \times W_d \to W_{d+e} : (X, Y) \mapsto AX + BY,$$

where W_t is the free module of polynomials of degree $< t$.

Prop. (2.2.2.10). The resultant can be seen as the determinant of the matrix with values the coefficient of A or B in different places, multiplying X^*s with different degree and add to the last row, we can get $A \cdot X^*$s and $B \cdot X^*$s, so: $\mathrm{res}(A, B) = AC + BD$ for some C, D.

Now if $R \subset S$ and A, B has common roots in S, then $\mathrm{res}(A, B) = 0$.

Cor. (2.2.2.11). Resultant is stable under Euclidean division, so it can be seen as a suitable division remainder of the two polynomial.

Prop. (2.2.2.12). When $R \subset L$ a field and A, B decompose into linear factors in L, let t_i be roots of A and u_j be roots of B, then

$$\mathrm{res}(A, B) = v_0^d w_0^e \prod_{i=1}^{d} \prod_{j=0}^{e} (t_i - u_j)$$

Proof: See the resultant as polynomials of the roots of A and B, then we proved that if they has the same root, then $res = 0$, so it is divisible by $(t_i - u_j)$ for all i, j. Then notice the RHS is homogenous of degree d in u_j and homogenous of degree e in t_i, so does res. So they are equal. □

Prop. (2.2.2.13). Let $k \in \texttt{Field}$ and $P \in k[X]$, then $x \in k$ is a double root of P iff $\gcd(P, P')(x) = 0$.

Proof: □

Cyclotomic Polynomials

Cf.[Cyclotomic Polynomials in Olympiad Number Theory].

Def. (2.2.2.14) [Cyclotomic Polynomials]. For $n \in \mathbb{Z}_+$, define the **cyclotomic polynomial**

$$\Psi_n(X) = \prod_{a \in (\mathbb{Z}/(n))^*} (X - e^{2\pi \mathrm{i} \frac{a}{n}}) \in \mathbb{C}[X].$$

Then in fact $\Psi_n(X) \in \mathbb{Z}[X]$.

Proof: Its coefficients are algebraic integers, and it is invariant under action of $\mathrm{Gal}_{\mathbb{Q}}$, so its coefficients are in $\mathbb{Q} \cap \mathcal{O}_{\overline{\mathbb{Q}}} = \mathbb{Z}$. □

Prop. (2.2.2.15) [Cyclotomic Polynomials are Irreducible]. For any $n \in \mathbb{Z}_+$, the cyclotomic polynomial $\Psi_n(x)$ is irreducible over $\mathbb{Z}$.

Proof: It suffices to show that for any irreducible factor $f|\Psi_n(x)$, if ξ is a root of f and $(p,n)=1$, then ξ^p is also a root of f. Cf.[Lan05].**?** □

Prop. (2.2.2.16). For $a, n \in \mathbf{P}$ and $(a,n)=1$, $\Psi_n(X^p) = \prod_{d|a} \Psi_{dn}(X)$.

Proof: This follows from counting. □

Cor. (2.2.2.17). For $n \in \mathbb{Z}_+$, $X^n - 1 = \prod_{d|n} \Psi_d(X)$. Thus by Möbius inversion, $\Psi_n(x) = \prod_{d|n}(X^d - 1)^{\mu(n/d)}$.

Prop. (2.2.2.18). For $n \in \mathbb{Z}_+$ and $p \in \mathbf{P}$,

$$\Psi_{np}(X) = \begin{cases} \Psi_n(X^p) & ,p|n \\ \frac{\Psi_n(X^p)}{\Psi_n(X)} & ,p\nmid n \end{cases}.$$

Proof: These follows from counting. □

Cor. (2.2.2.19). If $n \in \mathbb{Z}_{\geq 3}$ is odd, then $\Psi_{2n}(X) = \Psi_n(-X)$.

Proof: It suffices to show that $\Psi_{2n}(X^2) = \Psi_n(X)\Psi_n(-X)$. And this is because $\zeta \mapsto \zeta^2$ is an automorphism between primitive n-th roots, and $\varphi(n)$ is even. □

Prop. (2.2.2.20). For $m \neq n \in \mathbb{Z}_+$, $\Psi_m(X)$ and $\Psi_n(X)$ are coprime in $\mathbb{Q}(X)$. And if $m, n \in \mathbb{Z}_+ \setminus (p)$, then $\Psi_m(X)$ and $\Psi_n(X)$ are also coprime in $\mathbb{F}_p[X]$.

Proof: It suffices to show that $X^{mn} - 1$ doesn't have multiple roots. By(2.2.2.13), it suffices to notice that

$$\gcd(X^{mn} - 1, mnX^{mn-1}) = 1,$$

which is also true in $\mathbb{F}_p[X]$ if $m, n \in \mathbb{Z}_+ \setminus (p)$. □

Cor. (2.2.2.21). For $p \in \mathbf{P}$ and $n \in \mathbb{Z}_+ \setminus (p), a \in \mathbb{Z}$,

$$p|\Psi_n(a) \iff p \nmid a \quad \& \quad \mathrm{ord}(a, \mathbb{F}_p^\times) = n.$$

Cor. (2.2.2.22). For $p \in \mathbf{P}$ and $n \in \mathbb{Z}_+ \setminus (p)$, $p|\Psi_n(a)$ for some $a \in \mathbb{Z}$ iff $p \equiv 1 (\mathrm{mod}\ n)$.

Prop. (2.2.2.23). If $m \geq n \in \mathbb{Z}_+, h \in \mathbb{Z}$, and $A = \gcd(\Psi_n(h), \Psi_m(h)) \neq 1$, then there exists $p \in \mathbf{P}$ s.t. $A \in p^{\mathbb{Z}_+}$, and also $\frac{m}{n} \in p^{\mathbb{Z}_+}$.

Proof: Suppose $p|A$, and suppose $m = p^a c, n = p^b d, p \nmid cd$, then by(2.2.2.18),

$$\Psi_m(h) \equiv (\Psi_c(h))^{p^a} (\mathrm{mod}\ p), \quad \Psi_n(h) \equiv (\Psi_d(h))^{p^b} (\mathrm{mod}\ p).$$

Then it follows from(2.2.2.20) that $c = d$. Thus $\frac{m}{n} \in p^{\mathbb{Z}_+}$. The assertions follow easily from this. □

Prop. (2.2.2.24). For $n \in \mathbb{Z}_+$,

$$\Psi_n(1) = \begin{cases} p & ,n \in p^{\mathbb{Z}_+}, p \in \mathbf{P} \\ 1 & ,\text{otherwise} \end{cases}$$

Proof: This follows easily from induction and the fact

$$X^{n-1} + \ldots + X + 1 = \prod_{d|n, d\neq 1} \Psi_d(X).$$

□

Invariant Theory

Prop. (2.2.2.25) [Elementary Symmetric Polynomial]. For n indeterminants x_i, define the **elementary polynomials**

$$\sigma_k = \sum_{1\leq i_1<\ldots<i_k\leq n} x_{i_1}x_{i_2}\ldots x_{i_k} \in \mathbb{Z}[x_1,\ldots,x_n]$$

where for $k > n$ this expression means 0. Then any symmetric polynomial is a polynomial of the fundamental symmetric polynomials.

Proof: Set the first coordinate to 0, then the rest is a polynomial of the fundamental symmetric polynomials by induction, $f(0,x) = h(\sigma_1,\ldots,\sigma_n)$, then consider $f-h$, with h the same expression but x_n is included, we get it is a symmetric polynomial, and it is divisible by x_1, thus also divisible by $\prod x_i$, thus divide it by $\prod x_i$ and use induction, we get f is a polynomial of elementary symmetric polynomials. □

Prop. (2.2.2.26) [Newton Identities]. For n indeterminants x_i, define

$$s_k = \begin{cases} \sum x_i^k & ,k\geq 0 \\ 0 & ,k<0 \end{cases} \in \mathbb{Z}[x_1,\ldots,x_n],$$

then there are **Newton Identities**:

$$s_k - \sigma_1 s_{k-1} + \ldots + (-1)^n \sigma_n s_{k-n} = 0.$$

Proof: The case of $k \geq n$ is simple. Now if $k < n$, then we prove by induction on n: If n is already proven, then the term is 0 if one of them is 0, but this implies that this equation is divisible by $\prod_{i=1}^{n+1} x_i$, but is has degree $k \leq n$, so it must by 0. □

Prop. (2.2.2.27) [Chern Polynomials]. By(2.2.2.26) and induction there are polynomials $P_k \in \mathbb{Z}[x_1,\ldots,x_k]$ s.t. $P_k(\sigma_1,\ldots,\sigma_k) = s_k, k\geq 0$, called the **Chern polynomials**. Then they satisfy:

$$\log(1+c_1+c_2+\ldots+c_n+\ldots) = \sum_{p\geq 1}(-1)^{p-1}\frac{P_p}{p} \in \mathbb{Q}[[c_1,\ldots,c_n,\ldots]].$$

In particular, we can easily calculate via homogeneity that

$$P_1 = c_1, \quad P_2 = c_1^2 - 2c_2, \quad P_3 = c_1^3 - 3c_1c_2 + 3c_3, \quad P_4 = c_1^4 - 4c_1^2c_2 + 4c_1c_3 + 2c_2^2 - 4c_4.$$

Proof: We can define elementary power series

$$\sigma_k = \sum_{1\leq i_1<\ldots<i_k} x_{i_1}x_{i_2}\ldots x_{i_k} \in \mathbb{Z}[[x_1,\ldots,x_n,\ldots]],$$

and also

$$s_k = \begin{cases} \sum x_i^k & ,k\geq 0 \\ 0 & ,k<0 \end{cases} \in \mathbb{Z}[[x_1,\ldots,x_n,\ldots]].$$

Then the Newton identities also holds by taking limits. There is an injection

$$\mathbb{Q}[[c_1,\ldots,c_n,\ldots]] \to \mathbb{Q}[[x_1,\ldots,x_n,\ldots]] : c_i \mapsto \sigma_i,$$

and the LHS is mapped to

$$\log(\prod_i(1+x_i)) = \prod_i \log(1+x_i) = \sum_{p\geq 1}(-1)^p\frac{s_p}{p}$$

is the image of the RHS. □

Prop. (2.2.2.28) [Todd Polynomials]. There are **Todd polynomials** $Q_p \in \mathbb{Z}[\sigma_1,\ldots,\sigma_p], p\geq 1$ s.t.

$$\mathrm{Todd}(x_1,\ldots,x_n,\ldots) = \prod_{i=1}^n \frac{x_i}{1-e^{-x_i}} = 1+\sum_{p\geq 1}\frac{Q_p}{p!} \in \mathbb{Q}[[x_1,x_2,\ldots]]$$

for any $n\in\mathbb{Z}_+$, and

$$Q_1 = c_1, \quad ,Q_2 = c_1^2+c_2, \quad Q_3 = c_1c_2, \quad Q_4 = -c_1^4+4c_1^2c_2+3c_2^2+c-1c_3-c_4.$$

Proof: ? □

Prop. (2.2.2.29) [Conjugate Invariant Polynomials]. Any polynomial on the entries of matrixes $M_n(k)$ that is invariant under conjugation is generated by coefficients of $\det(\lambda I+X)$ and can also be generated by $\mathrm{tr}(X^k)$.

Proof: We notice that the matrixes having disjoint eigenvalues is dense in $M_n(k)$, thus the restriction of the polynomial on these matrixes is a symmetric polynomial(2.2.2.25) thus identical to a polynomial described above. Hence they are equal. □

Prop. (2.2.2.30). For any polynomial on the entries of matrixes $M_n(k)$ that $f(BA) = f(A)$ for $B\in O(n)$, there is a polynomial F that $f(A) = F(A^*A)$. Cf.[Heat Equation and the Index Theorem Atiyah P323].

Prop. (2.2.2.31) [Weyl]. Any linear map f from $(\mathbb{R}^m)^{\otimes n}$ to R that is $O(m,\mathbb{R})$-equivariant is a linear combinations of maps of the form:

$$v_1\otimes v_2\otimes\cdots\otimes v_n \mapsto \langle v_{i_1},v_{i_2}\rangle\langle v_{i_3},v_{i_4}\rangle\cdots\langle v_{n-1},v_n\rangle.$$

Where $i_1,\ldots,i_n$ is a permutation of $1,2,\cdots,n$ when n is even and when n is odd, f must be 0.

Proof: Cf,[Heat Equation and the Index Theorem]. □

3 Commutative Rings

Bézout Domain

Def. (2.2.3.1) [Bézout Domains]. A **Bézout domain** is an integral domain that any sum of two principal domains is also principal.

Prop. (2.2.3.2). The localization of a Bézout domain is Bézout. A local ring is Bézout iff it is a valuation ring by(10.3.2.8).

UFDs

Def. (2.2.3.3) [UFDs]. A non-zero element x in a domain R is called **irreducible** iff for any $y, z \in R$ that $x = yz$, either y or z is a unit.

A non-zero element x in a domain R is called a **prime** iff (x) is a prime ideal. Every prime is irreducible.

A domain R is called a **UFD** iff every non-zero element $x \in R$ has a factorization into irreducibles, unique up to units.

Prop. (2.2.3.4). if R is Noetherian domain, then each element has a decomposition into irreducible.

Proof: Trace the decomposition inductively, if it doesn't stop, then it contradicts with Noetherian hypothesis. □

Prop. (2.2.3.5). An integral domain R is a UFD iff each element x factors into irreducibles, and every irreducible element is a prime. Also this is equivalent to every non-zero element factors into prime elements.

Proof: If R is a UFD, then if x is irreducible, if $ab \in (x)$, $ab = xc$, then x is one irreducible in the decomposition of a and b, by UFD, so $a \in (x)$ or $b \in (x)$, and (x) is a prime ideal.

Conversely, if there are two decompositions $\prod a_i = \prod b_j$, then some $b_j \in (a_i)$ by primeness of (a_i), so $b_j = a_i u$, so u must by units, so by induction, this two decompositions are the same.

If every element factors into prime elements, then an irreducible element is a prime because it factors as a product of primes, and notice every prime is irreducible(2.2.3.3). □

Prop. (2.2.3.6) [Kaplansky]. An integral domain R is UFD iff every non-zero prime ideal contains a non-zero principle prime ideal. In particular, any prime of height1 is principal.

Proof: If R is a UFD, let $\mathfrak{p}$ be a non-zero prime ideal, choose $a \neq 0 \in \mathfrak{p}$, and write $a = \pi_1 \ldots \pi_n$ as a product of irreducibles. Then $\pi_i \in \mathfrak{p}$ for some i, so $\mathfrak{p}$ contains the prime ideal (π_i)(2.2.3.5).

Conversely, let S be the set of all finite products of prime ideals of R, then S is a multiplicative set of R. For any non-zero element $a \in R$, if $(a) \cap S = \varnothing$, then there is a prime ideal P containing (a) and is maximal among those avoiding elements of S. Then P contains a non-zero prime π, contradiction. So $(a) \cap S \neq \varnothing$. Let $b \in R$ that $ab = \pi_1 \ldots \pi_n$, then we show $a \in S$ by induction on n.

If $n = 1$, then a is a unit or a prime, so we are done. For general n, if $\pi_k | b$ for some k, then $b = \pi_k c$, and $ac = \pi_1 \ldots \pi_{k-1} \pi_{k+1} \ldots \pi_n$, then $a \in S$ by induction hypothesis. Otherwise $\pi_k | a$ for all k, thus $a = \pi_1 \ldots \pi_n c$ and $1 = bc$, thus c is a unit and $a \in S$.

Thus we proved that every non-zero element is a product of prime elements, so R is a UFD by(2.2.3.5). □

Prop. (2.2.3.7). A polynomial ring over a UFD is a UFD.

Proof: □

Prop. (2.2.3.8). Let k be a field, then the power series $k[[X_1, \ldots, X_n]]$ is a UFD.

Proof: Cf.[Algebra Lang P209]. □

Remark (2.2.3.9). WARNING: if A is a UFD, $A[[X]]$ may not be a UFD. Cf.[Matsumura, Commutative Ring Theory, P165].

Prop. (2.2.3.10) [Gauss Lemma].

Prop. (2.2.3.11) [Nagata]. If A is a Noetherian domain and $x \in A$ is a prime element s.t. $A[\frac{1}{x}]$ is a UFD, then A is a UFD.

Proof: $A[\frac{1}{x}]$ is normal by(4.3.5.2), and A is also normal: If $a \in \mathrm{Frac}(A)$ is integral over A, then $a = r/x^m$ for some $m \in \mathbb{Z}, r \in A\backslash(x)$. If $a \notin A$, then $r \in x$, contradiction.

Then we can use(7.1.2.25) to show that $\mathrm{Cl}(\mathrm{Spec}\, A) = 0$, and then A is a UFD by(7.1.5.6). □

Prop. (2.2.3.12). For a field k of characteristic$\neq 2$ and $n \geq m \geq 5$, $A = k[x_1, \ldots, x_n]/(-x_1^2 + x_2^2 + \ldots + x_m^2)$ is a UFD.

Proof: $A \cong k[x_1, \ldots, x_n]/(x_1x_2 + x_3^2 + \ldots + x_m^2)$, and (x_2) is a prime ideal of A s.t. $A[\frac{1}{x}]$ is a UFD by(2.2.3.7), so A is a UFD by Nagata'e lemma(2.2.3.11). □

Prop. (2.2.3.13)[Quadratic Extension of UFDs]. If $A \in \mathcal{CA}\mathrm{lg}$ is an integral domain and $Z^2 - gZ + f$ doesn't have a root in $\mathrm{Frac}(A)$, then $A[Z]/(Z^2 - gZ - f)$ is integral and normal.

Proof: If $(a + bZ)(c + dZ) = 0$, then by hypothesis $ad + bc + bdg = 0, ac + fbd = 0$. Then $b(fd^2 - c^2 - cdg) = 0$, so $b = 0$ or $c = d$ by hypothesis. If $(c, d) \neq (0, 0)$, then $ac = ad = 0$, so $a = b = 0$. □

PID

Def. (2.2.3.14) [Euclidean Domain].

Prop. (2.2.3.15) [Euclidean Domain is PID]. Euclidean domains(2.2.3.14) are PIDs.

Proof: □

Example (2.2.3.16).

- $\mathbb{Z}$ is a PID.
- For $k \in \texttt{Field}$, $k[X]$ is a PID.

Thm. (2.2.3.17) [Chinese Remainder Theorem, S. Tzu300-400].

Proof: □

Prop. (2.2.3.18) [PID Structures]. In a PID,

- An element t is irreducible iff (t) is maximal.
- A PID is UFD hence Noetherian.
- An element t is irreducible iff it is a prime.
-

Proof: 1:

2: By(2.2.3.6).

3: By item2 and(2.2.3.4).

□

4 Modules

Def. (2.2.4.1) [Modules]. For $R \in \mathcal{R}\text{ing}$, a (left)$R$-modules is defined to be ?. The category of R-modules is denoted by $\mathcal{M}\text{od}_R$.

Left modules are preferred. there are several proposition that is written in favor of right modules, they should be rectified.

Def. (2.2.4.2) [Finite Modules]. For $R \in \mathcal{R}\text{ing}$, a **finite R-module** is an R-module M that there is a surjection $R^n \to M$ for some $n \geq 0$.

Prop. (2.2.4.3). Let R be a nonzero commutative ring and M be an R-module generated by $n-1$ elements, then any R-module map $R^n \to M$ has a nonzero kernel.

Proof: Choose a surjection $R^{n-1} \to M$, then the map $R^n \to M$ can be extended to a map $R^n \to R^{n-1}$. It suffices to assume $M = R^{n-1}$. This map is represented by a matrix. If some entry $a_{ij} = a$ is not nilpotent, then we can localize R to R_a that a is a unit. We can assume $a_{11} = a$, and apply elementary row and column transformation to make $A = \text{diag}(1, B)$, then we finish by induction. Now if all a_{ij} are nilpotent, then $I = (a_{ij})$ is nilpotent, and if m is the maximal integer that $I^m \neq 0$, then $(I^m)^{\oplus n}$ is contained in the kernel of this morphism. □

Cor. (2.2.4.4) [Rank of Free Modules]. If M is a free module over a nonzero commutative ring R, then any basis of M is of the same cardinality, called the **rank** of M, and any spanning subset of M has greater cardinalities. In particular, $R^m \neq R^n$ as R-modules.

Prop. (2.2.4.5) [Fitting Lemma]. For an endomorphism T of a R module M, if we denote p the minimal integer that $R(T^p) = R(T^{p+1})$ and q the minimal integer that $N(T^q) = N(T^{q+1})$. Then the morphisms are stable afterward. Then if there is a m, n that $R(T^m) \oplus N(T^n) = X$ for a R-module endomorphism $T \in \text{End}(M)$, then $p, q < \infty$ and they are equal. Moreover, if we know $p, q < \infty$, then we have $R(T^p) \oplus N(T^q) = M$.

Proof: We notice that

$$T^i : N(T^{i+j})/N(T^i) \to R(T^i) \cap N(T^j), \quad T^i : M/(R(T^j) + N(T^i)) \to R(T^i)/R(T^{i+j})$$

are isomorphisms. Thus $R(T^m) \oplus N(T^n) = X$ shows $q \leq m$ and $p \leq n$, thus we have $R(T^p) \oplus N(T^q) = M$, which implies $p \geq q$ and $q \geq p$. thus the result. The rest also follows easily from these isomorphisms. □

Prop. (2.2.4.6) [Nakayama]. If M is a finite A-module, and $I \subset A$ is an ideal that $IM = M$, then there is a $a \in 1 + I$ that $aM = 0$.

In particular, if $I \subset \text{rad}(A)$, then a is a unit(4.2.6.2), so $M = 0$.

Proof: Because $M = IM$, choose a set of generators $\{x_i\}$ of M, then $x_i = \sum a_{ij} x_j$, where $a_{ij} \in I$. Then if the matrix $M = (\delta_{ij} - a_{ij})$, then $M x_i = 0$. So taking the adjoint matrix, then $\det(M) x_i = 0$. Notice $\det(M)$ is a morphism. But the determinant must be element like $1 + k, k \in I$, so we are done. □

Cor. (2.2.4.7). If M is a finite A-module, N a submodule and $M = \text{rad}(A)M + N$, then $M = N$.

Cor. (2.2.4.8). If a finite R-module M satisfies $M \otimes_R k(p) = 0$, then there is a $f \notin p$ that $M_f = 0$.

Proof: Because $M_p = 0$, and the support of M is closed(finiteness used). □

Cor. (2.2.4.9). If an endomorphism φ of a finite module M over R is surjective, then it is injective.

Proof: This endomorphism makes M a finite module over $R[X]$ by letting X acts by φ. So the hypothesis shows $IM = M$ where $I = (x) \subset R[x]$. Then Nakayama(2.2.4.6) shows there are some $(1 + f(X)X)M = 0$. Thus for any $m \in M$ that $X(m) = 0$, $m = 0$, so φ is injective. □

Prop. (2.2.4.10). If $A \in \mathcal{R}\mathrm{ing}/\mathbb{C}$ and $\alpha \in A$ is not nilpotent, then there exists a simple A-module M that $a|_M \neq 0$.

Proof: First we claim that there is some $\lambda \neq 0 \in \mathbb{C}$ that $a - \lambda$ is not invertible in A, this is nearly the same as the proof of(2.2.1.10), noticing that a is not nilpotent. Now we can take $M = A/(a-\lambda)A$, then $a1 = \lambda \neq 0$. □

Prop. (2.2.4.11) [Jordan-Horder]. Cf.(2.1.9.10).

Tensor Module and Hom Module

Def. (2.2.4.12) [Hom Module]. If B is an R-S-bimodule and C is a T-S-bimodule, then $\mathrm{Hom}_S(B, C)$ is naturally a $T - R$-module given by the action $(tfr)(b) = tf(rb)$.

Dually, if B is an $S - R$-bimodule and C is a $S - T$-bimodule, then $\mathrm{Hom}_S(B, C)$ is naturally an $R - T$-bimodule given by the action $(rft)(b) = f(br)t$.

Def. (2.2.4.13) [Tensor Product]. Given a ring R, a T-R-bimodule A and an R-S-bimodule B, their **tensor product** is a T-S-bimodule defined by universal properties: $A \times B \to A \otimes_R B$ is a T-S-bimodule map, and any T-S-bimodule map $A \times B \to C$ to a T-S-bimodule C factors uniquely through $A \otimes_R B \to C$.

The tensor product can be constructed as:

There is an adjoint:

$$- \otimes_R B : {}_T\mathcal{M}\mathrm{od}_R \leftrightarrows {}_T\mathcal{M}\mathrm{od}_S : \mathrm{Hom}_S(B, -) \ .$$

In particular, tensoring commutes with colimits.

Similarly, there is an adjoint:

$$A \otimes_R - : {}_R\mathcal{M}\mathrm{od}_S \leftrightarrows {}_T\mathcal{M}\mathrm{od}_R : \mathrm{Hom}_T(A, -) \ .$$

Proof: We need to give an isomorphism

$$\tau : \mathrm{Hom}_S(A \otimes_R B, C) \cong \mathrm{Hom}_R(A, \mathrm{Hom}_S(B, C)).$$

Given $f \in \mathrm{Hom}_S(A \otimes_R B, C)$, we define

$$\tau(f) : A \to \mathrm{Hom}_S(B, C) : (\tau(f)a)(b) = f(a \otimes b).$$

and conversely, for $g \in \mathrm{Hom}_R(A, \mathrm{Hom}_S(B, C))$,

$$\tau^{-1}(g)(a \otimes b) = (g(a))(b).$$

The verifications is routine and the isomorphism for left modules is dual. □

Prop. (2.2.4.14) [(Co)Induced Modules]. Given a ring homomorphism $S \to R$, then R is a $S - R$-bimodule as well as a R-S-bimodule, then we define:

- $f^* : {}_R\mathcal{M}\mathrm{od} \to {}_S\mathcal{M}\mathrm{od} : f^*M = {}_SM = \mathrm{Hom}_R(R, M) = R \otimes_R M$(2.2.4.12)(2.2.4.13), the **restriction**.
- $f_! : {}_S\mathcal{M}\mathrm{od} \to {}_R\mathcal{M}\mathrm{od} : f_!M = R \otimes_S M$ is the **induced module**, it is left adjoint to restriction, by(2.2.4.13).
- $f_* : {}_S\mathcal{M}\mathrm{od} \to {}_R\mathcal{M}\mathrm{od} : f_*M = \mathrm{Hom}_S(R, M)$ is the **coinduced module**, it is right adjoint to restriction, by(2.2.4.13).

Dually for left modules, we define:

- $f^* : \mathcal{M}\mathrm{od}_R \to \mathcal{M}\mathrm{od}_S : f^*M = M_S = \mathrm{Hom}_R(R, M) = M \otimes_R R$(2.2.4.12)(2.2.4.13), the **restriction**.
- $f_! : \mathcal{M}\mathrm{od}_S \to \mathcal{M}\mathrm{od}_R : f_!M = M \otimes_S R$ is the **induced module**, it is left adjoint to restriction, by(2.2.4.13).
- $f_* : \mathcal{M}\mathrm{od}_S \to \mathcal{M}\mathrm{od}_R : f_*M = \mathrm{Hom}_S(R, M)$ is the **coinduced module**, it is right adjoint to restriction, by(2.2.4.13).

Def. (2.2.4.15) [Algebras]. For $R \in \mathcal{CR}\mathrm{ing}$, a(n) (commutative/unital/associative)**algebra** over R is a (commutative/unital/associative)magma object in the monoidal category $(\mathcal{M}\mathrm{od}_R, \otimes)$.

The category of R-algebras is denoted by $\mathcal{A}\mathrm{lg}_R$. The category of commutative R-algebras is denoted by $\mathcal{CA}\mathrm{lg}_R$, the category of commutative unital associative algebra over R is denoted by $\mathcal{CR}\mathrm{ing}_R$. Notice $\mathcal{CR}\mathrm{ing}_R \cong \mathcal{CR}\mathrm{ing}\,/R$.

Torsion-Free Modules

Def. (2.2.4.16) [Torsion-Free Modules]. Let R be a ring, an R-module M is called **torsion-free** iff there are no non-zero divisor $x \in R, 0 \neq f \in M$ that $xf = 0$.

Prop. (2.2.4.17). If $0 \to M_1 \to M_2 \to M_3$ and M_1, M_3 are torsion-free, then M_2 is torsion-free. Torsion-free is a stalk-wise property(4.1.4.2).

Proof: Trivial. □

Prop. (2.2.4.18). Let M be a finite R-module, then M is torsion-free if it is a submodule of a finite free module.

Proof: One direction is trivial, for the other, if M is torsion-free, then $M \subset M \otimes_R K$, and $M \otimes_R K$ is a finite K-vector space, with basis e_i. Now let x_i be a basis of M, let $x_i = \sum a_{ij}/b_{ij}e_j$, then let $e = \prod_{ij} b_{ij}$, then $M \subset Re_1/b \oplus \ldots \oplus Re_n/b$. □

Prop. (2.2.4.19). If M, N are R-modules that M is torsion-free, then $\mathrm{Hom}(N, M)$ is torsion free.

Proof: Choose a surjection $\bigoplus_I R \to N \to 0$, then $\mathrm{Hom}(N, M) \hookrightarrow \prod_I M$ is torsion free. □

Modules over PIDs or Bézout Domains

Prop. (2.2.4.20) [Modules over a Bézout domain]. Let R be a Bézout domain, then

- any finite submodule of a free module over is finite free.
- any f.p. R-module M is a summand of a free R-module and M_{tor}, where $M_{\mathrm{tor}} = \oplus R/(f_i)$ where $f_i \in R^*$.

Proof: Cf.[Sta]0ASU.? □

Prop. (2.2.4.21) [Classification of Modules over PID].

1. Every submodule of a free module over a PID is free of smaller rank. Thus a projective module over a PID is free
2. Every finite torsion-free module over a PID is free.
3. Every finite module over a PID has a primary decomposition $M = \bigoplus_i R/(q_i)$,where (q_i) is primary ideals.

So projective $\iff$ free $\iff$ torsion-free(when f.g.).

Proof: 1: Choose a well ordering on the basis of F, let F_i is the submodule generated by $e_j, j \leq i$. Then $\pi_i(P \cap F_i) \subset R$ is a module of the form (a_i), thus choose $u_i \in P$ that $p_i(u_i) = a_i$. Then u_i is a basis for P: they are linearly independent, because for any finite linear combination that are 0, the maximal coordinate are 0. It also spans P, because we can choose an element in $P - \{u_i\}$ whose maximal nonzero coordinate α is minimal among them, by well-orderedness. But we can subtract a multiple of u_α, thus producing a smaller element, contradiction.

2: If it is finite torsion-free, then it is a submodule of a finite free module(2.2.4.18), so it is free by item1.

3: Follows immediately from(4.2.5.34) and(2.2.3.18). □

Prop. (2.2.4.22) [Primary Cyclic Decomposition]. There is a primary cyclic decomposition theorem for a torsion module M over a PID R. Thus the multisets of elementary divisors of M is a complete set of invariants for M.

Proof: Cf.[Advanced Linear Algebra P153]. □

Cor. (2.2.4.23) [Invariant Factor Decomposition]. By reordering the cyclic decomposition, we can get the **invariant factor decomposition** of M, there are scalars $d_m|d_{m-1}|\ldots|d_1$ that are called the **invariant factors** of M.

Proof: Cf.[Advanced Linear Algebra P157]. □

Cor. (2.2.4.24) [Elementary Factor Theorem]. Let F be a free module over a PID R, and let M be a f.g. submodule$\neq 0$, then there exists a basis $\mathcal{B}$ of F, elements $e_1, \ldots, e_m$ in this basis, and non-zero elements $a_1, \ldots, a_m \in R$ that

- the elements $a_1e_1, \ldots, a_me_m$ forms a basis of M.
- $a_i|a_{i+1}$.

And these a_i are uniquely determined up to units.

Transfinite Direct Sum Dévissage of Modules

Def. (2.2.4.25) [Direct Sum Dévissage of Modules]. Let M be a module over a ring R, then a **direct sum dévissage** is a family of submodules M_α indexed by an ordinal S such that

- $M_0 = 0$.
- if $\alpha + 1 \in S$, then M_α is a direct sum of $M_{\alpha+1}$.
- if α is a limit ordinal, then $M_\alpha = \cup_{\beta<\alpha} M_\beta$.
- $\cup_{\alpha\in S} M_\alpha = M$.

If moreover, for any $\alpha \in S, \alpha+1 \in S$, $M_{\alpha+1}/M_\alpha$ is countably generated , then M_α is called a **Kaplansky dévissage** of M.

Prop. (2.2.4.26). Let M_α be a direct sum dévissage of M, then $M \cong \bigoplus_{\alpha\in S, \alpha+1\in S} M_{\alpha+1}/M_\alpha$.

Proof: Cf. [Sta]058V. □

Cor. (2.2.4.27). M is a direct sum of countably generated modules iff M admits a Kaplansky dévissage.

Prop. (2.2.4.28). Suppose M is a direct sum of countably generated modules and P is a direct sum of M, then P is also a direct sum of countably generated modules.

Proof: Cf.[Sta]058X. □

Prop. (2.2.4.29)[Direct Summand Criterion of Free Modules]. Let M be a countably generated R-module that for any direct summand N of M and an element $x \in N$, x is contained in a free direct summand of N, then M is free.

Proof: Let $x_1, x_2, \ldots$ be a countable set of generators for M, then we can use inductions to find free submodules $F_1, F_2, \ldots$ of M s.t. $\oplus_{i=1}^n F_i$ are direct summands of M and contains $x_1, \ldots, x_n$ for any n, thus $M = \oplus F_i$ is free. □

5 Field Extensions

Prop. (2.2.5.1)[Artin]. If G is a monoid and K is a field, any distinct characters of G in K are linearly independent over K.

Proof: Consider the minimal length of linear combination that is 0, then we multiply a suitable z in it, then we can can cancel a character, contradicting the minimality. □

Cor. (2.2.5.2). If α_i are different elements in K and there are element a_i that $\sum a_i\alpha_i^v = 0$ for every $v \geq 0$, then $a_i = 0$ for all n. (Seen as characters from $\mathbb{Z}_{\geq 0} \to K$).

Def. (2.2.5.3)[Composition of Fields Extensions].

Field Extensions

Def. (2.2.5.4) [Distinguished Class of Extensions]. A family L of extensions are called **distinguished** iff

- It is closed under base change.
- $E/F/K \in L$ iff $F/K \in L$ and $E/F \in L$.

Def. (2.2.5.5) [Algebraic Extensions]. An **algebraic extension** is a field extension L/K s.t. for any element $\alpha \in L$, there exists a nonzero polynomial $f(X) \in K[X]$ s.t. $f(\alpha) = 0$.

Prop. (2.2.5.6). The family of finite extensions form a distinguished class.
The family of algebraic extensions form a distinguished class.
The family of f.g. extensions form a distinguished class.

Proof: Finite case is trivial. For the alg. extensions, for $k \subset F \subset E$, for any $\alpha \in E$, α satisfies an polynomial function with f.m coefficients in F, the coefficients form a subfield F_0 of F which is finite over k, so $k \subset F_0 \subset F_0(\alpha)$ is a finite tower, so it is finite, hence algebraic. The base change is easy to check.

For f.g. extensions, it suffice to check composition:? □

Prop. (2.2.5.7). For an alg.extension $k \subset E$, any injective field map $E \to E$ over k is an automorphism. (This is because it induce a permutation of any α with its conjugates in E, so it is surjective).

Lemma (2.2.5.8). Let $f \in k[X]$ be a polynomial of degree≥ 1, then there is a field K that f has a root in K. Hence for any finite set of polynomials, there is a field K that all of them have roots in K.

Proof: Cf.[Algebra Lang P231]. □

Lemma (2.2.5.9). For any $k \in \mathtt{Field}$, there exists $K \in \mathtt{Field}$ s.t. $k \subset K, \overline{K} = K$.

Proof: Firstly, we construct a field that every polynomial in $k[X]$ of degree≥ 1 has a root. Consider the polynomial ring $k[X_f]$, where there is a indeterminant X_f for each $f \in k[X]$ of deg≥ 1. Then the ideal generated by $f(X_f)$ is not a unit ideal, which can be seen by constructing a finite field extension that f_i all have a root in it(2.2.5.8).

So if $\mathfrak{m}$ is a maximal ideal containing all $f(X_f)$, then the quotient field is a field that all f have a root(X_f).

So now if we construct inductively like this, and consider their union, then it is clearly a field and any polynomial of degree≥ 1 have a root in it. □

Prop. (2.2.5.10) [Algebraic Closure]. Assume the axiom of choice, for any $K \in \mathtt{Field}$, there exists uniquely an algebraic field extension K/k s.t. K is alg.closed, up to isomorphism over k. Any such field K is called an **algebraic closure** of k, denoted by $\overline{k}$.

Proof: Let E be a field that is alg.closed and contains k by(2.2.5.9). Let k^a be the union of subextensions that are algebraic over k. k^a is a field, by(2.2.5.6), and k^a is alg.closed, because if $f(X)$ is a polynomial of degree≥ 1 in $k^a[X]$, then it has a root $\alpha \in E$, and α is algebraic over k^a, so $\alpha \in k^a$. □

Prop. (2.2.5.11) [Finite Algebraic Extensions]. Let L/K be a field extension and F/L be a finite extension, then there is a finite extension F'/K s.t. $F = LF'$.

Proof: Take a generator x_i of F/L, then x_i are algebraic over L, thus there are polynomials $f_i \in L[X]$ s.t. $f_i(x_i) = 0$. Let F' be the fields over K generated by all the coefficients of f_is, then $F = LF'$. □

Prop. (2.2.5.12). If E/F is an algebraic field extension, then for any R that $E \subset R \subset F$, R is a field.

Proof: If $\alpha \in R$, then α is algebraic over E, so there is a relation $\alpha^n + \ldots + a_0 = 0$, so $\alpha^{-1} = -a_0^{-1}(a_1 + \ldots \alpha^{n-1}) \in R$. □

Normal & Separable Extensions

Def. (2.2.5.13) [Normal Extensions]. A field extension K/k in $\overline{k}$ is called **normal extension** iff it satisfied the following equivalent conditions:

- Any embedding of K into $\overline{k}$ induce an automorphism on K.
- K is the splitting field of a family of polynomials in $k[X]$.
- Every irreducible polynomial in $k[X]$ that has a root in K splits in K.

Proof: Cf.[Algebra Lang P237]. □

Prop. (2.2.5.14). Normal extension are stable under base change and composition, by the first definition of(2.2.5.13).

Def. (2.2.5.15) [Normal Closure]. For any field extension F/K, there is a field extension E/F that E/K is normal, called the **normal closure** of F/K. It is the composite of conjugates of F/K.

Def. (2.2.5.16) [Separable Degree]. Define the **separable degree** $[E:k]_s$ of an extension E/k as the cardinality of embedding of E into $\overline{k}$. Separable degree commutes with composition, and when E/k is finite, $[E:k]_s \leq [E:k]$.

Def. (2.2.5.17) [Separable Polynomials]. A finite extension is called a **separable extension** iff $[E:k]_s = [E:k]$, an algebraic number α over k is called **separable over** K iff $k(\alpha)/k$ is separable. A polynomial $f \in k[X]$ is called a **separable polynomial** iff it has no multiple roots in $\overline{k}$.

Def. (2.2.5.18) [Separable Extensions]. An algebraic extension E/k is called a **separable extension** iff it satisfies the following equivalent conditions:

- every f.g. subfield is separable over k,(this is compatible because subfield of a finite separable extension is separable, by the compatibility of separable degree).
- Every element of E is separable.
- It is generated by a family of separable elements.

Proof: If E/k is separable and $k \subset k(\alpha) \subset E$, then by(2.2.5.17), $k(\alpha)$ is separable. And if it is generated by a family of separable elements $\{\alpha_i\}$, then any f.g. subfield can are f.g. by elements $\{\alpha_i\}$. Now it is a tower of separable extensions, hence separable by the compatibility of separable degree. □

Prop. (2.2.5.19). Separable extensions form a distinguished class.

Proof: Cf.[Algebra Lang P241]. □

Prop. (2.2.5.20) [Primitive element Theorem]. A finite extension E/k is primitive iff there are only f.m. middle fields. And if E/k is separable, this is satisfied.

Proof: If k is finite, this is simple. Assume k infinite, for any two elements α, β, consider $k(\alpha + c_i\beta)$, if there is only finitely many middle fields, there exists two that is equal, so $k(\alpha, \beta) = k(\gamma)$. Proceeding inductively, E is primitive.

Conversely, if $k(\alpha) = E$, every middle field corresponds to a divisor of the irreducible polynomial of α. This map is injective, because for any g_F, degree of α over F is the same over the degree over the coefficient field of g_F, so it must be equal to F.

If E/k is separable, Let

$$P(X) = \prod_{i \neq j} (\sigma_i\alpha + X\sigma_i\beta - \sigma_j\alpha - X\sigma_j\beta)$$

for different embedding σ_i, σ_j of $E(\alpha, \beta)$ into k^{alg}. Then it is not identically zero, thus there exists c that $\sigma_i(\alpha + c\beta)$ is all distinct, thus generate $K(\alpha, \beta)$. □

Inseparable Extensions

Prop. (2.2.5.21). Any irreducible polynomial of fields of characteristic 0 is separable and if char$= p$, then all roots have the same multiplicity and thus $[k(\alpha):k] = p^n[k(\alpha):k]$ for some n.

Proof: All roots have the same multiplicity because there are Galois actions. If the multiplicity is not 1, the derivative f' is zero, otherwise f is not irreducible. Then $f(X) = g(X^p)$. We can choose $f(X) = h(X^{p^n})$ with h separable, then $[k(\alpha):k(\alpha^{p^n})] = p^n$, thus the result. □

Def. (2.2.5.22). The **inseparable degree** $[E:k]_i$ is defined as the quotient $[E:k]/[E:k]_s$. An algebraic element α is called **purely inseparable** over k iff there is a n that $\alpha^{p^n} \in k$.

Def. (2.2.5.23). An extension is called **purely inseparable** if it satisfies the following equivalent conditions:

- $[E:k]_s = 1$.
- Every element α of E is purely inseparable over k.
- For every $\alpha \in E$, the irreducible equation of α over k is of type $X^{p^n} - a$.
- It is generated by a family of purely inseparable elements.

Proof: Cf.[Algebra Lang P249]. □

Cor. (2.2.5.24). A field over $\mathbb{F}_p$ is perfect iff there are no purely inseparable extensions of it.

Cor. (2.2.5.25) [Perfect Closure]. For any field k of char p, there is a unique purely inseparable field extension k^{perf}/k that k^{perf} is perfect, called the **perfect closure** of k. It is generated by adding all the p^n-th roots to k.

Prop. (2.2.5.26). Purely inseparably extensions form a distinguished class.

Proof: Cf.[Algebra Lang P250]. □

Prop. (2.2.5.27). If E/k is algebraic and E_0 be the maximal separable extension contained in E, then E/E_0 is purely inseparable. And if E/k is normal, then E_0/k is normal, too.

Proof: By the proof of(2.2.5.21), any α has a p^n that α^{p^n} that α^{p^n} is separable, hence it is purely inseparable over E_0 by(2.2.5.23). E_0/k is normal because any σ maps E to itself, and E_0 to $\sigma(E_0) \in E$ separable, hence $\sigma(E_0) \subset E_0$. □

Trace and Norm

Prop. (2.2.5.28) [Trace and Norm]. Let L/K be a finite field extension and Σ be the set of embeddings $\sigma : L \to \overline{K}$, then define the **trace map** $\mathrm{tr}_{L/K} : L \to K : x \mapsto [L:K]_i \sum_{\sigma\in\Sigma} \sigma(x)$ and the **norm map** $N_{L/K} : L \to K : x \mapsto (\prod_{\sigma\in\Sigma} \sigma(x))^{[L:K]_i}$.

Prop. (2.2.5.29). Let L/K be a field extension,

- The norm induces a multiplicative homomorphism $L^* \to K^*$, and the trace induces an additive homomorphism $L \to K$.
- If $E/F/K$ are field extensions, then $N_{E/K} = N_{F/K} \circ N_{E/F}$, and $\mathrm{tr}_{E/K} = \mathrm{tr}_{F/K} \circ \mathrm{tr}_{E/F}$.
- If $L = K(\alpha)$ and $F = \mathrm{Irr}(\alpha, k; X) = X^n - a_{n-1}X^{n-1} + \ldots + (-1)^n a_0$, then

$$N_{L/K}(\alpha) = a_0, \quad \mathrm{tr}_{L/K}(\alpha) = a_{n-1}.$$

Proof: Cf.[Lan05]P285. □

Prop. (2.2.5.30)[Calculating Dual Basis]. Let $L = K(\alpha)$ be a finite separable extension, let $f(X) = \mathrm{Irr}(\alpha, K; X)$, and

$$\frac{f(X)}{(X-\alpha)} = \beta_0 + \beta_1 X + \ldots + \beta_{n-1}X^{n-1},$$

then the dual basis of $(1, \alpha, \ldots, \alpha^{n-1})$ w.r.t. the trace form(2.2.5.32) is

$$\frac{\beta_0}{f'(\alpha)}, \ldots, \frac{\beta_{n-1}}{f'(\alpha)}.$$

Proof: Denote the roots of f be α_i, then they are pairwise different, and

$$\sum_i \frac{f(X)}{X-\alpha_i}\frac{\alpha_i^r}{f'(\alpha_i)} = X^r$$

for all r by Lagrange interpolation(2.2.2.2). But this is equivalent to

$$\mathrm{tr}(\frac{\alpha^r\beta_j}{f'(\alpha)}) = \delta_{ij}$$

□

Prop. (2.2.5.31). Let L/K be a field extension, then $x \in L$ acts on L via multiplication T_x. Then

$$\det(T_x) = N_{L/K}(x), \quad \mathrm{tr}(T_x) = \mathrm{tr}_{L/K}(x).$$

Proof: Let $F = K(x) \subset L$, and $p(X)$ be the minimal monic polynomial of x, then $\mathrm{char}(T_x|; X) = \mathrm{char}(T_x|_K; X)^{[L:K(x)]}$, thus we are done by(2.2.5.29). □

Prop. (2.2.5.32) [Trace Form]. If L/K is a finite extension, consider the pairing

$$Q_{L/K} : L \times L \to K : (x, y) \mapsto \mathrm{tr}(xy)$$

called the **trace form**. Then the following are equivalent:

- L/K is separable.
- $\mathrm{tr}_{L/K} \neq 0$.
- $Q_{L/K}$ is non-degenerate.

Proof: $2, 3$ are equivalent by a minute's thought. For $1 \iff 2$:

If L/K is inseparable, then by(2.2.5.29), if we consider $L/K'/K$ that L/K' is purely inseparable of degree p, then it is generated by some equation $x^p - a$, and the root is α. Then $L = K'(\alpha)$ and the minimal polynomial of $\alpha^i, 0 \leq i \leq p-1$ is $x^p - a^i$, so $\mathrm{tr}(\alpha^i) = 0$, and $\mathrm{tr}\, L/K = 0$.

If L/K is separable, $\mathrm{tr}_{L/K} \neq 0$ by the linear independence of characters(2.2.7.3). □

Def. (2.2.5.33) [Discriminant of a Basis]. Let α_i be a basis of a separable extension L/K, then the **discriminant of the basis** $d(\alpha_1, \ldots, \alpha_n)$ is defined to be $\det(\sigma_i(\alpha_j))^2$. Clearly, $d(\alpha_1, \ldots, \alpha_n)$ is invariant under the Galois action of L/K, thus it is an element of K.

Prop. (2.2.5.34). Notice $\mathrm{tr}_{L/K}(\alpha_i\alpha_j) = \sum_k \sigma_k(\alpha_i)\sigma_i(\alpha_j)$, thus $(\mathrm{tr}_{L/K}(\alpha_i\alpha_j))$ is the product of the matrices $(\sigma_k\alpha_i)^t$ and $(\sigma_k\alpha_j)$, thus

$$d(\alpha_1,\ldots,\alpha_n) = \det(\mathrm{tr}_{L/K}(\alpha_i\alpha_j)).$$

So the discriminant of $\{\alpha_1,\ldots,\alpha_n\}$ is the Gram matrix of the trace norm w.r.t. this basis(2.3.8.24). In particular, by(2.2.5.32),

$$d(\alpha_1,\ldots,\alpha_n) \neq 0.$$

Prop. (2.2.5.35). If $L = K(\theta)$ is a separable field extension of degree d, and $\theta_1 = \theta,\ldots,\theta_n$ are the conjugates of θ, then

$$d(1,\theta,\ldots,\theta^{d-1}) = (\det \mathrm{Van}(\theta_1,\ldots,\theta_d))^2 = \prod_{i<j}(\theta_i-\theta_j)^2.$$

6 Transcendental extension

Def. (2.2.6.1) [Transcendental Basis]. Let K be an extension of a field k, a **transcendental base** is an algebraically independent set that any element is algebraic over it.

Given any algebraically independent set $S \subset T$ a set over which K is algebraic, S can be extended to a transcendental base contained in T, by Zorn's lemma. In particular, a transcendental basis exists.

Prop. (2.2.6.2). Any two transcendental basis have the same cardinality, called the **transcendental degree** of K/k, denoted by $\mathrm{tr}\deg_k(K)$.

Proof: If K/k has a finite transcendental basis, then let $X = \{x_1,\ldots,x_m\}$ transcendental base of minimal number, $S = \{w_1,\ldots,w_n\}$ an algebraically independent set. If $n > m$, we proceed by changing one element in X a time using induction and prove that K is algebraic over $\{w_1,\ldots,w_r,x_{r+1},\ldots,x_m\}$, contradiction.

Because w_{r+1} is algebraic over $\{w_1,\ldots,w_r,x_{r+1},\ldots,x_n\}$, we have a minimal polynomial

$$f = \sum g_j(w_{r+1},w_1,\ldots,w_r,x_{r+2},\ldots,x_m)x_{r+1}^j$$

s.t. $f(w_{r+1},w_1,\ldots,x_m) = 0$ (after possibly renumbering x_i, this x must exists because S is itself algebraically independent). So x_r is algebraic over $\{w_1,\ldots,w_{r+1},x_{r+2},\ldots,x_m\}$, hence K is independent over it, too.

If K/k has an infinite basis B, let B' be another basis, then for any $\alpha \in B^*$, there is a finite set $B_\alpha \subset B$ that α is algebraic over $k(B_\alpha)$, because algebraic equation involves f.m. generators. Then we define $B^* = \cup_{\alpha\in B'}$, then it has cardinality smaller than B'. But $B^* = B$, because for any $\beta \in B$, β is algebraic over B' which is algebraic over $k(B^*)$, thus β is algebraic over $k(B^*)$, thus $\beta \in B^*$. □

Prop. (2.2.6.3). If K is of finite transcendental degree over k, then $\#K = \#k$.

Proof: We find a purely transcendental L/k that K/L is algebraic, then the element of L are all polynomials of finite indeterminants of elements of k, so $|L| = |k|$ by(1.2.8.4), and similarly $|K| = |L|$. □

Prop. (2.2.6.4). **??** For $k \in$ `Field`, any two alg.closed field extension $K_1/k, K_2/k$ of the same transcendental degree over k are isomorphic.

Proof: We define a bijection of the transcendental basis, and then extend it to an isomorphism of fields, by(2.2.5.10). □

Cor. (2.2.6.5). Any two alg.closed field of the same characteristic and cardinality are isomorphic.

Proof: It suffices to show that their transcendental basis over the base field are of the same cardinality? □

Prop. (2.2.6.6) [Lüroth]. The automorphism group of $K(T)$ is $PGL(2;K)$.

Proof: Consider $\theta = \sigma(x) = \frac{f(x)}{g(x)}$, then x is algebraic over $K(\theta) : \theta g(x) - f(x) = 0$. Now x is transcendental over K, thus θ is transcendental over K as well. Now the minimal polynomial of x over $K(\theta)$ is just $\theta g(x) - f(x)$, because it is irreducible, as it is linear over θ. But $K(x) = K(\theta)$, thus the polynomial must have degree 1, so $f(x), g(x)$ is of degree 1. Now the rest is clear. □

Prop. (2.2.6.7) [Lüroth]. Any subfield $K \not\subseteq L \subset K(T)$ is of the form $K(u)$ where $u \in K(X)$ is transcendental over K.

Proof: It is clearly transcendental over K, so this follows from(5.11.1.17) and Riemann-Hurewitz(5.11.1.32), notice that the field extension is separable by(4.3.9.4): The non-singular complete curve corresponding to L has genus0, and it has a rational point, so isomorphic to $\mathbb{P}^1_k$(5.11.8.2). □

7 Galois Theory

Def. (2.2.7.1) [Galois Extension]. A **Galois field extension** is a field extension that is both normal and separable.

Def. (2.2.7.2) [Galois Closures]. Let F/K be a separable extension, then the normal closure E/K is also separable, called the **Galois closure** of F/K.

In particular, the maximal separable extension k^{sep}/k, called the **separable closure** of k, is Galois over k, and $\text{Gal}(k^{\text{sep}}/k)$ is denoted by Gal_k.

Prop. (2.2.7.3) [Linear Independence of characters, Artin]. Let L be a field, G be a monoid and $\chi_i : G \to L$ be multiplicative maps, then χ_i are linearly independent over L.

Proof: Let $\sum_{i=1}^n a_i\chi_i = 0$ and $a_i \neq 0$ for any i, we use induction to derive contradictions: for all i. $n = 1$ is trivial, and for general n, assume $a_1, a_2 \neq 0$, then the two equations $\chi_1(h) \neq \chi_2(h)$, then $\sum_{i=1}^n a_i\chi_i(hg) = 0$ and $\sum_{i=1}^n a_i\chi_i(g) = 0$ gives us a equation with smaller n, thus we are done. □

Prop. (2.2.7.4) [Algebraic Independence of Automorphisms, Artin]. Let $K \in \texttt{Field}, \#K = \infty$, and $G = \{\sigma_1, \ldots, \sigma_n\}$ be a finite subgroup of automorphisms of K, then $\{\sigma_i\}$ are algebraically independent over K.

Proof: Cf.[Lang, P311].? □

Prop. (2.2.7.5) [Galois Main Theorem, Artin]. Let G be a finite group of automorphisms of K. Then K/K^G is Galois of Galois group G.

Proof: For every element x, set $\{\sigma_1 x, \ldots, \sigma_r x\}$ be distinct conjugates, then $f(X) = \prod_i^r = (X - \sigma_i x)$ shows that K is separable and normal over K^G. And primitive element theorem shows that $[K : K^G] \leq |G|$, so it must equals G. □

Prop. (2.2.7.6). If L/K is a finite Galois extension, then there is an isomorphism:

$$L\otimes_K L\cong L\times L\times\ldots\times L:(a,b)\mapsto(ab,a\sigma_1(b),\ldots,a\sigma_{n-1}(b))$$

where σ_i are Galois elements.

Proof: Choose a primitive element x and its minimal polynomial $f(x)$, then $L\cong K[X]/(f)$, and $L\otimes_K L\cong L[X]/(f)$, but f decomposes completely in $L[X]$, thus by Chinese remainder theorem(2.2.3.17), the given map is an isomorphism of rings. □

Prop. (2.2.7.7) [Infinite Galois Theorem]. The middle fields correspond to the closed subgp of $G(L/K)$.

Proof: The highlight is that $G(L/L^H)=H$ for a closed subgp H of $G(L/K)$. If σ fixes L^H but is not in H, because for every finite field M, $H\cdot G(L/M)$ corresponds to $M/(M\cap L^H)$, so $\sigma G(L/M)\cap H\neq\varnothing$. So σ is in the closure of H thus in H. □

Prop. (2.2.7.8) [Normal Basis Theorem]. For a finite Galois extension L/K, normal basis exists.

Proof: Finite case: The Galois group is cyclic, and the linear independent of characters shows that the minimal polynomial of σ is n-dimensional thus equals X^n-1. Regard L as a $K[X]$ module thus by (2.2.4.21) is a direct sum of modules of the form $K[X]/(f(x))$, $f(x)|X^n-1$ and the minimal polynomial for the action of X is X^n-1. So it must be isomorphic to $K(X)/(X^n-1)$.

Infinite Case: Let

$$f(\{X_\sigma\})=\det(t_{\sigma_i,\sigma_j})\in\mathbb{Z}[\{X_\sigma\}],\quad t_{\sigma,\tau}=X_{\sigma^{-1}\tau}$$

then $f\neq 0$ by substituting 1 for X_{id} and 0 otherwise. So it won't vanish for all $x\in L$ if we substitute $X_\sigma=\sigma(x)$ because $\{(\sigma(x))_\sigma\}$ are algebraically independent(2.2.7.4). Thus there exists $w\in L$ s.t.

$$\det(\sigma^{-1}\tau(w))\neq 0.$$

Now if

$$\sum a_\tau\tau(w)=0,\qquad a_\sigma\in K,$$

act by σ for all σ, we get $[\sigma^{-1}\tau(w)]_{\tau,\sigma}[a_\sigma]_\sigma=0$, thus $a_\sigma=0$ for each $\sigma\in\mathrm{Gal}(L/K)$. So $\{\tau(w)\}$ is a K-basis of L. □

Prop. (2.2.7.9) [Kummer Theory]. Let K be a field and containing the set n-th roots of unity μ_n where $n\in\mathbb{Z}\cap K^*$, a **Kummer extension** L/K of exponent n is a Galois extension that the Galois group is Abelian of exponent n.

Then there is an inclusion preserving isomorphism between the lattice of Kummer extensions L over K and the lattice of subgroups of $K^\times$ containing $(K^\times)^n$:

$$L\mapsto\Delta=(L^\times)^n\cap K^\times,\qquad\Delta\mapsto K(\sqrt[n]{\Delta}).$$

And $\Delta/(K^\times)^n$ is isomorphic to $\mathrm{Gal}(L/K)^\vee=\mathrm{Hom}(\mathrm{Gal}(L/K),\mathbb{Q}/\mathbb{Z})$.

Proof: The Galois cohomology of the Kummer sequence $1\to\mu_n\to L^\times\xrightarrow{n}(L^\times)^n\to 0$ says

$$1\to K^\times\xrightarrow{n}(L^\times)^n\cap K^\times\xrightarrow{\delta}H^1(\mathrm{Gal}(L/K),\mu_n)\to H^1(\mathrm{Gal}(L/K),L^\times)=1(10.1.3.2)$$

And $\mathrm{Gal}(L/K)$ acts trivially on $\mu_n \subset K^*$, so

$$H^1(\mathrm{Gal}(L/K), \mu_n) = \mathrm{Hom}(\mathrm{Gal}(L/K), \mathbb{Q}/\mathbb{Z})$$

and

$$\delta : a \mapsto \chi_a(\sigma) = \sigma(\sqrt[n]{a})/\sqrt[n]{a} \in \mu_n.$$

Now let L/K be the maximal Kummer extension of exponent n, then $(L^\times)^n = K^\times$. So the assertion follows form Galois theory on applied to L/K. □

Prop. (2.2.7.10) [Finite Fields]. $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) = \mathbb{Z}/(n)$. and is generated by the Frobenius.

Proof: □

Prop. (2.2.7.11) [Artin-Schreier Theory]. Let K be a field of characteristic $p > 0$ containing $\mathbb{F}_q$, where $q = p^k$, an **Artin-Schreier extension** L/K of exponent q is a Galois extension that the Galois group is Abelian of exponent q.

Then there is an inclusion preserving isomorphism between the lattice of Artin-Schreier extensions L over K of exponent q and the lattice of subgroups of $W^+_{p,k}(K)$ containing $(W^+_{p,k}(\mathrm{Frob}^k_p) - \mathrm{id})(W^+_{p,k}(K))$:

$$L \mapsto \Delta = (W^+_{p,k}(\mathrm{Frob}^k_p) - \mathrm{id})(W^+_{p,k}(L)) \cap W^+_{p,k}(K),$$

$$\Delta \mapsto K(\{b_{i1}, \ldots, b_{ik} | b_i = (b_{i1}, \ldots, b_{ik}), W^+_{p,k}(\mathrm{Frob}^k_p)(b) - b \in \Delta\}).$$

And $\Delta/(W^+_{p,k}(\mathrm{Frob}^k_p) - \mathrm{id})(W^+_{p,k}(K))$ is isomorphic to $\mathrm{Gal}(L/K)^\vee = \mathrm{Hom}(\mathrm{Gal}(L/K), \mathbb{Q}/\mathbb{Z})$.

Proof: The Galois cohomology of this exact sequence

$$0 \to W^+_{p,k}(\mathbb{F}_q) \to W^+_{p,k}(L) \xrightarrow{W^+_{p,k}(\mathrm{Frob}^k_p)-\mathrm{id}} (W^+_{p,k}(\mathrm{Frob}^k_p) - \mathrm{id})(W^+_{p,k}(L)) \to 0,$$

says

$$1 \to W^+_{p,k}(K) \xrightarrow{W^+_{p,k}(\mathrm{Frob}^k_p)-\mathrm{id}} (W^+_{p,k}(\mathrm{Frob}^k_p) - \mathrm{id})(W^+_{p,k}(L)) \cap W^+_{p,k}(K)$$
$$\xrightarrow{\delta} H^1(\mathrm{Gal}(L/K), W^+_{p,k}(\mathbb{F}_q)) \to H^1(\mathrm{Gal}(L/K), W^+_{p,k}(L)) = 0 \text{(10.1.3.3)}$$

And $\mathrm{Gal}(L/K)$ acts trivially on $W^+_{p,k}(\mathbb{F}_q)$, so by(4.5.3.22),

$$H^1(\mathrm{Gal}(L/K), W^+_{p,k}(\mathbb{F}_q)) = \mathrm{Hom}(\mathrm{Gal}(L/K), \mathbb{Q}/\mathbb{Z})$$

and

$$\delta : a \mapsto \chi_a(\sigma) = \sigma(b) - b \in W^+_{p,k}(\mathbb{F}_q), \quad W^+_{p,k}(\mathrm{Frob}^k_p)(b) - b = a.$$

Next we prove for any $b = (b_1, \ldots, b_k), W^+_{p,k}(\mathrm{Frob}^k_p)(b) - b \in W^+_{p,k}(K)$, $K(\{b_1, \ldots, b_k\})/K$ is Abelian of exponent q: Let $K_i = K(\{b_1, \ldots, b_i\})$. By(4.5.3.4),

$$(b_1^q, \ldots, b_k^q) - (b_1, \ldots, b_k) \in W^+_{p,k}(K)$$

implies $b_i^q - b_i \in K_{i-1}$. Thus K_i/K_{i-1} is an Artin-Schreier extension of exponent p. As the Galois action is always of the form $\sigma(s) - s \in \mathbb{F}_q$ for any $\sigma \in \mathrm{Gal}(K_k/K)$ and $s \in K_k$, we see K_k/K is also Artin-Schreier of exponent $q = p^k$.

Now let L/K be the maximal Artin-Schreier extension of exponent q, then $(W^+_{p,k}(\mathrm{Frob}^k_p) - \mathrm{id})(W^+_{p,k}(L)) = W^+_{p,k}(K)$. So the assertion follows form Galois theory on applied to L/K. □

Cor. (2.2.7.12) [Artin-Schreier of Exponent p]. Let K be a field of characteristic $p > 0$, then there is an inclusion preserving isomorphism between the lattice of Artin-Schreier extensions L over K of exponent p and the lattice of subgroups of K^+ containing $\{x^p - x | x \in K\}$:

$$L \mapsto \Delta = \{x^p - x | x \in L\} \cap K,$$

$$\Delta \mapsto K(\{b | b^p - b \in \Delta\}).$$

And $\Delta/\{x^p - x | x \in K\}$ is isomorphic to $\mathrm{Gal}(L/K)^\vee = \mathrm{Hom}(\mathrm{Gal}(L/K), \mathbb{Q}/\mathbb{Z})$.

<u>**Applications**</u>

Thm. (2.2.7.13) [Unsolvability of the Quintic by Radicals, Abel1826-Galois1832].

Proof: □

8 Ordered Rings

Def. (2.2.8.1) [Ordered Rings]. An **ordered ring** is a ring R together with a subset $P \subset R$ that R is a disjoint union $P \coprod \{0\} \coprod (-P)$, and if $x, y \in P$, then $x + y, xy \in P$. Elements in P are called **positive elements**.

An **ordered field** is an ordered ting that is also a field. An **orderable ring/field** is a ring/field that can be given an ordered structure.

Prop. (2.2.8.2). An orderable field has char0, because $0 \notin P \cup (-P)$.

A square> 0 in an ordered field(trivial).

Def. (2.2.8.3) [Convex Subgroup]. Let Γ be an ordered Abelian group(2.2.8.1), then a **convex subgroup** of A is a subgroup Δ that if $a < b < c$ and $a, c \in \Delta$, then $b \in \Delta$. Notice this is in fact equivalent to if $0 < c \in \Delta$, then $0 < b < c$ are also in Δ.

Prop. (2.2.8.4) [Height]. The set of all convex subgroups of Γ is well-ordered, and its ordinal is called the **height** of Γ.

Proof: If Δ_1, Δ_2 don't contains each other, let $a \in \Delta_1 - \Delta_2$ and $b \in \Delta_2 - \Delta_1$, then changing $\pm a, \pm b$, we may assume $0 < a < b$, so $a \in \Delta_2$, contradiction. □

Prop. (2.2.8.5) [Height 1 Case]. Let Γ be an ordered Abelian group, then the following are equivalent:

1. $\mathrm{ht}(\Gamma) = 1$.
2. for all $a, b \in \Gamma$ that $a > 0$ and $b \geq 0$, there is an integer n that $b \leq na$.
3. there exists an injection from Γ to $\mathbb{R}$.

Proof: $3 \to 1$ is easy.

$1 \to 2$: Consider the convex subgroup generated by a, then it is Δ by height condition, so b must by in it, i.e. $b \leq na$ for some n.

$2 \to 3$: Choose an $a > 0$, let the injection φ given by $\varphi(b) = \sup\{\frac{n}{k} | na \leq kb\}$ for $b > 0$ and extends to negative elements.

It is easily verified that $\varphi(c) + \varphi(b) \leq \varphi(c + b)$, and if $\varphi(c) + \varphi(b) < \varphi(c + b)$, choose a rational approximation of them, and multiply to get integers, then if $k(c+b) \leq \varphi(c+b)ka > \varphi(b)a + \varphi(c)a + a$, then either $kc \geq \varphi(c)ka + a$ or $kb \geq \varphi(b)ka + a$, contradiction.

So this map is truly a morphism of ordered Abelian groups, and it is injective because if $b > 0$, then by 2, there must be an n that $a \leq nb$, so $\varphi(b) \geq 1/n$. □

9 Real Fields

Def. (2.2.9.1) [Real Fields]. A field K is called **real** if -1 is not a sum of squares in K. A field K is called **real closed** iff it is real, and any alg.extension that is real must be itself. An ordered field is clearly a real field by(2.2.8.2), the converse is in fact true, by(2.2.9.11). In particular, a real field is of characteristic 0.

Prop. (2.2.9.2). If K is real, $a \in K$, a and $-a$ cannot both be sum of squares. If $-a$ is not a sum of squares in K, then $K(\sqrt{a})$ is real. Hence either $K(\sqrt{a})$ or $K(\sqrt{-a})$ is real.

Proof: Suppose $K(\sqrt{a})$ is not real. If a is a square, then $K(\sqrt{a}) = K$ is real. So a is not a square,

$$-1 = \sum (b_i + c_i\sqrt{a})^2 = \sum (b_i^2 + ac_i^2 + 2b_ic_i\sqrt{a})$$

Since $\sqrt{a} \notin K$, $-1 = \sum (b_i^2 + ac_i^2)$, so

$$-a = \frac{1 + \sum b_i^2}{\sum c_i^2}$$

This implies that $-a$ is a sum of squares. □

Prop. (2.2.9.3). If the minimal polynomial f of an α algebraic over a real field K is of odd degree, then $K(\alpha)$ is real.

Proof: If $K(a)$ is not real, then $-1 = \sum g_i(X)^2 + h(X)f(X)$, where g_i has degree smaller than n. This can happen if $h(X)$ has degree odd and $\leq n-2$. Then if β is a root of h, then $K(\beta)$ is also not real. So the proof is finished if we use induction. □

Def. (2.2.9.4) [Real Closure Exists]. For any real field K, there exists a **real closure** K^a of K. That is, it is real closed and algebraic over K.

Proof: This is an easy consequence of Zorn's lemma. □

Cor. (2.2.9.5) [Real Closed Fields Unique Ordering]. There exists a unique ordering on a real closed field R. The elements> 0 are just the squares in R. Now every real closed field is assumed to have this ordering tacitly. In particular, any real closed field has char0, so does any real field.

Proof: The set of finite sum of squares in R is closed under addition and multiplication, and all of them are squares, by(2.2.9.2) and maximality of R. Also by(2.2.9.2) either a is a square or $-a$ is a square, but not simultaneously. So it is truly an order on R. □

Prop. (2.2.9.6) [Fundamental Theorem of Algebra]. For a field R, R is real closed iff $R \neq R[\sqrt{-1}]$ and $\overline{R} = R(\sqrt{-1})$.

Proof: One direction is trivial, the other follows from the lemma below(2.2.9.7), it satisfies the condition by(2.2.9.2) and maximality. □

Lemma (2.2.9.7) [Equivalent Definition of Real Closed Fields]. If R is a real field that: for all $a \in R$, $\sqrt{a} \in R$ or $\sqrt{-a} \in R$, and any polynomial of odd degree has a root in R, then $K = R(i)$ is alg.closed.

Proof: For any order of R, the first condition in fact says that any $a > 0$ in R is a square. Now $\frac{a+\sqrt{a^2+b^2}}{2}$ is non-negative, so there is a $c^2 = \frac{a+\sqrt{a^2+b^2}}{2}$, that is $(c+\frac{b}{2c}i)^2 = a+bi$, so K has all squares.

As R is of char0(2.2.9.5)(2.2.8.2), so it suffices to show any Galois extension L/K is trivial. Let $G = G(L/R)$, and H be its 2-Sylow subgroup, then $G = H$ by condition. Now if $G_1 = G(L/K)$, then G_1 is nontrivial, because otherwise there is a subgroup of index 2, then its fixed field is a square extension of K, which is impossible by what we have proved. So $G = G_1$, that is $L = K$. □

Cor. (2.2.9.8) [Complex Numbers is Alg.Closed, Gauss1799]. $\mathbb{C} = \mathbb{R}[i]$ is alg.closed.

Prop. (2.2.9.9) [Intermediate Property]. An ordered field is real closed iff it has the intermediate property.

Proof: If R is real closed, as $R[i]$ is alg.closed(2.2.9.6), f can be decomposed into factors of degree 1 or 2. For a factor $X^2 + \alpha X + \beta$, $4\beta > \alpha^2$, otherwise it has a root hence not irreducible. So the change of sign is because of a linear factor, the rest is easy.

Conversely, if it has the intermediate property, then for $a > 0$, consider $p(X) = X^2 - a$, then $p(0) < 0, p(a+1) > 0$, so p has a root, that is, a is a square. For a polynomial of odd degree, for M large enough, $f(M) > 0, f(-M) < 0$, so f has a root. So by(2.2.9.7) R is real closed. □

Prop. (2.2.9.10) [Artin-Schreier]. If K is separably closed and F is a subfield of finite index in K, then $F = K$ or F is real closed and $K = F(i)$.

Proof: Cf.[Lan05]P299. □

Real Fields and Order

Prop. (2.2.9.11) [Real Field and Order]. If R is a real field, then it is orderable, in fact, if $-a$ is not a sum of squares in F, then there is an ordering that $a > 0$. So a real field is equivalent to an orderable field.

Proof: By(2.2.9.2), $F(\sqrt{a})$ is real, so it has a real closure(2.2.9.4) and has the induced order(2.2.9.5), and $a > 0$ because it is a square(2.2.8.2). □

Prop. (2.2.9.12) [Existence and Uniqueness of Real Closure]. For any ordered field F, there is a unique real closure R of F that every positive element of F is a square in R, thus the ordering is compatible.

Proof: The existence is by adding all the square roots of elements> 0 to F, the resulting field is real closed because of(2.2.9.2) and the fact a union of real fields(2.2.9.2) is real.

The uniqueness: because an ordered field is of char0(2.2.8.2), so the primitive element theorem(2.2.5.20) applies that each finite subextension of R_0 is of the form $F(\alpha)$, where α is a root of a irreducible separable polynomial f. Then the roots of f are different so can be ordered $\alpha_1 < \ldots < \alpha_n$. Similarly, f has the same number of different roots in R_1 $\beta_1 < \ldots < \beta_n$ by(2.2.9.14), so there is a map $h : \alpha_i \to \beta_i$, and it is the unique map that a ordered map from $F(\alpha)$ to R_1 extending id on F can be. it is this uniqueness that makes us able to use Zorn's lemma to show that there is a maximal ordered map, must be a map from R_0 to R_1, which is an isomorphism, by primitive element theorem again. □

Prop. (2.2.9.13) [Sturm's Algorithm]. Cf.[Model Theory Marker P327].

Cor. (2.2.9.14). If F is an ordered field and R_0, R_1 be two real closure of F that is compatible with the ordering, then any irreducible polynomial has the same number of roots in R_0 and R_1.

Proof: Cf.[Model Theory Marker P328]. □

Prop. (2.2.9.15) [Hilbert's 17th Problem]. If f is a positive semidefinite rational function over a real closed field F, then f is a sum of squares of rational functions.

Proof: Let $f(X_1, \ldots, X_n)$ be a positive semidefinite rational function, if f is not a sum of squares of rational functions, then by(2.2.9.11), there is an ordering on $F(\overline{X})$ that $f < 0$. Let R be a real closure of $F(\overline{X})$, then $R \models \exists \overline{v} F(\overline{v}) < 0$, as $F(\overline{X}) < 0$. But RCR is complete, by(1.5.5.6), thus $F \models \exists \overline{v} F(\overline{v}) < 0$ also, contradiction. □

2.3 Linear Algebra

Main references are [H-K71], [线性代数 谢启鸿], [Rom07] and [Determinant, 高等代数 notes, 安金鹏].

In this section, the category of vector spaces over a field k is studied, without considering any topology on K or V. More generally, the category of free modules over a commutative unital ring R is studied.

Def. (2.3.0.1) [Notations]. Throughout this section, k denote a field.

1 Basics

Def. (2.3.1.1) [Vector Spaces].

Def. (2.3.1.2) [Linear Operators]. A **linear operator** on a R-module V is an element of the endomorphism ring $\mathrm{End}_R(V)$

Def. (2.3.1.3) [Basis]. Let R be a field, then the sets S that are linearly independent over R has maximal objects by Zorn's lemma, and such a maximal object must span M, called a **basis** of M.

Prop. (2.3.1.4) [Dimension]. All basis of a linear k-vector space V have the same cardinality, this cardinality is called the **dimension** $\dim_k(V)$ of V. This follows immediately from(2.2.4.4).

Prop. (2.3.1.5) [Canonical way of Writing a Basis]. After so many years, I still find it confusing to write a basis and observing change of basis, so I will write it here:

A vector should always be written vertically, and so a basis should be $\overrightarrow{e}=(e_1,\ldots,e_n)$(horizontal), and a vector with basis $\overrightarrow{a}$(vertical) is in fact $\overrightarrow{e}\overrightarrow{a}$.

A change of basis should be written $\overrightarrow{e'}=ea$, with $a\in GL_n$, and then if an operator has matrix A w.r.t. the basis $\overrightarrow{e}$, it then map in the basis $\overrightarrow{e'}$ $v=\overrightarrow{e'}x=\overrightarrow{e}ax\mapsto\overrightarrow{e}Aax=\overrightarrow{e'}a^{-1}Aax$, so it has matrix $a^{-1}Aa$ w.r.t the basis $\overrightarrow{e'}$.

Prop. (2.3.1.6) [Extension of Basis].

Proof: □

Prop. (2.3.1.7). Let F is a subfield of K and U is a K-vector space with a F-subspace U'. Then if every finite F-linearly independent subset of U' is K-linearly independent, then $\dim_F(U')\leq\dim_K(U)$.

Proof: If the converse is true, there is a F-basis u'_j of U', then some of u'_j is K-linearly dependent, contradiction. □

Def. (2.3.1.8) [Matrices]. Let R be a commutative ring, the set of **matrices** of size $m\times n$ over R is an (non-commutative) algebra $M_{m\times n}(R)$ over R whose underlying module is $R^{\oplus n^2}=\oplus_{1\leq i\leq m,1\leq j\leq n}e_{ij}R$, and the algebra structure is given by

$$e_{ij}e_{ij}=e_{ik}.$$

An element $A=\sum_{1\leq i\leq m,1\leq j\leq n}a_{ij}e_{ij}\in M_{m\times n}(R)$ is denoted by $A=(a_{ij})$.

Prop. (2.3.1.9). A,B are two $n\times n$-matrices, if $1-AB$ is invertible, then so does $1-BA$, and

$$(1-BA)^{-1}=1+B(1-AB)^{-1}A.$$

Proof: Immediate from(2.2.1.5) or(2.3.10.12). □

Cor. (2.3.1.10). AB and BA has the same characteristic polynomials.

Prop. (2.3.1.11). For a ring R, there is an isomorphism of rings

$$M_n(R)^{op} \cong M_n(R^{op}).$$

The isomorphism is given by $A \mapsto A^t$.

Def. (2.3.1.12) [Notation for Matrix Group]. Let R be a ring, denote

- $GL(n, R)$ be the subgroup of $\mathrm{End}_R(\oplus R^{\oplus n})$ consisting of invertible matrices.
- $SL(n, R)$ be the subgroup of $GL(n, R)$ consisting of matrices of determinant 1(2.3.10.1).
- $U_n(R)$ be the subgroup of $GL(n, R)$ consisting of upper-triangular matrices.
- $P_n(R)$ be the subgroup of $GL(n, R)$ consisting of matrices $A = (a_{ij})$ that $a_{ni} = 0$ for $i < n$.
- $Q_n(R)$ be the subgroup of $GL(n, R)$ consisting of matrices $A = (a_{ij})$ that $a_{ni} = 0$ for $i < n$ and $a_{nn} = 1$.

Prop. (2.3.1.13). Let K be a topological field, there is a decomposition of spaces

$$U_n(K)\backslash GL(n, K) \cong GL(1, K) \times U_2(K)\backslash GL(2, K) \times \ldots \times Q_n(K)\backslash GL(n, K)$$

where $GL(n-1, K)$ embeds $GL(n, K)$ obviously.

Remark (2.3.1.14). ? This is wrong.

Proof: By induction, it suffices to show

$$U_n(K)\backslash GL(n, K) \times U_{n-1}(K)\backslash GL(n-1, K) \times Q_n(K) \times GL(n, K).$$

Consider the map $GL(n-1, K) \times GL(n, K) \to U_n(K)\backslash GL(n, K) : (x, y) \mapsto xy$, then $x_1y_1 = x_2y_2$ iff $x_1y_1 = ux_2y_2$ for some $u \in U_n(K)$, iff $y_1y_2^{-1} = x_1^{-1}ux_2$. This is possible iff $y_1y_2^{-1} \in Q_n$, and for all (y_1, y_2) that $y_1y_2^{-1} \in Q_n$, $x_1y_1 = ux_2y_2$ iff $x_1 = ux_2y_2y_1^{-1}$. □

2 Rank

Prop. (2.3.2.1) [Rank Nullity Theorem]. Let $T : V \to W$ be a linear map between vector spaces, then $\mathrm{rank}(T) + \dim \mathrm{Nul}(T) = V$.

Proof: This follows from the exact sequence $0 \to \ker(T) \to V \to \mathrm{Im}(T) \to 0$. □

Prop. (2.3.2.2) [Row Rank equals Column Rank]. The row rank of a $m \times n$ matrix A is the same as the column rank.

Proof: Let A be the matrix of a linear map $T : V \to W$, then column rank equals the range of T, and the row rank equals the range of T^t, so they are equal by(2.3.3.7). □

Prop. (2.3.2.3) [Sylvester's Inequality]. For U a $m \times n$ matrix and V a $n \times k$ matrix,

$$\mathrm{Rank}(UV) \geq \mathrm{Rank}(U) + \mathrm{Rank}(V) - n$$

Proof: This comes from $\dim\ker fg \leq \dim\ker f + \dim\ker g$, which is because $\ker fg = g^{-1}(\ker f)$. □

Prop. (2.3.2.4) [Finite Field General Linear Group]. Over finite field $\mathbb{F}_{p^k}$, $|GL_n(\mathbb{F}_{p^k})| = (p^n - 1)(p^n - p)\ldots(p^n - p^{n-1})$.

Proof: This is because choose the rows are equivalent to choosing a basis for $V = \oplus_{i=1}^n \mathbb{F}_{p^k}$, and when choosing n-th row, it suffices to avoid an element in the span of the first $n-1$ rows. □

Prop. (2.3.2.5) [Wedge and Rank]. Let $T : V \to V'$ be a linear map, then $\wedge^k(T) = 0$ iff $\mathrm{rank}(T) < k$.

Proof: If $\mathrm{rank}(T) < k$, then $\mathrm{Im}(\wedge^k(T)) \subset \wedge^k \mathrm{Im}(T) = 0$. Conversely, if $\mathrm{rank}(T) \geq k$, choose $\{Te_1, \ldots, Te_k\}$ linearly independent, then $T(e_1 \wedge \ldots \wedge e_k) = Te_1 \wedge \ldots \wedge Te_k \neq 0$. □

3 Dual spaces

Def. (2.3.3.1) [Dual Spaces]. Let V be a vector space over a field k, the set of linear functionals on V with value in k form another vector space, which is denoted by V^*, called the **dual space** of V.

Def. (2.3.3.2) [Annihilator]. Let V be a vector space and $W \subset V$ a subspace, then the **annihilator** $W^\perp$ is the subspace of W^* consisting of linear functionals l on V s.t. $l(W) = 0$.

Def. (2.3.3.3) [Dual Basis]. Let $V \in \mathcal{V}\mathrm{ect}_k$ and $(e_1, \ldots, e_n)$ is a basis of V, then there exists unique elements $\alpha_1, \ldots, \alpha_n$ of V^* s.t. $(e_i, \alpha_j) = \delta_{ij}$. Any such elements $\alpha_1, \ldots, \alpha_n$ constitute a basis for V^*, and is called the **dual basis** of $(e_1, \ldots, e_n)$.

Prop. (2.3.3.4) [Dimension of the Annihilator]. Let $W \subset V$ be f.d. vector spaces, then $\dim W + \dim W^\perp = \dim V$.

Proof: Let $\{e_1, \ldots, e_k\}$ be a basis of W and extend it to a basis $\{e_1, \ldots, e_k, e_{k+1}, \ldots, e_n\}$ of V by(2.3.1.6). Consider the dual space $e_1^*, \ldots, e_n^*$, then the annihilator of W is just $\mathrm{span}\{e_{k+1}^*, \ldots, e_n^*\}$. Thus $k + (n-k) = n = \dim V$. □

Def. (2.3.3.5) [Transpose]. Let $T : V \to W$ be a linear map of f.d. vector spaces, then T induces a map $T^t : W^* \to V^*$ given by $T^t(l) = l \circ T$. This is a linear map, called the **transpose** of T.

Prop. (2.3.3.6) [Adjoint Map and Transpose]. Let $T : V \to W$ be a linear map of f.d. vector spaces, such that w.r.t. a basis $\{e_1, \ldots, e_n\}$ of V and $\{f_1, \ldots, f_m\}$ of W, T is given by matrix $A = (a_{ij})$. Then w.r.t. the dual basis $\{f_1^*, \ldots, f_m^*\}$ of W^*, $\{e_1^*, \ldots, e_n^*\}$ of V^*, the transpose map(2.3.3.5) $T^t : W^* \to V^*$ is given by the a matrix $A^t = (b_{ij})$, where $b_{ij} = a_{ji}$. A^t is called the **transpose matrix** of A.

Proof: $\langle e_j, T^t(f_i^*)\rangle = \langle Te_j, f_i^*\rangle = a_{ji}$, thus $b_{ij} = a_{ji}$. □

Prop. (2.3.3.7) [Tranpose Range Nullity Duality]. Let $f : V \to V'$ be a linear map between f.d. vector spaces over a field k, then

- $\mathrm{rank}(T^t) = \mathrm{rank}(T)$.
- The range of T^t is the annihilator of the null space of T.

Proof: 1: Notice that $T^t(g) = 0$ iff $\langle g, T(v)\rangle = 0$ for any $v \in V$, thus the null space of T^t is just the annihilator of the range of T, which equals $\dim V' - \mathrm{rank}(T)$ by(2.3.3.4). But this space has dimension $\dim\ker(T^t) = \dim V' - \mathrm{rank}(T')$, so $\mathrm{rank}(T) = \mathrm{rank}(T^t)$.

2: This follows from the fact that $(T^t)^t = T$ and the argument above. □

Cor. (2.3.3.8). A linear map between f.d. vector spaces is surjective iff its transpose is injective.

Prop. (2.3.3.9) [Infinite Dual space]. If $\dim_K V$ is not finite, then $\dim_K V < \dim_K V^*$.

Proof: Notice $\mathrm{Hom}(\oplus_{i\in I} Ke_i, K) = \prod Ke_i^*$.

We prove first that if $|K|$ is at most countable, then $|V| = |I|$. Notice the set $S_n(I)$ of all n-element subsets of I is of the same cardinality of I(1.2.8.3). And the finite sums of K and e_i can be seen as a subset of $S_n(I)\times K^n$, so it has the same cardinality of I.

Now we can prove if $|K|$ is at most countable, then $\dim V < \dim V^*$. This is because V^* equals the functions from V to K, which is bigger than the functions from V to $\{0,1\}$, which is the power set of V, so having cardinality $2^{|V|}$ which is bigger than $|V|$, by Cantor theorem(1.2.7.4).

Now generally, K is not countable, but it has a base field F, which is countable, so we consider the F-vector space $W = \oplus_{i\in I} Fe_i$, then $\dim_F W = \dim_K V$, and $\dim_F W < \dim_F W^*$. If we can show $\dim_F W^* \leq \dim_K V^*$, then we are done.

For this, first consider the natural F-linear mapping $W^* \to V^*$, which is clearly an imbedding. Now we want to use(2.3.1.7), so we check the conditions, for F-linearly independent $\varphi_1,\ldots,\varphi_n$, if $\sum c_i\varphi = 0$, $c_i \in K$, then if we can find $w_k \in W$ that $\varphi_i(w_j) = \delta_{ij}$, then this is a contradiction. But this is true, by a simple argument, using the F-linearity of F. □

4 Rational Form and Jordan Form

Prop. (2.3.4.1) [Elementary and Invariant Factors]. A linear operator in $L(V)$ is equivalent to a $\mathbb{K}[X]$-module structure on V, and two operators are similar iff the module structure are isomorphic.

As $K[X]$ is a PID, the elementary factors, invariant factors, cyclic and elementary decomposition theorems(2.2.4.22) can be applied to the case.

Proof: Cf.[Advanced Linear Algebra P168]. □

Cor. (2.3.4.2) [Jordan Forms].

- For a matrix over an alg.closed field, it is similar to a matrix of blocks $\lambda_i I + N, Nx_i = x_i + 1$, called the **Jordan form**.
- For a real matrix, it is similar to a matrix of blocks of the above form together with $\begin{bmatrix} a & -b \\ b & a \end{bmatrix}$ on the diagonal and $I_{2\times 2}$ on the lower side.

Proof: 1: Over an alg.closed field, the elementary factors are all of the form $(x-c_i)^{m_{ij}}$. Now in the basis $v, (T-c_i)v, \ldots, (T-c_i)^{m_i-1}v$, the matrix is just the Jordan form.

2: Over $\mathbb{R}$, the elementary factors are all of the form $(x-c_i)^{m_{ij}}$ and $((x-a)^2+b^2)^{m_{ij}}$. Then complexify it and consider a cyclic vector v, for $(T-(a+bi)I)$, let $v_{n+1} = (T-(a+bi)I)v_n$, and let $v_n = X_n + iY_n$, then it can be verified that T is of the Jordan form given in the basis X_i, Y_i. □

Def. (2.3.4.3) [Companion matrix]. The **companion matrix** for a monic polynomial $p(x) = x^n + a_{n-1}x^{n-1} + \ldots + a_0 \in F[X]$ is the matrix

$$T_{p(x)} = \begin{bmatrix} 0 & 0 & \cdots & 0 & -a_0 \\ 1 & 0 & \ldots & 0 & -a_1 \\ 0 & 1 & \ddots & & \vdots \\ \vdots & \vdots & \ddots & 0 & \\ 0 & 0 & \ldots & 1 & -a_{n-1} \end{bmatrix}$$

Prop. (2.3.4.4) [Companion Matrix is Nonderogatory]. An operator is cyclic iff it is similar to a companion matrix.

A companion matrix is nonderogatory(2.3.5.2). In fact, the minimal polynomial and the maximal polynomial of the companion matrix of $p(X)$ are both $p(X)$.

Proof: The operator of the companion matrix is an operator A with a basis $\{v, Av, A^2v, \ldots, A^{n-1}v\}$ and $A^n v = -\sum_{i<n} a_i A^i v$, which just equivalent to the fact the action of A is cyclic.

The determinant of $T_{p(X)}$ equals $p(X)$ by(2.3.4.13), and for the minimal polynomial, in the basis of $\{v, Av, A^2v, \ldots, A^{n-1}v\}$, clearly for a polynomial $f(X)$ of degree $m < n$, $f(A)v \neq 0$, and $p(A)v = \sum_{i<n} a_i A^i v + A^n v = 0$. So the minimal polynomial of A is $p(X)$. □

Prop. (2.3.4.5) [Rational Canonical Form]. Every matrix is similar to splint of companion matrixes(2.3.4.3) corresponding to its elementary divisors.

Prop. (2.3.4.6) [Invariant Factor Form]. Every matrix is similar to splint of companion matrixes, corresponding to its invariant factors.

Computing the Invariant Factors

Def. (2.3.4.7) [Elementary Row Operation]. An **elementary row operation** for a matrix M over an algebra A is one of the following:

- Multiplying one row of M by a non-zero scalar in A.
- plus the r-th row by c-times the s-th row, where c is invariant A.

And an **elementary matrix** is a matrix obtained by the identity matrix by an elementary row operation.

Two matrix is called **row equivalent** iff they can be connected by f.m. elementary row operations, and this is equivalent to $M = PN$, where P is a product of f.m. elementary matrices, because left multiplication by an elementary matrix is equivalent to an elementary row operation.

Similarly we can define elementary column operations.

Lemma (2.3.4.8). The elementary row operation change the determinant only by an invariant element in A. (Clear).

Prop. (2.3.4.9). Let P be a matrix with entries in $F[X]$, then the following are equivalent:

- P is invertible.
- The determinant is a nonzero scalar.
- P is row equivalent to identity matrix.
- P is a product of elementary matrices.

Proof: The only hard part is $2 \to 3$: this is because it has determinant in F^*, thus the greatest common divisor of the first column is a scalar, thus we can use row operation to make it $(1, 0 \ldots, 0)^t$, and then we can continue to make it a upper triangular matrix with 1 in the diagonal, and also kill the upper half part. So it is row equivalent to the identity matrix. □

Cor. (2.3.4.10). Let M, N be two matrices with entries in $F[X]$, then they are equivalent iff $N = PM$ for some P that has determinant in F.

Def. (2.3.4.11). We call M, N **equivalent** iff M, N are connected by a sequence of elementary row operations and column operations. This is equivalent to $M = PNQ$ for P, Q invertible matrices in $M_n(F[X])$.

Prop. (2.3.4.12) [Normal Form of Companion Matrix]. For a monic polynomial $p(X)$, consider its companion matrix T_p, then the matrix $xI - T_p \in M_n(F[X])$ is equivalent to $\mathrm{diag}(p(X), 1, \ldots, 1)$.

Proof: Clear, if one reduces the x in the diagonal from the bottom row to the top row one by one. □

Cor. (2.3.4.13). For a companion matrix A of p, $\det(xI - A) = p$.

Proof: This is from(2.3.4.8), and the fact both the side are monic polynomials. □

Def. (2.3.4.14) [Smith Normal Form]. A matrix in $M_n(F[X])$ is called a **Smith normal form** iff it is diagonal and diagonal entries $f_i \in F[X]$ is monic and satisfies f_k divides f_{k+1}.

Prop. (2.3.4.15). Any matrix M with entries in $F[X]$ is equivalent to a unique Smith normal form.

Proof: This is immediate from(11.7.6.7) applied to the PID $F[X]$(2.2.3.16). □

Cor. (2.3.4.16) [Computing Invariant Factors]. The diagonal entries of the Smith form of the matrix $xI - M \in M_n(F[X])$ are just the invariant factors of M.

Proof: This is because of the uniqueness of Smith form(2.3.4.15) and the invariant factor(2.3.4.6) and(2.3.4.12). □

Applications

Prop. (2.3.4.17). For any two matrices $A, B \in M_{n\times n}(K)$, $(AB)^n$ and $(BA)^n$ are similar.

Proof: It suffices to show that they have the same elementary factors. Notice that for any irreducible polynomial p, if $p \neq x$, then if $p^k(AB)v = 0$, then $p^k(BA)Bv = 0$, if $p^k(BA)v = 0$, then $p^k(AB)Av = 0$. Thus there are maps $B : N(p^k(AB)) \to N(p^k(BA))$ and $A : N(p^k(BA)) \to N(p^k(AB))$. Now their composition are both injective, thus they have the same dimension.

And for $p = x$, these two both have nullity as the multiplicity of 0 in the charpoly of AB, BA(2.3.10.13), thus the same. So they have the same elementary factors, thus similar. □

Prop. (2.3.4.18) [Matrix Similar to Transpose]. Any matrix is similar to its transpose.

Proof: This is because the invariant factors can be computed using the greatest common divisors of minors by(2.3.4.15) and(2.3.4.16), and they are clearly invariant under conjugation. □

5 Minimal and Characteristic Polynomials

Def. (2.3.5.1) [Minimal Polynomials]. The **minimal polynomial** of a matrix A is the polynomial p of minimal degree that $p(A) = 0$. It is equivalent to the maximal invariant factor of A, by(2.3.4.1).

Def. (2.3.5.2)[Non-derogatory Operator]. An operator is called **nonderogatory** iff it has only one invariant factor.

Prop. (2.3.5.3) [Generalized Cayley-Hamilton]. The characteristic polynomial of A is the product of the elementary divisors of A, thus the characteristic polynomial and minimal polynomial(2.3.5.1) of A have the same set of irreducible factors, but may not with the same multiplicity.

In particular, the characteristic polynomial is divisible the minimal polynomial.

Proof: Because charpoly and minipoly are both invariant under similarity, assume A is in rational form(2.3.4.5), so the result follows from(2.3.4.4). □

Prop. (2.3.5.4). The linear functor $X \to AX - XC$ is an isomorphism iff the minimal polynomial of A and C has not common factor.

Proof: Notice if $AX = XC$, then we have $P(A)X = XP(C)$ for every polynomial P, in, particular for the minimal polynomials of A and C, thus $P(C)$ is non-invertible and A, C has a characteristic value in common. Conversely, if they have a characteristic value, then we upper triangularize A to see clearly that there is a X that $AX = XC$ (X has only the first row). □

Characteristic Polynomial Images

In this subsubsection, we consider the set of characteristic polynomials of elements in a subgroup of $GL(n, k)$ as a whole.

6 Diagonalization and Triangulation

Prop. (2.3.6.1). If a linear map has matrix form T in a basis (X_i) and there is another basis (Y_i) that $(Y_i) = (X_i)P$, then it has matrix form PTP^{-1} in the basis (Y_i). In particular, if T can be diagonalized, with eigenvectors (X_i), then $T = (X_i)D(X_i)^{-1}$.

Prop. (2.3.6.2) [Relation with Minimal Polynomial].

- An $n \times n$-matrix A is upper-triangulable over a field K iff its minimal polynomial is a product of linear factors.
- An $n \times n$-matrix A is diagonalizable over a field K iff its minimal polynomial is a product of linear factors with no multiple roots.

Proof: 1: If it is upper-triangulable, its minimal polynomial is a product of factors because its characteristic polynomial does(2.3.5.3). Conversely, we can find an eigenvector for A, then we quotient this vector and use induction.

2: If it is diagonalizable, then the minimal polynomial is clearly polynomials. Conversely, its elementary factors are all linear factors, thus its Jordan form is just diagonal(2.3.4.2). □

Cor. (2.3.6.3) [Upper Triangulation Alg.Closed Field]. If K is alg.closed, then any $n \times n$-matrix A is upper-triangulable over K. Similarly, it is lower-triangulable.

Proof: It suffices to find a flag that is stabilized by A. And for this, it suffices to find an eigenvector of A. This is clear, as the characteristic polynomial of A has a root in K. □

Prop. (2.3.6.4) [Simultaneously Triangulation]. If A_i is a commutating family of upper-triangulable $n \times n$-matrices, then they are simultaneously triangulable.

Proof: As in the proof of(2.3.6.3), by induction, it suffices to show there is a common eigenvector. Now assume there are f.m. matrices in $\mathcal{F}$, we induct on the number of matrices to show there is an eigenvector. Let λ be an eigenvalue of A_1 because it is upper-triangulable, then $N(A_1 - \lambda I)$ is invariant under $\mathcal{F}$, and all the matrices are upper-triangulable on $N(A_1 - \lambda I)$, which is seen by intersecting the flag with $N(A_1 - \lambda I)$. So by induction, there is a common eigenvector for $\mathcal{F}$. □

Prop. (2.3.6.5) [Simultaneously Diagonalizable]. If A_i is a commutating family of diagonalizable $n\times n$-matrices, then they are simultaneously diagonalizable.

If A_i is a commutating family of real symmetric matrixes, then they are simultaneously orthogonally diagonalizable.

Proof: We may assume there are f.m. matrices and use induction. Consider the diagonal decomposition V_i of V for A_1, then each V_i is invariant under $\mathcal{F}$. Notice then each A_i is diagonalizable on V_i, thus by induction, $\mathcal{F}$ is simultaneously diagonalizable on each V_i, then $\mathcal{F}$ is simultaneously diagonalizable.

For the second, induction on the numbers of matrices. If some matrix is cI, then clear, if some are not cI, then choose its eigenvalue decomposition, we conclude by induction hypothesis. □

Prop. (2.3.6.6) [Invariance of Field Extension]. Let $A\in M_n(F)$, and E be the subfield generated by the entries of A, then the invariant factors of A are polynomials over E. In particular, two matrix are similar over the smallest field that they are defined.

Proof: Clear, because we know how an irreducible polynomial over E factors through $\overline{E}$. □

Prop. (2.3.6.7) [Jordan Decomposition]. Let k be a perfect field and $A\in M_n(k)$, then there exists unique matrices A_s, A_n that A_s is semisimple, A_n is nilpotent, $A = A_s + A_n$, and A_s, A_n are polynomials of A, in particular, A_s commutes with A_n.

Moreover, if A is invertible, then there exists unique matrices A_s, A_u that A_s is semisimple, A_u is unipotent, $A = A_s \cdot A_u$, and A_s, A_u are polynomials of A, in particular, A_s commutes with A_u.

Proof: If k is alg.closed, then use(2.3.6.3). And Lagrange interpolation shows A_s, A_n are polynomials in A. For the uniqueness, notice that because they are polynomials in A, if there are two sets of Jordan decompositions $A = A_s + A_n = A_s' + A_n'$, then $(A_s - A_s') = (A_n' - A_n)$, but the sum of commuting semisimple/nilpotent matrices is semisimple/nilpotent, so it is semisimple and nilpotent, so it can only be 0, so $A_s = A_s'$.

In general, because k is perfect, taking a Galois field extension k'/k containing all eigenvalues of A, then $A = A_s + A_n$ where A_s, A_n has entries in k'. But then taking Galois action and using the uniqueness, A_s, A_n has entries in k.

Finally, by the Galois action again, A_s, A_n are polynomials in A.

If A is invertible, then A_s is also invertible, seen by base change to alg.closure. Then $A = A_s(1 + A_s^{-1}A_n)$, where $1 + A_s^{-1}A_n$ is unipotent. □

Prop. (2.3.6.8). If T is a diagonalizable operator on a subspace V, then for any invariant subspace V', $T|_{V'}$ is also diagonalizable.

Proof: Use the eigenvalue decomposition $V = \oplus_i V_{\lambda_i}$, then $V' = \oplus_i (V_{\lambda_i}\cap V')$, which is because if $\sum v_i \in V'$, where v_i are in different eigenspaces, then each $v_i\in V'$. □

7 Positivity(Inner Spaces)

Def. (2.3.7.1) [Inner Spaces]. A **real inner space** is a f.d. real quadratic space that $B(v,v) > 0$ for $v\neq 0$. It is necessarily non-degenerate.

A **complex inner space** is a f.d. Hermitian space V that $B(v,v) > 0$ for $v\neq 0$.

Prop. (2.3.7.2). An inner metric on a vector space will induce an inner metric on the dual space, that is, asserting the dual basis of an orthonormal basis to be orthonormal. On an arbitrary basis, the matrix on the dual basis is written as A^{-1}. because we can write $A = P^tP$, and the dual basis transformation is like $(P^t)^{-1}$, so the metric matrix is A^{-1}.

Prop. (2.3.7.3) [Positivity and Principal Minors]. A matrix is positive symmetric(Hermitian) iff it is symmetric, and all its upper principle minors has positive determinants.

A positive symmetric(Hermitian) matrix is equivalent to a real(complex) inner space.

Proof: Cf.[Hoffman P328]. □

Prop. (2.3.7.4)[Farkas' Lemma]. For a matrix A, and a vector b, exactly one of the following equation has a solution:

$$\begin{cases} AX = b, X \geq 0 \\ Y^t A \leq 0, Y^t b > 0 \end{cases}$$

Proof: First notice if both have a solution, then $0 \geq Y^t AX > 0$, contradiction. The rest follows form the Hahn-Banach separation theorem. □

Cor. (2.3.7.5) [Gordan's Theorem]. exactly one of the following has a solution:

$$\begin{cases} AX > 0 \\ Y^t A = 0, Y \geq 0, Y \neq 0 \end{cases}$$

Proof: If both have a solution, then $0 = Y^t AX > 0$, contradiction. If the first has no solution, then $A'x = e, z \geq 0$, where $A' = [A, -A, -I]$ has no solution, by Farkas' lemma, there is a solution of $Y^t A' \leq 0$ and $Y^t b = 0$. Which shows that $Y^t A = 0$ and $Y \neq 0$. □

Cor. (2.3.7.6). For any subspace in $\mathbb{R}^m$, either it has an intersection with the open first quadrant, or its orthogonal complement has an intersection with the closed first quadrant minus 0. (Regard it has the image of a AX).

8 Bilinear & Hermitian Forms

Prop. (2.3.8.1) [Hermitian Forms]. A complex vector space V is equivalent to a real vector space with an endomorphism J that $J^2 = -1$, by i acting by J.

A **Hermitian form** on (V, J) is an R-bilinear mapping $(-,-) : V \times V \to \mathbb{C}$ that satisfies

$$(Ju, v) = i(u, v), \quad (u, v) = \overline{(v, u)}.$$

If we write $(u, v) = \varphi(u, v) - i\psi(u, v)$, then

- φ is symmetric, $\varphi(Ju, Jv) = \varphi(u, v)$.
- ψ is alternating, $\psi(Ju, Jv) = \psi(u, v)$.
- $\psi(u, v) = -\varphi(u, Jv), \varphi(u, v) = \psi(u, Jv)$.

Conversely, if φ satisfies this condition, then

$$(u, v) = \varphi(u, v) + i\varphi(u, Jv).$$

is a Hermitian form. Also $(-,-)$ is positive or non-singular iff φ is.

Lemma (2.3.8.2). Any eigenvalue of a Hermitian(e.g., real symmetric) matrix M is real.

Proof: Consider the bilinear form defined by the matrix M, then if x is an eigenvector with eigenvalue λ, then $\lambda(x, x) = (Hx, x) = (x, Hx) = \overline{\lambda}(x, x)$, so if λ is not real, $x = 0$. □

Prop. (2.3.8.3) [Principal Axis Theorem]. A symmetric matrix A is orthogonally diagonalizable. Similarly, a Hermitian matrix is unitarily diagonalizable.

Proof: Firstly, we can find an eigenvector of A: Only the real case needs proof, and this is because any eigenvalue of A is real(2.3.8.2).

Let v be an eigenvector of A of length 1, then the orthogonal complement of v is preserved by A, so we can use induction to find an orthonormal basis consisting of eigenvectors of A, then these together with v forms an orthonormal basis consisting of eigenvectors of A. □

Prop. (2.3.8.4)[Complex Normal operators]. More generally, a normal operator over $\mathbb{C}$ is unitarily diagonalizable using resolution of identity(10.10.4.3) because the spectrum are discrete thus the point projection is orthogonal.

Prop. (2.3.8.5)[Gram-Schimidt]. Any symmetric matrix over fields of characteristic$\neq 2$ is congruent to a diagonal matrix.

Proof: Any symmetric matrix defines a bilinear form on V. If B is not identically 0, then there is a x that $x^tBx \neq 0$, by polarization identity. Then $W = \{Kx\}$ is non-degenerate, so we have $W \oplus W^\perp = V$ by(12.5.1.8). And by induction, we are done. □

Prop. (2.3.8.6) [Antonne-Takagi]. For any complex symmetric matrix A, there is unitarily matrix U that UAU^t is a real diagonal matrix with non-negative entries.

Proof: Consider $B = A^*A$ is Hermitian and positive-semi-definite, thus there is a unitary matrix V that V^*BV is diagonal with non-negative real entries by(2.3.8.3). Now $C = V^tAV$ is complex symmetric with C^*C real diagonal. If we let $C = X + iY$, then $XY = YX$. So by(2.3.6.5), there is a real orthogonal matrix W that WXW^t and WYW^t are diagonal. Now set $U = WV^t$, which is unitary, UAU^t is complex diagonal. And easily we can modify the diagonal entries to be non-negative. □

Prop. (2.3.8.7)[Skew-Symmetric Forms]. For any f.d. skew-symmetric vector space V over a field k with char $k \neq 2$, then there exists a basis $\{x_1, \ldots, x_r, y_1, \ldots, y_r, z_1, \ldots, z_k\}$ s.t. $(x_i, y_i) = -(y_i, x_i) = 1$, and the inner product of other pairs in this basis vanish.

In particular, if V is non-degenerate, then $\dim V$ is even.

Proof: Use induction on $\dim V$. If $\dim V = 0$, this is clear. For $\dim V > 0$, if there exists a pair $(x, y) \neq 0$, then we can take $(x, y) = 1$, and we can look at the complement $\{x, y\}^\perp \subset V$ and use induction. □

Prop. (2.3.8.8). Given a bilinear form on a field, the relation of orthogonality is symmetric iff it is symmetric or alternating, i.e. $B(x, x) = 0$.

Proof: Let $w = B(x, z)y - B(x, y)z$, then $B(x, w) = 0$, hence we have $B(w, x) = 0$, that is

$$B(x, z)B(y, x) - B(x, y)B(z, x) = 0.$$

Let $z = x$, then $B(x, x)[B(x, y) - B(y, x)] = 0$.

If some $B(u, v) \neq B(v, u)$ and $B(w, w) \neq 0$, then $B(u, u) = B(v, v) = 0, B(w, v) = B(v, w), B(w, u) = B(u, w)$, Let $x = u$ or v se get $B(w, v) = B(v, w) = 0 = B(w, u) = B(u, w)$. Now $B(u, w + v) \neq B(w + v, u)$, hence $B(w + v, w + v) = 0 = B(w, w)$, contradiction. □

Prop. (2.3.8.9). If B is a non-degenerate bilinear form on an associative algebra V, choose a basis x_i of V, then choose a dual basis y_i, then $\sum x_i \otimes y_i \in T(V)$ is independent of x_i chosen.

Proof: Let $V^\vee$ be the dual of the vector space V. There is an isomorphism $V \otimes V^\vee \cong \mathrm{End}(V)$ given by mapping (v, f) to the operator $v' \mapsto f(v')v$. The non-degenerate bilinear form induces naturally an isomorphism $\beta : V \cong V^\vee : v \mapsto (\cdot, v)$. Then under the isomorphisms

$$\mathrm{End}(V) \cong V \otimes V' \cong V \otimes V,$$

where the second isomorphism is $(\mathrm{id}_V, \beta^{-1})$. The identity map $\mathrm{id}_V \in \mathrm{End}(V)$ is send to $\sum x_i \otimes y_i \in T(V)$, so $\sum x_i \otimes y_i$ is independent of the basis chosen. □

Symmetric Bilinear Forms

For symmetric bilinear forms and more about quadratic forms, see12.5.

Real Spectral Theory

Remark (2.3.8.10). The general spectral theory4 applies to this case.

Prop. (2.3.8.11). For a normal operator N on a real inner product space, $N\alpha = 0$ iff $N^t\alpha = 0$. In particular, N and N^t has the same number of eigenvalues and dimension of eigenspaces.

Proof: This is because

$$(N\alpha, N\alpha) = (N^tN\alpha, \alpha) = (NN^t\alpha, \alpha) = (N^t\alpha, N^t\alpha).$$

□

Cor. (2.3.8.12). For a normal operator N on a real inner product space, $\mathrm{Im}(N) = \ker(N)^\perp$.

Proof: $\mathrm{Im}(N) = \ker(N^*) = \ker(N)$. □

Cor. (2.3.8.13). For a normal operator N on a real inner product space, if $N^2\alpha = 0$, then $N\alpha = 0$.

Proof: This is because $N\alpha \in \ker(N) \cap \mathrm{Im}(N) = \varnothing$. □

Lemma (2.3.8.14). If f, g are relatively prime polynomials and T is a normal operator, $f(T)\alpha = 0$ and $g(T)\beta = 0$, then α is orthogonal to β.

Proof: Choose polynomials a, b that $af + bg = 1$, then $\alpha = b(T)g(T)\alpha$, and

$$(\alpha, \beta) = (b(T)g(T)\alpha, \beta) = (b(T)\alpha, g(T)^*\beta)$$

Notice $g(T)$ is also normal, and $g(T)\beta = 0$, thus by(2.3.8.11) $g(T)^*\beta = 0$. Thus α, β are orthogonal. □

Lemma (2.3.8.15). Let V be a real inner product space and S an operator that $S^2 = -1$. Suppose $\alpha \in V$ and $S\alpha = -\beta$, then

$$S^*\alpha = \beta, \quad S^*\beta = -\alpha,$$

α, β are orthogonal, and $||\alpha|| = ||\beta||$.

Proof: Because

$$0 = ||S\alpha + \beta||^2 + ||S\beta - \alpha||^2 = ||S\alpha||^2 + ||\beta||^2 + 2(S\alpha, \beta) + ||S\beta||^2 + ||\alpha||^2 - 2(S\beta, \alpha),$$

and S is normal, we get

$$0 = ||S^*\alpha||^2 + ||\beta||^2 - 2(S^*\alpha, \beta) + ||S^*\beta||^2 + ||\alpha||^2 + 2(S^*\beta, \alpha) = ||S^*\alpha - \beta||^2 + ||S^*\beta + \alpha||^2,$$

which gives the desired equation. And also

$$(\alpha, \beta) = (-S^*\beta, \beta) = -(\beta, S\beta) = -(\beta, \alpha)$$

which implies $(\alpha, \beta) = 0$. □

Prop. (2.3.8.16) [Real Normal Operators]. Let A be a normal matrix, then A is orthogonally congruent to matrixes of the form $\mathrm{diag}(B_1, \ldots, B_n)$, where B_i are 1×1 or 2×2 matrices of the form $\begin{bmatrix} a & b \\ -b & a \end{bmatrix}$.

Proof: Firstly the minimal polynomial of A is a product of different irreducible polynomials $p = p_1 \ldots p_k$, by(2.3.8.13). Let $f_i = p/p_i$, then $f_1, \ldots, f_k$ are relatively prime, so there are polynomials g_i that $1 = \sum f_i g_i$. Then for any $v \in V$, $v = \sum f_i(T)g_i(T)v$, and $f_i(T)g_i(T)v$ is annihilated by $p_i(T)$. Let $W_i = \ker(p_i(T))$, then $V = \sum W_i$, and W_i is orthogonal to W_j by(2.3.8.14).

The restriction of T on W_i has minimal polynomial p_i. If p_i has degree1, then T is a scalar on W_i. If p_i has degree2, then $p_i = (x - a_i)^2 + b_i^2$ for some $a_i, b_i \in \mathbb{R}, b \neq 0$. Then we choose a maximal k that there exists subspaces $V_j \in W_i, j \leq k$ that

- $\dim V_j = 2$.
- V_j are pairwisely orthogonal.
- V_j is invariant under T, T^*, and $T|_{V_i}$ is orthogonal congruent to $\begin{bmatrix} a_i & b_i \\ -b_i & a_i \end{bmatrix}$.

Then denote $W = \oplus_{j=1}^k V_j$, we prove that $W = V$: Suppose not, then $W^\perp \neq 0$ is invariant under T and T'. Denote $S = b^{-1}(T - a)$, then $S^2 + 1 = 0$. Let $\alpha \neq 0 \in W^\perp$, $\beta = -S\alpha$, then $S\beta = \alpha$, $\alpha, \beta \in W^\perp$. Since $T = aI + bS$, we have

$$T\alpha = a\alpha - b\beta, \quad T\beta = b\alpha + a\beta.$$

Now lemma(2.3.8.15) implies $\{\alpha, \beta\}$ is invariant under S, S^* thus also T, T^*, so this gives another V_{k+1}, contradiction. □

Cor. (2.3.8.17) [Unitary Equivalence of Normal Operators]. Let T, T' be real(complex) normal matrices, then T is orthogonally(unitarily) congruent to T' iff T and T' have the same characteristic polynomial.

Proof: This follows from(2.3.8.16)(or (2.3.8.4)). □

Cor. (2.3.8.18) [Complex Structure Form]. A real normal matrix J s.t. $J^2 + 1 = 0$ is orthogonal congruent to $\langle \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \rangle_n$.

In particular, as such J is equivalent to a complex structure on $\mathbb{R}^n$, so the set of complex structures is bijective to $O(n)/U(\frac{n}{2})$ thus can be endowed with a structure of a homogenous space.

Proof: This is because J and $\langle\begin{bmatrix}0 & -1\\ 1 & 0\end{bmatrix}\rangle_n$ are both normal and they have the same characteristic polynomial, by(2.3.5.3). ☐

Def. (2.3.8.19)[Cayley-transformation]. For a field k of char$k \neq 2$ and a matrix $P \in M_n(k)$ that has no eigenvalue -1, there is a **Cayley transformation** $A = \frac{1-P}{1+P}$,. $1 + A$ is invertible, and $P = \frac{1-A}{1+A}$.

Then A is skew-symmetric iff P is orthogonal.

Proof: If $Av = -v$, then $v - Pv = -v - Pv$, so $2v = 0$, so $v = 0$. So $A + 1$ is invertible.

If P is orthogonal, then $A^t = \frac{1-P^t}{1+P^t} = \frac{1-P^{-1}}{1+P^{-1}} = -A$. Conversely, if $A^t = -A$, then $P^t = \frac{1+A}{1-A} = P^{-1}$. ☐

Prop. (2.3.8.20). If char$k \neq 2$ and P is an orthogonal matrix of odd dimension, then $\det P$ is an eigenvalue of P.

Proof: multiplying by -1, we can assume $\det P = -1$. Consider the Cayley transformation(2.3.8.19), then

$$\det P = \det(1 - A)\det(1 + A)^{-1} = \det(1 - A)^t \det(1 + A)^{-1} = 1.$$

Contradiction. ☐

Hermitian Spaces

Def. (2.3.8.21) [Hermitian Space]. Let E be a field, F a Galois extension of E of degree 2 with involution $x \mapsto \overline{x}$ or $E \oplus E$ with involution $\overline{(x, y)} = (y, x)$.

Then a **Hermitian space** over F/E is a free F-module V with a E-map $(\cdot, \cdot) : V \times V \to F$ s.t.

- $(cx, y) = (x, \overline{c}y) = c(x, y)$ for $c \in F$.
- $(x, y) = \overline{(y, x)}$.
- the pairing is non-degenerate.

Def. (2.3.8.22) [Hermitian Transpose]. Let $L : V \to W$ be a map between Hermitian spaces, then there is a **Hermitian transpose** F-anti-linear map $L^* : W^* \to V^*$ that satisfies

$$(Lu, w) = (u, L^*w).$$

As the pairing on V is non-degenerate, this is map is uniquely determined.

Def. (2.3.8.23) [Hermitian Matrix]. A **Hermitian matrix** is a matrix $A \in M_{n\times n}(\overline{F})$ that satisfies $A^t = \overline{A}$.

Prop. (2.3.8.24) [Gram Matrix]. Let V be a n-dimensional vector space with a canonical basis $e_1, \ldots, e_n$, then a $n \times n$ symmetric(Hermitian) matrix M defines a bilinear(sesqui-linear) form B on V by $(x, y) \mapsto x^t My(x^t M\overline{y})$. Conversely, for any bilinear(sesqui-linear) form B on V, let $M = (a_{ij})$ where $a_{ij} = (e_i, e_j)$, then M is symmetric(Hermitian) matrix, called the **Gram matrix** of B.

so we will interchange freely between a symmetric(Hermitian) matrix and a bilinear(sesqui-linear) form on V.

Proof: Trivial. ☐

9 Tensor Algebras

Def. (2.3.9.1) [Tensor Algebras]. The tensor product and tensor algebras of modules are defined in(2.2.4.13) and(4.1.1.20). In this subsection, we focus on tensor algebras of vector spaces.

Def. (2.3.9.2)[Symmetrized Tensors]. Let V be a vector field over a field of characteristic 0, for any n, we define a multilinear map

$$V^n \to T^n(V) : (v_1, \ldots, v_n) \mapsto \frac{1}{n!} \sum_{\sigma \in S_n} v_{\sigma(1)} \otimes \ldots \otimes v_{\sigma(n)}.$$

and descends to a linear map $\sigma : S^n(V) \to T^n(V)$, called the symmetrizer. Elements in $\mathrm{Im}(\sigma) = \widetilde{S}^n(V)$ is called **symmetrized tensors**.

Then $\sigma^2 = \sigma$, and $\ker(\sigma) = I \cap T^n$, where $I = \ker(T(V) \to Sym(V))$. In particular,

$$T^n(V) = \widetilde{S}^n(V) \oplus (T^n(V) \cap I).$$

Proof: $\sigma^2 = \sigma$ is easy. So $V = \mathrm{Im}(\sigma) \oplus \ker(\sigma)$. Now $T^n(V) \cap I \subset \ker(\sigma)$, and because $\mathrm{Im}(\sigma) \to S^n(V)$ is surjective, $T^n(V) \cap I = \ker(\sigma)$. □

Def. (2.3.9.3) [Anti-Symmetrized Tensors]. Let V be a vector field over a field of characteristic 0, for any n, we define a multilinear map

$$V^n \to T^n(V) : (v_1, \ldots, v_n) \mapsto \frac{1}{n!} \sum_{\sigma \in S_n} \mathrm{sgn}(\sigma) v_{\sigma(1)} \otimes \ldots \otimes v_{\sigma(n)}.$$

and descends to a linear map $\sigma : \wedge^n(V) \to T^n(V)$, called the anti-symmetrizer. Elements in $\mathrm{Im}(\tau) = \widetilde{\wedge}^n(V)$ is called **anti-symmetrized tensors**.

Then $\tau^2 = \tau$, and $\ker(\tau) = I \cap T^n$, where $I = \ker(T(V) \to \wedge(V))$. In particular,

$$T^n(V) = \widetilde{\wedge}^n(V) \oplus (T^n(V) \cap I).$$

Proof: $\sigma^2 = \sigma$ is easy. So $V = \mathrm{Im}(\sigma) \oplus \ker(\sigma)$. Now $T^n(V) \cap I \subset \ker(\sigma)$, and because $\mathrm{Im}(\sigma) \to S^n(V)$ is surjective, $T^n(V) \cap I = \ker(\sigma)$. □

10 Determinant and Trace

Def. (2.3.10.1) [Determinant]. For a linear operator $T \in L(V)$, as $\dim \wedge^n V^* = 1$, the **determinant** $\det(T) \in R$ is defined by $\wedge^n(T^t) = \det T \cdot \mathrm{id}_{\wedge^n V^*}$. That is: $L(T\alpha_1, \ldots, T\alpha_n) = \det T L(\alpha_1, \ldots, \alpha_n)$. And the determinant of a matrix is defined by the linear operator it associates in a canonical basis.

Prop. (2.3.10.2) [Properties of Determinants].

1. $\det(\mathrm{id}_V) = 1$.
2. $\det(UV) = \det U \cdot \det V$.
3. T is invertible iff $\det T$ is invertible, in which case $\det(T^{-1}) = (\det T)^{-1}$.
4. If $\{\alpha_1, \ldots, \alpha_n\}$ is a basis for V, and f_i is its dual basis, then $\det T = f_1 \wedge \ldots \wedge f_n(T\alpha_1, \ldots T\alpha_n)$.

Proof: All these are not hard. □

Cor. (2.3.10.3). $\det(P^{-1}AP) = \det(A)$.

Prop. (2.3.10.4). $\det T = \det T^t$.

Proof: Use(2.3.10.2), if $\{\alpha_1,\ldots,\alpha_n\}$ is a basis for V, and f_i is its dual basis, then

$$\det T^t = \alpha_1\wedge\ldots\wedge\alpha_n(T^t f_1,\ldots,T^t f_n) = f_1\wedge\ldots\wedge f_n(T\alpha_1,\ldots T\alpha_n) = \det T$$

□

Prop. (2.3.10.5) [Expansion of Determinants]. If A_i be the i-th column of A, then

$$\det A = f_1\wedge\ldots\wedge f_n(A\varepsilon_1,\ldots,A\varepsilon_n) = f_1\wedge\ldots\wedge f_n(A_1,\ldots,A_n) = \sum_{\sigma\in S_n}\operatorname{sgn}(\sigma)\prod_{1\le i\le n}A_{\sigma(i)i}.$$

Prop. (2.3.10.6). For a matrix, the determinant satisfies the following properties:

1. adding a multiple of a column/row to another column/row, the determinant doesn't change.
2. Multiplying a row or a column with a scalar, then the determinant multiplies with this scalar.
3. Changing two rows or two columns makes the determinant multiply by -1.

Proof: All this follows from 4 of(2.3.10.2). Notice the last one follows from the first two. □

Prop. (2.3.10.7) [Laplacian Expansion Formula]. Cf.[Determinant 安金鹏 P15].

Prop. (2.3.10.8). Adjunction matrix, Cf.[Determinant 安金鹏 P16].

Proof: □

Cor. (2.3.10.9). If $AB = 1$, then $BA = 1$.

Prop. (2.3.10.10) [Cramer's Rule]. Cf.[Determinant 安金鹏 P16].

Prop. (2.3.10.11) [Binet's Formula]. Let F/E be a Hermitian pair, $A \in M_{n\times m}(F)$, then

$$\det(A^*A) = \sum_{I\in\{0,\ldots,n\},\#I=m} |\det(A_I)|^2.$$

Proof: Let $L : F^m \to F^n$ be the corresponding map, then $\wedge^n(L^*)\circ\wedge^n(L) = \wedge^n(L^*\circ L)$. In the canonical basis, the matrices for $\wedge^n(L^*)$(resp. $\wedge^n(L)$) have only one column(resp. one row) with entries $\det(A_I)$ by definition(2.3.10.1), thus the assertion follows by(2.3.10.1) again. □

Prop. (2.3.10.12) [Sylvester's Determinant Identity]. If A and B are matrices of sizes $m\times n$ and $n\times m$, then

$$\det(I_m + AB) = \det(I_n + BA)$$

Proof: Notice

$$\begin{aligned}\begin{bmatrix}1 & A\\ B & 1\end{bmatrix} &= \begin{bmatrix}1 & 0\\ B & 1\end{bmatrix}\begin{bmatrix}1 & 0\\ 0 & 1-BA\end{bmatrix}\begin{bmatrix}1 & A\\ 0 & 1\end{bmatrix}\\ &= \begin{bmatrix}1 & A\\ 0 & 1\end{bmatrix}\begin{bmatrix}1-BA & 0\\ 0 & 1\end{bmatrix}\begin{bmatrix}1 & 0\\ B & 1\end{bmatrix}\end{aligned}$$

and use(2.3.10.2). □

Cor. (2.3.10.13). Multiplying by x, we see that the characteristic polynomial of AB and BA are the same.

Remark (2.3.10.14). There is another proof in case $m = n$: It suffices to show

$$\det(I + (A + xI)(B + xI)) = \det(I + (B + xI)(A + xI)).$$

But notice $A + xI$ and $B + xI$ are invertible in $M_{n\times n}(K(X))$, thus

$$\det(I + (A + xI)(B + xI)) = \det((A + xI)((A + xI)^{-1} + (B + xI))) = \det(I + (B + xI)(A + xI)).$$

Prop. (2.3.10.15).

$$\det \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \det(A)\det(D - CA^{-1}B).$$

Proof: As before, consider $\det \begin{bmatrix} A + xI & B \\ C & D + xI \end{bmatrix}$, then $A + xI$ is invertible, and this equals

$$\det \begin{bmatrix} A + xI & B \\ C & D + xI - C(A + xI)^{-1}B \end{bmatrix} = \det(A + xI)\det(D + xI - C(A + xI)^{-1}B).$$

Letting $x = 0$, we get the desired result. □

Prop. (2.3.10.16) [Symplectic Group Determinant]. The determinant of a symplectic matrix $\in \mathrm{Sp}(2n, \mathbb{R})$ has determinant 1.

Proof: A symplectic matrix preserves the symplectic structure thus the symplectic form ω, hence preserves ω^n which is $n!$ times the volume form, so it has determinant 1 by definition(2.3.10.1). □

Prop. (2.3.10.17) [Vandermonde Matrix]. The $n \times n$ Vandermonde matrix, with the k-th row $(1, x_k, \ldots, x_k^n)$, has determinant $\prod_{i<j}(x_i - x_j)$. So it is invertible when x_i are pairwisely different.

Proof: Eliminate the first row by adding columns. □

Prop. (2.3.10.18)[Pfaffian]. There is a polynomial Pf called **Pfaffian** s.t. $\det M = \mathrm{Pf}(M)^2$ for a skew-symmetric matrix. This is because a skew symmetric is equal to $A^t \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}^k A$ for A an orthogonal matrix (2.3.8.3), so it has determinant $(\det A)^2$ and A and depends polynomially on the entries of M.

Cor. (2.3.10.19).

$$\mathrm{Pf}(A^t MA) = \det A \cdot \mathrm{Pf}(M).$$

Because we only need to consider the sign and it is determined by letting $A = \mathrm{id}$.

Traces

Def. (2.3.10.20)[Trace]. For a $n \times n$-matrix A, define its **trace** $\mathrm{tr}(A)$ to be the minus of the coefficient of x^{n-1} in $\det(xI - A)$. It is clear that $\mathrm{tr}(A) = \sum_{i=1}^n a_{ii}$, and by(2.3.10.3) that traces are invariant under conjugacy.

Prop. (2.3.10.21). $\operatorname{tr}(AB) = \operatorname{tr}(BA)$.

Proof: This is because $\det(x - AB) = \det(x - BA)$ by Sylvester determinant identity(2.3.10.12). □

Prop. (2.3.10.22) [Trace Formula]. For $V \in \mathcal{V}\mathrm{ect}/k, F \in \operatorname{End}(V), d \in \mathbb{Z}_+$,

$$t\frac{d}{dt}\log\det(1 - FT^d)^{-1} = \sum_{i\geq 1} d\operatorname{tr}(F^i|V)T^i \in 1 + Tk[[T]].$$

In particular, if $\operatorname{char} k = 0$,

$$\det(1 - FT^d|V)^{-1} = \exp(\sum_{i\geq 1}\operatorname{tr}(F^i|V)\frac{T^{di}}{i}) \in 1 + Tk[[T]].$$

Proof: Pass to $\overline{k}$ and let $k_1, \ldots, k_r$ be the eigenvalues of F. □

11 (Real)Quaternion Algebra

Remark (2.3.11.1). The argument below are largely true for any skew field.

Def. (2.3.11.2) [Real Quaternion Algebra]. The **real quaternion algebra** $\mathbb{H}$ is the space $\mathbb{R}\{1, i, j, k\}$ subjects to the relations

$$ij = -ji = k, jk = -kj = i, ki = -ik = j, i^2 = j^2 = k^2 = -1.$$

In fact, by(12.5.5.6), any quaternion algebra over $\mathbb{R}$ is isomorphic to $\mathbb{H}$.

Prop. (2.3.11.3) [Module of Quaternion Algebras]. There is an involution on $\mathbb{H}$ that $\overline{x} = \overline{a + bi + cj + dk} = a - bi - cj - dk$. Then we define a the module of $x \in \mathbb{H}$ as

$$|x|^2 = x\overline{x} = \overline{x}x = a^2 + b^2 + c^2 + d^2.$$

Then every non-zero element of $\mathbb{H}$ is invertible. In particular, it is a skew field.

Prop. (2.3.11.4). $\mathbb{H}$ is isomorphic to subalgebra of matrices in $M(2, \mathbb{C})$ consisting of elements of the form

$$\{\begin{bmatrix}\alpha & -\overline{\beta}\\ \beta & \overline{\alpha}\end{bmatrix} | \alpha, \beta \in \mathbb{C}\}$$

Prop. (2.3.11.5). The center of $\mathbb{H}$ is $\mathbb{R}$, by(12.5.4.3).

Prop. (2.3.11.6) [Invertible Quaternion Matrices]. Denote $GL(n, \mathbb{H})$ the set of invertible matrices in $M_n(\mathbb{H})$. If $A \in M_n(\mathbb{H})$, A acts on $\mathbb{H}^n$, and determines a complex matrix A' in $M_{2n}(\mathbb{C})$.

- If $A, B \in M_n(\mathbb{H})$ satisfies $AB = 1$, then $BA = 1$.
- $A \in M = GL(n, \mathbb{H})$ iff $A' \in GL(2n, \mathbb{C})$. In particular if we define the determinant of $A \in M_n(\mathbb{H})$ as the determinant of A', then $\det(A) \neq 0$ iff A is invertible.

Proof: 1: $(AB)' = A'B'$, thus $M_n(\mathbb{H})$ is a subalgebra of $M_{2n}(\mathbb{C})$. Thus $B'A' = 1$ by(2.3.10.9).

2: If A' is invertible, then A is a bijection, thus there are vectors $v_1, \ldots, v_n$ that $Av_i = e_i$. This means

$$(v_1, \ldots, v_n)A = 1.$$

Thus by item1 A is invertible. □

Def. (2.3.11.7) [Sesquilinear Form on $\mathbb{H}^n$]. Let $V = \mathbb{H}^n$, then a **sesquilinear form** on $\mathbb{H}^n$ is a bi-additive function $(\cdot,\cdot) : V \times V \to \mathbb{H}$ such that

$$(x\alpha, y\beta) = \overline{\alpha}(x,y)\beta, \quad \alpha,\beta \in \mathbb{H}.$$

Moreover if it is called a Hermitian form iff $(x,y) = \overline{(y,x)}$, and skew-Hermitian iff $(x,y) = -\overline{(y,x)}$.

Prop. (2.3.11.8) [Quaternion Hermitian Forms].

- Every non-degenerate Hermitian quaternion form is of the form

$$(x,y) = \overline{x}_1 y_1 + \ldots \overline{x}_p y_p - \overline{x_{p+1}} y_{p+1} - \ldots - \overline{x}_n y_n$$

  in some basis. And p is uniquely determined.

- Every non-degenerate skew-Hermitian quaternion form is of the form

$$(x,y) = \overline{x}_1 j y_1 + \ldots + \overline{x}_n j y_n$$

  in some basis.

Proof: Firstly, there are some v that $(v,v) \neq 0$: If $(v,v) = 0$ for all v, then $(x,y) + (y,x) = 0$ for all x,y. If it is skew-Hermitian, this means (x,y) is real, which is impossible, unless $(x,y) = 0$. If it is Hermitian, this means (x,y) is imaginary, but $(x,yi),(x,yj),(x,yk)$ are all imaginary, thus $(x,y) = 0$.

Then choose this v, and take the orthogonal complement of v, then by induction we can find $v_1,\ldots,v_n$ that is mutually orthogonal.

If it is Hermitian, then $(v_i,v_i) \in \mathbb{R}$, thus we can find some $t_i \in \mathbb{R}$ that $(tv_i,tv_i) = \pm 1$. $2p$ is the multiplicity of the eigenvalue 1 of the eigenspace of to the matrix corresponding to the form, so p is uniquely defined.

If it is skew-Hermitian, then (v_i,v_i) is imaginary, thus by(11.7.4.7), there are $u_i \in \mathbb{H}$ that $(u_i v_i, u_i v_i) = \overline{u}_i (v_i,v_i) u_i = j$. □

Cor. (2.3.11.9).

- Every non-degenerate Hermitian quaternion form is of the form

$$(x,y) = B_1(x,y) + jB_2(x,y)$$

  in some basis, where $B_1(x,y)$ is the usual canonical Hermitian form of signature $(2p,2q)$, and B_2 is the usual canonical skew-symmetric bilinear form. Also $B_2(x,y) = B_1(xj,y)$.

- Every non-degenerate skew-Hermitian quaternion form is of the form

$$(x,y) = B_1(x,y) + jB_2(x,y)$$

  in some basis, where $B_1(x,y)$ is the usual canonical skew-Hermitian form that iB_1 is Hermitian of signature $(n,-n)$, and B_2 is the usual canonical symmetric bilinear form. Also $B_2(x,y) = B_1(xj,y)$. in some basis.

12 Others

Prop. (2.3.12.1). Let $H^* = \oplus_{i=0}^{2d} H^i$ be a graded algebra over a field s.t. $\dim H^i < \infty$ for each i. Assume that for each $0 \leq i \leq 2d$, there is a perfect pairing

$$H^i \times H^{2d-i} \to K$$

induced from an isomorphism $\mathrm{tr} : H^{2d} \cong K$, Let φ be a ring endomorphism of H^* that satisfies

- $\varphi(H^i) \subset H^i$,
- $\varphi_{2d} = \mathrm{id}$

Then each φ_i is invertible, and $\varphi_i^{-1} = \varphi_{2d-i}^t$, where φ_{2d-i}^t is the transpose of φ_{2d-i} w.r.t. the perfect pairing $H^i \times H^{2d-i} \to K$.

Proof: Let $a \in H^i$ be any element, if $a \neq 0$, then because the pairing $H^i \times H^{2d-i} \to K$ is perfect, there exists some $b \in H^{2d-i}$ s.t. $ab \neq 0$. Thus $\varphi_i(a)\varphi_{2d-i}(b) \neq 0$, thus φ_i is injective. Now $\mathrm{tr}(\varphi_i^{-1}(a)b = \mathrm{tr}(\varphi_{2d}(\varphi_i^{-1}(a)b)) = \mathrm{tr}(a\varphi_{2d-i}(b))$, thus $\varphi_i^{-1} = \varphi_{2d-i}^t$. □

2.4 More on (Non-Commutative)Algebras

Main references are [Noncommutative Rings, T.Y.Lam], [Lan05]Chap17 and [Sta]Chap11.

Notation (2.4.0.1).
- Use notations defined in Abstract Algebra.

1 Semisimplicity

Def. (2.4.1.1). For $R \in \mathcal{R}\text{ing}$, a **simple R-module** is a $E \in \mathcal{M}\text{od}_R$ that no submodules other than 0 and E. It is called **faithful** iff there is no nonzero element $a \in R$ that $ax = 0$ for any $x \in E$.
It is called **non-degenerate** if $RE = E$.

Prop. (2.4.1.2) [Shur's lemma]. For $R \in \mathcal{R}\text{ing}$ and E a simple R-module, $\mathrm{End}_R(E)$ is a division ring, this is because the kernel and image are all 0 or E.

Cor. (2.4.1.3) [Uniqueness of Decomposition of Modules]. If an R-module E can be written as a finite direct sum of simple R-modules in multiple ways, then the multiplicity of the irreducible modules appearing in it is uniquely determined.

Proof: Cf.[Lang, Algebra, P643] □

Def. (2.4.1.4) [Semisimple Modules]. For $R \in \mathcal{R}\text{ing}$, a **semisimple R-module** is a $E \in \mathcal{M}\text{od}_R$ iff it satisfies the following equivalent conditions:
- It is a sum of simple modules.
- It is a direct sum of simple modules.
- Any submodule F of E has a complement in E.

Proof: $3 \to 2$: By Zorn's lemma, it suffices to show any non-zero semisimple module contains a simple submodule: Take a $m \neq 0 \in M$, then we may assume $M = Rm$, and by Zorn's lemma there is a maximal submodule N that $m \notin N$, and let $N \oplus N' = M$, then we show N' is simple. because any submodule N'' satisfies $m \in N \oplus N''$ thus $N'' = N'$.

$2 \to 1$ is immediate, it suffices to show $1 \to 3$: for any submodule $N \subset M$, consider all the simple modules that intersect N trivially, denote their sum by V, I claim $N \oplus V = M$, otherwise, let S be a simple submodule that contained in $N + V$, then $S \cap (N + V) = 0$, so $N \cap (S + V) = 0$, contradicting the maximality. □

Cor. (2.4.1.5). For $R \in \mathcal{R}\text{ing}$, any submodule and quotient module of a semisimple R-module is semisimple.

Proof: The quotient is clearly a sum of simple modules, and for a submodule, its submodule has a complement. □

Density Theorems

Def. (2.4.1.6). If E be a semisimple R-module, let $R' = \mathrm{End}_R(E)$, then E is also a R'-module, where the action is given by $(\varphi, x) \mapsto \varphi(x)$. Then any element of R defines an element of $\mathrm{End}_{R'}(E)$ by left multiplication. If we called $\mathrm{End}_{R'}(E)$ the **bicommutatant** of E over R, then

Lemma (2.4.1.7). For a module E over R, let $\mathrm{End}_{R'}(E)$ be the bicommutant. If $f \in \mathrm{End}_{R'}(E)$ and $x \in E$, then there is an element $\alpha \in R$ that $\alpha x = f(x)$.

Proof: Since E is semisimple, write $E = Rx \oplus F$, and let π be the projection unto Rx, then $\pi \in \mathrm{End}_R(E)$, and $f(x) = f(\pi(x)) = \pi f(x) \in Rx$. □

Prop. (2.4.1.8) [Jacobson Density Theorem]. Let E be semisimple over R and let $R' = \mathrm{End}_R(E)$. If $f \in \mathrm{End}_{R'}(E)$ and $x_1, \ldots, x_n \in E$, then there is an element $\alpha \in R$ that $\alpha x_i = f(x_i)$ for all i.

In particular, if E is f.g. over R', the natural map $R \to \mathrm{End}_{R'}(E)$ is surjective.

Proof: Consider $f^n \in \mathrm{End}_R(E^n)$, then it is just a $n \times n$ matrix with entries in $R' = \mathrm{End}_R(E)$. Consider the lemma(2.4.1.7) shows there is an $\alpha \in R$ that

$$(\alpha x_1, \ldots, \alpha x_n) = (f(x_1), \ldots, f(x_n))$$

which is the result. □

Cor. (2.4.1.9) [Wedderburn Theorem]. Let $R \in \mathcal{R}\mathrm{ing}$ and E is a faithful simple R-module. Let $D = \mathrm{End}_R(E)$. If E is of f.g. over D, then $R = \mathrm{End}_D(E)$.

Proof: The density theorem(2.4.1.8) and the fact E is f.g. over D shows that $R \to \mathrm{End}_k(E)$ is surjective, and also injective because it is faithful, thus $R = \mathrm{End}_k(E)$. □

Cor. (2.4.1.10) [Burnside's Theorem]. Let E is an R-module that is f.d over an alg.closed field k and R is a subalgebra of $\mathrm{End}_k(E)$. If E is simple as an R-module, then $R = \mathrm{End}_k(E)$.

Proof: It follows from Shur's lemma(2.4.1.2) and(2.2.1.10) $R' = \mathrm{End}_R(E)$ is just k, so we can use Wedderburn's theorem(2.4.1.9). □

Cor. (2.4.1.11) [F.d. Simple Module over Commutative Algebra]. If R is commutative and E is a simple R-module of f.d. over an alg.closed field k, then E is of 1-dimensional.

Proof: The theorem shows the image of R in $\mathrm{End}_k(E)$ is all of $\mathrm{End}_k(E)$, but Shur's lemma(2.4.1.2) and(2.2.1.10) that the image of R consists of scalars, thus $\dim_k E = 1$. □

Prop. (2.4.1.12) [Projection Operators]. Let k be a field and R is a k-algebra. If $V_1, \ldots, V_n$ are pairwise non-isomorphic simple R-modules of f.d. over k, then there exists elements e_i in R that acts as identity on V_i and 0 on other V_j.

Proof: This is an immediate consequence of Jacobson density theorem(2.4.1.8) applied to the projection operator on $\oplus_i V_i$. □

Prop. (2.4.1.13)[Characters Determine F.D. Representations(Bourbaki)]. Let R be an algebra over a field k of char0, E_1, E_2 be two f.d. semisimple R-module over k, then if the character $\chi_1 = \chi_2$, then the R-modules E_1, E_2 are isomorphic.

Proof: E, F are isomorphic to direct sums of simple R-modules, so it suffices to show the multiplicities m, n of any simple module V is the same. We can find an element e that is identity on E and 0 on other simple modules V_i by(2.4.1.12), thus the trace of e on E, F are $m \dim_k(V), n \dim_k(V)$ respectively, thus $m = n$ because k is of char0. □

Def. (2.4.1.14) [Matrix Coefficients]. For an algebra R and an R-module M over a field k, then a **matrix coefficient** of M is a function $c : R \to k$ of the form $c(r) = L(rx)$, where L is a linear functional on M and $x \in M$.

Cor. (2.4.1.15). If R is an algebra over a field k and two simple R-modules that is f.d. over k have a nonzero matrix coefficient in common, then they are isomorphic.

Proof: Let $c(r) = L_1(rx_1) = L_2(rx_2)$. If they are non-isomorphic, then we can find a $e \in R$ that is identity on M_1 and 0 on M_2 by(2.4.1.12). Let $c(u) \neq 0$, then

$$c(ue) = L_1(uex_1) = L_1(ux_1) = c(u) \neq 0, \quad c(ue) = L_2(uex_2) = L_2(0) = 0$$

contradiction. □

Prop. (2.4.1.16) [Simple Modules of Tensor Product]. Let A, B be algebras over a field Ω, $R = A \otimes B$, then:

- If P be a simple R-module of f.d. over Ω, then there is a simple A-module M and a simple B-module N that P is isomorphic to a quotient of $M \otimes N$. Also the isomorphism classes of M, N are uniquely determined.
- If Ω is alg.closed and M, N are simple modules of A, B of f.d. over Ω, then $M \otimes N$ is a simple module over $A \otimes B$.

Proof: 1: because P is f.d., it contains a simple A-module M. Let $N_1 = \mathrm{Hom}_A(M, P)$, then it is a B-module as A, B commutes in $A \otimes B$. Then we can define a map $\lambda : M \otimes N_1 \to P$, which is a $A \otimes B$-module morphism. Now N_1 is also of f.d., so it contains a simple B-module N, and λ is clearly non-zero on $M \otimes N$, thus its image is all of P, as P is simple.

For the uniqueness, let $d = \dim N$, then P is isomorphic to $k \leq d$ copies of M as an A-module, so the isomorphism class of M is determined, so does that of N.

2: Consider the map of A, B to $\mathrm{End}_\Omega(M), \mathrm{End}_\Omega(N)$ are surjective by(2.4.1.10). Then it suffices to show that $M \otimes N$ are simple over $\mathrm{End}_\Omega(M) \otimes \mathrm{End}_\Omega(N)$, but this is just $\mathrm{End}_\Omega(M \otimes N)$, over which $M \otimes N$ is clearly simple. □

Semisimple Rings and Simple Rings

Def. (2.4.1.17) [Semisimple Ring]. A (left)**semisimple** ring is a ring R s.t. it is a (left)semisimple module over itself. In(2.4.1.23), we will see a semisimple ring is semisimple in both sides.

Prop. (2.4.1.18). Any semisimple ring is left Artinian and Noetherian.

Proof: Consider the decomposition $R = \oplus_\alpha \mathfrak{A}_\alpha$, where $\mathfrak{A}_\alpha$ are simple left R-ideals. Then by considering the decomposition of $1 \in R$, clearly this is a finite sum. The rest is easy. □

Prop. (2.4.1.19). If R is a semisimple ring, then any R-module is semisimple.

Proof: Any R-module is a quotient of a free R-module, thus semisimple, by(2.4.1.5). □

Prop. (2.4.1.20). R is semisimple iff all R-modules are projective.

Proof: If R is left-semisimple, for any R-module P and an exact sequence

$$0 \to N \to M \to P \to 0$$

by(2.4.1.19), there is a complement of N in M, thus this sequence splits and P is projective. The converse is also clear that any submodule of any R-module has a complement. □

Lemma (2.4.1.21). Let D be a division ring and $R = \mathrm{Mat}(n; D)$, then

- R is simple, left semisimple and left Noetherian.
- R has a unique left simple module V, and R acts faithfully on V, with $R \cong nV$.
- $\mathrm{End}_R(V) \cong D$.

Proof: Cf.[Lam, P31]. □

Prop. (2.4.1.22) [Wedderburn-Artin]. Any left semisimple ring is of the form $R \cong \mathrm{Mat}(n_1, D_1) \times \ldots \times \mathrm{Mat}(n_r, D_r)$, and D_k are uniquely determined division rings. There are exactly r different left simple R-modules and D_i are uniquely determined.

Proof: Consider the decomposition

$$R \cong n_1V_1 \oplus \ldots \oplus n_rV_r$$

where V_i are simple left R-modules. Then we can use Schur's lemma(2.4.1.2) and(2.4.1.21) to calculate the endomorphism ring, so

$$R \cong \mathrm{End}(n_1V) \times \ldots \times \mathrm{End}(n_rV_r) \cong \mathrm{Mat}(n_1, D_1) \times \ldots \times \mathrm{Mat}(n_r, D_r).$$

For the uniqueness, we use(2.4.1.21), which shows D_i and V_i both can be recovered. □

Cor. (2.4.1.23). $R \in \mathcal{R}\mathrm{ing}$ is left semisimple iff it is right semisimple.((2.3.1.11) is used).

Cor. (2.4.1.24). A semisimple commutative ring is a finite direct product of fields.

Def. (2.4.1.25) [Semisimple Categories]. Let $k \in \texttt{Field}$ and $\mathcal{A}$ a k-linear Abelian category that $\mathrm{End}(X)$ are all finite k-modules for $X \in \mathcal{A}$, then A is semisimple iff $\mathrm{End}(X)$ is a semisimple k-algebra for any X.

Proof: If $\mathcal{A}$ is semisimple, then any $X \in A$ is a direct sum of simple objects, so $\mathrm{End}(X)$ is semisimple.

Conversely, if $\mathrm{End}(X)$ is semisimple thus a product of matrix algebras over division algebras, so X can be indecomposable only if $\mathrm{End}(X)$ is a division algebra. Now if $f : M \to N$ is a morphism of indecomposable objects, if there is a map $g : N \to M$ that $g \circ f \neq 0$, then $g \circ f$ is an automorphism of M, and $(g \circ f)^{-1} \circ g$ is a right inverse to f, so N is a direct sum of M, and thus f is an isomorphism because M is indecomposable.

Now it suffices to show any indecomposable object is simple. If M is an indecomposable object properly contained in another indecomposable object, then

$$\begin{bmatrix} 0 & 0 \\ \mathrm{Hom}(M, N) & 0 \end{bmatrix} \subset \begin{bmatrix} \mathrm{End}(M) & \mathrm{Hom}(N, N) \\ \mathrm{Hom}(M, N) & \mathrm{End}(N) \end{bmatrix} = \mathrm{End}(M \oplus N)$$

is a two sided nilpotent nonzero ideal, contradicting the fact $\mathrm{End}(M \oplus N)$ is semisimple. □

Prop. (2.4.1.26) [Semisimplicity and Base Change]. If $A \in \mathcal{A}\mathrm{lg}_k$ and $A \otimes_k K$ is semisimple for some field extension K/k, then A is semisimple. Conversely, if A is semisimple, then $A \otimes_k K$ is semisimple for every separable field extension K/k.

Proof: Cf.[Milne, Lie Algebras, Lie Groups and Algebraic Groups]P48. □

Prop. (2.4.1.27) [Characters Determine F.D. Representations]. If R is a semisimple ring over a field k of characteristic 0, then its f.d. representations are determined by their characters, by(2.4.1.13).

Prop. (2.4.1.28) [Simple Artinian Algebras]. For a simple ring R(2.2.1.2), the following are equivalent:

- R is left semisimple.
- R is left Artinian.
- R has a minimal left ideal.
- $R \cong \mathrm{Mat}(n; D)$ for some division ring D.

Proof: The equivalence of $1, 4$ is by Wedderburn theorem(2.4.1.22) and(2.4.1.21). $2 \to 3$ is easy, and for $1 \to 2$, R is a finite direct sum of minimal ideals by Wedderburn theorem(2.4.1.22), so it is Artinian.

For $3 \to 1$, consider all the ideals in R that is isomorphic to the minimal ideal $\mathfrak{A}$, then it is also a right ideal of R, so equals R, hence R is semisimple. □

Cor. (2.4.1.29). And finite simple k-algebra A is of the form $\mathrm{Mat}(n; D)$ where D is a finite division ring over k. This is because A is clearly left Artinian.

Prop. (2.4.1.30) [Double Centralizer Property]. Let R be a simple ring and $\mathfrak{A}$ a nonzero left ideal. Let $D = \mathrm{End}_R(\mathfrak{A})$, then the natural map $f : R \to \mathrm{End}(\mathfrak{A}_D)$ is an isomorphism.

Proof: since R is simple, f is injective. To show it is surjective, let $E = \mathrm{End}(\mathfrak{A}_D)$, then for any $a, r \in \mathfrak{A}$ and $h \in E$, we have $h(ra) = h(r)a$, thus

$$(h \cdot f(r))a = h(ra) = h(r)a = f(h(r))a$$

which shows $f(R)$ is a left ideal in E. And because $\mathfrak{A}R = R$, we have $f(R) = f(\mathfrak{A})f(R)$, then

$$Ef(R) = Ef(\mathfrak{A})f(R) \subset f(\mathfrak{A})f(R) = f(R).$$

which shows $f(R)$ is a left ideal in E, and it contains 1, so $f(R) = E$. □

2 Jacobson Radical Theory

Def. (2.4.2.1) [Jacobson Radical]. For $R \in \mathcal{R}\mathrm{ing}$, the **Jacobson radical** is defined to be the intersection of all maximal left ideals in R.

R is called **Jacobson semisimple** if $\mathrm{rad}\, R = 0$.

R is called **semi-local** if $\overline{R} = R/\mathrm{rad}\, R$ is semisimple.

R is called **semi-primary** if R is semi-local and $\mathrm{rad}\, R$ is nilpotent.

Prop. (2.4.2.2) [Characterizing Jacobson Radicals]. For $y \in R$, the following are equivalent:

- $y \in \mathrm{rad}\, R$.
- $1 - xy$ is left-invertible for any $x \in R$.
- $yM = 0$ for any simple left R-module M.
- $1 - xyz$ is invertible for any $x, z \in R$.

Proof: $1 \to 2$: If $1 - xy$ is not left invertible, then it is contained in a maximal left ideal $\mathfrak{m}$, but $y \in \mathfrak{m}$, then $1 \in \mathfrak{m}$, contradiction.

$2 \to 3$: If $ym \neq 0$, then we must have $Rym = M$, so $xym = m$ for some $x \in R$, which shows $(1 - xy)m = 0$, but then $m = 0$.

$3 \to 1$: Consider the simple left R-module $R/\mathfrak{m}$ for any maximal left ideal $\mathfrak{m}$.

$4 \to 2$ is trivial, for $1 + 2 + 3 \to 4$: By item3 we know $\operatorname{rad} R$ is an ideal, so $yz \in \operatorname{rad} R$ and there is a u that $u(1 - xyz) = 1$. But then $u = 1 + u(xyz)$ is also left-invertible, so u is invertible and $1 - xyz$ is invertible. □

Cor. (2.4.2.3). $\operatorname{rad} R$ is the largest ideal $\mathfrak{A}$ of R that $1 + \mathfrak{A}$ are all units. In particular, the left radical agrees with the right radical.

Def. (2.4.2.4) [Locally Nilpotent Subsets]. A subset of a unital ring R is called **locally nilpotent** iff every element of it is nilpotent.

Lemma (2.4.2.5). if a left or right ideal $\mathfrak{A} \subset R$ is locally nilpotent, then $\mathfrak{A} \subset \operatorname{rad} R$.

Proof: Suppose $y \in \mathfrak{A}$, then $xy \in \mathfrak{A}$ is nilpotent. So $1 - xy$ has an inverse, for any x. Then $y \in \operatorname{rad} R$, by(2.4.2.2). □

Prop. (2.4.2.6) [Artinian Radical Nilpotent]. In a left Artinian ring, $\operatorname{rad} R$ is the largest nilpotent left ideal, and it is also the largest nilpotent right ideal.

Proof: By the above lemma, it suffices to show $J = \operatorname{rad} R$ is nilpotent. By Artinian property, the descending chain $J \supset J^2 \supset J^3 \supset \ldots$ is stabilizing, so there exists k s.t. $J^k = J^{k+1} = I$. Then $I = 0$, because otherwise we can choose a minimal non-zero left ideal $\mathfrak{A}$ s.t. $IA = 0$. Then if $a \neq 0 \in \mathfrak{A}$,

$$I(Ia) = I^2 a = Ia = 0,$$

so $\mathfrak{A} = Ia$, and $a = ya$ for some $y \in J$, so $(1 - y)a = 0$. But $1 - y$ is a unit by(2.4.2.2), contradiction. □

Cor. (2.4.2.7). In a left Artinian ring, any 1-sided locally nilpotent ideal is nilpotent. By left Artinian, there is a k that $(\operatorname{rad} R)^k = (\operatorname{rad} R)^{k+1} = I$. Now if $I \neq 0$, then we can choose a minimal left ideal $\mathfrak{A}$ that $I\mathfrak{A} \neq 0$ by Artinian property. Now there is an $a \in \mathfrak{A}$ that $Ia \neq 0$, so $I(Ia) = Ia \neq 0$, so $Ia = \mathfrak{A}$ and $a = ya$ for some $y \in I$. But $1 - y$ is invertible, so $a = 0$, contradiction.

Prop. (2.4.2.8) [Semisimplicity and Jacobson Semisimplicity]. For $R \in \mathfrak{R}\text{ing}$, the following are equivalent:

- R is semisimple.
- R is Jacobson semisimple and left Artinian.
- R is Jacobson semisimple and satisfies DCC on principal left ideals.

Proof: $1 \to 2$: R is left Artinian by(2.4.1.18), and consider $R = \operatorname{rad} R \oplus \mathfrak{B}$, then $\mathfrak{B}$ is contained in a maximal left ideal $\mathfrak{m}$, which cannot contain $\operatorname{rad} R$, unless $\operatorname{rad} R = 0$.

$3 \to 1$: 3 implies that ay left ideal $\mathfrak{A}$ contains a minimal left ideal I(the minimal principal one), and every minimal left ideal I is a direct summand of ${}_R R$(by choosing the maximal left ideal $\mathfrak{m}$ not containing I, because $I \oplus \mathfrak{m} = R$).

Then we can deduce 1: If R is not semisimple, then take a minimal left ideal $\mathfrak{B}_1$, then $R = \mathfrak{B}_1 \oplus \mathfrak{A}_1$, and $\mathfrak{A}_1 \neq 0$ otherwise R is semisimple, and we can choose a minimal left ideal $\mathfrak{B}_2 \subset \mathfrak{A}_1$, then $\mathfrak{A}_1 = \mathfrak{B}_2 \oplus \mathfrak{A}_2$. Continuing this way, we get a chain of left ideals $\mathfrak{A}_1 \supset \mathfrak{A}_2 \supset \ldots$, and they are both principal because they are direct summands of ${}_R R$, contradicting item3. □

Prop. (2.4.2.9) [Hokins-Levitzki Theorem]. Let R be a semi-primary ring(2.4.2.1), then for any R-module M, the following are equivalent:

- M is Noetherian.
- M is Artinian.
- M has a composition series.

In particular, a ring is left Artinian iff it is left Noetherian and semi-primary.

Proof: It suffices to prove if M is Noetherian or Artinian, M has a composition series. Denote $J = \operatorname{rad} R$, then J^n for some $n > 0$. We consider

$$0 \subset J^{n-1}M \subset \ldots \subset JM \subset M,$$

and the quotient $J^{k-1}M/J^kM$ is Artinian or Noetherian over $\overline{R} = R/\operatorname{rad} R$ which is semisimple, so it is a direct sum of simple modules, and the sum is finite, so there is a compostion series.

The last assertion: A left Artinian ring is semi-primary, by(2.4.2.6) and(2.4.2.8). So the assertion follows from the equivalence of item1 and 2. □

Lemma (2.4.2.10). Let $x \in \operatorname{rad} R$ where R is a k-algebra, then x is algebraic over k iff x is nilpotent.

Proof: One direction is trivial. For the other, if $x^r + a_1x^{r+1} + \ldots + a_nx^{r+n} = 0$, then because

$$1 + a_1x^1 + \ldots + a_nx^n$$

is invertible, we have $x^r = 0$. □

Prop. (2.4.2.11) [Amitsur]. Suppose k is a field and R is a k-algebra that $\dim_k R < |k|$, then $\operatorname{rad} R$ is the largest locally nilpotent ideal of R.

Proof: If $|k| < \infty$, then R is Artinian, so $\operatorname{rad} R$ is nilpotent by(2.4.2.6), and it is the largest by(2.4.2.6) again. Suppose now k is infinite. By the lemma above, it suffices to show every $r \in \operatorname{rad} R$ is algebraic over k. Notice that $a - r$ is invertible for $a \in k^*$, and $\{(a-r)^{-1}\}$ cannot be k-linearly independent because $\dim_k R < |k|$, so there is a dependence relation

$$\sum_{i=1}^{n} b_i(a_i - r)^{-1} = 0.$$

Hence r is algebraic over k. □

Prop. (2.4.2.12) [Amitsur]. Let R be a ring and $S = R[T]$. Let $J = \operatorname{rad} S$ and $N = R \cap J$, then N is a locally nilpotent ideal in R, and $J = N[T]$. In particular, if R is Jacobson semisimple, then S is also Jacobson semisimple(2.4.2.5).

Proof: Cf.[Lam, P71]. □

Lemma (2.4.2.13). Let $R \in \mathcal{R}\mathrm{ing}/k$ and K/k is a separable algebraic field extension, then if R is Jacobson semisimple, so is $R \otimes_k K$.

Proof: Cf.[Lam, P76]. □

Prop. (2.4.2.14) [Jacobson Radical Under Base Change of Fields]. Let $R \in \mathcal{R}\mathrm{ing}/k$ and K/k a separable algebraic extension, then $\operatorname{rad}(R \otimes_k K) = (\operatorname{rad} R) \otimes_k K$.

Proof: Cf.[Lam, P76]. □

3 Finite Semisimple k-Algebras

Reference for this subsection is [Sta]Chap 11.

Def. (2.4.3.1) [Azumaya Algebras]. A **central k-algebra** is an algebra A that the center of A is the image of $k \to A$.

Def. (2.4.3.2) [Azumaya Algebras]. An **Azumaya algebra** over k is defined to be a finite central k-algebra. The category of Azumaya algebras over k is denoted by Az_k.

Lemma (2.4.3.3). Let D be a division ring with central field k and $A \in \mathcal{R}\mathrm{ing}/k$, then any two-sided ideal I of $A \otimes_k D$ is of the form $J \otimes_k D$ for some two-sided ideal J of A. In particular, if A is simple, then $A \otimes_k D$ is also simple.

Proof: Cf.[Sta]074C. □

Lemma (2.4.3.4). Let $R \in \mathcal{R}\mathrm{ing}$ and $n \in \mathbb{Z}_+$, then

- The functors $M \mapsto M^{\oplus n}, N \mapsto e_{11}n$ defines an equivalence of categories between $\mathcal{M}\mathrm{od}_R$ and $\mathcal{M}\mathrm{od}_{\mathrm{Mat}(n,R)}$.
- Any two-sided ideal of $\mathrm{Mat}(n, R)$ is of the form $\mathrm{Mat}(n, I)$ for some two-sided ideal I of R.
- Then center of $\mathrm{Mat}(n, R)$ is the equal to the center of R.

Prop. (2.4.3.5). if A, A' are two simple k-algebras that A is finite central over k, then $A \otimes_k A'$ is simple.

Proof: Let A' be finite central over k, then by(2.4.1.28), $A' \cong \mathrm{Mat}(n, D)$ for some finite central division algebra over k. Then

$$A \otimes_k A' \cong \mathrm{Mat}(n, A \otimes D),$$

which is simple by(2.4.3.3) and(2.4.3.4). □

Cor. (2.4.3.6). The tensor product of two Azumaya k-algebras is an Azumaya k-algebra.

Proof: Combine the proposition with(2.2.1.14). □

Cor. (2.4.3.7) [Base Change]. If $k \in \mathtt{Field}$ and $A \in \mathcal{R}\mathrm{ing}/k$, then for any field extension k'/k, $A \otimes_k k' \in \mathrm{Az}_{k'}$ iff $A \in \mathrm{Az}_k$.

Proof: Combine(2.2.1.14) with(2.4.3.5). □

Prop. (2.4.3.8) [Skolem-Noether]. Let A be a finite central simple k-algebra and B is a simple k-algebra that $f, g : B \to A$ are two k-algebra homomorphisms. Then there exists an invertible element $x \in A$ that $f = x^{-1}gx$.

Proof: Choose a simple A-module M, then $L = \mathrm{End}_A(M)$ is a skew field, and M has two $B \otimes_k L^{op}$ structures by f and g. The k-algebra $B \otimes_k L^{op}$ is simple by(2.4.3.5), and also B is finite simple because there is a k-homomorphism $B \to A$, so $B \otimes_k L^{op}$ is finite simple, thus the two $B \otimes_k L^{op}$-structures on M are isomorphic, which means there is a $\varphi : M \to M$ intertwining these two structures. But φ commutes with L, meaning that φ is justing multiplying by some $x \in A$, so x is what we want. □

Cor. (2.4.3.9). Let A be a finite simple k-algebra, then any automorphism of A is inner.

Proof: Because the center of A is a finite field extension k' of k that A is central simple over k', thus the Skolem-Noether theorem applies. □

Splitting Fields

Prop. (2.4.3.10) [Centralizer Theorem]. Let $k \in \texttt{Field}$ and $A \in \mathrm{Az}_k$, and B a simple sub k-algebra of A, then

- $C = C_A(B)$ is also simple.
- $\dim_k A = \dim_k B \cdot \dim_k C$.
- $C_A(C) = B$.

Proof: Cf.[Sta]074T.**?** □

Cor. (2.4.3.11). Let $k \in \texttt{Field}$ and $B \subset A \in \mathrm{Az}_k$, then $C = C_A(B)$ is also in Az_k, and $A \cong B \otimes_k C$.

In particular, if a division ring D is of f.d. over its center k, then $D \in \mathrm{Az}_k$, and $\dim_k D$ is a square.

Proof: $\dim_k A = \dim_k (B \otimes_k C)$ by(2.4.3.10), and $B \otimes_k C$ is simple by(2.4.3.5), so the natural map $B \otimes_k C \to A$ is an isomorphism, and the center of C is k by(2.4.3.5). □

Prop. (2.4.3.12). For $k \in \texttt{Field}, A \in \mathrm{Az}_k$, If $K \subset A$ is a sub k-field, then the following are equivalent:

- $\dim_k A = [K : k]^2$.
- $C_A(K) = K$.
- K is a maximal commutative subring of A.

Proof: $1, 2$ are equivalent by(2.4.3.10), and $2, 3$ are clearly equivalent, as $C_A K$ is a commutative subring containing K. □

Cor. (2.4.3.13). If D is a division ring with center k, then every maximal subfield of D satisfies $\dim_k D = [K : k]^2$.

Proof: This is because any commutative subring of A is a field. □

Def. (2.4.3.14) [Splitting Fields]. For $k \in \texttt{Field}$ and B a finite semisimple k-algebra, then B is said to **split** if B is isomorphic to a product of matrix algebras over k. A field extension K/k is called a **splitting field** of B if B_K is split.

Prop. (2.4.3.15). If $k \in \texttt{Field}, k = \overline{k}$, then any finite semisimple k-algebra is split.

Proof: This follows from(2.4.1.22) and(2.2.1.10). □

Cor. (2.4.3.16) [Central Simple Algebras are of Square Dimensions]. Let $k \in \texttt{Field}, A \in \mathrm{Az}_k$, then $\dim_k A$ is a square.

Proof: This is true because $A \otimes_k \overline{k}$ is a matrix algebra. □

Prop. (2.4.3.17) [Maximal Subfields are Splitting]. Let $k \in \texttt{Field}, A \in \mathrm{Az}_k$, k'/k a finite field extension, then k is a splitting field of A iff there exists a $B \in \mathrm{Az}_k$ similar to A(9.2.1.5) s.t. $k' \subset B$ and $\dim_k B = [k' : k]^2$.

In particular, if D is a division ring, any maximal subfield of D is a splitting field of D, by(2.4.3.12),

Proof: Cf.[Sta]074Z.**?** □

Cor. (2.4.3.18). If $k \in \texttt{Field}$ and D is a central division ring with $\dim_k D = d^2, d \in \mathbb{Z}_+$ by(2.4.3.16), then for any splitting field k'/k, $d | [k' : k]$.

Proof: By(2.4.3.17), there exists $B \in \mathrm{Az}_k$ similar to D s.t. $\dim_k B = [k' : k]^2$. Then it follows from(9.2.2.1) that $B \cong \mathrm{Mat}(n, D)$ for some $n \in \mathbb{Z}_+$. Then $n^2 d^2 = [k' : k]^2$, so $d | [k' : k]$. □

Prop. (2.4.3.19)[Galois Splitting Fields, Noether-Köthe]. If $k \in \texttt{Field}$ and D is a central division ring over k, then there exists a maximal subfield $K \subset D$ s.t. K/k is finite separable. In particular, by(9.2.2.1)(2.4.3.17), any central simple algebra has a finite Galois splitting field.

Proof: Notice it suffices to prove that: if $D \neq k$, there exists $\alpha \in D \backslash k$ s.t. $k(\alpha)/k$ is separable. This is because if we find such α, then $D' = C_D(k(\alpha))$ is another simple division algebra with center $k(\alpha)$, by(2.4.3.10), so we can use induction on $D'/k(\alpha)$.

We may assume k is non-perfect of characteristic $p \in \mathbf{P}$, thus an infinite field. Suppose we cannot find such an element, then every element satisfies an equation of the form $T^{p^r} - a = 0$, where $a \in k$. And because $\dim_k D < \infty$, there exists an r s.t. $x^{p^r} \in k$ for any $x \in D$. Then we can use the fact $\# k = \infty$ to show that $x^{p^r} \in \overline{k}$ for any $x \in D \otimes_k \overline{k}$. But then every p^r-th power of $D \otimes_k \overline{k} \cong \mathrm{Mat}(n, \overline{k})$ is central, which is not true, as $n > 1$ and we can take e_{11}. □

Cor. (2.4.3.20). Let $k \in \texttt{Field}$, then for $A \in \mathcal{R}\mathrm{ing}/k$, $A \in \mathrm{Az}_k$ iff $A \otimes_k k^{\mathrm{sep}} \cong \mathrm{Mat}(n, k^{\mathrm{sep}})$ for some $n \in \mathbb{Z}_+$, by(2.4.3.7).

Def. (2.4.3.21) [Reduced Degree]. For $k \in \texttt{Field}$ and B a finite semisimple k-algebra, suppose $B = \prod_i B_i$ where B_i are simple k-algebras with center k_i, define the **reduced degree** of B over k to be

$$[B : k]_{\mathrm{red}} = \sum_i [B_i : k_i]^{1/2} [k_i : k],$$

which is an integer by(2.4.3.16). And for any field extension k'/k,

$$[B_{k'} : k']_{\mathrm{red}} = [B : k]_{\mathrm{red}}.$$

Proof: To show it is invariant, pass to the algebraic closure, then $B = \prod_j \mathrm{Mat}(n_j, \overline{k})$, and $[B : k]_{\mathrm{red}} = \sum n_j$. □

Def. (2.4.3.22)[Reduced Norms]. Let $k \in \texttt{Field}$ and B an Azumaya k-algebra. If $x \in B$, let $P(T)$ be the characteristic polynomial of $r(T) : B \to B$, Then by passing to Galois splitting fields(2.4.3.19), we get $P(T) = Q(T)^n$ where $\dim_k B = n^2$. Then because there are Galois actions, we get $Q(T) \in k[T]$, and this $Q(T)$ is called the **reduced characteristic** of x. We can also routinely define **reduced norms** and **reduced trace**, denoted by $\mathrm{Nmrd}_{B/k}$ and $\mathrm{trrd}_{B/k}$.

Then this reduced characteristic is just the usual one when $B \cong \mathrm{Mat}(n; k)$. And when K is a splitting field of B containing x, then this equals the characteristic polynomial of x in K/k.

More generally, if B is a simple algebra over k with center L, then we can define $\mathrm{Nmrd}_{B/k} = \mathrm{Nm}_{K/k} \circ \mathrm{Nmrd}_{B/K}$ and $\mathrm{trrd}_{B/k} = \mathrm{tr}_{K/k} \circ \mathrm{trrd}_{B/K}$

Proof: For the last assertion, notice $B = K \oplus K x_1 \oplus \ldots K x_n$ as modules over K. □

Prop. (2.4.3.23). For $k \in \texttt{Field}$ and B a finite semisimple k-algebra, any maximal étale k-subalgebra of B has rank $[B : k]_{\mathrm{red}}$ over k.

Proof: This follows from(2.4.3.13). □

Prop. (2.4.3.24). For $k \in \texttt{Field}$ and B a finite semisimple k-algebra, then for any faithful B-module M,

$$\dim_k M \geq [B : k]_{\mathrm{red}}.$$

And the equality holds iff B is split.

Proof: This is clear from(2.4.1.21). □

Prop. (2.4.3.25). If $k \in \texttt{Field}$ and $A \in \mathrm{Az}_k$, then $A \otimes_k A^{\mathrm{op}} \cong \mathrm{Mat}(n,k)$, where $n = \dim_k A$.

Proof: There is a map $A \otimes_k A^{\mathrm{op}} \to \mathrm{End}_k(A) : (a \otimes a') \mapsto (x \mapsto axa')$. By(2.4.3.6), $A \otimes_k A^{op}$ is simple, thus this is an injective map, but both sides have the same dimension, thus this is an isomorphism. □

Finite Semisimple k-Algebras with Involution

Def. (2.4.3.26) [Involution]. Let $*$ be an involution on a semisimple algebra B over a field k. It is called an **involution of first kind** if it fixes elements in the center of B. It is called an **involution of second kind** otherwise.

Prop. (2.4.3.27) [Decomposition]. Let $(B, *)$ be a f.d. semisimple k-algebra with an involution, if k is alg.closed and has characteristic 0, then it decomposes as products of pairs of the following types:

- $(A) : M_n(k) \times M_n(k), (a,b)^* = (b^t, a^t)$.
- $(C) : M_n(k), b^* = b^t$.
- $(BD) : M_{2n}(k), b^* = Jb^tJ^{-1}$, where $J = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}$.

Proof: Let $B = B_1 \times \ldots \times B_r$ be the decomposition into products of simple k-algebras, where B^* are the minimal two-sided ideals of B. Applying $*$, $B = B_1^* \times \ldots \times B_r^*$ so B_i^* is a permutation of B_i, so B is a a product of algebras either simple or product of two simple algebras that $*$ interchanges them.

If B is simple, then $B \cong M_n(k)$ as k is alg.closed, so $b^* = ub^tu^{-1}$ for some $u \in M_n(k)$ by Skolem-Noether(2.4.3.8). Then $b = b^{**} = (u^tu^{-1})^{-1}bu^tu^{-1}$, so u^tu^{-1} is in the center, denote it by c, then $u^t = cu$, $u = c^2u$, so $c = \pm 1$, and u is symmetric or skew-symmetric. Up to a congruence, we see the situation is (C) or (BD).

The other case is also easy. □

4 Idempotented Algebras

Lemma (2.4.4.1). Let R be a ring and e, f be idempotents of R that $ef = fe = e$, then $f = e + e'$, where e' is an idempotent and $M[f] = M[e] \oplus M[e']$.

Moreover, if R is an algebra over an alg.closed field k and $M[e]$ is a simple $R[e]$-module of f.d. over k, then $\dim \mathrm{Hom}_{R[e]}(M[e], M[f]) = 1$.

Proof: Let $e' = f - e$, then it is easily verified to be an idempotent, and $ee' = e'e = 0$, thus $M[f] = M[e] \oplus M[e']$ is clear.

For the second, because $R[e]$ acts by 0 in $R[e']$, $\mathrm{Hom}_{R[e]}(M[e], M[f]) = \mathrm{Hom}_{R[e]}(M[e], M[e])$ has dimension 1, by Shur's lemma(2.4.1.2) and(2.2.1.10). □

Def. (2.4.4.2) [Idempotented Algebra]. An **idempotented algebra** $\mathscr{H}$ is an algebra over a field k together with a set $\mathscr{E}$ of idempotents that if $e_1, e_2 \in \mathscr{E}$, then there exists $e_0 \in \mathscr{E}$ that

$$e_0e_1 = e_1e_0 = e_1, e_0e_2 = e_2e_0 = e_2,$$

and also for any $\varphi \in \mathscr{H}$, there exists $e \in \mathscr{E}$ that $e\varphi = \varphi e = \varphi$.

We can define a partial order on $\mathcal{E}$: $e < f$ iff $ef = fe = f$, then this order is cofinal.

If e is an idempotent, denote $\mathcal{H}[e] = e\mathcal{H}e$, which is a subring of $\mathcal{H}$ with unit e. Also if M is an $\mathcal{H}$-module, we denote $M[e]$ the $R[e]$-module eM.

Prop. (2.4.4.3). If $0 \to M_1 \to M_2 \to M_3 \to 0$ is an exact sequence of $\mathcal{H}$-modules, $e \in \mathcal{E}$, then $0 \to M_1[e] \to M_2[e] \to M_3[e] \to 0$ is also exact.

Proof: Because tensoring an idempotent is exact. □

Def. (2.4.4.4) [Smooth Representations of Idempotented Algebras]. Let $(\mathcal{H}, \mathcal{E})$ be an idempotented algebra, a **smooth $\mathcal{H}$-module** M is an $\mathcal{H}$-module $M = \cup_{e\in\mathcal{E}} M[e]$, and an **admissible $\mathcal{H}$-module** is a smooth $\mathcal{H}$-module that each $M[e]$ is of f.d. over k.

A smooth $\mathcal{H}$-module is clearly non-degenerate.

Def. (2.4.4.5) [Contragradient Module]. If M be a smooth $\mathcal{H}$-module, then we can define a **contragradient** $\widehat{M}$ of M, which is the smooth $\mathcal{H}$-module consisting of smooth vectors in M^*, where the action is defined as $((\varphi)\lambda)(m) = \lambda(\iota(\varphi)m)$. Notice if M is admissible, then so does $\widehat{M}$, because an element in $\widehat{M}[e]$ is determined by its restriction on $M[\iota(e)]$, so $\widehat{M}[e]$ is of f.d. if $M[\iota(e)]$ does.

Prop. (2.4.4.6) [Simpleness Checked on Idempotents]. Let M be a non-zero module over an idempotented algebra $(\mathcal{H}, \mathcal{E})$ over $\mathbb{C}$, $\mathcal{E}^0$ be a cofinal subset of $\mathcal{E}$, then M is a simple $\mathcal{H}$-module iff $M[e]$ is simple $\mathcal{H}[e]$-modules for any $e \in \mathcal{E}^0$.

Proof: If there exists a proper $\mathcal{H}$-submodule M_1 of M, let $M/M_1 = M_2$, then $M[e]/M_1[e] = M_2[e]$ for all e by(2.4.4.3), Thus we can choose e s.t. $M_1[e] \neq 0, M_2[e] \neq 0$, thus $M[e]$ is reducible. Conversely, If $W_0 \subset M[e_K]$ is a proper non-zero $\mathcal{H}[e_K]$-submodule, then $[\pi(\mathcal{H})W_0][e] = W_0$, thus $\pi(\mathcal{H})W_0$ is a proper submodule of M. □

Prop. (2.4.4.7) [Isomorphism Checked on Idempotents]. Let V_1, V_2 be two simple admissible modules over an idempotented algebra $(\mathcal{H}, \mathcal{E})$, if $e \in E$ that $V_1[e] \cong V_2[e] \neq 0$, then $V_1 \cong V_2$.

Proof: Choose an isomorphism $j : V_1[e] \to V_2[e]$, then the subspace $V' = \{(x, jx)\} \subset V_1[e] \oplus V_2[e] \subset V_1 \oplus V_2$ is a $\mathcal{H}[e]$-submodule. Let $V = \pi(\mathcal{H})V'$, then $V[e] = V'$, so V is not contained or contains any of V_1 or V_2, thus $V \cap V_1 = V \cap V_2 = 0$ as V_i are irreducible. Thus the projections $V \to V_1, V \to V_2$ are isomorphisms as V_i are irreducible, and $V_1 \cong V_2$. □

Prop. (2.4.4.8) [Extension Theorem]. Let $(\mathcal{H}, \mathcal{E})$ be an idempotented algebra and $e \in E$. If V_e is a simple $\mathcal{H}[e]$-module, then there is a simple $\mathcal{H}$-module V that $V[e] = V_e$.

Proof: Let $V_e \cong \mathcal{H}[e]/I$, where I is a left ideal of V_e. Let E_1, E_2 be the module generated by I and $\mathcal{H}[e]$ in $\mathcal{H}$ by left action of $\mathcal{H}$, then $E_1[e] = I$ and $E_2[e] = \mathcal{H}[e]$, thus $(E_3 = E_1/E_2)[e] \cong V_e$ by(2.4.4.3). Now if E' is a submodule of E_3, then either $E'[e] = 0$ thus $(E_3/E')[e] \cong L$, or $E'[e] = L$, thus $E' = E_3$ by(2.4.4.7). Thus if we choose the proper submodule E' that E_3/E' is irreducible by(15.1.2.8), then $E_3/E'[e] = L$. □

Prop. (2.4.4.9). If $\mathcal{H}$ is an idempotented algebra, then $\mathcal{M}(\mathcal{H})$ has enough projectives.

Proof: For any idempotent $e \in \mathcal{H}$, consider the module $\mathcal{H}e$, then it is projective, because $\mathrm{Hom}_{\mathcal{H}}(\mathcal{H}e, X) = eX$, thus it is clearly exact. Now any $m \in V$ has an idempotent $e \in \mathcal{H}$ that $ev = v$(use definition). Thus by taking the direct sum, we are done. □

Spherical Idempotents

Def. (2.4.4.10)[Spherical Idempotents]. Let $(\mathscr{H},\mathscr{E})$ be an idempotented algebra over a field Ω. Then an idempotent $e\in\mathscr{E}$ is called **spherical idempotent** if there exists an anti-involution $\iota:\mathscr{H}\to\mathscr{H}$ that $\iota(x)=x$ for any $x\in\mathscr{H}[e^0]$. Notice this implies $\mathscr{H}[e^0]$ is commutative, as $xy=\iota(xy)=yx$.

Def. (2.4.4.11) [Spherical Vectors]. Let e^0 be a spherical idempotent of the idempotented algebra $(\mathscr{H},\mathscr{E})$ and ι is the corresponding involution. If M is an admissible $\mathscr{H}$-module, then a **spherical(unramified) module** is a $\mathscr{H}$-module M that $M[e^0]\neq 0$, and elements in $M[e^0]$ are called **spherical vectors**.

Then if M is simple and spherical, then M has at most one spherical vector up to scalar, and $\widehat{M}$ is also spherical. Thus the space of spherical vectors is fixed by $\mathscr{H}[e^0]$, and the action of $\mathscr{H}[e^0]$ on that defines a **spherical character**.

Proof: In fact, $M[e^0]$ is a simple $\mathscr{H}[e^0]$-module(2.4.4.6), and is of f.d., and $\mathscr{H}[e^0]$ is commutative(2.4.4.10), so(2.4.1.11) shows it is of dimension 1. so if $m^0\neq 0\in M[e^0]$, then we can define a $\widehat{m}^0\neq 0\in\widehat{M}[e^0]$ as:

$$e^0m=\widehat{m}^0(m)\cdot m^0.$$

□

Prop. (2.4.4.12) [Isomorphism Checked on Spherical Idempotents]. Let $(\mathscr{H},\mathscr{E})$ be an idempotented algebra over a field Ω and e^0 is a spherical idempotent. If M,N are simple admissible spherical $\mathscr{H}$-modules that $M[e^0]\cong N[e^0]$ over $\mathscr{H}[e^0]$, then $M\cong N$ as $\mathscr{H}$-modules.

Proof: This follows from(2.4.4.7). □

Restricted Tensor Product

Def. (2.4.4.13) [Restricted Tensor Product]. Give an infinite number of vector spaces V_v indexed by a set Σ and elements $x_v^0\in V_v$ be given for a.e. v, we can define the **restricted tensor product** $\bigotimes' V_v$ as the direct limit

$$\varinjlim_{S\subset\Sigma\text{ finite}}\otimes_{v\in S}V_v.$$

It can be thought of as the vector spaces spanned by all symbols $\otimes_v x_v$ where $x_v=x_v^0$ for a.e. v.

Notice if V_v are idempotented algebras and $x_v^0\in V_v$ are idempotents for a.e. v, then $\prod' V_v$ also has a natural idempotented algebra structure.

Def. (2.4.4.14) [Tensor Product Module of Idempotented Algebras]. Given a set of idempotented algebras $(\mathscr{H}_v,\mathscr{E}_v)$ and specify an idempotent e_v^0 for a.e. v. Let M_v be $\mathscr{H}_v$-modules over k for all v, and assume $M_v[e_v^0]$ be of dimension 1 a.e. v, and specify a.e. a non-zero element $m_v^0\in M_v[e_v^0]$

Then we can define tensor product(2.4.4.13) $\prod'\mathscr{H}_v$ which is an idempotented algebra and $\prod' M_v$. Then we can define an **restricted tensor module** structure of M_v over $\prod'\mathscr{H}_v$ by the action

$$(\otimes_v\varphi_v)x_v=\otimes_v(\varphi_v)x_v.$$

Lemma (2.4.4.15) [Simple Module of Tensor Product]. Let $(\mathscr{H}_1,\mathscr{E}_1),(\mathscr{H}_2,\mathscr{E}_2)$ be idempotented algebras over an alg.closed field Ω, and let $(\mathscr{H},\mathscr{E})$ be the tensor product. If M_1,M_2 are simple admissible modules over $\mathscr{H}_1,\mathscr{H}_2$, respectively, then $M_1\otimes M_2$ are simple admissible modules over $\mathscr{H}_1\otimes\mathscr{H}_2$, and any simple admissible module over $\mathscr{H}$ comes uniquely from a pair (M_1,M_2) like this.

Proof: If M_1, M_2 are simple admissible over H_1, H_2 respectively, then if $e_1 \in \mathcal{E}_1, e_2 \in \mathcal{E}_2$, then $(M_1 \otimes M_2)[e_1 \otimes e_2] = M_1[e_1] \otimes M_2[e_2]$ is simple and of f.d. by(2.4.4.6) and(2.4.1.16), so $M_1 \otimes M_2$ is simple by(2.4.4.6).

Now if M is simple admissible over $\mathcal{H}_1 \otimes \mathcal{H}_2$, then we find an $e_1^0 \otimes e_2^0 \in \mathcal{E}$ that $M[e_1^0 \otimes e_2^0] \neq 0$. Let $\mathcal{E}_i^0 = \{e_i \in \mathcal{E}_i | e_i < e_i^0\}$, then $\mathcal{E}_i^0$ is cofinal in $\mathcal{E}_i$. Then for any $e_i \in \mathcal{E}_i^0$, $M[e_1 \otimes e_2]$ is non-zero thus simple, thus it is of the form

$$M[e_1 \otimes e_2] = M_1(e_1, e_2) \otimes M_2(e_1, e_2)$$

where $M_i(e_1, e_2)$ are simple $\mathcal{H}[e_i]$-modules by(2.4.1.16).

Now we show that $M_2(e_1, e_2)$ depends only on e_1: it suffices to show $M_2(e_1, e_2) = M_2(f_1, e_2)$ for $f_1 < e_1$. For this, notice that for any idempotents g_1, g_2,

$$M[g_1 \otimes g_2] = M_1(g_1, g_2) \otimes M_2(g_1, g_2)$$

is a finite direct sum of simple modules $M_2(g_1, g_2)$ as an $\mathcal{H}_2[g_2]$-module. Notice that by(2.4.4.1), $M[e_1 \otimes e_2] = M[f_1 \otimes e_2] \oplus M[e' \otimes e_2]$ for $e' = f_1 - e_1$, so by(2.4.1.3), $M_2(f_1, e_2) = M_2(e_1, e_2)$. Similarly we know $M_1(e_1, e_2)$ only depends on e_1.

Next we have:

$$\dim_k \mathrm{Hom}_{H_1[e_1]}(M_1[e_1], M_1[f_1]) \geq 1, \quad f_1 \leq e_1.$$

and similar for $\mathcal{H}_2$. For this, it suffices to prove that $\dim_k \mathrm{Hom}_{H_1[e_1]}(M[e_1 \otimes e_2], M[f_1 \otimes e_2]) \geq 1$, by what we just said, but this is by the decomposition

$$M[e_1 \otimes e_2] = M[f_1 \otimes e_2] \oplus M[e' \otimes e_2]$$

above. But

$$\dim_k \mathrm{Hom}_{H_1[e_1] \otimes H_2[e_2]}(M_1(e_1) \otimes M_2(e_2), M_1(f_1) \otimes M_2(f_2)) = 1, \quad f_1 \leq e_1, f_2 \leq e_2$$

by(2.4.4.1), so the $\geq$ above should change to $=$.

Now we know the homomorphism is of dimension 1, we want to choose a family of maps that is compatible for $g_1 \leq f_1 \leq e_1 \leq e_1^0$. For this, we can choose the maps $\lambda(e_1, e_1^0)$ arbitrarily, then choose $\lambda(e_1, f_1)$ to be be compatible with $\lambda(e_1, e_1^0)$ and $\lambda(f_1, e_1^0)$, then these are compatible choices. Hence we can define a direct limit

$$M_1 = \varinjlim_{(\mathcal{E}^0)^{op}} M(e_1).$$

It is easy to see $M_1(e_1) \to M_1$ are all injective, and $M_1(e_1) = M[e_1]$. Similarly, we can define an M_2 that $M_2[e_2] = M_2(e_2)$.

Finally, we have

$$M[e_1 \otimes e_2] = M_1[e_1] \otimes M_2[e_2] = (M_1 \otimes M_2)[e_1 \otimes e_2]$$

for all $e_1 \in \mathcal{E}_1^0, e_2 \in \mathcal{E}_2^0$, thus $M \cong M_1 \otimes M_2$ by(2.4.4.7).

As for the uniqueness of M_1, M_2, notice the decomposition of $M[e_1 \otimes e_2]$ is unique by(2.4.1.16), so $M_i[e_i]$ is uniquely determined, thus by(2.4.4.7) M_i are determined. □

Prop. (2.4.4.16)[Flath Theorem]. let $(\mathcal{H}_v, \mathcal{E}_v)$ be an indexed family of idempotented k-algebras, and for a.e. v let $e_v^0 \in \mathcal{E}_v$ be a spherical idempotent. Let $(\mathcal{H}, \mathcal{E})$ be the restricted tensor product of $\mathcal{H}_c$ w.r.t. e_v^0, which is an idempotented algebra. For each $v \in \Omega$, there is a simple $\mathcal{H}_v$-module M_v and for a.e. v we specify a non-zero spherical vector. Let $\otimes_v M_v$ be the tensor product module, then it is a simple admissible $\mathcal{H}$-module, and every simple admissible module is of this type, with M_v uniquely determined.

Proof: Firstly the tensor product is simple and admissible: For any idempotent $e = \otimes e_v \in \mathscr{E}$, there is a finite set S that if $v \notin S$, then $e_v = e_v^0$, hence for these v $\dim M_v[e_v] = 1$. Then

$$M[e] = \otimes_{v\in S} M_v[e_v].$$

which is simple of f.d. by(2.4.4.15), so M is simple admissible by(2.4.4.6).

Conversely, for any simple $\mathscr{H}$-module M, we need to show it is a tensor product. If there are only f.m. indices, then this follows from(2.4.4.15).

Suppose first that e_v^0 is defined and spherical for all v, and $e = \otimes_v e_v^0$, and $M[e] \neq 0$. Then $\dim M[e] = 1$(2.4.4.11). Let m be a spherical vector, then there is a ring homomorphism $\gamma : \mathscr{H}[e] \to k$ defined by $hm = \gamma(h)m$. Because $\mathscr{H}[e] = \otimes_v' \mathscr{H}_v[e_v^0]$, we have

$$\gamma(\otimes_v h_v) = \prod_v \gamma_v(h_v).$$

Now if we decompose $\mathscr{H} = \mathscr{H}_v \otimes \mathscr{H}_v'$, then by(2.4.4.15), there exists simple admissible module M_v over $\mathscr{H}_v$, M_v' over $\mathscr{H}_v'$ respectively, that $M = M_v \otimes M_v'$, thus $M[e] = M_v[e_v^0] \otimes M_v'[e_v']$. Now consider M_v for all v, and $N = \otimes_v' M_v$ w.r.t. m_v, then it is simple admissible $\mathscr{H}$-module, and we have $N[e] = \otimes_v' M_v[e_v^0] \cong M[e]$ as $\mathscr{H}[e]$-modules of dimension 1, which is because they are both simple and have the same character

$$\gamma(\otimes_v h_v) = \prod_v \gamma_v(h_v).$$

Hence $M \cong N$, by(2.4.4.12).

Now the general case follows from the two situations above: choose $e \in \mathscr{E}$ that $M[e] \neq 0$, then let S be large that for $v \notin S$, $e_v = e_v^0$. Then we decompose $\mathscr{H}$ as $\mathscr{H} = \bigotimes_{v\in S} \mathscr{H}_v \otimes (\bigotimes_{v\notin S} H_v)$, then

$$M = \bigotimes_{v\in S} M_v \otimes M' = \bigotimes_{v\in S} M_v \otimes (\bigotimes_{v\notin S} M_v) = \otimes_v M_v.$$

□

5 Miscellaneous

Lemma (2.4.5.1). Let R be a (possibly non-commutative) unital ring of characteristic 0 with the following properties:

- R has no zero-divisors,
- $\operatorname{rank}_{\mathbb{Z}} R \leq 4$,
- R has an involution $(-)^\wedge : R \to R^{\mathrm{op}}$,
- For any $\alpha \in R$, $\alpha\widehat{\alpha} \in \mathbb{N}$, and $\alpha\widehat{\alpha} = 0$ iff $\alpha = 0$.

Then R is isomorphic to exactly one of the following:

- $\mathbb{Z}$.
- a $\mathbb{Z}$-order in an imaginary quadratic extension over $\mathbb{Q}$.
- a $\mathbb{Z}$-order in a definite quaternion algebra over $\mathbb{Q}$.

And the third case won't happen in characteristic 0, by(13.9.1.24).

Proof: It suffices to show $K = R \otimes \mathbb{Q}$ is either $\mathbb{Q}$, an imaginary quadratic field or a definite quaternion algebra. For $\alpha \in K$, denote $N\alpha = \alpha\widehat{\alpha}, \operatorname{tr}\alpha = \alpha + \widehat{\alpha}$, then $\operatorname{tr}\alpha = 1 + N\alpha - N(1-\alpha) \in \mathbb{Q}$.

Assume $K \neq \mathbb{Q}$, let $\alpha \in K \backslash \mathbb{Q}$. We may replace α by $\alpha - \frac{1}{2} \operatorname{tr} \alpha$ to assume $\operatorname{tr} \alpha = 0$, then $\alpha^2 = -N\alpha < 0 \in \mathbb{Z}$. So $\mathbb{Q}(\alpha)$ is an imaginary quadratic field.

Assume $K \neq \mathbb{Q}(\alpha)$, let $\beta \in K \backslash \mathbb{Q}(\alpha)$. We may replace β by $\beta - \frac{1}{2} \operatorname{tr} \beta - \frac{\operatorname{tr}(\alpha\beta)}{\alpha^2}\alpha$ to assume $\operatorname{tr}(\beta) = \operatorname{tr}(\alpha\beta) = 0$. Hence $\beta^2 = -N\beta < 0 \in \mathbb{Z}$, and $\alpha\beta = -\beta\alpha$. So $\mathbb{Q}(\alpha, \beta)$ is a definite quadratic extension of $\mathbb{Q}$. Then $K = \mathbb{Q}(\alpha, \beta)$ because they are has rank 4 over $\mathbb{Z}$. $\square$

2.5 Lie Algebras

Basic references are [Car05], [Ser87], [Mil13], [Kna96] , [Lie Algebras and Lie Groups Serre], and[Eti21].

In this section, if not otherwise pointed out, k is assumed to be a field of char0 or just $\mathbb{C}$.

1 Basics

Def. (2.5.1.1) [Lie Algebras]. A **Lie algebra** L is an non-associative algebra over a field k with a bilinear **Lie bracket** operation that satisfies:

$$[x,x]=0,\quad [x[yz]]=[[xy]z]+[y[xz]](\text{Jacobi Identities}).$$

It is easily deduced that $[xy]=-[yx]$.

Denote $\mathrm{ad}x(y)=[xy]$, then $\mathrm{ad}x$ are all derivatives of L.

An element $x\in\mathfrak{g}$ is called **nilpotent** or **semisimple** if $\mathrm{ad}x$ is nilpotent or semisimple.

Prop. (2.5.1.2)[Associative Algebra]. For any associative algebra A over k, it can be given naturally a Lie algebra structure by defining $[xy]=xy-yx$. In this way, we get a natural functor $AssAlg_k\to Lie_k:A\mapsto[A]$.

Prop. (2.5.1.3) [Derivatives form a Lie Algebra]. Given a k-algebra A, the set of derivatives $\mathrm{Der}_k(A)=\mathrm{Der}_k(A,A)$ is a Lie algebra under the associative bracket.

Proof:

$$\begin{aligned}[D_1,D_2](ab)=&D_1(D_2(a)b+aD_2(b))-D_2(D_1(a)b+aD_1(b))\\=&D_1D_2(a)b+D_2(a)D_1(b)+D_1(a)D_2(b)+aD_1D_2(b)\\&-(D_2D_1(a)b+D_1(a)D_2(b)+D_2(a)D_1(b)+aD_2D_1(b))\\=&[D_1,D_2](a)b+a[D_1,D_2](b)\end{aligned}$$

□

Prop. (2.5.1.4) [Base Change of Fields]. Let $\mathfrak{a}$ be a subalgebra of a Lie algebra $\mathfrak{g}$ over k, and k'/k a field extension, then $\mathfrak{a}_{k'}$ is a subalgebra of $\mathfrak{g}_{k'}$, and

$$N_{\mathfrak{g}_{k'}}(\mathfrak{a}_{k'})=N_{\mathfrak{g}}(\mathfrak{a})_{k'}.$$

$$c_{\mathfrak{g}_{k'}}(\mathfrak{a}_{k'})=c_{\mathfrak{g}}(\mathfrak{a})_{k'}.$$

Proof: This is because the normalizer and centralizer is defined by linear equations with coefficients in k, thus the vector space is defined over k. □

Prop. (2.5.1.5). Let D be a derivative of a k-algebra A that is nilpotent, then e^D is an automorphism of A(as an algebra).

Proof: Routine calculation. □

Def. (2.5.1.6) [Semidirect Product of Lie Algebras]. Let $\mathfrak{g},\mathfrak{h}$ be Lie algebras and $\tau:\mathfrak{g}\to\mathrm{Der}(\mathfrak{h})$, then we can define a **semi-direct product Lie algebra** $\mathfrak{g}\ltimes\mathfrak{h}$ that is isomorphic to $\mathfrak{g}\oplus\mathfrak{h}$ as vector spaces, and $\mathfrak{g},\mathfrak{h}$ are subalgebras of $\mathfrak{g}\ltimes\mathfrak{h}$, with $[g,h]=\tau(g)(h)$. It can be shown that this is truly a Lie algebra.

Def. (2.5.1.7) [Elementary Automorphisms]. Let $\mathfrak{g}$ be a Lie algebra, a **special automorphism** is an automorphism of $\mathfrak{g}$ of the form $e^{\operatorname{ad}_{\mathfrak{g}} x}$, where x is in the nilpotent radical(2.5.1.34).

The group of **elementary automorphisms** is the subgroup of the automorphism group of $\mathfrak{g}$ generated by the automorphisms of the form $e^{\operatorname{ad}_{\mathfrak{g}}(x)}$ where $\operatorname{ad}(x)$ is nilpotent.

Def. (2.5.1.8) [Ideals]. A subspace $\mathfrak{a} \subset \mathfrak{g}$ is called an **ideal** of $\mathfrak{g}$ iff $[\mathfrak{g}, \mathfrak{a}] \subset \mathfrak{a}$. If I is an ideal of L, then L/I can be made into a Lie algebra by defining $[I + x, I + y] = I + [xy]$.

Def. (2.5.1.9) [Center]. The **center** of a Lie algebra $\mathfrak{g}$ is the elements a that $\operatorname{ad} a = 0$. It is an ideal.

Def. (2.5.1.10) [Simple Lie Algebras]. A Lie algebra $\mathfrak{g}$ is called **simple** if it is not 1-dimensional and it has no nontrivial ideal.

Def. (2.5.1.11) [Lie Algebra of Affine Maps]. Let V be a f.d. k-vector space. If we regard V as a commutative algebra, then $\operatorname{Der}_k(V) = \mathrm{gl}_V$. Then $V \rtimes \mathfrak{gl}_V$ is a Lie algebra, denoted by $\mathrm{af}(V)$.

Let $V' = V \oplus k$, and let $\mathfrak{h} = \{w \in \mathfrak{gl}_{V'} | w(V') \subset V\}$, which is a Lie subalgebra of $\mathfrak{gl}_{V'}$. If we define

$$\eta : \mathfrak{h} \to \mathfrak{gl}_V : \eta(w) = w|_V, \quad \zeta : \mathfrak{h} \to V : \zeta(w) = w(0, 1),$$

then (η, ζ) defines a Lie algebra homomorphism from $\mathfrak{h}$ to $\mathfrak{af}(V)$. This map is bijective, with the inverse given by sending $(v, f) \in \mathfrak{af}(V)$ to the morphism

$$(v', c) \mapsto (f(v') + cv, 0).$$

Lemma (2.5.1.12). Let $\lambda, \mu \in k$ and $x, y, z \in \mathfrak{g}$, then we have

$$(\operatorname{ad}(x) - \lambda - \mu)^m [y, z] = \sum_{i=1}^{m} \binom{m}{i} [(\operatorname{ad}(x) - \lambda)^i y, (\operatorname{ad}(x) - \mu)^{m-i} z].$$

Proof:

$$\begin{aligned}(\operatorname{ad}(x) - \lambda - \mu)^m [y, z] &= \sum_{p+q+r+s=m} (-1)^{r+s} \frac{m!}{p!q!r!s!} \lambda^r \mu^s [(\operatorname{ad} x)^p(y), (\operatorname{ad} x)^q(z)] \\ &= \sum_{k+l=m} \frac{m!}{k!l!} [(\operatorname{ad}(x) - \lambda)^k y, (\operatorname{ad}(x) - \mu)^l z]\end{aligned}$$

□

Def. (2.5.1.13) [Killing Form]. A bilinear form B on $\mathfrak{g}$ is called **invariant** if $B([x, y], z) + B(x, [y, z]) = 0$.

The **Killing form** on a Lie algebra $\mathfrak{g}$ of f.d. is the invariant symmetric bilinear form defined by $B(x, y) = \operatorname{tr}(\operatorname{ad} x \circ \operatorname{ad} y)$.

if $\mathfrak{a}$ is an ideal of a Lie algebra $\mathfrak{g}$, then the Killing form on $\mathfrak{a}$ is that of the Killing form on $\mathfrak{a}$ as a Lie algebra. This is linear algebra.

Prop. (2.5.1.14). Any invariant symmetric bilinear form on a simple Lie algebra $\mathfrak{g}$ is a multiple of the Killing form.

Prop. (2.5.1.15). A subalgebra $\mathfrak{h}$ of a Lie algebra $\mathfrak{g}$ is commutative if it consists of semisimple elements.

Proof: For an element $x \in \mathfrak{h}$, we need to show that $\mathrm{ad}_{\mathfrak{h}}(x) = 0$. If it is not, because $\mathrm{ad}\,\mathfrak{h}(x)$ is semisimple by(2.3.6.8), there is a nonzero eigenvector y at least after a base change, so $[x, y] = cy, y \neq 0 \in \mathfrak{h}$. So $\mathrm{ad}(y)(x) = -cy$, and $\mathrm{ad}(y)^2(x) = 0$, so $\mathrm{ad}(y)$ is non-semisimple on the subspace $\{x, y\}$, which means $\mathrm{ad}(y)$ is non-semisimple on $\mathfrak{g}$, by(2.3.6.8) again. □

Lemma (2.5.1.16). If $\mathfrak{g} \subset \mathfrak{gl}_n$ is a Lie subalgebra, and $a \in \mathfrak{g}$ is a nilpotent matrix, then $\mathrm{ad}(a)$ is also nilpotent.

Proof: This is because $\mathrm{ad}(a) = l(a) - g(a)$, where $l(a)$ is left multiplication and $r(a)$ is right multiplication. The left and right multiplication commutes, so it is clear $\mathrm{ad}(a)^{2n} = 0$ if $\mathrm{ad}(a)^n = 0$. □

Nilpotent and Solvable Lie Algebras

Def. (2.5.1.17) [Nilpotent and Solvable Lie Algebras]. Let $\mathfrak{g}$ be a Lie algebra, the **lower central series** of $\mathfrak{g}$ is the descending sequence of ideals of $\mathfrak{g}$ defined inductively by $C^1\mathfrak{g} = \mathfrak{g}$ and $C^n\mathfrak{g} = [\mathfrak{g}, C^{n-1}\mathfrak{g}]$.

Let $\mathfrak{g}$ be a Lie algebra, the **derived series** of $\mathfrak{g}$ is the descending sequence of ideals of $\mathfrak{g}$ defined inductively by $D^1\mathfrak{g} = \mathfrak{g}$ and $D^n\mathfrak{g} = [D^{n-1}\mathfrak{g}, D^{n-1}\mathfrak{g}]$.

A Lie algebra is called **nilpotent** if there is an n that $C^n\mathfrak{g} = 0$. This is equivalent to $\mathrm{ad}x_1\mathrm{ad}x_2 \ldots \mathrm{ad}x_n = 0$ for any n element $x - 1, \ldots, x_n$. It is called **solvable** if $D^n = 0$ for some n. It is clear that $D^n \subset C^n$, so nilpotent Lie algebra is solvable.

Prop. (2.5.1.18). The lower central series satisfies: $[C^n\mathfrak{g}, C^m\mathfrak{g}] \subset C^{m+n}\mathfrak{g}$.

The operation of taking derived series or lower central series commutes with base change of fields.

Proof: Prove by induction on n: $n = 0, 1$ is trivial, and if the assertion is true for $n \geq k$, then for $n = k + 1$, $[C^n\mathfrak{g}, C^m\mathfrak{g}] \subset [\mathfrak{g}, [C^{n-1}\mathfrak{g}, C^m\mathfrak{g}]] + [C^{n-1}\mathfrak{g}, C^{m+1}\mathfrak{g}] \subset C^{m+n}\mathfrak{g}$. □

Cor. (2.5.1.19). Let $\mathfrak{g}$ be a Lie algebra over a field k, and k'/k is a field extension, then $\mathfrak{g}$ is solvable/nilpotent iff $\mathfrak{g} \otimes_k k'$ is solvable/nilpotent.

Prop. (2.5.1.20). If $\mathfrak{g}$ is a nilpotent Lie algebra, then for any subalgebra $\mathfrak{h} \subsetneq \mathfrak{g}$, $N_{\mathfrak{g}}(\mathfrak{h}) \neq \mathfrak{h}$.

Proof: Because $\mathfrak{g}^n = 0$ for some n, take n to be the maximal one that $\mathfrak{h} \not\subset \mathfrak{g}^n$, the $[\mathfrak{g}^n, \mathfrak{h}] \subset \mathfrak{g}^{n+1} \subset \mathfrak{h}$, so $\mathfrak{g}^n \subset N_{\mathfrak{g}}(\mathfrak{h})$, so $N_{\mathfrak{g}}(\mathfrak{h}) \neq \mathfrak{h}$. □

Prop. (2.5.1.21). Subalgebras, quotient algebras and extension algebras of solvable algebras are solvable.

Proof: Let $\mathfrak{h} \subset \mathfrak{g}$, then $D^n(\mathfrak{h}) \subset D^n(\mathfrak{g})$, so if $\mathfrak{g}$ is solvable, then so is $\mathfrak{h}$. Also the quotient is clearly solvable. For an extension of Lie algebras

$$0 \to \mathfrak{h} \to \mathfrak{g} \to \mathfrak{r} \to 0,$$

if $\mathfrak{h}, \mathfrak{r}$ are both solvable, let $D^m(\mathfrak{h}) = 0, D^n(\mathfrak{r}) = 0$, then the image of $D^n(\mathfrak{g})$ is 0 in $\mathfrak{r}$, so $D^n(\mathfrak{g}) \subset \mathfrak{h}$, so $D^{m+n}(\mathfrak{g}) = 0$. □

Cor. (2.5.1.22) [Radical]. If $\mathfrak{a}, \mathfrak{b}$ are solvable ideals of a Lie algebra $\mathfrak{g}$, then the ideal $\mathfrak{a} + \mathfrak{b}$ is also solvable, because $0 \to \mathfrak{a} \to \mathfrak{a} + \mathfrak{b} \to \mathfrak{b}/\mathfrak{a} \cap \mathfrak{b}$.

Let $\mathfrak{r} \subset \mathfrak{g}$ be the sum of all solvable ideals of $\mathfrak{g}$, called the **radical** $\mathrm{Rad}(\mathfrak{g})$. When $\mathfrak{g}$ is of f.d., this is the maximal solvable ideal.

Def. (2.5.1.23) [Semisimple Lie Algebra]. A Lie algebra L is called **semisimple** if Rad $L = 0$, or equivalently $\mathfrak{g}$ has no solvable ideals or no commutative ideals. Notice $L/\mathrm{Rad}(L)$ is semisimple, by(2.5.1.22).

Prop. (2.5.1.24) [Lie]. Let $\mathfrak{g} \subseteq \mathfrak{gl}(V)$ be a solvable lie algebra over an alg.closed field k of char0, then $\mathfrak{g}$ is upper triangulable. Equivalently, there exists a vector $v \in V$ which is a common eigenvector for all $X \in \mathfrak{g}$, and moreover equivalently, any irreducible representation of $\mathfrak{g}$ is 1-dimensional.

Proof: Idea is to prove by induction on dimension of $\mathfrak{g}$.

Produce a codimension 1 ideal $\mathfrak{h}$ of $\mathfrak{g}$. Let $\mathfrak{g}$ be generated (as a vector space) by $\mathfrak{h}$ and Y. Being a subalgebra of solvable algebra $\mathfrak{g}$, $\mathfrak{h}$ is itself a solvable lie algebra. Apply induction step on $\mathfrak{h}$ and choose $v \in V$ such that v is an eigenvector for all $X \in \mathfrak{h}$.

The idea is to consider set W all common eigenvectors of elements of $\mathfrak{h}$ and produce an eigenvector of Y from this W. Let

$$W = \{v \in V | X(v) = \lambda(X)v \ \forall \ X \in \mathfrak{h} \text{ for a fixed } \lambda(X) \in \mathbb{C}\}.$$

Suppose W is an invariant subspace of Y, we then have restriction map $Y : W \to W$. As we are in complex vector space (algebraically closed) there exists an eigenvector for Y in W say w_0. Thus, w_0 is common eigenvector for all elements of $\mathfrak{g}$.

It remains to show that W is an invariant subspace of Y i.e., $Y(w) \in W$ for all $w \in W$ i.e., given $X \in \mathfrak{h}$, we need to have $X(Y(w)) = \lambda(X)Y(w)$.

Let $w \in W$, we have

$$\begin{aligned} X(Y(w)) &= Y(X(w)) + [X,Y](w) \\ &= Y(\lambda(X)w) + \lambda\left([X,Y]\right)w \\ &= \lambda(X)Y(w) + \lambda\left([X,Y]\right)w \end{aligned}$$

This is almost the same as what we want but with an extra term $\lambda([X,Y])\,w$. Suppose we prove $\lambda([X,Y]) = 0$ for all $X \in \mathfrak{h}$ then we are done.

Then considers subspace U spanned by elements $\{w, Y(w), Y^2(w), \cdots\}$ and then says that U is invariant subspace of each element of $\mathfrak{h}$ and (assuming n is the smallest integer such that $Y^{n+1}w$ is in the subsapce generated by $\{w, Y(w), \cdots, Y^n(w)\}$) representation of an element Z of $\mathfrak{h}$ with the basis $\{w, Y(w), \cdots, Y^n(w)\}$ is an upper triangular matrix with $\lambda(Z)$ in the diagonal. So, $\mathrm{tr}(Z) = n\lambda(Z)$.

So, $\mathrm{tr}([X,Y]) = n\lambda([X,Y])$. As $[X,Y] = XY - YX$, we have $\mathrm{tr}([X,Y]) = \mathrm{tr}(XY) - \mathrm{tr}(YX) = 0$. Thus, $\lambda([X,Y]) = 0$ and we are done. □

Cor. (2.5.1.25). If $\mathfrak{g}$ is a solvable algebra over an alg.closed field k of char 0, then all irreducible representations of $\mathfrak{g}$ is of dimension 1.

Cor. (2.5.1.26). $\mathfrak{g}$ is a solvable algebra iff $[\mathfrak{g},\mathfrak{g}]$ is nilpotent.

Proof: If $[\mathfrak{g},\mathfrak{g}]$ is nilpotent, then clearly $\mathfrak{g}$ is solvable. Conversely, if $\mathfrak{g}$ is solvable, we need to prove $[\mathfrak{g},\mathfrak{g}]$ is nilpotent. For this, we can assume k is alg.closed, and then $\mathrm{ad}(\mathfrak{g}) \subset \mathfrak{b}_{\mathfrak{g}}$ for some basis, thus $\mathrm{ad}([\mathfrak{g},\mathfrak{g}]) \subset \mathfrak{n}_{\mathfrak{g}}$ is nilpotent, and the kernel of ad is an Abelian subalgebra, so $[\mathfrak{g},\mathfrak{g}]$ is nilpotent. □

Cor. (2.5.1.27). If $\mathfrak{g}$ is a Lie subalgebra of $\mathfrak{gl}_n(k)$ where k is an alg.closed field of char0, then

$$\mathfrak{g} \text{ is solvable} \iff \mathrm{tr}(xy) = 0, \ \forall x \in \mathfrak{g}, y \in [\mathfrak{g},\mathfrak{g}].$$

Proof: Firstly if $\mathfrak{g}$ is solvable, then by Lie's theorem, we can assume $\mathfrak{g} \in \mathfrak{b}_V$ the upper-triangular matrices, so $[\mathfrak{g},\mathfrak{g}] \in \mathfrak{n}_V$ is nilpotent, and so $xy \in \mathfrak{n}_V$ is also nilpotent, and $\mathrm{tr}(xy) = 0$.

Conversely, if $\mathrm{tr}(xy) = 0$ for all $x \in \mathfrak{g}, y \in [\mathfrak{g},\mathfrak{g}]$, we only need to prove $[\mathfrak{g},\mathfrak{g}]$ is solvable, so we may change $\mathfrak{g}$ to $[\mathfrak{g},\mathfrak{g}]$ and assume $\mathrm{tr}(xy) = 0$ for all $x, y \in \mathfrak{g}$.

Now to show $\mathfrak{g}$ is solvable, it suffices to show $[\mathfrak{g},\mathfrak{g}]$ is nilpotent, or by Engel's theorem(2.5.1.29) all $x \in [\mathfrak{g},\mathfrak{g}]$ defines a nilpotent endomorphism on V. Choose a basis that x is upper-triangular by(2.3.6.3), and let x_s be the semisimple part of x, then it suffices to show $x_s = 0$, or equivalently $\mathrm{tr}(\overline{x_s}x) = 0$. To show this, notice $x \in [\mathfrak{g},\mathfrak{g}]$, so it suffices to show $\mathrm{tr}(\overline{x_s}[y,z]) = 0$ for any y, z. But this equals $\mathrm{tr}([\overline{x_s}, y], z)$. Finally, this is 0 because of the hypothesis and the fact $\overline{x_s}$ is a polynomial in x(2.3.6.7) so $[\overline{x_s}, y] \in \mathfrak{g}$. □

Cor. (2.5.1.28) [Cartan's Criteria for Solvability]. A Lie algebra $\mathfrak{g}$ over a field of characteristic 0 is solvable if $\kappa_{\mathfrak{g}}(x,y)$ for any $x \in \mathfrak{g}, y \in [\mathfrak{g},\mathfrak{g}]$, where κ is the Killing form.

Proof: By(2.5.1.19), it suffices to show for k alg.closed. Because the kernel of the adjoint map is the center of $\mathfrak{g}$, so $\mathfrak{g}$ is solvable iff $\mathrm{ad}(\mathfrak{g})$ is solvable. □

Prop. (2.5.1.29) [Engel]. If (V,ρ) is a representation of a Lie algebra $\mathfrak{g}$ that $\rho(x)$ is nilpotent for all $x \in \mathfrak{g}$, then there is a basis that $\rho(\mathfrak{g})$ is contained in $\mathfrak{n}_V$, in particular $\mathfrak{g}$ is nilpotent.

Proof: It suffices to show if a sub-Lie algebra of $\mathfrak{gl}_V$ consists of nilpotent elements, then there is a common 0-eigenvector. Use Induction, choose a maximal subalgebra K of L, then notice the normalizer of K in L is strictly containing K, because we can let K acts by adjoint on L/K, and notice $\mathrm{ad}\, x = \lambda_x - \rho_x$ is nilpotent for x a nilpotent matrix, so by induction hypothesis there is an $x \in L$ that $[x, K] \subset K$. But K is maximal, so it must be of codimension 1, and $L = K + Fz$. The 0-eigenvectors for K is a nonzero subspace by induction hypothesis. Now this space is invariant under z: for any $h \in K$,

$$h(z(v)) = [h,z](v) + zh(v) = 0.$$

So now a 0-eigenvector for z in this space will suffice. □

Cor. (2.5.1.30). If all elements of L are ad-nilpotent(i.e. $\mathrm{ad}x = 0$), then L is nilpotent. Equivalently, elements of L has a common 0-eigenvector.

Proof: Consider $ad : \mathfrak{g} \to \mathfrak{gl}_{\mathfrak{g}}$, then the image is nilpotent by Engel's theorem(2.5.1.29), and the kernel of ad is the center of $\mathfrak{g}$, so $\mathfrak{g}$ is also nilpotent. □

Cor. (2.5.1.31). Let $\mathfrak{a}$ be an ideal of a Lie algebra $\mathfrak{g}$. Then $\mathfrak{a}$ is nilpotent if $\mathrm{ad}_{\mathfrak{g}}(a)$ is nilpotent for any $a \in \mathfrak{a}$.

Proof: If $\mathrm{ad}_{\mathfrak{g}}(a)$ is nilpotent for any $a \in \mathfrak{a}$, then also $\mathrm{ad}_{\mathfrak{a}}(a)$ is nilpotent, so $\mathfrak{a}$ is nilpotent by Engel's theorem. Conversely, if $\mathfrak{a}$ is nilpotent, then $\mathrm{ad}_{\mathfrak{a}}(a)$ is nilpotent for any $a \in \mathfrak{a}$. And $\mathrm{ad}(a)(\mathfrak{g}) \subset \mathfrak{a}$, so $\mathrm{ad}_{\mathfrak{g}}(a)$ is nilpotent. □

Cor. (2.5.1.32). The sum of two nilpotent ideals of $\mathfrak{g}$ is nilpotent.

Proof: We need to show for any $a \in \mathfrak{a}, b \in \mathfrak{b}$, $\mathrm{ad}_{\mathfrak{g}}(a+b)$ is nilpotent. For this, we need to factor $\mathfrak{g}$ as Jordan sequence $0 \subset \mathfrak{g}_1 \subset \mathfrak{g}_2 \subset \ldots \subset \mathfrak{g}_n = \mathfrak{g}$ over itself via the adjoint representation, then I claim that $\mathrm{ad}(a)(\mathfrak{g}_k) \subset \mathfrak{g}_{k-1}$: Because $V = \mathfrak{g}_k/\mathfrak{g}_{k-1}$ is simple, let $V' \subset V$ consists of vectors v that $a(v) = 0$ for any $a \in \mathfrak{a}$, then it is non-empty by Engel's theorem, and also it is invariant under action of $\mathfrak{g}$: $a(gv) = [a,g](v) + g(av) = 0$. So it is all of V.

Then, we have $\mathrm{ad}(a+b)(\mathfrak{g}_k) \subset \mathfrak{g}_{k-1}$, thus $\mathrm{ad}(a+b)$ is nilpotent. □

Cor. (2.5.1.33) [Maximal Nilpotent Ideal]. For any Lie algebra $\mathfrak{g}$, there exists a maximal nilpotent ideal, denoted by $\mathfrak{n}$.

Def. (2.5.1.34) [Nilpotent Radical]. The **nilpotent radical** $\mathfrak{s} = s(\mathfrak{g})$ of a Lie algebra is the intersection of the kernels of simple representations of $\mathfrak{g}$.

$\mathfrak{s}$ is nilpotent for any f.d. representation of $\mathfrak{g}$, in particular the adjoint representation of $\mathfrak{g}$. Thus it is nilpotent, by(2.5.1.31).

Lemma (2.5.1.35). Let $\mathfrak{g} \subset \mathfrak{gl}_V$ be a subalgebra, and let $\mathfrak{a}$ a commutative ideal of $\mathfrak{g}$. If V is simple as a $\mathfrak{g}$-module, then $[\mathfrak{g}, \mathfrak{g}] \cap \mathfrak{a} = 0$.

Proof: Cf.[Mil13]P58. □

Prop. (2.5.1.36). Let $\mathfrak{g}$ be a Lie algebra, and $\mathfrak{r}$ its radical, $\mathfrak{s}$ it nilpotent radical, then

$$\mathfrak{s} = D(\mathfrak{g}) \cap \mathfrak{r} = [\mathfrak{g}, \mathfrak{r}].$$

In particular, $[\mathfrak{g}, \mathfrak{r}]$ is nilpotent(2.5.1.34).

Proof: To show $D(\mathfrak{g}) \cap \mathfrak{r} \subset \mathfrak{s}$, we need to show that $\rho(D(\mathfrak{g}) \cap \mathfrak{r}) = 0$ for any simple representation ρ. Because $\mathfrak{r}$ is solvable, let r be the smallest integer that $\rho(D^{r+1}(\mathfrak{r})) = 0$, then $\mathfrak{a} = \rho(D^r(\mathfrak{r}))$ is a commutative ideal of $\rho(\mathfrak{g})$. Hence by(2.5.1.35) $D(\rho(\mathfrak{g})) \cap \mathfrak{a} = 0$, so $\rho(D(\mathfrak{g}) \cap D^r(\mathfrak{r})) = 0$. Now if $r > 0$, then $\rho(D^r(\mathfrak{r})) = 0$, contradicting the minimality of r, so $\rho(D(\mathfrak{g}) \cap \mathfrak{r}) = 0$.

To show $\mathfrak{s} \subset [\mathfrak{g}, \mathfrak{r}]$, let $\mathfrak{q} = \mathfrak{g}/[\mathfrak{g}, \mathfrak{r}]$, and f the quotient map. Then because the kernel is solvable, $f(\mathfrak{r})$ is the radical of $\mathfrak{q}$(2.5.1.22), but it is also contained in the center of $\mathfrak{q}$, so $\mathfrak{q}$ is reductive, and thus has a faithful semisimple representation(2.5.4.4), then the kernel of this representation is just $[\mathfrak{g}, \mathfrak{r}]$, showing that $\mathfrak{s} \subset [\mathfrak{g}, \mathfrak{r}]$. □

Def. (2.5.1.37) [Levi Subalgebras]. Let $\mathfrak{g}$ be a Lie algebra and $\mathfrak{r}$ its radical, then a Lie subalgebra $\mathfrak{s}$ is called a **Levi subalgebra** if $\mathfrak{g} = \mathfrak{r} \oplus \mathfrak{s}$.

Prop. (2.5.1.38) [Levi-Malcev]. Every Lie algebra over a field k of char0 has a Levi subalgebra, and any two Levi subalgebras of $\mathfrak{g}$ are conjugate by a special automorphism of $\mathfrak{g}$(2.5.1.7).

Proof: If $\mathfrak{g}$ is reductive, then Levi subalgebra exists uniquely, by(2.5.4.2) and(2.5.4.3).

if $\mathfrak{r}$ is a minimal ideal of $\mathfrak{g}$, then $[\mathfrak{g}, \mathfrak{r}] = \mathfrak{r}$, and $[\mathfrak{r}, \mathfrak{r}] = 0 = Z(\mathfrak{g})$. Consider the adjoint action of $\mathfrak{g}$ on $\mathrm{End}_k(\mathfrak{g})$. Also consider the subspaces V, W of $\mathrm{End}_k(\mathfrak{g})$, where V is the subspace of maps from $\mathfrak{g}$ to $\mathfrak{r}$ that restriction to $\mathfrak{r}$ is a constant multiple of identity, and W is the subspaces of W consisting of maps vanishing on $\mathfrak{r}$. Both of V, W are invariant under action of $\mathfrak{g}$.

Let $\varphi : \mathfrak{r} \to \mathfrak{g}$ be the adjoint action, which is injective and has image $P \subset W$. Also $\mathfrak{P}$ is invariant under action of $\mathfrak{g}$(because $\mathfrak{r}$ is an ideal).

For $x \in \mathfrak{r}, y \in \mathfrak{g}, \alpha \in V$, $(x\alpha)(y) = [x, \alpha(y)] - \alpha([x, y]) = -\lambda(\alpha)[x, y]$, so $x\alpha = \mathrm{ad}(\lambda(\alpha)x)$, which means elements of $\mathfrak{r}$ map V into P. Thus now $\mathfrak{r}$ acts trivially on V/P, and W/P is invariant under the action of $\mathfrak{g}/\mathfrak{r}$, which is a semisimple Lie algebra. Thus by Weyl's theorem(15.8.1.2), there exists a $\mathfrak{g}$-stable line L that $V/P = W/P \oplus L$. But $\mathfrak{g}$ acts trivially on L by(15.8.1.1).

Let α_0 generates L and normalized that $\lambda(\alpha) = 1$, then $\mathfrak{g}\alpha_0 \in P$, We consider the map $\mathfrak{g} \xrightarrow{g \mapsto g\alpha_0} P \xrightarrow{\varphi^{-1}} \mathfrak{r}$, whose restriction to $\mathfrak{r}$ is the identity map, so its kernel is a Levi subgroup for $\mathfrak{r}$.

Still in this case, let $\mathfrak{s}'$ be a second Levi subgroup for $\mathfrak{r}$. For each $x \in \mathfrak{s}'$, there is a unique $h(x) \in \mathfrak{r}$ that $x + h(x) \in \mathfrak{s}$. Hence this h satisfies $h([x, y]) = [h(x), y] + [x, h(y)]$. But then by(15.8.1.3),

$h(x) = [a, x]$ for some $a \in \mathfrak{r}$. Then $1 + \mathrm{ad}(a)$ maps $\mathfrak{s}$ to $\mathfrak{s}'$, and $\mathrm{ad}(a)^2 = 0$ because $\mathfrak{r}$ is commutative. And $\mathfrak{r} = [\mathfrak{r}, \mathfrak{g}]$, so a is in the nilpotent radical of $\mathfrak{g}$, thus $\mathfrak{s}, \mathfrak{s}'$ are conjugate by a special automorphism.

For the general case, we can use induction on the dimension of $\mathfrak{g}$. After the first two cases, we can assume that $[\mathfrak{g}, \mathfrak{r}] \neq 0$ and $\mathfrak{r}$ contains a proper non-trivial ideal. As $[\mathfrak{g}, \mathfrak{r}]$ is nilpotent(2.5.1.36), its center is non-zero. So we can choose a maximal ideal $\mathfrak{m}$ contained in the center of $[\mathfrak{g}, \mathfrak{r}]$, and $\mathfrak{m} \neq \mathfrak{r}$. Now $\mathfrak{g}/\mathfrak{m}$ has radical $\mathfrak{r}/\mathfrak{m}$ because $\mathfrak{m}$ is solvable, so we can apply induction to find a Levi subgroup $\mathfrak{h}'$ for $\mathfrak{g}/\mathfrak{m}$ in $\mathfrak{g}/\mathfrak{m}$, and let $\mathfrak{h}''$ be its preimage in $\mathfrak{g}$. Then $\mathfrak{h}''$ has radical $\mathfrak{m}$, and thus by induction there is a Levi subgroup $\mathfrak{h}$ for $\mathfrak{m}$ in $\mathfrak{h}''$, and this $\mathfrak{h}$ is a Levi subgroup for $\mathfrak{r}$ in $\mathfrak{g}$. Similarly any two such Levi subgroups are conjugate by a special automorphism.

This has another cohomological proof in [Etingof, Section48].**?** □

2 Semisimple Lie Algebra

Prop. (2.5.2.1) [Cartan-Killing Criteria for Semisimplicity]. A f.d. Lie algebra $\mathfrak{g}$ is semisimple iff its Killing form(2.5.1.13) is non-degenerate.

Proof: If $\mathfrak{g}$ is semisimple, then the adjoint representation is faithful, thus by(2.5.9.6) the Killing form is non-degenerate. Conversely, if the Killing form is non-degenerate and $\mathfrak{a}$ is a commutative ideal of $\mathfrak{g}$ and $a \in \mathfrak{a}, g \in \mathfrak{g}$, then $(\mathrm{ad}\, a \circ \mathrm{ad}\, g)^2 = 0$, so $\mathrm{ad}\, a \circ \mathrm{ad}\, g$ is nilpotent and has trace 0. so $a \in \mathfrak{g}^\perp$, which is 0 because the Killing form is non-degenerate. □

Cor. (2.5.2.2). Let $\mathfrak{a}$ be a semisimple ideal of a Lie algebra $\mathfrak{g}$, then the orthogonal space $\mathfrak{a}'$ w.r.t the Killing form is an ideal and is a complement for $\mathfrak{a}$ in $\mathfrak{g}$, and $\mathfrak{g} \cong \mathfrak{a} \times \mathfrak{a}'$.

Proof: $\mathfrak{a}^\perp$ is an ideal because the Killing form is invariant. The Killing form of $\mathfrak{a}$ is the restriction of the Killing form of $\mathfrak{g}$(2.5.1.13), so $\mathfrak{a} \cap \mathfrak{a}' = 0$ because $\kappa_\mathfrak{a}$ is non-degenerate. □

Cor. (2.5.2.3). A Lie algebra is semisimple iff it is isomorphic to a product of simple algebras $\mathfrak{g} = \mathfrak{a}_1 \times \cdots \times \mathfrak{a}_r$, and these $\mathfrak{a}_i$ are all its minimal ideals, (Not only up to isomorphism).

Proof: The Killing form of $\mathfrak{a} \cap \mathfrak{a}^\perp$ is 0, thus it is solvable, by(2.5.1.28), and then 0, so we can continue the decomposition.

For any minimal nonzero ideal $\mathfrak{a} \subset \mathfrak{g}$, then $[\mathfrak{g}, \mathfrak{a}]$ is an ideal contained in $\mathfrak{a}$. which is nonzero because $\mathfrak{g}$ has trivial center. Then

$$\mathfrak{a} = [\mathfrak{g}, \mathfrak{a}] = \oplus_i [\mathfrak{a}, \mathfrak{a}_i]$$

so $\mathfrak{a} \subset [\mathfrak{a}, \mathfrak{a}_i] \subset \mathfrak{a}_i$, and then $\mathfrak{a} = \mathfrak{a}_i$ by simplicity. □

Cor. (2.5.2.4). If $\mathfrak{g}$ is semisimple, then $[\mathfrak{g}, \mathfrak{g}] = \mathfrak{g}$.

Cor. (2.5.2.5). Let $\mathfrak{g}$ be a Lie algebra over a field k and k'/k is a field extension, then $\mathfrak{g}$ is semisimple iff $\mathfrak{g} \otimes_k k'$ is semisimple.

Prop. (2.5.2.6) [Examples of Semisimple Lie Algebras].

- The subalgebra $\mathfrak{sl}(V)$ of all elements of $\mathrm{End}(V)$ of trace 0 is semisimple.

Prop. (2.5.2.7). If L is semisimple, then every derivative of L is inner.

Proof: This is a special case of(15.8.1.3) applied to the adjoint representation. □

Prop. (2.5.2.8). If $\mathfrak{g}$ is a semisimple algebra of $\mathfrak{gl}_n(k)$ where k is a field of char0, then it contains the semisimple and nilpotent parts of each of its elements under the Jordan decomposition(2.3.6.7).

Proof: We may assume k is alg.closed, because the Jordan decomposition is invariant of the field that contains $\mathfrak{g}$, and an element is contained is a vector space can be checked after base change to a larger field. For any subspace $W \subset V$, let $\mathfrak{g}_W = \{\alpha \in \mathfrak{gl}_V | \alpha(W) \subset W, \mathrm{tr}(\alpha|_W) = 0\}$, then if $\mathfrak{g}W \subset W$, then $\mathfrak{g} \subset \mathfrak{g}_W$, because every element of $\mathfrak{g}$ is a sum of brackets by(2.5.2.4), thus have zero trace. Now consider

$$\mathfrak{g}' = \mathfrak{n}_{\mathfrak{gl}_V}(\mathfrak{g}) \bigcap_{\mathfrak{g}W \subset W} \mathfrak{g}_W.$$

If $x \in \mathfrak{g}'$, then so does x_s and x_n, because they are polynomials in x without constant terms, and $\mathrm{ad}(x)_s = \mathrm{ad}(x_s), \mathrm{ad}(x)_n = \mathrm{ad}(x_n)$.

So it suffices to show that $\mathfrak{g} = \mathfrak{g}'$. We claim that $\mathfrak{g}' = \mathfrak{g}$: As $\mathfrak{g}$ is a semisimple ideal of $\mathfrak{g}'$, by(2.5.2.2), we have a decomposition

$$\mathfrak{g}' = \mathfrak{g} \oplus \mathfrak{g}^{\perp}.$$

Let $\alpha \in \mathfrak{g}^{\perp}$ and W a simple $\mathfrak{g}$-module of V, then α acts on W as a scalar, which must be 0 because $\alpha \in \mathfrak{g}_W$ and k has char 0. As W is a sum of simple $\mathfrak{g}$-modules by Weyl's theorem(15.8.1.2), we get the desired conclusion. □

Prop. (2.5.2.9) [Abstract Jordan Decomposition]. A **semisimple/nilpotent element** x in a Lie algebra $\mathfrak{g}$ is an element that $\rho(x)$ is semisimple/nilpotent for any representation (V, ρ) of $\mathfrak{g}$. And $x = x_s + x_n$ is called a **Jordan decomposition** iff $\rho(x) = \rho(x_s) + \rho(x_n)$ is a Jordan decomposition(2.3.6.7) for any representation ρ of $\mathfrak{g}$.

Every element of a semisimple Lie algebra $\mathfrak{g}$ over a field of characteristic 0 has a unique Jordan decomposition, and $x = x_s + x_n$ is a Jordan decomposition if $\rho(x) = \rho(x_s) + \rho(x_n)$ is a Jordan decomposition for one faithful representation ρ of $\mathfrak{g}$. In particular, this is holds for the adjoint representation ad.

Proof: Let $x \in \mathfrak{g}$ and (V, ρ) a faithful representation of $\mathfrak{g}$(for example the adjoint representation), then there is at most one $x = x_s + x_n$ that $\rho(x) = \rho(x_s) + \rho(x_n)$ is the Jordan decomposition, which proves the uniqueness.

Now for any $x \in \mathfrak{g}$, as(2.5.2.8) shows, there do exist these two elements that $\rho(x) = \rho(x_s) + \rho(x_n)$. But then it can be checked directly $\mathrm{ad}(x) = \mathrm{ad}(x_s) + \mathrm{ad}(x_n)$ is the Jordan decomposition of $\mathrm{ad}(x)$ as an endomorphism of $\mathfrak{g}$, by(2.5.1.16). As the adjoint representation is faithful, this shows the Jordan decomposition is independent of the faithful representation chosen.

Now every representation is a subrepresentation of a faithful representation, so we can prove the existence. □

Simple Lie Algebras

Main references are [Car05]Chap8 and [Kna96], more data about simple Lie algebras can be found in [Kna96]P508.

Def. (2.5.2.10) [Lie Algebras of Type A_n: $\mathfrak{sl}(n+1, \mathbb{C})$].

Def. (2.5.2.11) [Lie Algebras of Type A_1]. A_1 is also called $\mathfrak{sl}_2(\mathbb{C})$. It has a basis f, h, e with

$$[he] = 2e, \quad [hf] = -2f, \quad [ef] = h.$$

In matrix form,

$$h = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad e = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad f = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}.$$

It can also be realized by

$$H=\begin{bmatrix}0&-i\\ i&0\end{bmatrix},\quad R=\frac{1}{2}\begin{bmatrix}1&i\\ i&-1\end{bmatrix},\quad L=\frac{1}{2}\begin{bmatrix}1&-i\\ -i&-1\end{bmatrix}.$$

These two representation differ by a conjugation by the Cayley transformation $C=-\frac{1+i}{2}\begin{bmatrix}i&1\\ i&-1\end{bmatrix}$.

It is simple by?. The subalgebra $\mathfrak{b}$ generated by X and H is solvable, called the canonical Borel subalgebra of $\mathfrak{sl}_2$.

Proof: □

Prop. (2.5.2.12) [Lie Algebras of Type B_n: $\mathfrak{so}(2n+1,\mathbb{C})$].

Prop. (2.5.2.13) [Lie Algebras of Type C_n: $\mathfrak{sp}(n,\mathbb{C})$].

Prop. (2.5.2.14) [Lie Algebras of Type D_n: $\mathfrak{so}(2n,\mathbb{C})$].

Prop. (2.5.2.15) [Lie Algebras of Type G_2].

Prop. (2.5.2.16) [Lie Algebras of Type F_4].

Prop. (2.5.2.17) [Lie Algebras of Type E_8].

Prop. (2.5.2.18) [Classification of F.D. Complex Simple Lie Algebras].

Prop. (2.5.2.19) [Group Automorphisms of Simple Lie Algebras]. Cf.[Carter, P184].

Prop. (2.5.2.20). $\mathfrak{sl}_2(k)$ is simple if k has characteristic$\neq 2$.

Def. (2.5.2.21) [Exponent]. Let $\mathfrak{g}$ be a simple Lie algebra,

$$e=\sum e_i,\quad h=2\rho^\vee=\sum_i(2\rho^\vee,\omega_i)h_i,\quad f=\sum_i(2\rho^\vee,\omega_i)f_i,$$

then by definition, $[h,e]=2e,[e,f]=h$, and

$$\begin{aligned}[h,f]&=\sum_i\sum_j(2\rho^\vee,\omega_i)\alpha_i^\vee(\alpha_j)(2\rho^\vee,\omega_j)f_j\\ &=\sum_j[(\sum_i(2\rho^\vee,\omega_i)\alpha_i^\vee,\alpha_j)](2\rho^\vee,\omega_j)f_j\\ &=\sum_j(2\rho^\vee,\alpha_j)(2\rho^\vee,\omega_j)f_j\\ &=-2f\end{aligned}$$

So $\{h,e,f\}$ is a $\mathfrak{sl}_2$-tuple, called the **principal $\mathfrak{sl}_2$-subalgebra** of $\mathfrak{g}$. The highest weights of subrepresentation of the adjoint action of this subalgebra on $\mathfrak{g}$ is called the **exponents of $\mathfrak{g}$**, counted with multiplicity.

Equivalently, as $h|_{\mathfrak{g}^\alpha}=\mathrm{ht}(\alpha)\,\mathrm{id}$, if r_m is the number of roots of $\mathfrak{g}$ of height m, the exponents of $\mathfrak{g}$ is the numbers m that $r_m>r_{m+1}$.

Cor. (2.5.2.22). While $r_m = 0$ for m large and $r_1 = r(\mathfrak{g})$, there are r exponents of $\mathfrak{g}$. Since the roots of height 2 are all $\alpha_i + \alpha_j$ where i, j are connected by an edge in the Dynkin diagram, thus $r_2 = r - 1$, thus $1 = m_1 \le \ldots \le m_r$, $\sum_{i=1}^r = |R^+|$. And $\mathfrak{g} \cong \oplus_{r=1}^r L_{2m_i+1}$ as a representation of the principal $\mathfrak{sl}_2$-subalgebra.

Prop. (2.5.2.23) [Exponents of Simple Lie Algebras]. Let $\mathfrak{g}$ be a Lie algebra, the exponents are.

- $A_n : 1, 2, \ldots, n$.
- $B_n : 1, 3, \ldots, 2n - 1$.
- $C_n : 1, 3, \ldots, 2n - 1$.
- $D_n : 1, 3, \ldots, 2n - 3$ and n.
- $G_2 : 1, 5$.
- $F_4 : 1, 5, 7, 11$.
- $E_8 : 1, 7, 11, 13, 17, 19, 23, 29$.
- $E_7 : 1, 5, 7, 9, 11, 13, 17$.
- $E_6 : 1, 4, 5, 7, 8, 11$.

3 Cartan Subalgebras

Lie algebras in this subsection are assumed to be of f.d..

Def. (2.5.3.1) [Cartan Subalgebras]. A **Cartan subalgebra** of a Lie algebra $\mathfrak{g}$ is a nilpotent subalgebra $\mathfrak{h}$ that equals to its own normalizer in $\mathfrak{g}$.

Remark (2.5.3.2). As a proper subalgebra of a nilpotent algebra is never its own normalizer(2.5.1.20), a Cartan subalgebra is a maximal nilpotent subalgebra, but a maximal nilpotent subalgebra may not be a Cartan subalgebra.

If k'/k is a field extension, then $\mathfrak{h}$ is a Cartan subalgebra of $\mathfrak{g}$ iff $\mathfrak{h}_{\mathfrak{k}'}$ is a Cartan subalgebra of $\mathfrak{g}_{k'}$. This is because being nilpotent and the normalizer is also compatible with base change(2.5.1.4).

Prop. (2.5.3.3) [Diagonal Cartan Algebra]. Let $\mathfrak{g} \subset \mathfrak{gl}_V$ be a subalgebra containing a diagonal matrix $a = \mathrm{diag}(a_1, \ldots, a_n)$ with distinct a_i, and let $\mathfrak{h}$ be the subspace of all diagonal matrices in $\mathfrak{g}$, then $\mathfrak{h}$ is a Cartan subalgebra of $\mathfrak{g}$.

Proof: Firstly $\mathfrak{h}$ is Abelian, and if $b = \sum b_{ij} eij \in N_{\mathfrak{g}}(\mathfrak{h})$, then $[a, b] \in \mathfrak{h}$. But

$$[a, b] = \sum_{ij} (a_{ii} - a_{jj}) b_{ij} e_{ij}$$

is in $\mathfrak{h}$ iff $\mathfrak{b}$ is diagonal, or $b \in \mathfrak{h}$, so $\mathfrak{h} = N_{\mathfrak{g}}(\mathfrak{h})$ and $\mathfrak{h}$ is a Cartan subalgebra. □

Def. (2.5.3.4) [Regular Elements]. Let $\mathfrak{g}$ be a f.d. Lie algebra, for any $x \in \mathfrak{g}$, let $P_x(T)$ be the characteristic polynomial of $\mathrm{ad}(x)$:

$$P_x(T) = \det(T - \mathrm{ad}(x)) = T^m + a_{m-1}(x) T^{m-1} + \ldots + a_0(x).$$

Then the **rank of** $\mathfrak{g}$ is the minimal n that $n(x) \neq 0$ for some $x \in \mathfrak{g}$. A **regular element** is an element $x \in \mathfrak{g}$ that $a_n(x) \neq 0$.

Prop. (2.5.3.5) [Regular Elements and Cartan Subalgebras]. For any regular element $x\in\mathfrak{g}$, the nilspace $\mathfrak{g}_x^0$ is a Cartan subalgebra of $\mathfrak{g}$.

Proof: Let
$$U_1=\{y\in\mathfrak{g}_x^0|\operatorname{ad}_{\mathfrak{g}}(y)|_{\mathfrak{g}_x^0}\text{ is not nilpotent}\},$$
$$U_2=\{y\in\mathfrak{g}_x^0|\operatorname{ad}_{\mathfrak{g}}(y)|_{(\mathfrak{g}/\mathfrak{g}_x^0)}\text{ is invertible}\}.$$
They are both Zariski open subsets of $\mathfrak{g}_x^0$. According to Engel's theorem(2.5.1.29), to show $\mathfrak{g}$ is nilpotent, it suffices to show that U_1 is empty. U_2 is non-empty because it contains x, so if U_1 is non-empty, $U_1\cap U_2$ is non-empty and there is a $y\in U_1\cap U_2$. For this y, $n(y)<\dim\mathfrak{g}_x^0=n(x)$, contradicting the regularity of x.

It remains to show that $\mathfrak{g}_x^0$ is its own normalizer. If z normalizes $\mathfrak{g}_x^0$, then $[z,x]\in\mathfrak{g}_x^0$, which means $(\operatorname{ad}(x))^n[z,x]=0$, so $\operatorname{ad}(x)^{n+1}(z)=0$, thus $z\in\mathfrak{g}_x^0$. □

Cor. (2.5.3.6) [Cartan Subalgebras Exist]. Let $\mathfrak{g}$ be a Lie algebra over an infinity field k contains some Cartan subalgebra, and when k is alg.closed, all Cartan subalgebras come from some regular element, by(2.5.3.13).

Proof: Regular elements exist because k is infinite. □

Cor. (2.5.3.7). Every Lie algebra over an infinite field is a sum of Cartan subalgebras.

Proof: This is because the sum of Cartan subalgebras is a vector space thus Zariski closed but it contains all regular elements, which is a Zariski open subset. □

Cor. (2.5.3.8). Let $\mathfrak{a}$ be a subalgebra of a Lie algebra $\mathfrak{g}$ that $\operatorname{ad}_{\mathfrak{g}}(a)$ is semisimple for any $a\in\mathfrak{a}$, then $\mathfrak{a}$ is contained in a Cartan subalgebra of $\mathfrak{g}$.

Proof: Cf.[Mil13]P81.? □

Prop. (2.5.3.9). Let $\mathfrak{h}$ be a Cartan subalgebra of $\mathfrak{g}$ over an alg.closed field k. Consider the generalized eigenvalue decomposition(2.5.3.12), if $x\in\mathfrak{g}^\alpha$, then $\operatorname{ad}(x)(\mathfrak{g}^\beta)\in\mathfrak{g}^{\alpha+\beta}$(2.5.1.12), and thus $\operatorname{ad}(x)$ is nilpotent. Let $E(\mathfrak{h})$ be the subgroup of the group of elementary automorphisms(2.5.1.7) of $\mathfrak{g}$ generated by the set of all the automorphisms $e^{\operatorname{ad}_{\mathfrak{g}}(x)}$, where $x\in\mathfrak{g}^\alpha$ for some $\alpha\in\mathfrak{h}^*\backslash 0$.

Now let $\mathfrak{h},\mathfrak{h}'$ be two Cartan subalgebras of $\mathfrak{g}$, then there exists $u\in E(\mathfrak{h}),u'\in E(\mathfrak{h}')$ that $u(\mathfrak{h})=u'(\mathfrak{h}')$.

Proof: Number the elements of $\mathfrak{h}^*\backslash 0$ as $\alpha_1,\ldots,\alpha_n$, and consider the map
$$f:\mathfrak{g}^{\alpha_1}\times\ldots\times\mathfrak{g}^{\alpha_n}\times\mathfrak{h}\to\mathfrak{g}:(x_1,\ldots,x_n,h)\mapsto e^{\operatorname{ad}(x_1)}\ldots e^{\operatorname{ad}(x_n)}h.$$
Given a $h_0\in\mathfrak{h}$, it can be shown that
$$(df)|_{(0,\ldots,0,h_0)}:(x_1,\ldots,x_n,h)\mapsto h+\sum_i[x_i,h_0].$$
Thus if we choose a regular $h_0\in\mathfrak{h}$, then $(df)|_{(0,\ldots,0,h_0)}$ is surjective from $\mathfrak{g}$ to $\mathfrak{g}$. Thus $E(\mathfrak{h})\mathfrak{h}_r$ contains a dense open subset of $\mathfrak{g}$?. Similarly, $E(\mathfrak{h}')\mathfrak{h}'_r$ contains a dense open subset of $\mathfrak{g}$. So their intersection is not empty, i.e. $u(h)=u'(h')$ for some u,u',h,h'. Now
$$u(\mathfrak{h})=u(\mathfrak{g}_h^0)=\mathfrak{g}_{u(h)}^0=\mathfrak{g}_{u'(h')}^0=u'(\mathfrak{g}_{h'}^0)=u'(\mathfrak{h}')$$
□

Cor. (2.5.3.10). All Cartan subalgebras in a Lie algebra have the same dimension, which is the rank of $\mathfrak{g}$(2.5.3.4).

Proof: Because we can take a base change to an alg.closed field, under which a Cartan subalgebra is also a Cartan subalgebra by(2.5.3.2), then they have the same rank. □

Cor. (2.5.3.11) [Cartan Subalgebras are Conjugate]. Any two Cartan subalgebras of a f.d. Lie algebra over an alg.closed field k are conjugate by an elementary automorphism(2.5.1.7).

Cartan Subalgebra of Semisimple Lie Algebras

Lemma (2.5.3.12) [Decomposition w.r.t. a Cartan Subalgebra]. Let $\mathfrak{h}$ be a Cartan subalgebra of a semisimple Lie algebra $\mathfrak{g}$, and assume that

$$\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha \in \mathfrak{h}^\vee \setminus 0} \mathfrak{g}^\alpha.$$

where $R = R(\mathfrak{g}, \mathfrak{h})$ is called the **root system associated to** $(\mathfrak{g}, \mathfrak{h})$. This is true, for example, when k is alg.closed, by(2.5.9.10).(See(2.5.3.21) for when this decomposition is possible).

Cor. (2.5.3.13). If k is alg.closed, the set $\mathfrak{h}_r$ of regular elements h in $\mathfrak{h}$ that $\mathfrak{g}_h^0 = \mathfrak{h}$ is open and dense in $\mathfrak{h}$ in the Zariski topology.

Proof: The condition is equivalent to $\prod_{\alpha \in \mathfrak{h}^\vee \setminus 0} \alpha(h) \neq 0$, which is an open condition. □

Lemma (2.5.3.14). In the decomposition above, if $\alpha + \beta \neq 0$, then $\mathfrak{g}^\alpha$ and $\mathfrak{g}^\beta$ is orthogonal w.r.t. the Killing form.

Proof: $\mathrm{ad}(x)\,\mathrm{ad}(y)\mathfrak{g}^\gamma \subset \mathfrak{g}^{\alpha+\beta+\gamma}$, so if $\alpha + \beta \neq 0$, then $\mathrm{ad}(x)\,\mathrm{ad}(y)$ is nilpotent, thus $\kappa(x, y) = 0$. □

Prop. (2.5.3.15)[Cartan Subalgebras of Semisimple Lie Algebras]. Let $\mathfrak{h}$ be a Cartan subalgebra of a semisimple Lie algebra $\mathfrak{g}$, then

- Every element of $\mathfrak{h}$ is semisimple. In particular, $\mathfrak{h}$ is commutative(2.5.1.15).
- The centralizer of $\mathfrak{h}$ in $\mathfrak{g}$ is $\mathfrak{h}$.
- The restriction of the Killing form to $\mathfrak{h}$ is non-degenerate.

Proof: By(2.5.3.2), it suffices to prove this after k is replaced by its alg.closure, so the generalized eigenvalue decomposition(2.5.3.12) holds. We prove 3 first: by(2.5.3.14), $\mathfrak{h}$ is orthogonal to all $[\mathfrak{h}, x]$ for any x. But if $x \in \mathfrak{g}^\alpha$, we can see that $[\mathfrak{h}, x] = \mathfrak{g}^\alpha$, so $\mathfrak{h}$ is orthogonal to all $\bigoplus \mathfrak{g}^\alpha$, so κ must be non-degenerate on $\mathfrak{h}$.

Because $\mathfrak{g}$ has trivial center, the adjoint representation realizes $\mathfrak{h}$ as a subalgebra of $\mathfrak{gl}_\mathfrak{g}$, and Lie's theorem(2.5.1.24) shows there is a basis that $\mathfrak{h} \subset \mathfrak{b}_\mathfrak{g}$, hence $\mathrm{ad}([\mathfrak{h}, \mathfrak{h}]) \subset \mathfrak{n}_\mathfrak{g}$, and so $\mathrm{tr}(\mathfrak{h}, [\mathfrak{h}, \mathfrak{h}]) = 0$. As κ is non-degenerate on $\mathfrak{h}$, $[\mathfrak{h}, \mathfrak{h}] = 0$, thus $\mathfrak{h}$ is commutative. Now $\mathfrak{h} \subset c_\mathfrak{g}(\mathfrak{h}) \subset N_\mathfrak{g}(\mathfrak{h})$, thus $\mathfrak{h} = c_\mathfrak{g}(\mathfrak{h})$.

If $x \in \mathfrak{h}$, and $x = x_s + x_n$ is the Jordan decomposition(2.5.2.9), then $\mathrm{ad}(x_n)$ are polynomials of $\mathrm{ad}(x)$ thus lies in $\mathfrak{h}$. Now $\mathrm{ad}(x_n)$ commutes with all $\mathrm{ad}(y)$ for $y \in \mathfrak{h}$, thus $\mathrm{ad}(y)\,\mathrm{ad}(x_n)$ is nilpotent, thus $\kappa(y, x_n) = 0$. Thus $x_n = 0$ as κ is non-degenerate on $\mathfrak{h}$. □

Cor. (2.5.3.16) [Cartan Subalgebra Maximal Abelian]. The Cartan subalgebras of a semisimple Lie algebra are the maximal subalgebras consisting of semisimple elements(2.5.2.9), and they are maximal Abelian subalgebras.

WARNING: maximal Abelian subalgebra may not by Cartan subalgebras, as they may contain non-semisimple elements.

Proof: A subalgebra consisting of semisimple elements is contained in a Cartan subalgebra, by(2.5.3.8).

Conversely, if $\mathfrak{h}\subset\mathfrak{h}'$ and $\mathfrak{h}$ is a Cartan subalgebra and $\mathfrak{h}'$ consists of semisimple elements, then by(2.5.1.15), $\mathfrak{h}'$ is commutative, and thus $\mathfrak{h}'\subset c_{\mathfrak{g}}(\mathfrak{h})$, so $\mathfrak{h}=\mathfrak{h}'$.

Cartan subalgebras are Abelian by(2.5.3.15), and the are maximal Abelian because they are self-centralizing. □

Cor. (2.5.3.17). Every regular element is semisimple, because it is contained in a Cartan subalgebra by(2.5.3.5).

Split Semisimple Lie Algebras

Def. (2.5.3.18)[Split Semisimple Lie Algebras]. A **split Cartan subalgebra** of a semisimple Lie algebra $\mathfrak{g}$ over a field k is a Cartan subalgebra that all the eigenvalues of the linear maps $\mathrm{ad}(h)$ lies in k for all $h\in\mathfrak{h}$. A **split semisimple Lie algebra** is a pair $(\mathfrak{g},\mathfrak{h})$ where $\mathfrak{g}$ is semisimple and $\mathfrak{h}$ is a split Cartan subalgebra.

Remark (2.5.3.19). For example, the diagonal matrices in $\mathfrak{sl}_n$ is a splitting Cartan subalgebra over any field.

$\mathfrak{sl}_2(\mathbb{R})$ has a non-split Cartan subalgebra $\{\begin{bmatrix}0&-a\\a&0\end{bmatrix}|a\in\mathbb{R}\}$.

Prop. (2.5.3.20). Let α be a root of the split semisimple Lie algebra $(\mathfrak{g},\mathfrak{h})$, then

- The subspaces $\mathfrak{g}^\alpha$ and $\mathfrak{h}_\alpha=[\mathfrak{g}^\alpha,\mathfrak{g}^{-\alpha}]$ are both 1-dimensional.
- There is a unique element $h_\alpha\in\mathfrak{h}_\alpha$ such that $\alpha(h_\alpha)=2$, and $(h_\alpha,h_\alpha)\neq 0$.
- For each nonzero $x_\alpha\in\mathfrak{g}^\alpha$, there is a $y_\alpha\in\mathfrak{g}^{-\alpha}$ such that

$$[x_\alpha,y_\alpha]=h_\alpha,\quad [h_\alpha,x_\alpha]=2x_\alpha,\quad [h_\alpha,y_\alpha]=-2y_\alpha.$$

  i.e. $\mathfrak{s}_\alpha=\{x_\alpha,y_\alpha,h_\alpha\}\cong\mathfrak{sl}_2$.
- $k\alpha$ is a root iff $k=0,\pm1$.

Proof: Define $\mathfrak{h}_\alpha=[\mathfrak{g}^\alpha,\mathfrak{g}^{-\alpha}]\subset\mathfrak{h}$. Because the Killing form is non-degenerate on $\mathfrak{h}$, we can define for each $\alpha\in R$ a unique element $h^\alpha\in\mathfrak{h}$ that $\alpha(h)=\kappa(h,h^\alpha)$ for all $h\in\mathfrak{h}$. Then $\mathfrak{h}_\alpha$ is the subspace spanned by h^α: This is because for $x\in\mathfrak{g}^\alpha,y\in\mathfrak{g}^{-\alpha}$,

$$\kappa(h,[x,y])=\kappa([h,x],y)=\alpha(x)\kappa(x,y)$$

so $[x,y]=\kappa(x,y)h^\alpha$. Combine this with the fact $\kappa(\mathfrak{g}^\alpha,\mathfrak{g}^{-\alpha})\neq 0$, we get the fact $\mathfrak{h}_\alpha=kh^\alpha$ is 1-dimensional.

Next, there is a unique element $h_\alpha\in\mathfrak{h}_\alpha$ that $\alpha(h_\alpha)=2$. For this, it suffices to show that α doesn't vanish on $\mathfrak{h}_\alpha$: Otherwise let $x\in\mathfrak{g}^\alpha$ and $y\in\mathfrak{g}^{-\alpha}$ that $[x,y]=h\neq 0$, then $[h,x]=\alpha(h)x=0=[h,y]$. So $\{x,y,h\}$ spans a solvable subalgebra $\mathfrak{a}$ of $\mathfrak{g}$. As $h\in[\mathfrak{a},\mathfrak{a}]$. By Lie's theorem, $\rho(h)$ is nilpotent for any representation ρ of $\mathfrak{a}$. But h is in the Cartan subalgebra so $\mathrm{ad}_{\mathfrak{g}}(h)$ is semisimple(2.5.3.15), so $h=0$, contradiction.

If $(h_\alpha,h_\alpha)=0$, let $h_\alpha=[x_\alpha,y_\alpha]$ for $x_\alpha\in\mathfrak{g}^\alpha,y_\alpha\in\mathfrak{g}^{-\alpha}$, then $\{x_\alpha,y_\alpha,h_\alpha\}$ is solvable, so by Lie's theorem, there is a basis of $\mathfrak{g}$ that the adjoint action is upper-triangular(when pass to the alg.closure). But then $\mathrm{ad}(h_\alpha)$ is nilpotent, but it is also semisimple, so $h_\alpha=0$, contradiction.

Because $x_\alpha \neq 0$, there exists a unique $y_\alpha \in \mathfrak{g}^{-\alpha}$ that $[x_\alpha, y_\alpha] = h_\alpha$. Now $[h_\alpha, x_\alpha] = \alpha(h_\alpha)x_\alpha = 2x_\alpha, [h_\alpha, y_\alpha] = -\alpha(h_\alpha)y_\alpha = -2y_\alpha$.

Finally, $\mathfrak{h}_\alpha \bigoplus \oplus_{k\neq 0\in\mathbb{Z}}\mathfrak{g}^{k\alpha}$ is a subrepresentation of $x_\alpha, y_\alpha, h_\alpha \cong \mathfrak{sl}_2$, so if $\mathfrak{g}^{2\alpha} \neq 0$, then $\mathrm{ad}(x_\alpha)$ induces an isomorphism $\mathfrak{g}^\alpha \cong \mathfrak{g}^{2\alpha}$ by the representation theory of $\mathfrak{sl}_2$(15.8.1.11). But $\mathfrak{g}^\alpha$ is generated by x_α, contradiction. So $\mathfrak{g}^{k\alpha} \neq 0$ only for $k = 0, \pm 1$. □

Prop. (2.5.3.21)[Root Decompositions]. If $\mathfrak{h}$ is a split Cartan subalgebra, then $\mathrm{ad}(\mathfrak{h})$ is a commuting family of semisimple endomorphisms with eigenvalues in k(2.5.3.15). so the decomposition

$$\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha\in R} \mathfrak{g}^\alpha$$

holds as in(2.5.3.12). And it is in fact an eigenvalue decomposition, not only generalized eigenvalue decomposition, by(2.5.3.20).

Then R is a reduced root system(2.7.2.2) in $\mathfrak{h}^\vee$, with $s_\alpha(\beta) = \beta - \beta(h_\alpha)\alpha$. In particular, $\alpha^\vee = h_\alpha$.

Proof: Firstly R spans $\mathfrak{h}^\vee$: if $h \in \mathfrak{h}$ lies in the center of all $\alpha \in R$, then $[h, \mathfrak{g}^\alpha] = 0$ for all $\alpha \in R$, and as $[h, \mathfrak{h}] = 0$, this means h is in the center of $\mathfrak{g}$, which is trivial, so $h = 0$. So R spans $\mathfrak{h}^\vee$.

We need to prove that if $\alpha, \beta \in R$, then $\beta(h_\alpha) \in \mathbb{Z}$ and $\beta - \beta(h_\alpha)\alpha \in R$. For this, regard $\mathfrak{g}$ as a $\mathfrak{s}_\alpha$-module(2.5.3.20) under the adjoint action, then the assertion follows from the representation theory of $\mathfrak{sl}_2$(15.8.1.11): h_α acts on $\mathfrak{g}^\beta$ by $\beta(h_\alpha)$, and y_α^n induces an isomorphism $\mathfrak{g}^\beta \cong \mathfrak{g}^{\beta-n\alpha}$.

Finally, R is reduced by(2.5.3.20). □

Prop. (2.5.3.22) [Splitting Cartan Subalgebras are Conjugate]. The group of elementary automorphisms of $\mathfrak{g}$(2.5.1.7) acts transitively on the set of pairs $(\mathfrak{b}, \mathfrak{h})$ consisting of a Borel subalgebra(2.5.4.7) and a splitting Cartan subalgebra of $\mathfrak{g}$.

Proof: Cf.[Mil13]P98. □

Prop. (2.5.3.23)[Jacobson-Morozov]. Let $\mathfrak{g}$ be a semisimple Lie algebra and $e \in \mathfrak{g}$ is nilpotent, then there exists a homomorphism $\mathfrak{sl}_2 \to \mathfrak{g}$ mapping X to e.

Proof: Cf.https://people.math.harvard.edu/~ana/part1.pdf. □

Recovering Split Semisimple Lie Algebras from Dynkin Diagrams

Main references are [Car05]Chap7.

Def. (2.5.3.24) [Cartan Matrix]. Let $(\mathfrak{g}, \mathfrak{h})$ be a split semisimple Lie algebra with root system R, with notations in(2.5.3.20), define the Cartan matrix of $\mathfrak{g}$ to be the Cartan matrix A of R, $A = (a_{ij})$, where $a_{ij} = \alpha_j(h_{\alpha_i})$, where $\{\alpha_1, \ldots, \alpha_n\}$ is a base S of R.

Prop. (2.5.3.25) [Serre Relations]. Let $(\mathfrak{g}, \mathfrak{h})$ be a split semisimple Lie algebra with root system R and a base S, and Cartan matrix $A = (a_{ij})$. Denote $\mathfrak{n}_\pm = \oplus_{\alpha\in R^\pm}\mathfrak{g}^\alpha$, then $\mathfrak{g} = \mathfrak{n}_- \oplus \mathfrak{h} \oplus \mathfrak{n}_+$. Take $e_i \in \mathfrak{g}^{\alpha_i}, f_i \in \mathfrak{g}^{-\alpha_i}$ s.t. $\{e_i, f_i, h_i = [e_i, f_i]\} = \mathfrak{s}_i$ is a $\mathfrak{sl}_2$-triple(2.5.3.20). Then

- e_i, f_i, h_i generate $\mathfrak{g}$.
- (Serre Relations):

$$[h_i, h_j] = 0, \quad [h_i, e_j] = a_{ij}, \quad [h_i, f_j] = -a_{ij}f_j, \quad [e_i, f_j] = \delta_{ij}h_i,$$

$$(\mathrm{ad}(e_i))^{1-a_{ij}}e_j = 0, \quad (\mathrm{ad}(f_i))^{1-a_{ij}}f_j = 0, \quad i \neq j$$

Proof: 1: Because $\mathfrak{h}_i$ generate $\mathfrak{h}$, it suffices to show e_i generate $\mathfrak{n}_+$, then dually f_i generate $\mathfrak{n}_-$. We prove any $\mathfrak{g}^\alpha$ is in the span by induction on the height of α. If $\alpha = \sum n_i\alpha_i$, where $n_i > 0$, then $0 < (\alpha,\alpha) = \sum n_i(\alpha,\alpha_i)$, thus $(\alpha,\alpha_i) > 0$ for some i, thus by(2.7.2.21) $\alpha - \alpha_i$ is a root, and the representation theory of $\mathfrak{s}_i$ shows e_i induces an isomorphism $\mathfrak{g}^{\alpha-\alpha_i} \cong \mathfrak{g}^\alpha$. So we are done.

2: Only the last two assertions need a proof. The irreducible $\mathfrak{s}_i$ representation generated by e_j satisfies $[f_i, e_j] = 0, [h_i, e_j] = a_{ij}$, thus this submodule is isomorphic to $W_{a_{ij}}$, and $(\mathrm{ad}(e_i))^{1-a_{ij}} e_j = 0$. The f_i case is similar. □

Prop. (2.5.3.26) [Criterion of Semisimplicity]. Let $\mathfrak{g}$ be a Lie algebra and $\mathfrak{h}$ a commutative Lie subalgebra. If

- there is a decomposition
$$\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha\in R} \mathfrak{g}^\alpha,$$
where $R \in \mathfrak{h}^\vee$ is the finite set of $\alpha \in \mathfrak{h}^\vee\backslash\{0\}$ that $\mathfrak{g}^\alpha \neq 0$, and $\dim \mathfrak{g}^\alpha = 1$ for all $\alpha \in R$.
- R generates $\mathfrak{h}^\vee$.
- If $\alpha \in R$, then $-\alpha \in R$, and $[[\mathfrak{g}^\alpha, \mathfrak{g}^{-\alpha}], \mathfrak{g}^\alpha] \neq 0$.

Then $\mathfrak{g}$ is semisimple and $\mathfrak{h}$ is a split Cartan subalgebra of $\mathfrak{g}$ with root system R.

Proof: If I is a commutative ideal of $\mathfrak{g}$, by action of $\mathfrak{h}$, we can assume that $\mathfrak{g}^\alpha \subset I$ for some α. If $\alpha \neq 0$, then $\mathfrak{g}^\alpha$ and $[\mathfrak{g}^{-\alpha}, \mathfrak{g}^\alpha] \subset I$, so $[[\mathfrak{g}^\alpha, \mathfrak{g}^{-\alpha}], \mathfrak{g}^\alpha] = 0$, contradiction. If $I \subset \mathfrak{h}$, then by the hypothesis some $\alpha(I) \neq 0$, so $\mathfrak{g}^\alpha = [I, \mathfrak{g}^\alpha] \subset \mathfrak{g}^\alpha$, contradiction. So $I = 0$.

$\mathfrak{h}$ consists of semisimple elements and it is its own centralizer, so it is a Cartan subalgebra by(2.5.3.16). It is clearly split. □

Cor. (2.5.3.27) [Criterion of Simplicity]. Let $(\mathfrak{g}, \mathfrak{h})$ be a split semisimple Lie algebra. A decomposition $\mathfrak{g} = \mathfrak{g}_1 \oplus \mathfrak{g}_2$ of Lie algebras defines a decomposition $(\mathfrak{g}, \mathfrak{h}) = (\mathfrak{g}_1, \mathfrak{h}_1) \oplus (\mathfrak{g}_2, \mathfrak{h}_2)$, and hence a decomposition of the root system $R(\mathfrak{g}, \mathfrak{h})$.

In particular, if the root system $R(\mathfrak{g}, \mathfrak{h})$ is indecomposable, then $\mathfrak{g}$ is simple.

Proof: Let
$$\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha\in R} \mathfrak{g}^\alpha, \quad \mathfrak{g}_1 = \mathfrak{h}_1 \oplus \bigoplus_{\alpha\in R_1} \mathfrak{g}_1^\alpha, \quad \mathfrak{g}_2 = \mathfrak{h}_2 \oplus \bigoplus_{\alpha\in R_2} \mathfrak{g}_2^\alpha$$
be the eigenvalue decomposition of $\mathfrak{g}, \mathfrak{g}_1, \mathfrak{g}_2$ w.r.t. the adjoint action of $\mathfrak{h}$, then $\mathfrak{h} = \mathfrak{h}_1 \oplus \mathfrak{h}_2$, and $R = R_1 \coprod R_2$. □

Prop. (2.5.3.28)[Serre Presentations]. Let $\mathfrak{g}(R)$ be the Lie algebra generated by e_i, f_i, h_i with defining relations as in(2.5.3.25), then

- The Lie subalgebra $\mathfrak{n}_+$ generated by e_i has $(\mathrm{ad}(e_i))^{1-a_{ij}}(e_j) = 0$ as defining relations. The Lie subalgebra $\mathfrak{n}_-$ generated by f_i has $(\mathrm{ad}(f_i))^{1-a_{ij}}(f_j) = 0$ as defining relations. And h_i are linearly independent.
- $\mathfrak{g}(R)$ is a sum of f.d. modules over every $\mathfrak{sl}_2$-triple $\mathfrak{s}_i$.
- $\mathfrak{g}(R)$ is of f.d..
- $\mathfrak{g}(R)$ is semisimple and has root system R.
- $\mathfrak{g}(R_1 \oplus R_2) \cong \mathfrak{g}(R_1) \oplus \mathfrak{g}(R_2)$. In particular, by(2.5.3.27), $\mathfrak{g}(R)$ is simple iff R is indecomposable.

Proof: It suffices to prove for indecomposable root systems. Consider $\widetilde{\mathfrak{g}(R)}$ the Lie algebra generated by elements e_i, f_i, h_i with the defining relations in(2.5.3.25) without the final two Serre relations, then it is $\mathbb{Z}$-grated, with $\deg(e_i) = 1, \deg(f_i) = -1, \deg(h_i) = 0$. Thus we have a decomposition

$$\widetilde{g(R)} = \widetilde{\mathfrak{n}_+} \oplus \widetilde{\mathfrak{h}} \oplus \widetilde{\mathfrak{n}_-}$$

by degree, and clearly $\widetilde{\mathfrak{n}_+}$ is generated by e_i, $\widetilde{\mathfrak{h}}$ is generated by h_i and $\widetilde{\mathfrak{n}_-}$ is generated by f_i.

Now I claim that $\widetilde{\mathfrak{n}_+}$ is a free Lie algebra on generators e_i, $\widetilde{\mathfrak{n}_-}$ is a free Lie algebra on generators f_i and h_i are linearly independent. It suffices to prove for e_i, and f_i is true with the dual polarization. For this, let $\mathfrak{h}'$ be a vector space with basis h_i', and consider the Lie algebra $\mathfrak{a} = FL_r \rtimes \mathfrak{h}'$, where FL_r is the free Lie algebra generated by f_i', and $\mathfrak{h}'$ acts on FL_r by $[h_i', f_j'] = -a_{ij} f_j'$, then $U = U(\mathfrak{a}) = k\langle f_1', \ldots, f_n'\rangle \rtimes k[h_1', \ldots, h_n']$, and there is an action of $\widetilde{\mathfrak{g}(R)}$ on U that is defined on the generators as follows: if $w = f_{j_1}' \ldots f_{j_s}'$ is a word in f_i' of weight α and $P \in k[h_1', \ldots, h_n']$, then

$$h_i(w \otimes P) = w \otimes (h_i' - \alpha(h_i))P$$

$$f_i(w \otimes P) = fw \otimes P$$

$$e_i(f_{j_1}' \ldots f_{j_s}' \otimes P) = \sum_{k|j_k=i} f_{j_1}' \ldots \widehat{f_{j_k}'} \ldots f_{j_s}'(h_i' - (\alpha_{j_{k+1}} + \ldots + \alpha_{j_s})(h_i'))P.$$

It can be shown that this is truly a representation, and then it induces a map $\widetilde{g(R)} \to U : x \mapsto x(1)$, and this maps Lie polynomials of f_i in $\widetilde{\mathfrak{n}_+}$ to Lie polynomials of f_i', and h_i to h_i', so the assertions are true.

1: Now consider the elements $S_{ij}^+ = (\operatorname{ad} e_i)^{1-a_{ij}} e_j \in \widetilde{\mathfrak{n}_+}$ and $S_{ij}^- = (\operatorname{ad} f_i)^{1-a_{ij}} f_j \in \widetilde{\mathfrak{n}_-}$. Then $[f_k, S_{ij}^+] = 0$: If $k \neq i, j$, then this is true, and if $k = j$, then $[f_j[e_i e_j]] = [e_i[f_j e_j] = [h_j e_i] = a_{ji} e_i$, thus $[f_j(\operatorname{ad} e_i)^r(e_j)] = 0$ for $r \geq 2$. If $a_{ij} \geq -1$, then this is true, and if $a_{ij} = 0$, then $a_{ji} = 0$ too, so the assertion is also true. If $k = i$, then we can prove by induction that $[f_i(\operatorname{ad} e_i)^r(e_j)] = -r(a_{ij} + r - 1)(\operatorname{ad} e_i)^{r-1}(e_j)$. Thus $[f_i(\operatorname{ad} e_i)^{1-a_{ij}}(e_j)] = 0$, too.

So by induction we see that the ideals $I^\pm \in \widetilde{\mathfrak{n}_\pm}$ generated by such $S_{ij}^\pm$ is ideals $I_\pm$ of $\widetilde{g(R)}$. Then the ideal generated by the the Serre relations is the graded ideal $I = I_+ \oplus I_-$, which implies the assertion.

2: The Serre relations shows that e_j generates the representation $W_{-a_{ij}}$ of $\mathfrak{s}_i$ for $j \geq i$, and so does f_j. Also e_i, f_i, h_i generate W_2, and h_j generates W_0 or $W_0 \oplus W_2$, so $\mathfrak{g}(R)$ is a sum of f.d. modules over $\mathfrak{s}_i$, as the module generated by $[a, b]$ is a subquotient of $V \otimes W$ the modules generated by $\{a\}$ and $\{b\}$.

3: $\mathfrak{g}(R) = \oplus_{\alpha \in Q} \mathfrak{g}_\alpha$, where $\mathfrak{g}_\alpha$ is the subspace of $\mathfrak{g}(R)$ of weight α. Then $\mathfrak{g}_\alpha \neq 0$ only if $\alpha \in Q_+$ or Q_-, and each $\mathfrak{g}_\alpha$ is of f.d.. Now we show that $\mathfrak{g}_R \neq 0$ only if $\alpha \in R \cup \{0\}$, which will suffice. We prove by induction on the height of α: the height 1 case is trivial, and if $\alpha = ke_i$, then the statement is clear as $\mathfrak{g}^{k\alpha_i} = 0$ for $k \geq 2$, because $\mathfrak{n}_+$ is generated by e_i. If it is not of the form $\alpha = ke_i$, $(\alpha, \alpha_i) > 0$ for some i, so by the representation theory of $\mathfrak{s}_i \cong \mathfrak{sl}_2$, $\mathfrak{g}^{s_i\alpha} \neq 0$, where $s_i\alpha = \alpha - \alpha_i^\vee(\alpha)\alpha_i \notin Q_-$, thus $s_i\alpha \in Q_+$, and then by induction hypothesis $s_i\alpha \in R$, so $\alpha \in R$.

4: $\widetilde{\mathfrak{g}(R)}^\alpha$ is 1-dimensional for any α, so this is also true for $\mathfrak{g}(R)^\alpha$. Then $\mathfrak{g}(R)$ is semisimple with root system R by(2.5.3.26). □

Cor. (2.5.3.29) [Classification of Split Simple Lie Algebras]. By2, split simple Lie algebras over k are in bijection with Dynkin diagrams $A_l, l \geq 1, B_l, l \geq 2, C_l, l \geq 3, D_l, l \geq 4$ and E_6, E_7, E_8, F_4, G_2, by(2.7.3.5).

Notations for Split Semisimple Lie algebras

Def. (2.5.3.30) [Notations for a Split Semisimple Lie Algebra]. Let $(\mathfrak{g}, \mathfrak{h})$ be a split semisimple Lie algebra, then

- Its (positive/negative) root system is denoted by $(R^+/R^-)R$.
- Notation for root system is the same as in(2.7.4.1).
- $\mathfrak{g}$ has a weight decomposition $\mathfrak{g} = \mathfrak{h} \oplus_{\alpha\in R} \mathfrak{g}^\alpha$.
- $x_\alpha \in \mathfrak{g}^\alpha, y_\alpha \in \mathfrak{g}^{-\alpha}$, where $\alpha \in R^+$.
- $\mathfrak{s}_i = \{x_i, y_i, h_i\}$ is a $\mathfrak{sl}_2$-triple, where $x_i \in \mathfrak{g}^{\alpha_i}, y_i \in \mathfrak{g}^{-\alpha_i}$(2.5.3.20).
- $\alpha_i^\vee = h_i$(2.5.3.21).

4 Reductive Lie Algebra

Def. (2.5.4.1) [Reductive Lie Algebra]. A Lie algebra is called **reductive** if $\operatorname{rad}(L) = Z(L)$, or equivalently $Z(L) \subset \operatorname{rad}(L)$.

Prop. (2.5.4.2). The following conditions on a Lie algebra $\mathfrak{g}$ are equivalent:

- $\mathfrak{g}$ is reductive.
- The adjoint representation of $\mathfrak{g}$ is semisimple.
- $\mathfrak{g}$ is a product of a commutative Lie algebra $\mathfrak{c}$ and a semisimple Lie algebra $\mathfrak{b}$.

Proof: $1 \to 2$: The adjoint representation factors through the center of $\mathfrak{g}$, which is also the radical of $\mathfrak{g}$, so it is a representation of $\mathfrak{g}/\operatorname{rad}(\mathfrak{g})$, which is semisimple(2.5.1.23), so Weyl's theorem(15.8.1.2) shows the adjoint representation is semisimple.

$2 \to 3$: If the adjoint representation is semisimple, then $\mathfrak{g}$ decomposes as a sum of minimal nonzero ideals $\mathfrak{a}_i$ of $\mathfrak{g}$, and then $\mathfrak{g}$ is a product of these $\mathfrak{a}_i$. Let $\mathfrak{c}$ be the product of the one-dimensional ideals, then $\mathfrak{c}$ is in the center thus commutative, and $\mathfrak{b}$ the product of the remaining ideals, then $\mathfrak{b}$ is semisimple because it has no solvable ideals.

$3 \to 1$ is trivial. □

Cor. (2.5.4.3). The decomposition of $\mathfrak{g}$ into a product of commutative Lie algebra and a semisimple Lie algebra is unique: in fact $\mathfrak{c}$ is the center of $\mathfrak{g}$, and $\mathfrak{b} = [\mathfrak{g}, \mathfrak{g}]$, by(2.5.2.4).

Prop. (2.5.4.4). A Lie algebra $\mathfrak{g}$ is reductive iff it has a faithful semisimple representation iff it has a trivial nilpotent radical(2.5.1.34).

Proof: If $\mathfrak{g}$ has a faithful semisimple representation, then the nilpotent radical $\mathfrak{s} = 0$, thus by(2.5.1.36), $\mathfrak{r}$ is in the center of $\mathfrak{g}$, thus $\mathfrak{g}$ is reductive.

Conversely, if $\mathfrak{g}$ is reductive, then we need to show $\mathfrak{g}$ has a faithful semisimple representation: For this, we can take the tensor product of the trivial representation of the commutative part and the adjoint representation of the semisimple part(2.5.2.3).

The last assertion is clear from(2.5.1.36). □

Cor. (2.5.4.5) [Trace Form Criterion for Reductiveness]. If the trace form B_ρ(2.5.9.5) is non-degenerate for some representation (ρ, V) of $\mathfrak{g}$, then $\mathfrak{g}$ is reductive.

Proof: If $x \in \mathfrak{s}$, then $\rho(x) = 0$, thus $B_\rho(x, y) = 0$ for any y, thus $x = 0$. So $\mathfrak{s} = 0$, and $\mathfrak{g}$ is reductive. □

Cor. (2.5.4.6) [Classical Lie Algebras are Reductive]. All classical Lie groups over $\mathbb{R}$ or $\mathbb{C}$ are reductive.

Proof: Apply(2.5.4.5) their standard representations. □

Def. (2.5.4.7) [Borel Subalgebras]. Let $\mathfrak{g}$ be a split reductive Lie algebra and $\mathfrak{h}$ a Cartan subalgebra with a system of positive roots Π, and consider the corresponding triangular decomposition $\mathfrak{g} = \mathfrak{n}_- \oplus \mathfrak{h} \oplus \mathfrak{n}_+$(2.5.3.21). Denote $\mathfrak{b}_+ = \mathfrak{h} \oplus n_+$, and call any Lie subalgebra of $\mathfrak{g}$ conjugate to $\mathfrak{b}_+$ a **borel subalgebra** of $\mathfrak{g}$. The definition is independent of the choice of the Cartan subalgebra $\mathfrak{h}$, by(2.5.3.22).

5 Compact Lie Algebras

Main references are [李群讲义, 项武义] and [Kna96].

Def. (2.5.5.1) [Compact Lie Algebras]. A **compact Lie algebra** is Lie algebra that is the Lie algebra of a compact Lie group.

Prop. (2.5.5.2) [Killing Form of Compact Lie Algberas]. The Killing form of a compact Lie algebra $\mathfrak{g}$ is negatively semi-definite, with the kernel the center of $\mathfrak{g}$.

Proof: Choose an invariant inner product on $\mathfrak{g}$ w.r.t. the adjoint representation of G by(10.11.4.1). Take derivative w.r.t the equation $(\mathrm{Ad}(g)Y, \mathrm{Ad}(g)Z) = (Y, Z)$, we get by(11.7.1.12),

$$(\mathrm{ad}(X)Y, Z) + (Y, \mathrm{ad}(X)Z) = 0.$$

so $\mathrm{ad}(X)$ is skew-symmetric w.r.t. this inner product, thus the eigenvalues are all purely imaginary. Then $B(x, x) = \mathrm{tr}(\mathrm{ad}(x)\,\mathrm{ad}(x)) \leq 0$. □

Cor. (2.5.5.3) [Compact Lie Algebra is Reductive]. A compact Lie algebra $\mathfrak{g}$ is reductive.

Proof: Because of the invariant inner form, any ideal $\mathfrak{a}$ of $\mathfrak{g}$ has a complement $\mathfrak{a}^\perp$, thus the adjoint representation of $\mathfrak{g}$ is semisimple, thus $\mathfrak{g}$ is reductive(2.5.4.2). □

Cor. (2.5.5.4) [Compact Lie algebra Elements Semisimple]. For a compact Lie algebra $\mathfrak{g}$, every element is semisimple, and the eigenvalues of any adjoint operator $\mathrm{ad}(x)$ is purely imaginary.

Proof: Because the Killing form is negative definite, thus its negation is an inner product on $\mathfrak{g}$, and $\mathrm{ad}(x)$ acts by skew-Hermitian matrices, thus has purely imaginary eigenvalues. □

Prop. (2.5.5.5). If $\mathfrak{g}$ is reductive and the Killing form is negative definite on $[\mathfrak{g}, \mathfrak{g}]$, then $\mathfrak{g}$ is compact.

Proof: For the commutative part we can take the torus $(S^1)^n$, so it suffices to prove the semisimple case: for this, we consider $\mathrm{Int}(\mathfrak{g})^0 \subset GL(\mathfrak{g})$, it is contained in $O(\mathfrak{g})$ with the inner product defined by the negation of the Killing form, thus it is compact. And the Lie algebra of it is $\mathrm{Der}(\mathfrak{g}) = \mathrm{ad}(\mathfrak{g})$(2.5.2.7). □

Prop. (2.5.5.6) [Representation of Compact Lie Algebras]. Let $\mathfrak{g}$ be a compact Lie algebra that is the Lie algebra of a simply-connected compact Lie group, then $\mathrm{Rep}(\mathfrak{g})$ is semisimple.

Proof: □

6 Singular element

Introduction

Singular element in $\mathfrak{g}$ is a linear space and is defined by some homogenous ideal in $S(\mathfrak{g})$.

The paper [Singular element] of Kostant tells in fact it is defined by some r-homogenous functions M^r in $S(\mathfrak{g})$,and further describes the properties of this ideal such as the G-module decomposition and as span of determinant minors.

Preliminary

Let complex simple Lie algebra $\mathfrak{g} = \text{Lie } G$,$n = l + 2r$.The non-degenerate Killing form $\mathcal{B} \triangleq (x, y)$ on $\mathfrak{g}$ generate a nonsingular pair on $S(\mathfrak{g})$ and $\wedge(g)$ by

$$(x_1 \cdots x_k, y_1 \cdots y_k) = \sum_{\sigma \in \Sigma_k} (x_1, y_{\sigma(1)}) \cdots (x_k, y_{\sigma(k)})$$

$$(x_1 \wedge \cdots \wedge x_k, y_1 \wedge \cdots y_k) = \sum_{\sigma \in \Sigma_k} sg(\sigma)(x_1, y_{\sigma(1)}) \cdots (x_k, y_{\sigma(k)})$$

So $\mathfrak{g} \longleftrightarrow \mathfrak{g}'$,$S(\mathfrak{g}) \longleftrightarrow S(\mathfrak{g}') \longleftrightarrow$ polynomial functions on $\mathfrak{g}$; and $S(\mathfrak{g})$ and $\wedge(g)$ are $\mathfrak{g}$ thus G modules extending the adjoint representation.

recall that δ and ∂ are called $\mathcal{B}$-dual if $(\delta x, y) = (x, \partial y)$.Set antiderivation $-d$ $\mathcal{B}$-dual to the operator

$$\partial(x_1 \wedge \cdots \wedge x_p) = \sum_{i<j} (-1)^{i+j+1} [x_i, x_j] \wedge x_1 \wedge \cdots \widehat{x}_i \wedge \cdots \widehat{x}_j \wedge \cdots \wedge x_p$$

on $\wedge(\mathfrak{g})$ and antiderivation $\iota(u)$ $\mathcal{B}$-dual to the operator $\epsilon(u)v = u \wedge v$ on $\wedge(\mathfrak{g})$.

Element v of $S(\mathfrak{g})$ are called **invarient** iff $gv = v, \forall g \in G$ and element u of $S(\mathfrak{g})$ are called **harmonic** iff $(u, v) = 0,\ \forall v$ invariant and no constant term.

Denote by J, H respectively the graded subspace of invariant and harmonic elements, then:

Prop. (2.5.6.1) [Separation of Variables (in [Kos63])]. $S(\mathfrak{g}) \cong J \otimes H$.

the Ideal of Sing $\mathfrak{g}$

In the projection $\tau:\ T(\mathfrak{g}) \longrightarrow U(\mathfrak{g})$, PBW theorem asserts that $S(\mathfrak{g}) \longrightarrow U(\mathfrak{g})$ is an isomorphism. Denote:

$$\Gamma = \tau|_{S(\mathfrak{g})}^{-1} \circ \tau$$

Γ is a G-map (as a consequence of the next prop).

Denote by $\Gamma_{2r,2}$ the subgroup of permutation that preserves the set of unordered pairs $\{(1,2),(3,4),\ldots,(2r-1,2r)\}$ and let Π_r be a left coset representative of $\Gamma_{2r,2}$ in Γ_{2r} that $sg(\Pi_r) = 1$

In [Amitsur-Levitski],Kostant proved:

Prop. (2.5.6.2) [in [Kos81]].

$$\Gamma(\wedge^{2k}(\mathfrak{g})) = R^k \in S^k(\mathfrak{g})$$

$$\Gamma(x_1 \wedge \cdots \wedge x_k) \longrightarrow \sum_{v \in \Pi_k} [x_{v(1)}, x_{v(2)}] \cdots [x_{v(2k-1)}, x_{v(2k)}]$$

Prop. (2.5.6.3) [in [Kos81]].

$$M = R^r \in H^r$$

so it consists of harmonic functions.

Let $w \in \wedge^2\mathfrak{g}$ of rank k standardized as $v_1 \wedge v_2 + \cdots + v_{2k-1} \wedge v_{2k}$.Let

$$\mathrm{Rad}w = \{y \in \mathfrak{g} | \iota(y)w = 0\} = \{y \in \mathfrak{g} | (w, \epsilon(y)z) = 0, \forall z\}$$

then w of rank $2k \iff w^k \neq 0$ & $w^{k+1} = 0 \iff \dim \mathrm{Rad}w = n - 2k$.

Lemma (2.5.6.4).

$$\iota(y)dx = [y, x]$$

Thus

$$\mathrm{Rad}dx = \mathfrak{g}^x, \ \mathrm{Sing}\mathfrak{g} = \{x \in \mathfrak{g} | (dx)^r = 0\}.$$

Proof: $(\iota(y)dx, z) = (dx, y \wedge z) = (x, -[y, z]) = ([y, x], z)$ □

So in order to find the module M,it's the best to find the dual of

$$\gamma : S(\mathfrak{g}) \longrightarrow \wedge^{\text{even}}\mathfrak{g} : x \longrightarrow -dx$$

Luckily:

Prop. (2.5.6.5) [in [Kos81]]. γ is $\mathcal{B}$ dual to Γ,in particular,

$$(\Gamma(\zeta), x) = \frac{(-1)^r}{r!}(\zeta, (dx)^r) \ (\forall \zeta \in \wedge^{2r}\mathfrak{g} \text{ and } x \in \mathfrak{g})$$

So: $f(x) = 0, \forall f \in M \iff x \in \mathrm{Sing}\mathfrak{g}$.

Cor. (2.5.6.6). Let $\mathfrak{a}$ be a CSA of $\mathfrak{g}$,$\Delta_+(\mathfrak{a})$ be the positive roots, then

$$f|\mathfrak{a} = C_f \cdot \prod_{\beta \in \Delta_+(\mathfrak{a})} \beta \qquad (\forall f \in M)$$

Proof: This is because that an element in a CSA is singular iff it commutes with an element outside this CSA, and taking root decomposition, this is equivalent to annihilated by a root, and by counting degree, the cor follows. □

By propositions of [[Kos59]] a **regular nilpotent** element e is **uniquely** in a nilpotent radical $\mathfrak{n}$ of a Borel subalgebra and that $\mathfrak{g}^e \cap [\mathfrak{n}, \mathfrak{n}] = (\mathrm{Sing}\mathfrak{g}) \cap \mathfrak{g}^e$.So there is a linear function ξ on $\mathfrak{g}^e$ that $\ker \xi = (\mathrm{Sing}\mathfrak{g}) \cap \mathfrak{g}^e$.Thus:

Cor. (2.5.6.7). $f|\mathfrak{g}^e = C_f \cdot \xi^r \qquad (\forall f \in M)$.

Proof: By counting degree, the same reason as before. □

Now we think of a natural question:Can singular elements be defined be functions of even lower degree? The answer is NO.

Prop. (2.5.6.8). Assume $0 \neq f$ homogenous vanishes on $\mathrm{Sing}\mathfrak{g}$,then $\deg f \geq r$

Proof: By the last cor, if f has degree less than r then f vanish on any CSA, but semisimple regular element, thus CSAs are Zariski dense in $\mathfrak{g}$ (this is because semisimple element are defined by a polynomial), so $f = 0$. □

Thus we have established that $\mathrm{Sing}\mathfrak{g}$ is an algebraic set defined by a set of harmonic r-homogenous functions on $\mathfrak{g}$ and not by functions of degree lower than r.

Next we offer a different formation of M.

M **as minors of determinants**

for a $\mathcal{B}$ dual basis y_i, w_j,define a derivation

$$d_W(f \otimes u) = \sum_i^n \partial_{y_i} f \otimes \epsilon(w_i)u \qquad \text{on } S(\mathfrak{g}) \otimes \wedge\mathfrak{g}.$$

Here $\partial_{\sum a_i x_i}$ is defined as $\sum a_i \frac{\partial}{\partial x_1}$ for a standard basis x_i of $\mathfrak{g}$. It's easy to verify that d_W is well defined and is a G-map(Take a different basis Aw_i and Bz_i,then $AB^t = I$,substitute into the formula of d_W,it doesn't change).

Chevalley Thm tells us J is a polynomial ring $\mathbb{C}[p_1, \ldots, p_l]$, where p_i are homogenous polynomials of fixed degree d_i and $\sum_{j=i}^l (d_j - 1) = r$.So:

$$d_W p_1(x) \wedge \cdots \wedge d_W p_l(x) = \sum_{1 \le i_1 < \ldots < i_l \le n} \phi(y_{i_1}, \ldots, y_{i_l})(x) w_{i_1} \wedge \cdots \wedge w_{i_l}$$

Where $\phi(y_{i_1}, \ldots, y_{i_l}) = \det \partial_{y_i} p_j$ is homogenous of degree r.(counting degree).

To see this, notice that $f \otimes u$ acts as a function from $\mathfrak{g}$ to $\wedge\mathfrak{g}$: $f \otimes u(x) = f(x)u$.So:

$$d_W p_j(x) = \sum_{i=1}^n \partial_{z_i} p_j(x) w_i.$$

Prop. (2.5.6.9). for any CSA $\mathfrak{h}$ of $\mathfrak{g}$ and a basis $\{v_i\}$ of $\mathfrak{h}$,$\forall x \in \mathfrak{h}$,

$$d_W p_1(x) \wedge \cdots \wedge d_W p_l(x) = \kappa \cdot \prod_{\phi \in \Delta_+} \phi(y) v_1 \wedge \ldots \wedge v_l$$

Lemma (2.5.6.10) [in [Kos63]]. $\{d_W p_1(x), \cdots, d_W p_l(x)\}$ is linearly independant iff $x \in \mathrm{Reg}\mathfrak{g}$.

Proof: Notice that $d_W p_j$ is a $\mathfrak{g}$-map,ad$y \cdot d_W p_j = d_W p_j([y, x])$ so $d_W p_j(x)$ commutes with $\mathfrak{g}^x$; so $\in \mathfrak{g}^x$.Then the lm tells us when y is regular, $d_W p_j(y)$ forms a basis of $\mathfrak{g}^y$.Considering in $\mathfrak{g}^y, x$ is regular iff $\prod_{\phi \in \Delta_+} \phi(x) \neq 0$,the prop follows. □

Next we give an explicit expression for γ_r.

It can be verified (taking a z_i basis) that $dx = \frac{1}{2} \sum_{i=1}^n w_i \wedge [z_i, x]$.

Now $x \in \mathfrak{h}$,

$$dx = \sum_{\phi \in \Delta_+} \phi(x) e_\phi \wedge f_{-\phi}$$

(just take the basis w_i and z_i as a standard basis of $\mathfrak{g}$ consisting of $\{h_i, \ldots, h_l, e_\phi, f_\phi\}$)

So

$$\gamma_r(x^r) = r!(-1)^r \prod_{\phi \in \Delta_+} \phi(x) e_\phi \wedge f_{-\phi}$$

Let $\mu = i^r v_1 \wedge \cdots \wedge v_l \wedge \prod_{\phi \in \Delta_+} e_\phi \wedge f_{-\phi}$ then $(\mu, \mu) = 1$.

Denote $v^* = \iota(v)\mu$ for $v \in \wedge\mathfrak{g}$, then

$$(v_1 \wedge \cdots \wedge v_l)^* = i^r \prod_{\phi \in \Delta_+} e_\phi \wedge f_{-\phi} = C_o \gamma_r(x^r)$$

(notice that $\iota(u)\iota(v) = \iota(v \wedge u)$ and use lm 1)

Prop. (2.5.6.11). $(d_W p_1(x) \wedge \cdots \wedge d_W p_l(x))^* = \kappa_o \gamma_r(\frac{x^r}{r!}) \neq 0$.

Proof: For $y \in \mathfrak{h}$ regular, this follows from previous calculations, and notice both side are G-maps, and semisimple regular elements are Zariski open, conclusion follows. □

Lemma (2.5.6.12). $(s,t) = (s^*, t^*)$,so that $-^*$ is a $\mathcal{B}$-isomorphism.

Prop. (2.5.6.13). Let $\{w_1, \ldots, w_{2r}\}$ be linearly independent and $\{u_1, \ldots, u_l\}$ be a basis of $\{w_1, \ldots, w_{2r}\}^\perp$,then

$$\Gamma(w_1 \wedge \cdots \wedge w_{2r}) = \kappa_1 \det \partial_{u_i} p_j \neq 0$$

Thus,M is the span of all the minors $\det \partial_{u_i} p_j$.

Proof: By the preceding props,

$$\begin{aligned}
\det \partial_{u_i} p_j &= \phi(u_1, \ldots, u_l)(x) \\
&= (d_W p_1(x) \wedge \cdots \wedge d_W p_l(x), u_1 \wedge \cdots \wedge u_l) \\
&= ((d_W p_1(x) \wedge \cdots \wedge d_W p_l(x))^*, (u_1 \wedge \cdots \wedge u_l)^*) \\
&= \kappa_o \kappa_2 (\phi_r(\frac{x^r}{r!}), w_1 \wedge \cdots \wedge w_{2r}) \\
&= \kappa^{-1} \Gamma(w_1 \wedge \cdots \wedge w_{2r})(x).
\end{aligned}$$

□

<u>***G*-module structure of *M***</u>

Now we show the G-module structure of M.

Let θ be the derivative that $\theta(x)(y) = [x,y]$ on $\mathfrak{g}$. Cas $= \sum_{i=1}^n \theta(z_i)\theta(w_i)$.

It's in fact just the action of the Casimir element in center of $U(\mathfrak{g})$.Let m_l and M_l be the maximal eigenvalue and eigenspace of Cas.

For a commutative Lie subalgebra $\mathfrak{c}$ of rank l, denote by $[\mathfrak{c}]$ the line it defines on $\wedge^l \mathfrak{g}$.The span of these $[\mathfrak{c}]$ is denoted A_l.Notice that $[g^y] \subset A_l$ for a regular y,and A_l is a G-submodule.

Prop. (2.5.6.14) [in [Kos65]].

$$A_l = M_l; \qquad m_l = l.$$

An ideal in a Borel subalgebra of $\mathfrak{g}$ is necessarily spanned by root vectors and a prop of [[K-W09]] says any ideal of dim l is (denoted by $\mathcal{I}$) in fact abelian.

A prop in [[Kos65]] asserts that for two different ideals Φ_1, Φ_2,sum of their weight vectors $\langle \Phi \rangle$ is distinct.

So $G[\Phi_i]$ is an irreducible G-module V_Φ with highest weight $\langle \Phi \rangle$ and V_Φ are inequivalent G-modules(because an irreducible representation have only one highest vector).

Prop. (2.5.6.15) [in [Kos65]].

$$M_l = \oplus_{\Phi \in \mathcal{I}} V_\Phi.$$

Now denote M_{2r} image of M_l under the isomorphism $u \longrightarrow u^*$, then

Prop. (2.5.6.16) [in [K-W09]]. M_l is the span of $G \cdot [\mathfrak{g}^x]$ for x regular.

but by precious prop,

$$[\mathfrak{g}^x] = \mathbb{C} d_W p_1(x) \wedge \ldots \wedge p_l(x).$$

thus M_{2r} is the span of $G \cdot (\gamma_r(\frac{x^r}{r!})), x$ regular.

Prop. (2.5.6.17) [Final]. $\Gamma|_{M_{2r}} : M_{2r} \longrightarrow M$ is an isomorphism and $M \cong M_{2r} \cong M_l = A_l$ as G-module.

So M is a multiplicity one module with $|\mathcal{I}|$ irreducible components.

Proof: Notice that $\Gamma(\zeta)(x) = (\zeta, \gamma_r(\frac{x^r}{r!}))$ and M_{2r} is the span of $G \cdot (\gamma_r(\frac{x^r}{r!}))$,the first part follows, and the rest is a recapitulation of previous props. □

7 Real Lie Algebra

Prop. (2.5.7.1) [Passage from Real to Complex]. If $\mathfrak{g}_0$ is a Lie algebra over $\mathbb{R}$ and $\mathfrak{g} = \mathfrak{g}_0 \otimes \mathbb{C}$ its complexification, then $\mathfrak{g}_0$ is Abelian/nilpotent/solvable/semisimple iff $\mathfrak{g}$ does.

Def. (2.5.7.2). A **compact real form** is a real subalgebra $\mathfrak{l}$ of $\mathfrak{g}$ s.t. $\mathfrak{g}$ is the complexification of $\mathfrak{l}$ and $\mathfrak{l}$ is the lie algebra of a compact simply-connected Lie group.

Prop. (2.5.7.3). A real Lie algebra is compact iff there exists an invariant inner product iff the Killing form is negative definite.

Proof: One direction is easy, just use the average method to find a G-invariant inner product and then take derivative. For the other direction, the identity shows that a complement of an ideal is an ideal so $\mathfrak{g}$ is decomposed into simple lie groups and reduce to the case that $\mathfrak{g}$ is simple. The ideal is to show that $\mathfrak{g} \cong \mathrm{ad}(\mathfrak{g})$ is the whole outer derivative group $\partial(\mathfrak{g})$(the following lm). So $\mathfrak{g}$ equals to the identity component of $\mathrm{Aut}(\mathfrak{g})$ which is a closed subgroup thus closed but it is also a subgroup of the compact group $O(\mathfrak{g})$ thus it is compact. □

Lemma (2.5.7.4). If a real semisimple Lie algebra X has an invariant inner product, then every outer derivative is inner.(In fact, this is true by Cartan Criterion for semisimplicity (2.5.2.7)).

Proof: since $\mathrm{ad}(X)$ is skew-symmetric, it's diagonalizable and its eigenvalue is pure imaginary, so the Killing form of X is negative definite. Now choose the complement $\mathfrak{a}$ of $\mathrm{ad}(X)$ in $\partial(X)$, then $\mathfrak{a} \cap X = 0$. Thus for $D \in \mathfrak{a}$, $\mathrm{ad}(D(g)) = [D, \mathrm{ad}(g)] = 0$ for all g in X, so $D = 0$, thus $\mathrm{ad}(X) = \partial(X)$. □

Prop. (2.5.7.5). -

1. The complexification of the Lie algebra of a connected compact Lie group is reductive.
2. A complex Lie algebra is semisimple iff it is isomorphic to the complexification of the Lie algebra of a simply-connected compact Lie group. i.e. every complex semisimple Lie algebra has a compact real form.

Proof: 1: Because a connected compact Lie group is completely reducible so the does the Lie algebra and so does the complexification. So it is reductive by (2.5.4.1)4.

2: Cf.[Varadarajan Lie Groups Lie algebras and Their Representations]. The idea is to find a real form whose corresponding simply-connected group is compact. □

Prop. (2.5.7.6). If $\mathfrak{g}$ is the Lie algebra of a matrix Lie group G, then:

1. every Cartan subalgebra comes from a maximal commutative subalgebra of a compact real form and any two Cartan subalgebras are conjugate under the Ad-action of G.
2. any two compact real form is conjugate under the Ad-action of G.

3. any two maximal commutative subalgebra of a compact real form is conjugate under the Ad-action of the corresponding compact compact subgroup.

Prop. (2.5.7.7). A real Lie algebra is semisimple iff its complexification is semisimple. Cf.[Varadarajan].

Cor. (2.5.7.8). The real Lie algebra of a compact simply-connected group is semisimple.

Note: For the classification of real semisimple Lie algebras, Cf.[李群讲义项武义 §6]

Prop. (2.5.7.9). If a complex representation of a Lie group admits an invariant bilinear form, then it is non-degenerate and unique. In fact, this is equivalent to a G-map from V to V^*. Thus there is unique invariant inner product in a compact real form by the preceding proposition.

8 Universal Constructions

In this subsection k can be a field of any characteristics.

Def. (2.5.8.1) [Universal Enveloping Algebra]. The **universal enveloping algebra** of a Lie algebra $\mathfrak{g}$ is defined to be

$$U(g) = T(\mathfrak{g})/J, \quad T(\mathfrak{g}) = \bigoplus_{n=0}^{\infty} \mathfrak{g}^{\otimes n}$$

which is a graded algebra $T(\mathfrak{g})$ quotients the ideal $J = (\{x \otimes y - y \otimes x - [xy]\})$.

There is a natural linear map $\sigma : \mathfrak{g} \to U(\mathfrak{g})$.

Prop. (2.5.8.2). The universal enveloping algebra $U : \mathfrak{g} \mapsto U(\mathfrak{g})$ defines a functor $\mathcal{L}\text{ie}\mathcal{A}\text{lg} \to \mathcal{A}\text{lg}^{\text{asso}}$ that is left adjoint to the canonical functor ${\mathcal{A}\text{lg}^{\text{asso}}}_k \to \mathcal{L}\text{ie}\mathcal{A}\text{lg}_k$(2.5.1.2).

Proof: For any associative algebra A and a morphism of Lie algebras $\mathfrak{g} \to [A]$, there is easily seen a morphism $U(\mathfrak{g}) \to A$, and it is unique. □

Cor. (2.5.8.3) [Representation as Modules]. A representation of $\mathfrak{g}$(2.5.12.4) is he same as a representation of $U(\mathfrak{g})$.

Prop. (2.5.8.4) [Poincaré-Birkhoff-Witt]. Let $\mathfrak{g}$ be a Lie algebra, define a filtration on $U(\mathfrak{g})$ by assigning $F_nU(\mathfrak{g})$ = the image of $\bigoplus_{i=0}^n \mathfrak{g}^{\otimes i}$ in $U(\mathfrak{g})$. We have $[F_iU(\mathfrak{g}), F_jU(\mathfrak{g})] \subset F_{i+j-1}U(\mathfrak{g})$, thus $grU(\mathfrak{g})$ has a graded commutative ring structure. Thus there is an algebra homomorphism $S(\mathfrak{g}) \to grU(\mathfrak{g})$, and this homomorphism is an isomorphism.

If $\mathfrak{g}$ has a basis $\{x_i\}, i \in I$ and $<$ is an order on I, then $U(\mathfrak{g})$ has a basis consisting of elements $\{x_{i_1}^{r_1} \cdots x_{i_k}^{r_k}\}$ where $i_1 < i_2 < \ldots < i_r$.

Proof: We assign any monomial $a_{i_1} \ldots a_{i_n}$ in a_is a pair (k, N) where k is the number of factors in a monomial and N is the number of inversions(meaning the number of pairs $1 \le r, s \le n$ that $i_r > i_s$), pairs (k, N) are lexicographical ordered. Let $T^{(k,N)}$ be the space of $T(\mathfrak{g})$ generated by monomials of index (k, N), $T^k = \cup_{N=1}^{\infty} T^{(k,N)}$, and $\mathcal{U}^{(k,N)}, \mathcal{U}^k$ the space of $T(\mathfrak{g})$ the image of $T^{(k,N)}, T^k$ in $\mathcal{U}(\mathfrak{g})$. We will use induction on (k, N). Notice for any k, $T^k = T^{(k,N)}$ for N large.

To show that the monomials in $(\star)$ generates $\mathcal{U}(\mathfrak{g})$, if we have a monomial $a_{i_1}a_{i_2} \ldots a_{i_s}a_{i_{s+1}} \ldots a_{i_k}$ that $i_s > i_{s+1}$, then

$$a_{i_1}a_{i_2} \ldots a_{i_s}a_{i_{s+1}} \ldots a_{i_k} = a_{i_1}a_{i_2} \ldots (a_{i_{s+1}}a_{i_s} + [a_{i_s}, a_{i_{s+1}}]) \ldots a_{i_k},$$

which is in $\cup_{(k',N')<(k,N)}\mathcal{U}^{(k',N')}$. So we can use induction on (k,N) to show that any element of $\mathcal{U}(\mathfrak{g})$ is in $\cup_{k=1}^{\infty}T^{(k,0)}$.

From now on, we write $a_{i_1}a_{i_2}\dots a_{i_n}$ as $a_{i_1}a_{i_2}\dots a_{i_n}$ for simplicity.

To show that the monomials are linearly independent, we first show that there is a linear map

$$\theta : T(\mathfrak{g}) \to R = \mathbb{C}[z_i]_{i\in I}$$

satisfying the following conditions:

$$\theta(a_{i_1}\dots a_{i_n}) = z_{i_1}\dots z_{i_n}, \text{if } i_1 \le i_2 \dots \le i_n, \qquad (\star\star)$$

$$\begin{aligned} &\theta(a_1\dots a_{i_k}a_{i_{k+1}}\dots a_{i_n}) \\ &= \theta(a_1\dots a_{i_{k+1}}a_{i_k}\dots a_{i_n}) + \theta(a_1\dots[a_{i_k}a_{i_{k+1}}]\dots a_{i_n}). \qquad (\star\star\star) \end{aligned}$$

We construct this map by construction on $\cup_{(k',N')\le(k,N)}\mathcal{U}^{(k',N')}$ and use induction on (kN). For $k=0$, let $\theta(1)=1$. If θ is defined for any monomials of index (k,N) that $k<n$, define θ on $T^{n,0}$ by $\theta(a_{i_1}\dots a_{i_n}) = z_{i_1}\dots z_{i_n}$, then it satisfies $(\star\star)$.

And if θ is already defined for any $T^{n,k}$ that $k<i$, suppose that the monomial $a_{i_1}\dots a_{i_n}$ has index (n,i), then there is a smallest k that $a_{i_1}\dots a_{i_{k+1}}a_{i_k}\dots a_{i_n}$ has index $i-1$. Then we define

$$\theta(a_{i_1}\dots a_{i_n}) = \theta(a_{i_1}\dots a_{i_{k+1}}a_{i_k}\dots a_{i_n}) + \theta(a_{i_1}\dots[a_{i_k},a_{i_{k+1}}]\dots a_{i_n}).$$

Now we need to check that this definition satisfies $(\star\star\star)$:

If there is another k' that $i_{k'} > i_{k'+1}$, then $k<k'$. Suppose first that $k+1<k'$, let $a_{i_k} = a, a_{i_{k+1}} = b, a_{i_{k'}} = c, a_{i_{k'+1}} = d$, then

$$\begin{aligned} \theta(\dots ab\dots cd\dots) &= \theta(\dots ba\dots cd\dots) + \theta(\dots[a,b]\dots cd\dots) \\ &= \theta(\dots ba\dots dc\dots) + \theta(\dots ba\dots[cd]\dots) + \theta(\dots[ab]\dots dc\dots) + \theta(\dots[ab]\dots[cd]\dots) \\ &= \theta(\dots ab\dots dc\dots) + \theta(\dots ab\dots[cd]\dots) \end{aligned}$$

where the terms except the first one are all in $\cup_{(k',N')<(k,N)}T^{(k',N')}$ so the equalities come from induction hypothesis. So it satisfies $(\star\star\star)$.

Suppose next that $k'=k+1$, let $a_{i_k}=a, a_{i_{k+1}}=b, a_{i_{k+2}}=c$, then

$$\begin{aligned} \theta(\dots abc\dots) &= \theta(\dots bac\dots) + \theta(\dots[ab]c\dots) \\ &= \theta(\dots bca\dots) + \theta(\dots b[ac]\dots) + \theta(\dots c[ab]\dots) + \theta(\dots[[ab]c]\dots) \\ &= \theta(\dots cba\dots) + \theta(\dots[bc]a\dots) + \theta(\dots b[ac]\dots) + \theta(\dots c[ab]\dots) + \theta(\dots[[ac]b]\dots) + \theta(\dots[a[bc]]\dots) \\ &= \theta(\dots cab\dots) + \theta(\dots[ac]b\dots) + \theta(\dots a[bc]\dots) \\ &= \theta(\dots acb\dots) + \theta(\dots a[bc]\dots) \end{aligned}$$

where the terms except the first one are all in $\cup_{(k',N')<(k,N)}T^{(k',N')}$ so the equalities come from induction hypothesis, and in the third equality we used the Jacobi identity. So it satisfies $(\star\star\star)$.

Now all elements in J is a linear combination of elements of the form

$$a_1\dots a_{i_k}a_{i_{k+1}}\dots a_{i_n} - a_1\dots a_{i_{k+1}}a_{i_k}\dots a_{i_n} - a_1\dots[a_{i_k}a_{i_{k+1}}]\dots a_{i_n},$$

so the map θ factors through $T(\mathfrak{g}) \to \mathcal{U}(\mathfrak{g})$ to a map $\overline{\theta} : \mathcal{U}(\mathfrak{g}) \to R$, and the elements $a_{i_1}a_{i_2}\dots a_{i_k}, i_1 \le i_2 \le \dots \le i_k$ are mapped to $z_{i_1}\dots z_{i_n}$, which are linearly independent in R, so the elements $a_{i_1}a_{i_2}\dots a_{i_k}, i_1 \le i_2 \le \dots \le i_k$ are also linearly independent in $\mathcal{U}(\mathfrak{g})$. □

Cor. (2.5.8.5). The map $\mathfrak{g} \to U(\mathfrak{g})$ is injective.

Cor. (2.5.8.6). $U(\mathfrak{g})$ has no zero-divisors.

Proof: We can use the identities $x \otimes y - y \otimes x = [xy]$ to make any element in their right representations under the PBW prop(2.5.8.4), so it is clear that the product of two nonzero elements cannot be 0. □

Cor. (2.5.8.7). If $\mathfrak{h} \subset \mathfrak{g}$, then the subalgebra of $U(\mathfrak{g})$ generated by $\mathfrak{h}$ is isomorphic to $U(\mathfrak{h})$.

Proof: There is a natural map $U(\mathfrak{h}) \to U(\mathfrak{g})$, and the image is just the subgroup generated by $\mathfrak{h}$. The PBW theorem shows this map is injective. □

Cor. (2.5.8.8). If $\mathfrak{g} = \mathfrak{a} \times \mathfrak{b}$, then $U(\mathfrak{g}) = U(\mathfrak{a}) \otimes U(\mathfrak{b})$.

Def. (2.5.8.9) [Coproduct of $U(\mathfrak{g})$]. Let $\mathfrak{g}$ be a Lie algebra, there is a coproduct Δ on $T(\mathfrak{g})$ defined by $\Delta(g) = g \otimes 1 + 1 \otimes g$. This coproduct descends to a coproduct $\Delta : U(\mathfrak{g}) \to U(\mathfrak{g}) \otimes U(\mathfrak{g})$.

Proof: It suffices to check that $\Delta(J) \subset J \otimes T(\mathfrak{g}) + T(\mathfrak{g}) \otimes J$, and this is because

$$\begin{aligned}\Delta(x \otimes y - y \otimes x - [xy]) &= (x \otimes 1 + 1 \otimes x)(y \otimes 1 + 1 \otimes y) - (y \otimes 1 + 1 \otimes y)(x \otimes 1 + 1 \otimes x) - ([xy] \otimes 1 + 1 \otimes [xy]) \\ &= (x \otimes y - y \otimes x - [xy]) \otimes 1 + 1 \otimes (x \otimes y - y \otimes x - [xy])\end{aligned}$$

□

Prop. (2.5.8.10) [$\mathfrak{g}$-Module Structure]. Let $\mathfrak{g}$ be a Lie algebra, then $T(\mathfrak{g})$ is a $\mathfrak{g}$-module, and this action descends to a $\mathfrak{g}$-module structure on $U(\mathfrak{g})$.

Proof: It suffices to show that $\mathfrak{g}J \subset J$ and $\mathfrak{g}I \subset I$:

$$\begin{aligned}y(a \otimes b - b \otimes a - [ab]) &= [ya] \otimes b + a \otimes [yb] - [yb] \otimes a - b \otimes [ya] - [y[ab]] \\ &= [ya] \otimes b - b \otimes [ya] - [[ya]b] + a \otimes [yb] - [yb] \otimes a - [a[yb]]\end{aligned}$$

□

Prop. (2.5.8.11) [Transpose]. There is an anti-automorphism $u \mapsto u^t$ of $U(\mathfrak{g})$ that $X^t = -X$ for $X \in \mathfrak{g}$.

Proof: We first extend this t to an automorphism of $T(\mathfrak{g})$, then we compose with the obvious anti-automorphism $T(\mathfrak{g}) \to T(\mathfrak{g})$. Then we check that this map descends to $U(\mathfrak{g})$: $(X \otimes Y - Y \otimes X - [X, Y])^t = Y \otimes X - X \otimes Y - [Y, X] \in J$, so $J^t \in J$. □

Prop. (2.5.8.12) [Graded Algebra of $U(\mathfrak{g})$]. Let L be a Lie algebra, if we let $S(L) = T(L)/(x \otimes y - y \otimes x)$ be the universal symmetric algebra of L, then it is a graded algebra. There is a filtered structure on $U(L)$ given by $U_i = \{\text{subalgebra generated by } a_1 a_2 \ldots a_j, j \leq i\}$, then the associated graded algebra of $U(L)$ is isomorphic to $S(L)$ by PBW theorem.

Cor. (2.5.8.13). If W is a subspace of $T^n(L)$ that is sent isomorphically onto $S^n(L)$, then the image of W is a complement of $U_n(L)$ complementary to $U_{n-1}(L)$.

Cor. (2.5.8.14) [Symmetrization Map]. Over a field of characteristic 0, the symmetrization map $\sigma : S(\mathfrak{g}) \to T(\mathfrak{g}) \to U(\mathfrak{g})$(2.3.9.2) is an isomorphism of $\mathfrak{g}$-modules that

$$U^n(\mathfrak{g}) = \sigma(S^n(\mathfrak{g})) \oplus U^{n-1}(\mathfrak{g}).$$

Proof: It is clearly an isomorphism of vector spaces. It suffices to show the map is compatible with $\mathfrak{g}$-actions: Because

$$\sigma(y_1 \dots y_n) = \frac{1}{n!} \sum_{\sigma \in \Sigma_n} y_{\sigma(1)} \cdots y_{\sigma(n)},$$

$$\begin{aligned}
\sigma(g(y_1 \dots y_n)) &= \sigma([gy_1] \dots y_n + \dots + y_1 \dots [gy_n]) \\
&= \frac{1}{n!} \sum_{\sigma \in \Sigma_n} ([gy_{\sigma(1)}] \dots y_{\sigma(n)} + \dots + y_{\sigma(1)} \dots [gy_{\sigma(n)}]) \\
&= g(\frac{1}{n!} \sum_{\sigma \in \Sigma_n} y_{\sigma(1)} \dots y_{\sigma(n)})
\end{aligned}$$

□

Prop. (2.5.8.15). If $\mathfrak{g}$ is a Lie algebra over a field k of characteristic 0, then the set of primitive elements(2.9.1.3) are just $\mathfrak{g}$.

Proof: If f is primitive, then the leading term f_0 of f is also primitive in $grU(\mathfrak{g}) \cong S(\mathfrak{g})$. Now consider $S(\mathfrak{g}) \xrightarrow{\Delta} S(\mathfrak{g}) \otimes S(\mathfrak{g}) \xrightarrow{\mu} S(\mathfrak{g})$, then if f is of degree n, then $2^n f_0 = 2f_0$, which means $n = 1$. So $f = c + f_0$, and $c = 0$. □

Prop. (2.5.8.16) [$U(\mathfrak{g})$ is Notherian]. For a f.d. Lie algebra $\mathfrak{g}$, $U(\mathfrak{g})$ is left Noetherian.

Proof: This is because the graded stricture on $U(\mathfrak{g})$ satisfies $\mathrm{gr}U(\mathfrak{g}) \cong S(\mathfrak{g}) \cong \mathbb{C}[X_1, \dots, X_n]$ is Noetherian, so $U(\mathfrak{g})$ is Noetherian itself. □

Free Lie Algebras

Def. (2.5.8.17) [Free Lie Algebra]. Let X be a set, then we define the **free Lie algebra** $FL(X)$ to be the intersection of Lie subalgebras in $[F(X)]$ containing $\sigma(X)$, where $F(X)$ is the free algebra generated by X.

Then the free Lie algebra $FL : X \mapsto FL(X)$ defines a functor $Set \to LieAlg$ that is left adjoint to the forgetful functor.

Proof: We need to show that for any Lie algebra L and a map fo sets $\theta : X \to L$, there is a unique φ completing the upper left triangular diagram:

$$\begin{array}{ccccc}
X & \xrightarrow{i} & FL(X) & \longrightarrow & F(X) \\
\downarrow{\scriptstyle\theta} & \swarrow{\scriptstyle\varphi} & & \searrow{\scriptstyle\overline{\varphi}} & \downarrow{\scriptstyle\overline{\theta}} \\
L & & \xrightarrow{\quad\sigma\quad} & & U(L)
\end{array}$$

Notice $\overline{\varphi}^{-1}(\sigma(L))$ is a Lie algebra containing X thus containing $FL(X)$, so it induces a φ.

And for the uniqueness, if there are two φ_1, φ_2, then the element that they coincide is a Lie algebra containing X, thus containing $FL(X)$, so $\varphi_1 = \varphi_2$. □

Cor. (2.5.8.18). $U(FL(X)) \cong FX$ for any set X.

Proof: Because $U \circ FL$ and F are both left adjoint to the forgetful functor $AssAlg \to Set$. □

Center of $U(\mathfrak{g})$

Prop. (2.5.8.19) [$\mathfrak{g}$ Action on $U(\mathfrak{g})$]. $\mathfrak{g}$ acts on $T(\mathfrak{g})$ by adjoint(2.5.9.2), and notice

$$\mathrm{ad}(z)(x\otimes y - y\otimes x - [xy]) = [zx]\otimes y + x\otimes [zy] - [zy]\otimes x - y\otimes [zx] - [z[xy]] \in J,$$

so the action of $\mathfrak{g}$ descends to an action on $U(\mathfrak{g})$.

In fact, this action is inner: $\mathrm{ad}(g)(z) = gz - zg$ for $z\in U(\mathfrak{g})$. In particular,

$$Z(U(\mathfrak{g})) = U(\mathfrak{g})^{\mathrm{ad}(\mathfrak{g})}.$$

Invariant Polynomials

Prop. (2.5.8.20) [Chevalley]. The center of the universal enveloping algebra is isomorphic to the polynomial ring over $\mathbb{C}$ of l elements, where L is a semisimple lie algebra of rank l. In particular, The center for $\mathfrak{sl}_2$ is the algebra generated by the Casimir element $1/2h^2 + ef + fe$.

Proof: Because there is a commutative diagram of isomorphisms of algebras:

$$\begin{array}{ccc} S(L)^G & \xrightarrow{\alpha} & P(L)^G \\ \downarrow{\scriptstyle\eta} & & \downarrow{\scriptstyle\phi} \\ S(H)^W & \xrightarrow{\beta} & P(H)^W \end{array}$$

Where P is the polynomial ring$\cong S(L^*)$, the horizontal is Killing isomorphisms and vertical is the restriction maps. Cf.[Carter prop 13.32]**?**.

The twisted Harish-Chandra map gives an isomorphism of algebras $Z(L)\to S(H)^W$ (It just maps $z\in Z(L)$ to its pure H part and transform every indeterminants h_i to h_i-1). e.g. $z = h^2+2h+1+4fe\in Z(\mathfrak{sl}_2)$ is maped to h^2 in $S(H)$. And $P(H)^W$ is isomorphic to a polynomial ring in l generators over $\mathbb{C}$. □

Def. (2.5.8.21) [Casimir Element]. If L is semisimple Lie algebra, by(2.5.2.1) the Killing form is non-degenerate, thus we choose a basis x_i of L and a dual basis y_i, then $c=\sum x_iy_i$ is independent of x_i chosen by(2.3.8.9), and is called the **Casimir element** of $U(L)$.

Prop. (2.5.8.22). The Casimir element lies in the center of $U(L)$.

Proof: □

Prop. (2.5.8.23) [Quillen's lm]. If K is an alg.closed field of char 0 that $\mathfrak{g}$ is a f.d. Lie algebra over K. If $U=U(\mathfrak{g})$ is its universal enveloping algebra, then for any irreducible U-module M, $\mathrm{End}_U(M)=K$.

Miscellaneous

Prop. (2.5.8.24) [Grading on $U(\mathfrak{sl}_2(\mathbb{C}))$]. Let H,R,L be a basis of $\mathfrak{sl}_2(\mathbb{C})$(2.5.2.11), if we define a grading as $\deg R=1, \deg H=0, \deg L=-1$, then this is descends to a grading on $U(\mathfrak{g})$, and the degree 0 part is the ring $\mathcal{R}=\mathbb{C}[\Delta,H]$. Also, there is a decomposition:

$$U(\mathfrak{g}) = \bigoplus_{i\geq 0} L^i\mathcal{R}\oplus\bigoplus_{i>0} R^i\mathcal{R}.$$

9 Representations

Def. (2.5.9.1) [Representations]. A **representation of a Lie algebra** $\mathfrak{g}$ over a vector space V is a Lie homomorphism $\mathfrak{g} \to \mathfrak{gl}_V$.

Def. (2.5.9.2) [Tensor Product of Representations]. Let $(V_1, \pi_1), (V_2, \pi_2)$ be two representations of a Lie algebra $\mathfrak{g}$, then $(V_1 \otimes V_2, \pi_1 \otimes \pi_2)$ is a representation of $\mathfrak{g}$ given by

$$(\pi_1 \otimes \pi_2)(g)(v_1 \otimes v_2) = \pi_1(g)v_1 \otimes v_2 + v_1 \otimes \pi_2(g)v_2.$$

Def. (2.5.9.3) [Representation on Tensor Algebras]. If (V, ρ) is a representation of $\mathfrak{g}$, then $\mathfrak{g}$ acts on $T(V)$ via(2.5.9.2). Also, the ideals I, J are invariant under action of $\mathfrak{g}$, thus the representation extends to $\mathrm{Sym}(V)$ and $\wedge(V)$. Also it preserves degree, thus it induces representations on $\mathrm{Sym}^k(V)$ and $\wedge^k(V)$.

Proof:

$$g(a \otimes a) = g(a) \otimes a + a \otimes g(a) = (a + g(a)) \otimes (a + g(a)) - a \otimes a - g(a) \otimes g(a)$$

and

$$g(a \otimes b - b \otimes a) = g(a) \otimes b + a \otimes g(b) - g(b) \otimes a - b \otimes g(a) = g(a) \otimes b - b \otimes g(a) + a \otimes g(b) - g(b) \otimes a$$

□

Def. (2.5.9.4) [dual representation]. If (φ, V) is a representation of $\mathfrak{g}$, we define the **dual representation** $(\varphi^*, V^\vee)$ as

$$(\varphi^(g)(v^*), v) = (v^*, \varphi(g)v).$$

Def. (2.5.9.5) [Trace Form]. The **trace form** of a representation (V, ρ) of a Lie algebra $\mathfrak{g}$ is an invariant symmetric form β_ρ defined by $(x, y) \mapsto \mathrm{tr}(\rho(x) \circ \rho(y))$.

Proof: It is invariant because

$$\begin{aligned}\mathrm{tr}(\rho([x,y]) \circ \rho(z)) &= \mathrm{tr}(\rho(x)\rho(y)\rho(z)) - \mathrm{tr}(\rho(y)\rho(x)\rho(z)) \\ &= \mathrm{tr}(\rho(x)\rho(y)\rho(z)) - \mathrm{tr}(\rho(x)\rho(z)\rho(y)) \\ &= \mathrm{tr}(\rho(x)\rho([y,z])).\end{aligned}$$

□

Prop. (2.5.9.6). If ρ is a faithful representation of $\mathfrak{g}$ and $\mathfrak{g}$ is semisimple, then β_ρ is non-degenerate.

Proof: The Cartan's criteria(2.5.1.27) shows $\mathfrak{g}^\perp$ is a solvable sub-Lie algebra, so it must be 0 as $\mathfrak{g}$ is semisimple(2.5.1.23). □

Prop. (2.5.9.7). Let L be a simple lie algebra, then any two non-degenerate symmetric invariant bilinear forms on L is proportional. Because any of this form corresponds to a L-morphism from L to L^*. In particular, when $L \subset \mathfrak{gl}_n$, the usual trace is proportional to the Killing form.

Remark (2.5.9.8) [Rep($\mathfrak{g}$)]. Let $\mathfrak{g}$ be a Lie algebra over a field k, let $\mathrm{Rep}(\mathfrak{g})$ denote the category of f.d. representations of $\mathfrak{g}$.

Prop. (2.5.9.9) [Schur's Lemma]. Let $\mathfrak{g}$ be a finite Lie algebra, M be an irreducible $\mathfrak{g}$-module, then $\dim M$ is countable. In particular, Shur's lemma holds by(15.1.1.10).

Proof: It is of countable dimensional because $\dim U(\mathfrak{g})$ is countable. □

Prop. (2.5.9.10) [Generalized Eigenspace Decomposition for Nilpotent Lie Algebras]. Assume k is alg.closed, and $\mathfrak{g}$ is a nilpotent algebra, and (V,ρ) is a representation of $\mathfrak{g}$, then there is a generalized eigenspace decomposition

$$V=\oplus_{\lambda\in\mathfrak{g}^*}V^\lambda,$$

where V^λ are the generalized eigenspaces, and they are stable under action of $\mathfrak{g}$.

Proof: We use an induction argument:

If each $a\in\mathfrak{h}$ has only one eigenvalue, then V is the generalized eigenspace V_λ for some function λ on $\mathfrak{h}$. Then it suffices to show that λ is linear. But this is because by Lie's theorem elements of $\mathfrak{h}$ has a common eigenvector.

If for some a_0, $\mathrm{ad}(a_0)$ has two eigenvalues. Now $\mathfrak{h}$ is nilpotent, so $\mathfrak{h}\subset\mathfrak{h}_0^{a_0}$, and hence $\pi(h)V_\lambda^{a_0}\subset V_\lambda^{a_0}$ for any λ by(2.5.1.12).

As k is alg.closed, V can be written as a sum of generalized eigenspaces of a_0, and each generalized eigenspace is a subrepresentation of $\mathfrak{h}$, thus we can use induction. □

Def. (2.5.9.11)[Casimir Operator]. Let $\mathfrak{g}$ be a semisimple Lie algebra of dimension n, and $\beta:\mathfrak{g}\times\mathfrak{g}\to k$ a non-degenerate invariant bilinear form on $\mathfrak{g}$. Let e_i be a basis of $\mathfrak{g}$ and e_i' be the dual basis under β, then $c=\sum e_ie_i'\in U(\mathfrak{g})$ is independent of the basis, and lies in the center of $U(\mathfrak{g})$.

Now the trace form β_V for a faithful representation $\mathfrak{g}\to\mathfrak{gl}_V$ of $\mathfrak{g}$ is non-degenerate and invariant(2.5.9.6), then the corresponding elements c_ρ is called the **Casimir element** of (V,ρ), and the action c_V of c_ρ on V is called the **Casimir operator** of (V,ρ).

The Casimir operator c_V is a $\mathfrak{g}$-module homomorphism, and has trace n.

Proof: The independence of basis is by(2.3.8.9). To show it is in the center of $\mathcal{U}(\mathfrak{g})$, Cf.[Mil13].P50**?**.

Casimir operator c_V is a $\mathfrak{g}$-module homomorphism follows from the fact c_ρ is in the center of $U(\mathfrak{g})$, and its trace is

$$\mathrm{tr}(c_V)=\sum_i\mathrm{tr}(e_ie_i')=\sum_i(\beta_V(e_i,e_i'))=n$$

□

Def. (2.5.9.12) [Unimodular Lie Algebras]. A f.d Lie algebra $\mathfrak{g}$ is called **unimodular** if $\wedge\,\mathrm{ad}$ is a trivial representation of $\mathfrak{g}$.

Prop. (2.5.9.13).

- If $\mathfrak{g}=[\mathfrak{g},\mathfrak{g}]$, then $\mathfrak{g}$ is unimodular.
- If $\mathfrak{g}$ is nilpotent, then $\mathfrak{g}$ is unimodular.
- If $\mathfrak{g}_1,\mathfrak{g}_2$ is nilpotent, then $\mathfrak{g}_1\oplus\mathfrak{g}_2$ is unimodular.
- If $\mathfrak{g}$ is reductive, then $\mathfrak{g}$ is unimodular.

Lemma (2.5.9.14) [Zassenhaus]. Let $\mathfrak{g}$ be a Lie algebra and $\mathfrak{g}'$ an ideal of $\mathfrak{g}$. A representation ρ' of $\mathfrak{g}'$ extends to a representation ρ of $\mathfrak{g}$ that $\mathfrak{n}_{\rho'}(\mathfrak{g}')\subset\mathfrak{n}_\rho(\mathfrak{g})$ if there exists a Lie subalgebra $\mathfrak{h}$ of $\mathfrak{g}$ that $\mathfrak{g}=\mathfrak{g}'\oplus\mathfrak{h}$ and $[\mathfrak{h},\mathfrak{g}']\subset\mathfrak{n}_{\rho'}(\mathfrak{g}')$. If moreover $\mathrm{ad}_{\mathfrak{g}}(x)|_{\mathfrak{g}'}$ is nilpotent for all $x\in\mathfrak{h}$, then ρ can be chosen that $\mathfrak{h}\subset\mathfrak{n}_\rho(g)$.

Proof: Cf.[Mil13]P65. □

Prop. (2.5.9.15)[Nilpotent Representation Extension]. Let $\mathfrak{g}$ be a Lie algebra, $\mathfrak{a}$ a nilpotent ideal of $\mathfrak{g}$, and ρ a representation of $\mathfrak{a}$ that $\rho(x)$ is nilpotent for all $x \in \mathfrak{a}$. Then ρ extends to a representation ρ' of $\mathfrak{g}$ that $\rho'(x)$ is nilpotent for all $x \in \mathfrak{n}$ the largest nilpotent ideal of $\mathfrak{g}$.

Proof: □

Thm. (2.5.9.16) [Ado]. Let $\mathfrak{g}$ be a Lie algebra over a field k of char0, then there exists a faithful representation ρ of $\mathfrak{g}$ that $\rho(\mathfrak{n})$ consists of nilpotent endomorphisms, where $\mathfrak{n}$ is the largest nilpotent radical. If $\mathfrak{g}$ is of f.d., then this representation can be chosen to be of f.d.. In particular, any finite dimensional Lie algebra can be embedded in some $\mathfrak{gl}(n, k)$.

Proof: This is true for any commutative Lie algebras, for example we can use tensor products of $c \mapsto \begin{bmatrix} 0 & c \\ 0 & 0 \end{bmatrix}$. Choose a faithful representation of the center $\mathfrak{c}$ of $\mathfrak{g}$ that every element is mapped to a nilpotent endomorphism, and then extend it to a representation ρ_1 of $\mathfrak{g}$ by(2.5.9.15). Let ρ_2 be the adjoint representation of $\mathfrak{g}$, and $\rho = \rho_1 \oplus \rho_2$. Then $\ker(\rho) = \ker(\rho_1) \cap \ker(\rho_2) = \ker(\rho_1) \cap \mathfrak{c} = 0$, so this is faithful. And it sends an element in $\mathfrak{n}$ to a nilpotent endomorphism because each ρ_1 and ρ_2 do. □

Remark (2.5.9.17). In fact, this is true for Lie algebras over a field of char p, too, Cf.[JACOBSON, N. 1962. Lie algebras.]Chap 6.3.

Semisimple Representations

For representations of a semisimple Lie algebra, See15.8.

10 Lie Algebra Cohomology

Main references are [Wei94] and [Eti21].

Prop. (2.5.10.1) [Chevalley-Eilenberg resolution].

11 Amitsur-Levitski

Preliminary

Notice that in this paper, Kostant considers **reductive** lie groups. But in the range of this paper, the abelian part makes no contribution in the alternative part because they commutes with all elements. So We well just consider a **semisimple** Lie algebra in order to get a non-degenerate Killing form.

Prop. (2.5.11.1).

$$\Gamma(\wedge^{2k}(\mathfrak{g})) = R^k \in S^k(\mathfrak{g})$$

$$\Gamma(x_1 \wedge \cdots \wedge x_k) = \sum_{v \in \Pi_k} [x_{v(1)}, x_{v(2)}] \cdots [x_{v(2k-1)}, x_{v(2k)}]$$

Proof: The proof is in fact simple, just notice that for every $v \in \Pi_k$ a representative of the subgroup $\Sigma_{2k,2}$ permuting the unordered pairs $\{(1, 2), (3, 4), \ldots, (2k-1, 2k)\}$,the element in $v\Sigma_{2k,2}$ in fact combine in pairs to $[x_{v(2i-1)}, x_{v(2i)}]$ and together the $k!$ permutation of them compose a $[x_{v(1)}, x_{v(2)}] \cdots [x_{v(2k-1)}, x_{v(2k)}]$. □

Later he finds the dual of Γ,that is:

Prop. (2.5.11.2). γ is $\mathcal{B}$ dual to Γ,

$$(\Gamma(\zeta), y_1 \cdots y_r) = (-1)^r(\zeta, dy_1 \wedge \cdots \wedge dy_r) \qquad \forall \zeta \in \wedge^{2r}\mathfrak{g} \text{ and } y_i \in \mathfrak{g}.$$

In particular,

$$\Gamma(\zeta)(x) = \frac{(-1)^r}{r!}(\zeta, (dx)^r) \qquad \forall \zeta \in \wedge^{2r}\mathfrak{g} \text{ and } x \in \mathfrak{g}.$$

For the proof just notice that $(-dw, x_i \wedge x_j) = (w_i, [x_i, x_j])$ and

$$(x_1 \otimes \cdots \otimes x_r, y_1 \otimes \cdots \otimes y_r) = \sum_\sigma (x_1, y_{\sigma(1)}) \cdots (x_r, y_{\sigma(r)})$$

So dim of R^k equals the dim of image of γ_r,that is, spanned by $(dx)^k$(because they are dual).

We say that a representation of $\mathfrak{g}$ satisfies m-fold standard identity if the alternating sum of any m elements of image of $\mathfrak{g}$ is 0.Obviously, this is equivalent to:

$$\tau(R^k(\mathfrak{g})) \subset \ker \pi_V$$

Now let $o(\mathfrak{g})$ be the maximum rank of $dw, w \in \mathfrak{g}$,then by the discussion of the first paper, when $\mathfrak{g}$ is semisimple,$o(\mathfrak{g}) = r$.So the $2r$-identity is satisfied by any representation of $\mathfrak{g}$.

Furthermore a prop of [Harish-Chandra] assert for any nonzero element $u \in U(\mathfrak{g})$,there is a representation such that $\pi(U) \neq 0$.So this is a sharp bound for general representations.

But one might naturally ask:Can we find the specific bound for a particular representation of a specific $\mathfrak{g}$?The answer is YES.

Prop. (2.5.11.3). γ vanishes on the ideal $J_+' \cdot S(\mathfrak{g})$.

Proof: The proof comes from the observation π is a G-map and by **Cartan-Koszul** theory, invariant elements in $\wedge\mathfrak{g}$ are naturally isomorphic to the cohomology of $\mathfrak{g}$ and $\gamma(w) = -dw$ is clearly exact,Thus $\gamma(w_1 w_2 \dots w_i) = (-1)^i dw_1 \wedge \cdots \wedge dw_i$ is exact too. So $\gamma(w) = 0$.

□

Cor. (2.5.11.4). $M = R^r \in H^r$, so it consists of harmonic functions.

Proof: $(u, \Gamma(y)) = (\gamma(u), y) = 0\ \forall u$ invariant, by Thm; so R^k =Image Γ is harmonic. □

Generalized Amitsur-Levitski

Let $E^k \subset U(\mathfrak{g})$ be spanned be y^k, y nilpotent in $\mathfrak{g}$,and Z the center.

in [Kos97] Kostant proved that the PBW isomorphism $\delta : S(\mathfrak{g}) \longrightarrow U(\mathfrak{g})$ induces $\delta(J) = Z$,$\delta(H) = E$.

so $\tau : T(\mathfrak{g}) \longrightarrow U(\mathfrak{g})$ induces

$$\tau(A^{2k}(\mathfrak{g})) = \delta(R^k(\mathfrak{g})) \subset E^k.$$

Define $\epsilon(\pi)$ the minimum integer k that $\pi(y)^k = 0, \forall y$ nilpotent in $\mathfrak{g}$.Then clearly:

Prop. (2.5.11.5) [Generalized Amitsur-Levitski]. π satisfies the $2\epsilon(\pi)$-fold standard identity.

Prop. (2.5.11.6). If π satisfies the m-identity, it satisfies the $m+1$-identity(By taking a summation on a fixed first element $\sigma(1)$).

Prop. (2.5.11.7).

- Let π be the natural representation of $\mathfrak{gl}_n$ on $\mathbb{C}^n$ then $\epsilon(\pi) = n$.
- If n even and π the natural representation of skew-symmtric matrixs on $\mathbb{C}^n$ then $\epsilon(\pi) = n-1$.

From this one derives the **classical Amitsur-Levitski prop** that $GL_n(\mathbb{C})$ satisfies the n-fold standard identity.

Proof: 1: the **abstract Jordan decomposition** which assures x is nilpotent in $\mathfrak{gl}_n$ if $\pi(x)$ is nilpotent.

2: comes from the **Lacobson-Morosov** Thm that any nilpotent element of $\mathfrak{g}$ is contained in a $\mathfrak{sl}_2$-triple. Thus we only need to show that W is reducible considered as this $\mathfrak{sl}_2$-triple-module.

But then an irreducible representation of $\mathfrak{sl}_2$ preserves a non-degenerate bilinear form it must be odd dimensional cause a non-degenerate bilinear form is equivalent to a $\mathfrak{g}$-map from V to V^*.

And there can be constructed an anti-symmetric form defined on the $\mathfrak{sl}_2$-representation on $\mathrm{Sym}_{2k}[x,y]$ by(2.5.11.9), so there can't exist symmetric $\mathfrak{g}$-invariant form. So this representation must be reducible. □

Cor. (2.5.11.8) [Classical Amitsur-Levitski]. By(2.5.11.5),

$$[[x_1, x_2, \ldots, x_n]] = \sum_\sigma \mathrm{sgn}(\sigma) x_{\sigma(1)} x_{\sigma(2)} \cdots x_{\sigma(k)} = 0 \qquad \forall x_i \in \mathfrak{gl}_n$$

called n-fold **standard identity**.

Prop. (2.5.11.9). For a construction of the anti-symmetric form, notice

$$\pi(g) f(x_1, x_2) = f(g_{11}x_1 + g_{12}x_2, g_{21}x_1 + g_{22}x_2).$$

Set

$$v_k = \binom{m}{k} x_1^{m-k} x_2^k, \quad \Omega(v_k, v_{m-k}) = (-1)^k \binom{m}{k}. \quad \Omega(v_k, v_p) = 0, \qquad k+p \neq m.$$

One verifies:

$$\Omega(g\cdot u, g\cdot v) = (\det g)^m \Omega(u,v) \qquad \forall g \in GL(2, \mathcal{C})$$

So when $m = n-1$ is odd, this is a symplectic form preserved by $\mathfrak{sl}_2$.

A computable Formula

Finally, Kostant gave a computable formula for determining $\epsilon(\pi)$.Clearly we just need to consider irreducible representation.

Let π_λ be the irreducible representation of highest weight λ,then the dual representation $\pi_{\lambda'}$ has highest weight the negative of the lowest weight of π_λ,that is, $-w_o(\gamma)$.

But then $\lambda + \lambda'$ is a sum of simple positive roots.$\lambda + \lambda' = \sum_{i=1}^n m_i \alpha_i$.Put $\epsilon(\lambda) = 1 + \sum_{i=1}^n m_i$.then:

Prop. (2.5.11.10). $\epsilon(\pi_\lambda) = \epsilon(\lambda)$.

Proof: Just choose a $\mathfrak{sl}_2$-triple $\{e, x, f\}$ with $\alpha(x) = 2$ $\forall \alpha$ simple root.Then $\lambda(x)$ and $-\lambda'(x)$ are respectively the maximal and minimal eigenvalues of $\pi(x)$. $(\lambda + \lambda')(x) = 2(\epsilon(\lambda) - 1)$. Thus f has nilpotent degree $\epsilon(\lambda)$.And any nilpotent element action increases the eigenvalue of a eigenvector of x by at lest 2, the prop follows. □

Further Work

(cf. [Pro76]) Another different proof of the Amitsur-Levitski theorem is given by Kostant using techniques related to **trace identities**. It turns out that method sheds more light. Later is studied the polynomial of matrices invariant under the conjugation action.

Artin conjectured that all the invariants is polynomials of the Trace polynomial $Tr(A_1A_2\cdots A_n)$(Proved)

And further, the relations among these invariant all turned out to be consequences of the prop of Hamilton-Cayley. All this is made into the **Invariant Theory**.

Prop. (2.5.11.11) [Interesting results].

1. If an algebra over a field of characteristic 0 satisfies the identity $X^n = 0$,then it satisfies all the identities of $n\times n$ matrices.
2. The space of multilinear identities of degree m of $n\times n$ matrices can be described completely in terms of Young diagrams.

12 Lie p-Algebras

Remark (2.5.12.1). In this subsection, let k be a field of characteristic p.

Def. (2.5.12.2) [Lie p-Algebras]. Let x_0, x_1 be elements of a Lie algebra over k of characteristic p, then for $0<r<p$, let $s_r(x_0,x_1)$ denote $\frac{1}{r}$ times coefficient of t^{r-1} in the expression of $\mathrm{ad}^{p-1}_{tx+y}(x)$.

Then a **Lie p-algebra** is a Lie algebra $\mathfrak{g}$ over k equipped with a map $x\mapsto x^{[p]}:\mathfrak{g}\to\mathfrak{g}$ such that

- $(cx)^{[p]} = c^p x^{[p]}$ where $c\in k$.
- $\mathrm{ad}(x^{[p]}) = (\mathrm{ad}(x))^p$.
- $(x+y)^{[p]} = x^{[p]} + y^{[p]} + \sum_{r=1}^{p-1} s_r(x,y)$.

Example (2.5.12.3). If L is an Abelian Lie algebra, then it can be regarded as a Lie p-algebra by assigning $x^{[p]}=0$.

If A is an associative algebra, then it can be given a Lie p-algebra structure by assigning $x^{[p]}=x^p$.

Proof: To show A is a Lie p-algebra, we check $\mathrm{ad}(x)^p(y) = (l_x - r_x)^p(y) = l_x^p - r_x^p(y) = \mathrm{ad}(x^p)(y)$. For the third formula, notice

$$\mathrm{ad}(tx+y)^{p-1}(x) = \sum_{i=0}^{p-1}(-i)^i\binom{p-1}{i}(tx+y)^{p-1-i}x(tx+y)^i$$

Notice that $(-i)^i\binom{p-1}{i}\equiv 1 \mod p$, so $s_r(x,y)$ is equivalent to the sum of words of x,y with r xs. So the third formula clearly holds. □

Def. (2.5.12.4) [Representations]. A **representation of a Lie p-algebra** $\mathfrak{g}$ over a k-vector space V is a homomorphism $\mathfrak{g}\to\mathfrak{gl}_V$ of Lie p-algebras.

Def. (2.5.12.5) [Universal Enveloping p-Algebra]. The **universal enveloping p-algebra** of a Lie p-algebra $\mathfrak{g}$ is defined to be

$$U^{[p]}(g) = T(\mathfrak{g})/J^{[p]},\quad T(\mathfrak{g}) = \bigoplus_{n=0}^{\infty}\mathfrak{g}^{\otimes n}$$

which is a graded algebra $T(\mathfrak{g})$ quotients the ideal $J = (\{x\otimes y - y\otimes x - [xy], x^{\otimes p} - x^{[p]}\})$.

There is a natural linear map $\sigma:\mathfrak{g}\to U^{[p]}(\mathfrak{g})$.

Prop. (2.5.12.6). The universal enveloping p-algebra $U^{[p]}:\mathfrak{g}\mapsto U^{[p]}(\mathfrak{g})$ defines a functor $LiepAlg\to AssAlg$ that is left adjoint to the canonical functor $AssAlg_k\to LiepAlg_k$(2.5.12.3).

Proof: For any associative algebra A and a morphism of Lie p-algebras $\mathfrak{g}\to[A]$, there is easily seen a morphism $U^{[p]}(\mathfrak{g})\to A$, and it is unique. □

Cor. (2.5.12.7) [Representation as Modules]. A representation of $\mathfrak{g}$(2.5.12.4) is he same as a representation of $U^{[p]}(\mathfrak{g})$.

Prop. (2.5.12.8). Let e_i be a k-vector space basis of $\mathfrak{g}$, then the monomials

$$\{e_{i_1}^{n_{i_1}}e_{i_2}^{n_{i_2}}\dots e_{i_r}^{n_{i_r}}|i_1<i_2<\dots<i_r,0<n_{i_k}<p\}$$

for different r form a basis of $U^{[p]}(\mathfrak{g})$.

Proof: This is a consequence of PBW theorem(2.5.8.4). □

Cor. (2.5.12.9). If $\mathfrak{g}$ is of finite dimensional over k, then so does $U^{[p]}(\mathfrak{g})$, and the map $i:\mathfrak{g}\to U^{[p]}(\mathfrak{g})$ is injective.

2.6 Infinite Dimensional Lie Algebras

References are [What is moonshine?], [Vertex Operator Algebras and the Monster], [Infinite-Dimensional Lie Algebras, Kac], [Car05].

1 Kac-Moody Algebras

2 Vertex Operator Algebras

3 Moonshine Conjectures

Thm. (2.6.3.1) [Monstrous Moonshine]. There is a naturally defined graded infinite dimensional module, called the **Monstrous module** $V = \oplus_{n\in\mathbb{Z}} V_n$ of the monster group $\mathbb{M}$ s.t. for any $g \in \mathbb{M}$, the Mckay-Thompson series

$$T_g(\tau) = \sum_{n\geq -1} \mathrm{tr}(g|V_n) e^{2\pi inr}$$

is a Hauptmodul for a discrete subgroup $\Gamma \subset SL(2,\mathbb{Z})$ of genus 0 and period r at the cusp.

Proof: Cf.[Borcherds, 1992] □

Prop. (2.6.3.2) [Duncan-Mertens-Ono, 2017]. There exists an infinite dimensional module $V = \oplus_{n>0, n\equiv 0,3 \mod 4} V_n$ of the O'Nan group(2.1.13.5) $\mathbb{ON}$ s.t. for any $g \in \mathbb{ON}$, the Mckay-Thompson series

$$F_g(\tau) = q^{-4} + 2 + \sum_{n>0} \mathrm{tr}(g|V_n) e^{2piin\tau}$$

is a meromorphic modular form of weight $\frac{3}{2}$ on $\Gamma_0(4N)$, where N is the order of g.

Proof: □

2.7 Reflection Groups and Coxeter Groups

Main references are [Hum90], [Ser87], [Kna96].

Notation (2.7.0.1).

- Let $k \in \texttt{Field}, \operatorname{char} k = 0, V \in \mathcal{V}\mathrm{ect}/k$.

1 Reflection Groups

Def. (2.7.1.1) [Reflections]. Let $V \in \mathcal{V}\mathrm{ect}^d/k$, a **reflection** on V is a linear transformation $s \in \operatorname{End}(V)$ that has $d-1$ eigenvalues 1 and one eigenvalue -1.

Prop. (2.7.1.2). Let $\alpha \in V$ and $\alpha^\vee \in V^\vee$ that $(\alpha, \alpha^\vee) = 2$, then

$$s_\alpha : x \mapsto x - (x, \alpha^\vee)\alpha$$

is a reflection, and every reflection with vector α is of this form.

Proof: Clearly s_α is a reflection, and if s is any reflection, then $\alpha^\vee$ is the composition of the quotient map $V \to V/H$ with the map $V/H \to \mathbb{F}$ sending $\alpha + H$ to 1. □

Lemma (2.7.1.3). Let $R \subset V$ be a set s.t. $\operatorname{span}\{R\} = V$, then for any $\alpha \in V$, there exists at most one reflection s with vector α that $s(R) \subset R$.

Proof: Let s, s' be two such reflections, then $t = ss'$ is an automorphism that is identity on both $\mathbb{F}\alpha$ and $V/\mathbb{F}\alpha$. So $(t-1)^2 = 0$ on V. So the minimal polynomial of T divides $(T-1)^2$. Also because R is finite there exists an m that $t^m = 1$ on R thus on V, so $t = 1$ as the greatest divisor of $(T-1)^2$ and $T^m - 1$ is $T - 1$. □

Lemma (2.7.1.4). Let V be an inner product space, then for any vector α, there exists a unique reflection s_α that respects the inner product, which is

$$s_\alpha(x) = x - 2\frac{(x, \alpha)}{(\alpha, \alpha)}\alpha.$$

Def. (2.7.1.5) [Reflection Groups]. $\Gamma \le GL(n, k)$ is called a **reflection group** if it is generated by reflections.

Thm. (2.7.1.6) [Shephard-Todd-Chevalley]. Let $\Gamma \le GL(n, k)$, then Γ is a reflection group iff $k[X_1, \ldots, X_n]^\Gamma$ is a polynomial ring. And in this case,

- There are homogenous alg.ind polynomials $p_1, \ldots, p_r$, $d_i = \deg(p_i)$, $d_1 \le d_2 \le \ldots \le d_r$ s.t. $k[X_1, \ldots, X_n]^\Gamma = k[p_1, \ldots, p_r]$.
- $$\frac{1}{\#\Gamma} \sum_{\gamma \in \Gamma} \frac{\operatorname{tr}(\gamma)}{\det(1 - \gamma T)} = \prod_{i=1}^r \frac{1}{1 - T^{d_i}} \in k(T).$$
- $(d_1, \ldots, d_r)$ are determined by Γ.
- $\#\Gamma = \prod_i d_i$, and Γ contains $\sum_i (d_i - 1)$ reflections.
- If Γ is an irreducible subgroup of $GL(n, k)$, then it is an abstractly irreducible group, and $Z(\Gamma)$ is cyclic of order $pgcd(d_1, \ldots, d_r)$.

Proof: □

2 Root Systems

Def. (2.7.2.1) [Root System]. A subset R of a vector space V over $\mathbb{F}$ is called a **root system** if

- R spans V and doesn't contain 0.
- For each $\alpha \in R$, there exists a unique reflection $s_\alpha = \mathrm{id} - \alpha^\vee \otimes \alpha$ with vector α that $s_\alpha(R) \subset R$.
- For any $\alpha, \beta \in R$, $s_\alpha(\beta) - \beta$ is a multiple of α, or equivalently $\alpha^\vee(\beta) \in \mathbb{Z}$.

Elements of R are called the **roots** of R, and dimension of V is called the dimension of the root system. And the subgroup of $GL(V)$ generated by all s_α is called the **Weyl group** of R. The Weyl subgroup is a finite group, as a subgroup of the group of permutations of R.

A root system is called indecomposable iff it cannot be written as a direct sum of two root systems.

Def. (2.7.2.2) [Reduced Root System]. Let α, β be roots that are multiples of each other, then $\beta = c\alpha$ for some $c \in \mathbb{F}$, then $2(\beta, \alpha^\vee) = 2c \in \mathbb{Z}$, also $2c^{-1} \in \mathbb{Z}$, so $c \in \{-1, -1/2, 1/2, 1\}$. A **reduced root system** is a root system that there are no roots α, β that $\alpha = 2\beta$.

Prop. (2.7.2.3) [Invariant Quadratic Form]. Let R be a root system in V, then there is a positive bilinear form in V that is invariant under the action of the Weyl group of R.

Notice that for such a bilinear form, the reflection must be of the form given in(2.7.1.4), or in other words, $\alpha^\vee(\beta) = (\frac{2\alpha}{(\alpha,\alpha)}, \beta)$.

Proof: This follows entirely because the Weyl group of R is finite, as we can take the average of any positive bilinear form under the action of reflections. □

Def. (2.7.2.4) [Dual Root System]. Let R be a root system in V, the set of dual vectors $\alpha^\vee$ for $\alpha \in R$ is also a root system in $V^\vee$, called the **dual system** of R. And it has the same Weyl group as R.

Moreover, $R^{\vee\vee} \cong R$.

Proof: Take an invariant quadratic form on V(2.7.2.3), then it gives an isomorphism $V \to V^\vee$. Then $\alpha^\vee$ corresponds to $\frac{2\alpha}{(\alpha,\alpha)}$ under this isomorphism, and there obviously generates V. If $\alpha^\vee \in R^\vee$, we can take the corresponding reflection to be $s_{\alpha^\vee} = 1 - \alpha \otimes \alpha^\vee$. Then

$$\begin{aligned}
s_{\alpha^\vee}(\beta^\vee)(x) &= (\beta^\vee - \beta^\vee(\alpha)\alpha^\vee)(x) \\
&= (x, 2\beta/(\beta,\beta)) - \frac{(\alpha,\beta)}{(\beta,\beta)}(x, 2\alpha/(\alpha,\alpha)) \\
&= (x, \frac{2(\beta - \alpha(\alpha,\beta)/(\alpha,\alpha))}{(\beta,\beta)}) \\
&= (x, \frac{2s_\alpha(\beta)}{(\beta,\beta)}) = (s_\alpha(\beta))^\vee(x).
\end{aligned}$$

So $s_{\alpha^\vee}(\beta^\vee) = (s_\alpha(\beta))^\vee \in R^\vee$. In this way, we see $\alpha^{\vee\vee} = \alpha$, and $s_{\alpha^\vee}(\beta^\vee) - \beta^\vee = \beta^\vee(\alpha)\alpha^\vee$ is an integral multiple of $\alpha^\vee$. Also it can be seen easily from the formula above that the Weyl group is the same as the Weyl group of R. □

Prop. (2.7.2.5) [Real Root Systems]. Let R be a roots system in a vector space V over a field $\mathbb{F}$, and let V_0 be the $\mathbb{Q}$-vector space spanned by R, then R is a root system in V_0 and $V_0 \otimes_{\mathbb{Q}} \mathbb{F} \cong V$.

So from now on we focus on a real root system.

Proof: The non-trivial part is that the isomorphism $V_0 \otimes_{\mathbb{Q}} \mathbb{F} \cong V$. The natural map $i : V_0 \otimes_{\mathbb{Q}} \mathbb{F} \to V$ is surjective because R generates V, and consider its transpose

$$i^* : V^\vee \to V_0^\vee \otimes_{\mathbb{Q}} \mathbb{F},$$

then we can see that this maps $\alpha^\vee$ to $\alpha_0^\vee$, and $R_0^\vee$ is a root system in $V_0^\vee$(2.7.2.4), thus $\alpha_0^\vee$ generates $V_0^\vee$, and i^* is surjective, showing i is injective. □

Def. (2.7.2.6) [Base]. A subset $S \subset R$ is called a **base** of R if the every elements of R can be written uniquely as a linear integral combination of elements of S with the same sign.

If S is a base of R, then we let R^+ denote the set of R that is non-negative integral combinations of elements of S, called the **positive roots of** R, and R^- the set of R that is non-positive integral combinations of elements of S, called the **negative roots of** R. $R = R^+ \coprod R^-$.

Prop. (2.7.2.7) [Base exists]. Let $t \in V^\vee$ be an element that $t(\alpha) \neq 0$ for all $\alpha \in R$. Let $R_t^+(R_t^-)$ be the set of all $\alpha \in R$ that $t(\alpha) > 0 (< 0)$, then $R = R_t^+ \cup R_t^-$. An element of R_t^+ is called **indecomposable** if it cannot be written as the sum of two elements in R_t^+. Let S_t be the set of indecomposable elements of R_t^+, then S_t is a base of R.

In particular, every root system (R, V) contains a base. And if S is a base and $t \in V^\vee$ that $t(S) > 0$, then $S = S_t$.

Proof: Cf.[Ser87]P38. □

Cor. (2.7.2.8). If $t \in V^\vee$ and S_t is a basis of V contained in R_t^+ that attains the minimal value of t in R_t^+, then S_t is a base of R.

Prop. (2.7.2.9). Let S be a base of a root system (R, V), then every positive root β can be written as

$$\beta = \alpha_1 + \ldots + \alpha_k$$

in such a way that all the partial sums are roots.

Proof: Cf.[Ser87]P40. □

Prop. (2.7.2.10). Let R be a reduced root system and S a base, then for any $\alpha \in S$,

$$s_\alpha(R^+ \backslash \{\alpha\}) = R^+ \backslash \{\alpha\}.$$

In particular if $\rho = \frac{1}{2}(\sum_{\alpha \in R^+} \alpha)$, then $s_\alpha \rho = \rho - \alpha$.

Proof: If $\beta \in R^+$, then $s_\alpha(\beta) = \beta - c\alpha$ for some $c > 0$, Thus $s_\alpha(\beta) \in R^-$ iff $\beta = \alpha$. □

Prop. (2.7.2.11) [Base and Dual System]. Let R be a reduced system and S a base, then $S^\vee$ is a base of $R^\vee$.

Proof: By the isomorphism between V and $V^\vee$, it suffices to show the vectors $\{\alpha^\vee, \alpha \in S\}$ is a base for $R^* = \{\alpha^\vee, \alpha \in R\}$. But it is clear if S is a base corresponding to a vector $t \in V^*$, then $\{\alpha^\vee, \alpha \in S\}$ is the extremal vectors corresponding to t too, so it is a base by(2.7.2.7). □

Property of the Weyl Group

Prop. (2.7.2.12) [Weyl Group and Bases]. Let W be the Weyl group of a reduced root system R and S a base of R, then

1. For any $t \in V^*$, there exists $w \in W$ that $(w(t), \alpha) \geq 0$ for all $\alpha \in S$.
2. W acts transitively on the set of bases of R.
3. For each $\beta \in R$, there exists some $w \in W$ that $w(\beta) \in S$.
4. The group W is generated by s_α where $\alpha \in S$.
5. W acts simply transitively on the set of bases of R.

Proof: We can in fact prove this for W_S the group generated by s_α where $\alpha \in S$.

1: Let ρ be defined in(2.7.2.10), and choose an element $w \in W_S$ that $w(t)(\rho)$ is maximal, then $w(t)(\rho) \geq w(t)s_\alpha(\rho) = w(t)(\rho) - w(t)(\alpha)$. So $(w(t), \alpha) \geq 0$.

2: Let S' be a base and $t' \in V^\vee$ that $t'(S') > 0$(2.7.2.7), Also by 1 we can find $w \in W$ that $w(t)(\alpha) \geq 0$ for all $\alpha \in S$. And in fact $w(t)(\alpha) > 0$ for all $\alpha \in S$. So $S = S_t, S' = S_{w(t)}$. Thus w sends S' to S.

4: Finally we prove that $W_S = W$: because for any $\beta \in R$, there exists $w \in W_S$ that $w(\beta) \in S$, so $s_\beta = w^{-1} s_{w(\beta)} w \in W_S$.

5: See [Ser87]P70.**?** □

Def. (2.7.2.13) [Length]. Let $w \in W$, define the **length** of w to be the minimal number m that w can be written as a product of m simple reflections s_i.

Prop. (2.7.2.14). Let R be a root system with Weyl group W, $w \in W$.

- Let $n(w)$ be the number of elements α in R^+ that $w(\alpha) \in R^-$, then $n(w) = l(w)$.
- There is a unique element $w_0 \in W$ with length $|R^+|$.
- $w_0(R^+) = R^-$, and $w_0^2 = \mathrm{id}$.

Proof: 1: Cf.[Carter, P63]**?**.

2: By(2.7.2.12) there is a unique element $w_0 \in W$ mapping S to $-S$, and it has maximal length $|R^+|$ by item1.

3: $w_0^2(R^+) = R^+$, thus $l(w_0^2) = 0$ and $w_0^2 = \mathrm{id}$. □

Def. (2.7.2.15) [Weyl Chambers]. Let (V, R) be a real root system, then a **Weyl chamber** is a connected component of $V \backslash \bigcup_{\alpha \in R} H_\alpha$, where H_α is the fixed hyperplane of vectors fixed by s_α.

Prop. (2.7.2.16). The Weyl group W acts transitively on the set of Weyl chambers of R.

Proof: To show the action is transitive, if two Weyl chambers C, C' are adjacent with a common face $F \subset H_\alpha$, then clearly $s_\alpha(C) = C'$. In general, choose two generic vector in C, C' and connect them, then C, C' can be connected by adjacent chambers.

If $w \in W$ satisfies $w(C) = C$, we may assume C is the fundamental Weyl chamber, then $w(S) = S$, so by(2.7.2.14), $l(w) = 0$, so $w = \mathrm{id}$. □

Def. (2.7.2.17) [Height of Weights]. Let $\alpha = \sum n_i \alpha_i \in R$, then the **height of roots** α is denoted by $\mathrm{ht}(\alpha) = \sum n_i$.

Prop. (2.7.2.18) [Highest Root]. Let (R, V) be a root system and S a base. If S is indecomposable, then there exists a root $\widetilde{\alpha} = \sum_{\alpha \in S} n_\alpha \alpha$ that for any other root $\sum_{\alpha \in S} m_\alpha \alpha$, $n_\alpha \geq m_\alpha$.

Proof: □

Def. (2.7.2.19) [Kostant's Partition Function]. Let R be a root system, the **Kostant's partition function** $\mathfrak{P}$ is a function on $Q(R)$ that $\mathfrak{P}(\alpha)$ equals the number of ways to write α as an unordered sum of positive roots in R^+.

Cartan Matrix and Dynkin Diagrams

Prop. (2.7.2.20) [Angles Between Roots]. Let α, β be two non-propositional roots in a root system R, then we can put $n(\alpha,\beta) = \alpha^\vee(\beta) = 2(\alpha,\beta)/(\alpha,\alpha)$. Then $n(\alpha,\beta)$ are integers(2.7.2.1), and $n(\alpha,\beta)n(\beta,\alpha) = 4\cos^2\varphi_{\alpha,\beta}$, where $\varphi_{\alpha,\beta}$ is the angle between these two vectors. Then because $4\cos^2\varphi_{\alpha,\beta}$ is an integer, it can only take values $0, 1, 2, 3$. Then there are only 7 possibilities of the angles between α, β, and if α, β are not orthogonal, their ration of lengths are determined also by the angle.

Prop. (2.7.2.21) [String of Roots]. If α, β are not proportional and $n(\beta,\alpha) > 0$, then $\alpha - \beta$ is a root. In particular, for $\alpha, \beta \in S$ where S is a base of R, $n(\alpha,\beta) \le 0$.

Proof: (2.7.2.20) shows $n(\beta,\alpha) = 1$ or $n(\alpha,\beta) = 1$. Now $\alpha - \beta = s_\beta(\alpha)$ or $-s_\alpha(\beta)$ is a root of R. □

Def. (2.7.2.22) [Cartan Matrix]. Let R be a root system with a base S. Then the **Cartan matrix** is $(n(\alpha,\beta))_{\alpha,\beta\in S}$(2.7.2.20).

Prop. (2.7.2.23). The Cartan matrix depends only on (V, R) and not on S, and if R is reduced, R is determined by its Cartan matrix up to isomorphisms.

Proof: The first assertion follows from(2.7.2.12) as every two bases are conjugate. The Cartan matrix determines R because it determined the inner product between roots in a basis of V. □

Prop. (2.7.2.24). Let E be the group of automorphisms of S that leaves that Cartan matrix invariant, then it can be identified with the set of automorphisms of R that leave the base S invariant. Then the group $\mathrm{Aut}(R)$ is isomorphic to the semi-product $E \ltimes W$.

Proof: Let W is generated by s_α so invariant under $\mathrm{Aut}(R)$. Now if $u \in \mathrm{Aut}(R)$, then $u(S)$ is a base of R, so there exists some $w \in W$ that $w(u(S)) = S$, thus $u \in EW$. Also if $w \in W \cap E$, then □

Def. (2.7.2.25) [Coxeter graph]. A **coxeter graph** is a finite graph that each pair of distinct vertices are connected by $0, 1, 2$ or 3 vertices.

Def. (2.7.2.26) [Coxeter Graph associated to a Root System]. Let (R, V) be a root system and S a base of R, then the associated **coxeter graph** is a graph whose nodes are indexed by the elements of S, and two distinct nodes α, β are connected by $a(\beta,\alpha)a(\alpha,\beta) = 4\cos^2\varphi_{\alpha,\beta}$ edges(2.7.2.20). This is independent of the choice of S, by(2.7.2.23).

Prop. (2.7.2.27). R is indecomposable iff the Coxeter graph is connected.

Proof: By the formula in(2.7.1.4), R is decomposable iff $R = R_1 \coprod R_2$ where R_1, R_2 are orthogonal to each other. Then this is equivalent to $\varphi_{\alpha,\beta} = \pi/2$ for any $\alpha \in R_1, \beta \in R_2$. □

3 Simple Root System

Lemma (2.7.3.1) [Listing of Indecomposable Root Systems]. The coxeter graphs Γ arising from indecomposable root systems are exactly the graphs $A_n(n \geq 1), B_n(n \geq 2), D_n(n \geq 4), E_6, E_7, E_8, F_4, G_2$. (graphs are given in [Etingod, Lie algebras]P109.)

Proof: The existence is these types are given by(2.7.3.2).

For the converse, notice first that for a graph with vertices v_i and v_i, v_j are connected with A_{ij} edges, the quadratic form

$$Q(x_1, \ldots, x_n) = \sum_{i=1}^{n} x_i^2 - \sum_{1 \leq i < j \leq n} \sqrt{A_{ij}} x_i x_j = ||\sum x_i v_i||^2$$

is positive definite.

Next we show some constraints on the graph:

- Any subgraph of the coxeter graph, it can be shown that the corresponding quadratic form is also positive definite, in particular non-degenerate.
- : It is a tree: If it contains a circle, consider the subgraph of the circle, then the corresponding quadratic form vanishes on $(1, 1, \ldots, 1)$, contradiction.
- It doesn't contains subgraphs listed in P77 of[Car05].

Now if Γ contains a triple edge, then it must be G_2, otherwise it must contain a $\widehat{G}_2$. If Γ contains no triple edges, then it contains at most one double edge, otherwise it contains some $\widehat{C}_l$, $l \geq 2$. If it contains only one double edge, then it contains no branch points, otherwise it contains some $\widehat{B}_l, l \geq 3$, so it is a chain with an edge added. If the double edge is in one end, then it is B_l for some $l \geq 3$, otherwise it must by F_4, in order not to contain $\widehat{F}_4$.

Now we assume Γ contains only simple edges. If it contains no branch point, then it is A_l for some $l \geq 1$. But Γ contains at most one branch point, and only 3 edges, otherwise it contains some $\widehat{D}_l, l \geq 4$. If Γ has only one branch point, then the graph is a center with three branches. One of the branch must be a single vertex, otherwise it contains a $\widehat{E}_6$. Then a second branch must has≤ 2 vertices, otherwise it contains a $\widehat{E}_7$. If the second branch has a single vertex, then $\Gamma \cong D_l$ for some $l \geq 4$. If the second branch has two vertices, then the third branch has≤ 4 vertices, otherwise it contains some $\widehat{E}_8$. So $\Gamma \cong E_6, E_7$ or E_8. □

Prop. (2.7.3.2) [Listing of Indecomposable Root Systems]. Let e_n be the standard basis of $\mathbb{R}^n$ with the standard bilinear form, and let L_n be the subgroup generated by e_n. Then

- A_n: Let V be the hyperplane of $\mathbb{R}^{n+1}$ orthogonal to the vector $e_1 + \ldots + e_{n+1}$, and R be the subset of $L_{n+1} \cap V$ consisting of vectors of length $\sqrt{2}$. Then (R, V) is a root system, and the Weyl group is the permutation group S_n of $e_1, \ldots, e_{n+1}$. The polarization with $t(e_i) = n+1-i$ gives a base consisting of $\{e_i - e_{i+1},\ i = 1, \ldots, n\}$ by(2.7.2.8).
- B_n: Let $V = \mathbb{R}^n$ and R be the subset of L_n consisting of vectors of length 1 or $\sqrt{2}$. Then (R, V) is a root system, and the Weyl group is the permutation and sign changes of the vectors e_i, isomorphic to $\mathbb{Z}_2^n \rtimes S_n$. The polarization with $t(e_i) = n + 1 - i$ gives a base consisting of $\{e_1 - e_2, \ldots, e_{n-1} - e_n, e_n\}$ by(2.7.2.8).
- C_n: Let C_n be the dual system of B_n(2.7.2.4), which by the invariant form isomorphic to the set of $\mathbb{R}^n$ consisting of vectors $\pm e_i \pm e_j, \pm 2e_i$. It has the same Weyl group as B_n. It has a base consisting of $\{e_1 - e_2, \ldots, e_{n-1} - e_n, 2e_n\}$ by(2.7.2.8).

- D_n: Let $V = \mathbb{R}^n$ and R be the set of all vectors of L_n of length $\sqrt{2}$. The Weyl group consists of permutations and sign changes of an even number of the vectors e_i. The polarization with $t(e_i) = n - i$ gives a base consisting of $\{e_1 - e_2, \ldots, e_{n-1} - e_n, e_{n-1} + e_n\}$.
- G_2: Let $V = \mathbb{R}[\omega]$ and R be the subset of $\mathbb{Z}[\omega]$ of norm 1 or 3. The Weyl group is isomorphic to the dihedral group. It clearly has a base consisting of $\{1, \omega - 1\}$.
- F_4: Let $V = \mathbb{R}^4$, and let R be the set of vectors $\{\pm e_i, \pm e_i \pm e_j, \frac{1}{2}(\pm e_1 \pm e_2 \pm e_3 \pm e_4)\}$. It can be shown this is a root system. The polarization with

$$t(\varepsilon_1) = 8, t(\varepsilon_2) = 3, t(\varepsilon_3) = 2, t(\varepsilon_3) = 1,$$

gives a base consisting of $\{e_2 - e_3, e_3 - e_4, e_4, \frac{1}{2}(e_1 - e_2 - e_3 - e_4)\}$.
- E_8: Let $V = \mathbb{R}^8$ and

$$R_{E_8} = \{\pm e_i \pm e_j, i \neq j\} \cup \{\frac{1}{2}(\sum_{i=1}^{8} \pm e_i) \text{ with even number of minus signs}\}.$$

The polarization with

$$t(e_1) = 23, t(e_2) = 6, t(e_3) = 5, \ldots, t(e_8) = 0$$

gives a base consisting of $\{e_2 - e_3, \ldots, e_7 - e_8, e_7 + e_8, \frac{1}{2}(e_1 - e_2 - \ldots - e_7 + e_8)\}$.
- E_7: E_7 is the intersection of E_8 with the hypersurface $\sum x_i = 0$, so

$$R_{E_7} = \{\pm(e_i - e_j), i \neq j\} \cup \{\frac{1}{2}(\sum_{i=1}^{8} \pm e_i) \text{ with 4 minus signs}\}.$$

The polarization with

$$t(\varepsilon_1) = 18, t(\varepsilon_2) = 7, t(\varepsilon_3) = 6, \ldots, t(\varepsilon_8) = 1$$

gives a base consisting of $\{\varepsilon_2 - \varepsilon_3, \ldots, \varepsilon_7 - \varepsilon_8, \frac{1}{2}(\varepsilon_1 - \varepsilon_2 - \varepsilon_3 - \varepsilon_4 - \varepsilon_5 + \varepsilon_6 + \varepsilon_7 + \varepsilon_8)\}$.
- E_6: E_6 is the intersection of E_7 with the hypersurface $x_7 + x_8 = 0$.

$$R_{E_6} = \{\varepsilon_i - \varepsilon_j | i \neq j \leq 6\} \cup \{\pm(\varepsilon_7 - \varepsilon_8)\} \cup \{\frac{1}{2}(\pm\varepsilon_1 \pm \varepsilon_2 \pm \ldots \pm \varepsilon_7) \pm \frac{1}{2}(\varepsilon_7 - \varepsilon_8) \text{ with 3 minus signs before } v_i, i \leq 6\}.$$

The polarization

$$t(\varepsilon_1) = 11, t(\varepsilon_2) = 4, t(\varepsilon_3) = 3, t(\varepsilon_4) = 2, t(\varepsilon_5) = 1, t(\varepsilon_6) = 0, t(\varepsilon_7) = 4, t(\varepsilon_8) = 3$$

gives a base consisting of $\{\varepsilon_2 - \varepsilon_3, \ldots, \varepsilon_5 - \varepsilon_6, \varepsilon_7 - \varepsilon_8, \frac{1}{2}(\varepsilon_1 - \varepsilon_2 - \varepsilon_3 - \varepsilon_4 + \varepsilon_5 + \varepsilon_6 - \varepsilon_7 + \varepsilon_8)\}$.

$A_n^\vee \cong A_n, B_n^\vee \cong C_n, D_n^\vee \cong D_n, G_2^\vee \cong G_2, F_4^\vee \cong F_4, E_8^\vee \cong E_8, E_7^\vee \cong E_7, E_6^\vee \cong E_6$.

Remark (2.7.3.3). The polarizations t are intimately related to the averaged coroot $\rho^\vee$(2.7.3.12).

Def. (2.7.3.4)[Dynkin Diagram]. The coxeter graph cannot determine the root system up to isomorphism, because it cannot distinguish between $n(\alpha, \beta), n(\beta, \alpha)$. So there is a **Dynkin diagram** which is constructed from the coxeter diagram by adding a vector from the longer vector to the shorter vector when $n(\alpha, \beta)n(\beta, \alpha) = 2$ or 3.

Prop. (2.7.3.5) [Listing of Dynkin Diagrams]. The Dynkin diagrams arising from indecomposable root systems are exactly the diagrams $A_n(n\geq 1), B_n(n\geq 2), C_n(n\geq 3), D_n(n\geq 4), E_6, E_7, E_8, F_4, G_2$. (graphs are given in [Etingod, Lie algebras]P109.)

Proof: This follows easily from(2.7.3.1) and(2.7.3.2). □

Prop. (2.7.3.6) [Non-Reduced Root Systems]. For any $n\geq 1$, there is exactly one non-reduced indecomposable root system of rank n, which is BC_n, the union of B_n and C_n in(2.7.3.2).

Cor. (2.7.3.7). Cf.[Kna96]P139.

Weight Lattices

Def. (2.7.3.8) [Weight Lattice]. Let (R,V) be a root system, we can define the **root lattice** as the $\mathbb{Z}$-lattice $Q(R)$ generated by R, and also the **weight lattice** $P(R)=\{x\in V|\alpha^\vee(x)\in\mathbb{Z},\forall\alpha\in R\}$ $P(R)$ has a generator by fundamental weights ω_i that $(\omega_i,\alpha_j^\vee)=\delta_{ij}$. Then $Q(R)\subset P(R)$, and $[P(R):Q(R)]$ is finite as they are both complete lattices.

Prop. (2.7.3.9). Let $\rho=1/2\sum_i\alpha_i$, then $\rho=\sum_i\omega_i$.

Proof: It follows from(2.7.2.10) that $s_\alpha\rho=\rho-\alpha$, so $(\rho,\alpha_i^\vee)=1$, thus $\rho=\sum_i\omega_i$ by definition(2.7.2.10). □

Prop. (2.7.3.10) [Weight Lattices of Indecomposable Root Systems]. Let R be a root system, notation as in(2.7.3.2),

- A_n: $\alpha_i^\vee=\alpha_i$ for $i\leq n$, so $\omega_i=(\frac{n+1-i}{n+1},\ldots,\frac{n+1-i}{n+1},\frac{-i}{n+1},\ldots,\frac{-i}{n+1})$($i$ terms) for $1\leq i\leq n$. Then $P=\{(x_i)\in\mathbb{R}^n|x_i-x_j\in\mathbb{Z},\sum x_i=0\}, Q=\{(x_i)\in\mathbb{Z}^n|\sum x_i=0\}$, and $P/Q\cong\mathbb{Z}/(n+1)\mathbb{Z}$.
- B_n: $\alpha_i^\vee=\alpha_i$ for $i<n$ and $\alpha_n^\vee=2e_n$, so $\omega_i=(1,\ldots,1,0,\ldots,0)$($i$ ones) for $1\leq i<n$, and $\omega_n=(\frac{1}{2},\ldots,\frac{1}{2})$. Then $P=\mathbb{Z}^n$ and $Q=\mathbb{Z}^n\cup[(\frac{1}{2},\ldots,\frac{1}{2})+\mathbb{Z}^n]$, $P/Q\cong\mathbb{Z}/2\mathbb{Z}$.
- C_n: $\alpha_i^\vee=\alpha_i$ for $i<n$ and $\alpha_n^\vee=e_n$, so $\omega_i=(1,\ldots,1,0,\ldots,0)$($i$ ones) for $1\leq i\leq n$. Then $P=\{(x_i)\in\mathbb{Z}^n|\sum x_i\in 2\mathbb{Z}\}$ and $Q=\mathbb{Z}^n$, $P/Q\cong\mathbb{Z}/2\mathbb{Z}$.
- D_n: $\alpha_i^\vee=\alpha_i$ for $i\leq n$, so $\omega_i=(1,\ldots,1,0,\ldots,0)$($i$ ones) for $1\leq i\leq n-2, \omega_{n-1}=(\frac{1}{2},\ldots,\frac{1}{2}), \omega_n=(\frac{1}{2},\ldots,\frac{1}{2},-\frac{1}{2})$. So $P/Q\cong(\mathbb{Z}/2\mathbb{Z})^2$ for n even and $\mathbb{Z}/4\mathbb{Z}$ for n odd.
- G_2: It is clear $\omega_1=\omega+1,\omega_2=2\omega+1$. Then $P=Q=\mathbb{Z}[\omega]$.
- F_4: $\omega_1=(1,1,0,0),\omega_2=(2,1,1,0),\omega_3=(\frac{3}{2},\frac{1}{2},\frac{1}{2},\frac{1}{2}),\omega_4=(1,0,0,0)$. So $P=Q=\frac{1}{2}\mathbb{Z}^4$.
- E_8: **?** $\omega_1=(1,1,0,\ldots,0)$, So $P=Q=\{(x_1,\ldots,x_8)|x_i\in\mathbb{Z}\text{ or }x_i\in\frac{1}{2}+\mathbb{Z},\sum x_i\in 2\mathbb{Z}\}$.
- E_7:**?**, $P/Q\cong\mathbb{Z}/2\mathbb{Z}$.
- E_6: **?**, $P/Q\cong\mathbb{Z}/3\mathbb{Z}$.

Proof: □

Prop. (2.7.3.11) [Maximal Roots]. For A_n, the maximal root is $\theta=e_1-e_{n+1}=\alpha_1+\ldots+\alpha_n=\omega_1+\omega_n$. For C_n, the maximal root is $\theta=2e_1=2\alpha_1+\ldots+2\alpha_{n-1}+\alpha_n=2w_1$.

But for any other indecomposable root system R, the maximal root θ is a fundamental root:

- B_n: $\theta=e_1+e_2=\alpha_1+2\alpha_2+\ldots+2\alpha_n=\omega_2$.
- D_n: $\theta=e_1+e_2=\alpha_1+2\alpha_2+\ldots+2\alpha_{n-2}+\alpha_{n-1}+\alpha_n=\omega_2$.

- G_2: $\theta = 2\omega + 1 = 3\alpha_1 + 2\alpha_2 = \omega_2$.
- F_4: $\theta = e_1 + e_2 = 2\alpha_1 + 3\alpha_2 + 4\alpha_3 + 2\alpha_4 = \omega_1$.
- E_8: $\theta = e_1 + e_2 = 2\alpha_1 + 3\alpha_2 + 4\alpha_3 + 5\alpha_4 + 6\alpha_5 + 4e_6 + 3e_7 + 2e_8 = \omega_1$.
- E_7: $\theta = e_1 - e_8 = \alpha_1 + 2\alpha_2 + 3\alpha_3 + 4\alpha_4 + 3\alpha_5 + 2\alpha_6 + 2\alpha_7 = \omega_6$.
- E_6: $\theta = \varepsilon_1 - \varepsilon_6 = \alpha_1 + 2\alpha_2 + 3\alpha_3 + 2\alpha_4 + \alpha_5 + 2\alpha_6 = \omega_4$.

Prop. (2.7.3.12) [ρ and $\rho^\vee$]. $\rho^\vee$ is ρ of the dual system $R^\vee$. Under the identification of V and V^*, If (R, S) is simply laced, then $R \cong R^\vee$ via $\alpha \mapsto \alpha^\vee$, so by(2.7.3.10),

- $A_n : \rho_{A_n} = \rho^\vee_{A_n} = (\frac{n}{2}, \frac{n-2}{2}, \ldots, -\frac{n}{2}) = \sum_i \frac{i(n+1-i)}{2}\alpha_i$.
- $B_n : \rho_{B_n} = \rho^\vee_{C_n} = (\frac{2n-1}{2}, \frac{2n-3}{2}, \ldots, \frac{3}{2}, \frac{1}{2}) = \sum_i \frac{i(2n-i)}{2}\alpha_i$.
- $C_n : \rho_{C_n} = \rho^\vee_{B_n} = (n, n-1, \ldots, 1) = \sum_{i\leq n-1} \frac{i(2n+1-i)}{2}\alpha_i + \frac{n(n+1)}{4}\alpha_n$.
- $D_n : \rho_{D_n} = \rho^\vee_{D_n} = (n-1, n-2, \ldots, 0) = \sum_{i\leq n-2} \frac{i(2n-1-i)}{2}\alpha_i + \frac{1}{2}\alpha_{n-1} + \frac{n(n-1)}{4}\alpha_n$.
- $G_2 : \rho_{G_2} = 3\omega + 2 = 5\alpha + 3\beta, \rho^\vee_{G_2} = \frac{10}{3}\omega + \frac{8}{3} = 6\alpha + \frac{10}{3}\beta$.
- $F_4 : \rho_{F_4} = (\frac{11}{2}, \frac{5}{2}, \frac{3}{2}, \frac{1}{2}), \rho^\vee_{F_4} = (8, 3, 2, 1)$.
- $E_8 : \rho_{E_8} = \rho^\vee_{E_8} = (23, 6, 5, 4, 3, 2, 1, 0)$.
- $E_7 : \rho_{E_7} = \rho^\vee_{E_7} = (18, 7, 6, \ldots, 1) - (\frac{23}{4}, \ldots, \frac{23}{4})$.
- $E_6 : \rho_{E_6} = \rho^\vee_{E_6} = (\frac{15}{2}, \frac{1}{2}, -\frac{1}{2}, -\frac{3}{2}, -\frac{5}{2}, -\frac{7}{2}, \frac{1}{2}, -\frac{1}{2})$.

Def. (2.7.3.13) [Coxeter Numbers]. Let (R, S) be an indecomposable root system, defined the **Coxeter root** to be $h_R = (\theta, \rho^\vee) + 1 = \mathrm{ht}(\theta) + 1$, and the **dual Coxeter number** $h^\vee_R = (\rho, (\theta)^\vee) + 1$. Clearly if (R, S) is simply laced, then $R \cong R^\vee$ via $\alpha \mapsto \alpha^\vee$, so if $\theta = \sum m_i\alpha_i$, then $\theta^\vee = \sum m_i\alpha_i^\vee$, so $h^\vee_R = h_R = \sum m_i + 1$.

Prop. (2.7.3.14) [Listing of Coxeter Numbers]. We can determine the Coxeter numbers and dual coxeter numbers of indecomposable root systems:

- $h_{A_n} = h^\vee_{A_n} = n + 1$.
- $h_{B_n} = 2n$, and $\theta^\vee = e_1 + e_2 = \alpha_1^\vee + 2\alpha_2^\vee + \ldots + \alpha_n^\vee$, so $h^\vee_{B_n} = 2n - 1$.
- $h_{C_n} = 2n$, and $\theta^\vee = e_1 = \alpha_1^\vee + \ldots + \alpha_n^\vee$, so $h^\vee_{C_n} = n + 1$.
- $h_{D_n} = h^\vee_{D_n} = 2n - 2$.
- $h_{G_2} = 6$, and $\theta^\vee = \frac{2}{3}(2\omega + 3) = \alpha_1^\vee + 2\alpha_2^\vee$, so $h^\vee_{G_2} = 4$.
- $h_{F_4} = 12$, and $\theta^\vee = e_1 + e_2 = 2\alpha_1^\vee + 3\alpha_2^\vee + 2\alpha_3^\vee + \alpha_4^\vee$, so $h^\vee_{F_4} = 9$.
- $h_{E_8} = h^\vee_{E_8} = 30$.
- $h_{E_7} = h^\vee_{E_7} = 18$.
- $h_{E_6} = h^\vee_{E_6} = 12$.

Minuscule Weights

Def. (2.7.3.15) [Minuscule Weights]. Let (R, S) be a root system, then a dominant weight ω is called **minuscule** if $(\omega, \beta^\vee) \leq 1$ for any positive coroot $\beta^\vee$.

Prop. (2.7.3.16) [Minuscule and Fundamental Weights]. Let $\theta^\vee = \sum m_i \alpha_i^\vee$ the maximal coroot, where m_i are positive integers, and $m_i = (\omega_i, \theta^\vee)$. Then any minuscule weight is fundamental, and a fundamental weight ω_i is minuscule iff $m_i = 1$.

Proof: The definition of minuscule weight requires $m_i \le 1$, and any other coroot is of the form $\beta^\vee = \sum n_i \alpha_i^\vee$, where $n_i \le m_i$, so $n_i = (\omega_i, \beta^\vee) \le 1$. □

Lemma (2.7.3.17). If $\omega \in Q$ and $|(\omega, \beta^\vee)| \le 1$ for any coroot β, then $\omega = 0$.

Proof: If not, choose a counterexample $\omega = \sum m_i \alpha_i$ with $\sum |m_i| > 0$ minimum, then $(\omega, \omega) = \sum m_i (\omega, \alpha_i^\vee) > 0$, so changing ω to $-\omega$ if necessary, we can assume $m_i > 0, (\omega, \alpha_i^\vee) > 0$ for some i, so $(\omega, \alpha_i^\vee) = 1$, and $s_i \omega = \omega - \alpha_i$ is another counterexample with smaller $|m_i|$, contradiction. □

Prop. (2.7.3.18). The following are equivalent for a dominant integral weight ω of a root system:
- ω is minuscule(2.7.3.15).
- If λ is a dominant integral weight and $\omega - \lambda \in Q^+$, then $\lambda = \omega$.

Proof: Cf.[Etingof, P141]?. □

Prop. (2.7.3.19) [Number of Minuscule Roots]. Every coset in P/Q contains a unique minuscule weight. This gives a bijection between the P/Q and the set of minuscule weights. In particular, the number of minuscule weights equals the determinant of the Cartan matrix.

Proof: For any $a \in P$, let $C = a + Q$ be a coset, let $\omega \in C \cap P^+$ be an element with minimum (ω, ρ), then for any dominant weight $\lambda < \omega \in C$, $(\omega - \lambda, \rho) \ge 0$, so $\lambda = \omega$. Thus ω is minuscule(2.7.3.18).

Conversely, if $\omega_1 \ne \omega_2 \in C$ are minuscule, then by(2.7.3.17), there is a positive coroot $\beta^\vee$ that $|(\omega_1 - \omega_2, \beta)| > 2$. But then as ω_1, ω_2 are both dominant, $|(\omega_1 - \omega_2, \beta)| \le 1$, contradiction. □

Cor. (2.7.3.20) [Listing of Minuscule Weights]. By(2.7.3.19) and(2.7.3.2)(2.7.3.10), we can determine minuscule weights for indecomposable root system (R, S),
- A_n: $P/Q \cong \mathbb{Z}/(n+1)\mathbb{Z}$, so it has $n+1$ minuscule weight, which are all the fundamental weights ω_i and 0.
- B_n: $P/Q \cong \mathbb{Z}/2\mathbb{Z}$, so there is exactly one non-zero minuscule weight, which is $\omega_n = (\frac{1}{2}, \dots, \frac{1}{2})$, by(2.7.3.18).
- C_n: $P/Q \cong \mathbb{Z}/2\mathbb{Z}$, so there is exactly one non-zero minuscule weight, which is $\omega_n = (1, 0, \dots, 0)$, by(2.7.3.18). The corresponding fundamental representation is the standard representation of $\mathfrak{sp}_{2n}$.
- D_n: $|P/Q| = 4$, so there are exactly 3 non-zero minuscule weights, which are ω_1, ω_{n-1} and ω_n, with corresponding fundamental representations of dimension $2n, 2^{n-1}, 2^{n-1}$. This is because the maximal coroot $\beta^\vee = \alpha_1^\vee + 2\alpha_2^\vee + \dots + 2\alpha_{n-2}^\vee + \alpha_{n-1}^\vee + \alpha_n^\vee$.
- G_2: $|P/Q| = 1$, so there are no non-zero minuscule weights.
- F_4: There are no non-zero minuscule weights.
- E_8: There are no non-zero minuscule weights.
- E_7: $P/Q \cong \mathbb{Z}/2\mathbb{Z}$, so there is exactly one non-zero minuscule weight.
- E_6: $P/Q \cong \mathbb{Z}/3\mathbb{Z}$, so there are exactly two non-zero minuscule weights.

Prop. (2.7.3.21) [w_0]. Notice $-w_0$ is an automorphism of (R, S) that permutes fundamental weights and simple roots, so it induces an automorphism of the Dynkin diagram of R. So if the Dynkin diagram of $\mathfrak{g}$ has no non-trivial automorphism, $w_0 = -1$. This is case for $R = A_1, B_n, C_n, G_2, F_4, E_7$ and E_8.

For D_n, if n is even, then $-1 \in W$ so $w_0 = -1$. If n is odd, then $w_0(e_i) = -e_i$ for $i < n$ and $w_0(e_n) = e_n$.

Notice also each s_i acts trivially on P/Q, so $-w_0$ acts by -1 on P/Q. For $A_n, n \geq 2$, $P/Q \cong \mathbb{Z}/(n+1)\mathbb{Z}$, thus $-w_0$ is the flip of the chain. Likewise for E_6, $P/Q \cong \mathbb{Z}/3\mathbb{Z}$, thus $-w_0$ flips the two minuscule weights. But for D_n, $P/Q \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ for n even and $P/Q \cong \mathbb{Z}/4\mathbb{Z}$ for n odd, so $-w_0$ preserves the minuscule weights or flip w_{n-1} and w_n.

4 Notations for a Root System

Def. (2.7.4.1) [Notations for a Root System]. Let (R, S) be a root system, then

- R^+/R^- is the positive/negative roots w.r.t. S.
- $S = \{\alpha_1, \ldots, \alpha_r\}$.
- s_i is the reflection w.r.t. α_i.
- θ is the maximal root.
- $\theta^\vee$ is the maximal coroot(maximal root of the dual root system).(It may not be dual to θ)
- $\rho = \frac{1}{2}\sum_i \alpha_i = \sum \omega_i$.
- $\rho^\vee$ is ρ of the dual system $R^\vee$.
- The height of weights is defined as in(2.7.2.17).
- W is the Weyl group.
- $w_0 \in W$ is the unique element with length $|R^+|$(2.7.2.14).
- n_{ij} is the Cartan number $n(\alpha_i, \alpha_j)$.
- $Q(R)$ is the root lattice(2.7.3.8).
- $P(R)$ is the weight lattice, generated by the fundamental weights ω_i(2.7.3.8).
- $P^+(R)$ is the dominant integral weights.
- $\mathfrak{P}$ is the Kostant partition function on $Q(R)$.

2.8 Algebraic K-Theory

Main references are [Algebraic K-Theory of Fields, Suslin, in Proc. ICM 1986, P222-244], [Algebraic K-Theory, Olivier Isely] and [G-S17], [nLab]. [Totaro, Milnor K-theory is the Simplest Part of Algebraic K-Theory, K-theory 6, 177-189, 1992].

1 Milnor K-Groups of Fields

Def. (2.8.1.1) [K_0]. The Grothendieck group $K_0(A)$ for a ring A is the free group generated by f.g. projective module over A modulo exact sequences. Then we have $P\sim Q$ iff $P\oplus A^n\cong Q\oplus A^n$ for some n. This is a functor $\mathcal{CA}\mathrm{lg}\to\mathcal{A}\mathrm{b}$.

Def. (2.8.1.2)[Milnor K-Groups]. For $k\in\mathtt{Field}$, define the n-th **Milnor K-group** to be the groups

$$K_0^{\mathrm{Mil}}(k)=\mathbb{Z},\quad K_1^{\mathrm{Mil}}(k)=k^\times,\quad K_n^{\mathrm{Mil}}(k)=(k^\times)^{\otimes n}/\{a_1\otimes\ldots\otimes a_n|\exists 1\leq i<j\leq n, a_i+a_j=1\}, n\geq 2.$$

The elements in $K_n^{\mathrm{Mil}}(k)$ are called **symbols**, and the class of $a_1\otimes\ldots\otimes a_m$ is denoted by $\{a_1,\ldots,a_n\}$.

Prop. (2.8.1.3) [Total Milnor K-Groups]. For $m,n\in\mathbb{N}$, the tensor product $(k^\times)^{\otimes m}\times(k^\times)^{\otimes n}\to(k^\times)^{\otimes(m+n)}$ induces a surjective map

$$K_m^{\mathrm{Mil}}(k)\otimes K_m^{\mathrm{Mil}}(k)\to K_{m+n}^{\mathrm{Mil}}(k),$$

which induces a graded group structure on

$$K_*^{\mathrm{Mil}}(k)=\bigoplus_{n\in\mathbb{N}}K_n^{\mathrm{Mil}}(k).$$

Then $K_*^{\mathrm{Mil}}(k)$ is graded commutative.

Proof: Firstly we show that $\{x,-x\}=0$:

$$\{x,-x\}+\{x,-(1-x)x^{-1}\}=\{x,1-x\}=0,$$

so

$$\{x,-x\}=-\{x,1-x^{-1}\}=\{x^{-1},1-x^{-1}\}=0.$$

Thus for any $x,y\in k^\times$,

$$0=\{xy,-xy\}=\{x,y\}+\{x,-x\}+\{y,-y\}+\{y,x\}.$$

The general cases follow by induction. □

Prop. (2.8.1.4) [Finite Fields]. If $k\in\mathtt{Field}$, $\#k<\infty$, then for any $n\geq 2$, $K_n^{\mathrm{Mil}}(k)=0$.

Proof: By(2.8.1.3), it suffices to show that $K_2^{\mathrm{Mil}}(k)=0$. And if ω is a generator of the cyclic group $k^\times$, then it suffices to show that $\{\omega,\omega\}=\{\omega,-1\}=0$. If $\#k=2^m$, then

$$0=\{1,\omega\}=\{\omega^{2^m-1},\omega\}=(2^m-1)\{\omega,\omega\},$$

thus we are done. And if $\mathrm{char}\,k\neq 2$, then we can find two non-squares in $k^\times$ s.t. $a+b=1$. Then

$$0=\{a,b\}=\{\omega^l,\omega^k\}=kl\{\omega,\omega\},$$

so $\{\omega,\omega\}=0$. □

Def. (2.8.1.5) [Residue Maps and Specialization Mpas]. Let (R,K,k) be a DVR, then for any $n\in\mathbb{Z}_+$, there exists a unique homomorphism

$$\partial^{\mathrm{Mil}}:K_n^{\mathrm{Mil}}(K)\to K_{n-1}^{\mathrm{Mil}}(k)$$

s.t. for any uniformizer ϖ and units $u_1,\ldots,u_{n-1}\in R^*$,

$$\partial^{\mathrm{Mil}}(\{\varpi,u_1,\ldots,u_{n-1}\})=\{\overline{u}_1,\ldots,\overline{u}_{n-1}\}.$$

Moreover, for any uniformizer ϖ and $n\in\mathbb{Z}_+$, there exists a **specialization map**

$$s_\varpi^{\mathrm{Mil}}:K_n^{\mathrm{Mil}}(K)\to K_n^{\mathrm{Mil}}(k)$$

s.t.

$$s_\varpi^{\mathrm{Mil}}(\{\varpi^{i_1}u_1,\ldots,\varpi^{i_n}u_n\})=\{\overline{u}_1,\ldots,\overline{u}_n\}$$

for any $u_1,\ldots,u_n\in R^*$.

Proof: Cf.[Central Simple Algebras]P217.? □

Cor. (2.8.1.6). $\partial^{\mathrm{Mil}}(\{a,b\})=(-1)^{v(a)v(b)}\overline{a^{-v(b)}b^{v(a)}}$.

Proof: □

Thm. (2.8.1.7) [Berrick-Keating]. Let $R,S\in\mathfrak{Ring}$ and $U\in\mathfrak{Mod}_{R\text{-}S}$, let $T=\begin{bmatrix}R&U\\&S\end{bmatrix}\in\mathfrak{Ring}$, then the map

$$\pi_i:K_i(T)\to K_i(T)\oplus K_i(S)$$

is an isomorphism for any $i\in\mathbb{Z}$.

Proof: [The K-Theory of Triangular Matrix Rings, Berrick-Keating, in Applications of algebraic K-theory to algebraic geometry and number theory, 1986]. □

2 Bloch-Kato Conjecture

Lemma (2.8.2.1) [Hilbert's Theorem90 for K_2]. Let K/k be a cyclic Galois field extension with a generator $\sigma\in\mathrm{Gal}(K/k)$, then the complex

$$K_2^{\mathrm{Mil}}(K)\xrightarrow{\sigma-1}K_2^{\mathrm{Mil}}(K)\xrightarrow{\mathrm{Nm}_{K/k}}K_2^{\mathrm{Mil}}(k)$$

is exact.

Proof: Cf.[Central Simple Algebras]P276.? □

Prop. (2.8.2.2) [Galois Symbols]. Let $k\in\texttt{Field}, m\in\mathbb{Z}\cap k^\times, n\in\mathbb{Z}_+$, the boundary map

$$\partial k^\times\to H^1(k,\mu_m)$$

induces a map

$$\partial^n:(k^\times)^{\otimes n}\to(H^1(k,\mu_m))^{\otimes n}\xrightarrow{\cup}H^n(k,\mu_m^{\otimes n}),$$

and this map factors through $K_n^{\mathrm{Mil}}(k)$ and gives a **Galois symbol map**

$$h_{k,m}^n:K_n^{\mathrm{Mil}}(k)\to H^n(k,\mu_m^{\otimes n}).$$

Proof: To show this map factors through $K_n^{\mathrm{Mil}}(k)$, it suffices to show for $n=2$ and $\partial^2(a\otimes(1-a))=0$. Take an irreducible factorization

$$x^m - a = \prod_l f_l \in k[x],$$

and let α_l be a root of f_l in k_{sep}, $K_l = k(\alpha_l)$, then

$$(1-a) = \prod_l \mathrm{Nm}_{K_l/k}(1-\alpha_l).$$

and

$$\partial^2(a\otimes(1-a)) = \sum_l \partial^2(a\otimes \mathrm{Nm}_{K_l/k}(1-\alpha_l)).$$

But

$$\begin{aligned}\partial^2(a\otimes \mathrm{Nm}_{K_l/k}(1-\alpha_l)) &= \partial(a)\cup\partial(\mathrm{Nm}_{K_l/k}(1-\alpha_l)) = \partial(a)\cup \mathrm{cor}_k^{K_l}(1-\alpha_l)\\ &= \mathrm{cor}(\mathrm{res}_k^{K_l}(\partial(a))\cup(1-\alpha_l)) = \mathrm{cor}(\partial_{K_l}(a)\cup(1-\alpha_l))\end{aligned}$$

But by definition $a\in(K_l^\times)^m$, so $\partial_{K_l}(a)=0$, by(10.1.3.9). Thus $\partial^2(a\otimes(1-a))=0$. □

Thm. (2.8.2.3) [Bloch-Kato Conjecture, Voevodsky-Rost/Merkurjev – Suslin]. Situation as in(2.8.2.2), the Galois symbol(2.8.2.2) induces an isomorphism

$$K_n^{\mathrm{Mil}}(k)/mK_n^{\mathrm{Mil}}(k) \xrightarrow{h^n_{k,m},\cong} H^n(k,\mu_m^{\otimes n}).$$

Proof: The $n=1$ case follows from(10.1.3.9).

For the $n=2$ case**?** □

2.9 Hopf Algebras

Main references are [Quantum Groups, Drinfeld], [A Brief Introduction To Quantum Groups Pavel Etingof And Mykola Semenyakin].

1 Hopf Algebras

Coalgebras and Bialgebras

Def. (2.9.1.1) [Coalgebras]. Let R be a commutative ring, a **coalgebra** is a monoid object in the category $\mathcal{M}\mathrm{od}_R^{op}$.

Remark (2.9.1.2) [Yoneda Interpretation]. We do not need to verify all the relations defining a coalgebra C, whenever we have a functorial monoidal structure on all the set $\mathrm{Hom}_R(H,T)$, we immediately recover the maps

- (Comultiplication):$\mu : C \to C \otimes_R C$ as $i_1 \cdot i_2$ in $\mathrm{Hom}_R(C, C \otimes C)$,
- (Counit):$\varepsilon : C \to R$ as 1 in $\mathrm{Hom}_R(C,R) = C^\vee$.

by Yoneda lemma.

$C^\vee$ is an monoid by definition, and C is called **cocommutative** iff $C^\vee$ is commutative.

Def. (2.9.1.3) [Primitive Elements]. Let H be a coalgebra over R, an element $x \in H$ is called **primitive** if $\mu(x) = 1 \otimes x + x \otimes 1$. It is called **group-like** if $\Delta(x) = x \otimes x$.

Def. (2.9.1.4) [Bialgebras]. Let R be a commutative ring, a **bialgbera** is a monoid object in the category of coalgebras over R. Equivalently, in the Yoneda interpretation, C is an R-algebra that Δ is a homomorphism of algebras.

Def. (2.9.1.5) [Hopf Algebra]. A **Hopf algebra** over a commutative algebra R is a bialgebra A together with a R-linear map $S : A \to A$ that satisfies:

$$m \circ (\mathrm{id} \otimes S) \circ \mu = m \circ (S \otimes \mathrm{id}) \circ \mu = \eta \circ \varepsilon : A \to A.$$

If $S^2 = \mathrm{id}_A$, then A is called an **involutive Hopf algebra**.

Prop. (2.9.1.6). In a Hopf algebra, S is an anti-homomorphism both for the algebra structure and coalgebra structure.

Proof: Cf.https://ncatlab.org/nlab/show/Hopf+algebra. □

Example (2.9.1.7) [Group Algebras]. Let Γ be a group, the group algebra $R[\Gamma]$ with the coalgebra structure

$$\mu : R[\Gamma] \to R[\Gamma] \times R[\Gamma] : g \mapsto g \otimes g, \varepsilon : R[\Gamma] \to R : \sum a_g g \mapsto \sum a_g$$

and

$$S : R[\Gamma] \to R[\Gamma] : g \mapsto g$$

is a Hopf algebra.

Def. (2.9.1.8) [Dual Hoof Algebra]. Let H be a Hopf algebra, matrix coefficients. H^0.

Prop. (2.9.1.9). $\mathrm{Rep}(H) = \mathcal{M}\mathrm{od}_{H^0}$.

Co-modules

Def. (2.9.1.10)[Co-Module]. Ket A be a coalgebra over a field k, then a right **co-module** is a k-vector space V together with a k-linear map $\rho : V \to V \otimes A$ that satisfies

$$(\mathrm{id}_V \otimes \mu) \circ \rho = (\rho \otimes \mathrm{id}_A) \circ \rho, \quad (\mathrm{id}_V \otimes \varepsilon) \circ \rho = \mathrm{id}_V .$$

The map ρ is called the **co-action**, and a k-subspace $W \subset V$ that $\rho(W) \subset W \otimes A$ is called a **sub-comodule** of V.

Def. (2.9.1.11) [Tensor Product of Co-modules].

Topologists' Hopf Algebras

Def. (2.9.1.12) [Topologist's Hopf Algebra]. A **topologist's Hopf algebra** over a commutative ring R is a unital magma object in the dual category of graded algebras with 0-degree term R, given by maps $\Delta : A \to A \otimes A$, and $\varepsilon : A \to R$ the canonical projection map. So in particular, Δ is of the form

$$\Delta(\alpha) = 1 \otimes \alpha + \alpha \otimes 1 + \sum_i \alpha_i' \otimes \alpha_i'', |\alpha_i'| > 0, |\alpha_i''| > 0$$

Prop. (2.9.1.13). The tensor product of two topologists' Hopf algebra is a topologists' Hopf algebra.

Prop. (2.9.1.14). Let $\mathbb{F}$ be a field, then $\mathbb{F}[\alpha]/(\alpha^n)$, where α is placed at even dimension or $\mathbb{F}$ has characteristic 2, is a topologists' Hopf algebra iff $\mathbb{F}$ has positive characteristic p and n is a power of p.

Proof: By definition, it is easy to see that α is primitive, thus

$$\Delta(\alpha^n) = 0 = \sum_{0<i<n} \binom{n}{i} \alpha^i.$$

Which then implies that n is a p-power. □

Prop. (2.9.1.15) [Hopf-Borel]. Let A be a topologists' Hopf algebra over a perfect field K, and A is of f.d. in each degree, then:

- If K has characteristic 0, A is isomorphic as an algebra to the tensor product of an exterior product of odd-dimensional generators and a polynomial ring of even-dimensional generators.
- If K has characteristic p, then A is isomorphic as an algebra to the tensor product of algebras of the following types:
  - $K[\alpha]$, where α is even-dimensional if $p \neq 2$.
  - $\wedge_K[\alpha]$ where α is odd-dimensional.
  - $K[\alpha]/(\alpha^{p^i})$, where α is even-dimensional if $p \neq 2$.

Proof: We only prove the 0-characteristic case, Cf.[Hat02]P285.? □

2 Commutative Hopf Algebras

Prop. (2.9.2.1) [Commutative Hopf Algebra]. Let R be a commutative ring, a commutative Hopf algebra is equivalent to a cogroup object in $\mathcal{CA}lg_R$. A homomorphism of Hopf algebras is a morphism of algebras that represents a natural transformation of functors from $\mathcal{CA}lg_R$ to $\mathcal{G}rp$.

Proof: The critical point is to look at the definition of Hopf algebra. In this case, S is a homomorphism of algebras(2.9.1.6), and notice tensor product is just the product in the dual category, and $m : A \otimes A \to A$ is the diagonal in the dual category, thus a cogroup object is a map $\Delta : A \to A \otimes A$ together with a map $inv : A \to A$ that

$$m \circ (\mathrm{id} \otimes inv) \circ \Delta = m \circ (inv \otimes \mathrm{id}) \circ \Delta \, \mathrm{id} = \mathrm{id} : A \to A,$$

which is exactly the definition of the Hopf algebra(2.9.1.5). □

Cor. (2.9.2.2) [Yoneda Interpretation]. We do not need to verify all the relations defining a Hopf algebra H, whenever we have a functorial commutative group structure on all the set $\mathrm{Hom}_R(H, T)$, we immediately recover the maps:

- (Comultiplication):$\mu : H \to H \otimes_R H$ as $i_1 \cdot i_2$ in $\mathrm{Hom}_R(H, H \otimes H)$,
- (Antipode):$\iota : H \to H$ as inv in $\mathrm{Hom}_R(H, H)$,
- (Counit):$\varepsilon : H \to R$ as 1 in $\mathrm{Hom}_R(H, R) = H^\vee$.

by Yoneda lemma.

For convenience, we denote the structure maps $\eta_H : R \to H, \mu : H \times_R H \to H, (-)^{-1} : H \to H$.

Prop. (2.9.2.3) [Group Algebras]. Let Γ be a commutative group, then the group algebra $R[\Gamma]$(2.9.1.7) represents the group functor that maps a commutative R-algebra S to the commutative group $\mathrm{Hom}_{\mathcal{G}rp}(\Gamma, S)$.

Cor. (2.9.2.4) [Multiplicative Groups]. $\mathbb{G}_{m,R} = R[t, t^{-1}]$ is a Hopf algebra that represents the group functor of multiplicative groups on $\mathcal{CA}lg_R$.

Cor. (2.9.2.5) [Roots of Unity $\mu_{n,R}$]. Let $\Gamma \cong \mathbb{Z}/n\mathbb{Z}$, then $R[\Gamma] \cong R[t]/(t^n - 1)$ is a Hopf algebra that represents the group functor of multiplicative groups of n-th roots of unity on $\mathcal{CA}lg_R$.

Prop. (2.9.2.6) [Additive Groups]. $R[t]$ can be given a Hopf algebra structure that represents the group functor that maps a commutative R-algebra S to the additive group S^+.

Def. (2.9.2.7) [$G_{(a,b),R}$]. Given elements $a, b \in R$ that $ab = 2$, for any commutative R-algebra S, the group $G_{(a,b),R}(S)$ of elements x of S that $x^2 + ax = 0$ is a group under the mapping $(m, n) \mapsto m + n + bmn$. Notice the inverse of m is m itself. Then $R[t]/(t^2 + at)$ can be given a Hopf algebra that represents the functor $S \mapsto G_{(a,b),R}(S)$.

Def. (2.9.2.8) [$V_\mathfrak{a}$]. Let V be a vector space over k, then $\mathrm{Sym}(V^\vee)$ can be given a Hopf algebra structure representation the functor $V_\mathfrak{a} : R \mapsto R \otimes_k V \cong \mathrm{Hom}_k(V^\vee, R)$.

Def. (2.9.2.9) [Locally Constant Functions]. Let Γ be a group, then $\underline{\Gamma}_R = \prod_{\gamma \in \Gamma} R$ represents the group functor that maps an R-algebra T to the group of locally constant functions on $\mathrm{Spec}\, R$ with value in Γ.

Remark (2.9.2.10). To illustrate the philosophy of(8.1.1.2), we figure out the Hopf structure of the local constant functions: a map $\prod_{\gamma\in\Gamma} R \to T$ is equivalent to a set of idempotents e_γ of T that $\sum e_\gamma = 1$. This is equivalent to a locally constant function on $\operatorname{Spec} T$ that takes value γ on $V(e_\gamma)$. Then the product takes values $\gamma\delta$ on $V(e_\gamma \otimes e_\delta) \subset \operatorname{Spec} T \otimes T$, or equivalently takes values γ on $V(\sum_{gg'=\gamma} e_g \otimes e_{g'})$, so $\Delta(e_\gamma) = \sum_{gg'=\gamma} e_g \otimes e_{g'}$.

Lemma (2.9.2.11)[Modulo $\ker(\varepsilon)$]. For a Hopf algebra A over R, the comultiplication and counit are determined by $\ker \varepsilon$:

- $R \oplus \ker\varepsilon \to A : (a, b) \mapsto a + b$ is an isomorphism of R-modules.
- $\mu(a) \equiv -\varepsilon(a) + a \otimes 1 + 1 \otimes a \mod \ker\varepsilon \otimes_R \ker\varepsilon$.
- $\iota(a) \equiv -a \mod (\ker\varepsilon)^2$ for $a \in \ker\varepsilon$.

Proof: 1: this is because the counit $0 \to \ker\varepsilon \to A \to R \to 0$ has an inverse by the R-algebra map $R \to S$.

2: item1 allows us to write

$$A \otimes_R A = R \oplus (\ker\varepsilon \otimes_R R) \oplus (R \otimes_R \ker\varepsilon) \oplus (\ker\varepsilon \otimes \ker\varepsilon)$$

so for $a \in A$,

$$\mu(a) = b + c \otimes 1 + 1 \otimes d + z$$

where $b \in R, c, d \in \ker\varepsilon, z \in \ker\varepsilon \otimes_R \ker\varepsilon$. Then $a = (\varepsilon \otimes \mathrm{id}_A)(b + c \otimes 1 + 1 \otimes d + z) = b + d$, and also $a = b + c$. Applying ε shows $b = \varepsilon(a)$, and thus

$$\mu(a) = \varepsilon(a) + (a - \varepsilon(a)) \otimes 1 + 1 \otimes (a - \varepsilon(a)) + z = -\varepsilon(a) + a \otimes 1 + 1 \otimes a + z.$$

3: Let $\iota(a) = b + c$ where $b \in R, c \in \ker\varepsilon$, then

$$\varepsilon(a) = (multi)(\iota \otimes \mathrm{id})(-\varepsilon(a) + a \otimes 1 + 1 \otimes a + z) = -\varepsilon(a) + \iota(a) + a + (multi)(\iota \otimes \mathrm{id})(z)$$

so for $a \in \ker\varepsilon$, $\iota(a) \equiv -a \mod (\ker\varepsilon)^2$, as $(multi)(\iota \otimes \mathrm{id})(z) \in (\ker\varepsilon)^2$, because ι commutes with ε. $\square$

Def. (2.9.2.12)[Hopf Ideal and Quotient Hopf Algebra]. Let A be a Hopf algebra, then a quotient Hopf algebra is a quotient A/I that has a Hopf algebra structure compatible with that of A. In another words, there are commutative diagrams

$$\begin{array}{ccc} A & \xrightarrow{\mu} & A \otimes_R A \\ \downarrow & & \downarrow \\ A/I & \xrightarrow{\overline{\mu}} & A/I \otimes_R A/I \end{array} \qquad \begin{array}{ccc} A & \xrightarrow{\varepsilon} & R \\ \downarrow & \nearrow & \\ A/I & & \end{array} \qquad \begin{array}{ccc} A & \xrightarrow{\iota} & A \\ \downarrow & & \downarrow \\ A/I & \xrightarrow{\overline{\iota}} & A/I \end{array}$$

In particular, quotient Hopf algebra corresponds to ideals of A that

$$\mu(I) \subset \ker(A \otimes_R A \to A/I \otimes_R A/I), \quad \varepsilon(I) = 0, \quad \iota(I) \subset I,$$

called **Hopf ideals** of A.

Remark (2.9.2.13)[Examples]. If Γ' is a subgroup of a commutative group Γ, then $R[\Gamma]$ has a quotient Hopf algebra $R[\Gamma/\Gamma']$. In particular, $R[t]/(t^n - 1)$ is a quotient Hopf algebra of $R[t, t^{-1}]$.

Prop. (2.9.2.14) [Hopf Ideals of Additive Groups]. Let $f = \sum_{i=0}^{d} a_i t^i \in R[t]$ be a monic polynomial$\neq t$, then (f) is a Hopf ideal of $R[t]$ iff R is of char $p > 0$ and the derivative $f' = 0$.

Proof: We check conditions in(2.9.2.12), the first says $\sum a_i(t\otimes 1 + 1\otimes t)^i$ vanishes in $R[t]/(f)\otimes_R R[t]/(f)$. But f is monic, so this is equivalent to $a_i\binom{i}{j} = 0$ for any $0 < j < i \leq d$, But we have $gcd_{0<j<i}\{\binom{i}{j}\} = p$ if $i = p^r$ for some $r \geq 1$ and 1 otherwise, so $a_d = 0$ unless d is a power of p, and $p = 0 \in R$ because $a_d = 1$. In particular, $f = \sum_{i=0}^{k} b_i t^{p^i}$, and it automatically satisfies the other two conditions. □

Cor. (2.9.2.15) $[\alpha_{p^r,R}]$. Let R be a commutative ring of char $p > 0$, then the quotient Hopf algebra $R[t]/(t^{p^r})$ corresponding to the Hopf ideal (t^{p^r}) is denoted by $\alpha_{p^r,R}$.

WARNING: $\alpha_{p^r,R}$ is isomorphic to $\mu_{p^r,R}$ as R-algebras, but they are not isomorphic as Hopf algebras.

Prop. (2.9.2.16)[Irreducibility of Hopf Algebras]. Let k be a field, then the following Hopf algebra contains no proper Hopf ideals:

- $\mathbb{G}_{a,k}$ if char$R = 0$.
- $\alpha_{p,k}$ if char$R = p > 0$.

Proof: Any Hopf ideal fo $k[t]$is principal, thus this proposition follows from(2.9.2.14). □

Def. (2.9.2.17) [Cokernel Hopf Algebra]. Let $A \to B$ be a homomorphism of Hopf Algebras over R, then the **cokernel Hopf algebra** is the algebra $B\otimes_A R = B/B\otimes_A \ker(\varepsilon_A)$, which represents the functor of kernels of $\mathrm{Hom}_R(B,T) \to \mathrm{Hom}_R(A,T)$, thus is a Hopf algebra.

Lemma (2.9.2.18). A Hopf algebra over a field k is direct limit of Hopf algebra of f.t. over k.

Def. (2.9.2.19)[Group-Like Elements]. Let A be a Hopf algebra, then a **group-like element** $a \in A$ is an invertible element that satisfies $\mu(a) = a\otimes a \in A\otimes A$.

If a is a group-like element in a Hopf algebra A, then $a = (\varepsilon, \mathrm{id})\mu(a) = \varepsilon(a)a$, so $\varepsilon(a) = 1$.

Prop. (2.9.2.20) [Group-Like Elements are Linearly Independent]. Let A be a Hopf algebra over a field k, then the set of group-like elements are linearly independent over k.

Proof: If $e = \sum a_i e_i$ that e, e_i are all group-like elements, then

$$\mu(e) = e\otimes e = \sum c_i c_j e_i \otimes e_j = \sum c_i \mu(e_i) = \sum c_i e_i \otimes e_i$$

so $c_i^2 = c_i$ and $c_i c_j = 0$. Now also notice $1 = \varepsilon(e) = \sum c_i \varepsilon(e_i) = \sum c_i$(2.9.2.19), contradiction. □

Cor. (2.9.2.21). The set of group-like elements in the Hopf algebra $k[\Gamma]$(2.9.2.3) are just the set $\Gamma \subset k[\Gamma]$.

Prop. (2.9.2.22) [Cartier Theorem]. A Hopf algebra A over a field k of characteristic 0 is reduced.

Proof: We can base change to the algebraic closure $\overline{k}$ of k and assume k is alg.closed. Because reducedness is stalkwise and Hilbert's Nullstellensatz, it suffices to show A_s is reduced at each $s \in G(k)$. The translation by $g \in G(k)$ acts transitively on $G(k)$, so it suffices to show it vanishes at the kernel of the counit map $\ker(\varepsilon)$. Cf.[Jakob, Stix].

We may assume by taking direct limits that A is f.g. over k. Let $\mathfrak{m}$ be the kernel of the counit $\varepsilon : A \to k$, then $\mathfrak{m}/\mathfrak{m}^2$ is a f.g. k-vector space with a basis lifting to $x_1,\ldots,x_r \in \mathfrak{m}$.

We prove that $\mathrm{gr}_{\mathfrak{m}}(A)$ is a polynomial ring in x_i, Cf.[Shatz]. □

Prop. (2.9.2.23) [Faithfully Flatness]. If $A \subset B$ are f.g. Hopf algebras over a field k, then B is f.f. over A.

Proof: Cf.[Milne, P73]**?**. □

Cor. (2.9.2.24). If $A \subset B$ are Hopf algebras that B is an integral domain, and let K, L be their fraction field, then $B \cap L = A$. In particular, if $K = L$, then $A = B$.

Proof: Since $A \to B$ is f.f. by(2.9.2.23), $cB \cap A = cA$ for any $c \in A$ by(2.9.2.23). Thus if $a/c \in B$ for $a, c \in A$, then $a \in cB \cap A = cA$, so $a/c \in A$. □

3 Categories and Algebraic Topology

3.1 Categories

Main references are [?], [Bor94], [Coend Calculus, Fosco Loregian].

1 Basics

Def. (3.1.1.1)[Categories, Eilenberg-Mac.Lane1945]. A **category** $\mathcal{C}$ consists of the following data:

- A set $\mathrm{Ob}(\mathcal{C})$ of **objects of** $\mathcal{C}$.
- For any $x, y \in \mathrm{Ob}(\mathcal{C})$ a set $\mathrm{Mor}(x, y)$ of **morphisms from** x **to** y.
- For any $(x, y, z) \in \mathrm{Ob}(\mathcal{C})$, a map of sets $\circ : \mathrm{Mor}(y, z) \times \mathrm{Mor}(x, y) \to \mathrm{Mor}(x, z)$, called the **composition law** of $\mathcal{C}$.

that satisfies:

- (Identity)For any $x \in \mathrm{Ob}(\mathcal{C})$, there exists an element $\mathrm{id}_x \in \mathrm{Mor}(x, x)$ s.t. $\mathrm{id}_x \circ \varphi = \varphi, \psi \circ \mathrm{id}_x = \psi$ whenever these composition makes sense. It is clear such an element is unique.
- (Associativity)$(\varphi \circ \psi) \circ \chi = \varphi \circ (\psi \circ \chi)$ whenever these compositions make sense.

Remark (3.1.1.2). Let $\mathcal{C}$ be a category, we will sometimes say $x \in \mathcal{C}$ to mean that x is an element of $\mathrm{Ob}(\mathcal{C})$ and $f : x \to y \in \mathcal{C}$ or f is a morphism in $\mathcal{C}$ to mean: $x, y \in \mathrm{Ob}(\mathcal{C})$ and $f \in \mathrm{Mor}(x, y)$. Hopefully this won't make any confusions.

Def. (3.1.1.3)[Dual Categories]. Let $\mathcal{C}$ be a category, then the **dual category** of $\mathcal{C}$ is a category $\mathcal{C}^{\mathrm{op}}$ with

- $\mathrm{Ob}(\mathcal{C}^{\mathrm{op}}) = \mathrm{Ob}(\mathcal{C})$.
- For $x, y \in \mathrm{Ob}(\mathcal{C}^{\mathrm{op}}) = \mathrm{Ob}(\mathcal{C})$, $\mathrm{Mor}_{\mathcal{C}^{\mathrm{op}}}(x, y) = \mathrm{Mor}_{\mathcal{C}}(y, x)$.
- The composition law of $\mathcal{C}^{\mathrm{op}}$ is induced from that of $\mathcal{C}$.

Def. (3.1.1.4) [Isomorphisms]. Let $\mathcal{C}$ be a category, an **isomorphism** in $\mathcal{C}$ is a morphism $\varphi \in \mathrm{Mor}(x, y)$ in $\mathcal{C}$ s.t. there exists a morphism $\psi \in \mathrm{Mor}(y, x)$ s.t. $\varphi \circ \psi = \mathrm{id}_y$ and $\psi \circ \varphi = \mathrm{id}_x$. it is clear that such a ψ is unique, and if it exists, it is called the **inverse morphism** of φ.

For $x, y \in \mathcal{C}$, if there exists an isomorphism in $\mathrm{Mor}(x, y)$, x, y are said to be **equivalent objects**.

Def. (3.1.1.5) [Functors]. Let $\mathcal{C}, \mathcal{C}'$ be categories, a **functor** F from $\mathcal{C} \to \mathcal{C}'$ consists of the following data:

- a morphism of sets $\mathrm{Ob}(\mathcal{C}) \to \mathrm{Ob}(\mathcal{C}') : x \mapsto F(x)$.
- for any $x, y \in \mathrm{Ob}(\mathcal{C})$, a morphism of sets $\mathrm{Mor}(x, y) \to \mathrm{Mor}(F(x), F(y)) : f \mapsto F(f)$.

that satisfies:

- $F(\mathrm{id}_x) = \mathrm{id}_{F(x)}$.
- $F(\varphi \circ \psi) = F(\varphi) \circ F(\psi)$ whenever $\varphi \circ \psi$ is defined.

A **contravariant functor** from $\mathcal{C}$ to $\mathcal{C}'$ is defined to be a functor from $\mathcal{C}^{\mathrm{op}}$ to $\mathcal{C}'$.

Def. (3.1.1.6) [Identity Functor $\mathrm{id}_{\mathcal{C}}$]. For any category $\mathcal{C}$, there exists a trivial functor $\mathrm{id}_{\mathcal{C}} : \mathcal{C} \to \mathcal{C}$.

Def. (3.1.1.7) [Natural Transformations]. Let $\mathcal{C}, \mathcal{C}'$ be categories and $F, G : \mathcal{C} \to \mathcal{C}'$ be functors between categories, then a **natural transformation** η from F to G consists of an element η_x for each $x \in \mathrm{Ob}(\mathcal{C})$ s.t. for any $f : x \to y \in \mathcal{C}$, the following diagram is commutative:

$$\begin{array}{ccc} F(x) & \xrightarrow{F(f)} & F(y) \\ \downarrow{\scriptstyle \eta_x} & & \downarrow{\scriptstyle \eta_y} \\ G(x) & \xrightarrow{G(f)} & G(y) \end{array}.$$

Then for any two categories $\mathcal{C}, \mathcal{C}'$, there is a category $\mathrm{Fun}(\mathcal{C}, \mathcal{C}')$ consisting of the set of functors from $\mathcal{C}$ to $\mathcal{C}\prime$, and natural transformations as morphisms between functors.

Def. (3.1.1.8) [Final and Initial Objects]. An object Z of a category is called a **final object** if $\# \mathrm{Hom}(X, Z) = 1$ for any object X. It is called **weakly final** if $\mathrm{Hom}(X, Z) \neq \varnothing$ for every object X.

Dually an object is called **(weakly)initial** if it is (weakly)initial as an object of $\mathcal{C}^{\mathrm{op}}$.

Def. (3.1.1.9) [Filtered Categories]. A **filtered category** is a category $\mathcal{I}$ that:

- It is nonempty.
- for any $a, b \in \mathcal{I}$, there is some $c \in \mathcal{I}$ with morphisms $a \to c, b \to c$
- for any two morphisms $a, b : x \to y$, there is a morphism $c : y \to z$ that $c \circ a = c \circ b$.

Def. (3.1.1.10) [Fully Faithful Functors]. A functor of category $F : \mathcal{C} \to \mathcal{D}$ is called:

- a **full/faithful functor** if for any $x, y \in \mathrm{Ob}(\mathcal{C})$, $F : \mathrm{Hom}(X, Y) \to \mathrm{Hom}(F(x), F(y))$ is surjective/injective.
- an **essentially surjective functor** if any object of $\mathcal{D}$ is equivalent to some $f(x)$, where $x \in \mathcal{C}$.
- an **equivalence** if there is a functor $G : \mathcal{D} \to \mathcal{C}$ that $F \circ G \cong \mathrm{id}_{\mathcal{D}}$ and $G \circ F \cong \mathrm{id}_{\mathcal{C}}$.

Prop. (3.1.1.11) [Category Equivalences]. A Functor $\mathcal{C} \to \mathcal{D}$ is an equivalence if and only if it's fully faithful and essentially surjective.

Proof: There exist an object $G(X) \in \mathcal{C}$ and an isomorphism $\xi_X : FG(X) \to X$ for every $X \in \mathcal{D}$. Because F is fully faithful, there exists a unique morphism $G(f) : G(X) \to G(Y)$ such that $F(G(f)) = \xi_Y^{-1} \circ f \circ \xi_X$ for every morphism $f : X \to Y$ in $\mathcal{D}$. Thus we obtain a functor $G : \mathcal{C} \to \mathcal{D}$ as well as a natural isomorphism $\xi : F \circ G \to \mathrm{Id}_{\mathcal{D}}$. Moreover, the isomorphism $\xi_{F(Z)} : FGF(Z) \to F(Z)$ decides an isomorphism $\eta_Z : GF(Z) \to Z$ for every $Z \in \mathcal{C}$. This yields a natural isomorphism $\eta : G \circ F \to \mathrm{Id}_{\mathcal{C}}$. □

Def. (3.1.1.12) [Setoids]. A **setoid** is a category that is equivalent to a category that has only the identity morphisms.

Def. (3.1.1.13) [Groupoids]. A **groupoid** is a category that all morphisms are isomorphisms. The full subcategory of $\mathcal{C}at$ consisting of groupoids is denoted by $\mathcal{G}rpd$.

Prop. (3.1.1.14) [Equivalence Relations]. An **equivalence relation** is a groupoid that $\# \mathrm{Mor}_{\mathcal{C}}(x, y) \le 1$ for any $x, y \in \mathcal{C}$.

Prop. (3.1.1.15). A category is equivalent to a setoid iff it is an equivalence relation.

Proof:

□

Def. (3.1.1.16) [Subcategories]. Let $\mathcal{C}$ be a category, a **subcategory** $\mathcal{C}'$ of $\mathcal{C}$ is a category together with a functor $F : \mathcal{C}' \to \mathcal{C}$ s.t. $F : \mathrm{Ob}(\mathcal{C}') \to \mathrm{Ob}(\mathcal{C})$ is injective and F is faithful. And it is called a **full subcategory** if F is fully fatihful. It is called a **strictly full subcategory** if for any $y \in \mathcal{C}$, y is equivalent to some $F(x), x \in \mathrm{Ob}(\mathcal{C}')$ iff $y \in F(\mathcal{C}')$.

Def. (3.1.1.17) [Comma Categories]. For a category $\mathcal{C}$ and an object S, the **comma category** $\mathcal{C}/S$ is defined to be the category of arrows $T \to S$ with the arrows being compatible arrows over S.

Def. (3.1.1.18) [Category of Arrows]. For a category $\mathcal{C}$, the category of arrows $\mathcal{A}\mathrm{rr}(\mathcal{C})$ is a category whose objects are arrows in $\mathcal{C}$ and a morphism $f \to g$ is a commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{h} & B \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ A' & \xrightarrow{k} & B' \end{array}$$

Def. (3.1.1.19) [Twisted Arrow Category]. For a category $\mathcal{C}$, the category of twisted arrows $TW(\mathcal{C})$ is a category whose objects are arrows in $\mathcal{C}$ and a morphism $f \to g$ is a diagram

$$\begin{array}{ccc} A & \xleftarrow[h]{} & B \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} \\ A' & \xrightarrow{k} & B' \end{array}$$

Def. (3.1.1.20) [Epimorphisms and Monomorphisms]. An **epimorphism** in a category is a morphism $X \to Y$ that the map $\mathrm{Hom}(Y, Z) \to \mathrm{Hom}(X, Z)$ induced by composition is injective. Dually, an **monomorphism** is an epimorphism in the dual category.

Def. (3.1.1.21) [Projective and Injective]. A **projective object** X in a category is an object that for any epimorphism(3.1.1.20) $Y \to Z$, $\mathrm{Hom}(X, Y) \to \mathrm{Hom}(X, Z)$ is surjective. Dually, an **injective object** X is a projective object in the dual category.

Def. (3.1.1.22) [Retract]. A morphism f in a category $\mathcal{C}$ is called a **retract** of g if there are morphisms $F, G : f \to g$ in $\mathrm{Mor}(\mathcal{C})$(3.1.1.18) that $G \circ F = \mathrm{id}_f$.

Def. (3.1.1.23) [Equivalence relations]. For $\mathcal{C} \in \mathcal{C}\mathrm{at}$ has finite products, $X_0 \in \mathcal{C}$, an **equivalence relation on** X_0 is a tuple (X_1, u), where $X_1 \in \mathcal{PS}\mathrm{h}(\mathcal{C})$ and $u \in \mathrm{Hom}(X_1, X_0 \times X_0)$ s.t for any $X \in \mathcal{C}$, the map

$$\widetilde{X}_1(T) \xrightarrow{u} \widetilde{X}_0(T) \times \widetilde{X}_0(T)$$

is a bijection of $\widetilde{X}_1(T)$ onto the graph of an equivalence relation on $\widetilde{X}_1(T)$. Similarly, we can define **pre-relations on** X_0, **relations on** X_0 and **pre-equivalence relations on** X_0.

Prop. (3.1.1.24) [Involutions]. Situation as in(3.1.1.23), then there is a morphism $\sigma : F_0 \to F_0$, $\sigma^2 = \mathrm{id}, u_0 \circ \sigma = u_1, u_1 \circ \sigma = u_0$, by the symmetry in the definition of equivalence relations.

Def. (3.1.1.25) [Categorical Quotients]. Situation as in(3.1.1.23), for an equivalence relation $u : X_1 \to X_0 \times X_0$, a morphism $v : X_0 \to X$ is called a categorical quotient if

- u factors through $u : X_1 \to X_0 \times_X X_0$, and $u : X_1 \to X_0 \times_X X_0$ is an isomorphism.
- For any $T \in \mathcal{C}$, there is a cokernel sequence
$$\mathrm{Mor}(X, T) \to \mathrm{Mor}(X_0, T) \rightrightarrows \mathrm{Mor}(X_1, T)$$
is exact.

Representable Functors

Def. (3.1.1.26) [Presheaves]. A **presheaf** on a category $\mathcal{C}$ is defined to be a contravariant functor from $\mathcal{C}$ to $\mathcal{S}\mathrm{et}$. The category of presheaves on $\mathcal{C}$ is denoted by $\mathcal{PS}\mathrm{h}(\mathcal{C})$.

Prop. (3.1.1.27) [Representability Criterion]. Let $\mathcal{C}$ be a complete category, $F : \mathcal{C} \to \mathcal{S}\mathrm{et}$ be a functor. Assume that F commutes with small limits, and the category $\mathcal{I}$ of pairs (x, f) where $x \in \mathcal{C}, f \in F(x)$ has a cofinal family of objects indexed by a set I, then F is representable, i.e. there is an object x that $F(y) = \mathrm{Mor}_{\mathcal{C}}(x, y)$, functorial in y.

Proof: Because $\mathcal{C}$ has small limits, let $\mathcal{I}'$ be the full subcategory of $\mathcal{I}$ generated by (x_i, f_i), set $x = \varprojlim_{(x_i,f_i)\in\mathcal{I}'} x_i$. As F commutes with limits, $F(x) = \varprojlim_{(x_i,f_i)\in\mathcal{I}} F(x_i)$. Hence there is a universal element $f \in F(x)$ that maps to f_i under $F(x \to x_i)$. f induces a natural transformation $\xi : \mathrm{Mor}_{\mathcal{C}}(x, -) \to F(-)$.

The assumption shows ξ is surjective. Now let $x' \to x$ be the equalizer of all maps $\varphi : x \to x$ that $F(\varphi)f = f$, then there is a $f' \in F(x')$ mapping to f. then the transformation ξ' defined by f' is also surjective. Now we also want to show it is injective: if $a, b \in \mathrm{Mor}_{\mathcal{C}}(x', y)$ mapsto the same element, then we consider the equalizer $e' : x'' \to x'$ of a, b, then the assumption and the fact F commutes with equalizer shows there is a $f'' \in F(x'')$ mapping to f'.

By universality consider a morphism $\psi : x \to x''$ that $F(\psi)f = f''$, then $e \circ e' \circ \psi$ is a morphism $x \to x$ that fixes f, thus by construction $ee'\psi e = e$, so $e'\psi e = \mathrm{id}$, because e is a monomorphism. Then e' is an epimorphism, thus $a = b$. □

Adjunctions

Def. (3.1.1.28) [Adjunction Pairs]. A pair of functors (f, g) where $f : \mathcal{C} \to \mathcal{D}, g : \mathcal{D} \to \mathcal{C} \in \mathcal{C}\mathrm{at}$ are called an **adjunction pair** iff there is natural isomorphism of functors:
$$\mathcal{C}^{\mathrm{op}} \times \mathcal{D} \to \mathcal{S}\mathrm{et} : \mathrm{Hom}(f(-), -) \cong \mathrm{Hom}(-, g(-)).$$
Equivalently this means that for any $X_1 \to X_2 \in \mathcal{C}, Y_1 \to Y_2 \in \mathcal{D}$,
$$\begin{array}{ccc} f(X_1) & \longrightarrow & Y_1 \\ \downarrow & & \downarrow \\ f(X_2) & \longrightarrow & Y_2 \end{array}$$
is commutative iff its corresponding map
$$\begin{array}{ccc} X_1 & \longrightarrow & g(Y_1) \\ \downarrow & & \downarrow \\ X_2 & \longrightarrow & g(Y_2) \end{array}$$

is commutative.

Denoted an adjunction pair by $(f,g):\mathcal{C}\rightleftarrows\mathcal{D}$.

Prop. (3.1.1.29) [Units and Counits]. If f,g are adjoints, then there are natural transformations $u:\mathrm{id}\to gf$, and $v:fg\to\mathrm{id}$, called the **unit/counit maps**. They satisfies $f\xrightarrow{u}fgf\xrightarrow{v}f$ is id, and $g\xrightarrow{u}gfg\xrightarrow{v}f$ is id.

Conversely, if there are natural morphisms u,v satisfying these two identities, then (f,g) is an adjuntion, by

$$\mathrm{Hom}(fX,Y)\to\mathrm{Hom}(gfX,gY)\to\mathrm{Hom}(X,gY)\to\mathrm{Hom}(fX,fgY)\to\mathrm{Hom}(fX,Y).$$

Proof: □

Lemma (3.1.1.30). Let (f,g) be an adjunction pair, then

- If $g\circ f$ is fully faithful, then f is fully faithful.
- If $f\circ g$ is fully faithful, then g is fully faithful.

Proof: Cf.[Sta]0FWV. □

Prop. (3.1.1.31). Let (f,g) be an adjunction pair, then

- f is fully faithful iff $u:\mathrm{id}\to gf$ is an isomorphism.
- g is fully faithful iff $v:fg\to\mathrm{id}$ is an isomorphism.

Proof: 1: If $\mathrm{id}\cong gf$, then gf is fully faithful, so f is fully faithful by(3.1.1.30). If f is fully faithful, then for any X,Y,

$$\mathrm{Hom}(X,Y)\xrightarrow{u}H(X,gfY)\cong H(fX,fY)\cong H(X,Y)$$

is a canonical isomorphism, so u is an isomorphism.

2 is dual to 1. □

Cor. (3.1.1.32) [Units and Equivalences]. Let (F,G) be an adjunction pair, then the following are equivalent:

- F,G are both fully faithful.
- the unit and counit are both isomorphisms.
- F,G defines an equivalence of categories.

Proof: $1\to2\to3$ follow from(3.1.1.31). And $3\to1$ is clear. □

Prop. (3.1.1.33) [Adjunction Preserves (Co)Limits]. A right adjoint functor is left exact and it preserves injectives if its left adjoint is exact.

A left adjoint functor is right exact and it preserves projectives if its right adjoint is exact.

Prop. (3.1.1.34) [Adjoint Functor Theorem]. Let $G:\mathcal{C}\to\mathcal{D}\in\mathcal{C}at$, assume $\mathcal{C}$ is complete and G commutes with small limits. Assume for every $y\in\mathcal{D}$, the category of pairs (x,f) where $x\in\mathcal{C}$ and $f\in\mathrm{Mor}_{\mathcal{D}}(y,G(x))$ has a cofinal family of objects indexed by a set I, then G has a left adjoint.

Similarly the dual statement holds.

Proof: The assumption shows that for any $y\in\mathcal{D}$, the functor $x\mapsto\mathrm{Mor}_{\mathcal{D}}(y,G(x))$ satisfies the condition of(3.1.1.27), thus it is representable by an object denoted by $F(y)$. By Yoneda lemma, F underlies a functor, and this functor is a left adjoint of G. □

Prop. (3.1.1.35) [Groupoidification]. There is a functor $\mathcal{G}\mathrm{rpd} : \mathcal{C}\mathrm{at} \to \mathcal{G}\mathrm{rpd}$ that is left adjoint to the inclusion functor, called the **groupoidification functor**.

Proof: □

Prop. (3.1.1.36) [Examples of Adjunction pairs].

- The valuation at k-th coordinate is left adjoint to the functor $k_*(A)(i) = \prod_{\mathrm{Hom}\, i,k} A$ and is exact. So k_* preserves injectives.
- The sheaf Γ functor is right adjoint to the constant sheaf functor over arbitrary site.
- The inclusion functor is right adjoint to the shifification functor over arbitrary site.
- The forgetful functor is right adjoint to the Shifification functor, and shifification is exact, so it preserves injectives.
- The stalk functor is left adjoint to the skyscraper sheaf operator.

Limits and Colimits

Prop. (3.1.1.37) [Products and Equalizers Implies Limits]. If a category admits arbitrary(resp. finite) products and equalizers, then it admits arbitrary(resp. finite) limits. Dually a category that admits coproducts and coequalizers admits all colimits.

Proof: The limits over a category $\mathcal{C}$ is an equalizer of products over the category of arrows in $\mathcal{C}$. □

Def. (3.1.1.38) [Exact Functors]. A functor $F : \mathcal{C} \to \mathcal{D}$ is called a **left exact functor** if it maps finite limits to finite limits. It is called a **right exact functor** if it maps finite colimits to finite colimits. It is called an **exact functor** if it is both left exact and right exact.

Def. (3.1.1.39) [(Co)Complete Category]. A category is called **(co)complete** if it has all small (co)limits, i.e. (co)limits over small categories(3.1.2.1).

Def. (3.1.1.40) [Inverse Systems]. An **inverse system** in $\mathcal{C}$ is a diagram $\mathbb{Z}_+^{\mathrm{op}} \to \mathcal{C}$, where $\mathbb{Z}_+$ is the category of non-negative integers with a unique morphism $n \to m$ iff $n \leq m$.

Prop. (3.1.1.41)[Equivalent Inverse System]. Two inverse systems $\{A_n\}, \{B_n\}$ are called equivalent if there are two non-decreasing unbounded maps $\alpha, \beta : \mathbb{Z}_+ \to \mathbb{Z}_+$ and maps $\alpha : A_n \to B_{\alpha(n)}, \beta : B_n \to A_{\beta(n)}$ that is compatible with the transition maps and for any n, there is a m large that $A_m \to A_{\beta\alpha(m)} \to A_n$ coincide with the transition map $A_m \to A_n$, and similar for B_n. And similarly for colimits.

The limit for two inverse systems are the same, and similarly for colimits.

Prop. (3.1.1.42) [Filtered Colimit of Sets]. ?

Prop. (3.1.1.43) [Cofiltered Limits of Sets]. A cofiltered limit of nonempty sets is nonempty.

Proof: Cf.[Sta]086J. □

Def. (3.1.1.44) [Mittag-Leffler]. If (A_i, φ_{ji}) is a directed inverse system of sets over I, then it is said to satisfy the **Mittag-Leffler condition** if $\varphi_{ji}(A_j) \in A_i$ stabilizes. This is clearly true if φ_{ji} is surjective for any i, j.

Prop. (3.1.1.45). If (A_n) where $n \in \mathbb{Z}$ is a Mittag-Leffler inverse system of nonempty sets, then $\lim A_i$ is also nonempty.

Proof: Let $A'_j = \cap_{j\geq i}\varphi_{ji}A_j$, then (A'_j) is a filtered system that the transition maps are all surjective, and clearly $\lim A_j = \lim A'_j$, so it is nonempty by(3.1.1.43). □

Prop. (3.1.1.46). $\mathfrak{Cat}$ is complete and cocomplete.

Proof: □

Fiber Product

Prop. (3.1.1.47). For a category C, the following are equivalent:

- It has arbitrary limits.
- it has arbitrary products and equalizer.
- it has arbitrary products and fibered products.

Proof: $1\to 2, 1\to 3$ is trivial. $3\to 2$: The equalizer for $f,g: X\to Y$ can be constructed as the base change of $Y\to Y\otimes Y$ along $(f,g): X\to Y\times Y$. $2\to 1$: for any diagram $F: I\to C$, the fibered pullback can be constructed as the equalizer of two morphisms:

$$s,t: \prod_{i\in \mathrm{Ob}(I)} F(i)\to \prod_{f:j\to k\in \mathrm{Mor}(I)} F(k)$$

where $\pi_{(f:j\to k)}s = \pi_k$, and $\pi_{(f:j\to k)}t = (Ff)\pi_j$. □

Prop. (3.1.1.48) [Diagonal Base Change]. The diagonal commutes with base change:

$$\begin{array}{ccc} X\times_Y Z & \xrightarrow{\Delta} & (X\times_Y Z)\times_Z (X\times_Y Z) \\ \downarrow & & \downarrow \\ X & \xrightarrow{\Delta} & X\times_Y X \end{array}$$

Proof: □

Prop. (3.1.1.49). $(X\times_E Y)\times_S (Z\times_F W) = (X\times_S Z)\times_{E\times_S F}(Y\times_S W)$.

Proof: □

Prop. (3.1.1.50). For $f: X\to T$ and $g: Y\to T$ and $h: T\to S$, $X\times_T Y = T\times_{T\times_S T}(X\times_S Y)$. In particular, $X\times_T Y\to X\times_S Y$ is a base change of $T\to T\times_S T$.

Proof: For any object U,

$$\mathrm{Hom}(U, X\times_T Y) = \{s: U\to X, t: U\to Y | f\circ s = g\circ t\},$$

$$\mathrm{Hom}(U, T\times_{T\times_S T}(X\times_S Y)) = \{r: U\to T, s: U\to X, t: U\to Y | h\circ f\circ s = h\circ g\circ t, r = g\circ t, r = f\circ s\},$$

so they are functorially isomorphic. Then by Yoneda lemma we have the desired isomorphism. □

Prop. (3.1.1.51). The diagonal map $X\to X\times_Y X$ is an isomorphism iff $X\to Y$ is monomorphism. (Because this is equivalent to $\mathrm{pr}_1 = \mathrm{pr}_2$).

Def. (3.1.1.52) [Mapping graph]. Let $f: X\to Y$ be a morphism in a category with fiber products and finite products, then the **mapping graph** Γ_f of f is defined to be the pullback

$$\begin{array}{ccc} \Gamma_f & \longrightarrow & X\times Y \\ \downarrow & & \downarrow \\ Y & \xrightarrow{\Delta} & Y\times Y \end{array}.$$

it can be seen that Γ_f is isomorphic to X.

Localizations

Def. (3.1.1.53) [Localizing Categories]. Let $\mathcal{C} \in \mathcal{C}at$ and S be a class of morphisms in $\mathcal{C}$, then a functor $F : \mathcal{C} \to \mathcal{D}$ is called a **localizing category** of $\mathcal{C}$ w.r.t S if it maps morphisms in S to isomorphisms, and any other functor with this property factors uniquely through F.

Def. (3.1.1.54) [Localizing Systems]. A class of morphisms S in a category is called a left(resp. right) **localizing system** if:

(LS1): S is closed under composition and contains all the identities.

(LS2): for every $s \in S$ and f with the same source(resp. target), there is a $t \in S$ and a g, s.t. $t \circ f = g \circ s$(resp. $f \circ t = s \circ g$).

(LS3): the existence of a $t \in S$ s.t. $ft = gt$ implies(resp. is implied by) the existence of a $s \in S$ s.t. $sf = sg$.

It is called **localizing system** if it is both left localizing and right localizing.

Def. (3.1.1.55) [Saturated Localizing Systems]. Let S be a localizing system, then it is called a **saturated localizing system** is moreover it satisfies

- if $f, g, h \in S$ and $fg, gh \in S$, then $g \in S$.

Def. (3.1.1.56) [Gabriel-Zisman Localization]. Cf.[Sta]04VD.

Cor. (3.1.1.57). If $\mathcal{C}$ is a category and S is a left localizing system, then the rule $X \mapsto X, (f : X \to Y) \mapsto \mathrm{id}^{-1} f$ is a functor $Q : \mathcal{C} \to S^{-1}\mathcal{C}$ that represents $S^{-1}\mathcal{C}$ as a localizing category of $\mathcal{C}$ w.r.t S(3.1.1.53). And Q preserves finite colimits.

The dual is true for a right localizing system S.

Proof: Cf.[Sta]04VG, [Sta]05Q2. □

Cor. (3.1.1.58). If $\mathcal{C}$ is a category and S is a localizing system, then the left localizing category and the right localizing category is canonically isomorphic, by the universal property(3.1.1.53).

Prop. (3.1.1.59) [Saturation]. If S is a localizing system in a category $\mathcal{C}$, then the morphisms in $\mathcal{C}$ that is mapped to an isomorphism in $S^{-1}\mathcal{C}$ is the smallest saturated localizing system containing S, called the **saturation of** S.

Proof: Cf.[Sta]05Q9. □

Prop. (3.1.1.60) [Full Subcategories of Localized Categories]. If S is a left localizing system in a category $\mathcal{C}$, $\mathcal{C}'$ is a full subcategory of $\mathcal{C}$ and S' is a left localizing system of $\mathcal{C}'$ that $S' \subset S$. If for any $s : X \to Y \in S$ and $X \in \mathcal{C}'$, there is a morphism $t : Y \to Z$ that $Z \in \mathcal{C}'$ and $t \circ s \in S'$, then the natural functor $(S')^{-1}\mathcal{C}' \to S^{-1}\mathcal{C}$ is fully faithful. And the dual is true for right localizing systems.

Proof: This is not hard from the Gabriel-Zisman localization description(3.1.1.56). □

Def. (3.1.1.61) [Reflective Localizations]. A **reflective localization** is an adjunction $(L, R) : \mathcal{C} \rightleftarrows \mathcal{D}$ s.t. R is fully faithful.

Prop. (3.1.1.62) [Reflective Localizations as Localizations]. Let $(L, R) : \mathcal{C} \rightleftarrows \mathcal{D}$ be a reflective localization(3.1.1.61), then $\mathcal{D}$ is equivalent to the localization $\mathcal{C}[S^{-1}]$, where S is the class of morphisms of $\mathcal{C}$ that are sent to isomorphisms by L

Proof: Cf.[Bor94]P190. □

Def. (3.1.1.63) [S-Local Equivalences]. Let $\mathcal{C} \in \mathcal{C}\mathrm{at}$ and S a class of morphisms in $\mathcal{C}$.

- $c \in \mathcal{C}$ is called **S-local** if $\mathrm{Hom}(c_2, c) \to \mathrm{Hom}(c_1, c)$ is a bijection for any $c_1 \to c_2 \in S$.
- $f : c_1 \to c_2 \in \mathcal{C}$ is called an **S-local equivalence** if for any S-local object $c \in \mathcal{C}$, $\mathrm{Hom}(c_2, c) \to \mathrm{Hom}(c_1, c)$ is a bijection.

Prop. (3.1.1.64). Let $(L, R) : \mathcal{C} \rightleftarrows \mathcal{D}$ is a reflective localization, and let S be the class of morphisms in $\mathcal{C}$ that is mapped sent to isomorphisms by L, then

- The essential image of R consists precisely of S-local objects.
- The S-local

Group Objects

Def. (3.1.1.65) [Group Object]. In a category C with finite products and a final object e, a(n) **(Abelian)group object** is an object G that h_G is a functor from C to $\mathcal{G}\mathrm{rp}$(resp. $\mathcal{A}\mathrm{b}$). And a homomorphism of group objects is a natural transformation as a functor from C to $\mathcal{G}\mathrm{rp}$.

This is in fact equivalent to a morphism $m_G : G \times G \to G$ and $i_G : G \to G$, $e_G : e \to G$ that satisfy the desired commuting diagrams.

Def. (3.1.1.66) [Group Action]. A **(left)action** of a group object G on an object X is a map of presheaves $h_G \times h_X \to h_X$ that for any U, $h_G(U) \times h_X(U) \to h_X(U)$ is a group action. This is equivalent to a morphism $\mu : G \times X \to X$ that satisfies the desired commuting diagrams.

Prop. (3.1.1.67). Let $\mu : G \times X \to X$ be an action of a group object G on an object X, there is a commutative diagram

$$\begin{array}{ccc} G \times X & \xrightarrow{(g,x)\mapsto(g,gx)} & G \times X \\ \downarrow{\scriptstyle (g,x)\mapsto gx} & & \downarrow{\scriptstyle \pi_2} \\ X & \xrightarrow{\quad id \quad} & X \end{array}$$

and the horizontal maps are isomorphisms.

Cor. (3.1.1.68). Considering the action of G on itself, we get

$$\begin{array}{ccc} G \times G & \xrightarrow{(g,h)\mapsto(g,gh)} & G \times G \\ \downarrow{\scriptstyle m} & & \downarrow{\scriptstyle \pi_2} \\ G & \xrightarrow{\quad id \quad} & G \end{array}$$

and the horizontal maps are isomorphisms.

Prop. (3.1.1.69). A unital magma object G in the category of groups is an Abelian group.

Proof: A unital magma object structure endows G with maps $(\widetilde{m}, \widetilde{e})$, and $\widetilde{m}(ab, cd) = \widetilde{m}(a, c)\widetilde{m}(b, d)$, because $\widetilde{m}$ is a morphism of groups. So we can use Eckmann-Hilton argument2 to show the category multiplication is the same as the group multiplication. So the commutativity of $\widetilde{m}$ with the inverse i implies that it is Abelian. $\square$

Prop. (3.1.1.70). A right-lax monoidal functor(3.1.5.11) between Cartesian monoidal structures maps a unital magma object to a unital magma object.

Def. (3.1.1.71) [Categorical Quotient]. Let C be a category with finite products, G be a group object in C, $G\times X\to X$ is a left action(3.1.1.66), then a morphism $X\to Y$ is called the **categorical quotient** of X iff Y is the coequalizer of $G\times X \overset{\rho}{\underset{pr_2}{\rightrightarrows}} X$. It is called the **universal categorical quotient** of X iff its product with S is the categorical quotient for each element $S\in C$, in the category $C_{/S}$.

2 Presentable Categories

Main references are [Locally presentable and accessible categories].

Def. (3.1.2.1) [Small Categories]. Given a regular cardinal κ(1.2.12.2), $S\in \mathcal{S}\mathrm{et}$ is called **κ-small** if it has cardinality smaller than κ. $\mathcal{C}\in\mathcal{C}\mathrm{at}$ is called **κ-small** if $\mathrm{Ob}(\mathcal{C})$ is κ-small, and the set of all morphisms of $\mathcal{C}$ is κ-small.

Through out the whole book, we will fix a strongly inaccessible cardinal κ and call a set or category **small** if it is κ-small. And a category is called **essentially small** if it is equivalent to a small category.

Prop. (3.1.2.2). Any small cocomplete category is a poset.

Proof: [MacLane]P114. □

Def. (3.1.2.3) [Compact Objects]. For a regular cardinal κ. Let $\mathcal{C}\in\mathcal{C}\mathrm{at}$ be a category that admits small colimits, and J be a κ-filtered poset and a diagram $\{Y_\alpha\}$ indexed by J, then for $X\in\mathcal{C}$, there is a natural map

$$\varinjlim \mathrm{Hom}(X,Y_j)\to \mathrm{Hom}(X,\varinjlim Y_j).$$

X is called **κ-compact** if this is an isomorphism for any κ-filtered diagram J. X is called **small** if it is κ-compact for some small(3.1.2.1) regular cardinal κ.

Def. (3.1.2.4) [κ-Accessible Categories]. For a regular cardinal κ, a **κ-accessible category** is a locally small category(3.1.2.1) $n\,\mathcal{C}\mathrm{at}$ that satisfies:

- $\mathcal{C}$ admits all κ-filtered colimits.
- $\mathcal{C}$ is generated by a κ-small set S consisting of κ-compact objects of $\mathcal{C}$ under κ-filtered colimits.

$\mathcal{C}$ is called **accessible** if it is κ-accessible for some small regular cardinal κ. A **κ-accessible functor** is a functor $F:\mathcal{C}\to\mathcal{D}$ between κ-cocomplete categories that preserves κ-filtered colimits. And a functor is called a **accessible functor** if it is κ-accessible for some small regular cardinal κ.

Def. (3.1.2.5) [Locally Presentable Categories]. A **locally presentable category** is a category that is both cocomplete and accessible(3.1.2.4).

Prop. (3.1.2.6). Any locally presentable category is complete.

Proof:

□

Example (3.1.2.7) [Locally Presentable Categories].

- $\mathcal{S}\mathrm{et}$ is locally presentable.

- If $\mathcal{C}$ is a small category, then $\mathcal{PSh}^{\mathcal{Set}}(\mathcal{C})$ is locally presentable.
- For $R \in \mathcal{CRing}$, $\mathcal{Mod}_R$ and $\mathrm{Ch}(R)$ are locally presentable.
- If $T : \mathcal{C} \to \mathcal{C}$ is an accessible monad on a locally presentable category, then the category of T-algebras is locally presentable.
- Every Grothendieck topos is locally presentable.
- If $\mathcal{M}$ is a locally presentable symmetric monoidal category, then $\mathcal{Cat}_{\mathcal{M}}$ is locally presentable.
- $\mathcal{Top}$ is not locally presentable, but $\mathcal{CG}$ is locally presentable.

Proof: □

Cor. (3.1.2.8). $\mathcal{Cat}$ is locally presentable.

Prop. (3.1.2.9)[Adjoint Functor Theorem]. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between locally presentable categories, then

- F is a left adjoint iff it preserves small colimits.
- F is a right adjoint iff it is accessible and preserves small limits.

Proof: □

Def. (3.1.2.10) [Accessible Reflective Localizations]. An **accessible reflective localization** is a reflective localization(3.1.1.61) $(L, R) : \mathcal{C} \rightleftarrows \mathcal{D}$ s.t. R is accessible(3.1.2.4).

Prop. (3.1.2.11) [Classifying Locally Presentable Categories]. A category is locally presentable iff it is equivalent to an accessible reflective localization(3.1.2.10) of $\mathcal{PSh}^{\mathcal{Set}}(\mathcal{A})$ for some small category A.

Proof: Cf.[Locally presentable and accessible categories]. □

3 Ends and Coends

Def. (3.1.3.1) [Dinatural Transformation]. Given categories $\mathcal{C}, \mathcal{D}$ and functor $P, Q : \mathcal{C}^{\mathrm{op}} \times \mathcal{C} \to \mathcal{D}$, then a **dinatural transformation** $\alpha : P \to Q$ is a family of arrows $\alpha_C : P(C, C) \to Q(C, C)$ where $C \in \mathcal{C}$ that for any arrow $C \to C' \in \mathcal{C}$, there is a commutative diagram

$$\begin{array}{ccccc} P(C',C) & \longrightarrow & P(C,C) & \xrightarrow{\alpha_C} & Q(C,C) \\ \downarrow & & & & \downarrow \\ P(C',C') & \xrightarrow{\alpha_{C'}} & Q(C',C') & \longrightarrow & Q(C,C') \end{array}$$

Def. (3.1.3.2) [Wedge and Cowedge]. Let $P : \mathcal{C}^{\mathrm{op}} \times \mathcal{C} \to \mathcal{D}$ be a functor, then a **wedge** for P is a binatural functor $\Delta_D \to P$, where D is an object of $\mathcal{C}$. Similarly a **cowedge** is a binatural functor $P \to \Delta_D$.

Def. (3.1.3.3) [End and Coend]. For a functor $P : \mathcal{C}^{\mathrm{op}} \times \mathcal{C} \to \mathcal{D}$, the wedges and cowedges of P form categories, and we define **end** of P is just a terminal wedge, denoted by $\int_C F(C, C)$, and the **coend** of P is the initial cowedge, denoted by $\int^C F(C, C)$.

Ends and coends are functorial w.r.t natural transformations.

Prop. (3.1.3.4) [Ends as Colimits]. There is a morphism

$$F \mapsto \overline{F} : \mathrm{Fun}(\mathcal{C}^{\mathrm{op}} \times \mathcal{C}, \mathcal{D}) \to \mathrm{Fun}(Tw(\mathcal{C}), \mathcal{D})(3.1.1.19)$$

where we maps $f : C \to C'$ to $F(C, C')$. Then it can be checked that

$$\int_C F(C,C) = \lim_{Tw(\mathcal{C})} \overline{F}, \quad \int^C F(C,C) = \mathrm{colim}_{TW(\mathcal{C})} \overline{F}.$$

Cor. (3.1.3.5). A functor that preserves (co)limits preserves (co)ends.

Cor. (3.1.3.6). For an object $D \in \mathcal{D}$, we have isomorphisms:

$$\mathrm{Hom}(\int^C F(C,C), D) \cong \int_C \mathrm{Hom}(F(C,C), D),$$

$$\mathrm{Hom}(D, \int_C F(C,C)) \cong \int_C \mathrm{Hom}(D, F(C,C)).$$

Prop. (3.1.3.7) [Fubini]. Cf.[Coend Calculus, P20].

Prop. (3.1.3.8) [Natural Transformation as Ends]. Let $F, G : \mathcal{C} \to \mathcal{D}$ be functors, then the set of natural transformations is an coend.

$$\mathrm{Map}(F,G) \cong \int_C \mathrm{Hom}_{\mathcal{D}}(FC, GC)$$

Kan Extension

Cf.[All Concepts are Kan Extensions].

Def. (3.1.3.9) [Kan Extensions]. Given functors $F : \mathcal{C} \to \mathcal{E}$ and $K : \mathcal{C} \to \mathcal{D}$, a **left Kan extension** of F along K is a functor $Lan_K F : \mathcal{D} \to \mathcal{E}$ together with a natural transformation $\eta : F \to Lan_K F \circ K$ that for any other pair $(G : \mathcal{D} \to \mathcal{E}, \gamma : F \to G \circ K)$, γ factors uniquely through η.

Dually, a **right Kan extension** of F over K is equivalent to a left Kan extension of F^{op} over K^{op}.

Prop. (3.1.3.10) [(Co)Limits as Kan Extensions]. If $\mathcal{D}$ is the final category 1, then the left Kan extension is just the colimit of the diagram defined by F, and the right Kan extension is just the limit of the diagram defined by F.

Prop. (3.1.3.11) [Yoneda Lemma]. $h_X : Y \mapsto \mathrm{Hom}(Y, X)$ is a presheaf, and $\mathrm{Hom}(h_X, \mathcal{F}) \cong \mathcal{F}(X)$ for any presheaf $\mathcal{F}$.

So $X \to h_X$ is a fully faithful embedding よ $: \mathcal{C} \to \mathcal{PSh}^{\mathrm{Set}}(\mathcal{C})$. In particular, if a $X \to Y$ induces isomorphism $\mathrm{Hom}(W, X) \to \mathrm{Hom}(W, Y)$ for every W, then $X \cong Y$.

So we can regard $\mathcal{C}$ as a fully faithful subcategory of $\mathcal{PSh}^{\mathrm{Set}}(\mathcal{C})$.

Proof: The map $\mathrm{Hom}(h_X, \mathcal{F}) \to \mathcal{F}(X)$ maps a u to $u(X)(\mathrm{id}_X)$. And the inverse map is defined to be $x \in \mathcal{F}(X) \mapsto (s \in \mathrm{Hom}(Y, X) \mapsto s^*(x) \in \mathcal{F}(Y)) \in \mathrm{Hom}(h_X, \mathcal{F})$. □

Cor. (3.1.3.12). A **universal object** for a presheaf $\mathcal{F}$ is a pair (X, ζ) that $\zeta \in F(X)$ with the property that for any U and a $\sigma \in \mathcal{F}(U)$, there is a unique arrow $U \to X$ that $Ff(\zeta) = \sigma$.

In fact, a universal object is equivalent to an isomorphism $h_X \cong \mathcal{F}$.

Prop. (3.1.3.13) [Presheaves as Colimits of Presentable Presheaves]. For $\mathcal{C} \in \mathcal{C}\mathrm{at}$, any presheaf of sets on $\mathcal{C}$ is a colimit of presentable presheaves on $\mathcal{C}$. More precisely, there is an isomorphism

$$\mathcal{F} \cong \varinjlim_{h_X \to \mathcal{F}} h_X.$$

From this we see that any functor $\mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \to \mathcal{D}$ compatible with colimits is determined by its restriction on $\mathcal{C}$.

Proof: For any presheaf $\mathcal{G}$, there is a morphism $\mathrm{Hom}(\mathcal{F}, \mathcal{G}) \to \mathrm{Hom}(\varinjlim_{h_X \to \mathcal{F}} h_X, \mathcal{G})$, i.e. a set of sections $f_s \in \mathcal{G}(X)$ for every $h_X \xrightarrow{s} \mathcal{F}$, that if $t \circ u = s$, then $u^*(f_t) = f_s$. Conversely, by Yoneda lemma, this just says that there is a morphism of presheaves $\mathcal{F} \to \mathcal{G} : F(X) \to G(X) : s \mapsto f_s$. □

Cor. (3.1.3.14) [Yoneda Extensions]. For any $\mathcal{C} \in \mathcal{C}\mathrm{at}$ and a cocomplete category $\mathcal{D}$, then any functor $Q : \mathcal{C} \to \mathcal{D}$ extends to a functor $|\cdot|_Q : \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \to \mathcal{D}$ s.t.

$$\begin{array}{ccc} \mathcal{D} & \xrightarrow{Q} & \mathcal{D} \\ \downarrow よ & \nearrow_{|\cdot|_Q} & \\ \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) & & \end{array}$$

is commutative. Moreover, there is a functor

$$\mathrm{Sing}_Q : \mathcal{C} \to \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) : C \mapsto (X \mapsto \mathrm{Hom}_{\mathcal{D}}(QX, C)).$$

And there is an adjunction

$$|\cdot|_Q : \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \rightleftharpoons \mathcal{D} : \mathrm{Sing}_Q .$$

Moreover, this assignment $Q \mapsto (|\cdot|_Q, \mathrm{Sing}_Q)$ induces an equivalence of categories:

$$\mathrm{Func}(\mathcal{C}, \mathcal{D}) \cong \mathrm{Adj}(\mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}), \mathcal{D}).$$

Proof: Define $|\cdot|_Q$ by colimit as in(3.1.3.13), then? □

Cor. (3.1.3.15). Any contravariant functor $Q : \mathcal{C} \to \mathcal{S}\mathrm{et}$ that take colimits to limits is representable.

Proof: Use Sing_Q as in the last proof, Q is representable by $\mathrm{Sing}_Q(\mathrm{pt})$. □

Def. (3.1.3.16) [$\mathcal{I}$-Free Diagram]. For a cocomplete category $\mathcal{C}$ and a small category $\mathcal{I}$, let $\mathcal{I}^\delta$ be the subcategory of $\mathcal{I}$ that has the same objects but only the identity morphisms, then an $\mathcal{I}$-diagram in $\mathcal{C}$ is called $\mathcal{I}$**-free** iff it is a left Kan extension of some diagram $\mathcal{I}^\delta \to \mathcal{C}$.

4 n-Categories

Remark (3.1.4.1) [2-Categories]. For $n \in \mathbb{N}$, n-categories are defined as in(3.6.1.28).

Prop. (3.1.4.2) [$\mathcal{C}\mathrm{at}$]. There is a 2-category $\mathcal{C}\mathrm{at}$ consisting of small categories and functors and natural transformations.

Def. (3.1.4.3) [(2, 1)-Categories]. A $(2, 1)$**-category** is a 2-category that all the 2-morphisms(corresponding to a 2-simplex) are isomorphisms.

Prop. (3.1.4.4) [Final Objects]. An object in a $(2,1)$-category is a final object(3.6.3.2) iff for any y there is a morphism $y \to x$, and any two morphisms $y \to x$ are isomorphic by a unique 2-morphism.

Lemma (3.1.4.5) [2-Commutative diagrams]. Let $\mathcal{C}$ be a 2-category, and $g : y \to z, f : x \to z$ are arrows in $\mathcal{C}$, then the diagrams in $\mathcal{C}$:

$$\begin{array}{ccc} w & \xrightarrow{a} & x \\ \downarrow{\scriptstyle b} & & \downarrow{\scriptstyle f} \\ y & \xrightarrow{g} & z \end{array}$$

together with a 2-morphism from gb to fa, naturally form a 2-category. A diagrams with invertible 2-morphisms are called **2-commutative digram** in $\mathcal{C}$.

Def. (3.1.4.6) [2-Fibered Products]. Let $\mathcal{C}$ be a 2-category, and $g : y \to z, f : x \to z$ are arrows in $\mathcal{C}$, a **2-fibered product** of f, g is a final object in the $(2,1)$-category of 2-commutative diagrams as defined in(3.1.4.5), and it is denoted by $x \times_z y$.

5 Monoidal Categories

Main references are [Tensor Categories, Etingof], [Lur09].

Def. (3.1.5.1) [Monoidal Categories]. A **monoidal category** is a category $\mathcal{C}$ with a functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ and a unit object 1 together with isomorphisms

$$\eta_{A,B,C} : (A \otimes B) \otimes C \to A \otimes (B \otimes C), \quad \alpha_A : A \otimes \mathbb{1} \to A, \quad \beta_A : \mathbb{1} \otimes A \to A$$

s.t.

- $\eta_{A,B,C}, \alpha_A, \beta_B$ are functorial in each coordinate.
- (MacLane Pentagon)The following diagram is commutative:

$$\begin{array}{ccccc} & & ((A\otimes B)\otimes C)\otimes D & & \\ & \swarrow{\scriptstyle \eta_{A,B,C}\otimes \mathrm{id}_D} & & \searrow{\scriptstyle \eta_{A\otimes B,C,D}} & \\ (A\otimes(B\otimes C))\otimes D & & & & (A\otimes B)\otimes(C\otimes D) \\ \downarrow{\scriptstyle \eta_{A,B\otimes C,D}} & & & & \downarrow{\scriptstyle \eta_{A,B,C\otimes D}} \\ A\otimes((B\otimes C)\otimes D) & & \xrightarrow{\mathrm{id}_A\otimes \eta_{B,C,D}} & & A\otimes(B\otimes(C\otimes D)) \end{array}$$

- The following diagram is commutative:

$$\begin{array}{ccc} (A\otimes \mathbb{1})\otimes B & \xrightarrow{\eta_{A,\mathbb{1},B}} & A\otimes(\mathbb{1}\otimes B) \\ & {\scriptstyle \alpha_A\otimes \mathrm{id}_B}\searrow \quad \swarrow{\scriptstyle \mathrm{id}_A\otimes \beta_B} & \\ & A\otimes B & \end{array}$$

Def. (3.1.5.2) [Dual and Opposed Category]. Let $\mathcal{C}$ be a monoidal category, then the **opposed category** $\mathcal{C}^{opp}$ is the same category as $\mathcal{C}$ with the tensoring switched, which is also a monoidal category.

The dual category $\mathcal{C}^{\mathrm{op}}$ with the same tensoring is also a monoidal category.

Def. (3.1.5.3) [Strict Monoidal Categories]. A **strict monoidal category** is a monoidal category that the isomorphisms above(3.1.5.1) are all identities.

Prop. (3.1.5.4) [Mac Lane Coherence]. In a monoidal category, any two morphisms between two bracketings of a product $X_1 \otimes \ldots X_n$ constructed using the isomorphisms $\eta_{A,B,C}$ are equal. Also if some X_i are 1, then we can also use α_A and β_A.

Prop. (3.1.5.5) [Cartesian Monoidal Categories]. For a category with a final object and finite products, the product makes $\mathcal{C}$ a symmetric monoidal category, called the **Cartesian monoidal structure**.

Prop. (3.1.5.6). For any category $\mathcal{C}$, the category $[\mathcal{C},\mathcal{C}]$ of endofunctors has a natural monoidal structure.

Def. (3.1.5.7) [Closedness]. A monoidal category $(\mathcal{C},\otimes)$ is called **left-closed** if for every $A \in \mathcal{C}$, the functor $N \mapsto A \otimes N$ has a right adjoint $Y \mapsto {}^{A}Y$(or denoted by $\mathcal{H}om(A,Y)$ when $\mathcal{C}$ is symmetric). Dually it is called **right-closed** if $\mathcal{C}^{opp}$ is left-closed. It is called **closed** if it is both left-closed and right-closed.

For a Cartesian monoidal category $\mathcal{C}$, $\mathcal{C}$ is called **Cartesian-closed** if it is closed for the Cartesian monoidal structure.

Prop. (3.1.5.8). $\mathcal{C}at$ is Cartesian closed, and for any $\mathcal{A},\mathcal{B},\mathcal{C} \in \mathcal{C}at$, there is an equivalence of categories

$$\mathrm{Func}(\mathcal{A},\mathrm{Func}(\mathcal{B},\mathcal{C})) \cong \mathrm{Func}(\mathcal{A}\times\mathcal{B},\mathcal{C}).$$

Proof: □

Def. (3.1.5.9) [Reflexive Objects]. Let $(\mathcal{C},\otimes)$ be a symmetric monoidal category that is closed, then we denote $\mathcal{H}om(Y,1)$ by $Y^\vee$, then there is a natural map $Y \to (Y^\vee)^\vee$. If such a map is reflexive, then Y is called a **reflexive object**.

Prop. (3.1.5.10). If $\mathcal{C}$ is closed, then

$$ {}^{\varinjlim A_i}B \cong \varprojlim({}^{A_i}B) \quad {}^{A}(\varprojlim B_i) \cong \varprojlim({}^{A}B_i)$$

Proof: Because $\mathcal{C}$ is closed, left and right tensor $A\otimes -$ and $-\otimes A$ are both left adjoints thus commutes with colimits. Now $B \mapsto {}^{A}B$ is a right adjoint, thus it commutes with limits. And for any $C \in \mathcal{C}$,

$$\begin{aligned}\mathrm{Hom}(C, {}^{\varinjlim A_i}B) &\cong \mathrm{Hom}(C\otimes(\varinjlim A_i),B) \cong \mathrm{Hom}(\varinjlim C\otimes A_i,B)\\ &\cong \varprojlim \mathrm{Hom}(C\otimes A_i,B) \cong \varprojlim \mathrm{Hom}(C,{}^{A_i}B) \cong \mathrm{Hom}(C,\varprojlim({}^{A_i}B))\end{aligned}$$

so ${}^{\varinjlim A_i}B \cong \varprojlim({}^{A_i}B)$ by Yoneda lemma. □

Def. (3.1.5.11) [Monoidal Functor]. Let $(\mathcal{C},\otimes),(\mathcal{D},\otimes)$ be monoidal categories, then a **right-lax monoidal functor** from $\mathcal{C}$ to $\mathcal{D}$ is a functor G together with morphisms $\gamma_{A,B}: G(A)\otimes G(B) \to G(A\otimes B)$ for any $A,B\in\mathcal{C}$ and a morphism $e: \mathbb{1}_{\mathcal{D}} \to G(\mathbb{1}_{\mathcal{C}})$ s.t.

- $\gamma_{A,B}$ is functorial in each coordinate.
- (Hexagon Diagram)The following diagram is commutative:

$$\begin{array}{ccc}
(G(A)\otimes G(B))\otimes G(C) & \xrightarrow{\eta_{G(A),G(B),G(C)}} & G(A)\otimes(G(B)\otimes G(C))\\
\downarrow{\scriptstyle\gamma_{A,B}} & & \downarrow{\scriptstyle\gamma_{B,C}}\\
G(A\otimes B)\otimes G(C) & & G(A)\otimes G(B\otimes C)\\
\downarrow{\scriptstyle\gamma_{A\otimes B,C}} & & \downarrow{\scriptstyle\gamma_{A,B\otimes C}}\\
G((A\otimes B)\otimes C) & \xrightarrow{G(\eta_{A,B,C})} & G(A\otimes(B\otimes C))
\end{array}$$

- The following diagrams are commutative:

$$\begin{array}{ccccc} G(A)\otimes \mathbb{1}_{\mathcal{D}} & \xrightarrow{\mathrm{id}_{G(A)}\otimes e} & G(A)\otimes G(\mathrm{id}_{\mathcal{C}}) & \xrightarrow{\gamma_{A,\mathbb{1}_{\mathcal{C}}}} & G(A\otimes \mathbb{1}_{\mathcal{C}}) \\ & \searrow^{\alpha_{G(A)}} & & \swarrow_{G(\alpha_A)} & \\ & & G(A) & & \end{array}$$

$$\begin{array}{ccccc} \mathbb{1}_{\mathcal{D}}\otimes G(B) & \xrightarrow{e\otimes\mathrm{id}_{G(B)}} & G(\mathrm{id}_{\mathcal{C}})\otimes G(B) & \xrightarrow{\gamma_{\mathbb{1}_{\mathcal{C}},B}} & G(B\otimes \mathbb{1}_{\mathcal{C}}) \\ & \searrow^{\alpha_{G(B)}} & & \swarrow_{G(\beta_B)} & \\ & & G(B) & & \end{array}$$

Moreover, it is called a **monoidal functor** if $\gamma_{A,B}$ and e are all isomorphisms.

A **monoidal natural transformation** between right-lax monoidal functors is a natural transformation that commutes with the maps $\gamma_{A,B}$ and e.

Def. (3.1.5.12) [Equivalence of Monoidal Categories]. An equivalence of monoidal categories is a map that is an equivalence of categories as well as a monoidal functor.

Prop. (3.1.5.13) [Mac Lane Strictness]. Any monoidal category is equivalent to a strict monoidal category.

Proof: □

Prop. (3.1.5.14) [Examples]. For a monoidal category $(\mathcal{C},\otimes)$, the functor $X\mapsto \mathrm{Hom}(\mathbb{1},X)$ is a right-lax monoidal functor from $\mathcal{C}\to\mathcal{S}\mathrm{et}$(3.1.5.5).

The morphism $\pi_0: A\mapsto \pi_0(A)$ is a monoidal functor from the category of topological spaces $\mathcal{T}\mathrm{op}$ to the category $\mathcal{S}\mathrm{et}$ because it commutes with products.

Proof: □

Symmetric Monoidal Categories

Def. (3.1.5.15) [Symmetric Monoidal Category]. A **symmetric monoidal category** is a monoidal category $(\mathcal{C},\otimes)$ together with a natural transformation ψ between $\otimes$ and $\otimes\circ\iota:\mathcal{C}\times\mathcal{C}\to\mathcal{C}$ that $\psi^2=\mathrm{id}$ and the following commutative hexagon diagram is commutative:

A **symmetric monoidal functor** between symmetric monoidal categories are required to commutes with the braiding?.

Rigid Monoidal Categories

Def. (3.1.5.16) [Duals]. Let $\mathcal{C}$ be a monoidal category and $V\in\mathcal{C}$, a **left dual** of V is an element V^* together with maps

$$\mathrm{ev}_V: V^*\otimes V\to 1,\quad coev_V: 1\mapsto V\otimes V^*$$

that satisfies

$$V\to V\otimes V^*\otimes V\to V,\quad V^*\to V^*\otimes V\otimes V^*\to V^*$$

are identities.

Similarly we can define right dual. if Y is a left/right dual to X, then X is right/left dual to Y.

Def. (3.1.5.17)[Dual Morphisms]. Let $f; X \to Y$ be a morphism and X^*, Y^* the left duals of X and Y, then there is a natural **left dual map**: $f^*: Y^* \to X^*$ given by

$$Y^* \to Y^* \otimes X \otimes X^* \to Y^* \otimes Y \otimes X^* \to X^*.$$

Prop. (3.1.5.18) [Monoidal Functor Preserves Duals]. Let $F: \mathcal{C} \to \mathcal{D}$ be a monoidal functor(3.1.5.11) between monoidal categories, $X \in \mathcal{C}$ is an object with left dual X^*. Then $F(X^*)$ is a left dual of $F(X)$ with evaluation and coevaluation maps

$$\mathrm{ev}_{F(X)}: F(X^*) \otimes F(X) \to F(X^* \otimes X) \to F(1_{\mathcal{C}}) \to 1_{\mathcal{D}},$$

$$coev_{F(X)}: 1_{\mathcal{D}} \to F(1_{\mathcal{C}}) \to F(X \otimes X^*) \to F(X) \otimes F(X^*).$$

and similarly for right duals.

Prop. (3.1.5.19)[Adjointness]. Let $\mathcal{C}$ be a monoidal category and $V \in \mathcal{C}$ with left dual V^*, then there are natural adjunction maps

$$\mathrm{Hom}(U \otimes V, W) \cong \mathrm{Hom}(U, W \otimes V^*), \quad \mathrm{Hom}(V^* \otimes U, W) \cong \mathrm{Hom}(U, V \otimes W).$$

Proof: The first adjunction map is given by $f \mapsto (f \otimes \mathrm{id}_{V^*}) \circ (\mathrm{id}_U \otimes coev_V)$, and the inverse given by $g \mapsto (W \otimes ev_V) \circ (g \otimes \mathrm{id}_V)$. The verification and the second one: □

Cor. (3.1.5.20). In particular, we can use Yoneda lemma to show the left/right adjoints are unique if they exist.

<u>**Invertible Objects and Grothendieck Categories**</u>

Def. (3.1.5.21)[Invertible Objects]. An **invertible object** in a monoidal category is a rigid object L that the evaluation maps and coevaluation maps are all isomorphisms.?

6 Tensor Categories

Notation (3.1.6.1).

- Let $k \in \mathtt{Field}$.

Def. (3.1.6.2)[Tensor Categories]. A **tensor category** over a field k is an Artinian Abelian category over k together with a strict monoidal structure that is bilinear and satisfies $\mathrm{End}(\mathbb{1}) = k$.

A **tensor functor** is a functor between tensor categories that is additive and monoidal.

Prop. (3.1.6.3) [End($\mathbb{1}$)]. If $\mathcal{C}$ is a rigid tensor category, then $\mathrm{End}(\mathbb{1})$ is a ring that acts on objects $X \in \mathcal{C}$ via $X \cong \mathbb{1} \otimes X$. The action of $\mathrm{End}(\mathbb{1})$ commutes with $\mathrm{End}(X)$, in particular, $\mathrm{End}(\mathbb{1})$ is commutative and $\mathcal{C}$ is $\mathrm{End}(\mathbb{1})$-linear.

<u>**Rigid Tensor Categories**</u>

Def. (3.1.6.4)[Rigid Tensor Categories]. Let $\mathcal{C}$ be a monoidal category, an element $X \in \mathcal{C}$ is called **rigid object** if it has left and right duals. A **rigid tensor category** is a tensor category(3.1.6.2) s.t. every object is rigid. In particular, by(3.1.5.19), a rigid tensor category is closed.

Prop. (3.1.6.5). If $\mathcal{C}$ is a rigid tensor category, then the functor

Equivalence of $\mathcal{C}^{\mathrm{op}}$ and $\mathcal{C}^{opp}$.?

Cor. (3.1.6.6). Any natural transformation of monoidal functors between rigid tensor categories is an isomorphism.

Proof: Cf.[Milne, Tannakian Categories, P13].? □

Prop. (3.1.6.7) [Trace and Rank]. Let $\mathcal{C}$ be a symmetric rigid tensor category, we can define a trace morphism

$$\mathrm{tr}_X : \mathrm{End}(X) \to \mathrm{End}(\mathbb{1}) : f \mapsto 1 \to X \otimes X^* \xrightarrow{f \otimes \mathrm{id}} X \otimes X^* \to X^* \otimes X \to 1$$

And the **dimension** of X is defined to be $\mathrm{tr}_X(\mathrm{id}_X) \in \mathrm{End}(1)$.

Prop. (3.1.6.8) [Abelian Rigid Tensor Categories Exact]. If $\mathcal{C}$ is an Abelian rigid tensor category, then $\otimes$ commutes with inverse limits and direct limits in each variable.

Proof: It commutes with direct limits because it is left adjoint to the Hom functor, and it commutes with inverse limits by considering the opposite category(3.1.6.5). □

Prop. (3.1.6.9). $\dim(X \otimes Y) = \dim X \cdot \dim Y$. If there is an exact sequence $0 \to X \to Z \to Y \to 0$, then $\dim(Z) = \dim(X) + \dim(Y)$.

Prop. (3.1.6.10) [Decompositions]. Let $(\mathcal{C}, \otimes)$ be a rigid Abelian tensor category and if U is a subobject of 1, then $1 = U \oplus U^\perp$ where $U^\perp = \ker(1 \to U^\vee)$. Consequently, 1 is a simple object iff $\mathrm{End}(1)$ is a field. And any rigid tensor category can be decomposed as rigid Abelian tensor categories $\mathcal{C}_I$ with $\mathrm{End}(1_i)$ being fields.

Proof: Let $V = \mathrm{Coker}(U \to 1)$, by tensoring $0 \to U \to 1 \to V \to 0$ with $U \hookrightarrow 1$, we get exact sequences

$$\begin{array}{ccccccccc} 0 & \longrightarrow & U & \longrightarrow & 1 & \longrightarrow & V & \longrightarrow & 0 \\ & & \uparrow & & \uparrow & \overset{0}{\nearrow} & \uparrow & & \\ 0 & \longrightarrow & U \otimes U & \longrightarrow & U & \longrightarrow & V \otimes U & \longrightarrow & 0 \end{array}$$

thus $V \otimes U = 0$ and $U \otimes U = U$ via $1 \otimes 1 \cong 1$.

For the rest, Cf.[Tannakian Categories, Milne, P14]. □

Def. (3.1.6.11) [Associative Algebra in a Symmetric Tensor Category].

Tannakian Categories

Def. (3.1.6.12) [Fiber Functor]. Let $\mathcal{C}$ be a k-linear tensor category, then a **fiber functor** on $\mathcal{C}$ with values in a k-algebra R is a k-linear exact faithful tensor functor $\eta : \mathcal{C} \to \mathcal{M}\mathrm{od}_R$ that takes values in the subcategory $\mathbf{Proj}_R$.

Def. (3.1.6.13) [Tannakian Category]. A **Tannakian category** is a symmetric rigid tensor category(3.1.6.4) $\mathcal{C}$ that $\mathrm{End}(\mathbb{1}) = k$ together with a fiber functor(3.1.6.12) with values in $R \in \mathcal{CR}\mathrm{ing}_k$.

Def. (3.1.6.14) [Neutral Tannakian Categories]. A **neutral Tannakian category** is a Tannakian category that the fiber functor is valued in k. By(15.5.2.9), such a category is equivalent to $\mathrm{Rep}_k(G)$ for some affine group scheme G, and such G is uniquely defined up to inner automorphisms.

In particular, a Tannakian category can be thought of as an abstract version of the category of representations of an affine group scheme that has no distinguished "forgetful"functor, just as a vector space is an abstract version of k^n that has no distinguished basis.

7 Enriched Category

Def. (3.1.7.1) [Enriched Categories]. Given a monoidal category $(\mathcal{C}, \otimes)$, an **enriched category** $\mathcal{D}$ over $\mathcal{C}$ consists of the following data:

- a collection of objects.
- For objects $X, Y \in \mathcal{D}$, a mapping object $\mathrm{Map}_{\mathcal{D}}(X, Y) \subset \mathcal{C}$.
- For objects $X, Y, Z \in \mathcal{D}$, a composite map $\mathrm{Map}_{\mathcal{D}}(X, Y) \otimes_{\mathcal{C}} \mathrm{Map}_{\mathcal{D}}(Y, Z) \to \mathrm{Map}_{\mathcal{D}}(X, Z)$ that is associative.
- For every $X \in D$, a morphism $1 \mapsto \mathrm{Map}_{\mathcal{D}}(X, X)$ that satisfies the commutative diagrams of the identity morphism.

Def. (3.1.7.2) [Category of Enriched Categories]. We can naturally define morphisms and natural transformations of categories enriched over a monoidal category $\mathcal{C}$. The resulting category is denoted by $\mathcal{C}at_{\mathcal{C}}$.

Prop. (3.1.7.3) [Completeness and Cocompleteness]. Let $\mathcal{C}$ be a complete and cocomplete symmetric monoidal closed category, then $\mathcal{C}at_{\mathcal{C}}$ is also complete and cocomplete.

Proof: Cf.[H. Wolff. V-cat and V-graph].**?** □

Prop. (3.1.7.4) [Transfer of Enriched Structure]. Given a right-lax monoidal functor between monoidal categories $F : \mathcal{C} \to \mathcal{C}'$ and a category $\mathcal{D}$ enriched over $\mathcal{C}$, we may obtain a category $F(\mathcal{D})$ enriched over $\mathcal{C}'$ by asserting $\mathrm{Map}_{F(\mathcal{D})}(X, Y) = F(\mathrm{Map}(X, Y))$. It is an enriched category just by the definition of right-lax monoidal functors.

Prop. (3.1.7.5) [Underlying Category]. For a category enriched $\mathcal{D}$ over $\mathcal{C}$, by(3.1.5.14), we can transfer the structure via $\mathcal{C} \to \mathcal{S}et : X \mapsto \mathrm{Hom}(1, X)$, and the resulting category is called the underlying category of $\mathcal{D}$.

Prop. (3.1.7.6).

- A category enriched in $\mathcal{S}et$ is just a usual category.
- A right-closed monoidal category is enriched over itself if we define $\mathrm{Map}(X, Y) = Y^X$.(Check).

Def. (3.1.7.7) [Tensored Category]. Let $\mathcal{C}$ be a right-closed monoidal category and $\mathcal{D}$ a category enriched over $\mathcal{C}$, then $\mathcal{D}$ is called **tensored over** $\mathcal{C}$ if for any $C \in \mathcal{C}$ and $X \in \mathcal{D}$, there is an isomorphism of functors

$$\eta : \mathrm{Map}_{\mathcal{D}}(X, -)^C \cong \mathrm{Map}_{\mathcal{D}}(X \otimes C, -).$$

for some element $X \otimes C \in \mathcal{D}$.

In particular, this implies $\mathrm{Hom}_{\mathcal{C}}(C, \mathrm{Map}(X, Y)) \cong \mathrm{Hom}_{\mathcal{D}}(X \otimes C, Y)$, thus $X \otimes C$ is determined up to a unique isomorphism, and the map $(X, C) \mapsto X \otimes C$ defines a functor $\mathcal{D} \times \mathcal{C} \to \mathcal{D}$ that there are natural morphisms

$$X \otimes (C \otimes D) \cong (X \otimes C) \otimes D.$$

Dually, if $\mathcal{C}$ is left-closed and there is an object ${}^C X$ that there is an isomorphism of functors

$${}^C\mathrm{Map}(-, X) \cong \mathrm{Map}(-, {}^C X)$$

then $\mathcal{D}$ is called **cotensored** over $\mathcal{C}$.

Proof:

□

Prop. (3.1.7.8). If $\mathcal{C}$ is a right-closed monoidal category, then it is naturally tensored over itself, as defined in(3.1.7.6).

Lifting Property and Small Object Argument

Def. (3.1.7.9) [lifting Properties]. Let $\mathcal{C}$ be a category and $p : A \to B, q : X \to Y$ be morphisms, then p is said to have **left lifting property** w.r.t q and q is said to have **right lifting property** w.r.t p if given any diagram $\begin{array}{ccc} A & \longrightarrow & X \\ \downarrow p & \nearrow & \downarrow q \\ B & \longrightarrow & Y \end{array}$, there is a dotted arrow completing the diagram.

For a set A of morphisms of $\mathcal{C}$, let $l(A)$ denote the morphisms that have left lifting property w.r.t A and $r(A)$ the morphisms that have right lifting property w.r.t A.

Def. (3.1.7.10) [Weakly Saturated Class]. Let $\mathcal{C}$ be a category with all small colimits, then a class of morphisms of $\mathcal{C}$ is called **weakly saturated** if it satisfies:

- Closed under pushout.
- Closed under transfinite composition: Let α be an ordinal and $\{D_\beta\}_{\beta<\alpha}$ be a system of objects in $\mathcal{C}_{C/}$ indexed by α. For $\beta < \alpha$, let $D_{<\beta}$ be the colimit of system $\{D_\gamma\}_{\gamma<\beta}$ in $\mathcal{C}_{C/}$, then if each $D_{<\beta} \to D_\beta$ is in S, then $C \to D_{<\alpha}$ is in S.
- Closed under Retraction: In the category of morphisms of $\mathcal{C}$, if there is a morphism $F : f \to g, G : g \to f$ that $G \circ F = \mathrm{id}$, and $g \in S$, then $f \in S$.

Cor. (3.1.7.11). The second condition implies all isomorphisms are in S, and S is closed under composition.

Prop. (3.1.7.12) [Lifting and Retraction]. For a diagram $\begin{array}{ccc} X & = & X \\ \downarrow i & \overset{s}{\nearrow} & \downarrow p \\ Z & \xrightarrow{f} & Y \end{array}$ represents p as a retraction of u, as the diagram $\begin{array}{ccccc} X & \xrightarrow{i} & Z & \xrightarrow{s} & X \\ \downarrow p & & \downarrow f & & \downarrow p \\ Y & = & Y & = & Y \end{array}$ shows.

Dually a diagram $\begin{array}{ccc} X & \xrightarrow{i} & Y \\ \downarrow q & \overset{s}{\nearrow} & \downarrow f \\ Z & = & Z \end{array}$ represents q as a retraction of i.

Prop. (3.1.7.13) [Small Object Argument]. Let $\mathcal{C}$ be a presentable category and $A_0 = \{\varphi_i : C_i \to D_i\}$ be a small collection of morphisms in $\mathcal{C}$, then there is a morphism $T : \mathcal{C}^{[1]} \to \mathcal{C}^{[2]}$ taking morphisms $f : X \to Z$ in $\mathcal{C}$ to the diagram

$$\begin{array}{ccccc} & & Y & & \\ & \overset{f'}{\nearrow} & & \overset{f''}{\searrow} & \\ X & & \xrightarrow{\quad f \quad} & & Z \end{array}$$

That f' belongs to the weakly saturated class generated by A_0 and $f'' \in r(A_0)$.

Moreover, if κ is a regular cardinal that each C_i, D_i is κ-compact, then T commutes with κ-filtered colimits.

Proof: Cf.[HTT, P788]. □

Lemma (3.1.7.14). $l(A)$ is weakly saturated for any set of morphisms A(Clear).

Cor. (3.1.7.15) [Generated Weakly Saturated Class]. For any presentable category $\mathcal{C}$ and A a set of morphisms in $\mathcal{C}$, $l(r(A))$ is the smallest weakly saturated class of morphisms containing A.

Proof: One direction of inclusion is by(3.1.7.14), for the other, if $f : X \to Z \in l(r(A))$, then there is a factorization $X \xrightarrow{f'} Y \xrightarrow{f''} Z$, where $f' \in \overline{A}$ and $f'' \in r(A)$, thus $f \in l(f'')$, thus f is retraction of f':

$$\begin{array}{ccc} X & \xrightarrow{f'} & Y \\ \downarrow f & \overset{g}{\nearrow} & \downarrow f'' \\ Z & \longrightarrow & Z \end{array} \Rightarrow \begin{array}{ccccc} X & \longrightarrow & X & \longrightarrow & X \\ \downarrow f & & \downarrow f' & & \downarrow f \\ Z & \xrightarrow{g} & Y & \xrightarrow{f''} & Z \end{array}$$

Thus $f \in \overline{A}$. □

8 Fibered Categories

Categories of Categories

Def. (3.1.8.1) [2-Category of Categories over Categories]. There is a 2-category of categories over $\mathcal{C}$, where the 1-morphisms are morphisms of categories over $\mathcal{C}$ and the 2-morphisms are base-preserving natural transformations.

Two categories over $\mathcal{C}$ are called **equivalent** if they are equivalent in this 2-category.

Prop. (3.1.8.2) [2-Fibered Products in the Categories of Categories]. 2-fibered products exists in the categories of categories.

Proof: Let $F : \mathcal{A} \to \mathcal{C}, G : \mathcal{B} \to \mathcal{C}$ be functors, then we can define a category $\mathcal{A} \times_{\mathcal{C}} \mathcal{B}$ as follows:

- Objects are the triples (A, B, f) where $A \in \mathcal{A}, B \in \mathcal{B}$ and $f : F(A) \to G(B)$ is an isomorphism in $\mathcal{C}$.
- Morphisms from (A, B, f) to (A', B', f') are pairs (a, b) where $a : A \to A', b : B \to B'$ s.t. the diagram

$$\begin{array}{ccc} F(A) & \xrightarrow{f} & G(B) \\ \downarrow F(a) & & \downarrow G(b) \\ F(A') & \xrightarrow{f'} & G(B') \end{array}$$

  is commutative.

$\mathcal{A}\times_{\mathcal{C}}\mathcal{B}$ is a category both over $\mathcal{A}$ and over $\mathcal{B}$, and it fits into a 2-fiber products diagram

$$\begin{array}{ccc} \mathcal{A}\times_{\mathcal{C}}\mathcal{B} & \longrightarrow & \mathcal{B} \\ \downarrow & & \downarrow \\ \mathcal{A} & \longrightarrow & \mathcal{C} \end{array}$$

where the invertible 2-morphism is given by $\psi_{(A,B,f)} = f : F(A) \to G(B)$.

The verification that this defines a final object in the 2-category of 2-commutative diagrams is in[Sta]02X9. □

Cor. (3.1.8.3). The 2-fibered product $\mathcal{A}\times_{\mathcal{C}}\mathcal{B}$ is a groupoid iff $\mathcal{A},\mathcal{B}$ are all groupoids.

Prop. (3.1.8.4). Let $\mathcal{A}\to\mathcal{C},\mathcal{B}\to\mathcal{C},\mathcal{C}\to\mathcal{D}$ be functors between categories, then there is a 2-fiber product diagram

$$\begin{array}{ccc} \mathcal{A}\times_{\mathcal{C}}\mathcal{B} & \longrightarrow & \mathcal{A}\times_{\mathcal{D}}\mathcal{B} \\ \downarrow & & \downarrow \\ \mathcal{C} & \xrightarrow{\Delta_{\mathcal{C}/\mathcal{D}}} & \mathcal{C}\times_{\mathcal{D}}\mathcal{C} \end{array}$$

Proof: □

Prop. (3.1.8.5) [2-Fibered Products of Categories]. The $(2,1)$-category of categories over $\mathcal{C}$ has 2-fiber products(3.1.4.6). More explicitly, suppose $F:\mathcal{X}\to\mathcal{S},\mathcal{Y}\to\mathcal{S}$ be morphisms of categories over $\mathcal{C}$, $\mathcal{X}\times_{\mathcal{S}}\mathcal{Y}$ is given as follows:

- Objects of $\mathcal{X}\times_{\mathcal{C}}\mathcal{Y}$ are quadruples (U,x,y,f), where $U\in\mathcal{C},x\in\mathcal{X}_U,y\in\mathcal{Y}_U$, and $f:F(x)\to G(y)$ is an isomorphism in $\mathcal{S}_U$.
- A morphism $(U,x,y,f)\to(U',x',y',f')$ is given by a pair (a,b), where $a:x\to x'$ is a morphism in $\mathcal{X}$ and $y\to y'$ is a morphism in $\mathcal{Y}$ that
  - a,b induce the same morphism $U\to U'$.
  - the diagram

$$\begin{array}{ccc} F(x) & \xrightarrow{f} & G(y) \\ \downarrow{\scriptstyle F(a)} & & \downarrow{\scriptstyle G(b)} \\ F(x') & \xrightarrow{f'} & G(y') \end{array}$$

    is an isomorphism.

$\mathcal{X}\times_{\mathcal{S}}\mathcal{Y}$ is endowed with morphisms to $\mathcal{X}$ and $\mathcal{Y}$ over $\mathcal{C}$ that the invertible 2-morphism giving the 2-commutativity is $\psi_{(U,x,y,f)}:F(x)\to G(y)$.

The verification of the universal properties are similar to that of(3.1.8.2).

Cor. (3.1.8.6). There is an equivalence of fibre categories:

$$(\mathcal{X}\times_{\mathcal{S}}\mathcal{Y})_U\cong\mathcal{X}_U\times_{\mathcal{S}_U}\mathcal{Y}_U.$$

Fibered Categories

Def. (3.1.8.7) [(Co)Cartesian Arrows]. Let $p:\mathcal{F}\to\mathcal{C}$ be a morphism, then a **Cartesian arrow** is an arrow $\varphi:C'\to C$ in $\mathcal{F}$ that for any object $C''\in\mathcal{F}$ the map

$$\mathrm{Hom}(C'',C')\to\mathrm{Hom}(C'',C)\times_{\mathrm{Hom}(p(C''),p(C))}\mathrm{Hom}(p(C''),p(C'))$$

is a bijection. A **coCartesian arrow** is an arrow that corresponds to a Cartesian diagram in $\mathcal{F}^{op}\to\mathcal{C}^{\mathrm{op}}$.

Prop. (3.1.8.8).

- If f is Cartesian, then $f\circ g$ is Cartesian iff g is Cartesian.
- An arrow in $\mathcal{F}$ whose image is an isomorphism is Cartesian iff it is itself an isomorphism.

Proof: Easy. □

Def. (3.1.8.9) [Quasi-Fibrantion]. A functor $F:\mathcal{C}\to\mathcal{D}$ is called a **quasi-fibration** if for any $X\in\mathcal{C}$ and an isomorphism $f:F(X)\cong Y$, there is an isomorphism $\overline{f}:X\to\overline{Y}$ mapping to f.

Def. (3.1.8.10) [2-Category of Fibered Categories]. A **fibered category** over $\mathcal{C}$ is a category over $\mathcal{C}$ $p:\mathcal{F}\to\mathcal{C}$ that for any $\eta\in\mathcal{F}$ and an arrow $f:U\to p(\eta)$, there is a Cartesian arrow $\xi\to\eta$ in $\mathcal{F}$ lifting f. A **cofibered category** over $\mathcal{C}$ is a category $p:\mathcal{F}\to\mathcal{C}$ that the dual category $p^{op}:\mathcal{F}^{op}\to\mathcal{C}^{\mathrm{op}}$ is a fibered category.

A morphism of fibered categories over $\mathcal{C}$ is a morphism of categories over $\mathcal{C}$ that maps Cartesian morphisms to Cartesian morphisms. A 2-morphism of fibered categories is the same as a 2-morphism of categories over categories.

Def. (3.1.8.11) [Split Fibered Categories]. A **split fibered category** is a fibered category $\mathcal{F}\to\mathcal{C}$ that comes from a functor $\mathcal{C}^{\mathrm{op}}\to\mathcal{C}\mathrm{at}$.

Def. (3.1.8.12) [Cleavage]. A **cleavage** of a fibered category $\pi:\mathcal{F}\to\mathcal{C}$ is a choice of Cartesian arrow f^* lifting f for any $f\in\mathcal{A}\mathrm{rr}(\mathcal{C})$.

Lemma (3.1.8.13). Let $F:\mathcal{F}\to\mathcal{G}$ be a morphism of fibered categories over $\mathcal{C}$ that $\mathcal{F}(U)\to\mathcal{G}(U)$ are fully faithful for any $U\in\mathcal{C}$, then F is fully faithful.

Proof: To show F is fully faithful, it suffices to show for objects X,Y lying over U,V, F induces a bijection of morphisms from x to y lying over a fixed $f:U\to V$. Choose a Cartesian morphism $f^*y\to y$ in $\mathcal{S}_1$ lying over f, then this induces a bijection between morphisms from x to y lying over f and $\mathrm{Hom}_{\mathcal{S}_{1,U}}(x,f^*y)$. Similarly, because F preserves Cartesian morphisms, we get a bijection between morphisms $F(x)\to F(y)$ lying over f and $\mathrm{Hom}_{\mathcal{S}_{2,U}}(F(x),F(f^*y))$. Then the desired bijection follows from the hypothesis. □

Prop. (3.1.8.14) [Equivalence of Fibered Categories]. Let $F:\mathcal{F}\to\mathcal{G}$ be a morphism of fibered categories. Then F is an equivalence iff the restriction $F_U:\mathcal{F}(U)\to\mathcal{G}(U)$ is an equivalence of categories for any object U of $\mathcal{C}$.

Proof: One direction is trivial, for the other, the proof is similar to the fact essentially surjective+fully faithful implies equivalence.

Because $F(U)$ are equivalences, for any object ξ of $\mathcal{G}$ over U, pick an object $G\xi$ in $\mathcal{F}(U)$ together with an isomorphism $\alpha_\xi:\xi\cong F(G\xi)$. And for any morphism $\xi\to\eta$, by(3.1.8.13), there is a unique arrow $G\varphi:G\xi\to G\eta$ that $F(G\varphi)=\alpha_\eta\circ\varphi\circ\alpha_\xi^{-1}$.

Thus clearly there is a 2-isomorphism $\mathrm{id}_{\mathcal{G}} \cong F \circ G$. It remains to construct an 2-isomorphism $\mathrm{id}_{\mathcal{F}} \cong G \circ F$: For any object ξ' over U, since $F(U)$ is fully faithful, there is a unique isomorphism $\beta_{\xi'} : \xi' \cong G \circ F(\xi)$ in $\mathcal{F}(U)$ that $F\beta_{\xi'} = \alpha_{F\xi'}$. Then this is easily checked to be an 2-isomorphism $\beta : \mathrm{id}_{\mathcal{F}} \cong F \circ G$. □

Prop. (3.1.8.15)[2-Fiber Products of Fibered Categories]. 2-fiber products exists in the category of fibered categories, and it coincides with that defined in(3.1.8.5).

Proof: it suffices to show for fibered categories $\mathcal{X}, \mathcal{Y}$ over $\mathcal{C}$, $\mathcal{X} \times_{\mathcal{C}} \mathcal{Y}$ is also fibered over $\mathcal{C}$. Let (x, y, φ) be an object of $\mathcal{X} \times_{\mathcal{C}} \mathcal{Y}$ mapping to $U \in \mathcal{C}$ and $f : V \to U$ is a morphism in $\mathcal{C}$, choose Cartesian morphisms $a : f^*x \to x$, $b : f^*y \to y$ lying over f, then $F(a)$ and $G(b)$ are Cartesian. Since $\varphi : F(x) \to G(y)$ is an isomorphism, by the property of Cartesian morphisms, there exists a unique isomorphism $f^*\varphi : F(f^*x) \to G(f^*y) \in \mathcal{S}_V$ that $G(b) \circ f^*\varphi = \varphi \circ F(a)$. In other words, $(F(a), F(b)) : (V, f^*x, f^*y, f^*\varphi) \to (U, x, y, \varphi)$ is a morphism in $\mathcal{X} \times_{\mathcal{S}} \mathcal{Y}$.

The verification that this morphism is Cartesian is omitted**?**. □

Lemma (3.1.8.16). Let $\mathcal{S} \to \mathcal{C}$ be a fibered category that factors through $\mathcal{C}/U$ where $U \in \mathcal{C}$, then $\mathcal{S} \to \mathcal{C}/U$ is also a fibered category.

Proof: Cf.[[Sta]02XR]. □

Def. (3.1.8.17) [G-Equivariant Object]. Let $G : \mathcal{C}^{\mathrm{op}} \to (Grp)$ be a group functor and $p_{\mathcal{F}} : \mathcal{F} \to \mathcal{C}$ a fibered category, and X an object of $\mathcal{C}$ with an action of G. A **G-equivariant object** of $\mathcal{F}(X)$ is an object ρ of $\mathcal{F}(X)$ that there is an action of $G \circ p_{\mathcal{F}}$ on ρ and for any object U and $\xi \in \mathcal{F}(U)$, the function $p_{\mathcal{F}} : \mathrm{Hom}_{\mathcal{F}}(\xi, \rho) \to \mathrm{Hom}_{\mathcal{C}}(U, X)$ is $G(U)$-equivariant.

The category $\mathcal{F}^G(X)$ of G-equivariant objects of $\mathcal{F}(X)$ consisting of $G \circ p_{\mathcal{F}}$-equivariant morphism of G-equivariant objects.

Prop. (3.1.8.18). Let π_2 is the projection $G \otimes X \to X$, ρ be an object of $\mathcal{F}(X)$, then a G-equivariant structure on ρ is the same as a Cartesian arrow $\beta : \pi_2^*\rho \to \rho$ that $p_{\mathcal{F}}\beta = \alpha$, and satisfies the desired commutative diagram corresponding to $(gh)x = g(h(x))$. And a morphism of G-equivariant objects just corresponds to a morphism of pairs (ρ, β).

Proof: Cf.[Vistoli, P68]. □

Def. (3.1.8.19) [Presheaf of Arrows]. Let $\mathcal{F}$ be a fibered category over $\mathcal{C}$, and $\xi, \eta \in \mathcal{F}(S)$, then we can define a quasi-functor $\mathcal{H}om_S(\xi, \eta) \to (\mathcal{C}/S)$, where

$$\mathcal{H}om_S(\xi, \eta)(U/S) = \{(\xi_1 \to \xi, \eta_1 \to \eta, \varphi)\}$$

where $\xi_1 \to \xi, \eta_1 \to \eta$ are Cartesian arrows over $U \to S$, and $\varphi : \xi_1 \to \eta_1 \in \mathcal{F}(U)$. The arrows in $\mathrm{Hom}_S(\xi, \eta)$ are uniquely defined by the property of Cartesian arrows. Then it is a quasi-functor, by(3.1.8.30).

Then it is equivalence to a presheaf $\underline{\mathrm{Hom}}_S(\xi, \eta)$, by(3.1.8.31). Equivalently, this presheaf can be defined by designating a choice of Cartesian arrows.

Prop. (3.1.8.20)[Splitting a Fibered Category]. Let $\mathcal{F} \to \mathcal{C}$ be a fibered category, then there exists a canonically defined split fibered category $\widetilde{\mathcal{F}} \to \mathcal{C}$ with a canonical equivalence of fibered categories $\widetilde{\mathcal{F}} \to \mathcal{F}$ over $\mathcal{C}$.

Proof: There is a functor $\mathcal{C}^{\mathrm{op}} \to \mathcal{C}at : U \mapsto \mathrm{Hom}(h_U, \mathcal{F})$, with corresponds to a split fibered category $\widetilde{\mathcal{F}}$. There is an obvious morphism $\widetilde{\mathcal{F}} \to \mathcal{F}$, sending an object $\varphi : h_U \to \mathcal{F}$ to $\varphi(\mathrm{id}_U) \in \mathcal{F}(U)$. And for any $f : U \to V \in \mathcal{C}$ and a $\varphi : h_U \to \mathcal{F}$, we send $f^*\varphi \to \varphi \in \widetilde{\mathcal{F}}$ to $\varphi(f : V/U \to U/U) \in \mathcal{F}$, Then we get a canonical map of fibered categories $\widetilde{\mathcal{F}} \to \mathcal{F}$ over $\mathcal{C}$. It is an equivalence of categories by(3.1.8.14) and(3.1.8.33). □

Categories Fibered in Groupoids, Sets and Equivalence Relations

Def. (3.1.8.21) [Category Fibered in Groupoids]. A **category (co)fibered in groupoids/sets/equivalence relations** over $\mathcal{C}$ is a category $\mathcal{F}$ (co)fibered over $\mathcal{C}$ that $\mathcal{F}(U)$ is a groupoid/setoids/equivalence relations(3.1.1.14) for any $U \in \mathcal{C}$. Also we call a category fibered in equivalence relations over $\mathcal{C}$ a **quasi-functor**.

Prop. (3.1.8.22) [Characterization of Category Fibered in Groupoids]. Let $\mathcal{F}$ be a category over $\mathcal{C}$, then $\mathcal{F}$ is fibered over groupoids over $\mathcal{C}$ iff

- Every morphism in $\mathcal{F}$ is Cartesian.
- Given any $\eta \in \mathcal{F}, U \in \mathcal{C}$ and a morphism $f : U \to p_{\mathcal{F}}(\eta)$, there is an arrow $\varphi : \xi \to \eta \in \mathcal{F}$ mapping to f.

And dually for cofibered categories.

Proof: If these two holds, then $\mathcal{F}$ is clearly fibered over $\mathcal{C}$, and for any arrow $f : \xi \to \eta$ in $\mathcal{F}(U)$, there is a morphism $g : \eta \to \xi$ that is right inverse to f, then clearly it is the inverse.

Conversely, if $\mathcal{F}$ is fibered over $\mathcal{C}$, it suffices to check1: for any arrow f, the image in $\mathcal{C}$ can be lifted to a Cartesian diagram in $\mathcal{F}$, and differs f by an isomorphism, thus f is also Cartesian by(3.1.8.8). □

Cor. (3.1.8.23). if $\mathcal{A}$ is a category fibered in groupoids over $\mathcal{B}$ and $\mathcal{B}$ is a category fibered in groupoids over $\mathcal{C}$, then $\mathcal{A}$ is a category fibered in groupoids over $\mathcal{C}$.

Prop. (3.1.8.24) [Associated Category Fibered in Groupoids]. Let $\mathcal{F} \to \mathcal{C}$ be a fibered category, then the **associated category fibered in groupoids** $\mathcal{F}_{cart}$ is the category obtained by deleting all the non-Cartesian arrows. Then $\mathcal{F}_{cart}$ is a category fibered in groupoids over $\mathcal{C}$.

Proof: Firstly $\mathcal{F}_{cart}$ is a category by(3.1.8.8), and it is a category fibered in groupoids by(3.1.8.22). □

Def. (3.1.8.25) [RIgid Fibered Categories]. A **rigid fibered category** is a fibered category whose associated category fibered groupoids is fibered in setoids. Equivalently, there are no isomorphisms above any id_U.

Prop. (3.1.8.26) [2-Fibered Products of Categories Fibered in Groupoids]. The 2-fibered products of categories fibered in groupoids over $\mathcal{C}$ is a category fibered in groupoids over $\mathcal{C}$.

Proof: The 2-fibered products exist by(3.1.8.15), and using (3.1.8.6), it is fibered in groupoids because the 2-fibered products of groupoids is a groupoid by(3.1.8.3). □

Prop. (3.1.8.27) [Characterization of Categories Fibered in Setoids]. Let $\mathcal{F}$ be a category over $\mathcal{C}$, then $\mathcal{F}$ is fibered in setoids over $\mathcal{C}$ iff for any object η of $\mathcal{F}$ and an arrow $f : U \to p_{\mathcal{F}}\eta \in \mathcal{C}$, there is a unique arrow $\xi \to \eta$ mapping to f.

Proof: Let $\mathcal{F}$ be a category fibered in sets, then pick a Cartesian arrow $\widetilde{f}$ over f, then any other lifting factors through this lifting by the property of Cartesian, then it is identity, because $\mathcal{F}(U)$ is a setoid.

Conversely, if the hypothesis holds, then clearly $\mathcal{F}(U)$ is a setoid, and the fibered category condition holds, because of the uniqueness. □

Cor. (3.1.8.28) [Presheaves and Categories Fibered in Setoids]. Let $\mathcal{C}$ be a category, then categories fibered in setoids over $\mathcal{C}$ are exactly those equivalent to a presheaf over $\mathcal{C}$.

Cor. (3.1.8.29). In particular, for any object $X \in \mathcal{C}$, the presheaf h_X determines a category fibered in sets, which is just the comma category $\mathcal{C}/X \to \mathcal{C}$.

Prop. (3.1.8.30) [Characterization of Quasi-Functors]. A category $\mathcal{F}$ over $\mathcal{C}$ is a quasi-functor iff:

- Given any object $\eta \in \mathcal{F}$ and an arrow $f : U \to p_{\mathcal{F}}\eta$, there is a lifting $\xi \to \eta$ mapping to f. And given any two such extensions, there is a morphism $\xi' \to \xi$ commuting them.
- Given any two objects $\xi, \eta \in \mathcal{F}$ and an arrow $f : p_{\mathcal{F}}\xi \to p_{\mathcal{F}}\eta$, there is at most one arrow $\widetilde{f} : \xi \to \eta$ lifting f.

Proof: □

Prop. (3.1.8.31). A fibered category over $\mathcal{C}$ is a quasi-functor iff it is equivalent to a presheaf.

Proof: If it is equivalent to a functor, then $\mathcal{F}(U)$ is equivalent to a setoid, thus it is an equivalent relation, by(3.1.1.15). Conversely, if $\mathcal{F}$ is a quasi-functor, then it is fibered in groupoids, thus by(3.1.8.22) every morphism is Cartesian, and if we denote $\Phi(U)$ the equivalence classes of $\mathcal{F}(U)$, then a morphism $U \to V$ will induce a morphism $\Phi(V) \to \Phi(V)$ by the property of Cartesian arrows. Then clearly this defines a presheaf that is equivalent to $\mathcal{F}$. □

Representability

Def. (3.1.8.32) [Representable Fibered Category]. A fibered category is called **representable** if it is equivalent to the fibered category $\mathcal{C}/X$ defined in(3.1.8.29) for some $X \in \mathcal{C}$.

Prop. (3.1.8.33) [2-Categorical Yoneda Lemma]. Let $\mathcal{F}$ be a fibered category over $\mathcal{C}$ and $X \in \mathcal{C}$, there is an equivalence of categories:

$$\mathrm{Hom}_{\mathcal{C}}((\mathcal{C}/X), \mathcal{F}) \cong \mathcal{F}(X) : \varphi \mapsto \varphi(\mathrm{id}_X)$$

Proof: To show this functor is essentially surjective, choose a choice of pullbacks of $\mathcal{F}$, for any $\xi \in \mathcal{F}(X)$, we define a $F : \mathcal{C}/X \to \mathcal{F}$ that maps a $\varphi : U \to X$ to $\varphi^*\xi$, and to any morphism in $\mathcal{C}/X$ an arrow in $\mathcal{F}$ induced by Cartesian property.

To show it is fully faithful, notice a natural transformation of $\varphi, \psi \in \mathrm{Hom}_{\mathcal{C}}((\mathcal{C}/X), \mathcal{F})$ is determined by their value on id_X, and any map $\varphi(\mathrm{id}_X) \to \psi(\mathrm{id}_X)$ induces a natural transformation, by Cartesian properties. □

Cor. (3.1.8.34) [Characterization of Representability]. Translating the 2-Yoneda lemma and(3.1.8.14), we see that a fibered category $\mathcal{F}$ is representable by $X \in \mathcal{C}$ iff $\mathcal{F}$ is fibered in groupoids, and there is an object $\xi \in \mathcal{F}(X)$ that for any object $\rho \in \mathcal{F}$, there is a unique arrow $\rho \to \xi$.

Cor. (3.1.8.35). If $\mathcal{X}, \mathcal{Y}$ are fibered categories over $\mathcal{C}$ representable by U, V resp., then there is an isomorphism of sets

$$\mathrm{Hom}_{\mathcal{C}}(\mathcal{X}, \mathcal{Y})/2-\text{isomorphisms} \cong \mathrm{Hom}_{\mathcal{C}}(U, V)$$

Proof: By Yoneda lemma there is an equivalence $\mathrm{Hom}_{\mathcal{C}}(\mathcal{X}, \mathcal{Y}) \cong \mathrm{Hom}_{\mathcal{C}}(U, V)$, and then $\mathrm{Hom}_{\mathcal{C}}(\mathcal{X}, \mathcal{Y})$ is an equivalence relation by(3.1.1.15), so the isomorphism is clear. □

Def. (3.1.8.36) [Representable 1-Morphisms]. Let $\mathcal{C}$ be a category and $F : \mathcal{X} \to \mathcal{Y}$ be a morphism of categories fibered over $\mathcal{C}$, then F is called **representable** if for any $U \in \mathcal{C}$ and a morphism $\mathcal{C}/U \to \mathcal{Y}$, the fibered category $(\mathcal{C}/U) \times_{\mathcal{Y}} \mathcal{X} \to \mathcal{C}/U$ is representable(3.1.8.32)(Notice it is a fibered category by(3.1.8.15) and(3.1.8.16)).

Prop. (3.1.8.37) [Diagonal and Representability]. Let $\mathcal{S}$ be a category fibered in groupoids over $\mathcal{C}$. Assume $\mathcal{C}$ has fibered product, then the following are equivalent:

- $\Delta_S : \mathcal{S} \to \mathcal{S} \times_{\mathcal{C}} \mathcal{S}$ is representable.
- For every $U \in \mathcal{C}$, any $G : \mathcal{C}/U \to \mathcal{S}$ is representable.

Proof: Cf.[Sta]02YA.

The key to this proposition is the fibered product diagram(3.1.8.15)(3.1.1.48)

$$\begin{array}{ccc} X \times_{\mathcal{F}} Y & \longrightarrow & \mathcal{F} \\ \downarrow & & \downarrow \Delta \\ X \times_S Y & \xrightarrow{f \times g} & \mathcal{F} \times_S \mathcal{F} \end{array}$$

which still holds in the 2-commutative sense.

So if $\Delta_{\mathcal{F}}$ is schematic, then $X \times_{\mathcal{F}} Y$ is a scheme, so $X \to \mathcal{F}$ is schematic, for any scheme X. Conversely, consider the fibered products

$$\begin{array}{ccccc} \mathcal{F} \times_{\mathcal{F} \times_S \mathcal{F}} X & \longrightarrow & X \times_{\mathcal{F}} X & \longrightarrow & \mathcal{F} \\ \downarrow & & \downarrow & & \downarrow \Delta \\ X & \xrightarrow{\Delta} & X \times_S X & \xrightarrow{f \times g} & \mathcal{F} \times_S \mathcal{F} \end{array}$$

induced by $h = f \times g : X \mapsto \mathcal{F} \times_S \mathcal{F}$. So in order to prove $\Delta_{\mathcal{F}}$ is schematic, it suffices to prove $\mathcal{F} \times_{\mathcal{F} \times_S \mathcal{F}} X$ is a scheme, and for this, it suffices to prove $X \times_{\mathcal{F}} X$ is a scheme. But $X \times_{\mathcal{F}} X \to X$ is a pullback of $X \to \mathcal{F}$, so it is a scheme. $\square$

3.2 Categorical Logic

Main references are [Categorical Logic Notes, Jacob Lurie], [Coend Calculus, Fosco Loregian], [Harder-Narasimhan Filtrations, Huayi Chen], [Harder-Narasimhan Theory, Jonathan Pottharst], [Coend Calculus].

1 Monads and Categories

Def. (3.2.1.1) [Monad]. Let $\mathcal{C}$ be a category, a **monad** on $\mathcal{C}$ is an endofunctor $\mathcal{C} \to \mathcal{C}$ together with two natural morphisms:

- (multiplication)$\mu : T \circ T \to T$.
- (unit)$\mathrm{id}_{\mathcal{C}} \to T$.

that satisfies associativity and unit diagrams.

Def. (3.2.1.2) [Algebras over Monads]. An **algebra over a monad** T is an object X together with a morphism $\alpha : TX \to X$ that satisfies the diagrams for an algebra.

2 Group Formation

The goal of this subsection is to give a formation that encompass both the group theory and algebraic group theory.

Def. (3.2.2.1) [Group Formations]. A **group formation** is a category $\mathcal{C} \in \mathcal{C}\mathrm{at}$ with a class of arrows $\mathcal{S} \in \mathcal{C}$ consisting of monomorphisms, satisfying the following axioms:

- G is complete and cocomplete.
- G has a zero object e.
- $\mathcal{S}$ is stable under pullbacks.
- If $N \to H \to G \in \mathcal{S}$ and $H \to G$ is a monomorphism, then $N \to H \in \mathcal{S}$.
- Let $N \to G \in \mathcal{S}$, then N is called a **normal subobject** of G, and $N = \ker(G \to \mathrm{Coker}(N \to G))$.
- For $G \in \mathcal{C}$, coproducts exist in $\mathcal{C}/G$, and if $N \to G, H \to G \in \mathcal{S}$, then the coproduct is also in $\mathcal{S}$, denoted by $NH \to G$.
- Let $N \to G \in \mathcal{S}$ and $H \to G$ a monomorphism, then
  - there is a natural isomorphism: $H/N \cap H \cong HN/N$.
  - If $N \to G \in \mathcal{S}$, then there is a natural isomorphism $G/NH \cong (G/N)/(H/H \cap N)$.

Prop. (3.2.2.2).

3 Filtrations of a Category

Def. (3.2.3.1) [Filtrations in a Category]. Let $\mathcal{C}$ be a category with an initial object, a **filtration** of an object X in $\mathcal{C}$ is a family $\mathcal{F} = (X_t)_{t \in \mathbb{R}}$ of subobjects of X indexed by $\mathbb{R}$ that satisfies:

- (decreasing property) if $s \le t$, then $X_s \to X$ factors through X_t.
- (separation property) for sufficiently small t, X_t is the initial object.
- (exhaustiveness) for sufficiently large s, $X_s = X$.

- (right locally constant property) for any $t \in \mathbb{R}$, there exists $\delta > 0$ that for any $s \in [t, t+\delta)$, the morphism $X_t \to X_s$ are isomorphisms.
- (finite jump)the jump set of $\mathcal{F}$ is finite.

Naturally, we define morphisms of filtrations.

Def. (3.2.3.2) [Pullback and Pushforward Filtrations]. Suppose fibered products exist in $\mathcal{C}$, for any morphism $f : X \to Y$ and a filtration $\mathcal{G} = (Y_t) \to Y$, then the family $f^*\mathcal{G} = (Y_t \otimes_Y X) \to X$ is a filtration on X, called the **pullback filtration**.

If $f : X \to Y$ and $\mathcal{F} : (X_t) \to X$ is a filtration on X, then if there is a filtration $f_*\mathcal{F}$ on Y and a morphism of filtrations $\mathcal{F} \to f_*\mathcal{F}$ compatible with f, then $f_*\mathcal{F}$ is called the **pushforward filtrations**.

4 Harder-Narasimhan Formalism

Main references are[Jon20].

Def. (3.2.4.1) [Harder-Narasimhan Formalism]. A **Harder-Narasimhan formalism** consists of

- An exact category $\mathcal{C}$(3.7.2.1).
- A function $\deg : \mathrm{Ob}(\mathcal{C}) \to \mathbb{Z}$ that is additive w.r.t. short exact sequences.
- An exact faithful **generic fiber functor** to an Abelian category $F : \mathcal{C} \to \mathcal{A}$ that induces for each object $F : \mathcal{E} \in \mathcal{C}$ a bijection

$$\{\text{strict objects of } \mathcal{E}\} \cong \{\text{subobjects of } F(\mathcal{E})\}$$

  where a **strict subobject** is an object that can be prolonged to an exact sequence.
- An additive function rank: $\mathcal{A} \to \mathbb{N}$ on $\mathcal{A}$ that $\mathrm{rank}(\mathcal{L}) = 0 \iff \mathcal{L} = 0$, and its composition with F is also called rank.
- If $u : \mathcal{E} \to \mathcal{E}'$ is a morphism in $\mathcal{C}$ that $F(u)$ is an isomorphism, then $\deg(\mathcal{E}) \leq \deg(\mathcal{E}')$ with equality iff u is an isomorphism.

Cor. (3.2.4.2).

- We are free to choose the "kernel" for u that $F(u)$ is surjection.
- The subobjects of subobjects are subobjects, by axiom3.

Def. (3.2.4.3) [Saturation]. Let X' be a subobject of X, then we let $\widetilde{X'}$ denote the strict subobject of X corresponding to the subobject $F(X')$ of $F(X)$, called the **saturation** of X'. The saturation satisfies:

-
-
-

Proof: Cf.[Jon20]P3. □

Prop. (3.2.4.4). Every morphism $f : X \to Y$ has a kernel and a image in $\mathcal{C}$, and $0 \to \ker f \to X \to \mathrm{Im}\, f \to 0$ is an exact sequence.

Proof: Cf.[Jon20]P3. □

Prop. (3.2.4.5) [HN-Formalism on the Category of Filtered Vector Spaces]. If L/K is a field extension, there is a category $\mathcal{V}\mathrm{ect\,Fil}_{L/K}$ consisting of $(V, \mathrm{Fil}^\bullet)$ where $V \in \mathcal{V}\mathrm{ect}_K$ and $\mathrm{Fil}^\bullet$ is a finite filtration on $V \otimes_K L$. It is an exact category by declaring exact sequences be those induce exact sequences on the gradeds.

The generic fiber functor is $\mathcal{V}\mathrm{ect\,Fil}_{L/K} \to \mathcal{V}\mathrm{ect}_K : (V, \mathrm{Fil}^\bullet) \mapsto V$, and rank is as usual, the **Hodge-Tate degree** is defined to be

$$t_{\text{H-T}}((V, \mathrm{Fil}^\bullet)) = \sum i \dim_L \mathrm{gr}^i(V \otimes_K L).$$

This is a HN-filtration.

Proof: The axioms can be directly checked, noticing that a subfiltration W_n of a filtration V_n is a strict object iff $W_k = W_n \cap V_k$. □

Def. (3.2.4.6) [Slope]. In a HN-formalism, the **slope** is defined to be $\mathrm{slope}(E) = \frac{\deg(E)}{\mathrm{rank}(E)}$.

$\mathcal{E}$ is called **semistable of slope** λ iff $\mathrm{slope}(\mathcal{E}) = \lambda$, and $\mathrm{slope}(\mathcal{E}') \leq \lambda$ for any nonzero strict subobject $\mathcal{E}' \subset \mathcal{E}$.

Prop. (3.2.4.7). If $0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0$ be a short exact sequence in $\mathcal{C}$, then:

- If two of them have the same slope, then so does the third.
- If two of them have different slope, then we know the ordering of these slopes.

Proof: Just notice that the degree and rank are all additive functions. □

Prop. (3.2.4.8). If $\mathcal{E}$ is semistable of slope λ, then for any morphism $u : \mathcal{E} \to \mathcal{E}''$ that $F(u)$ is surjective, $\mu(\mathcal{E}'') \geq \lambda$.

Proof: Take the kernel of $F(u)$ in $\mathcal{A}$, which corresponds to a strict object $\mathcal{E}'$ of $\mathcal{E}$, and $0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0$ is exact, so we can use(3.2.4.19). □

Cor. (3.2.4.9). If $\mathcal{E}, \mathcal{F}$ are semistable of slopes $\lambda > \mu$, then $\mathrm{Hom}_{\mathcal{C}}(\mathcal{E}, \mathcal{F}) = 0$.

Proof: Notice F is faithful. □

Prop. (3.2.4.10) [Semistable Objects]. If $f : \mathcal{E} \to \mathcal{F}$ be a map of vector bundles of the same slope λ, then $\ker(f)$ and $\mathrm{Coker}(f)$ are all semistable vector bundles of slope λ, and if $0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0$ is exact and $\mathcal{E}', \mathcal{E}''$ are semistable of slope λ, then so does $\mathcal{E}$.

Proof: Use $F(f)$ to find the "coimage" A and the "image" B of f, then there is a map from $F(A)$ to $F(B)$ which is an isomorphism, but they have the same degree and rank, thus $A \cong B$ by the last axiom. And the image must has slope λ. Then $\ker(f), \mathrm{Coker}(f)$ all can be defined, and they have the same slope λ by(3.2.4.19).

$\ker(f)$ is semistable because strict subobjects of $\ker(f)$ are also strict subobjects of $\mathcal{E}$(3.2.4.2). And for $\mathrm{Coker}(f)$, if it is not semistable, choose $\overline{\mathcal{F}'} \subset \mathrm{Coker}(f)$ that has slope$> \lambda$, let $\mathcal{F}'$ be the inverse image, then $0 \to \mathrm{Im}(f) \to \mathcal{F}' \to \overline{\mathcal{F}'} \to 0$, then by(3.2.4.19) $\mathrm{slope}(\mathcal{F}') > \lambda$, contradicting the semi-stability of $\mathcal{F}$.

For the extension, $\mathrm{slope}(\mathcal{E}) = \lambda$ by(3.2.4.19), and for a strict subobject $\mathcal{F}$ of $\mathcal{E}$, then we can find F', F'' be strict objects of $\mathcal{E}'$, $\mathcal{E}''$ respectively that there is an exact sequence $0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0$?, which shows $\mathrm{slope}(\mathcal{F}) \leq \lambda$, so $\mathcal{E}$ is semistable. □

Harder-Narasimhan Filtration

Lemma (3.2.4.11) [Final Subobjects of Maximal Slope]. Let X be an object of $\mathcal{C}$ and X', X'' its subobjects of maximal slope, then $X' + X''$ and $X' \cap X''$ are also of maximal slope.

Proof: Cf.[Jon20]P8. □

Def. (3.2.4.12). Given an object X of $\mathcal{C}$, consider the following condition on a nonzero subobject X' of X:

For all subobjects X'' of X properly containing X', $\mu(X'') < \mu(X')$.

Def. (3.2.4.13) [SCSS]. Let X' be a subobject of X, then the following conditions are equivalent:

- X' satisfies condition(3.2.4.12) and is semistable.
- X' satisfies condition(3.2.4.12) and is of maximal slope.
- X' is the final object of X of maximal slope.

If X' satisfies these equivalent conditions and $X' \neq X$, then X is called a **strongly contradicting semi-stability** or SCSS of X.

Proof: Cf.[Jon20]P8. □

Prop. (3.2.4.14). Every object X of $\mathcal{C}$ admits a SCSS.

Def. (3.2.4.15) [Harder-Narasimhan Filtration]. Let $\mathcal{E} \in \mathcal{C}$, a chain of strict objects $0 \subset \mathcal{E}_0 \subsetneq \mathcal{E}_1 \subsetneq \ldots \subsetneq \mathcal{E}_m = \mathcal{E}$ is called a **Harder-Narasimhan filtration** iff each quotient $\mathcal{E}_i/\mathcal{E}_{i-1}$ is semistable of slope λ_i and $\lambda_1 > \lambda_2 > \ldots > \lambda_m$.

Prop. (3.2.4.16) [Faltings]. Every object $\mathcal{E} \in \mathcal{C}$ has a unique functorial Harder-Narasimhan filtration.

Proof: For uniqueness: if there are two filtrations, it suffices to show that $\mathcal{E}'_1 = \mathcal{E}_1$, because notice by(3.2.4.2) $\mathcal{E}_i$ is a strict subobjects of $\mathcal{E}_j$ for any $i < j$, so we finish by induction on the length of the filtration and considering $\mathcal{E}/\mathcal{E}_1$.

For this, firstly $\lambda_1 = \lambda'_1$, suppose the contrary and $\lambda_1 > \lambda'_1$, then $\lambda_1 > \lambda'_i$ for each i, so $\mathrm{Hom}(\mathcal{E}_1, \mathcal{E}'_i/\mathcal{E}'_{i-1}) = 0$ for each i by(3.2.4.32), so by induction $\mathrm{Hom}(\mathcal{E}_1, \mathcal{E}) = 0$, contradiction.

Next by the same reason as in the proof above, $\mathcal{E}_1 \hookrightarrow \mathcal{E}$ has image in $\mathcal{E}'_1$, and the reverse is true for $\mathcal{E}'_1$, so $\mathcal{E}_1 \cong \mathcal{E}'_1$ in $\mathcal{E}$.

For existence: Use induction on $\mathrm{rank}(\mathcal{E})$. If $\mathcal{E}$ is semistable, then we finish. Otherwise, there is a strict subobject $\mathcal{F}$ and $0 \to \mathcal{F} \to \mathcal{E} \to \mathcal{G} \to 0$ that $\mathrm{slope}(\mathcal{F}) > \mathrm{slope}(\mathcal{E})$, so $\mathrm{rank}(\mathcal{F}), \mathrm{rank}(\mathcal{G}) < \mathrm{rank}(\mathcal{E})$. Now by induction $\mathcal{F}$ and $\mathcal{G}$ has HN-filtration, thus by argument as above, we see that $\mathcal{E}$ cannot have strict subobject with slope bigger than slopes appearing in the HN-filtration of $\mathcal{F}, \mathcal{G}$. So if we choose a strict subobject of $\mathcal{E}_1$ of maximal rank among the strict subobjects of maximal slope, we claim the subobjects of $\mathcal{E}/\mathcal{E}_1$ all have slopes smaller than $\mathrm{slope}(\mathcal{E}_1)$: if some $\mathrm{slope}(\mathcal{G}) \geq \mathrm{slope}(\mathcal{E}_1)$, consider its inverse image $\mathcal{G}'$, then $0 \to \mathcal{E}_1 \to \mathcal{G}' \to \mathcal{G} \to 0$, thus $\mathrm{slope}(\mathcal{G}') \geq \mathrm{slope}(\mathcal{E}_1)$ and has bigger rank, contradiction. So we can use induction on $\mathcal{E}/\mathcal{E}_1$. □

HN-Polygons

Harder-Narasimhan Categories

This subsection is unnecessary. Main references are [Harder-Narasimhan Categories]

Def. (3.2.4.17) [Harder-Narasimhan Categories]. A **Harder-Narasimhan category** consists of a geometric exact category $(\mathcal{C}, \mathcal{E}, A)$(3.7.2.4) consists of

1. A function $\deg : Ob(\mathcal{C}_A) \to \mathbb{R}$ that is additive w.r.t short exact sequences in $\mathcal{E}_A$.
2. A function rank: $Ob(\mathcal{C}) \to \mathbb{N}$ on $\mathcal{A}$ that is additive w.r.t short exact sequences in $\mathcal{E}$, $\operatorname{rank}(X) = 0 \iff X = 0$.

The **slope** of a nonzero object X is defined to be $\mu(X) = \deg(X)/\operatorname{rank} X$. And $\mathcal{X}$ is called **semistable of slope** λ iff $\mu(X) = \lambda$, and $\mu(X') \le \lambda$ for any nonzero geometric subobject $X' \subset X$.

And the category satisfies the following axiom:

- **NH**: For any nonzero geometric object X, there exists a geometric subobject $X_{des} \subset X$ that
$$\mu(X_{des}) = \sup\{\mu(Y) | Y \text{is a non-zero geometric subobject of } X\}$$
and moreover, any nonzero geometric subobject Z of X that $\mu(Z) = \mu(X_{des})$ is a geometric subobject of X_{des}.

Notice that X_{des} is semistable and unique up to isomorphisms, called the **destablization** of X.

Cor. (3.2.4.18). A geometric object of rank 1 is semistable.

Proof: For any nonzero geometric subobject $X' \subset X$, $\operatorname{rank} X' = \operatorname{rank} X = 1$, so $\operatorname{rank} X/X' = 0$ hence $X/X' = 0$ and $X' \cong X$. Then clearly $\mu(X') = \mu(X)$ and X is semistable. □

Cor. (3.2.4.19). If $0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0$ be a short exact sequence in $\mathcal{E}_A$, then:

- If two of them have the same slope, then so does the third.
- If two of them have different slope, then we know the ordering of these slopes.

Proof: Just notice that the degree and rank are all additive functions. □

Prop. (3.2.4.20) [Abelian Categories as Harder-Narasimhan Categories]. Let $(\mathcal{C}, \mathcal{E}, A)$ be a geometric exact category with functions deg and rank, and $\mathcal{C}$ is an Abelian category, $\mathcal{E}$ is the set of short exact sequences, then $(\mathcal{C}, \mathcal{E}, A, \deg, \operatorname{rank})$ is a Harder-Narasimhan category.

Proof: We need to check HN: induct on $\operatorname{rank} X$: The condition is clear when X is semistable, in particular when $\operatorname{rank} X = 1$(3.2.4.18), and when X is not semistable, let Y be a geometric subobject of X that $\mu(X') > \mu(X)$ and $\operatorname{rank} X'$ is maximal, then by induction hypothesis, there is a destablization Y_{des}, and we want to show X'_{des} is just X_{des}: Let Y be a nonzero geometric subobject of X. If Y is a geometric subobject of X', then $\mu(Y) \le \mu(X'_{des})$. If Y is not a geometric subobject of X', then $Y + X'$ is greater than X', and $\operatorname{rank}(Y + X') > \operatorname{rank} X'$, so by maximality, $\mu(Y + X') \le \mu(X) < \mu(X')$. Moreover, there is an exact sequence

$$0 \to Y \cap X' \to Y \oplus X' \to Y + X' \to 0$$

so

$$\begin{aligned}
\deg Y &= \deg(Y \cap X') + \deg(Y + X') - \deg(X') \\
&< \mu(X'_{des}) \operatorname{rank}(Y \cap X') + \mu(X')(\operatorname{rank}(Y + X') - \operatorname{rank}(X')) \\
&\le \mu(X'_{des})(\operatorname{rank}(Y \cap X') + \operatorname{rank}(Y + X') - \operatorname{rank}(X')) \\
&= \mu(X'_{des}) \operatorname{rank}(Y).
\end{aligned}$$

In particular, if $\mu(Y) = \mu(X'_{des})$, then Y must be a geometric subobject of X' hence a geometric subobject of X'_{des}. so HN holds for X. □

Def. (3.2.4.21) [Harder-Narasimhan Filtration]. Let $\mathcal{X}$ be a nonzero geometric object, a chain of admissible monomorphisms $0 = X_0 \to X_1 \to \ldots \to X_m = X$ is called a **Harder-Narasimhan filtration** of X iff each quotient $\mathcal{E}_i/\mathcal{E}_{i-1}$ are all semistable of slope λ_i and $\lambda_1 > \lambda_2 > \ldots > \lambda_m$, called the slopes associated to X.

Prop. (3.2.4.22) [Harder-Narasimhan Filtrations Exist]. Let $(\mathcal{C}, \mathcal{E}, A, \deg, \mathrm{rank})$ be a Harder-Narasimhan category, then the Harder-Narasimhan filtration exists for any nonzero geometric object X.

Proof: We induct on the rank of X: if X is semistable, this is clear, so we are done in the case $\mathrm{rank}\, X = 1$ by(3.2.4.18). We choose $X_1 = X_{des}$, then X_{des} is semistable and $X' = X/X_{des} \neq 0$. Now $\mathrm{rank}\, X' < \mathrm{rank}\, X$, we can apply induction hypothesis to obtain a HN-filtration $0 = X'_1 \xrightarrow{f'_1} X'_2 \to \ldots \to X'_{n-1} \xrightarrow{f'_{n-1}} X'_n = X'$. Now let $X_i = X \times_{X'} X'_i$(exists by Ex6(3.7.2.1)), then $X_1 = X_{des}$. Since $X \to X'$ is an admissible epimorphism, $X_i \to X'_i$ are also admissible epimorphisms, and there are Cartesian diagrams

$$\begin{array}{ccc} X_i & \xrightarrow{f_i} & X_{i+1} \\ \downarrow{\scriptstyle \pi_i} & & \downarrow{\scriptstyle \pi_{i+1}} \\ X'_i & \xrightarrow{f'_i} & X'_{i+1} \end{array}$$

and f_i are monomorphisms, so f_i is the kernel of $X_{i+1} \to X'_{i+1}/X'_i$, which is an admissible epimorphism, so f_i is admissible. There are natural isomorphisms $\varphi_i : X_{i+1}/X_i \to X'_{i+1}/X'_i$(**?** Cf.[Harder-Narasimhan Filtrations]), and axiom A6(3.7.2.4) shows φ is compatible with the geometric structure, so X_{i+1}/X_i are all semistable, and notice

$$\mu(X_2/X_1) = \frac{\mathrm{rank}(X_2)\mu(X_2) - \mathrm{rank}(X_1)\mu(X_1)}{\mathrm{rank}(X_2) - \mathrm{rank}(X_1)} < \mu(X_1)$$

so $0 \to X_1 \to X_2 \to \ldots \to X_m = X$ is a HN-filtration for X. □

Prop. (3.2.4.23) [HN-Formalism for Filtrations in an Abelian Category]. Let $\mathcal{C}$ be an Abelian category and $\mathcal{E}$ the set of all short exact sequences in $\mathcal{C}$, $A(X)$ is the set of isomorphism classes of filtrations on X, then $(\mathcal{C}, \mathcal{E}, A)$ is a geometric exact category, by(3.7.2.8), given any additive rank function on $\mathcal{C}$, and define a degree function for any filtration $\mathcal{F} = (X_\lambda)$ as

$$\deg(\mathcal{F}) = \int_{\mathbb{R}} \lambda(d\,\mathrm{rank}\, X_\lambda),$$

then deg is additive w.r.t short exact sequences of filtrations, and $(\mathcal{C}, \mathcal{E}, A, \deg, \mathrm{rank})$ is a Harder-Narasimhan filtration.

Then a filtration is semistable iff it has only one jump. Then the HN-filtration of a filtration is just the jump set ordered decreasingly.

Prop. (3.2.4.24) [HN Formalism for Vector Spaces with Two Norms]. The vector spaces with two norms is a Harder-Narasimhan category, Cf.[Harder-Narasimhan Filtrations, P9].

Prop. (3.2.4.25) [HN-Formalism for Torsion-Free Sheaves]. The category of torsion-free sheaves on a geometrically normal projective variety of dimension $d \geq 1$ over a field K is a Harder-Narasimhan category. Cf.[Harder-Narasimhan Filtrations, P10].

Prop. (3.2.4.26) [HH-Formalism for Hermitian Adelic Bundle]. Let K be a number field, then the category of Hermitian adelic bundle over K is a Harder-Narasimhan category. Cf.[Harder-Narasimhan Filtrations, P10].

Prop. (3.2.4.27) [HN Formalism for Filtered Vector Spaces Field]. If L/K is a field extension, there is a category $VectFil_{L/K}$ consisting of (V, Fil) where V is a K-vector space and Fil is a (finite) filtration of vectors spaces over L on $V \otimes_K L$(3.2.3.1). It is a geometric exact category by(3.7.2.8) and a Harder-Narasimhan category by(3.2.4.20).

The rank is as usual, and the degree is defined to be

$$\deg((V, Fil)) = \int_{\mathbb{R}} \lambda(d\,\mathrm{rank}\, V_\lambda)\text{(3.2.4.23)}$$

<u>**Slope Inequalities and Functoriality**</u>

Def. (3.2.4.28) [Additional Conditions]. In this subsubsection, we assume the Harder-Narasimhan filtration satisfies the following axiom that is

Def. (3.2.4.29) [Slope Inequality Axioms]. To show the functoriality of the Harder-Narasimhan filtration, we need the following axiom:

- (SI): If X_1, X_2 are two semistable geometric objects that $\mu(X_1) > \mu(X_2)$, then there are no non-zero morphism from X_1 to X_2 compatible with the geometric structures(3.7.2.5).

Prop. (3.2.4.30). If SI holds, then

Prop. (3.2.4.31). If $\mathcal{E}$ is semistable of slope λ, then for any morphism $u : \mathcal{E} \to \mathcal{E}''$ that $F(u)$ is an isomorphism, slope$(\mathcal{E}'') \geq \lambda$.

Proof: Take the kernel of $F(u)$ in $\mathcal{A}$, which corresponds to a strict object $\mathcal{E}'$ of $\mathcal{E}$, and $0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0$ is exact, so we can use(3.2.4.19). □

Cor. (3.2.4.32). If $\mathcal{E}, \mathcal{F}$ are semistable of slopes $\lambda > \mu$, then $\mathrm{Hom}_{\mathfrak{C}}(\mathcal{E}, \mathcal{F}) = 0$.

Prop. (3.2.4.33) [Semistable Vector Bundles Form a Weak Serre Subcategory]. If $f : \mathcal{E} \to \mathcal{F}$ be a map of vector bundles of the same slope λ, then $\ker(f)$ and $\mathrm{Coker}(f)$ are all semistable vector bundles of slope λ, and if $0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0$ is exact and $\mathcal{E}', \mathcal{E}''$ are semistable of slope λ, then so does $\mathcal{E}$.

Proof: Use $F(f)$ to find the "coimage" A and the "image" B of f, then there is a map from $F(A)$ to $F(B)$ which is an isomorphism, but they have the same degree and rank, thus $A \cong B$ by the last axiom. And the image must has slope λ. Then $\ker(f), \mathrm{Coker}(f)$ all can be defined, and they have the same slope λ by(3.2.4.19).

$\ker(f)$ is semistable because strict subobjects of $\ker(f)$ are also strict subobjects of $\mathcal{E}$(3.2.4.2). And for $\mathrm{Coker}(f)$, if it is not semistable, choose $\overline{\mathcal{F}'} \subset \mathrm{Coker}(f)$ that has slope$> \lambda$, let $\mathcal{F}'$ be the inverse image, then $0 \to \mathrm{Im}(f) \to \mathcal{F}' \to \overline{\mathcal{F}'} \to 0$, then by(3.2.4.19) slope$(\mathcal{F}') > \lambda$, contradicting the semi-stability of $\mathcal{F}$.

For the extension, slope$(\mathcal{E}) = \lambda$ by(3.2.4.19), and for a strict subobject $\mathcal{F}$ of $\mathcal{E}$, then we can find F', F'' be strict objects of $\mathcal{E}'$, $\mathcal{E}''$ respectively that there is an exact sequence $0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0$?, which shows slope$(\mathcal{F}) \leq \lambda$, so $\mathcal{E}$ is semistable. □

3.3 Topology I

Main references are [Mun00], [Mor19], [?].

1 Basics

Def. (3.3.1.1) [Topologies].

Def. (3.3.1.2) [Continuous Functions].

Def. (3.3.1.3) [Semicontinuous Functions]. A function from $X \to [-\infty, \infty]$ is called **upper semicontinuous** iff $f^{-1}([-\infty, a))$ are all open. It is called **lower semicontinuous** iff $f^{-1}((a, \infty])$ are all open.

Def. (3.3.1.4) [Separable Topological Spaces]. A topological space is called **separable** if it has a countable dense subset.

Def. (3.3.1.5) [Product Topology]. Arbitrary product exists in the category of topological spaces. It is constructed as follows: for a family of topology spaces X_i indexed over an index set I, the product $\prod_I X_i$ is the set-theoretic product endowed with the topology generated by the basis $\pi_i^{-1}(U_i)$ for U_i open in X_i.

Prop. (3.3.1.6) [Limits and Colimits]. Arbitrary limits and colimits exist in the category of topological spaces. The limits is given as a subspace of the product topology, and the colimits $X = \operatorname{colim} X_i$ is given a topology that $U \subset X$ is open iff $U \cap X_i$ is open for each i.

Prop. (3.3.1.7) [Pullback Space]. Let $E \to X$ and $f : X' \to X$ be maps of spaces, then there is a pullback map $f^*E = E \times_X X' \to X'$, called the **pullback space**.

Def. (3.3.1.8) [Quotient Topology]. Let $f : X \to Y$ be a surjective map of spaces, and X has a topology, then we can define a **quotient topology** on Y that $U \subset Y$ is open iff $f^{-1}(U)$ is open in X.. It has the universal property that any continuous map $X \to Z$ that factors through f set-theoretically factors through f as a continuous map.

Such a map is called a **quotient map**.

Prop. (3.3.1.9). A surjective open map pr is a quotient map.

Proof: It is clearly that a subset U is open iff $\mathrm{pr}^{-1}(U)$ is open. □

Def. (3.3.1.10) [Glueing Space]. Let $A \subset X$ and $f : A \to Y$, then we have the glueing space $Y \coprod_f X$.

Def. (3.3.1.11) [Mapping Cylinder]. Let $f : X \to Y$ be a map, then we define the **mapping cylinder** $M(f) = Y \coprod_f X \times I$, where $X \times \{0\} \subset X \times I$ mapsto Y by f.

Def. (3.3.1.12) [Cone]. For $X \in \mathcal{T}\mathrm{op}$, define the **cone over** X to be the space $C(X) = (X \times \mathbb{I})/(X \times \{1\})$. Notice that $C(\varnothing) = \mathrm{pt}$.

Def. (3.3.1.13) [Mapping Cone]. Let $f : X \to Y$ be a map, then we define the **mapping cone** $C(f) = M(f)/X \times \{1\}$.

Lemma (3.3.1.14). If $f : X \to Y$ is a surjective continuous map that $f(E) \neq Y$ for any proper closed subspace of X, then for any $U \subset X$ open, $f(U) \subset \overline{Y \backslash f(X \backslash U)}$.

Proof: Take $y \in f(U)$ and a nbhd V of y in Y, we show that V intersect $Y\backslash f(X\backslash U)$: $W = U \cap f^{-1}(V)$ is nonempty, thus $f(X\backslash W) \neq Y$, take $y' \in Y\backslash f(X\backslash W)$, then it is clear $y' \in Y\backslash f(X\backslash U)$, and $y' \in V$. □

Def. (3.3.1.15) [Locally Closed Subset]. A subset Z of X is called **locally closed** if for any $z \in Z$, there is a nbhd U of z in X that $U \cap Z$ is closed in Z. Equivalently, a locally closed subset is the intersection of an open subset with a closed subset.

Proof: An intersection of an open subset and a closed subset is clearly locally closed. Conversely, if Z is locally closed, we choose for each $z \in Z$ a nbhd U_z that $U_z \cap Z$ is closed in U_z, then we can show $Z = \overline{Z} \cap \bigcup_z U_z$. This is because if $x \in \overline{Z} \cap \bigcup_z U_z$, then $x \in U_z$ for some z, and also $x \in \overline{Z}$, thus x is in Z. □

Filter Langrange

Def. (3.3.1.16) [Convergence and Filter]. For a filter $\mathcal{F}$ on a topological space, $\mathcal{F}$ **converges** to a point y iff any open set containing y is in $\mathcal{F}$.

If X is a set and Y is a topological space and $X \to Y$ is a function, then $y \in Y$ is a **$\mathcal{F}$-limit of f** if $f_*\mathcal{F}$ converges to Y.

Prop. (3.3.1.17) [Ultrafilter Convergence Theorem]. Let X, Y be a topological space, then:

1. Y is compact iff any ultrafilter on Y has a limit point.
2. Y is Hausdorff iff any ultrafilter on Y has at most one limit point.
3. a function $f : X \to Y$ is continuous iff for any filter on X converging to x, the filter $f_*(\mathcal{F})$ converges to y.

Proof:

1. If Y is compact but every point is not a limit point, then for any x, there is an open set U_x that $U_x \notin \mathcal{F}$, but then f.m. of them covers Y, which is in $\mathcal{F}$, so one of them must be in $\mathcal{F}$ by(1.2.10.7), contradiction.
   Conversely, if $\cup_I U_i = X$ but no finite union of them cover X, then $X - U_i$ satisfies the finite intersection property, so there is an ultrafilter containing all $X - U_i$ by(1.2.10.4) and(1.2.10.5). Then clearly any point x is not a limit point of $\mathcal{F}$.
2. If Y is Hausdorff and x, y are both limit point of a filter $\mathcal{F}$, then there are two non-intersecting nbhd of them in $\mathcal{F}$, so its intersection $\varnothing \in \mathcal{F}$, contradiction.
   Conversely, if x, y are two point that their nbhds both intersect, then their nbhds together satisfies the finite intersection property, so there is an ultrafilter containing all of them, by(1.2.10.4) and(1.2.10.5), thus converging to both x and y.
3. This is an easy consequence considering the filter of all the nbhd containing x.

□

Connected Components

Def. (3.3.1.18) [Connectedness]. A space X is called **connected** if it satisfies: for any open subset U, V of X that $U \cup V = X$ and $U \cap V = \varnothing$, either $U = \varnothing$ or $V = \varnothing$.

X is called **locally connected** if there is a basis of X consisting of connected open subsets of X.

Def. (3.3.1.19) [Path-Connectedness]. A space X is called **path-connected** if any two points of X can be connected by an arc.

X is called **locally path-connected** if there is a basis of X consisting of path-connected open subsets of X.

Prop. (3.3.1.20). If X is an ordered set with the least upper bound property and satisfies: for any $x < y \in X$, there exists $z \in X$ s.t. $x < z < y$. Then X is connected, so are intervals and rays in X.

Proof: Let Y be an interval or ray in X. Suppose for contradiction $Y = A \coprod B$, where A, B are open and non-empty in Y. Choose $a \in A, b \in B$, then $[a, b] \subset Y$. Let $A_0 = A \cap [a, b]$ and $B_0 = B \cap [a, b]$, and $c = \sup A_0 \in [a, b]$.

Then $c \notin B_0$: If $c \in B_0$, then $c \neq a$, and because B_0 is open, there exists some $a \leq d < c$ s.t. $(d, c] \subset B_0$. So d is a smaller upper bound for A_0, contradiction.

And also $c \notin A_0$: If $c \in A_0$, then $c \neq b$, and because A_0 is open, there exists some $c < e \leq b$ s.t. $[c, e) \subset A_0$. Then by hypothesis, there exists $z \in (c, e) \subset A_0$, contradicting the fact c is an upper bound for A_0.

Then we derived a contradiction that $c \notin Y$, which proves Y is connected. □

Def. (3.3.1.21) [Connected Components]. In a topological space X, if $x \in X$, the **connected component** of x is the maximal connected subspace of X containing x. The **path-connected component** of x is the maximal path-connected subspace of X containing x

Prop. (3.3.1.22).

- Any connected component of X is closed.
- If X is locally connected, then any connected component of X is clopen.
- If X is locally path-connected, then any path-connected component of X is open, and any connected component is also open.

Prop. (3.3.1.23) [Clopen Subsets and Connected Components]. Let X be a normal topological space and $x \in X$, then the connected component of X containing x is the intersection of clopen subsets containing x, denoted by A.

Proof: Assume A splits into two components B, D. Since A is closed, B and D are both closed, because X is normal there are disjoint open neighborhoods U and V around B and D, respectively. The open sets U and V cover the intersection of all clopen neighborhoods of A, so cause X is compact, there must exist a finite number of clopen sets around A, say $A_1, \ldots, A_n$ such that $U \cup V$ covers $K = \bigcap_1^n A_i$.

Note that K is clopen. We can assume that $x \in U$. It is not difficult to see that $K \cap U$ is clopen and does not contain all of A, contradicting the definition of A. □

Cor. (3.3.1.24). For a compact Hausdorff topological space X and a point $x \in X$, the connected component of X containing x is the intersection of all compact open neighborhoods of x, because X is normal(3.3.7.6).

Def. (3.3.1.25) [Totally Disconnected Space]. A space is called **totally disconnected** iff any connected subset of X contains only one point.

Prop. (3.3.1.26). A subspace of a totally disconnected space is totally disconnected, because totally disconnected is equivalent to the only connected subsets are pt sets.

Extremally Disconnected Space

Def. (3.3.1.27) [Extremally Disconnected Space]. A topological space S is called **extremally disconnected** if the closure of any open subset of X is open.

Prop. (3.3.1.28). Let X be an extremally disconnected space, If U, V are disjoint open subsets of X, then $\overline{U}, \overline{V}$

Proof: Because $V \cap \overline{U} = \varnothing$, thus similarly $\overline{V} \cap \overline{U} = \varnothing$. □

Lemma (3.3.1.29). Let $f : X \to Y$ be a continuous surjective map of compact Hausdorff spaces that Y is extremally disconnected and $f(Z) \neq Y$ for any proper closed subspace of X, then f is a homeomorphism.

Proof: By(3.3.2.11) it suffices to show that f is injective. Suppose $f(x) = f(x') = y$, then choose disjoint nbhd U, U' of x, x', and $T = f(X \backslash U), T' = f(X \backslash U')$ closed in Y, then $Y = T \cup T'$ and y is contained in the closure of $Y \backslash T$ and $Y \backslash T'$ by(3.3.1.14), but this contradicts(3.3.1.28). □

Prop. (3.3.1.30)[Projective Spaces]. Compact Hausdorff extremally disconnected spaces are exactly the projective objects in the category of compact Hausdorff spaces.

Proof: Assume X is projective, let $U \subset X$ be open, and the complement by Z, then consider the surjection $\overline{U} \coprod Z \to X$, and let σ be the projection, then $\sigma(U) \subset \overline{U}$, thus $\sigma^{-1}(\overline{U}) = \overline{U}$, and it is open.

Conversely, if X is extremally disconnected, then by(3.3.2.13), there is a compact subset $E \subset Y$ that $f(E) = X$ and $f(E') \neq X$ for all closed subspace $E' \subset E$. Then(3.3.1.29) says $f|_E$ is a homeomorphism, and the inverse of it gives a desired section. □

Prop. (3.3.1.31) [Gleason]. In an extremally disconnected space X, a convergent sequence is eventually constant. In particular, $\mathbb{Z}_p$ is a profinite group that is not extremally disconnected.

Proof: Cf.[Projective Topological Spaces] □

2 Compactness

Def. (3.3.2.1) [Quasi-Compact Space]. A topological space is called **compact** or **quasi-compact** iff any open covering of it has a finite sub-covering. A subspace of a topological space is called **precompact** if its closure is compact.

Def. (3.3.2.2)[Quasi-Compact Morphism]. A map of topological spaces is called a **quasi-compact morphism** if the inverse image of any quasi-compact open subset is quasi-compact open.

Prop. (3.3.2.3) [Alexander Subbase Theorem]. A topological space is compact iff the closed subsets has the finite intersection property(1.2.10.3). In fact, it suffices to show that the family of complements of a subbasis of open sets has the finite intersection property.

Proof: Cf.[Sta]08ZP. □

Prop. (3.3.2.4). Let X be a totally ordered set with the least upper bound property, then each closed interval of X is compact in the order topology. In particular, this applies to a complete totally ordered set X(1.2.3.19).

Proof: Let $a < b$ and $\mathcal{U}$ a covering of $[a, b]$. We first show that for any $x \in [a, b)$, there exists some $x < y \leq b$ that $[x, y]$ can be covered by at most two elements of $\mathcal{U}$: If x has an immediate successor, then take y to be it. If x has no immediate successor, choose an element U of $\mathcal{U}$ containing x, then U contains some $[x, c)$. Choose $y \in [x, c)$, then $[x, y]$ is covered by a single element of $\mathcal{U}$.

Now let C be the set of points $y \in (a, b]$ that $[a, y]$ can be covered by f.m. elements of $\mathcal{U}$. We showed before this set is non-empty. Let c be the least upper bound of C, then $a < c \leq b$.

Next, we show $c \in C$: take an element U of $\mathcal{U}$ containing c, then U contains some $(d, c]$. There must be some element of C lying in the interval $(d, c]$, otherwise d is an upper bound of C. Then $[a, y]$ is covered by f.m. elements of $\mathcal{U}$, so $c \in C$.

Finally, we show $c = b$, but this is because otherwise we can find $c < y \leq b$ that $[c, y]$ is covered by 2 elements, thus $y \in C$, so $y \leq c$, contradiction. □

Prop. (3.3.2.5) [Tychonoff]. An arbitrary direct product of compact topological spaces is compact.

Proof: We prove the finite intersection property. If A is a family of subsets that any finite intersection of closure of them is nonempty, then consider a maximal family $\mathfrak{D}$ of subsets containing A that any finite intersection of closures of them is nonempty, it exists by Zorn's lemma. Consider the projection of $\mathfrak{D}$ onto a coordinate, then by Hypothesis, it has an intersection x_α. Now we want to show $x = (x_\alpha)$ belongs to each $D \in \mathfrak{D}$.

If U_β is any subbasis element containing x, then U_β intersect each $\mathfrak{D}$ because $x_\beta \in \pi_\beta(D)$, so it is in $\mathfrak{D}$, by maximality of $\mathfrak{D}$. So the finite intersections are also in $\mathfrak{D}$, so all local basis of x are in $\mathfrak{D}$. This means that local basis intersect each element of $\mathfrak{D}$, that is, all closure of elements in $\mathfrak{D}$ contains x. □

Def. (3.3.2.6) [Sequentially Compact]. A subset A in a space X is called **sequentially compact** iff any sequence of points in A has a convergent subsequence in X. It is called **self sequentially compact** if it is sequentially compact in itself.

Prop. (3.3.2.7). $f : X \to Y$, X is compact and Y is Hausdorff, then for a descending chain Y_i of closed subsets of X,

$$f(\bigcap_n Y_n) = \bigcap_n f(Y_n).$$

Proof: The left side is compact, so if $x \notin f(\bigcap_n Y_n)$, there is a closed subsets $x \in T$ that $T \cap f(\bigcap_n Y_n)$=0, so $f^{-1}(T) \bigcap_n Y_n = 0$, so $f^{-1}(T) \cap Y_n = 0$ for some n, hence $x \notin f(Y_n)$. □

Prop. (3.3.2.8) [Fixed Point Theorem]. If X is a compact metric space M, T is a continuous map $X \to X$ that $d(x, y) < d(Tx, Ty)$, then T has a unique fixed point in X.

Proof: The uniqueness is obvious, for the existence, first notice T is obviously continuous, so consider $d(x, Tx)$, this is a continuous function on M, so it contains a minimum value, if it not 0, then $d(Tx, T^2x) < d(x, Tx)$, which is a contradiction. □

Def. (3.3.2.9) [Proper Map]. A **proper map** is a continuous map s.t. the inverse image of compact subsets are compact.

Prop. (3.3.2.10). If X is compact and Y is Hausdorff, then a continuous map $f : X \to Y$ is proper.

Cor. (3.3.2.11). A continuous bijective map from a compact space to a Hausdorff space is a homeomorphism.

Prop. (3.3.2.12) [Proper Continuous Maps Closed]. Let $f : X \to Y$ be a proper continuous map with Y locally compact Hausdorff, then f is a closed map.

Proof: Let $K \subset X$ closed, and $y \in \overline{f(K)}$. Choose precompact open nbhd U of y, then $f^{-1}(\overline{U})$ is compact in X, so $f(K \cap f^{-1}(\overline{U})) = f(K) \cap \overline{U}$ is compact and thus closed in Y. Then $y \in f(K)$, and $f(K)$ is closed. □

Lemma (3.3.2.13). Let $f : X \to Y$ be a continuous map of compact Hausdorff spaces, then there exists a smallest closed subset E of X that $f(E) = Y$.

Proof: Use Zorn's lemma, noticing that the intersection of a chain of possible E_is also maps to Y, by the intersection property(3.3.2.3). □

Stone-Čech Compactification

Def. (3.3.2.14) [Stone-Čech Compactification]. The **Stone-Čech Compactification** β is defined to be a functor from the category of sets to the category of compact Hausdorff space that is left adjoint to the forgetful functor.

The construction of $\beta(X)$ is as follows: βX =the set of all ultrafilters on X, and the topology is generate by $U_A = \{\mathcal{F} | A \in \mathcal{F}\}$ as a basis of clopen subsets. For a map $f : X \to Y$, the map $\beta X \to \beta Y$ is given by f_*.

Proof: First βX is a compact Hausdorff space: it is compact because if there are sets A_i that any ultrafilter contains at least one of them, then f.m. of them must cover X, otherwise $X - A_i$ satisfies the finite intersection property thus is contained in some ultrafilter, by(1.2.10.4) and(1.2.10.5), contradiction, Then by(1.2.10.7) shows that any ultrafilter contains one of them. It is Hausdorff because for any two different ultrafilter, there must be an A that $A \in \mathcal{F}_1$ and $X - A \in \mathcal{F}_2$. f_* is continuous because $f^{-1}(U_A) = U_{f^{-1}(A)}$.

Now for any map $f : X \to Y$ where Y is a topological space, map an ultrafilter $\mathcal{F}$ to the unique limit point of $f_*\mathcal{F}$ in Y(existence and uniqueness by(3.3.1.17)). This map is continuous from βX to Y because for any open set $V \subset Y$, $U_{f^{-1}(V)}$ is mapped into V. And for any $\beta X \to Y$ continuous, consider $X \to Y$ which maps x to the image of the principle ultrafilter $\mathcal{F}_x$ in Y.

This two map are mutually converses to each other, first for a $f : X \to Y$, $X \to \beta X \to Y$ is f itself, because the pushout of the principle ultrafilter clearly converges to $f(x)$. And for a $\beta X \to Y$, if $\mathcal{F}$ doesn't map to $\lim f_*\mathcal{F}$ but mapped to some t, then by definition, there is a nbhd U of t that $f^{-1}(U) \notin \mathcal{F}$, but by continuity, there is a $\mathcal{F} \in U_B$ mapped into U. But then $B \in f^{-1}(U)$, otherwise if $x \in B - f^{-1}(U)$, then $\mathcal{F}_x$ is mapped to U, contradiction, so $f^{-1}(U)$ containing B is also in $\mathcal{F}$, contradiction. □

Lemma (3.3.2.15). In fact, the spaces in the image of the Stone-Čech compactification are all profinite spaces.

Proof: As shown before, for any two different ultrafilter, there must be an A that $A \in \mathcal{F}_1$ and $X - A \in \mathcal{F}_2$, U_A is open and closed. □

Prop. (3.3.2.16) [Stone Representation Theorem]. The Stone-Čech compactification β gives an equivalent of categories from the category of Boolean algebras to the category of profinite spaces.

Proof: βB is a profinite space by lemma(3.3.2.15), and B can be recovered from βB as the Boolean algebra of all clopen subsets of βB, because βB is compact. This is a inverse isomorphism because**?**.
□

Prop. (3.3.2.17). The Stone-Čech compactification of a set βS_0 is extremally disconnected.

Proof: We check condition(3.3.1.30): For any surjection $S' \to \beta S_0$, we may take a lift $S_0 \to S$ arbitrarily, then by definition there is a morphism $\beta S_0 \to S'$ extending this morphism. It is a section by the universal property. □

Locally Compact Space

Def. (3.3.2.18) [Locally Compact Space]. A Hausdorff space is called **locally compact** if for any point x, there is a compact subset containing a nbhd of x.

Prop. (3.3.2.19). If X is Hausdorff, then X is locally compact iff for any $x \in X$ and $x \in U$ open, there exists a precompact nbhd V that $x \in V \subset \overline{V} \subset U$.

Proof: One direction is trivial. For the other, for any $x \in X$ and a nbhd U of x, let U_0 be a precompact nbhd of X, then $\overline{U}_0 \backslash U$ is closed thus compact and disjoint from x. Because X is Hausdorff, we can find a nbhd V' of x that $\overline{V'}$ is disjoint from $\overline{U}_0 \backslash U$. Now let $V = V' \cap U_0$, then $\overline{V} \subset \overline{U}_0$ is closed thus compact, and $\overline{V} \subset \overline{V'} \cap \overline{U}_0 \subset U$. □

Cor. (3.3.2.20). Open subsets and closed subsets of a locally compact Hausdorff space X is locally compact Hausdorff.

Proof: If $A \subset X$ is closed and $x \in A$, then there exists a precompact nbhd U of $x \in X$, then $A \cap \overline{U}$ is closed in $\overline{U}$ thus compact, and contains the nbhd $U \cap A$ of $x \in A$, so A is locally compact.

If $A \subset X$ is open, $x \in A$, let $x \in U \subset A$, and U open in X, then we can apply(3.3.2.19) to find a precompact nbhd V that $x \in V \subset \overline{V} \subset U$, so A is locally compact. □

Prop. (3.3.2.21) [One-Point Compactification]. Let X be a space, then X is locally compact Hausdorff iff there exists a compact Hausdorff space Y containing X s.t. $Y \backslash X$ is a single point. Moreover, in this case, Y is unique up to homeomorphisms, called the **one-point compactification** of X.

Proof: Cf.[Mun00]P183. □

Cor. (3.3.2.22). A space X is homeomorphic to an open subset of a compact open subspace iff it is locally compact Hausdorff, by(3.3.2.21) and(3.3.2.20).

Prop. (3.3.2.23). A locally compact second countable Hausdorff space X has a countable basis consisting of precompact open subsets. In particular, X is σ-compact.

Proof: Choose a countable basis $\{U_n\}$ of X. For any $x \in X$ and any nbhd U of x, there exists a precompact $U_x \subset U$ containing x by(3.3.2.19). Then for some $n(x)$, $U_{n(x)} \subset U_x$ containing x, so $U_{n(x)}$ is precompact. Thus the set of U_n that is precompact forms a countable basis of X. □

Prop. (3.3.2.24). If $f : X \to Y$ is a quotient map and Z is locally compact, then $X \times Z \to Y \times Z$ is also a quotient map.

Proof: Consider W as $Y \times Z$ in the quotient map topology, then $X \times Z \to W$ is continuous, which means $X \to \mathrm{Map}(Z, W)$ is continuous. But then $Y \to \mathrm{Map}(Z, W)$ is continuous because Y is a quotient map. Applying(3.3.3.7), we see $Y \times Z \to W$ is continuous. $W \to Y \times Z$ is continuous by quotient map hypothesis, so $Y \times Z \cong W$. □

Compactly Generated Spaces

Def. (3.3.2.25) [Compactly Generated Spaces]. A **compactly generated space** is a space that is the colimit of its compact Hausdorff subspaces. The category of compactly generated spaces is denoted by $\mathcal{CG}$.

Prop. (3.3.2.26). For $X \in \mathcal{CG}$ and $Y \in \mathcal{T}op$, a set-theoretical map $f : X \to Y$ is continuous iff for any $K \in \mathcal{T}op$ compact Hausdorff and a map $i : K \to X$, the composite map $K \to Y$ is continuous.

Prop. (3.3.2.27) [Compact Generating Functor]. There is a **compact generating functor** $(-)_c : \mathcal{T}op \to \mathcal{CG}$ right adjoint to the inclusion functor.

Proof: k is constructed by $X \mapsto \varinjlim_{K\subset X, K \text{ compact}} K$. Notice $X_c = X$ set-theoretically. It is easy to verify that if $Y \in \mathcal{CG}$ and $Y \to X$ is continuous, then the set-theoretical map $Y \to X_c$ is also continuous. So $(-)_c$ is right adjoint to the inclusion functor. □

Cor. (3.3.2.28). $\mathcal{CG}$ is both complete and cocomplete, and the colimits coincide with colimits in $\mathcal{T}op$.

Cor. (3.3.2.29). $\mathcal{CG}$ is Cartesian closed(3.1.5.7).

Cor. (3.3.2.30). The right adjoint to the Cartesian product is the compactification of the mapping space functor(3.3.3.1), by(3.3.3.6) and(3.3.2.27).

Prop. (3.3.2.31). Locally compact Hausdorff topological spaces are compactly generated.

Proof: For $X \in \mathcal{T}op$, if $Z \subset X$ satisfies $Z \cap K$ is closed for any compact Hausdorff subset $K \subset X$, for any $x \in X$, there exists a precompact nbhd U of $x \in X$, so $Z \cap \overline{U}$ is closed, and $Z \cap U$ is closed in U. Thus Z is closed in X. □

Prop. (3.3.2.32). Quotients and closed subspaces of a compactly generated space are compactly generated. Colimits of compactly generated spaces are compactly generated.

Proof: These follow from(3.3.2.25). □

Prop. (3.3.2.33). If $X \in \mathcal{CG}$ and Y is locally compact Hausdorff, then $X \times Y \in \mathcal{CG}$.

Proof: Notice by(3.3.3.7), a map $X \times Y \to Z$ is continuous iff $C \times Y \to Z$ is continuous for any compact Hausdorff subset $C \subset X$. The assertion is equivalent to $X \times Y \to (X \times Y)_c$ is continuous, which is then equivalent to $C \times Y \to (X \times Y)_c$ continuous for any compact subset $C \subset X$. But Y is compactly generated, and C is locally compact, thus it suffices to show $C \times C' \to (X \times Y)_c$ is continuous for any compact subset $C' \subset Y$. Then this is true because $C \times C'$ is compact. □

3 Mapping Spaces

Compact-Open Topology on Mapping Spaces

Def. (3.3.3.1) [Compact-Open Topology]. The **compact-open topology** on a function space $\mathrm{Map}(X, Y)$ is a topology generated by the sets $(K, U) = \{f : f(K) \subset U\}$, where K is compact in X and U is open in Y.

Prop. (3.3.3.2). For $X' \to X, Y \to Y' \in \mathcal{T}op$, the induced map $\mathrm{Map}(X, Y) \to \mathrm{Map}(X', Y')$ is continuous. In particular, if $X \cong X'$ and $Y \cong Y'$, then $\mathrm{Map}(X, Y) \cong \mathrm{Map}(X', Y')$.

Prop. (3.3.3.3). If Y is compact and X a metric space, this the compact open topology on $\mathrm{Map}(Y,X)$ coincides with the uniform topology on functions.

Proof: If $f \in (K,U)$, then $f(K) \subset U$, then there is a $\varepsilon > 0$ that $B(K,\varepsilon) \subset U$, thus $B(f,\varepsilon) \subset (K,U)$.

For any $f \in \mathrm{Map}(Y,X)$, $f(Y)$ is compact thus there are f.m. open balls $B(f(y_i),\frac{\varepsilon}{3})$ that covers $f(Y)$. Now if $K_i = \overline{f^{-1}(B(f(y_i),\frac{\varepsilon}{3}))}$, then $\cup K_i = Y$, and $f \in \cap_i(K_i, B(f(y_i),\frac{\varepsilon}{2}))$. Also $\cap_i(K_i, B(f(y_i),\frac{\varepsilon}{2})) \subset B(f,\varepsilon)$, because for any $g \in \cap_i(K_i, B(f(y_i),\frac{\varepsilon}{2}))$ and $y \in K_i$, $|f(y)-g(y)| \le |f(y)-f(y_i)| + |f(y_i)-g(y)| < \frac{\varepsilon}{2}+\frac{\varepsilon}{2} = \varepsilon$. □

Def. (3.3.3.4) [Relative Maps]. Let $A \subset X$ and $B \subset Y$, we denote by $\mathrm{Map}((X,A),(Y,B))$ the subspace of $\mathrm{Map}(X,Y)$ consisting of continuous functions $f: X \to Y$ that map A into B.

Prop. (3.3.3.5) [Composition is Continuous]. If Y is locally compact Hausdorff, then the composition map

$$\mathrm{Map}(Y,Z) \times \mathrm{Map}(X,Y) \to \mathrm{Map}(X,Z)$$

is continuous.

Proof: For any compact $K \subset X$, open $U \subset Y$ and $g \circ f \in (K,U)$, $f(K) \subset g^{-1}(U) \subset Y$. Because Y is locally compact, there is an precompact open subset V that $f(K) \subset V \subset \overline{V} \subset g^{-1}(U)$, then $(\overline{V},U) \times (K,V)$ maps into (K,U). □

Lemma (3.3.3.6) [Subbasis]. Let X be Hausdorff, W_α be a subbasis of Y, then (K,W_α) where $K \subset X$ compact is a subbasis of $\mathrm{Map}(X,Y)$.

Proof: If $f \in (K,U) \subset \mathrm{Map}(X,Y)$, let $U = \bigcup_\beta U_\beta$, where $U_\beta = \bigcap_{j=1}^{k(\beta)} W_{\beta,j}$. Now $K \subset \bigcup_\beta f^{-1}(U_\beta)$, because K is compact Hausdorff thus the partition of unity(3.3.7.9) gives us f.m. compact subsets $K_1,\ldots,K_n$ of K that $K_i \subset f^{-1}(U_{\beta_i})$ for some β. Then

$$f \in \bigcap_{i=1}^n \bigcap_{j=1}^{k(\beta_i)} (K_i, W_{\beta_i,j}) = \bigcap_{i=1}^n (K_i, U_{\beta_i}) \subset (K, \bigcup_{i=1}^n U_{\beta_i}) \subset (K,U).$$

□

Prop. (3.3.3.7) [Adjointness of Mapping Space]. Let Y be a locally compact Hausdorff space, then

$$\mathrm{Map}(X \times Y, Z) \cong \mathrm{Map}(X, \mathrm{Map}(Y,Z))$$

as sets. And if moreover X is Hausdorff, then it is a homeomorphism.

Proof: Let $\varphi \in \mathrm{Map}(X\times Y, Z)$, for any $x \in X$, take $\varphi(x): Y \to Z: \varphi(x)(y) = \varphi(x,y)$, then $\varphi(x)$ is continuous, and $\widetilde{\varphi}: X \mapsto \mathrm{Map}(Y,Z): x \mapsto \varphi(x)$ is continuous: for any compact $K \subset Y$ and open $U \subset Z$, $\widetilde{\varphi}^{-1}((K,U)) = \{x \in X | \varphi(x \times K) \subset U\}$, which is open.

Conversely, for any $\psi: X \to \mathrm{Map}(Y,Z)$, let $\widetilde{\psi}: X \times Y \to Z$ be given by $\widetilde{\psi}(x,y) = \psi(x)(y)$. Then $\widetilde{\psi}$ is continuous: For any open $U \subset Z$, if $(x,y) \in \widetilde{\psi}^{-1}(U)$, then $\psi(x)y \subset U$. Because $\psi(x)$ is continuous, there is a nbhd W of $y \in Y$ that $\varphi(x)(W) \subset U$. Then because Y is locally compact Hausdorff, there is a precompact nbhd V of $y \in Y$ that $y \in V \subset \overline{V} \subset W$. Then $\psi^{-1}((\overline{V},U))$ is a nbhd of $x \in X$, and $(x,y) \in (\psi^{-1}((\overline{V},U)),V) \subset \widetilde{\psi}^{-1}(U)$, thus $\widetilde{\psi}^{-1}(U)$ is open, and $\widetilde{\psi}$ is continuous.

Now let $F: \varphi \mapsto \widetilde{\varphi}$ and $G: \psi \mapsto \widetilde{\psi}$, then we show F,G are both continuous: By(3.3.3.6), $(K,(L,U))$ is a subbasis of $\mathrm{Map}(X,\mathrm{Map}(Y,Z))$. F is continuous because $F((K\times L,U)) = (K,(L,U))$.

G is continuous because $X \times Y$ is Hausdorff and for any J compact in $X \times Y$, $J \times J \xrightarrow{(\mathrm{pr}_1,\mathrm{pr}_2)} X \times Y$ is continuous, so for any $U \subset Z$ open, there exists $J_1 \subset X, J_2 \subset Y$ compact s.t. $G((J_1,(J_2,U))) \subset (J,U)$. □

Cor. (3.3.3.8). If Y is locally compact and Hausdorff, $A \subset X, B \subset Y, C \subset Z$, then

$$\mathrm{Map}((X \times Y, X \times B \cup A \times Y),(Z,C)) \cong \mathrm{Map}((X,A),\mathrm{Map}((Y,B),(Z,C)))$$

as sets, and if moreover X is Hausdorff, then it is a homeomorphism.

Def. (3.3.3.9) [Admissible Topology]. For $X, Y \in \mathcal{T}\mathrm{op}$, an **admissible topology** on $\mathrm{Map}(X,Y)$ is a topology that makes the evaluation map $e : \mathrm{Map}(X,Y) \times X \to Y$ continuous.

Prop. (3.3.3.10). The compact-open topology on $\mathrm{Map}(X,Y)$ is coarser than admissible topology on it(3.3.3.9). And if X is locally compact Hausdorff, then it is admissible.

Proof: It suffices to show any (K,U) is open in $\mathrm{Map}(X,Y)$. Let $f \in (K,U)$, then for any $x \in K$, $e(f,x) \in U$, thus there is a nbhd U_x of f and a nbhd W_x of x that $e(U_x \times W_x) \subset U$. Now because K is compact, we can choose a nbhd V of f that $e(V \times K) \subset U$. Thus $f \in V \subset (K,U)$, and (K,U) is open in $\mathrm{Map}(X,Y)$. If Y is locally compact Hausdorff, then $\mathrm{Map}(Y,Z) \times Y \to Z$ continuous by applying(3.3.3.5) with $X = \mathrm{pt}$. □

<u>**Mapping Spaces in $\mathcal{CG}$**</u>

Def. (3.3.3.11) [Mapping Spaces]. For $X, Y \in \mathcal{CG}$, the mapping space $\mathrm{Map}_c(X,Y)$ is the compact generation(3.3.2.27) of the space of continuous functions from X to Y with the topology generated by the sets $(K,U) = \{f : f(i(K)) \subset U\}$, where K is a compact Hausdorff space, $i : K \to X$ and U is open in Y.

Prop. (3.3.3.12). For $X' \to X, Y \to Y' \in \mathcal{CG}$, the induced map $\mathrm{Map}_c(X,Y) \to \mathrm{Map}_c(X',Y')$ is continuous. In particular, if $X \cong X'$ and $Y \cong Y'$, then $\mathrm{Map}_c(X,Y) \cong \mathrm{Map}_c(X',Y')$.

Lemma (3.3.3.13) [Evaluations are Continuous]. For $X, Y \in \mathcal{CG}$, the composition map

$$\mathrm{Map}_c(Y,X) \times_c Y \to X$$

is continuous.

Proof: It suffices to prove that for any compact Hausdorff space K, F mapping into $\mathrm{Map}(Y,X), Y$, $K \times F \to X$ is continuous: For $(f_0,y) \in \mathrm{Map}_c(Y,X) \times_c Y$ and $f_0(y) \in U$, as f_0 is continuous, there exists a nbhd N of $y \in Y$ s.t. $f_0(\overline{N \cap F}) \subset U$, and then $(f_0,y) \in (K \cap (\overline{N \cap F},U), N \cap F)$ is mapped into U. □

Prop. (3.3.3.14) [Adjointness of Mapping Space]. For $X, Y, Z \in \mathcal{CG}$, there is a natural homeomorphism

$$\mathrm{Map}_c(X \times_c Y, Z) \cong \mathrm{Map}_c(X, \mathrm{Map}_c(Y,Z))$$

Proof: Let $\varphi \in \mathrm{Map}_c(X \times_c Y, Z)$, for any $x \in X$, take $\varphi(x) : Y \to Z : \varphi(x)(y) = \varphi(x,y)$, then $\varphi(x)$ is continuous, and $\widetilde{\varphi} : X \mapsto \mathrm{Map}(Y,Z) : x \mapsto \varphi(x)$ is continuous: if $\varphi(x) \in (K,U)$, $\widetilde{\varphi}^{-1}((K,U)) = \{x \in X | \varphi(x \times i(K)) \subset U\}$, which is open.

To prove this construction is continuous, notice we have already seen that if $f : X \times_c Y \to Z$ is continuous then $f : Y \to \mathrm{Map}_c(Y, Z)$ is continuous. Apply this to

$$\mathrm{Map}_c(Y \times_c X, Z) \times_c Y \times_c X \to Z$$

we see that

$$X \times_c \mathrm{Map}_c(Y \times_c X, Z) \to \mathrm{Map}_c(Y, Z)$$

is continuous, and

$$\mathrm{Map}_c(Y \times_c X, Z) \to \mathrm{Map}_c(X, \mathrm{Map}_c(Y, Z))$$

is continuous. Similarly, as

$$\mathrm{Map}_c(X, \mathrm{Map}_c(X, Z)) \times_c Y \times_c X \to Z$$

is continuous, we get

$$\mathrm{Map}_c(X, \mathrm{Map}_c(Y, Z)) \to \mathrm{Map}_c(X \times_c Y, Z)$$

is continuous, and it is clearly the inverse to the construction above. □

Cor. (3.3.3.15). For $X, Y, Z \in \mathcal{CG}$, $A \subset X, B \subset Y, C \subset Z$, then there is a natural homeomorphism

$$\mathrm{Map}((X \times Y, X \times B \cup A \times Y), (Z, C)) \cong \mathrm{Map}((X, A), \mathrm{Map}((Y, B), (Z, C)))$$

Cor. (3.3.3.16). products in $\mathcal{CG}$ commute with colimits.

Cor. (3.3.3.17) [Compositions are Continuous]. For $X, Y, Z \in \mathcal{CG}$, the composition map

$$\mathrm{Map}_c(Y, Z) \times_c \mathrm{Map}_c(X, Y) \to \mathrm{Map}_c(X, Z)$$

is continuous.

Proof: It suffices to show that

$$\mathrm{Map}_c(Y, Z) \times_c \mathrm{Map}_c(X, Y) \times_c X \to Z$$

is continuous, and this follows from(3.3.3.13). □

Construction of Spaces

Def. (3.3.3.18) [Path Spaces]. For $f : A \to B \in \mathcal{T}op$, let E_f be the subspace of $A \times \mathrm{Map}(I, B)$ consisting of pairs (a, γ) that $\gamma(0) = a$.

The fibers of $E_f \to B$ are called **homotopy fibers** of f.

Def. (3.3.3.19) [n-Loop Space]. The **n-loop space** of X is defined to be $\Omega^n(X, x_0) = M(I^n, \partial I^n; X, x_0)$. Then by(3.3.3.8) we have

$$\Omega(\Omega^n(X, x_0), \widetilde{x}_0) \cong \Omega^{n+1}(X, x_0).$$

Prop. (3.3.3.20) [Loop spaces are Homotopy Fibers]. Let $f : x_0 \to B$ be a point, then E_f is the **path space** PB of all paths starting from x_0, and the homotopy fiber over x_0 is just the loop space $\Omega(X, x_0)$. PB is contractible, with the contraction given by $H : PB \times I \to PB : \gamma_t(x) = \gamma(tx)$.

4 Profinite Space

Def. (3.3.4.1) [Profinite Space]. A space is called a **profinite space** if it is a cofiltered limit of discrete topological spaces. The category of profinite spaces is denoted by $\mathcal{P}rof$.

A profinite space is the same thing as a totally disconnected, compact Hausdorff topological space. Thus a closed subspace of a profinite space is profinite.

Proof: The profinite spaces are clearly totally disconnected, compact Hausdorff(by Tychonoff).

Conversely, if it is totally disconnected and compact Hausdorff, let $\mathcal{I}$ be the set of clopen decompositions $X = \coprod_I U_i$ of X, then for each $I \subset \mathcal{I}$, there is a map $X \to I$, and there is a partial order on the decompositions of X. We show that the map $X \to \lim_{I\subset\mathcal{I}} I$ is a homeomorphism. It is injective by(3.3.1.25)(3.3.1.23)(3.3.7.6). It is surjective by compactness of X, and it is clearly open, thus homeomorphism by(3.3.2.11). □

Cor. (3.3.4.2). A cofiltered limit of profinite spaces is profinite.

Prop. (3.3.4.3). Any open covering of a profinite space has a clopen disjoint subcover.

Proof: By(3.3.4.1), we may assume that $X = \lim_{i\in I} X_i$, where X_i is finite. Let f_i be the projection, as the limit is filtered, a fundamental family of nbhds of a point (x_i) $f_i^(x_i)$, Then for each covering, we may assume it is finite $X = \cup_{i\in I} f_i^{-1}(x_i)$, choose a $j > i$ for each i, as I is cofiltered, then $X = \coprod_{x\in X_j} f_j^{-1}(x)$ satisfies the desired property. □

Prop. (3.3.4.4). If X is quasi-compact and any connected component of X is the intersection of clopen sets containing it (e.g. X is normal(3.3.1.23)), then $\pi_0(X)$ is a profinite space.

Proof: $\pi_0(X)$ is an image of X, so it is quasi-compact, also it is clearly totally disconnected. To show it is Hausdorff, let C, D be disjoint connected components of X, then $C = \cap U_\alpha$, where U_α are clopen. Since $C \cap D = \varnothing$, $U_\alpha \cap D = \varnothing$ for some α. and then the image of U_α separates C and D in $\pi_0(X)$. □

Locally Profinite Space

Def. (3.3.4.5)[Locally Profinite Space]. A space is called **locally profinite** iff it is a totally disconnected, locally compact Hausdorff topological space.

Prop. (3.3.4.6). A locally closed subsets of a locally profinite space is locally profinite. And compact subsets are profinite.

Proof: Closed subsets are clearly locally profinite, for the open subsets, it is also locally compact. □

Cor. (3.3.4.7). Any open covering of a compact subsets of a locally profinite space has an clopen disjoint subcover, by(3.3.4.3).

Prop. (3.3.4.8). The set of all compact open subsets form a basis of the topology of G.

Prop. (3.3.4.9). If X is locally profinite and K is a compact subspace of X. Let $K \subset \cup U_\alpha$ be an open covering, then there exist f.m. disjoint open compact subsets $V_i \subset X$ that each $V_i \cap K \subset U_\alpha$ for some α, and $K \subset \cup V_i$.

Proof: Because K is profinite(3.3.4.6), (3.3.4.3) shows there is a finite disjoint compact open subcover W_i of U_α, then $W_i = V_i \cap K$ for V_i compact, and using compactness of W_i, we can assume V_i is compact. Finally to make V_i disjoint, we can let $V_i = V_i \backslash (\cup_{k=1}^{i-1} V_k)$. □

5 Real Numbers

References are [?]Chap10 and [Mun00].

Topology

Prop. (3.3.5.1) [$\mathbb{R}$ is Connected]. $\mathbb{R}$ is connected, and so are intervals and rays in $\mathbb{R}$.

Proof: This follows from(3.3.1.20), as the hypothesis is satisfied by(1.2.9.1) and the fact for any $a < b \in \mathbb{R}, a < \frac{a+b}{2} < b$. □

Prop. (3.3.5.2). $\mathbb{R}^n$ satisfies the Heine-Borel property(3.3.8.3), i.e. bounded closed sets are compact.

Proof: It suffices to consider the square metric. If A is bounded, then A is in $[-N, N]^n$ for some number N. $[-N, N]^n$ is compact by(3.3.2.4) and(3.3.2.5). □

Borel Set

Def. (3.3.5.3). Let U be a ultrafilter on a set I and $\{a_I\}$ be a bounded sequence of real numbers. Then a number a is called the U**-limit** of $\{a_I\}$ is for every $\varepsilon > 0, \{i \in I | |a_i - a| < \varepsilon\} \in U$.

There is at most one limit, because $\{i \in I | |a_i - a| < \varepsilon\}, \{i \in I | |a_i - b| < \varepsilon\}$ will be disjoint hence cannot both be in U.

Prop. (3.3.5.4) [Generalized Limit]. Let U be an ultrafilter on $\mathbb{N}$, then for any bounded sequence of real numbers $\{a_n\}$, $\lim_U a_n$ exists. i.e. There is a functional from l^∞ to $\mathbb{R}$.

And if $\{a_n\}$ has a limit pt a in the usual sense, then $\lim_U a_n = a$ for any non-principal ultrafilter U, because any $\{i \in I | |a_i - a| < \varepsilon\}$ is cofinite hence in U(1.2.10.9).

Proof: Let $A_x = \{n | a_n < x\}$. Then A_x is monotone, then we can choose $c = \sup\{x | A_x \notin U\}$(1.2.3.19). And it is easily verified that $c = \lim_U a_n$. □

Cor. (3.3.5.5) [Density Measure]. There exists a measure m on $\mathbb{N}$ that $m(A) = d(A)$ for each set $A \subset \mathbb{N}$ that has a density $d(A)$.

Proof: Let U be a non-principal ultrafilter on $\mathbb{N}$(1.2.10.9), let $m(A) = \lim_U \frac{A(n)}{n}$. It is clearly additive and monotone. And it equals the density by(3.3.5.4) □

6 Separation Axioms

Prop. (3.3.6.1). Any Quasi-compact T_0 space X contains a closed point.

Proof: Consider the family of non-empty closed subsets of X, there is a minimal element by quasi-compactness. Choose a minimal element T, and let $x \in T$, then $\overline{\{x\}} = T$. Then x is closed, otherwise there is some $x' \neq x \in \overline{\{x\}}$, and $\overline{\{x'\}} \neq \overline{\{x\}}$ because X is T_0. □

Hausdorff

Hausdorffization

Cf.[the Hausdorff Quotient].

Regular

Completely Regular

Normal (T4)

Prop. (3.3.6.2) [Urysohn lemma]. Let X be normal, A and B two closed subset of X, then there exists a continuous map from X to $[0,1]$ that maps A to 0 and B to 1.

Proof: Use the countability of rational numbers to construct a family of U_q s.t.

$$p < q \Rightarrow \bar{U}_p \subset U_q$$

Then choose $f(x) = \inf\{p \in \mathbb{Q} | x \in U_p\}$, then this f meets the requirement. □

Cor. (3.3.6.3) [Tietze extension]. If X is normal and Y is a closed subspace, then any continuous function f on Y can be extended to a continuous function on X.

Proof: □

7 Paracompactness

Def. (3.3.7.1) [Paracompactness]. A space X is called **paracompact** if any open covering $\mathcal{U}$ has a locally finite open refinement covering.

Prop. (3.3.7.2) [Characterization of Paracompactness]. If X is regular, then TFAE:

1. Each open cover of X has an open locally finite refinement.
2. Each open cover of X has a locally finite refinement.
3. Each open cover of X has a closed locally finite refinement.
4. Each open cover of X is even. i.e. for any cover, there is an open nbhd V of diagonal of $X \times X$ such that $\forall x$, $V[x] = \{y | (x,y) \in V\}$ refines the cover.
5. Each open cover of X has an open σ-discrete refinement.
6. Each open cover of X has an open σ-locally finite refinement.

If this is satisfied, then X is called **paracompact**.

Proof: $6 \to 2$:Just minus every open set the part of open sets that appeared in families that ordered before it. $2+4 \to 1$:Use the lemma below, we can transform the cover $\mathcal{A}$ into $V[\mathcal{A}] \cap U_A$ which is an open locally finite cover
Cf.[General Topology Kelley] and [Mun00]P254. □

Lemma (3.3.7.3). If X satiesfies 4, let U be a nbhd of diagonal of $X \times X$, then their exists a symmetric nbhd of diagonal s.t. $V \circ V \subset U$, where $U \circ V = \{(x,z) | (x,y) \in U, (y,z) \in V, \exists y\}$.

Proof: $\forall x$ in X, there is a nbhd s.t. $W[x] \times W[x] \subset U$, this is an open cover, so there is a nbhd R of diagonal s.t. $R[x]$ refines it. Hense $R[x] \times R[x] \subset U$. Let $V = R \cap R^{-1}$, $V \circ V$ is the union of sets $V[x] \times V[x]$, so $V \circ V \subset U$. □

Lemma (3.3.7.4). In the preceding proposition, if X satisfies 4, Let $\mathcal{A}$ be a locally finite(resp. discrete i.e. intersect only one) family of subsets of X, then use the last lemma, there is a nbhd V of diagonal of $X \times X$ such that $V[A] = \{y | (x,y) \in V, \exists x \in A\}$ is locally finite(resp. discrete).

Proof: Choose for every pt a nbhd satisfy the property, then it is an open cover. Choose a diagonal nbhd U for the property 4, then choose coordinate symmetric nbhd V of diagonal s.t. $V \circ V \subset U$. If $V[x]$ intersect $V[A]$, then $V \circ V[x]$ intersect A. Done. $\square$

Prop. (3.3.7.5). A locally compact second countable Hausdorff space X is paracompact.

Proof: Let $\mathcal{U}$ be a covering of X, because X is second countable and locally compact, by(3.3.2.23), we may assume $\mathcal{U}$ is a countable covering and consisting of precompact subsets. Moreover, we can change U_n to $U_n' = \cup_{i=1}^n U_i$, because if $\{B_\alpha\}$ is a locally finite refinement of $\{\cup_{i=1}^n U_i\}$, then $\{B_\alpha \cap U_\alpha\}$ is a locally finite refinement of $\{U_i\}$. So $U_n \subset U_{n+1}$, and because $\overline{U}_n$ is compact, we may assume $\overline{U}_n \subset U_{n+1}$.

Now let $K_n = \overline{U}_{n+1} \backslash U_n$(where $U_0 = \varnothing$), then K_n are all compact, and $W_n = U_{n+1} \backslash \overline{U}_{n-2}$ is an open subset containing K_n. So there are f.m. open subsets of W_n that cover K_n. There open subsets is then a refinement covering of $\mathcal{U}$, and they are locally finite, because any $x \in X$ is contained in U_n for some n. $\square$

Prop. (3.3.7.6) [Paracompact Spaces are Normal]. A Hausdorff paracompact space X is normal. In particular, a compact Hausdorff space is normal.

Proof: Firstly X is regular: Let $x \in X$ and B a closed subset disjoint from x, then because X is Hausdorff, there is a covering of B by open subsets V_α that $x \notin \overline{V}_\alpha$. Now consider the open covering $\{X \backslash B, V_\alpha\}$ of X, then there is a locally finite refinement $\{B_\beta\}$. Those B_α that intersect B is then a locally finite covering of B. Let U be the union of these open subsets, then $B \subset U$ and $x \notin \overline{U}$, because of the locally finiteness.

To prove X is normal, we do the same but x replaced by a closed subset disjoint from B and use regularity. $\square$

Prop. (3.3.7.7) [Paracompactness for Manifolds]. For a connected Hausdorff locally Euclidian space, the condition of paracompact, second countable and a compact exhaustion is equivalent.

Proof: Cf.[Paracompactness and second countable]. $\square$

Lemma (3.3.7.8) [Shrinking Lemma]. Let X be a paracompact Hausdorff space and $\{U_\alpha\}_{\alpha \in I}$ an open covering of X, then there is an open covering $\{V_\alpha\}$ of X that $\overline{V}_\alpha \subset U_\alpha$ for any α.

Proof: Let $\mathcal{A}$ be the family of open subsets A of X that $\overline{A} \subset U_\alpha$ for some α, then because X is normal(3.3.7.6), $\mathcal{A}$ is a covering of X. Then we find a locally finite open covering $\mathcal{B}$ of $\mathcal{A}$, and let the covering map be $B_\beta \subset U_{f(\beta)}$, then we can get a covering $\mathcal{V}$ of X indexed by I that $V_\alpha = \cup_{f(\beta)=\alpha} B_\beta$. This is also locally finite, and $\overline{V}_\alpha \in U_\alpha$ by the locally finiteness of $\mathcal{B}$. $\square$

Prop. (3.3.7.9) [Partition of unity]. In a paracompact Hausdorff space, given any open cover $\{U_\alpha\}$, there exists a partition of unity $\{\rho_\alpha\}$ that supp$\rho_\alpha \subset U_\alpha$, and $\{\mathrm{Supp}(\rho_\alpha)\}$ is locally finite. Moreover, if X is locally compact, we can assume

Proof: Using shrinking lemma(3.3.7.8) twice, we can find locally finite open coverings $\{W_\alpha\}, \{V_\alpha\}$ that $\overline{W}_\alpha \subset V_\alpha$, $\overline{V}_\alpha \subset U_\alpha$. Because X is normal, we can find functions ψ_α on X that $\psi(W_\alpha) = 1, \psi_\alpha(X \backslash V_\alpha) = 0$. Then $\mathrm{Supp}(\psi) \subset \overline{V}_\alpha \subset U_\alpha$, so $\{\mathrm{Supp}(\psi_\alpha)\}$ is locally finite. So we can define $\Phi(x) = \sum_\alpha \psi_\alpha(x)$. $\Phi(x) > 0$ for any x because $\{W_\alpha\}$ is a covering of X. Finally, we define $\rho_\alpha = \psi_\alpha / \Phi$, then this is a partition of unity dominated by $\{U_\alpha\}$. $\square$

8 Metric Space

Def. (3.3.8.1) [Metric Balls]. Let X be a metric space and $x \in X, \delta \in \mathbb{R}_+$, define the metric balls

$$U(x,\delta) = \{y \in X : d(x,y) < \delta\}, \quad \mathbb{D}(x,\delta) = \{y \in X : d(x,y) \le \delta\}.$$

Prop. (3.3.8.2) [Metric Spaces are Paracompact]. Any metric space is paracompact.

Proof: Cf.[Mun00]P257. □

Def. (3.3.8.3) [Heine-Borel Property]. A metric space X is said to satisfy the **Heine-Borel property** if every closed and bounded subset of X is compact.

Complete Metric Space

Def. (3.3.8.4). A set E in a metric space is called **totally bounded** iff for every $\varepsilon > 0$, there exists a finite set F that $E \subset B(F,\varepsilon)$. This definition is compatible with that in the case of a topological vector space when it is metrizable.

Prop. (3.3.8.5). The closure of a totally bounded set in a metric space is totally bounded.

Proof: For each $\varepsilon > 0$, choose a finite set F that $E \subset B(F,\varepsilon/2)$, then $\overline{E} \subset B(F,\varepsilon)$. □

Prop. (3.3.8.6). A totally bounded metric space X is separable.

Proof: $\cup N_n$ is dense and countable in X, where N_n is a finite $1/n$-net of X. □

Prop. (3.3.8.7) [Hausdorff]. Let X be a metric space, then:

1. A sequentially compact(3.3.2.6) subset M is totally bounded and the converse is true if X is complete.
2. A subset M is compact iff it is self-sequentially compact iff it is closed and sequentially compact.
3. A subset M is precompact iff it is sequentially compact(3.3.2.6).

Proof: 1: If M is not totally bounded, then for some $\varepsilon > 0$, we can choose consecutively a sequence of points x_i that $d(x_i,x_j) \ge \varepsilon$, this cannot has a convergent subsequence in X.

Conversely, if M is totally bounded, choose a $1/k$-net for each k, then for any sequence in M, there is a y_i that some infinite subsequence $\{x_n^{(1)}\} \subset B(y_1,1)$, and consecutively find infinite subsequences $\{x_n^{(m)}\} \subset B(y_k,1/k)$, then finally choose the diagonal, then it is a Cauchy sequence.

2: If it is compact, given a sequence, if no point is a convergent point, then each point has a nbhd that contains at most one point of the sequence. Then by compactness, there are at most f.m. points, contradiction. A compact set must has the convergent point in itself because it is closed as M is Hausdorff.

Conversely, if it is self-sequentially compact, then it is totally bounded by 1. so if M is not compact, then for each n it has $1/n$-net N_n, then there is at least one x_n that $B(x_n,1/n)$ cannot by covered by f.m. of the covering, The sequence $\{x_n\}$ has a subsequence $\{x_{n_k}\}$ that is convergent to x. But $x \in M$ is in some open cover, so $B(x_{n_k},1/n_k)$ is contained in some open cover, contradiction.

That closed and sequentially compact is equivalent to self sequentially compact is obvious.

3: If it is precompact, then it is sequentially compact by 2, conversely, if x_i is a sequence in $\overline{M}$, then choose $|y_n - x_n| \le 1/n$, so some sequence y_{n_k} is convergent to $y_0 \in \overline{M}$, so x_{n_k} also converges to y_0. So $\overline{M}$ is self-sequentially compact, so it is compact by 2. □

Cor. (3.3.8.8) [Arzela-Ascoli]. For $X \in$ CHaus, $F \subset C(X)$ is a sequentially compact(precompact, by(3.3.8.7)) subset iff it is uniformly bounded and equicontinuous.

Proof: As $C(M)$ is complete metric space, sequentially compact is equivalent to totally bounded. If it is totally bounded, then it is clearly uniformly bounded, and for every $\varepsilon > 0$, find a $\varepsilon/3$-net for F, which means f.m. functions in F that any other function is $\varepsilon/3$-close to one of them. So they are equicontinuous.

Conversely, if it is uniformly bounded and equicontinuous, for every $\varepsilon > 0$, find a finite covering of M that for any two points x, y in one cover of them, $|f(x) - f(y)| < \varepsilon/3$ for all $f \in F$. Then choose for each covering a point x_i, consider $f : F \to \mathbb{C}^n : \varphi \mapsto (\varphi(x_1), \ldots, \varphi(x_n))$, then the image is bounded, hence precompact by(3.3.5.2), so it is totally bounded by(3.3.8.7). So we can choose a $\varepsilon/3$-net φ_k for x_i simultaneously, and it is by $\varepsilon/3$ argument that these φ_k is a ε-net for F. □

Prop. (3.3.8.9) [Fixed point theorem]. If X is a complete metric space and $f : X \to X$ satisfies $d(f(x), f(y)) \le \lambda d(x, y)$ for some $0 \le \lambda < 1$, then f has a unique fixed point in X. If X is moreover compact, then and f that $d(f(x), f(y)) < d(x, y)$ will have a unique fixed point.

Proof: $x + f(x) + f^2(x) + \cdots$ is the fixed point. And uniqueness is easy. For compact case, notice the image $\operatorname{Im} f^n$ is a descending chain, it must stable to some T. If $x, y \in Y$ attains the diameter of Y, and let $x = f(X), y = f(Y)$, where $X, Y \in T$, then $d(x, y) < d(X, Y) \le d(x, y)$, contradiction. □

Prop. (3.3.8.10) [Dilation Closed]. If X, Y are metric spaces that X is complete metric space, then if $f : X \to Y$ is continuous function that is a dilation, i.e. $d(f(x_1), f(x_2)) \ge d(x_1, x_2)$, then $f(X)$ is closed.

So a continuous dilation map on a complete metric space is a closed map.

Proof: If $y \in \overline{f(X)}$, then because Y is metric, there are x_n that $y = \lim f(x_n)$. Thus $\{f(x_n)\}$ is Cauchy in Y, and $\{x_n\}$ is Cauchy too. So there is a $x = \lim x_n$, and clearly $f(x) = y$. □

Compact Metric Space

Lemma (3.3.8.11) [Lebesgue Number Lemma]. For any open covering U_i of a compact metric space X, there exists a $\delta > 0$ that any subset X of diameter smaller than δ is contained in some U_i.

Proof: If X is in the covering U_i, then there is nothing to prove, otherwise, it suffices to assume the covering is a finite covering, let $C_i = X - U_i$, and let $f(x) = \frac{1}{n}\sum d(x, C_i)$. Notice $f(x) > 0$, because $x \notin C_i$ for some C_i. Now it is also continuous, so it has a minimal value$> \delta > 0$.

Now if B has diameter smaller than δ, then if $x_0 \in B$, $\delta < f(x_0) < d(x, C_{i_0})$, where $d(x, C_{i_0})$ is the maximal among $d(x, C_k)$, and $B \in B(x, \delta)$, thus $B \in U_{i_0}$. □

Prop. (3.3.8.12) [Uniform Continuity Theorem]. If $f : X \to Y$ is a continuous map between two metric spaces that X is compact, then f is uniformly continuous.

Proof: Take an open covering of Y with balls $B(y_i, \varepsilon/2)$ of diameter $\varepsilon/2$, and consider their inverse image, then choose the lebesgue number δ for this covering(3.3.8.11), we see that for any $d(x, y) < \delta$, $d(f(x), f(y)) < \varepsilon$. □

Prop. (3.3.8.13). If f is an isometry of a compact metric space X, then it is a bijection thus an homeomorphism.

Proof: It is clearly injective. If it is not surjective, then choose a $x \notin \mathrm{Im}(f)$, because $\mathrm{Im}(f)$ is compact hence closed in X, $d(x, \mathrm{Im}(f)) = \varepsilon > 0$. Now consider the minimal N that we can cover X with open subsets of diameter smaller than ε, this N exists because X is compact. Now if U_i covers X, then the one that contains x cannot intersect with $\mathrm{Im}(f)$. But $f^{-1}(U_i)$ is an open cover of X with smaller numbers of open subsets, contradiction. □

9 Baire Space

Def. (3.3.9.1) [Baire Spaces]. A subset of a topological space X is called of **first category** if it is contained in some countable union of closed subsets of X having no interior point. It is called of **second category** if it is not of first category.

A **Baire space** is a topological space that any nonempty open subsets of X is of second category.

Prop. (3.3.9.2) [Baire Category Theorem]. Every complete metric space & locally compact Hausdorff space is a Baire space.

Proof: Choose consecutively (precompact)open subsets that doesn't intersect $\overline{E_n}$ to find a limit point. □

10 Uniform Space

Def. (3.3.10.1) [Uniform Spaces].

Def. (3.3.10.2) [Cauchy Filter in the Topological Group Case]. A **Cauchy filter** is a topological Abelian group is a filter $\mathcal{F}$ that for any nbhd U of 0, there exists $E \in \mathcal{F}$ that $x - y \in U$ if $x, y \in E$.

Def. (3.3.10.3) [Complete Uniform Spaces]. A topological Abelian group is called **complete uniform space** iff it is Hausdorff, and any Cauchy filter has a limit.

11 Manifolds

Def. (3.3.11.1) [Manifolds]. A (topological) **manifold** of dimension n is a topological space that is Hausdorff, second countable and locally Euclidean. By(3.3.7.7), the last condition is equivalent to say it is paracompact.

The category of topological manifolds is denoted by $\mathcal{M}\mathrm{ani}$.

Thm. (3.3.11.2) [Annulus Theorem, Rado-Moise-Quinn-Kirby]. For any map $h : \mathbb{R}^n \to \mathbb{R}^n$ that maps $\mathbb{D}^n$ into its interior, there is a homeomorphism $\mathbb{D}^n \backslash h(\mathbb{D}^n) \cong \mathbb{S}^{n-1} \times \mathbb{I}$ that identifies $\partial\mathbb{D}^n$ and $h(\partial\mathbb{D}^n)$ with $\mathbb{S}^{n-1} \times \{0\}, \mathbb{S}^{n-1} \times \{1\}$ resp.

Proof:

□

Thm. (3.3.11.3) [Jordan Curve Theorem, Jordan1887]. .

Proof: □

Triangularizations

Def. (3.3.11.4) [Triangularizations]. A **triangularizable space** is a space that is homeomorphic to the geometrization of a simplicial set(3.5.3.8). Any such homeomorphism is called a **triangularization** of this space.

Thm. (3.3.11.5) [Triangularization of Surfaces]. All compact connected surface is triangularizable.

Proof: ? □

Surfaces

Def. (3.3.11.6) [Topological Surfaces]. A **topological surface** (with boundaries) is a topological manifold of dimension 2 (with boundaries).

Def. (3.3.11.7) [Planer Glueing Diagram]. A **planer glueing diagram** is a polygon with some glueing of its edges with orientations clockwise such that no three edges are glued together. We can label the edges by symbols and their inverses. different symbols are considered not glued together. For example, $aba^{-1}b^{-1}, abab$.

A **compact planer glueing diagram** is a planer glueing diagram that every symbol appear exactly twice in the the edges of the polygon.

Prop. (3.3.11.8). The space correspond to a planer glueing diagram is a compact topological surface with boundaries.

The space correspond to a compact planer glueing diagram is a compact topological surface.

Proof: It is compact as a quotient of a compact space. It can verified that it is locally Euclidean at each space. And it is clearly Hausdorff. □

Lemma (3.3.11.9). $\mathbb{T}^2\#\mathbb{RP}^2 \cong \mathbb{RP}^2\#\mathbb{RP}^2\#\mathbb{RP}^2$.

Proof: By**??**, it suffices to show that $aabcb^{-1}c^{-1}$ is homeomorphic to $eeffgg$. For this, use cut-and-paste.? □

Thm. (3.3.11.10) [Classification of Surfaces]. Any compact topological surface is homeomorphic to exactly one of the following: $\mathbb{S}^2, \#^n\mathbb{T}^2$ or $\#^n\mathbb{RP}^2$, $n \in \mathbb{Z}_+$. The corresponding planer diagram is aa^{-1}, $a_1b_1a_1^{-1}b_1^{-1}\dots a_nb_na_n^{-1}b_n^{-1}$, $e_1e_1e_2e_2\dots e_ne_n$.

Proof: By triangularization theorem(3.3.11.5), it is easy to see that any compact surface is the space corresponding to a compact planer diagram. Then it suffices to show any compact planer diagram is isomorphic to either aa^{-1}, $a_1b_1a_1^{-1}b_1^{-1}\dots a_nb_na_n^{-1}b_n^{-1}$, $e_1e_1e_2e_2\dots e_ne_n$.

Firstly we can reduce to the case where all vertices are glued together: Take a vertex P, then we can spot all the vertices that are glued to P. If these are not all the vertices, we can find an edge $e = PQ$, and let RPQ be a triangle, then we can cut this triangle out to paste along the edge pairing e. Then we can reduce the number of vertices glued to P. Eventually, we can eliminate P.

Secondly we can collet all edges with the same orientation(i.e. $\dots a\dots a\dots$) to be adjacent: (i.e. $\dots aa\dots$). To do this, suppose $a = P_1Q_1 = P_2Q_2$, we simply cut along the line P_1P_2 and glue a together.

Now if all edges glued together are of the same orientations, then it is clearly isomorphic to $\#^n\mathbb{RP}^2$. Otherwise there are edged a, a^{-1} glued together with the opposite orientation. Then there must be another pair b, b^{-1} s.t. these four pairs are ordered by a, b, a^{-1}, b^{-1}. This is because otherwise there will be two vertices. Then by some cut-and-paste, we can move these edges together as $\dots aba^{-1}b^{-1}\dots$. By induction, we can make all edges with the opposite orientations together and in pairs.

Thus our diagram is a connected sum of $\mathbb{T}^2$ and $\mathbb{RP}^2$. Then we can reduce the diagram to one of the three kinds by(3.3.11.9).

Finally, it suffices to show these three kinds are different: Their Euler characteristics are

$$\chi(\mathbb{S}^2) = 2, \quad \chi(\#^n\mathbb{T}^2) = 2 - 2n, \quad \chi(\#^n\mathbb{RP}^2) = 2 - n.$$

So the only case their Euler characters equal are $\chi(\#^n\mathbb{T}^2) = \chi(\#^{2n}\mathbb{RP}^2)$. But in this case, they are still not homeomorphic, as $H_2(\#^n\mathbb{T}^2) = \mathbb{Z}$ and $H_2(\#^{2n}\mathbb{RP}^2) = 0$. □

12 Common Spaces

Def. (3.3.12.1) [Torus]. The (n-dimensional) torus $\mathbb{T}^n$ is defined to be $\mathbb{T}^n = (\mathbb{S}^1)^n$.

Def. (3.3.12.2) [$\mathbb{RP}^n$]. The **real projective space** $\mathbb{RP}^n$ is the $\mathbb{R}$-points of $\mathbb{RP}_{\mathbb{R}}$ with the canonical topology.

Def. (3.3.12.3) [Möbius Band]. The **Möbius band** is the space defined to be the planer glueing diagram $abac$.

Def. (3.3.12.4) [Klein Bottle]. The **Klein bottle** $\mathbb{K}^2$ is the space defined by the planer glueing diagram $aba^{-1}b$.

3.4 Model Categories

Main references are [Model Category and Simplicial Methods, Goerss], [Model Categories, Kantor], [Homotopy Theories and Model Categories, Dwyer/Spalinski], [Lur09], [Hovey, Model Categories].

Def. (3.4.0.1). If $\mathcal{C} \in \mathcal{C}at$ and S is a class of morphisms in $\mathcal{C}$, we denote $l(S)$ the set of morphisms that has left lifting property w.r.t. all morphisms in $\mathcal{C}$, and $r(S)$ the set of morphisms that have right lifting property w.r.t. all morphisms in $\mathcal{C}$. Then $l(S)$ is stable under pushout and $r(S)$ is stable under pull backs.

Def. (3.4.0.2)[Model Structure]. A **model structure** on a category $\mathcal{C}$ is three classes of morphisms: **fibrations**, **cofibrations** and **weak equivalences** that satisfy the following axioms: (Denote a A **trivial (co)fibration** is a (co)fibration that is also a weak equivalence.)

M1 C has finite limits and colimits.

M2 (two out of three)If two of f, g, fg is weak equivalence, then so is the third.

M3 (retracts) Fibrations, cofibrations and weak equivalences are closed under retract.

M4 (lifting property)We have a lifting property with a cofibration i and fibration p when either of them is a weak equivalence.

M5 (factorization)Any map f can be factored as pi where i is trivial cofibration and p is a fibration, and also as pi where i is a cofibration and p is a trivial fibration.

Remark (3.4.0.3). Notice the axioms are symmetric in fibrations and cofibrations, thus the opposite category $\mathcal{C}^{op}$ has a natural model structure. So whenever we write a theorem, we should always remember its dual counterpart.

Lemma (3.4.0.4) [Closedness]. A model category satisfies the retraction axiom iff:

- fibration= r(trivial cofibrations),
- cofibration= l(trivial fibrations),
- weak equivalence= uv, where $v \in l$(fibrations) and $u \in r$(cofibrations).

Proof: If these are satisfied, retraction axiom is easy: A retract satisfies the same lifting properties. Hence retraction of a (co)fibration is a (co)fibration. For retracts weak equivalences, Cf.[Quillen, Homotopical Algebra, Chap5.2].

Conversely, using(3.1.7.12), we first factorize a $p = f \circ i$, where i is a trivial cofibration, then because $p \in r(i)$, pis a retraction of f hence a fibration. And similarly for cofibrations and weak equivalences. □

Cor. (3.4.0.5). In a model category,
trivial fibrations= r(cofibrations),
trivial cofibrations= l(fibrations).

Proof: The proof is the same as that of(3.4.0.4). □

Cor. (3.4.0.6). In a model category, the class of (trivial)fibrations is stable under base change and the class of (trivial)cofibrations is stable under cobase change.

Prop. (3.4.0.7). Let p be a fibration in C_{cf}, then $p \in r(\mathrm{Cof})$ iff $\gamma(p)$ is an isomorphism, Cf.[Quillen 5.2]. So if conditions of(3.4.0.4) are satisfied (i.e. C is a closed model category), $\gamma(f)$ is an isomorphism iff f is a weak equivalence by the characterization of weak-equivalence of(3.4.0.4).

Proof: □

Def. (3.4.0.8) [Left Proper Model Categories]. A model category is called **left proper** if weak equivalences are stable under cobase change by cofibrations. Dually it is called **right proper** if weak equivalences are stable under base change by fibrations.

Prop. (3.4.0.9) [Cofibration is Left Proper]. For a pushout diagram

$$\begin{array}{ccc} A & \xrightarrow{i} & B \\ \downarrow{\scriptstyle j} & & \downarrow{\scriptstyle j'} \\ A' & \xrightarrow{i'} & B' \end{array}$$

in a model category $\mathcal{C}$, if i is cofibration and A, A' are cofibrant, and j is weak equivalence, then j' is also weak equivalence.

Proof: It suffices to show j' is an isomorphism in $\mathrm{Ho}(\mathcal{C})$(3.4.1.15). For this, by Yoneda lemma, it suffices to show $\mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(B', Z) \cong \mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(B, Z)$ for any fibrant object Z.

For surjectivity, by(3.4.1.18), it suffices to show $\pi(B', Z) \cong \pi(B, Z)$. Given a map $f : B \to Z$, because j is weak equivalence, there is a map $g : A' \to Z$ that $g \circ j \sim f \circ i$. Then by(3.4.1.10), there is a $f' \sim f$ that $f' \circ i = g \circ j$, which determines a morphism $B' \to Z$.

For injectivity, If P is a path object that $H : B \to P$ induces a homotopy between maps $s \circ j', s' \circ j'$, then we need to extend this homotopy to $\widetilde{H} : B' \to P$, and the method is the argument is the same as above. □

Cor. (3.4.0.10). If $\mathcal{M}$ is a model category s.t. each object is cofibrant, then $\mathcal{M}$ is left proper.

1 Homotopies

Def. (3.4.1.1) [Cylinder Objects]. A **cylinder object** for an object X is an object $X \wedge I$ which gives a factorization of the natural map $X \coprod X \to X$ as $X \coprod X \xrightarrow{i} X \wedge I \xrightarrow{j} X$, where $j \in W$. It is called a **good cylinder object** if i is a cofibration, and **very good cylinder object** if j is trivial fibration. By factorization axiom, every object has a very good cylinder object.

There are two natural morphisms $X \mapsto X \wedge I$, denoted by ∂_0 and ∂_1.

Dually we can define **path object** Y^I for Y, and every object has a very good path object.

Prop. (3.4.1.2). If A is cofibrant and $A \wedge I$ is a cylinder object for A, then $\partial_i : A \to A \times I$ are trivial cofibrations.

Proof: Because it's pushout of $\varnothing \to A$ and $\sigma \circ \partial_i = \mathrm{id}_A$. □

Cor. (3.4.1.3). if $f \sim^l g$, then f is a weak equivalence iff g is a weak equivalence.

Proof: This is because $f = H \circ \partial_0, g = H \circ \partial_1$, and we can use(3.4.1.2). □

Def. (3.4.1.4) [Homotopies]. Two morphisms $f, g : X \to Y$ are called **(good/very good) left homotopic**, denoted by $f \sim^l g$ iff there is a (good/very good) cylinder object $X \coprod X \to X \wedge I$ with $X \wedge I \to Y$ that induce $(f, g) : X \coprod X \to Y$. Dually for right homotopies. And we denote by $\pi^l(A, B)/\pi^r(A, B)$ the equivalence classes of $\mathrm{Hom}(A, B)$ under the equivalence relation generated by left/right homotopies.

If $f, g \in \mathrm{Hom}(X, Y)$ and $\varphi \in \mathrm{Hom}(Y, Z)$ that $\varphi \circ f = \varphi \circ g$, then f, g is called **left homotopic over** Z if there is a homotopy H of $f \sim^l g$ that φH is the trivial homotopy. Dually for **right homotopic under** X.

Lemma (3.4.1.5) [Very Good Homotopies]. For $f, g \in \mathrm{Hom}(X, Y)$, if $f \sim^l g$, then f, g are good left homotopic. And if Y if fibrant, then f, g are moreover very good left homotopic.

Proof: The first assertion is each, just choose a factorization of the cylinder object $X \coprod X \xrightarrow{i} X \wedge I' \xrightarrow{j} X \wedge I$ that i is cofibrant. If Y is fibrant, then we further factorize $X \wedge I' \xrightarrow{i} X \wedge I'' \xrightarrow{j} X$, where i is cofibrant and j is trivial fibration, then by two out of three, i is also trivial cofibration, and it suffices to extend the homotopy $X \wedge I' \to Y$ to $X \wedge I'' \to Y$, and this is because Y is fibrant. □

Prop. (3.4.1.6) [Homotopy is Equivalence Relation]. If A is cofibrant, then the left homotopy is an equivalence relation on $\mathrm{Hom}(A, B)$.

Proof: Reflexivity and symmetry is trivial, the only problem is transitivity, so we construct a glueing $A \wedge I''$ as the pushout of $\partial_1 : A \to A \wedge I$ and $\partial_0' : A \to A \wedge I'$. $A \wedge I'' \to A$ is a weak equivalence by the universal property and(3.4.0.4), so this is a cylinder object. The rest is easy. □

Prop. (3.4.1.7) [Properties of Left Homotopies]. If A is cofibrant and $f, g \in \mathrm{Hom}(A, B)$, then

1. If f, g are right homotopic, then $s \to B^I$ can be chosen to be trivial Cof.
2. If f, g are right homotopic, then so does $uf \sim ug$ or $fv \sim gv$. Thus if A is cofibrant, there is a composition map: $\pi^r(A, B) \times \pi^r(B, C) \to \pi^r(A, C)$.
3. For any trivial fibration $X \to Y$, $\pi^l(A, X) \to \pi^l(A, Y)$ is a bijection.

And dual arguments hold for fibrant objects.

Proof:

1. factorize $B \to B^I$ to $B \to B^{I'} \to B^I$ where $B \to B^{I'} \in TCof$ and $B^{I'} \to B^I \in W$, so $B^{I'}$ is also a cylinder object and the homotopy $A \to B^I$ can be lifted to $A \to B^{I'}$.
2. there is a diagram $\begin{array}{ccc} B & \xrightarrow{su} & C^I \\ \downarrow{\scriptstyle s} & & \downarrow{\scriptstyle (d_0, d_1)} \\ B^I & \xrightarrow{(d_0 u, d_1 u)} & C \times C \end{array}$ which has a lifting φ, then composed with $A \to B^I$ will give the desired homotopy.
3. the map is well-defined, it is surjective because of lifting property, and it is injective because $A \coprod A \to A \times I \in \mathrm{Cof}$ so the homotopy can be lifted to X.
   Cf.[Homotopy Theories and Model Categories, P20, 21].

□

Lemma (3.4.1.8) [Left and Right Homotopies]. If X is cofibrant, then for $f, g \in \mathrm{Hom}(X, Y)$, if $f \sim_l g$, then $f \sim_r g$. And the dual conclusion holds for Y fibrant.

In particular, for morphisms between bifibrant objects, left and right homotopic are equivalent.

Proof: Consider a cylinder object $j : X \wedge I \to X$ for X and a path object for Y. Soppse f, g are left homotopic via a map $H : X \wedge I \to Y$, then we consider the diagram

$$\begin{array}{ccccc} X & \xrightarrow{f} & Y & \longrightarrow & Y^I \\ \downarrow{\scriptstyle \partial_1} & & & \nearrow & \downarrow \\ X \wedge I & & \xrightarrow{(f\circ j)\times H} & & Y \times Y \end{array} .$$

Then it can be solved by some $\widetilde{H}$ because ∂_1 is trivial cofibration(3.4.1.2), and then it can be checked $H \circ \partial_1$ gives the desired right homotopy. □

Prop. (3.4.1.9) [Whitehead's Theorem]. Let $X, Y \in \mathcal{C}$ be bifibrant, then a map $f : X \to Y$ is an equivalence iff there is a $g : X \to Y$ that fg and gf are homotopic to id.

Proof: Cf.[Homotopy Theories and Model Categories, P23]. □

Prop. (3.4.1.10) [Lifting Criterion]. Let $\mathcal{C}$ be a model category and $i : A \to B$ be a cofibration between cofibrant objects, and X is fibrant, $g : B \to X, f : A \to X$ satisfies $g \circ i \sim f$, then there is a $g' \sim g$ that $g' \circ i = f$.

Proof: Choose a good cylinder object $C(A)$ for A and factorize

$$C(A) \coprod_{A \coprod A} (B \coprod B) \to C(B) \to B$$

where the first map is cofibration and the second is trivial fibration, then $C(B)$ is a good cylinder object for B.

The homotopy is given by a map $C(A) \coprod_A B \to X$, and we check $(A) \coprod_A B \to C(B)$ is a trivial cofibration(check $C(A) \coprod_A B \to B$ is weak equivalence using(3.4.0.6) and check $C(A) \coprod_A B \to C(A) \coprod_{A \coprod A} (B \coprod B)$ is a cofibration as a cobase change of $A \to B$ and $C(A) \coprod_{A \coprod A} (B \coprod B) \to C(B)$ is a cofibration by definition), so the homotopy extends to a homotopy $C(B) \to X$, which is a homotopy between g and some g' and $g' \circ i = f$. □

Def. (3.4.1.11). Let C_c, C_f, C_{cf} denote the full subcategory of cofibrant, fibrant and cofibrant-fibrant objects. And we define πC_c as the category module right homotopy equivalence between morphisms, dually for πC_f.

Notice(3.4.1.7) assures $\pi C_c, \pi C_f$ are truly categories.

Notice for C_{cf}, left homotopy is equivalent to right homotopy by(3.4.1.8), so πC_{cf} is full subcategory for both πC_c and πC_f.

Lemma (3.4.1.12) [Fibrant and Cofibrant Replacement]. For an object X in a model category $\mathcal{C}$, the axioms show there is a cofibrant object QX and a trivial fibration $QX \to X$. Also there is a fibrant object RX and a trivial cofibration $X \to RX$. We fix choices of Q, R that is identity on bifibrant objects, and consider it a mapping from $\mathcal{C}$ to $\mathcal{C}$.

Then given any morphism $f : X \to Y$, there is a morphism $\widetilde{f} : QX \to QY$ lifting f, and $\widetilde{f}$ depends up to left and right homotopy only on f. And if Y is fibrant, then it depends up to left and right homotopy only on the left homotopy classes of f.

Dually assertions also holds, so we have functors: $Q : \mathcal{C} \to \pi\mathcal{C}_c$ and $R : \mathcal{C} \to \pi\mathcal{C}_f$.

Proof: The existence of the lifting follows from the fact QX is fibrant and $QY \to Y$ is trivial fibration. The uniqueness of left homotopy follows from(3.4.1.7), and also right homotopy, because QX is cofibrant and use(3.4.1.8). For the last assertion, notice when Y is fibrant,(3.4.1.7) shows the left homotopy class of $QX \to Y$ is determined, and use(3.4.1.7) again, the class of $\widetilde{f}$ is also determined. □

Cor. (3.4.1.13). The restrictions define functors $Q' : \pi\mathcal{C}_c \to \pi\mathcal{C}_{cf}$ and $R' : \pi\mathcal{C}_f \to \pi\mathcal{C}_{cf}$.

Def. (3.4.1.14) [Homotopy Category]. For any model category $\mathcal{C}$, we construct a **homotopy category** $\mathrm{Ho}(\mathcal{C})$ whose objects are the same as $\mathcal{C}$, but $\mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(X,Y) = \mathrm{Hom}_{\pi C_{cf}}(RQX, RQY) = \pi(RQX, RQY)$.

There is a functor $\gamma : \mathcal{C} \to \mathrm{Ho}(\mathcal{C})$ by sending X to RQX, by(3.4.1.12).

Prop. (3.4.1.15) [Weak Equivalence and Isomorphisms]. A morphism in $\mathcal{C}$ maps to an isomorphism in $\mathrm{Ho}(\mathcal{C})$ iff it is a weak equivalence. The morphisms in $\mathrm{Ho}(\mathcal{C})$ are generated by the image of morphisms in $\mathcal{C}$ and the inverse of images of weak equivalences in $\mathcal{C}$.

Proof: If $f \in \mathcal{C}$ is a weak equivalence, then $f' = RQ(f)$ is also a weak equivalence, by two out of three lemma. Then Whitehead theorem(3.4.1.9) shows f' is an isomorphism in πC_{cf} hence in $\mathrm{Ho}(\mathcal{C})$. Conversely, if f' has an inverse in $\mathrm{Ho}(\mathcal{C})$, then f' is a weak equivalence by Whitehead(3.4.1.9) again, and so is f.

For the last assertion, just notice $\mathrm{Hom}(RQX, RQY) \to \mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(X,Y)$ is a surjection, and $X \to RQX, Y \to RQY$ are weak equivalence hence are isomorphisms in $\mathrm{Ho}(\mathcal{C})$. □

Cor. (3.4.1.16). If $F, G : \mathrm{Ho}(\mathcal{C}) \to \mathcal{D}$ are two functors and $t : F\circ\gamma \to G\circ\gamma$ is a natural transformation, then t also gives a natural transformation $F \to G$.

Proof: This is because the objects of $\mathrm{Ho}(\mathcal{C})$ are the same as that of $\mathcal{C}$, and the morphisms are generated by $\gamma(f)$ and $\gamma(g)^{-1}$ where g is a weak equivalence. Then the desired transformation commutative diagrams commute. □

Lemma (3.4.1.17). Let $\mathcal{C}$ be a model category and $F : \mathcal{C} \to \mathcal{D}$ be a functor taking weak equivalences to isomorphisms, then if $f \sim^l g$ or $f \sim^r g$, $F(f) = F(g)$.

Proof: We only prove for left homotopy and the right homotopy is dual: given the cylinder object $A \wedge I$, just need to prove that $F(\partial_0) = F(\partial_1)$. □

Prop. (3.4.1.18). Suppose A is cofibrant and X is fibrant, then the map $\gamma : \mathrm{Hom}(A,X) \to \mathrm{Hom}_{\mathrm{Ho}(C)}(A,X)$ is surjective, and induces a bijection $\pi(A,X) \cong \mathrm{Hom}_{\mathrm{Ho}(C)}(A,X)$.

Proof: (3.4.1.17) shows γ identifies homotopic maps. Consider the following commutative diagram:

$$\begin{array}{ccc} \pi(RA, QX) & \longrightarrow & \pi(A,X) \\ \downarrow{\scriptstyle\gamma} & & \downarrow{\scriptstyle\gamma} \\ \mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(RA, QX) & \longrightarrow & \mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(A,X) \end{array}.$$

The second vertical arrow is isomorphism by(3.4.1.15), the first arrow is isomorphism by(3.4.1.7). The left vertical arrow is identity by construction, so the right vertical arrow is also isomorphism. □

Cor. (3.4.1.19). There is a natural isomorphism $\pi\mathcal{C}_{cf} \cong \mathrm{Ho}(\mathcal{C})$.

Prop. (3.4.1.20) [Homotopy Category as Localizing Category]. Let $\mathcal{C}$ be a model category and W the class of weak equivalences, then the functor $\gamma : \mathcal{C} \to \mathrm{Ho}(\mathcal{C})$ is the localizing category of $\mathcal{C}$ w.r.t W.

Proof: Cf.[Homotopy Theories and Model Categories, P29].**?** □

2 Quillen Adjunctions and Derived Functors

Def. (3.4.2.1) [Quillen Adjunctions]. An adjunction $(F,G):\mathcal{C}\rightleftarrows\mathcal{D}$ between model categories is called a **Quillen adjunction** if F preserves cofibrations and G preserves fibrations. By adjointness and(3.4.0.4), in fact F preserves also trivial cofibrations and G preserves trivial fibrations.

Moreover, it is called a **Quillen equivalence** if for any cofibrant object $C\in\mathcal{C}$ and fibrant object $D\in\mathcal{D}$, a map $C\to G(D)$ is a weak equivalence iff the adjoint map $F(C)\to D$ is a weak equivalence.

Def. (3.4.2.2) [Derived Functors]. Let $\mathcal{C}$ be a model category and $F:\mathcal{C}\to\mathcal{D}$ a functor, then a **left derived functor** of F is a left Kan extension of F along $\gamma:\mathcal{C}\to\mathrm{Ho}(\mathcal{C})$.

Dually we can define **right derived functors**.

Prop. (3.4.2.3) [Existence of Derived Functors]. In the situation of(3.4.2.2), if F maps weak equivalences between cofibrant objects to isomorphisms in $\mathcal{D}$, then the left derived functor (LF,t) exists, and for each cofibrant object X, the morphism $t_X:LF(X)\to F(X)$ is an isomorphism.

Dually for the right derived functor case.

Proof: Cf.[Homotopy Theories and Model Categories, P42]. □

Lemma (3.4.2.4). Let $\mathcal{C}$ be a model category and $F:\mathcal{C}_c\to\mathcal{D}$ be a functor that maps trivial cofibrations in C_c to isomorphisms, then F maps right-homotopic morphisms to the same morphism.

Proof: Let $H:A\to B^I$ be a right homotopy between f and g, where B^I is a very good path object(3.4.1.5), then $B\to B^I$ is a trivial cofibration, and thus mapped by F to an isomorphism. Then we can show $F(\partial_0)=F(\partial_1)$, and then $F(f)=F(g)$. □

Def. (3.4.2.5) [Total Left Derived Functors]. Let $F:\mathcal{C}\to\mathcal{D}$ be a morphism of model categories, then a **total derived functor**

$$LF:\mathrm{Ho}(\mathcal{C})\to\mathrm{Ho}(\mathcal{D})$$

is defined to be a left derived functor of the morphism $\mathcal{C}\to\mathcal{D}\to\mathrm{Ho}(\mathcal{D})$.

Lemma (3.4.2.6) [Brown]. Let F be a morphism of model categories that maps trivial cofibration between cofibrant objects to weak equivalences, then it preserves weak equivalences between cofibrant objects.

Proof: If $f:A\to B$ is a weak equivalence between cofibrant objects, then we can factor the morphism $(f,\mathrm{id}):A\coprod B\to B$ as $A\coprod B\xrightarrow{q}C\xrightarrow{p}B$ that q is cofibration and p is trivial fibration. It can be shown that $q\circ\partial_i:B\to C$ are trivial fibrations and C is cofibrant, thus $F(q\circ\partial_i)$ are weak equivalences, and hence also $F(p)$ is weak equivalence and so does $F(f)$. □

Prop. (3.4.2.7) [Total Derived Functors and Quillen Equivalence]. If (F,G) is a pair of Quillen functors between two model categories $\mathcal{C},\mathcal{D}$, then total derived functors

$$LF:\mathrm{Ho}(\mathcal{C})\rightleftarrows\mathrm{Ho}(\mathcal{D}):RG$$

exists and form an adjunction pair. And if (F,G) is a Quillen equivalence, then (LF,RG) defines an equivalence of homotopy categories.

Proof: By(3.4.2.3) and its dual and(3.4.2.6), the total derived functors LF,RG exist.

Next for A cofibrant in $\mathcal{C}$ and X fibrant in $\mathcal{D}$, we can show the adjunction map $\mathrm{Hom}(A,G(X))\cong\mathrm{Hom}(F(A),X)$ preserves homotopy equivalence relations(3.4.1.8) and induces an isomorphism

$\pi(A, G(X)) \cong \pi(F(A), X)$: If $H : A \wedge I \to X$ is a good homotopy between f, g, then $A \wedge I$ is cofibrant, and because F preserves colimits and because of(3.4.2.6), $F(A \wedge I)$ is cylinder object for $F(A)$, thus $f^\flat \sim g^\flat$. A dual argument shows the converse.

Now for any $A \in \mathcal{C}$ and $X \in \mathcal{D}$, there is a bijection

$$\mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(A, RG(X)) \cong \pi(QA, G(SX)) \cong \pi(F(QA), SX) \cong \mathrm{Hom}_{\mathrm{Ho}(D)}(LFA, X)$$

where the first isomorphism is due to the fact $QA \to RQA$ is trivial cofibration and $G(SX)$ is fibrant, thus we can use(3.4.1.7), dually for the last isomorphism.

Finally if (F, G) is a Quillen equivalence, then consider the unit map:

$$A \to RG(LF(A)).$$

If A is cofibrant, then this is $A \to G(SF(A))$ which is a weak equivalence because $F(A) \to SF(A)$ does, so it is an isomorphism in $\mathrm{Ho}(\mathcal{C})$. Now any object in $\mathrm{Ho}(C)$ is isomorphic to a cofibrant object, we know the unit map is an isomorphism. Dually the counit map is an isomorphism, thus LF, GF are a pair of equivalences. □

3 Combinatorial Model Structure

Cf.[HTT, A.2.6]

Def. (3.4.3.1) [Cofibrantly-Generated Model Categories]. A **cofibrantly-generated model category** is a model category $\mathcal{C}$ that

- there is a small set I of generating cofibrations that generates the class of cofibrations as the minimal weakly saturated class containing I.
- there is a small set J of generating trivial cofibrations that generates the class of trivial cofibrations as the minimal weakly saturated class containing J.

Def. (3.4.3.2) [Combinatorial Model Categories, Smith]. A **combinatorial model category** is a cofibrantly generated(3.4.3.1) and locally presentable**??** model category.

Prop. (3.4.3.3) [Smith]. Let $\mathcal{M}$ be a combinatorial model category and $\mathcal{M}^{[1]}$ the category of arrows, then the full subcategory generated by fibrations, weak equivalences, or trivial fibrations are all full accessible(3.1.2.4) subcategories of $\mathcal{M}^{[1]}$.

Proof: Cf.[Lur09]P818. □

Prop. (3.4.3.4) [Constructing Combinatorial Model Categories]. Let $\mathcal{M}$ be a locally presentable category and W, C be classes of morphisms in $\mathcal{M}$ s.t.

- C is a weakly saturated class generated by a small subset C_0.
- $C \cap W$ is a weakly saturated class.
- $W \subset A^{[1]}$ is a full accessible subcategory.
- W satisfies the 2-out-of-3 property.
- $r(C) \subset W$.

Then $\mathcal{M}$ admits a combinatorial model category with

- Cofibrations: C.
- Weak equivalences: W.

- Fibrations: $r(C\cap W)$.

Proof: Cf.[Lur09]P821. □

Lemma (3.4.3.5). Situation as in(3.4.3.4), the class $C\cap W$ is a weakly saturated class generated by a small subset $S\subset C\cap W$.

Proof: Cf.[Lur09]P819. □

Prop. (3.4.3.6) [Constructing Left Proper Model Categories]. Let $\mathcal{M}$ be a locally presentable category with a class W of morphisms and a small set of morphisms C_0 s.t.

- W is a perfect class**??**,
- C_0 is stable under cobase change.
- W is stable under cobase change by C_0.
- $r(C_0)\subset W$.

Then there is a left proper combinatorial model category on $\mathcal{M}$ with

- Cofibrations: The weakly saturated closure C of C_0.
- Weak Equivalences: W.
- Fibrations: $r(C\cap W)$.

Moreover, any left proper combinatorial model category arises in this way.

Proof: Cf.[Lur09]P823. □

4 Generating new Model Categories

Prop. (3.4.4.1) [Overcategories and Undercategories]. If $\mathcal{C}$ is a model category and $A\in\mathcal{C}$, then the undercategory $\mathcal{C}_{A/}$ and the overcategory $\mathcal{C}_{/A}$ have natural model structures.

Proof: □

Prop. (3.4.4.2) [Transfer Model Structures via Left Adjoint]. Let

$$F:\mathcal{C}\rightleftarrows\mathcal{D}:G$$

be an adjoint pair of categories and

- $\mathcal{C},\mathcal{D}$ are complete and cocomplete,
- $\mathcal{C}$ is a cofibrantly generated model category,
- $\mathcal{C},\mathcal{D}$ are presentable categories and G is an accessible functor.
- If we define a morphism f in $\mathcal{B}$ a fibration/weak equivalent iff $G(f)$ is a fibration/weak equivalence, and a cofibration iff it has left lifting property w.r.t. trivial fibrations, then $\mathcal{B}$ has a path object factorization and a fibrant replacement operator.

Then this defines a cofibrantly generated model category on $\mathcal{B}$, and makes (F,G) a Quillen adjunction.

Proof: It suffices to show that the factorization property holds: In fact, it suffices to show if I, J are generating classes of cofibrations and trivial cofibrations, then $F(I)$, $F(J)$ are generating classes of cofibrations and trivial cofibrations. But this suffices to show $F(J)$ is are weak equivalence. For this, show that any morphism in $\mathcal{B}$ that has left lifting properties w.r.t. all fibrations is a weak equivalence using hypothesis item4.**?** □

Bousfield Localizations

Cf.[P.S. Hirschhorn. Model categories and their localizations].

Def. (3.4.4.3) [Bousfield Localizations]. Let $\mathcal{M}, \mathcal{M}'$ be model categories with the same underlying category, then $\mathcal{M}'$ is called a **Bousfield localization** of $\mathcal{M}$ if

- $\mathrm{Cof}(\mathcal{M}) = \mathrm{Cof}(\mathcal{M}')$.
- $\mathrm{Weak}(\mathcal{M}) \subset \mathrm{Weak}(\mathcal{M}')$.

5 Enriched and Monoidal Model Categories

Def. (3.4.5.1) [Left Quillen Bifunctor]. Let $\mathcal{A}, \mathcal{B}, \mathcal{C}$ be model categories, then a functor $\mathcal{A} \times \mathcal{B} \to \mathcal{C}$ is called a **left Quillen bifunctor** if

- For any cofibrations $i : A \to A' \in \mathcal{A}, B \to B' \in \mathcal{B}$, the induced map

$$i \wedge j : F(A', B) \coprod_{F(A,B)} F(A, B') \to F(A', B')$$

  is a cofibration in $\mathcal{C}$.
- F preserves small colimits separably in each variables.

Def. (3.4.5.2) [Monoidal Model Category]. A **monoidal model category** is a monoidal category $\mathcal{S}$ equipped with a model structure that:

- The tensor product $\otimes : S \times S \to S$ is a left Quillen bifunctor.
- The unit objects $1 \in \mathcal{S}$ is cofibrant.
- The monoidal structure is closed.

Def. (3.4.5.3) [Enriched Model Category]. Given a monoidal model category $\mathcal{S}$, an $\mathcal{S}$**-enriched model category** is an $\mathcal{S}$-enriched category $\mathcal{A}$ with a model structure satisfying:

- $\mathcal{A}$ is tensored and cotensored over $\mathcal{S}$**?**.
- the tensor product $\mathcal{A} \times \mathcal{S} \to \mathcal{S}$ is a left Quillen bifunctor(3.4.5.1).

Prop. (3.4.5.4). The second condition in(3.4.5.3) is equivalent to the following: For a cofibration $i : U \to V$ and a fibration $p : X \to Y$, the induced map

$$\mathrm{Map}(V, X) \xrightarrow{(i^*, p_*)} \mathrm{Map}(U, X) \times_{\mathrm{Map}(U,Y)} \mathrm{Map}(V, Y)$$

is a fibration in $\mathcal{S}$, and trivial fibration if any of i, p is weak equivalence.

Proof: Use the adjunction relations to write it out**?**. □

Def. (3.4.5.5) [Fibrant Enriched Categories]. Let $\mathcal{A}$ be a $\mathcal{S}$-enriched category, the we denote $\mathcal{A}^\circ$ the subcategory of bifibrant objects of $\mathcal{A}$, which is also a $\mathcal{S}$-enriched category.

6 Diagram Categories

[Lur09]A.2.8. A.3.3., A.3.5.

Prop. (3.4.6.1) [(Injective)Projective Model Categories]. Let S be an excellent model category and $\mathcal{A}$ a combinatorial $\mathcal{S}$-enriched model category, $\mathcal{C}$ a small $\mathcal{S}$-enriched category, then there are two model structures on $\mathcal{A}^{\mathcal{C}}$:

- The **projective model category** $\mathrm{Func}(\mathcal{C}, A)_{\mathrm{Proj}}$ with
  - Fibrations: **projective fibrations** F s.t. $F(C) \to G(C)$ is a fibration in $\mathcal{A}$ for each $C \in \mathcal{C}$.
  - Weak equivalences: F s.t. $F(C) \to G(C)$ is a weak equivalence in $\mathcal{A}$ for each $C \in \mathcal{C}$.
  - Cofibrations: **projective cofibrations** determined by the above two.
- The **injective model category** $\mathrm{Func}(\mathcal{C}, A)_{\mathrm{inj}}$ with
  - Cofibrations: **injective cofibrations** F s.t. $F(C) \to G(C)$ is a cofibration in $\mathcal{A}$ for each $C \in \mathcal{C}$.
  - Weak equivalences: F s.t. $F(C) \to G(C)$ is a weak equivalence in $\mathcal{A}$ for each $C \in \mathcal{C}$.
  - Fibrations: **injective fibrations** determined by the above two.

Proof: Cf.[Lur09]P868, P828. □

Cor. (3.4.6.2). Both model categories are left/right proper iff $\mathcal{A}$ is.

Cor. (3.4.6.3). Projective cofibrations are injective cofibrations, and injective fibrations are projective fibrations.

Prop. (3.4.6.4). Let $\mathcal{C}$ be a model category and let

$$\begin{array}{ccc} A & \xrightarrow{j} & A_1 \\ \downarrow{\scriptstyle i} & & \downarrow \\ A_0 & \longrightarrow & A_0 \coprod_A A_1 \end{array}$$

be a pushout diagram, then it is a homotopy pushout diagram if either of the following is satisfied:

- j is a cofibration and A, A_0 are cofibrant.
- j is a cofibration and $\mathcal{C}$ is left proper.

Proof:

□

Reedy Model Categories

Homotopy Colimits and Limits

Should be redone in the general language of diagram categories.?

Def. (3.4.6.5) [Homotopy Colimits and Limits]. In a model category $\mathcal{M}$, for any diagram $A_0 \leftarrow A \to A_1$, there exists a commutative diagram

$$\begin{array}{ccccc} A_0' & \xleftarrow{i} & A' & \xrightarrow{j} & A_1' \\ \downarrow & & \downarrow & & \downarrow \\ A_0 & \longleftarrow & A & \longrightarrow & A_1 \end{array}.$$

such that A' is cofibrant, and i, j are both cofibrant, and the vertical arrows are weak equivalences.

Then it can be shown that $A_0' \coprod_{A'} A_1'$ only depends on $A_0 \leftarrow A \to A_1$ up to weak equivalence. Then a commutative diagram

$$\begin{array}{ccc} A & \longrightarrow & A_1 \\ \downarrow & & \downarrow \\ A_0 & \longrightarrow & C \end{array}$$

is called a **homotopy colimit** if for any such cofibrant replacement,

$$A_0' \coprod_{A'} A_1' \to A_0 \coprod_{A} A_1 \to C$$

is a weak equivalence.

Dually we can define homotopy limits.

Proof: ? □

Cor. (3.4.6.6). Weakly equivalent diagrams induce weakly equivalent homotopy colimits.

Prop. (3.4.6.7). In a model category $\mathcal{M}$, a diagram

$$\begin{array}{ccc} A & \xrightarrow{j} & A_1 \\ \downarrow & & \downarrow \\ A_0 & \longrightarrow & A_0 \coprod_A A_1 \end{array}$$

is a homotopy limit if j is cofibrant, and either

- A, A_0 are cofibrant, or
- $\mathcal{M}$ is left proper.

Proof: ? □

7 Model Structures on $\mathcal{C}at_{\mathcal{S}}$

Def. (3.4.7.1) [Homotopy Category]. Let $\mathcal{S}$ be a monoidal model category, then there is a natural monoidal structure on the homotopy category $h\mathcal{S}$(3.4.1.14), and the functor $S \mapsto h\mathcal{S}$ is monoidal, thus we can transfer from a category $\mathcal{C}$ enriched over $\mathcal{S}$ to an $h\mathcal{S}$-enriched category, called the **homotopy category** of $\mathcal{C}$.

Def. (3.4.7.2) [Weak Equivalences of Enriched Categories]. Let $\mathcal{S}$ be a monoidal model category and $\mathcal{C}at_{\mathcal{S}}$ be the category of categories enriched over $\mathcal{S}$, then a morphism $F : \mathcal{C} \to \mathcal{D} \in \mathcal{C}at_{\mathcal{S}}$ is called a **weak equivalence** if it induced an isomorphism of their homotopy categories, or equivalently,

- F is essentially surjective,
- For any $X, Y \in \mathcal{C}$, $\mathrm{Map}_{\mathcal{C}}(X,Y) \to \mathrm{Map}_{\mathcal{D}}(FX,FY)$ is a weak equivalence in $\mathcal{S}$.

Def. (3.4.7.3) [Generating Cofibrations in $\mathcal{C}at_{\mathcal{S}}$]. Let $\mathcal{S}$ be a monoidal model category, A is an object of $\mathcal{S}$, then we can denote $[1]_A$ the $\mathcal{S}$-enriched category consists of objects $\{X,Y\}$ and that $\mathrm{Hom}(X,X) = \mathrm{Hom}(Y,Y) = 1_{\mathcal{S}}, \mathrm{Hom}(X,Y) = A, \mathrm{Hom}(Y,X) = \varnothing$. And if 1_S is the initial object of $\mathcal{S}$, then we denote $[1]_{1_{\mathcal{S}}}$ by $[1]_{\mathcal{S}}$. Also we denote $[0]_{\mathcal{S}}$ the $\mathcal{S}$-enriched category consisting of one element and the morphism space is $1_{\mathcal{S}}$.

Let $[1]_{\mathcal{S}}^{\sim}$ be the category consisting of two objects $\{X,Y\}$ that $\mathrm{Hom}(Z_1,Z_2) = 1_{\mathcal{S}}$ for any $Z_1, Z_2 \in \mathcal{S}$.

Let C_0 be the class of morphisms in $\mathcal{C}at_{\mathcal{S}}$ consisting of

- $\varnothing \to [0]_{\mathcal{S}}$.
- The induced map $[1]_S \to [1]_{S'}$ where $S \to S'$ ranges over a generating class of cofibrations of $\mathcal{S}$.

Prop. (3.4.7.4) [Model Category on $\mathcal{C}at_{\mathcal{S}}$]. Let $\mathcal{S}$ be a combinatorial monoidal model category that every object of $\mathcal{S}$ is cofibrant and the collection of weak equivalences of $\mathcal{S}$ is stable under filtered colimits, then there exists a left proper combinatorial model structure on $\mathcal{C}at_{\mathcal{S}}$ that

- The class of cofibrations in $\mathcal{C}at_{\mathcal{S}}$ is the smallest weakly saturated class generated by C_0 defined in(3.4.7.3),
- The weak equivalences are as defined in(3.4.7.2).

Proof: Cf.[HTT, P856]. □

Cor. (3.4.7.5). Let

$$f : \mathcal{S} \rightleftarrows \mathcal{S}' : g$$

be a Quillen adjunction between monoidal model categories satisfying conditions in(3.4.7.4), then they induces a Quillen adjunction

$$F : \mathcal{C}at_{\mathcal{S}} \rightleftarrows \mathcal{C}at_{\mathcal{S}'} : G$$

and this is a Quillen equivalence if (f,g) is.

Proof:

□

Prop. (3.4.7.6). Let $\mathcal{C}, \mathcal{D}$ be $\mathcal{S}$-enriched model categories and

$$F : \mathcal{C} \underset{}{\overset{\text{Quillen}}{\rightleftarrows}} \mathcal{D} : G$$

is a Quillen adjunction of underlying model categories. Assume every objects of $\mathcal{C}$ is cofibrant and the maps $\beta_{X,S} : S \otimes F(X) \to F(S \otimes X)$ is a weak equivalence for $X \in \mathcal{C}, S \in \mathcal{S}$ cofibrant, then the following are equivalent:

- (F,G) is a Quillen equivalence.
- G determines a weak equivalence(3.4.7.2) of the underlying $\mathcal{S}$-enriched categories $\mathcal{D}_{cf} \to \mathcal{C}_{cf}$.

Proof: Cf.[HTT, P853]. □

Def. (3.4.7.7) [Local Fibrations]. Let $\mathcal{C}$ be an $\mathcal{S}$-enriched category where $\mathcal{S}$ is a monoidal model category, then a morphism $f \in \mathcal{C}$ is called an **equivalence** if it maps to an isomorphism in $h\mathcal{C}$.

$\mathcal{C}$ is called **locally fibrant** if for any $X, Y \in \mathcal{C}$, the mapping space $\mathrm{Map}(X, Y)$ is fibrant in $\mathcal{S}$.

An $\mathcal{S}$-enriched functor $F : \mathcal{C} \to \mathcal{C}'$ is called a **local fibration** if the following conditions are satisfied:

- for any $X, Y \in \mathcal{C}$, the induced map $\mathrm{Map}(X, Y) \to \mathrm{Map}(FX, FY)$ is a fibration in $\mathcal{S}$.
- the induced map $h\mathcal{C} \to h\mathcal{C}'$ is a quasi-fibration of categories.

Def. (3.4.7.8) [Invertibility Hypothesis]. We say a monoidal model category $\mathcal{S}$ satisfies the **invertibility hypothesis** if: For any cofibrant morphism $[1]_{\mathcal{S}} \to \mathcal{C}$(3.4.7.3) of $\mathcal{S}$-enriched categories, and maps to a morphism f which is invertible in the homotopy category $h\mathcal{C}$, take the pushout:

$$\begin{array}{ccc} [1]\,\mathcal{S} & \xrightarrow{i} & \mathcal{C} \\ \downarrow & & \downarrow j \\ [1]_{\mathcal{S}}^{\sim} & \longrightarrow & \mathcal{C}\langle f^{-1}\rangle \end{array} .$$

then j is a weak equivalence of $\mathcal{S}$-enriched categories(3.4.7.2).

Def. (3.4.7.9) [Excellent Model Category]. An **excellent model category** is a monoidal model category $\mathcal{S}$ that The monoidal structure is symmetric.

- $\mathcal{S}$ is combinatorial,
- Every monomorphism in $\mathcal{S}$ is a cofibration, and the collection of cofibrations is stable under products,
- The class of weak equivalences in $\mathcal{S}$ is stable under filtered colimits,
- $\mathcal{S}$ satisfies the invertibility condition(3.4.7.8)

Lemma (3.4.7.10). Let $T : \mathcal{S} \to \mathcal{S}'$ be a monoidal functor between monoidal model categories satisfies axioms besides invertibility hypothesis, that is also a left Quillen functor, then if S' satisfies invertibility hypothesis, so does S.

Proof: Cf.[HTT, P862].**?** □

Prop. (3.4.7.11) [Fibration and Local Fibration]. If $\mathcal{S}$ is an excellent model category, then

- An $\mathcal{S}$-enriched category $\mathcal{C}$ is a fibrant object in $\mathcal{C}at_{\mathcal{S}}$ iff it is locally fibrant(3.4.7.7).
- Let $F : \mathcal{C} \to \mathcal{D}$ be an $\mathcal{S}$-enriched functor and $\mathcal{D}$ is fibrant in $\mathcal{C}at_{\mathcal{S}}$, then F is fibrant in $\mathcal{C}at_{\mathcal{S}}$ iff it is a local fibration.

Proof: Cf.[HTT, P863]. □

Path Spaces

Homotopy Colimits of Enriched Categories

8 Examples

Prop. (3.4.8.1)[Kan-Quillen Model Structure]. By(3.5.3.47), $s\,\mathcal{S}\mathrm{et}$ is a combinatorial left and right proper Kan-Quillen model category with

- Weak equivalences: weak equivalences,

- Cofibrations: inclusions,
- Fibrations: Kan fibrations.

Prop. (3.4.8.2) [Dwyer, Kan]. $s\mathcal{S}\mathrm{et}$ has an excellent model category with the Kan model structure and the Cartesian monoidal structures.

Proof: □

Prop. (3.4.8.3) [q-Model Structure]. For a unital ring R, then the category $\mathrm{Ch}_{\mathbb{N}} R$ has the structure of a model category with a morphism $f : M_\bullet \to N_\bullet$ being

- a weak equivalence if $H_n(f)$ is isomorphism for any n.
- a fibration if $M_n \to N_n$ is surjective for any $n \geq 1$.
- a cofibration if $M_n \to N_n$ is injective with projective cokernel for any $n \geq 0$.

Proof: [Model category and simplicial methods, P5] or [Homotopy Theories and Model Categories]. □

Prop. (3.4.8.4)[Serre-Quillen]. By(3.12.6.28), the category $\mathcal{CG}$ can be given a **Serre-Quillen model structure** with

- Weak equivalences: weak homotopy equivalence,
- Fibrations: Serre fibrations,
- Cofibrations: Retracts of morphisms $X \to Y$ where Y is obtained from X by attaching cells.

And this restricts to a model category on the category $\mathcal{CGH}$ of compactly generated weak Hausdorff spaces.

Prop. (3.4.8.5) [Hurewicz-Str∅m]. The category $\mathcal{T}\mathrm{op}$ can be given a **Hurewicz-Str∅m model structure** with

- Weak equivalences: homotopy equivalences.
- Cofibrations: closed Hurewicz cofibrations.
- Fibrations: Hurewitz fibrations.

Proof: See(3.12.6.31). □

Prop. (3.4.8.6) [Derived Categories Model Structure]. If $\mathcal{A}$ is an Abelian category with enough injectives, then $K^+(\mathcal{A})$ is a model category with

- Weak equivalence: quasi-isomorphisms,
- Fibration: epimorphisms with ker in $K^+(\mathcal{I})$,
- Cofibration: monomorphisms.

Proof: □

Prop. (3.4.8.7) [Joyal Model Structures]. By(3.5.4.19), there is a Joyal Model category structure on $s\mathcal{S}\mathrm{et}$ with

- Cofibrations: monomorphisms.
- Weak equivalences: categorical equivalences defined in(3.5.4.12).
- Fibrations: **categorical fibrations** or **Joyal fibrations** which has the right lifting property w.r.t. trivial cofibrations.

Prop. (3.4.8.8) [Reedy Model Structures]. Cf.[HTT, A.2.9].

Prop. (3.4.8.9) [Bergner-Model Structure]. There is a Bergner model structure on $s\,\mathcal{C}\mathrm{at}$**?**.(3.5.4.4)

3.5 Simplicial Homotopy Theory

Main references are [Jardine Simplicial Homotopy Theory], [Lur09].

Notation (3.5.0.1).
- Use notations from Model Categories.

1 Simplicial Objects

Def. (3.5.1.1) [Simplex Category]. The **simplex category** Δ consists of simplicial objects $[n]$ for each $n \geq 0$ and there maps are order-preserving maps.

Δ has a subcategory Δ_+ consisting of the same objects but the morphisms are all surjective order-preserving maps.

For $\mathcal{C} \in \mathcal{T}op$, a **simplicial object** in $\mathcal{C}$ is a functor $\Delta^{op} \to \mathcal{C}$. A **cosimplicial object** in $\mathcal{C}$ is a simplicial object in $\mathcal{C}^{\mathrm{op}}$. The category of simplicial objects in $\mathcal{C}$ is denoted by $s\mathcal{C}$.

Given a simplicial or cosimplicial object in $\mathcal{A}$, its **underlying degeneracy map** is defined to be?

Prop. (3.5.1.2). If $\mathcal{C}$ is complete or cocomplete, then so is $s\mathcal{C}$.

Def. (3.5.1.3). Δ^n is the simplicial set $\Delta^n([m]) = \mathrm{Hom}([m], [n])$.

Def. (3.5.1.4) [Augmentation]. If X is a simplicial object in a category, then an **augmentation** of X is a morphism $d : A \to X$ that $dd_0 = dd_1$. In case $\mathcal{C}$ is $\mathcal{M}od_R$, this is equivalent to a morphism $\pi_0(X) \to A$(4.8.2.2).

Def. (3.5.1.5) [s-Free Simplicial Objects]. $X \in s\mathcal{C}$ is called **s-free** if the underlying category $\Delta_+^{\mathrm{op}} \to \mathcal{C}$ is Δ^{op}-free(3.1.3.16).

Equivalently, an s-free object is a simplicial object X that there are objects $Z_n \in \mathcal{C}$ that $X_n = \coprod_{\varphi:[n]\twoheadrightarrow[k]} \varphi^* Z_k$. Moreover, a simplicial morphism of simplicial objects are called s-free if the underlying diagram $X_+ \to Y_+$ is of the form $X_+ \to X_+ \coprod Y_0$ where Y_0 is s-free.

Prop. (3.5.1.6) [$s\mathcal{C}$ is a Simplicial Category]. Let $s\mathcal{C}$ be the category of simplicial $\mathcal{C}$-objects, then it can be made into a simplicial category which is also tensored and cotensored(3.1.7.7) over $\mathcal{S}et_\Delta$.

Proof: We define first a action of $\mathcal{S}et_\Delta$ on $s\mathcal{C}$:

$$\otimes : \mathcal{S}et_\Delta \times s\mathcal{C} \to s\mathcal{C} : (K, X) \mapsto (K \otimes X)_n = \coprod_{K_n} X_n,$$

with the simplicial maps determined by that of K and X.

Also there is a action of $s\,\mathrm{Set}^{\mathrm{op}}$ on $s\mathcal{C}$:

$$(-)^- : \mathcal{S}et_\Delta^{op} \times s\mathcal{C} \to s\mathcal{C} : (K \otimes X)_n = \prod_{K_n} X_n$$

with the simplicial maps determined by that of K and X.

Then there is an adjointness

$$\mathrm{Hom}_{s\mathcal{C}}(K \otimes X, Y) \cong \mathrm{Hom}_{s\mathcal{C}}(X, Y^K)$$

for any simplicial set K.

Next we define $\mathrm{Map}_{s\mathcal{C}}(X,Y) \subset \mathcal{S}\mathrm{et}_\Delta$ as $(\mathrm{Map}_{s\mathcal{C}}(X,Y))_n = \mathrm{Hom}_{s\mathcal{C}}(X \otimes \Delta^n, Y)$, then there are functorial isomorphisms

$$\mathrm{Map}_{s\mathcal{C}}(K \otimes X, Y) \cong \mathrm{Map}_{s\mathcal{C}}(X, Y^K) \cong \mathrm{Map}_{\mathcal{S}\mathrm{et}_\Delta}(K, \mathrm{Map}_{s\mathcal{C}}(X,Y))$$

(easy to check). So we are done. □

Remark (3.5.1.7) [Realization Functor]. For $\mathcal{C} \in \mathcal{C}\mathrm{at}$ that has countable colimits, there is a **simplicial realization functor**

$$|-| : s\mathcal{C} \to \mathcal{C} : X \mapsto \varinjlim_{\Delta_+^{\mathrm{op}}} X_n.$$

2 Topological Categories

Def. (3.5.2.1) [Topological Categories]. A **topological category** is a category that is enriched over the category $\mathcal{CG}$ of compactly generated and Hausdorff spaces. The category of topological categories is denoted by $\mathcal{C}\mathrm{at}_{\mathcal{CG}}$.

Two topological categories is called **strongly equivalent** if they are equivalent as enriched categories.

Def. (3.5.2.2) [Homotopy Category of a Topological Category]. Given a topological category $\mathcal{C}$, the **homotopy category** $h\mathcal{C}$ of $\mathcal{C}$ is defined to be the category transferred from $\mathcal{C}$(3.1.7.4) by the right-lax monoidal functor π_0(3.1.5.14).

Def. (3.5.2.3) [Homotopy Category of Spaces]. Let $\mathcal{C}$ be the category of CW complexes that the morphisms are given the compact-open topology, then its homotopy category $\mathscr{H}$ is called the **homotopy category of spaces**.

3 Simplicial Sets

Simplicial Sets

Remark (3.5.3.1). The fact that any simplicial set X is a colimit of Δ^n (3.1.3.13) is important in proving properties of constructions of simplicial set.

Def. (3.5.3.2) [Objects and Morphisms]. Given a simplicial set S, its **objects** are just objects in $S([0])$, and its **morphisms** are objects in $S([1])$.

Def. (3.5.3.3) [Simplicial Sets and Categories]. There is an embedding $\Delta \to \mathcal{C}\mathrm{at} : [n] \to [n]$ regarding $[n]$ as a category, which by Yoneda extension(3.1.3.14) and(3.1.1.46) corresponds to an adjunction

$$\tau_1 : s\,\mathcal{S}\mathrm{et} \rightleftharpoons \mathcal{C}\mathrm{at} : N$$

where τ_1 is called the **fundamental category functor** and $N : \mathcal{C}\mathrm{at} \to s\,\mathcal{S}\mathrm{et}$ is the **nerve functor**.

Prop. (3.5.3.4) [Nerve Functor is Fully Faithful]. The nerve functor $N : \mathcal{C}\mathrm{at} \to s\,\mathcal{S}\mathrm{et}$ is fully faithful. Equivalently, by(3.1.1.31), for any $\mathcal{C} \in \mathcal{C}\mathrm{at}$, there is a natural isomorphism $\tau_1(N(\mathcal{C})) \cong \mathcal{C}$.

Prop. (3.5.3.5) [Natural Transformation and Homotopy]. A natural transformation will induce homotopic nerve map. thus a pair of adjoint functors will induce a simplicial homotopy between their nerve.

Proof: □

Prop. (3.5.3.6) [Characterizing Nerves]. For $K \in s\,\mathcal{S}\mathrm{et}$,

- there exists $\mathcal{C} \in \mathcal{C}\mathrm{at}$ that $K \cong N(\mathcal{C})$ iff for each $0 < i < n$ and each diagram

$$\begin{array}{ccc} \Lambda_i^n & \longrightarrow & K \\ \big\downarrow & \nearrow & \\ \Delta^n & & \end{array}$$

  there exists uniquely a dotted arrow.
- there exists $\mathcal{C} \in \mathcal{G}\mathrm{rpd}$ that $K \cong N(\mathcal{C})$ iff for each $0 \le i \le n$ and each diagram

$$\begin{array}{ccc} \Lambda_i^n & \longrightarrow & K \\ \big\downarrow & \nearrow & \\ \Delta^n & & \end{array}$$

  there exists uniquely a dotted arrow.

Proof: [HTT, P9]. □

Def. (3.5.3.7) [Fundamental Groupoid Functor]. Let $\pi_1 = \mathcal{G}\mathrm{rp} \circ \tau_1 : s\,\mathcal{S}\mathrm{et} \to \mathcal{G}\mathrm{rpd}$, called the **fundamental groupoid functor**, then by(3.5.3.3) and(3.1.1.35), there is an adjunction

$$\pi_1 : s\,\mathcal{S}\mathrm{et} \rightleftharpoons \mathcal{G}\mathrm{rpd} : N$$

Def. (3.5.3.8) [Topological Realization Functor]. There is a functor $\Delta \to \mathcal{CG} : [n] \mapsto \Delta^n$, which by Yoneda extension(3.1.3.14) corresponds to an adjunction

$$|\cdot| : s\,\mathcal{S}\mathrm{et} \rightleftharpoons \mathcal{CG} : \mathrm{Sing}$$

called the **topological geometrization** functor and the singular complex functor.

Prop. (3.5.3.9). The geometrization as a functor from $s\,\mathcal{S}\mathrm{et} \to \mathcal{CG}$ preserves finite limits.

The three kinds of geometrization of a bisimplicial set is the same: geometrization the diagonal simplicial set, the twice geometrization of left(resp. right) simplicial set.

Proof: Cf.[Jardine P9].? □

Def. (3.5.3.10) [Weak (Homotopy) Equivalences]. A morphism of simplicial sets $S \to T$ is called a **weak equivalence** if the induced map $|S| \to |T|$(3.5.3.8) is a weak homotopy equivalence.

Constructing Simplicial Sets

Def. (3.5.3.11) [Opposite Simplicial Sets]. There is an involution in the simplex category $\iota : \Delta \to \Delta$ that maps any ordered set to its reverse order. Then for any simplicial set $S : \Delta^{\mathrm{op}} \to \mathcal{S}\mathrm{et}$, there is another simplicial set $S^{\mathrm{op}} = S \circ \iota$, called the **opposite simplicial set**.

Prop. (3.5.3.12). For $\mathcal{C} \in \mathcal{C}\mathrm{at}$, there is a natural isomorphism of simplicial sets $N(\mathcal{C})^{\mathrm{op}} \cong N(\mathcal{C}^{\mathrm{op}})$.

Def. (3.5.3.13) [Mapping Spaces]. For $X, Y \in s\,\mathcal{S}\mathrm{et}$, the **mapping space** $\mathrm{Map}(X,Y)$ or Y^X is a simplicial set s.t.

$$\mathrm{Map}(X,Y)_n = \mathrm{Hom}_{s\,\mathcal{S}\mathrm{et}}(\Delta^n \times X, Y).$$

Prop. (3.5.3.14) [Closed Cartesian Monoidal Structure]. $s\,\mathcal{S}\mathrm{et}$ is a closed Cartesian monoidal category, and for any $X, Y, Z \in s\,\mathcal{S}\mathrm{et}$, there is an isomorphism of simplicial sets

$$\mathrm{Map}(X, \mathrm{Map}(Y,Z)) \cong \mathrm{Map}(X \times Y, Z).$$

Proof:

□

Prop. (3.5.3.15). For $\mathcal{A}, \mathcal{B} \in \mathcal{C}\mathrm{at}$, then there is a natural isomorphism of simplicial sets $N(\mathrm{Func}(\mathcal{A},\mathcal{B})) \cong \mathrm{Map}(N(\mathcal{A}), N(\mathcal{B}))$.

Proof: There are natural bijections

$$\begin{aligned} N(\mathrm{Func}(\mathcal{A},\mathcal{B}))_n &= \mathrm{Func}([n]\times\mathcal{A},\mathcal{B}) \\ (3.5.3.4) &\cong \mathrm{Map}(N([n]\times\mathcal{A}), N(\mathcal{B})) \\ &\cong \mathrm{Map}(\Delta^n \times N(\mathcal{A}), N(\mathcal{B})) \\ &= \mathrm{Map}(N(\mathcal{A}), N(\mathcal{B}))_n, \end{aligned}$$

and they form an isomorphism of simplicial sets. □

Cor. (3.5.3.16). For any $x \in S_m, x' \in S'_n$, there is a unique $y \in (S * S')_{m+n+1}$ s.t. $y|_{[0,\ldots,m]} \cong x, y|_{[m+1,\ldots,m+n+1]} \cong x'$.

Def. (3.5.3.17) [Joins]. Let $S, S' \in s\,\mathcal{S}\mathrm{et}$, then the **join** of S, S' is defined to be the simplicial set that for all any finite ordered set J,

$$(S \star S')(J) = \cup_{J=I\coprod I'} S(I) \times S(I').$$

where I, I' satisfies $i < i'$ for any $i \in I, i' \in I'$. And the glueing is natural.

Prop. (3.5.3.18).

- $\Delta^i \star \Delta^j \cong \Delta^{i+j+1}$.
- The join operation is a functor $s\,\mathcal{S}\mathrm{et} \to s\,\mathcal{S}\mathrm{et}$ that preserves colimits in each coordinate,
- $s\,\mathcal{S}\mathrm{et}$ is a symmetric monoidal category under the join operation.
- If $\mathcal{C}, \mathcal{C}' \in \mathcal{C}\mathrm{at}$, there is a natural isomorphism $N(\mathcal{C}) \star N(\mathcal{C}') \cong N(\mathcal{C} \star \mathcal{C}')$.

Proof: All these are clear. □

Def. (3.5.3.19) [Cones]. For a simplicial set K, the **left/right cone** of K are defined to be the join $K^{\triangleleft} = \Delta^0 \star K$ and $K^{\triangleright} = K \star \Delta^0$.

For a map $f : X \to S$, the **left/right cone** of f are defined to be $S \coprod_X X^{\triangleleft}$ and $S \coprod_X X^{\triangleright}$.

Example (3.5.3.20). $(\Lambda^2_2)^{\triangleleft} \cong (\Lambda^2_0)^{\triangleright} \cong \Delta^1 \times \Delta^1$.

Def. (3.5.3.21) [Overcategories and undercategories]. For $p : K \to S \in s\,\mathcal{S}\mathrm{et}$, there is a simplicial set $S_{/p}$ that

$$\mathrm{Hom}(Y, S_{/p}) \cong \mathrm{Hom}_p(Y \star K, S) \triangleq \mathrm{Hom}_{s\,\mathcal{S}\mathrm{et}_{K/}}(Y \star K, S)$$

And dually we can define the **undercategories**.

There are canonical maps $S_{/p} \to S$ and $S_{p/} \to S$.

Proof: We just define $(S_{/p})_n = \mathrm{Hom}_p(K \star \Delta^n, S)$, then the condition holds for Δ^n, and use the fact every simplicial set is a colimit of Δ^ns(3.5.3.1), and both sides commutes with colimits in Y by(3.5.3.18). □

Def. (3.5.3.22). For $\mathcal{C}_0 \subset \mathcal{C} \in s\,\mathcal{S}\mathrm{et}$ and any diagram $p : K \to \mathcal{C}$, denote $\mathcal{C}^0_{/p} = \mathcal{C}^0 \times_{\mathcal{C}} \mathcal{C}_{/p}$.

Prop. (3.5.3.23). For $p : A \to B \in \mathcal{C}\mathrm{at}$, there is a natural isomorphism of simplicial sets

$$N(B_{/p}) \cong N(B)_{/N(p)}.$$

Proof: There is a natural map from LHS to RHS, and we also have natural isomorphisms

$$\begin{aligned}
N(B_{/p})_n &= \mathrm{Hom}([n], B_{/p}) \\
&= \mathrm{Hom}_{\mathcal{C}\mathrm{at}_{A/}}(A \to [n] \star A, A \xrightarrow{p} B) \\
\text{(3.5.3.4)} &= \mathrm{Hom}_{s\,\mathcal{S}\mathrm{et}_{N(A)/}}(N(A) \to N([n] \star A), N(A) \xrightarrow{N(p)} N(B)) \\
\text{(3.5.3.18)} &= \mathrm{Hom}_{s\,\mathcal{S}\mathrm{et}_{N(A)/}}(N(A) \to \Delta^n \star N(A), N(A) \xrightarrow{N(p)} N(B)) \\
&= \mathrm{Hom}_{s\,\mathcal{S}\mathrm{et}}(\Delta^n, N(B)_{/N(p)}) = (N(B)_{/N(p)})_n
\end{aligned}$$

□

Prop. (3.5.3.24) [Generating Simplicial Sets]. Let $\mathcal{U}$ be a collection of simplicial sets that:

- $\mathcal{U}$ is stable under isomorphisms,
- $\mathcal{U}$ is stable under disjoint union,
- $\Delta^n \subset \mathcal{U}$ for any n,
- If there is a pushout diagram $\begin{array}{ccc} X & \longrightarrow & X' \\ \downarrow f & & \downarrow \\ Y & \longrightarrow & Y' \end{array}$ and $X, X', Y \in \mathcal{U}$ and f is a monomorphism, then $Y' \in \mathcal{U}$,
- suppose we are given a sequence of monomorphisms between objects in $\mathcal{U}$ indexed over $\mathbb{N}$, then the colimit belongs to $\mathcal{U}$.

Then $\mathcal{U} = s\,\mathcal{S}\mathrm{et}$.

Proof: Use induction on the dimension of S, and notice S is glued together using their simplexes. □

Fibrations and Anodynes

Def. (3.5.3.25) [Fibrations]. A morphism of simplicial sets is called a

- **Kan fibration** iff it has right lifting property w.r.t all $\Lambda^n_i \to \Delta^n, 0 \leq i \leq n$.
- **left fibration** iff it has right lifting property w.r.t. all inclusions $\Lambda^n_i \subset \Delta^n, 0 \leq i < n$.
- **right fibration** iff it has right lifting property w.r.t all inclusions $\Lambda^n_i \subset \Delta^n, 0 < i \leq n$.
- **inner fibration** iff it has right lifting property w.r.t all inclusions $\Lambda^n_i \subset \Delta^n, 0 < i < n$.

So a morphism between topological spaces $X \to Y$ is a Serre fibration iff $S(X) \to S(Y)$ is a Kan fibration(3.5.3.8).

Def. (3.5.3.26) [Anodynes]. A morphism of simplicial set is called a

- **anodyne** iff it has left lifting property w.r.t. all Kan fibrations.
- **left anodyne** iff it has left lifting property w.r.t. all left fibrations.
- **right anodyne** iff it has left lifting property w.r.t all right fibrations.
- **inner anodyne** iff it has right lifting property w.r.t all inner fibrations.

Def. (3.5.3.27) [Trivial (Kan)Fibrations]. A morphism $X \to S$ of simplicial sets that has right lifting property w.r.t. all inclusions $\partial\Delta^n \to \Delta^n$ is called a **trivial fibration**.

A **cofibration** is a morphism that has left lifting property w.r.t all trivial fibrations. By(3.1.7.15) a cofibration of simplicial sets is just an inclusion.

Lemma (3.5.3.28) [Join and Anodynes]. If $f : A_0 \subset A$ and $g : B_0 \subset B$ are inclusions of simplicial sets, then

$$h : (A_0 \star B) \coprod_{A_0 \star B_0} (A \star B_0) \subset A \star B$$

is a(n)

- inner anodyne if either f is right anodyne or g is left anodyne, then
- left anodyne if f is left anodyne.

Proof: 1: By symmetry we assume f is right anodyne. Notice the class of all morphisms f that the conclusion holds is weakly saturated because $\star$ commutes with colimits, so it suffice to check for $f : \Lambda^n_j \subset \Delta^n$. Then similarly it suffices to check for $g : \partial\Delta^m \subset \Delta^m$, but then the inclusion is just $\Lambda^{m+n+1}_j \subset \Delta^{m+n+1}$, which is left anodyne.

2 is similar. □

Prop. (3.5.3.29) [Anodynes].

- The saturated class generated by either of the following three classes of monomorphisms are both left anodynes:
  1. $\Lambda^n_k \subset \Delta^n$, $0 \leq k < n$.
  2. $(\Delta^m \times \{0\} \coprod (\partial\Delta^m \times \Delta^1) \subset \Delta^m \times \Delta^1$.
  3. $(S' \times \{0\}) \coprod (S \times \Delta^1) \subset S' \times \Delta^1$, where $S \subset S'$.

  Similar conclusion holds for right anodynes and together implies the similar conclusion for anodynes.
-

Proof:

- 2 and 3 are equivalence because any inclusion comes from attaching cells(3.5.3.3). Now inclusions in 2 are compositions of pushouts of inclusions $\Lambda^{n+1}_k \subset \Delta^{n+1}$, where $0 \leq k \leq n$, thus it is generated by 1. Conversely, $\Lambda^n_i \subset \Delta^n$ is a retract of $(\Delta^n \times \{0\}) \coprod (\Lambda^n_i \times \Delta^1) \subset \Delta^n \times \Delta^1$: Cf.[HTT, P64].
-

□

Cor. (3.5.3.30) [Products and Anodynes]. Let $A \subset A'$ be a(n) left(inner) anodyne and $B \subset B'$, then so does the induced map

$$(A \times B') \coprod_{A \times B} (A' \times B) \to A' \times B'.$$

Proof: For left anodyne, the proof is similar to that of(3.5.3.28), just check for classes 3 of(3.5.3.29), and use the fact

$$(S' \times \Delta^1) \times B \coprod (S' \times \{0\} \coprod S \times \Delta^1) \times B' \to (S' \times \Delta^1) \times B'$$

is just

$$(S' \times B \coprod S \times B') \times \Delta^1 \coprod (S' \times B') \times \{0\} \to (S' \times B') \times \Delta^1.$$

which is left(inner) anodyne. And similarly for inner anodynes. □

Left Fibration

Remark (3.5.3.31) [Left and Right Fibrations Dual]. The theory of left fibrations is dual to the theory of right fibrations, thus we don't study right fibrations.

Prop. (3.5.3.32) [Left Fibration and CoFibered in Groupoids]. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor, then $\mathcal{C}$ is a category cofibered in groupoids over $\mathcal{D}$ iff the induced functor $N(F) : N(\mathcal{C}) \to N(\mathcal{D})$ is a left fibration of simplicial sets.

Proof: By(3.5.3.6), $N(F)$ is an inner fibration, thus it suffices to check for $\Lambda^n_0 \to \Delta^n$. For $n = 1$, this is the definition of cofibered category(3.1.8.10), and $n = 2$ is just the surjectivity of the map defining CoCartesian arrows(3.1.8.7), and $n = 3$ is equivalent to the injectivity of the map defining Cocartesian arrows. And for $n > 3$, then extension is automatic for nerves. □

Remark (3.5.3.33) [Right Fibrations and Fibered Categories]. The (left)right fibration is the ∞-categorial analogue of (co)fibered categories in usual category theory.

Remark (3.5.3.34). Given a left fibration $X \to S$ is more or less similar to given a functor from the homotopy category hS to the ∞-category $\mathcal{H}$ of spaces.

Proof: Cf.[HTT, P58].? □

Prop. (3.5.3.35) [Over(Under)categories and Fibrations]. Given a digram of simplicial sets:

$$A \subset B \xrightarrow{p} X \xrightarrow{q} S.$$

Let $r = q \circ p$, $p_0 = p|_A, r_0 = r|_A$, and q is an inner fibration, then

- the induced map $X_{p/} \to X_{p_0/} \times_{S_{r_0/}} S_{r/}$ is a left fibration. And dual argument holds for overcategories.

- If q is a left fibration or $A \subset B$ is right anodyne, then $X_{p/} \to X_{p_0/} \times_{S_{r_0/}} S_{r/}$ is a trivial fibration.
- If q is moreover a left fibration, then the induced map $X_{/p} \to X_{/p_0} \times_{S_{/r_0}} S_{/r}$ is a left fibration.

Proof: These just follow from(3.5.3.28). □

Prop. (3.5.3.36) [Homotopy Extension Lifting Property]. Let $p : X \to S$ be a map of simplicial sets and $i : A \subset B$, consider the map

$$q : X^B \to X^A \times_{S^A} S^B.$$

- If p is a left fibration, then q is a left fibration.
- If p is a left fibration i is a left anodyne, then q is a trivial fibration.
- If $i : \{0\} \subset \Delta^1$, then p is a left fibration iff q is a trivial fibration.
- If p is an inner fibration, then q is an inner fibration.
- If p is an inner fibration and i is an inner anodyne, then q is a trivial fibration.

Proof: First notice that a right lifting of q w.r.t a map $Z \to Z'$ is equivalent to a right lifting of p w.r.t the map $Z \times B \coprod Z' \times A \to Z' \times B$. Then the conclusions follow from(3.5.3.30) and(3.5.3.29). □

Prop. (3.5.3.37) [Homotopy Section and Left Fibration]. Let $p : X \to S \in s\mathcal{S}\mathrm{et}$ and $s : S \to X$ be section of p, and let $h \in \mathrm{Hom}_S(X \times \Delta^1, X)$ that $h|_{X\times\{0\}} = s \circ p$ and $h|_{X\times\{1\}} = \mathrm{id}$, then s is a left anodyne.

Proof: Cf.[HTT, P65]. □

Prop. (3.5.3.38) [Left Fibration and Functor to Spaces]. Let $X \to S$ be a left fibration, then the fibers are all Kan complexes by(3.6.1.27), and for any edge $f : s \to s' \in S$, we can solve the lifting diagram

$$\begin{array}{ccccc} \{0\} \times X_s & \longrightarrow & & & X \\ \downarrow & & & \nearrow & \downarrow \\ \Delta^1 \times X_s & \longrightarrow & \Delta^1 & \xrightarrow{f} & S \end{array}$$

because the left hand side is left anodyne by(3.5.3.30), thus getting a morphism $f_! : X_s \to X_{s'}$.

Then this determines a functor from hS to $\mathcal{H}$ the homotopy category of spaces.

Proof: First notice $f_!$ is uniquely defined up to homotopy: given to dotted arrow solving the diagram, we can use the lifting property w.r.t. the map

$$\Delta^1 \times \partial\Delta^1 \times X_s \coprod_{\{0\}\times\partial\Delta^1\times X_s} \{0\} \times \Delta^1 \times X_s \to \Delta^1 \times \Delta^1 \times X_s$$

which is a left anodyne by(3.5.3.30), to get a homotopy between them.

Next if $\eta \in \mathrm{Hom}_{\mathcal{H}}(K, X_s), \eta' \in \mathrm{Hom}_{\mathcal{H}}(K, X_{s'})$, then $\eta' = f_! \circ \eta$ iff there is a map $q : K \times \Delta^1 \to X$ that $q \circ p$ is given by the mapping $X_s \times \Delta^1 \to \Delta^1 \xrightarrow{f} S$, and $p|_{K\times\{0\}}, p|_{K\times\{1\}}$ have homotopy types η, η' resp..

Then for any $g \circ f \cong h \in S$, which is depicted by a 2-complex, we can use the left anodyne $X_u \times \{0\} \subset X_u \times \Delta^2$ to get a morphism $p : X_u \times \Delta^2 \to X$, then $p|_{X_u\times\{1\}} \cong f_!$, $p|_{X_u\times\{2\}} \cong h_!$, and the map $p|_{X_u\times\Delta^{\{1,2\}}}$ witnesses the fact $g_! \circ f_! \cong h_!$. □

Kan Fibrations

Remark (3.5.3.39) [Kan Complexes and Groupoids]. Kan complexes are ∞-categorical analogy of groupoids, by(3.6.1.27) and(3.5.3.6).

Lemma (3.5.3.40). If a left fibration $p: S \to T$ is a weak homotopy equivalence of Kan complexes, then it is a surjection on vertices.

Proof: Because it is homotopy equivalence, for any $t \in T$, there is a morphism $p(s) \to t$ for some $s \in S$(Kan complex used), thus it lifts to a morphism in S, so surjective on vertices. □

Lemma (3.5.3.41) [Fibrations of Kan Complexes]. If $S \to T$ is a left fibration and T is a Kan complex, then p is a Kan fibration.

Proof: Firstly S is a Kan complex. Let $A \subset B$ be anodyne morphisms, we need to show $p: S^B \to S^A \times_{T^A} T^B$ is surjective on vertices. Since S, T are complexes, $S^B \to S^A$ and $T^B \to T^A$ are trivial fibrations by(3.5.3.36). Cf.[HTT, P66].?

Notice this is an immediate consequence of(3.5.3.46), because the homotopy category of a Kan complex is a groupoid, by(3.6.1.27), so $f_!$ must be isomorphisms. □

Prop. (3.5.3.42) [Examples of Kan Complexes].

- The singular complex of topological space is a Kan complex.
- The nerve of a category is a Kan complex iff the category is a groupoid, by(3.5.3.32).
- Simplicial R-module are Kan complexes, by(4.8.1.1).

Proof:

□

Prop. (3.5.3.43). The bar resolution BG is a Kan fibration for every group G.

Proof: □

Prop. (3.5.3.44). A principal G fibration, i.e. $X \to X/G$ where X is a simplicial object of G-sets that G acts freely on X_n, is a Kan fibration.

Lemma (3.5.3.45) [Left Fibrations and Trivial Kan Fibrations]. Let $p: S \to T \in s\mathcal{S}\mathrm{et}$ be a left fibration that all the fibers are contractible, then p is a trivial Kan fibration.

Proof: By duality, it suffices to prove for right fibrations. Because fiber is nonempty, it has right lifting property w.r.t $\varnothing \subset \Delta^0$, and for $n > 0$, let $\partial\Delta^n \to S$ be any map, then to show the lifting property, we may take fiber product and assume $T = \Delta^n$, thus S is an ∞-category. Cf.[HTT, P66]. □

Prop. (3.5.3.46) [Characterizing Kan Fibrations]. Let $p: S \to T$ be a left fibration of simplicial sets, then p is a Kan extension iff the morphism $f_!$ defined in(3.5.3.38) is an isomorphism in $\mathcal{H}$ for any morphism $f \in T$.

Proof: Cf.[HTT, P66]. □

Def. (3.5.3.47) [Kan-Quillen Model Structure]. There is a combinatorial left and right proper model structure on $s\mathcal{S}\mathrm{et}$ called the **Kan-Quillen model structure** with

- Weak equivalences: weak equivalences(3.5.3.10).

- Cofibrations: inclusions,
- Fibrations: Kan fibrations.

Proof: Cf.[Jardine P62].? □

Prop. (3.5.3.48) [Quillen]. The geometrization functor and the singular complex functor(3.5.3.8) defines a Quillen equivalence:

$$|\cdot| : s\,\mathcal{S}\mathrm{et} \rightleftarrows \mathcal{CG} : \mathrm{Sing}$$

where the RHS is Serre-Quillen model category(3.12.6.28) and the LHS is the Kan-Quillen model category(3.5.3.47).

The functor $|-|\circ\mathrm{Sing}$ is also denoted by $\Gamma : \mathcal{CG} \to \mathcal{CG}$.

Proof: Cf.[May, P125].? □

Cor. (3.5.3.49). The localized category of $\mathcal{CG}$ and $s\,\mathcal{S}\mathrm{et}$ at weak homotopy equivalence classes are the same, and it is just the homotopy category of spaces $\mathscr{H}$, by(3.4.2.7).

Cor. (3.5.3.50). By(3.5.3.42), for any $S \in s\,\mathcal{S}\mathrm{et}$, $S \to \mathrm{Sing}\,|S|$ is a fibrant replacement w.r.t. the Kan-Quillen model category.

<u>**Marked Simplicial Sets**</u>

Def. (3.5.3.51) [Marked Simplicial Sets]. A **marked simplicial set** is a pair $(X, \mathcal{E}_X)$ where X is a simplicial set and $\mathcal{E}_X \subset X_1$ is a set of edges containing all the degenerate ones. The category of simplicial sets is denoted by $s\,\mathcal{S}\mathrm{et}^+$.

4 Simplicial Categories

Def. (3.5.4.1) [Simplicial Categories]. The category $s\,\mathcal{C}\mathrm{at}$ of **simplicial categories** consists of categories enriched over the Cartesian monoidal category $s\,\mathcal{S}\mathrm{et}$. $s\,\mathcal{C}\mathrm{at}$ is complete and cocomplete, by(3.1.7.3) and(3.5.3.14)(3.5.1.2).

Def. (3.5.4.2)[Homotopy Category]. There are singular complex functor and geometrization functor that induce isomorphism of $h(s\,\mathcal{S}\mathrm{et}) \cong h(\mathcal{CG})$ by(3.5.3.49), thus the theory of simplicial categories and topological categories are the same.

<u>**Bergner Model Structure**</u>

Def. (3.5.4.3)[Dwyer-Kan Equivalences]. A **Dwyer-Kan equivalence of simplicial categories** is a weak equivalence of simplicial categories as enriched categories(3.5.4.16).

Def. (3.5.4.4) [Bergner Model Structure]. There is a left proper combinatorial model structure **Bergner model structure** on $s\,\mathcal{C}\mathrm{at}$ called the **Bergner model structure** with

- Weak equivalences: Dwyer–Kan equivalences(3.5.4.3).
- Fibrations: $F : \mathcal{C} \to \mathcal{D}$ that is an quasi-fibration(3.1.8.9) and for any $x, y \in \mathcal{C}$, $\mathrm{Map}_{\mathcal{C}}(x, y) \to \mathrm{Map}_{\mathcal{D}}(Fx, Fy)$ is a Kan-fibration.
- Cofibrations:

Proof: ?Cf.[Bergner. A model category structure on the category of simplicial categories] or [Lurie]. □

Simplicial Nerves

Def. (3.5.4.5) [Thickened Finite Ordered Sets]. Let J be a finite ordered set, define a simplicial category $\mathfrak{C}[\Delta^J]$ as follows:

- The objects are elements of J.
- For $i,j\in J$, $\mathrm{Mor}(i,j)=N(P_{i,j})$, where $P_{i,j}$ is the poset $\{I\subset[i,j]|i,j\in I\}$.
- The composition of simplicial sets is induced by the union of partially ordered sets $P_{i,j}\times P_{j,k}\subset P_{i,k}$.

Def. (3.5.4.6) [Coherent Nerves]. by Yoneda extension and(3.5.4.1), the functor $\Delta\to s\,\mathcal{C}\mathrm{at}:[n]\mapsto\mathfrak{C}[\Delta^n]$ corresponds to an adjunction

$$\mathfrak{C}:s\,\mathcal{S}\mathrm{et}\rightleftarrows s\,\mathcal{C}\mathrm{at}:N_\Delta$$

where N_Δ is called the **coherent nerve** functor, and

$$(N_\Delta(\mathcal{C}))_n=\mathrm{Hom}_{\mathcal{C}\mathrm{at}_\Delta}(\mathfrak{C}[\Delta^n],\mathcal{C}).$$

If $\mathcal{C}$ is a topological category, then define the **topological nerve** to be the simplicial nerve of $\mathrm{Sing}(\mathcal{C})$.

By the definition and the adjointness of(3.5.3.8), the nerve functor N_Δ is right adjoint to the functor $|\cdot|\circ\mathfrak{C}$ or $\mathfrak{C}$.

Remark (3.5.4.7). It should be checked that to give a 2-complex in $N_\Delta(\mathcal{C})$ is equivalent to giving morphisms $f,g,h\in\mathcal{C}$ and a path from $g\circ f$ to h.

Thm. (3.5.4.8)[$\mathfrak{C}:s\,\mathcal{S}\mathrm{et}\overset{\textbf{Quillen}}{\rightleftarrows}s\,\mathcal{C}\mathrm{at}:N_\Delta$]. The adjunction(3.5.4.6) is a Quillen adjunction w.r.t. the Joyal model category on $s\,\mathcal{S}\mathrm{et}$(3.5.4.19) and the Bergner model category on $s\,\mathcal{C}\mathrm{at}$(3.5.4.4).

In particular, a theory of $(\infty,1)$-categories given by the model of simplicial sets and the model of simplicial categories are the same**?**.

Proof: Cf.[HTT, P89].**?**

Firstly we show $\mathfrak{C}$ preserves cofibrations. It suffices to show that $\mathfrak{C}[\partial\Delta^n]\subset\mathfrak{C}[\Delta^n]$ is a cofibration(3.4.7.4). But notice this two simplicial category only differ at $\mathrm{Hom}_{\mathfrak{C}[\partial\Delta^n]}(0,n)$ is the boundary of the simplicial cube $(\Delta^1)^{n-1}\cong\mathrm{Hom}_{\mathfrak{C}[\Delta^n]}(0,n)$, thus the inclusion is a pushout of the inclusion $[1]_{\partial(\Delta^1)^{n-1}}\subset[1]_{(\Delta^1)^{n-1}}$, which is a cofibration by(3.4.7.3).

Left properness is clear(3.4.0.9). $\mathfrak{C}$ preserves weak equivalences by(3.5.4.12) and(3.4.7.4), so $(\mathfrak{C},N)$ is a Quillen adjunction. To show it is a Quillen equivalence: It suffices to check for each simplicial set S and fibrant simplicial category $\mathcal{C}$, a map $u:S\to N(\mathcal{C})$ is a categorical equivalence iff the adjoint map $v:\mathfrak{C}[S]\to\mathcal{C}$ is an equivalence of simplicial categories. But v factors as

$$\mathfrak{C}[S]\xrightarrow{\mathfrak{C}[u]}\mathfrak{C}[N(\mathcal{C})]\xrightarrow{w}\mathcal{C}$$

and the counit map w is an equivalence by(3.5.4.14). □

Cor. (3.5.4.9). The coherent nerve of a Bergner-fibrant(3.5.4.4) simplicial category is an ∞-category.

Prop. (3.5.4.10)[Kan Fibrations Nerve Inner Fibrations]. Let $F:\mathcal{C}\to\mathcal{D}$ be a a map of simplicial categories that for any $C,C'\in\mathcal{C}$, $\mathrm{Map}(C,C')\to\mathrm{Map}(F(C),F(C'))$ is a Kan fibration, then the induced map of simplicial sets $N(\mathcal{C})\to N(\mathcal{D})$ is an inner fibration.

Proof: This is because a lifting of $N(\mathcal{C}) \to N(\mathcal{D})$ w.r.t. $\lambda^n_j \subset \Delta^n$ is equivalent to a lifting of $\mathcal{C} \to \mathcal{D}$ w.r.t $\mathfrak{C}[\Lambda^n_j] \subset \mathfrak{C}[\Delta^n]$. But this lifting is equivalent to a lifting of $\mathrm{Map}(F(0), F(n)) \to \mathrm{Map}(F'(0), F'(n))$ w.r.t. the anodyne map $\mathrm{Map}_{\mathfrak{C}[\Lambda^n_j]} \subset \mathrm{Map}_{\mathfrak{C}[\Delta^n]}$, which is a cube removing the interior and a face. □

Cor. (3.5.4.11). The topological nerve of a topological category $\mathcal{C}$ is an ∞-category, as the singular complex of a topological space is always a Kan complex, by(3.5.3.42).

Def. (3.5.4.12) [Homotopy Category]. For $S \in s\mathcal{S}\mathrm{et}$, the **homotopy category** hS is defined to be the homotopy category(3.5.3.49) of the simplicial category $\mathfrak{C}[S]$(3.5.4.6), which is an $\mathscr{H}$-enriched category. A map of simplicial sets is called a **categorical equivalence** if their homotopy categories are equivalent as $\mathscr{H}$-enriched categories.

Remark (3.5.4.13). $f : S \cong T \in s\mathcal{S}\mathrm{et}$ is a categorical equivalence iff $\mathfrak{C}(f) : \mathfrak{C}[S] \to \mathfrak{C}[T]$ is a Dwyer-Kan equivalence(3.5.4.3).

Lemma (3.5.4.14). Let $\mathcal{C}$ be fibrant simplicial category, then the counit map $u : \mathrm{Map}_{\mathfrak{C}[N_\Delta(\mathcal{C})]}(x, y) \to \mathrm{Map}_{\mathcal{C}}(x, y)$ is a weak homotopy equivalence of simplicial sets.

Proof: Cf.[HTT, P72]. □

Lemma (3.5.4.15). Let $\mathcal{C}$ be a topological category, then the counit map $|\mathfrak{C}(N(\mathcal{C}))| \cong \mathcal{C}$(3.5.4.6) is an equivalence of topological categories.

Proof: By the Quillen equivalence between $s\mathcal{S}\mathrm{et}$ and $\mathcal{C}\mathcal{G}$(3.5.3.48), this follows from(3.5.4.14), as by(3.4.7.11) and(3.5.3.42), $\mathrm{Sing}(\mathcal{C})$ is a fibrant simplicial category. □

Prop. (3.5.4.16) [Topological Category and ∞-Category Equivalent]. The adjunction pair $(|\mathfrak{C}[\cdot]|, N)$ defines a bijection between equivalent classes of topological(or simplicial) categories and ∞-categories.

Proof: It suffices to show the units and counits are equivalences:

$$|\mathfrak{C}[N(\mathcal{C})]| \cong \mathcal{C}, \quad S \mapsto N(|\mathfrak{C}[S]|).$$

The first is(3.5.4.15), and the second follows from the first by remark(3.5.4.13). □

Prop. (3.5.4.17). For $S, S' \in s\mathcal{S}\mathrm{et}$, the natural map $\mathfrak{C}[S \times S'] \to \mathfrak{C}[S] \times \mathfrak{C}[S']$ is an equivalence of simplicial categories.

Proof: If S, S' are nerves of fibrant simplicial categories $\mathcal{C}, \mathcal{C}'$, then we have a diagram $\mathfrak{C}[S \times S'] \to \mathfrak{C}[S] \times \mathfrak{C}[S'] \to \mathcal{C} \times \mathcal{C}'$. Then by the two out of three axiom, the assertion follows from the fact that for any fibrant simplicial category $\mathcal{D}$, $\mathfrak{C}[N(\mathcal{D})] \to \mathcal{D}$ is an equivalence(3.5.4.15).

Now for general S, S', we can find a categorical equivalences $S \to N(|\mathfrak{C}[S]|) = T$, and then $S \times S' \to T \times T'$ is also categorical equivalence by(3.5.4.17), and we are done, by(3.5.4.19). □

Joyal Model Structure

Lemma (3.5.4.18) [Inner Anodyne is Categorical Equivalence]. Every inner anodyne map $A \to B$ of simplicial sets is a categorical equivalence.

Proof: The class of morphisms f that $\mathfrak{C}(f)$ is a trivial cofibration is weakly saturated(because $\mathfrak{C}$ is a left adjoint(3.5.4.6) and(3.4.0.5)), then it suffices to check for $\Lambda^n_j \subset \Delta^n$. Then $\mathfrak{C}[\Lambda^n_j] \subset \mathfrak{C}[\Delta^n]$ is a pushout of $[i]_K \subset [1]_{(\Delta^1)^{n-1}}$, where K is obtained form $(\Delta^1)^{n-1}$ by moving a face and the interior. Thus it is a trivial cofibration(3.4.7.4). □

Prop. (3.5.4.19) [Joyal Model Structure]. There is a left proper combinatorial model structure called **Joyal model structure** on $s\,\mathcal{S}\mathrm{et}$, with:

- Cofibrations: monomorphisms.
- Weak equivalences: categorical equivalences defined in(3.5.4.12).
- Fibrations: **categorical fibrations** or **Joyal fibrations** which has the right lifting property w.r.t. trivial cofibrations.

Proof: Cf.[HTT, P89].**?** □

Cor. (3.5.4.20). if $K, A, B \in s\,\mathcal{S}\mathrm{et}$ and $f : A \to B$ is a categorical equivalence, then $A \times K \to B \times K$ is also a categorical equivalence.

Proof: Choose a factorization $B \to Q$, which is an inner anodyne and Q is an ∞-category, by small object argument(3.1.7.13), then $B \times K \to Q \times K$ is also an inner anodyne map(3.5.3.30), hence a categorical equivalence(3.5.4.18), so we can assume B is an ∞-category. Similarly we can reduce to the case A, K are also ∞-categories.

For the rest, Cf.[HTT, P92]. □

Prop. (3.5.4.21) [∞-Category Fibrant in Joyal Model]. $C \in s\,\mathcal{S}\mathrm{et}$ is Joyal-fibrant iff it is an ∞-category.

Proof: Fibrant objects are ∞-categories, by(3.5.4.18). For the converse, fix an ∞-category and an inclusion $A \subset B$, given a map $A \to \mathcal{C}$, the inclusion $\mathcal{C} \subset C \coprod_A B$ is also a categorical equivalence because Joyal model structure is left proper(3.5.4.19), thus $\mathcal{C}$ is a retract of $\mathcal{C} \coprod_A B$ by(3.5.4.22), which gives an extension $B \to \mathcal{C}$. □

Lemma (3.5.4.22). Let $\mathcal{C} \subset \mathcal{D} \in s\,\mathcal{S}\mathrm{et}$ be a categorical equivalence and $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$, then $\mathcal{C}$ is a retract of $\mathcal{D}$.

Proof: Include $\mathcal{D}$ into an ∞-category by small object argument and(3.5.4.18), we may assume $\mathcal{D}$ is also an ∞-category. So we finish by applying(3.6.1.25) for $A = \mathcal{C}$ and $B = \mathcal{D}$. □

Cor. (3.5.4.23). Any $S \in s\,\mathcal{S}\mathrm{et}$ is weakly equivalent to an ∞-category.

Def. (3.5.4.24) [Joyal Joins]. For $X, Y \in s\,\mathcal{S}\mathrm{et}$, define the **Joyal Join**

$$X \diamond Y = X \coprod_{X \times Y \times \{0\}} (X \times Y \times \Delta^1) \coprod_{X \times Y \times \{1\}} Y = (X \coprod Y) \coprod_{X \times Y \times \partial\Delta^1} (X \times Y \times \Delta^1).$$

By(3.4.6.7), this is a homotopy colimit w.r.t. the Joyal model cateogry, so if $X \to X', Y \to Y'$ are categorical equivalences, $X \diamond Y \to X' \diamond Y'$ is also a categorical equivalence(3.4.6.6).

Prop. (3.5.4.25). There is a projection map $X \diamond Y \to \Delta^1$, and a map $X \times Y \times \Delta^1 \to X \star Y$ that is compatible with projection onto Δ^1, thus inducing a map

$$X \diamond Y \to X \star Y$$

that is compatible with projection onto Δ^1. Then this map is a categorical equivalence.

Proof: Because both $\diamond$ and $\star$ commutes with filtered colimits, by(3.4.3.3), it suffices to show for X with only f.m. non-degenerate simplexes. Then we use induction. The case $X=\varnothing$ is trivial, and if $X=X'\coprod_{\partial\Delta^n}\Delta^n$, because Joyal model category is left proper(3.5.4.19), by(3.4.6.7), $X\diamond Y\to X\star Y$ is a homotopy pushout of $X'\diamond Y\to X'\star Y$. Then it suffices to show for $X=\Delta^n$.

By similar reason, because $\Delta^{\{0,1\}}\coprod_{\{1\}}\Delta^{\{1,2\}}\coprod_{\{2\}}\coprod\cdots\coprod_{\{n-1\}}\Delta^{\{n-1,n\}}\to\Delta^n$ is an anodyne**?**, and anodyne are categorical equivalences(3.5.4.18), and homotopy limits of categorical equivalences are categorical equivalences by(3.4.6.6), it suffices to prove for $X=\Delta^0$ or $X=\Delta^1$. The same argument then shows it suffices to prove for $Y=\Delta^0$ or $Y=\Delta^1$. And in each case the desired map is an isomorphism. □

Cor. (3.5.4.26). If $S\to S',T\to T'$ are categorical equivalences, then $S\star T\to S'\star T'$ is also a categorial equivalence, by(3.5.4.24).

Cor. (3.5.4.27). For $X,Y\in s\,\mathcal{S}\mathrm{et}$, there is a natural equivalence of simplicial categories

$$\mathfrak{C}[X\star Y]\cong\mathfrak{C}[X]\star\mathfrak{C}[Y].$$

Proof: Cf.[Lur09]P240. □

5 Simplicial Model Categories

Def. (3.5.5.1) [Simplicial Model Categories]. A **simplicial model category** is a $s\,\mathcal{S}\mathrm{et}$-enriched model category(3.4.5.3).

Prop. (3.5.5.2) [Simplicial Model Category Criterion]. Let $\mathcal{C}$ be a simplicial category that is equipped with a model structure that every object of $\mathcal{C}$ is cofibrant and the collection of weak equivalences in stable under filtered colimits, then $\mathcal{C}$ is a simplicial model category iff the following conditions holds:

- $\mathcal{C}$ is both tensored and cotensored over $\mathcal{S}\mathrm{et}_\Delta$.
- Given a cofibration of simplicial sets $i:K\to L$ and a cofibration $C\to D\in\mathcal{C}$, the induced map $(C\otimes L)\coprod_{C\otimes K}D\otimes K\to D\otimes L$ is a cofibration in $\mathcal{C}$.
- The natural map $C\otimes\Delta^n\to C\otimes\Delta^0\cong C$ is a weak equivalence in $\mathcal{C}$.

Proof: Cf.[HTT, P850]. □

Prop. (3.5.5.3). Let $\mathcal{C}$ be a simplicial model category and X cofibrant and Y fibrant, then $K=\mathrm{Map}(X,Y)$ is a Kan complex, and there is a canonical bijection $\pi_0K\cong\mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(X,Y)$.

Proof: Use(3.4.5.4). □

Model-Categorical Yoneda Extensions

Def. (3.5.5.4) [$U(\mathcal{C})$]. For $\mathcal{C}\in\mathcal{C}\mathrm{at}$, denoted $U(\mathcal{C})=\mathcal{PS}\mathrm{h}(\mathcal{C},s\,\mathcal{S}\mathrm{et})_{\mathrm{Proj}}$, which is a left and right proper combinatorial model category, by(3.5.3.47) and(3.4.6.1)(3.4.6.2). And there is a natural functor

$$s\,\text{よ}:\mathcal{C}\mapsto\mathcal{PS}\mathrm{h}(\mathcal{C},\mathcal{S}\mathrm{et})\to\mathcal{PS}\mathrm{h}(\mathcal{C},s\,\mathcal{S}\mathrm{et}).$$

Prop. (3.5.5.5) [Model-Categorical Yoneda Extensions]. Let $\mathcal{C}\in\mathcal{C}\mathrm{at}$, $\mathcal{M}$ be a model category, then for any functor $Q:\mathcal{C}\to\mathcal{M}$, there is a Quillen adjunction $(L,R):U(\mathcal{C})\overset{\text{Quillen}}{\rightleftharpoons}\mathcal{M}$ together with a natural weak equivalence $L\circ s\,\text{よ}\cong Q\in\mathrm{Func}(\mathcal{C},\mathcal{M})$. And the category of such extensions is contractible.

Proof: Cf.[D. Dugger. Universal homotopy theories]. □

Exponentiation in Model Categories

Localizations and Presentations

Def. (3.5.5.6) [S-Local and S-Equivalences].

Prop. (3.5.5.7) [Localizations of Simplicial Model Categories]. Let $\mathcal{M}$ be a left proper combinatorial simplicial model category and $S \subset \mathrm{Cof}(M)$ be a small subset, then there is a left proper combinatorial simplicial model category $S^{-1}\mathcal{M}$ with the same underlying category as $\mathcal{M}$ and

- Cofibrations: $\mathrm{Cof}(\mathcal{M})$.
- Weak Equivalences: S-equivalences in $\mathcal{M}$.
- Fibrations: defined by the above two.

And $X \in \mathcal{M}$ is fibrant in $S^{-1}A$ iff X is S-local and fibrant in $\mathcal{M}$.

Proof: Cf.[Lur09]P906. □

Prop. (3.5.5.8). Let $\mathcal{M}$ be a left proper combinatorial simplicial model category, then

- Any combinatorial Bousfield localization(3.4.4.3) of $\mathcal{M}$ is of the form $S^{-1}\mathcal{M}$, where $S \subset \mathrm{Cof}(\mathcal{M})$ is a small subset.
- For any two small subset $S, T \subset \mathrm{Cof}(\mathcal{M})$, $S^{-1}\mathcal{M}$ and $T^{-1}\mathcal{M}$ coincide iff the class of S-local objects and T-local objects coincide.

Proof: Cf.[Lur09]P908. □

Prop. (3.5.5.9) [Combinatorial Model Categories have Presentations]. Every combinatorial model category $\mathcal{M}$ has a presentation, i.e. there exists a $\mathcal{C} \in \mathcal{C}at$ a set S of morphisms in $U(A)$ and a Quillen equivalence

$$U(\mathcal{C})[S^{-1}] \underset{}{\overset{\text{Quillen}}{\rightleftarrows}} \mathcal{M}(3.5.5.7).$$

Proof: [D. Dugger. Combinatorial model categories have presentations]. □

6 Covariant Model Structure

Prop. (3.5.6.1) [Covariant Model Structure]. For $S \in s\,\mathcal{S}\mathrm{et}$, a map $X \to Y \in (\mathcal{S}\mathrm{et}_\Delta)_{/S}$ is called a

- **covariant cofibration** if it is a monomorphism.
- **covariant equivalence** if the induced map $X^{\triangleleft} \coprod_X S \to Y^{\triangleleft} \coprod_Y S$ is a categorical equivalence(3.5.4.12).

Then these define a left proper combinatorial model structure on $(\mathcal{S}\mathrm{et}_\Delta)_{/S}$.

Proof: Cf.[HTT, P69]. □

Lemma (3.5.6.2). Every left anodyne map in $(\mathcal{S}\mathrm{et}_\Delta)_{/S}$ is a covariant equivalence.

Proof: Cf.[HTT, P69]. □

Prop. (3.5.6.3) [Covariant Model Structure]. $(\mathcal{S}\mathrm{et}_\Delta)_{/S}$ is a simplicial model category with the contravariant model structure and the simplicial structure where

$$\mathrm{Map}(X, Y) = Y^X \times_{S^X} \{\varphi\} \in \mathcal{S}\mathrm{et}_\Delta$$

where $\varphi : X \to S$ is the structure map.

Proof: We use(3.5.5.2), it suffices to check that $X \times \Delta^n \to X \times \Delta^0$ is a covariant equivalence. But it has a section, which is a left anodyne by(3.5.3.30), thus it is a covariant equivalence by(3.5.6.2). □

Cor. (3.5.6.4)[Contravariant Model Structure]. Let S be a simplicial set, then the covariant model is usually not self-dual, and we can define a **contravariant model structure** as follows:

- A **contravariant cofibration** is a monomorphism of simplicial sets.
- f is a **contravariant equivalence** in $(\mathcal{S}\mathrm{et})_{/S}$ iff f^{op} is a covariant equivalence in $(\mathcal{S}\mathrm{et})_{/S^{op}}$.
- f is a **contravariant fibration** in $(\mathcal{S}\mathrm{et})_{/S}$ iff f^{op} is a covariant fibration in $(\mathcal{S}\mathrm{et})_{/S^{op}}$.

Prop. (3.5.6.5) [Base Change]. Let $S \to S'$ be a map of simplicial sets, then the forgetful functor and base change functor $j_!, j^*$ defines a Quillen adjunction of covariant models:

$$j_! : (\mathcal{S}\mathrm{et}_\Delta)_{/S} \underset{}{\overset{\text{Quillen}}{\rightleftarrows}} (\mathcal{S}\mathrm{et}_\Delta)_{/S'} : j^*$$

Proof: it is clearly a pair of adjoints, and $j_!$ preserves cofibrations. $j_!$ also preserves covariant equivalences: Cf.[HTT, P71]**?**. Thus it is a Quillen adjunction. □

Lemma (3.5.6.6). Let $S' \subset S$ be simplicial sets, let $p : X \to S$ be a map and $q : Y \to S$ be a right fibration. Let $X' = X \times_S S', Y' = Y \times_S S'$, then the restriction map

$$\varphi : \mathrm{Map}_{(\mathcal{S}\mathrm{et}_\Delta)_{/S}}(X, Y) \to \mathrm{Map}_{(\mathcal{S}\mathrm{et}_\Delta)_{/S'}}(X', Y')$$

is a Kan fibration.

Proof: Firstly it is a right fibration because it has right lifting property w.r.t. right anodyne inclusion $A \to B$: this is because $(A \times X') \coprod (A \times X) \subset B \times X$ is also a right anodyne(3.5.3.30). Next we apply this to the inclusion $\varnothing \subset S'$ to see that $\mathrm{Map}_{(\mathcal{S}\mathrm{et}_\Delta)_{/S'}}(X', Y')$ is a Kan complex(3.6.1.27), and then φ is a Kan fibration by(3.5.3.41). □

Lemma (3.5.6.7). Let $p : X \to S$ be an object of $(\mathcal{S}\mathrm{et}_\Delta)_{/S}$, then p is a right fibration iff it is a covariant fibrant object in $(\mathcal{S}\mathrm{et}_\Delta)_{/S}$.

Proof: Cf.[HTT, P85]. □

Def. (3.5.6.8) [Pointwise Equivalence]. Let $X \to Y$ be a map in $RFib(S)$, then f is called a **pointwise equivalence** iff the induced map $X_s \to Y_s$ is a homotopy equivalence of Kan complexes(3.6.1.27) for any $s \in S$.

Lemma (3.5.6.9). Let $f : X \to Y$ be a morphism in $RFib(S)$, then the following are equivalent:

- f is a pointwise equivalence.
- f is an equivalence in the simplicial category $(\mathcal{S}\mathrm{et})_{/S}$.
- For any $A \in (\mathcal{S}\mathrm{et})_{/S}$, f induces a homotopy equivalence of Kan complexes: $\mathrm{Map}_{(\mathcal{S}\mathrm{et}_\Delta)_{/S}}(A, X) \to \mathrm{Map}_{(\mathcal{S}\mathrm{et}_\Delta)_{/S}}(A, Y)$.

Proof: Cf.[HTT, P82]. □

Prop. (3.5.6.10) [Equivalences]. In the situation of(3.5.6.8), f is a pointwise equivalence iff it is a contravariant equivalence iff it is a categorical equivalence.

Proof: Cf.[HTT, 2.2.3.13, 3.3.1.5]**?**. □

Prop. (3.5.6.11) [Contravariant Fibration as Right Fibration]. Let $f : X \to Y$ be a map in $RFib(S)$, then f is a contravariant fibration in $(s\,\mathcal{S}\mathrm{et})_{/S}$ iff it is a right fibration.

Proof: Cf.[HTT, P86]. □

Straightening and Unstraightening

Def. (3.5.6.12) [Straightening and Unstraightening]. Fix a simplicial set S, a simplicial category $\mathcal{C}$ and a functor $\mathfrak{C}[S] \to \mathcal{C}^{op}$. Given an object $X \in (\mathcal{S}\mathrm{et}_\Delta)_{/S}$, let v be the cone point of $X^\triangleright$. Then the simplicial category $\mathcal{M} = \mathfrak{C}[X^\triangleright] \coprod_{\mathfrak{C}[X]} \mathcal{C}^{op}$ can be viewed as a correspondence?? between $\mathcal{C}^{\mathrm{op}}$ and Δ^0, thus giving a simplicial functor

$$\mathrm{St}_\varphi X : \mathcal{C} \to \mathcal{S}\mathrm{et}_\Delta : C \mapsto \mathrm{Map}_{\mathcal{M}}(C, v).$$

Then St_φ is called the **straightening functor** associated to φ. And we denote by St_S the functor St_φ where $\varphi : \mathrm{id}_{\mathfrak{C}[S]}$.

By the adjoint functor theorem(3.1.1.34), St_φ has a left adjoint called **unstraightening functor** $UnSt_\varphi$**?**.

Prop. (3.5.6.13). Let S be a simplicial set, $\mathcal{C}$ a simplicial category and $\varphi : \mathfrak{C}[S] \to \mathcal{C}^{\mathrm{op}}$ a simplicial functor, then the straightening and unstraightening functor determines a Quillen adjunction

$$\mathrm{St}_\varphi : (\mathcal{S}\mathrm{et}_\Delta)_{/S} \underset{}{\overset{\text{Quillen}}{\rightleftarrows}} \mathcal{S}\mathrm{et}_\Delta^{\mathcal{C}} : UnSt_\varphi$$

determines a Quillen adjunction, where the LHS has the contravariant model structure and the RHS has the projective model structure. And if φ is an equivalence of simplicial categories, then $(St_\varphi.Un_\varphi)$ is a Quillen equivalence.

Proof: □

Unstraightening of Right Fibrations

Prop. (3.5.6.14). For every simplicial set S, the unstraightening Un_S induces an equivalence of simplicial categories

$$(\mathcal{S}\mathrm{et}_\Delta^{\mathfrak{C}[S]^{op}})_{cf} \to RFib(S).$$

(3.4.5.5), where the RHS is the category of fibrations $X \to S$.

Proof: Cf.[HTT, P83]. □

7 Cartesian Fibrations

Remark (3.5.7.1). The theory of Cartesian fibrations is an analogue of the theory of fibered categories8.

Def. (3.5.7.2) [p-Cartesian]. Let $p : X \to S$ be an inner fibration and $f : x \to y$ is an edge of X, then f is called a p-**Cartesian** if the induced map

$$X_{/f} \to X_{/y} \times_{S_{/p(y)}} S_{/p(f)}$$

is a trivial Kan fibration.

Remark (3.5.7.3). For $\mathcal{C} \in \mathcal{C}\mathrm{at}$ and $p : N(\mathcal{C}) \to \Delta^1 \in s\,\mathcal{S}\mathrm{et}$, a morphism $f \in \mathcal{C}$ is p-Cartesian iff it is Cartesian in the usual sense.

Prop. (3.5.7.4) [Characterization of Cartesian Fibrations]. Let $p : \mathcal{C} \to \mathcal{D}$ be an inner fibration of ∞-categories, then an edge $f : Y \to Z \in \mathcal{C}$ is p-Cartesian iff for every object $X \in \mathcal{C}$, there is a Cartesian diagram

$$\begin{array}{ccc} \mathrm{Map}(X,Y) & \longrightarrow & \mathrm{Map}(X,Z) \\ \downarrow & & \downarrow \\ \mathrm{Map}(p(X),p(Y)) & \longrightarrow & \mathrm{Map}(p(X),p(Z)) \end{array}.$$

Proof: Cf.[HTT, P131]. □

<u>**Cartesian Fibrations**</u>

Def. (3.5.7.5) [Cartesian Fibration]. A **Cartesian fibration** is an inner anodyne map $p : X \to S$ that for any edge $f : x \to y \in S$ and a vertex $\widetilde{y}$ mapping to y, there is a p-Cartesian edge $\widetilde{f}$ with $p(\widetilde{f}) = f$. The dual of a Cartesian fibration is called a **coCartesian fibration**.

Prop. (3.5.7.6). The class of Cartesian fibrations is stable under compositions and base change.

Prop. (3.5.7.7) [Cartesian Fibration and Right Fibration]. Let $p : X \to S$ be an inner fibration, then the following are equivalent:

- p is a Cartesian fibration and the every edge of X is p-Cartesian.
- p is a right fibration.
- p is a Cartesian fibration and every fiber X_s is a Kan complex.

Proof: Cf.[HTT, P122].? □

Def. (3.5.7.8) [Locally Cartesian Fibration]. A map $X \to S$ of simplicial sets is called a **locally Cartesian fibration** if it is an inner fibration and for every edge $\Delta^1 \to S$, the pullback $X \times_S \Delta^1 \to \Delta^1$ is a Cartesian fibration.

Prop. (3.5.7.9) [Cartesian and Locally Cartesian]. Let $p : X \to S$ be a locally Cartesian fibration, then the following are equivalent:

- p is a Cartesian fibration.
- Given a composition $fg \cong h$ in the homotopy category, if f, g are both locally p-Cartesian, then h is also locally p-Cartesian.
- Every locally p-Cartesian edge in X is p-Cartesian.

Proof: Cf.[HTT, P124]. □

Prop. (3.5.7.10). Given maps of ∞-categories: $\mathcal{C} \xrightarrow{p} \mathcal{D} \xrightarrow{q} \mathcal{E}$, if $q, q \circ p$ are both locally Cartesian fibrations and p maps locally $(q \circ p)$-Cartesian maps to locally q-Cartesian maps and for any $Z \in \mathcal{E}$, p induces a categorial equivalence $\mathcal{C}_Z \to \mathcal{D}_Z$, then p is a categorical equivalence.

Proof: Cf.[HTT, P132].? □

Prop. (3.5.7.11). Categorical equivalences between ∞-categories are stable under base change of Cartesian fibrations of ∞-categories.

Proof: Cf.[HTT, P132]. □

8 Simplicial Homology

Prop. (3.5.8.1). For a Kan fibration X, there can be defined a homotopy groups π_n that they agree with $\pi_i(|X|)$ thus also $\pi_i(S|X|)$, Cf.[Weibel P263]. Thus we see that $|BG|$ is truly the Eilenberg-Maclane spaces BG.

9 Cyclic Homology Theory(欧阳恩林)

Combinatorial Category

Def. (3.5.9.1). The **Segal category** Fin_* is the category of pointed finite sets. A morphism is called **inert** iff $|f^{-1}(\{i\})| = 1$ for all $i \neq *$. It is called **active** iff $f^{-1}(\{*\}) = \{*\}$.

A morphism can be uniquely factorized as a composition gh, where h is inert and g is active.

Prop. (3.5.9.2). There is a morphism $\mathrm{Cut} : \Delta^{op} \to \mathrm{Fin}_*$ where we interpret $[n] \in \mathrm{Fin}_*$ as the set of cut in $[n]$, and

$$\mathrm{Cut}(\alpha)(i) = \begin{cases} j & \text{if there are } j \text{ s.t. } \alpha(j-1) < i \leq \alpha(j) \\ 0 & \text{otherwise} \end{cases}$$

Prop. (3.5.9.3). The category of functors from the $E_\infty = \mathrm{Fin}_*$ to $\mathcal{C}at$ that

$$X([n]) \xrightarrow{\prod_{i=2}^n X(\rho^i)} \prod_{i=1}^n X([1]) \quad n \geq 0$$

and $X([0])$ is the final object, is equivalent to the category of symmetric unital monoidal categories with base category $(X([1]))$. (Because the commutativity of morphisms encodes the fact that the tensor action is symmetric).

Similarly, the category of functors from the Δ^{op} to Cat that

$$X([n]) \xrightarrow{\prod_{i=2}^n X(\rho^i)} \prod_{i=1}^n X([1]) \quad n \geq 0$$

is equivalent to the category of symmetric unital monoidal categories $(X([1]))$. And it is symmetric iff it factors through $\mathrm{Cut}:\Delta^{\mathrm{op}} \to \mathrm{Fin}_*$.

Def. (3.5.9.4). The **Conne cyclic category** Δ_C is a category containing Δ that $\mathrm{Aut}_{\Delta C}([n])$ is C_{n+1}. And every morphism $[n] \to [m]$ in Δ_C can be uniquely written as the form φg, where $\varphi \in \mathrm{Hom}_\Delta([n],[m])$ and $g \in \mathrm{Aut}_{\Delta_C}([n])$.

Δ_C^{op} is isomorphic to Δ_C Cf.[杨恩林循环同调 P31], thus Δ and Δ^{op} are all subcategories of Δ_C.

Def. (3.5.9.5). The category Δ_S is the category that $\mathrm{Aut}_{\Delta_S}([n]) \cong S^n$ and every morphism $[n] \to [m]$ in Δ_S can be uniquely written as the form φg, where $\varphi \in \mathrm{Hom}_\Delta([n],[m])$ and $g \in \mathrm{Aut}_{\Delta_S}([n])$.

Def. (3.5.9.6). For a category C, a **cyclic object** in C is a functor $\Delta_C^{op} \to C$.

For example, the functor that maps $[n]$ to C_{n+1} and the functor maps to the pull back of the order of the cyclic, is a cyclic object.

Hochschild Homology(Jeremy Hahn)

Def. (3.5.9.7)[Hochschild Homology Group]. Let R be a commutative ring and A a flat R-algebra, $A^{env} = A \otimes_R A^{op}$. Then an A^{env}-module is equivalent to an (A, A)-bimodule.

If M is an (A, A)-bimodule, then we define **Hochschild homology group** $HH_n(A/R, M) = \mathrm{Tor}_n^{env}(M, A)$. And also we denote $HH_n(A/R) = HH_n(A/R, M)$.

$H_n(A, M)$ is a $Z(A)$ module by the action of $Z(A)$ on M and HH_* defines a functor $\mathcal{CR}\mathrm{ing}_R \to \mathcal{M}\mathrm{od}_R$.

Def. (3.5.9.8)[Hochschild Complex]. Let R be a commutative ring and A a flat R-algebra, we define $A^{env} == A \otimes_R^L A^{op}$, and $HH(A/R) = A \otimes_{A^{env}}^L A \in D(A)$.

Def. (3.5.9.9) [Flat Case]. For a flat R-algebra A and a (A, A)-bimodule M, there is a simplicial module $C(A, M)$ called the **Hochschild complex** of A with coefficient in M, with $M_n = M \otimes A^n$ that

$$d_i(m, a_1, \ldots, a_n) = \begin{cases} (m_0 a_1, a_2, \ldots, a_n) & i = 0 \\ (a_n m_0, a_1, \ldots, a_{n-1}) & i = n \\ (m_0, a_1, \ldots, a_i a_{i+1}, \ldots, a_n) & \text{otherwise} \end{cases}$$

$$s_j(m, a_1, \ldots, a_n) = (m, a_1, \ldots, a_{j-i}, 1, a_{j+1}, \ldots, a_n)$$

The homology group of the Moore complex associated to the Hochschild complex is just $HH_n(A, M)$. The Moore complex is of the form

$$\ldots \to M \otimes A \otimes A \otimes A \xrightarrow{\partial_3} M \otimes A \otimes A \xrightarrow{\partial_2} M \otimes A \xrightarrow{\partial_1} M \xrightarrow{\partial_0} 0 \to 0 \to \ldots$$

where

$$\partial_1(m \otimes a) = ma - am, \quad \partial_2(m \otimes a_1 \otimes a_2) = ma_1 \otimes a_2 - m \otimes a_1 a - 2 + a_2 m \otimes a_1$$

$$\partial_3(m \otimes a_1 \otimes a_2 \otimes a_3) = ma - 1 \otimes a_2 \otimes a_3 - m \otimes a_1 a_2 \otimes a_3 + m \otimes a_1 \otimes a_2 a_3 - a_3 m \otimes a_1 \otimes a_2.$$

Proof: □

Example (3.5.9.10).

- $HH_n(R, R) = R$ if $n = 0$ and 0 otherwise.
- $HH_0(A/R, A/R) = A^{ab}$.
- If A is commutative, $HH_1(A, A) \cong \Omega^1_{A/R}$ giving by $a \otimes x \mapsto adx$ by(4.4.3.4).
- For a symmetric (A, A)-module M, thus we have $H_1(A, M) = M \otimes_A A^{ab}$ and $H_1(A, M) = M \otimes_A \Omega^1_{A/R}$. And if M is flat, $H_n(A, M) = M \otimes_A H_n(A, A)$.?
- $HH_n(R[X]/R) = \begin{cases} R[X] & n = 0 \\ \Omega^1_{R[X]/R} & n = 1 \\ 0 & \text{otherwise} \end{cases}$.

Example (3.5.9.11) [$HH(\mathbb{F}_p/\mathbb{Z})$]**.** Because $\mathbb{F}_p \otimes_{\mathbb{Z}}^L \mathbb{F}_p = (\mathbb{F}_p \xrightarrow{0} \mathbb{F}_p)$.?

$$HH_*(\mathbb{F}_p, \mathbb{Z}) \cong \mathbb{F}_p[X_1, X_2, \ldots,]/(X_i X_j = \binom{i+j}{i} X_{i+j})$$

where $\deg(X_i) = 2i, \partial X_i = 0$.

Prop. (3.5.9.12). Suppose A, B are R-algebras, then

$$HH(A \otimes_R^L B/R) = HH(A/R) \otimes_R^L HH(B/R).$$

Cor. (3.5.9.13). $HH(R[X_1, \ldots, X_n]/R) = \Omega^*_{R[X_1,\ldots,X_n]/R}$.

Prop. (3.5.9.14). If A is a commutative R-algebra, then $HH(A/R)$ is naturally a commutative dga. In particular, $HH_*(A/R)$ is a graded ring.

Prop. (3.5.9.15) [Spectral Sequence]. For a commutative ring A and a symmetric A-bimodule M, there is a spectral sequence

$$E^2_{pq} = \mathrm{Tor}^R_p(H_p(A, A), M) \Rightarrow H_{p+q}(A, M).$$

Hochschild Homology

Prop. (3.5.9.16) [Hochschild-Kostant-Rosenberg]. The isomorphism $\Omega^1_{A/R} \cong HH_1(A)$ extends to a graded ring map

$$\Psi : \Omega^*_{A/k} \to H_*(A, A)$$

. If A/R be smooth algebra and R Noetherian, then Ψ is an isomorphism of graded algebra. Cf.[Weibel P322], [阳恩林循环同调 P133].

Def. (3.5.9.17) [Tsygan's Double Complex]. For a cyclic objec M in an Abelian category, let t_* be the cyclic morphism and $\partial_n = \sum_{i=0}^n (-1)^i d_i$, $\partial'_n = \sum_{i=0}^{n-1} (-1)^i d_i$, $N_n = \sum_{k=0}^n ((-1)^n t_n)^k$, then there is a double complex $CC(M)$:

$$\begin{array}{ccccccc}
\downarrow \partial & & \downarrow -\partial' & & \downarrow \partial & & \\
M_1 & \xleftarrow[1-(-1)^1 t]{} & M_1 & \xleftarrow[N]{} & M_1 & \xleftarrow[1-(-1)^1 t]{} & \\
\downarrow \partial & & \downarrow -\partial' & & \downarrow \partial & & \\
M_0 & \xleftarrow[1-(-1)^0 t]{} & M_0 & \xleftarrow[N]{} & M_0 & \xleftarrow[1-(-1)^0 t]{} &
\end{array}$$

That the column are 2-cyclic. Cf.[Weibel P337]. The first column is called the **Hochschild complex of** M: $C^h(M)$, the second column is called **acyclic complex of** M(3.5.9.18) $C^a(M)$. And we can even augment a cokernel column on the left, which is the complex of M modulo the cyclic action, called the **Conne complex** $C^\lambda(M)$.

We define the **Cyclic Homotopy Group** $HC_n(M) = H_n(\mathrm{Tot}CC(M))$ and when M is the cyclic module $C(A)$(3.5.9.9), denote $CC(C(A)) = CC(A)$, $HC_n(A) = HC_n(C(A))$.

Lemma (3.5.9.18). The second column is exact and $h = t_{n+1}s_n$ is a null-homotopy. Cf.[阳恩林循环同调 P122].

Lemma (3.5.9.19). Notice the rows are in fact a group homology $\mathrm{Hom}(\mathbb{Z}/(n+1)\mathbb{Z}, M_n)$, thus when $\mathbb{Q} \in R$, we have the rows are acyclic because the group homology is killed by $|G|$**??**, thus $HC_*(M) \cong H^\lambda_*(M)$ are isomorphisms by spectral sequence.

Prop. (3.5.9.20) [Conne SBI Sequence]. For a cyclic module M, there is a long exact sequence

$$\cdots \to HH_n(M) \xrightarrow{I} HC_n(M) \xrightarrow{S} HC_{n-2}(M) \xrightarrow{B} HH_{n-1}(M) \to \cdots$$

Proof: shift the diagram 2 column right, then there is an exact sequence of double complexes and notice the second column is exact(3.5.9.18), thus we have the kernel is quasi-isomorphic to $C^h(M)$. So the sequence follows. □

Cor. (3.5.9.21). $HC_0(A) = HH_0(A) = A^{ab}$.

When A is commutative, $HC_1(A) = \mathrm{Coker}(HC_0(A) \xrightarrow{B} HH_1(A)) = \Omega^1_{A/R}/dA$ as a R module, because we can verify that $B(a) = a \otimes 1 - 1 \otimes A$.

Cor. (3.5.9.22). For a morphism of two cyclic objects, $HH_*(M) \cong HH_*(M')$ iff $HC_n(M) \cong HC_n(M')$. (Use five lemma).

Def. (3.5.9.23). A **mixed complex** (M, b, B) is a complex with $b : M_n \to M_{n-1}$ and $B : M_n \to M_{n+1}$ that makes M into a double chain complex. And there is a **Conne double complex** associated with this mixed complex. And similarly there is a same SBI sequence associated to the following diagram:

$$\begin{array}{ccccc}
\downarrow & & \downarrow & & \downarrow \\
M_2 & \xleftarrow[B]{} & M_1 & \xleftarrow[B]{} & M_0 \\
\downarrow{\scriptstyle b} & & \downarrow{\scriptstyle b} & & \\
C_1 & \xleftarrow[B]{} & C_0 & & \\
\downarrow{\scriptstyle b} & & & & \\
C_0 & & & &
\end{array}$$

From a cyclic object M, we notice that the $2k$-th column is acyclic(3.5.9.18), thus there is a snake-like connection homomorphism B that makes M into a mixed complex BM. Cf.[Weibel P344]. And the Conne double complex will compute the same cyclic homology with previous defined cyclic homology, Cf.[Weible P345].

Notice for this B, B_* on homology is exactly the composition BI.

Prop. (3.5.9.24). Let R be a unital commutative ring and A is a commutative R-algebra and M is a A-module, then there is a natural morphism

$$M \otimes_A \Omega^n_{A/R} \xrightarrow{\varepsilon_n} H_n(A, M) \xrightarrow{\pi_n} M \otimes_A \Omega^n_{A/R}.$$

such that $\pi_n \circ \varepsilon_n = n!$.

We first define a map $\varepsilon_n : M \otimes \wedge^n A \to H_n(A, M)$ that

$$\varepsilon_n(m, a_1, \ldots, a_n) = \sum \mathrm{sgn}(\sigma)(m, a_{\sigma^{-1}(1)}, \ldots, a_{\sigma^{-1}(n)})$$

then define $\varepsilon_n(m \otimes x da_1 \wedge \cdots \wedge da_n) = \varepsilon_n(mx, a_1, \ldots, a_n)$. And we verify that this map is well-defined and maps into $Z_n(C(A, M))$,Cf.[阳恩林循环同调 P99].

Then we define $\pi_n(m, a_1, \ldots, a_n) = m \otimes da_1 \wedge \cdots \wedge da_n$ and verify easily that this vanish on $B_n(C(A, M))$. And it is easy to verify $\pi_n \circ \varepsilon_n = n!$.

Prop. (3.5.9.25). When A is a unital R-algebra, there is a commutative diagram

$$\begin{array}{ccc} \Omega^n_{A/R} & \underset{d}{\overset{(n+1)d}{\rightrightarrows}} & \Omega^{n+1}_{A/R} \\ \pi_n \Big\uparrow\Big\downarrow \varepsilon_n & & \pi_{n+1} \Big\uparrow\Big\downarrow \varepsilon_{n+1} \\ HH_n(A) & \xrightarrow{B_*} & HH_{n+1}(A) \end{array}$$

Proof: We notice $B = (1-(-1)^n t)sN$:

$$(m,a_1,\ldots,a_n)\mapsto \sum_{i=0}^n (-1)^{in}(1,a_i,\ldots,a_n,m,a_1,\ldots,a_{i-1}) - \sum_{i=0}^n (-1)^{in}(a_i,1,a_{i+1},\ldots,a_n,m,a_1,\ldots,a_{i-1}).$$

Cf.[阳恩林循环同调 P128]. □

Cor. (3.5.9.26). For a commutative unital R-algebra A, there is a functorial $\varepsilon_n : \Omega^n_{A/R}/d\Omega^{n-1}_{A/R} \to HC_n(A)$ making the following diagram commutative:

$$\begin{array}{ccccccccc} \xrightarrow{0} & \Omega^{n-1}/d\Omega^{n-2} & \xrightarrow{d} & \Omega^n & \longrightarrow & \Omega^n/d\Omega^{n-1} & \xrightarrow{0} & \Omega^{n-2}/d\Omega^{n-3} & \longrightarrow \cdots \\ & \downarrow \varepsilon_{n-1} & & \downarrow \varepsilon_n & & \downarrow \varepsilon_n & & \downarrow \varepsilon_{n-2} & \\ \longrightarrow & HC_{n-1} & \xrightarrow{B} & HH_n & \xrightarrow{I} & HC_n & \xrightarrow{S} & HC_{n-2} & \xrightarrow{B} \cdots \end{array}$$

which is induced by the cokernel. Cf.[阳恩林循环同调 P130]. When $\mathbb{Q}\in R$, ε_n is a split injection.

Prop. (3.5.9.27). When $\mathbb{Q} \in R$, $\frac{1}{n!}\pi_n$ induces a morphism of mixed complexes $(BA,\partial,B) \to (\Omega^*_{A/R},0,d)$ by(3.5.9.24), thus there is a natural map

$$HC_n(A)\to \Omega^n_{A/R}/d\Omega^{n-1}_{A/R}\bigoplus_{i>0} H^{n-2i}_{dR}(A).$$

Prop. (3.5.9.28) [Morita Invariance]. $Tr : HH_*(M_r(A), M_r(M)) \cong HH_*(A,M)$ by the trace and inclusion functors. Cf.[阳恩林循环同调 Morita Invariance]. In particular, there is an isomorphism $HH_*(M_r(A))\cong HH_*(A)$, thus also $HC_*(M_r(A))\cong HC_*(A)$ by(3.5.9.20).

Prop. (3.5.9.29) [Karoubi]. BG is a cyclic group, and then the cyclic homology group $HC_n(G,A)\cong \bigoplus_{k\geq 0} H_{n-2k}(G,A)$. Cf.[Weibel P339].

3.6 ∞-Categories

References are [Joy02], [Lur09], [Lur11], [Infinity Categories from Scratch], [A whirlwind tour of the world of $(\infty, 1)$-categories], [Gro15], [Introduction to ∞-Categories].

Notation (3.6.0.1).

- Use notations defined in Simplicial Homotopy Theory.

1 ∞-Categories

Def. (3.6.1.1) [∞-Category]. An **∞-category** is a simplicial set that has lifting property w.r.t any $\Lambda_i^n \to \Delta^n$, where $0 < i < n$.

Cor. (3.6.1.2). By(3.5.3.6), the nerve of a category is an ∞-category.

Def. (3.6.1.3)[Sub−∞-Categories]. Let $\mathcal{C} \in \mathcal{C}at_\infty$ and $\mathcal{D}_0 \subset \mathcal{C}_0$ be a subset of vertices, then there is a sub-simplicial set $\mathcal{D} \subset \mathcal{C}$ consisting of simplexes with all vertices in $\mathcal{C}$. Then it is also an ∞-category, called the **∞-category spanned by** $\mathcal{D}_0$.

Prop. (3.6.1.4) [Characterizing ∞-Categories]. $\mathcal{C} \in s\,\mathcal{S}et$ is an ∞-category iff the restriction map

$$\mathrm{Map}(\Delta^2, \mathcal{C}) \to \mathrm{Map}(\Lambda_1^2, \mathcal{C})$$

is a trivial Kan fibration.

Proof: This follows immediately from(3.5.3.29). □

Def. (3.6.1.5) [Homotopy Categories of ∞-Categories]. For $\mathcal{C} \in \mathcal{C}at_\infty$, the homotopy category of $\mathcal{C}$(3.5.4.12) has a simpler description: Let $f, g : X \to Y \in \mathcal{C}$ be called **homotopic maps** if there is a 2-complex of the form $\begin{array}{ccc} & X & \\ {}^{\mathrm{id}}\nearrow & & \searrow^{f} \\ X & \xrightarrow{g} & Y \end{array}$. $f : X \to Y$ is called an **equivalence** if there exists a map $g : Y \to X$ s.t. $f \circ g \cong \mathrm{id}_Y$ and $g \circ f \cong \mathrm{id}_X$.

Then the homotopy relation is an equivalence relation, and the composition of homotopic maps are homotopic, and we get a category $\mathrm{Ho}(\mathcal{C})$. Then this category is naturally isomorphic to $\tau_1(\mathcal{C})$(3.5.3.3).

Proof: [Lur09]P32. □

Prop. (3.6.1.6) [Equivalence of ∞-Categories]. Categorical equivalence(3.5.4.12) between ∞-categories is an equivalence relation(3.5.4.12), by Joyal model category(3.5.4.19).

Def. (3.6.1.7)[Underlying ∞-Categories of Simplicial Model Categories]. Let $\mathcal{M}$ be a simplicial model category(3.5.5.1), then $N_\Delta(\mathcal{M}_{cf})$ is an ∞-category by(3.5.4.4)?, called the **underlying ∞-category** of $\mathcal{M}$.

Lemma (3.6.1.8). Let $\mathcal{S} = s\,\mathcal{S}et$, then the map $\beta_{X,S}$ is a weak equivalence for every cofibrant object $X \in \mathcal{C}$.

Proof: Cf.[HTT, P853]. □

Prop. (3.6.1.9) [Quillen Equivalent Simplicial Model Categories Give Equivalent Underlying ∞-Categories]. Let $\mathcal{C}, \mathcal{D}$ be simplicial model categories and

$$F : \mathcal{C} \underset{}{\overset{\text{Quillen}}{\rightleftarrows}} \mathcal{D} : G$$

is a Quillen equivalence, every element of $\mathcal{C}$ is cofibrant, and G is a simplicial functor, then G induces an equivalence of their underlying ∞-categories $N_\Delta(\mathcal{D}_{cf}) \cong N_\Delta(\mathcal{C}_{cf})$.

Proof: This is because $G : \mathcal{D}_{cf} \to \mathcal{C}_{cf}$ is an equivalence of simplicial categories, by(3.4.7.6) and (3.6.1.8), and then(3.5.4.16) shows $N_\Delta(G) : N_\Delta(\mathcal{D}_{cf}) \to N_\Delta(\mathcal{C}_{cf})$ is an equivalence of ∞-categories. □

Def. (3.6.1.10) [Homotopy Coherent Diagrams]. Let $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ and $\mathcal{I} \in \mathcal{C}\mathrm{at}$, then a **homotopy coherent $\mathcal{I}$-diagram** is a map $N(\mathcal{I}) \to \mathcal{C} \in s\,\mathcal{S}\mathrm{et}$.

Categorical Constructions

Def. (3.6.1.11) [Categorical Constructions]. A **categorical construction** is a functorial construction $T : (s\,\mathcal{S}\mathrm{et})^m \times (s\,\mathcal{S}\mathrm{et}^{\mathrm{op}})^n \to s\,\mathcal{S}\mathrm{et}$ s.t.

- For $\mathcal{C}_i \in \mathcal{C}\mathrm{at} \subset s\,\mathcal{S}\mathrm{et}$, $T(\mathcal{C}_1, \ldots, \mathcal{C}_n) \subset \mathcal{C}\mathrm{at} \subset \mathcal{C}\mathrm{at}_\infty$.
- For $\mathcal{C}_i \in \mathcal{C}\mathrm{at}_\infty \subset s\,\mathcal{S}\mathrm{et}$, $T(\mathcal{C}_1, \ldots, \mathcal{C}_n) \subset \mathcal{C}\mathrm{at}_\infty$.
- If for each i, $\mathcal{C}_i, \mathcal{D}_i \in \mathcal{C}\mathrm{at}_\infty \subset s\,\mathcal{S}\mathrm{et}$ are categorically equivalent, then $T(\mathcal{C}_1, \ldots, \mathcal{C}_n)$ and $T(\mathcal{D}_1, \ldots, \mathcal{D}_n)$ are equivalent ∞-categories.

Prop. (3.6.1.12) [Opposite ∞-Categories]. For $\mathcal{C}, \mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$,

- The opposite(3.5.3.11) $\mathcal{C}^{\mathrm{op}}$ is also an ∞-category.
- If $\mathcal{C} \to \mathcal{D}$ is a categorical equivalence, then $\mathcal{C}^{\mathrm{op}} \to \mathcal{D}^{\mathrm{op}}$ is also a categorical equivalence.

Thus the opposite construction is a categorical construction, by(3.5.3.12).

Proof: □

Prop. (3.6.1.13) [Mapping Spaces of ∞-Categories]. Let $\mathcal{C}, \mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$ and $K, K' \in s\,\mathcal{S}\mathrm{et}$, then

- $\mathrm{Map}(K, \mathcal{C})$ is also an ∞-category.
- If $f : \mathcal{C} \to \mathcal{D}$ is a categorical equivalence, then the induced map $\mathrm{Map}(K, \mathcal{C}) \to \mathrm{Map}(K, \mathcal{D})$ is also a categorical equivalence.
- If $g : K \to K'$ is a categorical equivalence, then the induced map $\mathrm{Map}(K', \mathcal{C}) \to \mathrm{Map}(K, \mathcal{C})$ is also a categorical equivalence.

In particular, mapping space is a categorical construction, by(3.5.3.15).

Proof: 1 follows from(3.5.3.30). 2, 3 follow from [HTT, P94].**?** □

Prop. (3.6.1.14) [Joins of ∞-Categories]. Let $\mathcal{C}, \mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$, then

- The join(3.5.3.17) $\mathcal{C} * \mathcal{D}$ is also an ∞-category.
- If $\mathcal{C} \to \mathcal{C}', \mathcal{D} \to \mathcal{D}' \in \mathcal{C}\mathrm{at}_\infty$ are categorical equivalences, then $\mathcal{C} * \mathcal{D} \to \mathcal{C}' * \mathcal{D}'$ is also a categorical equivalence.

In particular, the join is a categorial construction by(3.5.3.18).

Proof: 1: Given a morphism $p:\Lambda^n_i\to S\star S'$, if the image is in S or S', then it can be extended to Δ^n by hypothesis. Thus we may assume that it maps $\{0,\ldots,j\}$ into S and $\{j+1,\ldots,n\}$ into S', then we restricts p to get a morphism $\Delta^{\{0,\ldots,j\}}\to S,\Delta^{\{j+1,\ldots,n\}}\to S'$, which determines a map $\Delta^n\cong\Delta^j*\Delta^{n-j-1}$(3.5.3.18) $\to S\star S'$, and it extends p by(3.5.3.16).

2 follows from(3.5.4.26). □

Prop. (3.6.1.15) [Homotopic Maps]. If X is an ∞-category, then so does X^B for any simplicial set B, by(3.5.3.36).

And we can call two maps in $\mathrm{Map}(B,X)$ **homotopic** if they are equivalent as vertices in X^B(3.6.1.5).

Lemma (3.6.1.16). Let $p:\mathcal{C}\to\mathcal{D}$ be a left fibration of ∞-categories and $f:X\to Y$ be a morphism that $p(f)$ is an equivalence in $\mathcal{D}$, then f is an equivalence in $\mathcal{D}$. Compare with(3.1.8.8).

Proof: Let $\overline{g}$ be a homotopy inverse to f, then there is a 2-complex

$$\begin{array}{ccc} & p(Y) & \\ {\scriptstyle p(f)}\nearrow & & \searrow{\scriptstyle \overline{g}} \\ p(X) & \longrightarrow & p(X) \end{array}$$

and by left fibration property lifts to a 2-complex

$$\begin{array}{ccc} & Y & \\ {\scriptstyle f}\nearrow & & \searrow{\scriptstyle g} \\ X & \longrightarrow & X \end{array}.$$

So f admits a left homotopy inverse, and by the same reason, g admits a left homotopy inverse, thus g has a left homotopy inverse, and it can be chosen to be f. □

Lemma (3.6.1.17) [Equivalence Lifts via Left Fibrations]. Let $p:\mathcal{C}\to\mathcal{D}$ be a left fibration of ∞-categories, if $\overline{X}\in\mathcal{D}$ and $Y\in\mathcal{C}$ and $\overline{f}:\overline{X}\to p(Y)$ is an equivalence, then $\overline{f}$ can be lifted to a morphism in $\mathcal{C}$.(Which is also an equivalence by(3.6.1.16)).

Proof: □

Prop. (3.6.1.18) [Equivalence and Left Extension]. Let $\mathcal{C}$ be an ∞-category and φ an edge, then φ is an equivalence iff for any $n\geq 2$ and every map $\Lambda^n_0\to\mathcal{C}$ that $f_0|\Delta^{\{0,1\}}=\varphi$, there exists an extension of f_0 to Δ^n.

Proof: If φ is an equivalence, then consider the diagram

$$\begin{array}{ccc} \{0\} & \longrightarrow & \mathcal{C}/\Delta^{n-2} \\ \big\downarrow & \nearrow & \big\downarrow{\scriptstyle q} \\ \Delta^1 & \xrightarrow{\varphi'} & \mathcal{C}/\partial\Delta^{n-2} \end{array}$$

Because $\mathcal{C}/\partial\Delta^{n-2}\to\mathcal{C}$ is right fibration(3.5.3.35), and by the dual of(3.6.1.16), φ' is an equivalence, thus by the dual of(3.6.1.17) the dotted arrow exists.

Conversely, if the condition holds, then we can use a diagram $\Lambda^2_0\to\mathcal{C}$ to find a morphism ψ that $\psi\circ\varphi\cong\mathrm{id}$, and we can also use a diagram $\Lambda^3_0\to\mathcal{C}$ to witness the fact $\varphi\circ\psi\cong\mathrm{id}$, so φ is an equivalence. □

Cor. (3.6.1.19). An equivalence in $\mathrm{Map}(K, \mathcal{C})$ is equivalent to a map $K \times \Delta^1 \to \mathcal{C}$ that $\{x\} \times \Delta$ are all mapped to equivalences in $\mathcal{C}$.

Proof: ? Cf.[HTT, P106]. □

Def. (3.6.1.20) [Space of Morphisms]. For vertices x, y in a simplicial set S, we want to defines a representative for $\mathrm{Map}_{h\mathcal{S}}(x, y)$ other than $\mathrm{Map}_{\mathfrak{C}[S]}(x, y)$. We define the **space of right morphisms**

$$\mathrm{Hom}^R_S(x, y) = S_{/y} \times_S \{x\}.$$

The definition is not symmetric, instead, we define the **space of left morphisms** $\mathrm{Hom}^L_S(x, y) = (\mathrm{Hom}^R_{S^{op}}(x, y))^{op}$.

Also we can define $\mathrm{Hom}_S(x, y) = \{x\} \times_S S^{\Delta^1} \times_S \{y\}$, then there are natural inclusions:

$$\mathrm{Hom}^R_S(x, y) \longrightarrow \mathrm{Hom}_S(x, y) \longleftarrow \mathrm{Hom}^L_S(x, y) \ .$$

Prop. (3.6.1.21). If $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ and $x, y \in \mathcal{C}$, then $\mathrm{Hom}^R_{\mathcal{C}}(x, y)$ is a Kan complex, and the inclusions defined in(3.6.1.20) are weak equivalences.

Proof: This is obvious, because the right lifting diagram w.r.t. $\Lambda^n_j \subset \Delta^n, 0 < j \leq n$ is equivalent to an extension $\Lambda^n_j \star \Delta^0 \subset \Delta^{n+1}$ that satisfies $\widetilde{u}|_{\Delta^{\{0,\ldots,n\}}} = x$. It can be solved by a two-step extension where the first is by identity extension and then extend using inner fibration property.

For the last assertion, Cf.[HTT, 4.2.1.8].? □

Prop. (3.6.1.22). Let $p : \mathcal{C} \to \mathcal{D}$ be an inner fibration of ∞-categories, then the the induced maps on the spaces of right morphisms are Kan fibrations.

Proof: Since p is an inner fibration, the induced map $\widetilde{\varphi} : \mathcal{C}_{/Y} \to \mathcal{D}_{/p(Y)} \times_{\mathcal{D}} \mathcal{C}$ is a right fibration by(3.5.3.35), and the morphism on $\mathrm{Hom}^R_{\mathcal{C}}(X, Y)$ is obtained from $\widetilde{\varphi}$ by restricting to fiber over X, thus also a right fibration. And by(3.6.1.21) and(3.5.3.41). □

Lemma (3.6.1.23). Let $\mathcal{C} \to \mathcal{D}$ be a fully faithful map of ∞-categories and $p : K \to \mathcal{C} \in s\mathcal{S}\mathrm{et}$, then the map of ∞-categories(3.6.1.24)

$$\mathcal{C}_{j/} \times_{\mathcal{C}} \{x\} \to \mathcal{D}_{pj/} \times_{\mathcal{D}} \{p(x)\}$$

is a homotopy equivalence.

Proof: Cf.[HTT, P134]. □

Prop. (3.6.1.24) [Overcategories and Undercategories].

- If $\mathcal{C}$ be an ∞-category and $p : K \to \mathcal{C}$ be an morphism, then the projection $\mathcal{C}_{p/} \to \mathcal{C}$ is a left fibration. In particular, $\mathcal{C}_{p/}$ is itself an ∞-category. Dually, $C_{/p}$ is also an ∞-category.
- Let $p : \mathcal{C} \to \mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$ be an equivalence of ∞-categories and let $j : K \to \mathcal{C} \in s\mathcal{S}\mathrm{et}$, then the induced map $\mathcal{C}_{j/} \to \mathcal{D}_{pj/}$ is an equivalence of ∞-categories. The dual holds for undercategories.

In particular, the overcategories and undercategories are categorial constructions, by(3.5.3.23).

Proof: 1: We use the proposition(3.5.3.35) in case $S = \Delta^0, A = \varnothing, X = \mathcal{C}$.

2: There is a factorization $\mathcal{C}_{j/} \xrightarrow{f} \mathcal{D}_{pj/} \times_{\mathcal{D}} \mathcal{C} \xrightarrow{g} \mathcal{D}_{pj/}$. (3.6.1.23)(3.6.1.24) shows $C_{j/}$ and $\mathcal{D}_{pj/} \times_{\mathcal{D}} \mathcal{C}$ are fiberwise equivalent left fibrations over $\mathcal{C}$, thus by(3.5.7.7) and(3.5.7.10), f is a categorical equivalence. Also, g is a categorical equivalence by(3.5.7.11). So we are done. ? Cf.[HTT, P135]. □

Prop. (3.6.1.25)[Lifting of Homotopies]. Let $p : \mathcal{C} \to \mathcal{D}$ be a categorical equivalence of ∞-categories and $A \subset B$ be an inclusion of simplicial sets. Let $f_0 : A \to \mathcal{C}, g : B \to \mathcal{D}$ be any maps that $h_0 : A \times \Delta^1 \to \mathcal{D}$ be an equivalence between $g|_A$ and $p \circ f_0$, then there exists a map $B \to \mathcal{C}$ and an equivalence $h : B \times \Delta^1 \to \mathcal{D}$ between g and $p \circ f$ that $h_0 = h|_{A\times\Delta^1}$.

Proof: Working with simplexes, it suffices to prove for $A = \partial\Delta^n \subset B = \Delta^n$. The case $n = 0$ is true because categorical equivalence is essentially surjective. For $n > 0$, we need to construct h from $h|_{\Delta^n\times\{0\}\coprod \partial\Delta^n\times\Delta^1}$, and this is a composition of pushout of $\Lambda^{n+1}_k \subset \Delta^{n+1}$. For $k \neq 0$, the extension is clear because $\mathcal{D}$ is ∞-category, and for $k = 0$, we need to use [HTT, P136]. □

∞-Groupoids(or Kan Complexes/Spaces)

Def. (3.6.1.26) [∞-Groupoid]. An **∞-groupoid** or an **anima** is an ∞-category $\mathcal{C}$ that $\mathrm{Ho}(\mathcal{C})$ is a groupoid(3.6.1.5), or equivalently, all morphisms are equivalences. The full subcategory of $\mathcal{C}at_\infty$ consisting of ∞-groupoids are denoted by $\mathcal{G}rpd_\infty$.

Prop. (3.6.1.27) [∞-Groupoids ⟺ Kan Complex]. For $\mathcal{C} \in s\,\mathcal{S}et$, the following are equivalent:

- $\mathcal{C}$ is an ∞-groupoid.
- $\mathcal{C} \to \Delta^0$ is a left fibration.
- $\mathcal{C} \to \Delta^0$ is a right fibration.
- $\mathcal{C}$ is a Kan complex.

Proof: $1, 2$ are equivalent by(3.6.1.18), and dually $1, 3$ are equivalent, and $4 = 2 + 3$. □

n-Categories

Def. (3.6.1.28) [n-Categories]. For $\mathcal{C} \in s\,\mathcal{S}et$ and $n \geq -1$, then $\mathcal{C}$ is called an **n-category** if it is an ∞-category and:

- Given any maps $f, f' : \Delta^n \to \mathcal{C}$ that are homotopic(3.6.1.15) relative to $\partial\Delta^n$, then $f = f'$.
- For any $m > n$ and maps $f, f' : \Delta^m \to \mathcal{C}$ that coincide on $\partial\Delta^m$, then $f = f'$.

Also $\mathcal{C}$ is called an (-2)-category iff it is isomorphic to Δ^0.

The definition of an n-category is equivalent to the following: if $f, f' : K \to \mathcal{C}$ satisfies $f|_{sk^n K}$ is homotopic to $f'|_{sk^n K}$ relative to $\mathrm{sk}^{n-1}K$, then $f = f'$.

Cor. (3.6.1.29). If $\mathcal{C}$ is an n-category and $m > n$, then the restriction map $\mathrm{Hom}(\Delta^m, \mathcal{C}) \to \mathrm{Hom}(\partial\Delta^m, \mathcal{C})$ is bijective.(use ∞-category property to extend).

Prop. (3.6.1.30). A (-1)-category is seen to be isomorphic to $\varnothing$ or Δ^0. A 0-category is equivalent to the nerve of a partially ordered set.

Proof: □

Prop. (3.6.1.31) [$\mathcal{C}at$ and $\mathcal{C}at_1$]. For a simplicial set S, the following are equivalent:

- $u : S \to N(hS)$(3.5.3.3) is an isomorphism of simplicial sets.
- There is a small category $\mathcal{C}$ that $S \cong N(\mathcal{C})$.
- S is a 1-category.

Proof: It suffices to show 3 → 1: we induct on the dimension: $n = 0$ is trivial and $n = 1$ follows from the definition of 1-category(3.6.1.28). For $n > 1$, the injectivity of u follows from induction hypothesis and(3.6.1.28), and for surjectivity, for a map $\Delta^n \to N(hS)$, choose $0 < i < n$ and let lift Λ^n_i to S, then use the fact S is an ∞-category to lift to Δ^n, and now it coincide on $N(hS)$ because it is a nerve of a category. □

Prop. (3.6.1.32). If $\mathcal{C}$ is an n-category, then for any simplicial set X, $\mathcal{C}^X$ is also an n-category.

Proof: This is because $sk^p(K \times X) \subset sk^p(K) \times X$ for any simplicial set K and integer p, and use(3.6.1.28). □

Prop. (3.6.1.33). Let $n \geq 1$ and $\mathcal{C}$ an ∞-category, then $\mathcal{C}$ is an n-category iff it satisfies the unique lifting property w.r.t. the inclusion $\Lambda^m_i \subset \Delta^m$, where $0 < i < m$.

Proof: Cf.[HTT, P109]. □

Def. (3.6.1.34) [n-Truncated Kan Complexes]. Let X be a Kan complex and $k \geq -1$, then a Kan complex is called **k-truncated** if for every $i > k$ and every point $x \in X$, we have $\pi_i(X, x) \cong *$. And it is called (-2)**-truncated** if it is contractible.

Prop. (3.6.1.35). A (-1)-truncated Kan complex is either empty or contractible. A 0-contractible Kan complex is a Kan complex that $X \to \pi_0(X)$ is a homotopy equivalence.

Proof: ?. □

Prop. (3.6.1.36) [Equivalent to an n-Category]. Let $\mathcal{C}$ be an ∞-category and $n \geq -1$, then the following conditions are equivalent:

- There is a minimal model $\mathcal{C}' \subset \mathcal{C}$ that is n-truncated.
- $\mathcal{C}$ is categorically equivalent to an n-truncated category.
- For any $X, Y \in \mathcal{C}$, the mapping space $\mathrm{Map}(X, Y)$ is $(n-1)$-truncated.

Proof: Cf.[HTT, P112]. □

Cor. (3.6.1.37). A Kan complex is categorically equivalent to an n-category iff it is n-truncated.

Proof: Cf.[HTT, P113]?. □

Cor. (3.6.1.38). Let $\mathcal{C}$ be an ∞-category and K a simplicial set, if $\mathrm{Map}(C, D)$ is n-truncated for any objects $C, D \in \mathcal{C}$, then the ∞-category $\mathcal{C}^K$ has the same property.

Proof: Cf.[HTT, P114]. □

2 ∞-Category of ∞-Categories

Def. (3.6.2.1) [Models on $s\,\mathcal{S}\mathrm{et}^+$]. There is a simplicial model structure on $s\,\mathcal{S}\mathrm{et}^+$(3.5.3.51) s.t. the fibrant and cofibrant objects are exactly objects of the form $\mathcal{C}^\natural$ where $\mathcal{C}$ is an ∞-category, and $\mathcal{C}^\natural = (\mathcal{C}, \mathcal{E}_\mathcal{C})$ where $\mathcal{E}_\mathcal{C}$ is the set of equivalences in $\mathcal{C}$(3.6.1.5).

Proof: ? □

Def. (3.6.2.2) [$\mathcal{C}\mathrm{at}_\infty$]. The underlying ∞-category $\mathcal{C}\mathrm{at}_\infty = N_\Delta(s\,\mathcal{S}\mathrm{et}^+_{cf})$ of $s\,\mathcal{S}\mathrm{et}^+$ is called the **∞-category of ∞-category of ∞-categories**. It can be verified that the fundamental category of $\mathcal{C}\mathrm{at}_\infty$ consists of equivalent classes of ∞-categories.

Def. (3.6.2.3) [Relative Mapping Spaces]. Let $p : X \to S, q : Y \to S \in s\,\mathcal{S}\mathrm{et}$, then define $\mathrm{Map}_S(X, Y) = \mathrm{Map}_{\mathcal{C}\mathrm{at}_\infty/T}(X, Y) \in s\,\mathcal{S}\mathrm{et}$.

(∞, n)-Categories

Def. (3.6.2.4) [**(∞, n)-Categories**]. For $n \in \mathbb{N}$, an (∞, n)-category is an ∞-category s.t. for $k > n$, any k-maps is invertible**?**. In particular, an $(\infty, 0)$-category is just an ∞-groupoid.

Def. (3.6.2.5) [$\mathcal{G}\mathrm{rpd}_\infty$]. The underlying ∞-category $N_\Delta(\mathrm{Kan})$ of $s\,\mathcal{S}\mathrm{et}$ with the Joyal model structure(3.5.4.19) is denoted by $\mathcal{G}\mathrm{rpd}_\infty$. Then it is an sub-$\infty$-category of $\mathcal{C}\mathrm{at}_\infty$, and it is an $(\infty, 1)$-category.

Proof: **?** □

3 Limits and Colimits

Remark (3.6.3.1)[Universal Properties]. The objects in an ∞-category characterized by a universal property will be a contractible Kan complex.

Def. (3.6.3.2) [Final Objects]. For $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$, $x \in \mathcal{C}$ is called a **final object** if the canonical map $\mathcal{C}_{/x} \to \mathcal{C} \in s\,\mathcal{S}\mathrm{et}$ is a trivial Kan fibration. Equivalently, for any $y \in \mathcal{C}$, $\mathrm{Map}^R_{\mathcal{C}}(y, x)$ is a contractible Kan complex. It is clear that the sub-∞-category of final objects in $\mathcal{C}$ is either empty or a contractible Kan complex.

Dually we can define initial objects.

Proof: If x is a final object, then $\mathrm{Map}^R_{\mathcal{C}}(y, x)$ is the fiber of $\mathcal{C}_{/x} \to \mathcal{C}$ over x(3.6.1.20), so it is a contractible Kan-complex by(3.6.1.27). The converse follows from(3.5.3.45). □

Cor. (3.6.3.3). For $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ with a final object $*$, we fix a final object, then there is a section $\mathcal{C} \to \mathcal{C}_{/*}$, which maps each $C \in \mathcal{C}$ to a morphism $C \to * \in \mathcal{C}$. We fix such a morphism. The dual is true for initial objects.

Prop. (3.6.3.4). If $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ and $* \in \mathcal{C}$ is final, then for any diagram $p : K \to \mathcal{C}$, $*$ is also final in $\mathcal{C}_{p/}$.**?**

Def. (3.6.3.5) [Limits and Colimits]. For $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ and $p : K \to \mathcal{C} \in \mathcal{C}\mathrm{at}$, a **colimit** of p is defined to be an initial object of $\mathcal{C}_{p/}$, and a **limit** of p is defined to be a final object of $\mathcal{C}_{/p}$. By(3.6.3.2), (co)limits are defined up to a contractible choice, and we may use $(\varinjlim_p)\ \varprojlim_p$ to denote any one of them.

Def. (3.6.3.6). For $\mathcal{C}, \mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$, let $\mathrm{Func}^L(\mathcal{C}, \mathcal{D})$ denote the sub-∞-category of $\mathrm{Func}(\mathcal{C}, \mathcal{D})$ consisting of functors preserving colimits, and let $\mathrm{Func}^R(\mathcal{D}, \mathcal{C})$ denote the sub-∞-category of $\mathrm{Func}(\mathcal{D}, \mathcal{C})$ consisting of functors preserving limits.

Prop. (3.6.3.7). For $\mathcal{C}, \mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$, there is a natural equivalence of ∞-categories $\mathrm{Func}^L(\mathcal{C}, \mathcal{D}) \cong \mathrm{Func}^R(\mathcal{D}, \mathcal{C})^{\mathrm{op}}$.

Proof: Cf.[Lur09]P356. □

Cofinal Diagrams

Def. (3.6.3.8) [Cofinal Maps]. A **cofinal map** $p : S \to T \in s\,\mathcal{S}\mathrm{et}$ is a map s.t. for any right fibration $X \to T \in s\,\mathcal{S}\mathrm{et}$,

$$\mathrm{Map}_T(T, X) \to \mathrm{Map}_T(S, X) \in s\,\mathcal{S}\mathrm{et}(3.6.2.3)$$

is a homotopy equivalence.

Prop. (3.6.3.9) [Cofinal Maps give Same Colimits]. For $v : K' \to K \in s\mathcal{S}\mathrm{et}$, the following are equivalent:

- v is cofinal.
- for any $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ and $p : K \to \mathcal{C} \in s\mathcal{S}\mathrm{et}$, the induced map $\mathcal{C}_{p/} \to \mathcal{C}_{p\circ v/}$ is an equivalence of ∞-categories.

Proof: Cf.[Lur09]P226. □

Computing Diagrams

Prop. (3.6.3.10) [Reducing to Coherent Colimits]. For any $K \in s\mathcal{S}\mathrm{et}$, there exists a category $\mathcal{I} \subset \mathcal{C}\mathrm{at}$ and a cofinal map $N(\mathcal{I}) \to K \in s\mathcal{S}\mathrm{et}$.

Proof: Cf.[Lur09]P255. □

Prop. (3.6.3.11) [Colimits in Overcategories]. Let $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ and $q : T \to \mathcal{C} \in s\mathcal{S}\mathrm{et}, p : K \to \mathcal{C}_{/q}$, and $p_0 : K \xrightarrow{p} \mathcal{C}_{/q} \to \mathcal{C}$. If p_0 has a colimit, then

- p also has a colimit, and the colimit is preserved by the $\mathrm{pr} : \mathcal{C}_{/q} \to \mathcal{C}$.
- $x \in \mathcal{C}_{/q}$ is a colimit of p iff $\mathrm{pr}(x) \in \mathcal{C}$ is a colimit of p_0.

Proof: Cf.[Lur09]P48. □

Cor. (3.6.3.12) [Colimits in Diagram Categories]. For $K, S \in s\mathcal{S}\mathrm{et}$, let $\mathcal{C}$ be an ∞-category that admits K-indexed colimits, then

- the ∞-category $\mathrm{Func}(S, \mathcal{C})$(3.6.1.13) also admits K-indexed colimits.
- $p : K^\triangleright \to \mathrm{Func}(S, \mathcal{C})$ is a colimit diagram iff for each $C \in \mathcal{C}$, the evaluation $p_C : K^\triangleright \to \mathcal{C}$ is a colimit diagram.

Proof: Cf.[Lur09]P315. □

Kan Extensions

Def. (3.6.3.13) [p-Left Kan Extensions]. For a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C}^0 & \xrightarrow{F_0} & \mathcal{D} \\ \big\downarrow & \overset{F}{\nearrow} & \big\downarrow p \\ \mathcal{C} & \longrightarrow & \mathcal{D}' \end{array},$$

F is called a **p-left Kan extension** of F_0 if for any $C \in \mathcal{C}$, the induced diagram

$$\begin{array}{ccc} \mathcal{C}^0_{/C} & \xrightarrow{F_C} & \mathcal{D} \\ \big\downarrow & \overset{F}{\nearrow} & \big\downarrow p \\ (\mathcal{C}^0_{/C})^\triangleright & \longrightarrow & \mathcal{D}' \end{array},$$

exibits C as a p-colimit? of F_C.

Lemma (3.6.3.14) [Existence of p-Left Kan Extensions]. Given a commutative diagram of ∞-categories

$$\begin{array}{ccc} \mathcal{C}^0 & \xrightarrow{F_0} & \mathcal{D} \\ \downarrow & \overset{F}{\nearrow} & \downarrow p \\ \mathcal{C} & \longrightarrow & \mathcal{D}' \end{array},$$

then there exists a p-left Kan extension F iff for any $C \in \mathcal{C}$ the composition

$$\mathcal{C}^0_{/p} \to \mathcal{C}^0 \xrightarrow{F_0} \mathcal{D}$$

admits a p-colimit.

Proof: Cf.[Lur09]P282. □

Lemma (3.6.3.15). Let $\mathcal{C} \to \mathcal{D}' \overset{p}{\leftarrow} \mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$ where p is a Joyal-fibration, and $\mathcal{C}^0 \subset \mathcal{C}$ a full subcategory, the the restriction functor

$$i^* : \mathrm{Func}_{\mathcal{D}'}(\mathcal{C}, \mathcal{D}) \to \mathrm{Func}_{\mathcal{D}'}(\mathcal{C}^0, \mathcal{D})$$

has right lifting property w.r.t. all $\partial\Delta^n \to \Delta^n$ s.t. the map $\partial\Delta^n$ maps $\{0\}$ to a functor $F : \mathcal{C} \to \mathcal{D}$ which is a p-left Kan extension(3.6.3.13) of $F|_{\mathcal{C}^0}$,

Proof: Cf.[Lur09]P279. □

Prop. (3.6.3.16). Let $\mathcal{C} \to \mathcal{D}' \overset{p}{\leftarrow} \mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$ where p is a Joyal-fibration, and $\mathcal{C}^0 \subset \mathcal{C}$ a full subcategory. Let

- $\mathcal{K} \subset \mathrm{Func}_{\mathcal{D}'}(\mathcal{C}, \mathcal{D})$ be the full subcategory of functors $F : \mathcal{C} \to \mathcal{D}$ which are p-left Kan extensions(3.6.3.13) of $F|_{\mathcal{C}^0}$,
- $\mathcal{K}' \subset \mathrm{Func}_{\mathcal{D}'}(\mathcal{C}^0, \mathcal{D})$ be the category of functors $F_0 : \mathcal{C}^0 \to \mathcal{D}$ s.t. for any $C \in \mathcal{C}$, the induced functor $\mathcal{C}^0_{/C} \to \mathcal{D}$ has a p-colimit.

Then the restriction functor $i^* : \mathcal{K} \to \mathcal{K}'$ is a trivial Kan fibration.

Proof: This follows immediately from(3.6.3.14) and(3.6.3.15). □

Cor. (3.6.3.17) [Functorial Left Kan Extensions]. Let $\mathcal{C} \to \mathcal{D}' \overset{p}{\leftarrow} \mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$ where p is a Joyal-fibration, and $\mathcal{C}^0 \subset \mathcal{C}$ a full subcategory. Suppose that every functor $F_0 : \mathcal{C}^0 \to \mathcal{D}$ over $\mathcal{D}'$ admits a p-left Kan extension(3.6.3.13), then the restriction

$$i^* : \mathrm{Func}_{\mathcal{D}'}(\mathcal{C}, \mathcal{D}) \to \mathrm{Func}_{\mathcal{D}'}(\mathcal{C}^0, \mathcal{D})$$

admits a section $i_!$ whose essential image are exactly those F which are p-left Kan extension of $F|_{\mathcal{C}^0}$. Any such $i_!$ is called the **left Kan extension functor**. Moreover, this $i_!$ is left adjoint to i^*:

$$i^* : \mathrm{Func}_{\mathcal{D}'}(\mathcal{C}, \mathcal{D}) \rightleftarrows \mathrm{Func}_{\mathcal{D}'}(\mathcal{C}^0, \mathcal{D}) : i_!$$

Proof: Cf.[Lur09]P284. □

4 Adjunctions

Correspondences

Def. (3.6.4.1) [Correspondence]. Let $\mathcal{C}, \mathcal{D}$ be ∞-categories, an **correspondence** between $\mathcal{C}, \mathcal{D}$ is defined to be an ∞-category $\mathcal{M}$ and a map $\mathcal{M} \to \Delta^1$ s.t. $\mathcal{C} \cong \mathcal{M}_0$ and $\mathcal{D} \cong \mathcal{M}_1$.

Adjunctions

Def. (3.6.4.2) [Adjunctions]. An **adjunction** between ∞-categories $\mathcal{C},\mathcal{D}\in\mathcal{C}\mathrm{at}_\infty$ is a map $q:\mathcal{M}\to\Delta^1\in s\,\mathcal{S}\mathrm{et}$ that is both Cartesian fibration and coCartesian fibration, together with equivalences $\mathcal{M}_{\{0\}}\cong\mathcal{C},\mathcal{M}_{\{1\}}\cong\mathcal{D}$.

If $\mathcal{M}\to\Delta^1$ is an adjunction and $f:\mathcal{C}\to\mathcal{D},g:\mathcal{D}\to\mathcal{C}$ are the associated functors, then f is said to be **left adjoint** to g and g is said to be **right adjoint** to f.

Def. (3.6.4.3) [Unit Transformations]. For a pair of functors $f:\mathcal{C}\to\mathcal{D},g:\mathcal{D}\to\mathcal{C}$ between ∞-categories, a **unit transformation** for (f,g) is a morphism $u:\mathrm{id}\to g\circ f\in\mathrm{Func}(\mathcal{C},\mathcal{C})$ s.t. for any $C\in\mathcal{C},D\in\mathcal{D}$, the composition

$$\mathrm{Map}_{\mathcal{D}}(f(C),D)\xrightarrow{g}\mathrm{Map}_{\mathcal{C}}(gf(C),g(D))\xrightarrow{u(C)}\mathrm{Map}_{\mathcal{C}}(C,g(D))$$

is a homotopy equivalence.

Prop. (3.6.4.4) [Unit Transformations and Adjunctions]. For a pair of functors $f:\mathcal{C}\to\mathcal{D},g:\mathcal{D}\to\mathcal{C}$, f is left adjoint to g iff there is a unit transformation $u:\mathrm{id}\to g\circ f$.

Proof: Cf.[Lur09]P339. □

Prop. (3.6.4.5)[Adjunction and Limits]. Left adjoints between ∞-categories preserve small colimits and right adjoints between ∞-categories preserves small limits.

Proof: Cf.[Lur09]P345. □

Localizations

Def. (3.6.4.6) [Localization of ∞-Categories]. A functor $\mathcal{C}\to\mathcal{D}\in\mathcal{C}\mathrm{at}_\infty$ is called a **localization of ∞-category** if it admits a fully faithful right adjoint.

5 Presentable ∞-Categories

∞-Categories of Presheaves

Def. (3.6.5.1) [∞-Category of Presheaves]. For $S\in s\,\mathcal{S}\mathrm{et}$, there exists an ∞-category $\mathcal{PS}\mathrm{h}^{\mathrm{Set}}_\infty(S)=\mathrm{Func}(S^{\mathrm{op}},\mathcal{S})\subset\mathcal{C}\mathrm{at}_\infty$ by(3.6.1.13), called the **∞-category of presheaves on** S. More generally, for any $\mathcal{C}\in\mathcal{C}\mathrm{at}_\infty$, $\mathcal{PS}\mathrm{h}^{\mathrm{Set}}_\infty(S;\mathcal{C})=\mathrm{Func}(S^{\mathrm{op}},\mathcal{C})$ is called the **∞-category of $\mathcal{C}$-valued presheaves on** S.

Prop. (3.6.5.2)[Cocompleteness]. For $S\in s\,\mathcal{S}\mathrm{et}$ and $\mathcal{C}\in\mathcal{C}\mathrm{at}_\infty$ that is cocomplete, then $\mathcal{PS}\mathrm{h}(S;\mathcal{C})$ is also cocomplete by(3.6.3.12). In particular, $\mathcal{PS}\mathrm{h}^{\mathrm{Set}}_\infty(S)$ is cocomplete.

Def. (3.6.5.3) [Yoneda Embedding]. For $K\in s\,\mathcal{S}\mathrm{et}$, let $\mathcal{C}=\mathfrak{C}[K]$, then the mapping space construction defines a map

$$\mathcal{C}^{\mathrm{op}}\times\mathcal{C}\to\mathrm{Kan}:(X,Y)\mapsto\mathrm{Sing}\,|\,\mathrm{Map}_{\mathcal{C}}(X,Y)|$$

by(3.5.3.42). And there is a natural map $\mathfrak{C}[K^{\mathrm{op}}\times K]\to\mathcal{C}^{\mathrm{op}}\times\mathcal{C}$, so we have a map

$$\mathfrak{C}[K^{\mathrm{op}}\times K]\to\mathrm{Kan}$$

which corresponds to a map

$$K^{\mathrm{op}}\times K\to N_\Delta(\mathrm{Kan})=\mathcal{G}\mathrm{rpd}_\infty.$$

and induces a map

$$よ_\Delta : K \mapsto \mathrm{Func}(K^{\mathrm{op}}, \mathcal{G}\mathrm{rpd}_\infty) = \mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(K),$$

When $\mathcal{C} \in \mathcal{C}\mathrm{at}$ and $K = N(\mathcal{C})$ this is compatible with the usual Yoneda embedding composed with simplicial enhencement, so it is called the the **Yoneda embedding**.

Prop. (3.6.5.4) [∞-Categorical Yoneda Lemma]. For $K \in s\,\mathcal{S}\mathrm{et}$, the Yoneda embedding(3.6.5.3) $よ : K \to \mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(K)$ is fully faithful.

Proof: Cf.[Lur09]P316. □

Prop. (3.6.5.5). let $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$, then $よ_\Delta : \mathcal{C} \to \mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(\mathcal{C})$ preserves all small limits.

Proof: Cf.[Lur09]P316. □

Lemma (3.6.5.6). Let $S \in s\,\mathcal{S}\mathrm{et}$, and $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$, then

- Any functor $F : \mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S) \to \mathcal{C}$ is a left Kan extension of $f|_S$ iff f preserves all small colimits.
- If $\mathcal{C}$ is cocomplete, then any functor $S \to \mathcal{C}$ has a left Kan extension $\mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S) \to \mathcal{C}$.

Proof: Cf.[Lur09]P322. □

Thm. (3.6.5.7) [∞-Categorical Yoneda Extensions]. Let $S \in s\,\mathcal{S}\mathrm{et}$ and $\mathcal{C}$ be a cocomplete ∞-category, the Yoneda embedding $よ_\Delta : S \to \mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S)$ induces an equivalence of ∞-categories

$$\mathrm{Func}^L(\mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S), \mathcal{C}) \cong \mathrm{Func}(S, \mathcal{C}).$$

Proof: This follows from(3.6.3.17) and(3.6.5.6). □

Cor. (3.6.5.8). For $S \in s\,\mathcal{S}\mathrm{et}$, $\mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S)$ is generated by S under small colimits. In particular, $\mathcal{G}\mathrm{rpd}_\infty$ is generated by Δ^0 under small colimits.

Proof: If $\mathcal{C} \subset \mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S)$ is a strictly full subcategory stable under small colimits containing $よ_\Delta(S)$, then $\mathcal{C}$ is cocomplete by(3.6.5.2), and then $よ_\Delta : S \to \mathcal{C}$ is of the form $F \circ よ_\Delta$ by(3.6.5.7) where $F : \mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S) \to \mathcal{C}$ preserves small colimits. Then we can regard F as a self-map of $\mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S)$ that is identity on $\mathrm{id} : S \to S$. Thus by(3.6.5.7) again, F is equivalent to id_S. Thus every object of $\mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S)$ is equivalent some elements in $\mathcal{C}$, so $\mathcal{C} = \mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(S)$. □

Accessible ∞-Categories

Presentable ∞-Categories

Def. (3.6.5.9) [Presentable ∞-Category]. An ∞-category is called a **presentable ∞-category** if it is accessible and cocomplete.

Prop. (3.6.5.10) [Simpson]. For $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ is presentable iff it is an accessible reflective localization**?** of an $\mathcal{PS}\mathrm{h}_\infty^{\mathcal{S}\mathrm{et}}(\mathcal{D})$ for some $\mathcal{D} \in \mathcal{C}\mathrm{at}_\infty$.

Proof: Cf.[HTT, P5.5.1.1]. □

Prop. (3.6.5.11). A presentable ∞-category is complete.

Proof: Cf.[HTT, P5.5.2.4]. □

Prop. (3.6.5.12) [Presentable ∞-Categories as Simplicial Model Categories]. $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ is presentable iff it is equivalent to the underlying category $N_\Delta(\mathcal{M}_{cf})$ for some combinatorial simplicial model category $\mathcal{M}$.

Proof: □

Thm. (3.6.5.13) [Adjoint Functor Theorem]. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between presentable ∞-categories, then

- F admits a right adjoint iff it preserves small colimits.
- F admits a left adjoint iff it preserves small limits and κ-filtered colimits for some regular cardinal κ.

Proof: [HTT. 5.5.2.9]. □

Compactly Generated ∞-Categories

Def. (3.6.5.14).

6 ∞-Topoi

7 Topological Cyclic Homology(Scholze)

3.7 Homological Algebra

Main references are [Sta]and [G-M03].

1 Additive Category

Def. (3.7.1.1) [Preadditive Categories]. a **preadditive category** is a category A that satisfies:

- **A1**: $\mathcal{A}$ is enriched over the Cartesian category of Abelian groups.

Def. (3.7.1.2) [Zero Element]. Let $\mathcal{A}$ be a preadditive category and $x \in \mathcal{A}$, then the following are equivalent:

- x is initial.
- x is final.
- $\mathrm{id}_x = 0 \in \mathrm{Mor}(x, x)$.

Such an element is called a **zero element** in $\mathcal{A}$, denoted by 0. If 0 exists, then a morphism $\alpha : x \to y$ factors through 0 iff $\alpha = 0$.

Proof: Cf.[Sta]00ZZ. □

Cor. (3.7.1.3). An additive functor transforms a zero object to a zero object.

Prop. (3.7.1.4) [Finite Direct Sums]. If $\mathcal{A}$ is a preadditive category and $x, y \in \mathcal{A}$. If one of $x \times y$ and $x \coprod y$ exists, then so does the other, and they are isomorphic, called the **direct sum** of x, y.

Proof: Cf.[Sta]0101. □

Def. (3.7.1.5) [Additive Functors]. A functor between preadditive categories $F : \mathcal{C} \to \mathcal{D}$ is called **additive** if it is a morphism of $\mathcal{A}b$-enriched categories.

Def. (3.7.1.6) [Kernels, Cokernels, Images and Coimages]. Let $\mathcal{A}$ be a preadditive category and $f : X \to Y$ is a map, then

- the **kernel** of f is the fiber product $\begin{array}{ccc} \ker(f) & \longrightarrow & X \\ \downarrow & & \downarrow f \\ 0 & \longrightarrow & Y \end{array}$.
- the **cokernel** of f is the fiber pushforward $\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow & & \downarrow \\ 0 & \longrightarrow & \mathrm{Coker}(f) \end{array}$.
- the **image** of f is the cokernel of the kernel.
- the **coimage** of f is the kernel of the cokernel.

Cor. (3.7.1.7). If they exist, then kernel and coimage are monomorphisms, and cokernel and image are epimorphisms, by general non-sense.

Prop. (3.7.1.8). If the image and coimage of f exist, then there is a natural decomposition $f : X \to \mathrm{Im}(f) \to \mathrm{Coim}(f) \to Y$, by the universal property.

Def. (3.7.1.9) [Exact Sequence]. A diagram $X \xrightarrow{f} Y \xrightarrow{g} Z$ is an **exact sequence** if f is the kernel of g and g is the cokernel of f.

Additive Categories

Def. (3.7.1.10) [Additive Categories]. A preadditive category $\mathcal{A}$ is called an **additive category** iff moreover it satisfies

- **A2**:There exists an element that is both initial and final, called the **zero element**.
- **A3**: $\mathcal{A}$ admits finite sums and finite products, and they are equal. Also, the sum induce the Abelian structure of $\mathrm{Hom}(X, Y)$.

Prop. (3.7.1.11) [Characterizing Direct Sum Decompositions]. If $\mathcal{A}$ is a preadditive category with zero object, $x, y, z \in \mathcal{A}$, then z is the product and sum of x, y in $\mathcal{A}$ iff there are four morphism that satisfies some identities.

Proof: Cf.[Sta]0102. □

Cor. (3.7.1.12). An additive functor between additive categories transforms finite direct sums to direct sums.

Def. (3.7.1.13)[Kernel of an Additive Functor]. The kernel of an additive functor between additive categories is is the full subcategory of objects that are mapped to 0.

Def. (3.7.1.14) [Compact Object]. Let $\mathcal{D}$ be an additive category with arbitrary direct sums, then a **compact object** $K \in \mathcal{D}$ is an object that

$$\bigoplus_i \mathrm{Hom}(K, E_i) \to \mathrm{Hom}(K, \bigoplus_i E_i)$$

is bijective for any set I and objects $E_i \in \mathcal{D}$.

Karoubian Categories

Def. (3.7.1.15) [Karoubian Categories]. A **Karoubian category** is an additive category $\mathcal{C}$ that satisfies the following equivalent conditions:

- Every idempotented endomorphism of an object of $\mathcal{C}$ has a kernel.
- Every idempotented endomorphism of an object of $\mathcal{C}$ has a cokernel.
- Every idempotented endomorphism $p : z \to z$ induces a direct sum decomposition $z = x \oplus y$(exists by A3) that p corresponds to the projection $z \to x$.

Proof: $1 \to 3$: Let $p : z \to z$ be an idempotent, let $x = \ker(p), y = \ker(1 - p)$, then there are maps $x \to z, y \to z$. Then $p : z \to z$ factors through $z \to y \to z$. Similarly $(1 - p) : z \to z$ factors through $z \to x \to z$. Then it can be verified that $z = x \oplus y$ is a direct sum decomposition(3.7.1.11).

$2 \to 3$ is dual.

$3 \to 1, 3 \to 2$ are easy by(3.7.1.11). □

Prop. (3.7.1.16). Let $\mathcal{D}$ be a preadditive category,

- if $\mathcal{D}$ has countable products and kernels of morphisms that have a right inverse, then $\mathcal{D}$ is Karoubian.
- Dually, if $\mathcal{D}$ has countable coproducts and cokernels of morphisms that have a left inverse, then $\mathcal{D}$ is Karoubian.

Proof: Given any idempotented morphism $e : X \to X$, e has a kernel iff $W \mapsto \ker(\mathrm{Mor}(M,X) \xrightarrow{e} \mathrm{Mor}(M,X))$ is representable. Notice that for any Abelian group A,

$$\ker(e : A \to A) = \ker(\Phi : \prod_{\mathbb{Z}} A \to \prod_{\mathbb{Z}} A)$$

where

$$\Phi(a_1, a_2, \ldots) = (ea_1 + (1-e)a_2, ea_2 + (1-e)a_3, \ldots)$$

and it has a right inverse

$$\Psi(a_1, a_2, \ldots) = (a_1, (1-e)a_1 + ea_2, (1-e)a_2 + ea_3, \ldots)$$

thus the kernel exists. □

2 Exact Categories

Main references are [Exact categories, Theo].

Def. (3.7.2.1) [Exact Categories]. Let $\mathcal{C}$ be an small additive category and $\mathcal{E}$ be a set of short sequences

$$0 \to X \to Y \to Z \to 0$$

in $\mathcal{C}$. If $0 \to X \xrightarrow{\varphi} Y \xrightarrow{\psi} Z \to 0$ is in $\mathcal{E}$, then we call φ an **admissible monomorphism** and ψ an **admissible epimorphism**. then $(\mathcal{C}, \mathcal{E})$ is called an **exact category** if it satisfies:

- **Ex1**: For any complex $0 \to X \xrightarrow{\varphi} Y \xrightarrow{\psi} Z \to 0$, φ is the kernel of ψ and ψ is the cokernel of φ.
- **Ex2**: For any $X, Y \in \mathcal{C}$, $0 \to X \to X \times Y \to Y \to 0$ is in $\mathcal{E}$.
- **Ex3**: $\mathcal{E}$ is saturated in the category of short sequences.
- **Ex4**: if f, g are admissible monomorphisms, then so is gf.
- **Ex5**: If f is an admissible monomorphism, then any pushout of f exists and is an admissible monomorphism.
- **Ex6**: If g is an admissible epimorphism, then any pullback of g exists and is an admissible epimorphism.

Cor. (3.7.2.2). If $\mathcal{C}$ is an Abelian category and $\mathcal{E}$ the set of all exact sequences in $\mathcal{C}$, then $(\mathcal{C}, \mathcal{E})$ is an exact category.

Cor. (3.7.2.3). If $(\mathcal{C}, \mathcal{E})$ is an exact category, then

- **Ex7**: if $f : X \to Y \in \mathcal{C}$ is a morphism having a kernel and there is a morphism $g : Z \to X$ that fg is an admissible monomorphism, then so is f. Dual argument holds for admissible epimorphisms.

Proof: Cf.[Bernhard Keller, Chain complexes and stable categories, P28].? □

Def. (3.7.2.4) [Geometric Exact Categories]. A **geometric exact category** consists of an exact category $(\mathcal{C}, \mathcal{E})$ and a mapping A from $\mathrm{Ob}(\mathcal{C})$ to $\mathcal{S}\mathrm{et}$ together with morphisms:

- a morphism $f^* : A(X) \to A(Y)$ for any admissible monomorphism $f : X \to Y$.
- a morphism $g_* : A(X) \to A(Z)$ for any admissible epimorphism $g : X \to Z$.

that satisfies the following axioms:

- **A1**: $A(0) = \text{pt}$.
- **A2**: If i, j are admissible monomorphisms, then $(ji)^* = i^* j^*$.
- **A3**: If p, q are admissible epimorphisms, then $(qp)_* = q_* p_*$.
- **A4**: $\text{id}_X^* = (\text{id}_X)_* = \text{id}_{A(X)}$.
- **A5**: If $f : X \to Y$ is an isomorphism, then $f^* f_* = f_* f^* = \text{id}$.
- **A6**: For any Cartesian and Cocartesian diagram $\begin{array}{ccc} X & \xrightarrow{u} & Y \\ \downarrow p & & \downarrow q \\ Z & \xrightarrow{v} & W \end{array}$, if u is admissible monomorphism or q is admissible epimorphism, then $v^* q_* = p_* u^*$.
- **A7**: If $X \xrightarrow{u} Y \xrightarrow{v} Z$ is a diagram in $\mathcal{C}$ that u is an admissible epimorphism and v is an admissible monomorphism, and if $h_X \in A(X), h_Z \in A(Z)$ satisfy $u_*(h_X) = v^*(h_Z)$, then there exists $h \in A(X \oplus Z)$ that $(\text{id}, vu)^*(h) = h_X$ and $\pi_{2*}(h) = h_Z$. (Notice (id, vu) is an admissible monomorphism because it is composition of $X \to X \oplus Z$ with the isomorphism $(\pi_1, vu\pi_1 + \pi_2) : X \oplus Z \to X \oplus Z$.

For any $X \in \mathcal{C}$, an element of $A(X)$ is called a **geometric structure** on X.

Exact categories can be viewed as geometric exact categories by asserting $A(X) = \text{pt}$ for all $X \in \mathcal{C}$.

Def. (3.7.2.5) [Morphisms compatible with the Geometric Structure]. Let $(\mathcal{C}, \mathcal{E}, A)$ be a geometric exact category, if $(X', h'), (X'', h'')$ are two geometric objects, then a morphism $f : X' \to X''$ is said to be a **morphism compatible with the geometric structure** if there exists a geometric object (X, h) and an admissible monomorphisms $u : X' \to X$ and an admissible epimorphism $v : X \to X''$ that $h' = u^*(h)$ and $h'' = v_*(h)$ and $f = vu$.

The composition of two morphisms compatible with the geometric structure is also a morphism compatible with the geometric structure.

We denote $\mathcal{C}_A$ the category of geometric objects of $\mathcal{C}$, and $\mathcal{E}_A$ the set of diagrams of geometric objects $0 \to X' \xrightarrow{u} X \xrightarrow{v} X'' \to 0$ that the underlying diagram is in $\mathcal{E}$ and u, v are compatible with the geometric structures.

Prop. (3.7.2.6) [Hermitian Spaces]. The f.d. Hermitian spaces over $\mathbb{C}$ or f.d. normed vector spaces over $\mathbb{R}$ form a geometric exact category.

Proof: Cf.[Harder-Narasimhan Categories, P4]. □

Prop. (3.7.2.7) [F.D. Ultranormed Banach Spaces]. Let K be a complete valued field, then the category of f.d. ultranormed Banach spaces over K(12.2.4.5) is a geometric exact category.

Proof: It suffices to check axiom A7, but vu has norm≤ 1, and for any $\varphi : E \to F$ of norm≤ 1, we can endow $E \oplus F$ with the maximum norm, then in the decomposition $E \xrightarrow{(\text{id}, \varphi)} E \oplus F \xrightarrow{\pi_2} F$, we have $(\text{id}, \varphi)^*(h) = h_E$ and $(\pi_2)_*(h) = h_F$. □

Prop. (3.7.2.8) [Filtrations in an Abelian Category]. The filtrations(3.2.3.1) in an Abelian category form a geometric exact category.

Proof: Cf.[Harder-Narasimhan Categories, P5]. □

Def. (3.7.2.9) [K_0 Group]. Let $\mathcal{A}$ be an exact category, then K_0**-group** $K_0(\mathcal{A})$ is defined to be the quotient Abelian group

$$\bigoplus_{[0\to A\to B\to C\to 0]\in\mathcal{E}}\mathbb{Z}\to\bigoplus_{A\in\mathcal{C}}\mathbb{Z}\to K_0(\mathcal{A})\to 0,$$

where $e_{0\to A\to B\to C\to 0}$ is mapped to $e_B - e_A - e_C$.

3 Abelian Categories

Def. (3.7.3.1) [Abelian Categories]. An **Abelian category** $\mathcal{A}$ is an additive category that satisfies the follows axiom:

- **A4**: $\mathcal{A}$ admits kernels and cokernels, and for any morphism $f\in\mathcal{A}$, the natural map $\mathrm{Im}(f)\to\mathrm{Coim}(f)$ are isomorphisms.

Remark (3.7.3.2). WARNING: An additive category that epimorphism+monomorphism is isomorphism need not be an Abelian category. Cf.[https://mathoverflow.net/questions/41722/is-every-balanced-pre-abelian-category-abelian] for a counter-example.

Prop. (3.7.3.3). In an Abelian category, the functor $X\mapsto \mathrm{Hom}(X,Y)$ and $X\mapsto \mathrm{Hom}(Y,X)$ is both left exact.(Note that left and right is seen on the image).

Def. (3.7.3.4) [Injectives and Surjectives]. A morphism f is an Abelian category $\mathcal{A}$ is called an **injection** if $\ker f = 0$. It is called a **surjection** if $\mathrm{Coker}\, f = 0$. f is an injection iff it is a monomorphism, it is a surjection iff it is an epimorphism.

Prop. (3.7.3.5). Axiom A3 asserts the good existence of product and sum of objects as we wanted, and it can be used to prove that monomorphism and epimorphism are stable under pushout and pullback.

But this uses $A4$ strongly, Cf.[MacLane Categories for working mathematicians P203]. (For epimorphism, first prove $0\to X\times_U Y\to X\times Y\to U\to 0$ is exact when $X\to U$ is epi).

Prop. (3.7.3.6). equalizer and finite product derives finite limit, thus finite limits and finite colimits exists in Abelian categories.

Prop. (3.7.3.7)[Mitchell's embedding theorem]. If $\mathcal{A}$ is a small Abelian category, then there exists a unital ring R, not necessary commutative and a fully faithful and exact functor $\mathcal{A}\to R-\mathrm{Mod}$ that preserves kernel and cokernel. WARNING: it may not preserve sum and product, let alone limits and colimits.

Proof: □

Prop. (3.7.3.8). If $\mathcal{C},\mathcal{A}$ are categories and $\mathcal{A}$ is Abelian, then $\mathcal{H}om(\mathcal{C},\mathcal{A})$ is an Abelian category. In particular, $\mathrm{Ch}(\mathcal{A})$ is Abelian.

Localization

Prop. (3.7.3.9) [Localization Category]. If $\mathcal{C}$ is a preadditive category and S is a left or right localizing system of $\mathcal{C}$, then there exists a natural additive structure on $\mathcal{S}^{-1}\mathcal{C}$ and a localizing functor $\mathcal{C}\to S^{-1}\mathcal{C}$ that is additive.

Proof: Cf.[Sta]05QD. □

Lemma (3.7.3.10). If $\mathcal{C}$ is additive and S is localizing, let X be an element of $\mathcal{C}$, then: $Q(X) = 0$ iff there is a morphism $0 : X \to Y$ that is an element of S iff there is a morphism $0 : Z \to X$ that is an element of S iff there is a morphism $0 : Z \to X$ that is an element of S

Proof: If such $0 : X \to Y \in S$, then it maps to isomorphisms in $S^{-1}(\mathcal{C})$ by(3.1.1.57), so $Q(X) = 0$. If $Q(X) = 0$, then the morphism $0 \to X$ is mapped to an isomorphism, so by(3.1.1.59), there are g, h that $fg = hf = 0$, so $Z \to 0 \to X \in S$. Dually for the other direction. □

Prop. (3.7.3.11) [Localized Abelian Categories]. If $\mathcal{A}$ is Abelian and S is localizing, then $S^{-1}\mathcal{A}$ is an Abelian category and $\mathcal{A} \to S^{-1}\mathcal{A}$ is exact.

Proof: By(3.1.1.57) and its dual, $\mathcal{A} \to S^{-1}\mathcal{A}$ preserves finite limits and colimits. □

Serre Subcategory

Def. (3.7.3.12) [Serre Subcategories]. A **Serre subcategory** of an Abelian category is a non-empty full subcategory $\mathcal{C}$ that if

$$A \to B \to C$$

is exact and $A, C \in \mathrm{Ob}(\mathcal{C})$, then $B \in \mathrm{Ob}(C)$.

A **weak Serre subcategory** of an Abelian category is a non-empty full subcategory $\mathcal{C}$ that if

$$A \to B \to C \to D \to E$$

is exact and $A, B, D, E \in \mathcal{C}$, then $C \in \mathcal{C}$.

Prop. (3.7.3.13).

- A Serre category is equivalent to a full subcategory $\mathcal{A}$ that contains 0, all the subobjects and quotient objects of $\mathcal{A}$, and extensions of objects of $\mathcal{A}$ are in $\mathcal{A}$.
- A weak Serre category is equivalent to a full subcategory $\mathcal{A}$ that contains 0, and all the kernels, cokernels between objects in $\mathcal{A}$, and all the extensions of objects in $\mathcal{A}$.

In these cases, $\mathcal{A}$ is an Abelian category and the functor $i : \mathcal{A} \to \mathcal{C}$ is exact.

Proof: One direction of these two are trivial, it suffices to prove the converse. For the first, $0 \to \mathrm{Im}\, A \to B \to \mathrm{Im}\, B \to 0$, so $B \in \mathcal{C}$. For the second, $0 \to \mathrm{Coker}(A \to B) \to C \to \ker(D \to E) \to 0$, so $C \in \mathcal{C}$. □

Prop. (3.7.3.14) [Quotients by Serre Subcategory]. For an exact functor F between Abelian categories, the kernel of F is a Serre subcategory. And any Serre subcategory is the kernel of an essentially surjective exact functor $Q : \mathcal{A} \to \mathcal{A}/\mathcal{C}$, and this functor satisfies the universal property that any exact functor between Abelian categories $F : \mathcal{A} \to \mathcal{C}$ that $\mathcal{C} \subset \ker(F)$ factors uniquely through $\mathcal{A}/\mathcal{C}$.

Proof: The full subcategory of $\ker(F)$ is clearly a Serre subcategory by checking the definition. Conversely, consider S =all the morphisms that has kernel and cokernel in $\mathcal{C}$, first we prove it is a localizing system(3.1.1.54).

The long exact seuqence(3.7.5.4) shows that if $f, g \in S$, then $gf \in S$. For other verifications, Cf.[Sta]02MS?.

Next we construct $\mathcal{C}/\mathcal{A}$ as $S^{-1}\mathcal{C}$. Consider which objects are mapped to 0 in $\mathcal{C}/\mathcal{A}$, use(3.7.3.10) and consider the kernel and cokernel, it is easy to see that $\ker(Q) = \mathcal{C}$. If another category $\mathcal{D}$ and $F : \mathcal{C} \to \mathcal{D}$ satisfies $\mathcal{C}$ is mapped to0, then it is clear that elements in S is mapped to isomorphism, so it factors through $\mathcal{C}/\mathcal{A}$ by universal property(3.1.1.57). □

Prop. (3.7.3.15) [K_0 Group of Serre Subcategory]. Let $\mathcal{A}$ be an Abelian category and $\mathcal{C}$ a Serre subcategory, with $\mathcal{A}/\mathcal{C} = \mathcal{B}$(3.7.3.14). Then

- The exact functors $\mathcal{C} \to \mathcal{A} \to \mathcal{B}$ induces an exact sequence

$$K_0(\mathcal{C}) \to K_0(\mathcal{A}) \to K_0(\mathcal{B}) \to 0,$$

- The kernel of $K_0(\mathcal{C}) \to K_0(\mathcal{A})$ is generated by elements of the form

$$[\ker(\psi)/\operatorname{Im}(\varphi)] - [\ker(\varphi)/\operatorname{Im}(\psi)]$$

where $\varphi, \psi : M \to M$ are pairs of maps that $\varphi \circ \psi = \psi \circ \varphi = 0$.

Proof: Cf.[Sta]02MX. □

Artinian Abelian Categories

Def. (3.7.3.16) [Artinian Abelian Categories]. An **Artinian Abelian category** is an Abelian category that

- $\operatorname{Hom}(A, B)$ are all f.d. vector spaces over k.
- Then length of any filtrations $0 = X_0 \subset X_1 \subset \ldots \subset X_l = X$ for any object X is bounded. The maximal length is called the **length** of X.

Prop. (3.7.3.17) [Jordan-Holder]. Let $\mathcal{C}$ be an Artinian category, then any maximal length filtration of an element X has the same length, and the set of quotients X_{k+1}/X_k is the same, up to order.

Proof: □

Others

Def. (3.7.3.18) [Essential Morphism]. In an Abelian category, an injection $A \to B$ is called **essential** iff every non-zero subobject of B intersects A. A surjection is called **essential** iff every proper subobject of A is not mapped to B.

Def. (3.7.3.19) [Noetherian Abelian Category]. In a Grothendieck Abelian category $\mathcal{A}$, an object M is called **finitely generated** if for every ascending chain

$$M_1 \subset M_2 \subset \ldots \subset M$$

with $\cup_i M_i = M$, we have $M_i = M$ for some i.

$\mathcal{A}$ is called **Noetherian** iff a subobject of a f.g. object is f.g.. $\mathcal{A}$ is called **Artinian** iff every f.g. object has finite length?.

Grothendieck Abelian Category

Main references are [Rings of Quotients]

Def. (3.7.3.20) [Grothendieck Abelian Category]. A **Grothendieck Abelian category** is an Abelian category $\mathcal{A}$ satisfying the following axioms:

AB3: It is a locally small cocomplete Abelian category.

AB5: Small filtered colimits are exact. This is equivalent to { for any family of subobjects $\{A_i\}$ of A to B indexed by inclusion can induce a morphism $\sum A_i \to B$ (internal sum)}?

GEN: It has a **generator**, which is an object $U \in \mathcal{A}$ s.t. for any proper subobject $N \subsetneq M$, there is a map $U \to M$ that doesn't factor through N.

Def. (3.7.3.21) [Further Grothendieck Axioms]. For a Grothendieck Abelian category $\mathcal{A}$, we can also formulate the following axioms:

AB4: Arbitrary direct sums are exact.

AB6: For any index set J and filtered categories $I_j, j \in J$ and diagrams indexed over I_j, the natural map

$$\varinjlim_{i_j \in I_j} \prod_{j \in J} M_{i_j} \to \prod_{j \in J} \varinjlim_{i_j \in I_j} M_{i_j}$$

is an isomorphism.

Dual Axioms: Axioms with an * meaning that the dual category satisfies something.

Prop. (3.7.3.22). If $\mathcal{A}$ is a Grothendieck Abelian category, then so is $\mathcal{PSh}^{\mathcal{Set}}(\mathcal{A})$.

Proof: For the presheaf, the only problem is the existence of generator, for that, just construct a family of presheaves and sum them. Take $Z_X = i_{f_X}(U)$, where U is the generator of $\mathcal{A}$ and $f = \mathrm{pt} \to \mathcal{A}^C : \mathrm{pt} \to U$. Then $F(X) = \mathrm{Hom}(Z_X, F)$ by adjointness(5.1.2.9). So they are a family of generators. □

Prop. (3.7.3.23). Any Grothendieck Abelian category has a functorial injective embedding.

Proof: Cf.[Sta]079H.**?** □

Prop. (3.7.3.24) [Representability on Grothendieck Category]. A contravariant functor from a Grothendieck category to $\mathcal{Set}$ is representable iff it takes colimits to limits.

Proof: $M \oplus M \to M$ with induce a map $F(M) \times F(M) \to F(M)$ thus $F(M)$ is a semigroup, and the inverse of id_Min $\mathrm{Hom}(M, M)$ maps to a $F(M) \to F(M)$ which is the inverse, Thus in fact F is a left adjoint functor to $\mathcal{Ab}$.

Let U be a generator, $A = \sum_{s \in F(U)} U$, let $s_{univ} = (s) \in F(A) = \prod_{s \in F(U)} F(U)$. let A' be the largest objects that s_{univ} restrics to 0 in A', let $\overline{s}_{univ}$ be in $F(A/A')$ that maps to s_{univ} in $F(A)$ (because F is left exact). Then we claim $(A/A', \overline{s}_{univ})$ represents F. Cf.[Sta]07D7.**?** □

Cor. (3.7.3.25) [Grothendieck Categories are Cocomplete]. Any Grothendieck category satisfies AB3*.

Proof: It suffices to show that small direct products exist. And this is because $F = \prod_i \mathrm{Hom}(-, M_i)$ commutes with colimits. □

Prop. (3.7.3.26) [Grothendieck Categories are Locally Presentable]. Any Grothendieck category is locally presentable. In fact, for an Abelian category with exact filtered colimits, it is a Grothendieck Abelian category iff it is locally presentable.

Proof: Cf.[Colimits and homological algebra, Krause]Cor5.2.**?** □

Cor. (3.7.3.27). If $F : \mathcal{C}^{\mathrm{op}} \to \mathcal{Set}$ commutes with small colimits, then F is a left adjoint.

Proof: **?** □

Examples of Grothendieck Category

Prop. (3.7.3.28) [Modules]. For $R \in \mathcal{A}\mathrm{lg}$, $\mathcal{M}\mathrm{od}_R$ is a Grothendieck Abelian category. More generally, for $R, S \in \mathcal{A}\mathrm{lg}$, $\mathcal{M}\mathrm{od}_{R-S} = \mathcal{M}\mathrm{od}_{R\otimes S^{op}}$ is a Grothendieck Abelian category.

Proof: This is clear, by(4.1.1.24). □

Prop. (3.7.3.29) [Sheaf of Modules]. $\mathcal{S}\mathrm{h}(\mathcal{O})$ for a ringed site $(\mathcal{C}, \mathcal{O})$ is a Grothendieck Abelian category.

Proof: It is obviously an Abelian category and have filtered colimits as presheaves, which are exact because colimits in the category of Abelian groups are exact, and for a family of generators, take $j_!\mathcal{O}_U$ as the representative for $\Gamma(U, -)$, which is the sheaf associated to the sheaf Z_U in the proof of(3.7.3.22). □

Cor. (3.7.3.30). Let $\mathcal{C}$ be a site, the categories $\mathcal{PS}\mathrm{h}(\mathcal{C})$ and $\mathcal{S}\mathrm{h}(\mathcal{C})$ are Grothendieck Abelian categories.

Proof: For the presheaf, C.f(3.7.3.22). For the sheaf, it follows from (3.7.3.29). □

Remark (3.7.3.31). The category of Abelian sheaves doesn't satisfy AB4*, i.e. not every limit of epimorphisms is epimorphism.

Proof: Consider the constant sheaf $\prod_{\frac{p}{q}\in[0,1]} B(\frac{p}{q}, \frac{1}{q})$ on $[0, 1]$. □

Prop. (3.7.3.32) [Quasi-Coherent Sheaves]. For $X \in \mathcal{S}\mathrm{ch}$, $\mathcal{QC}\mathrm{oh}(X)$ is Grothendieck category, and there is a **coherentor** left adjoint to the forgetful functor.

Proof: Firstly by(5.5.1.3), $\mathcal{QC}\mathrm{oh}(X)$ is an Abelian category, and on affine open set, the colimit is an Qco sheaf, thus the colimit exists in Qco and equals the colimit in the category of sheaves, thus filtered colimits is exact because $\mathcal{M}\mathrm{od}(\mathcal{O}_X)$ is Grothendieck(3.7.3.29). The generator exists, Cf.[Sta]077P.

The coherentor exists by the fact that $h_{\mathcal{F}}$ commutes with colimits and by the property of Grothendieck category(3.7.3.24). □

4 Chain Complexes

Def. (3.7.4.1) [Chain Complex]. A **chain complex** over an additive category $\mathcal{A}$ is**?**. The category of complexes over $\mathcal{A}$ is denoted by $\mathrm{Ch}^{\mathbb{Z}}(\mathcal{A})$.

Prop. (3.7.4.2). For any Abelian category $\mathcal{A}$, $\mathrm{Ch}^{\mathbb{Z}}(\mathcal{A})$ is an Abelian category.

Prop. (3.7.4.3). The natural inclusion $\mathcal{A} \subset \mathrm{Ch}^{\mathbb{Z}}(A)$ embeds $\mathcal{A}$ as a full subcategory of $\mathrm{Ch}^{\mathbb{Z}}(A)$, and H^0 is just the left adjoint.

An object $K \in \mathrm{Ch}^{\mathbb{Z}}(A)$ is called **discrete** if it is in the essential image of this embedding.

Def. (3.7.4.4) [Shifting of Complexes]. Remember the translation operator $K[n]$ makes the complex lower n dimensions.

Def. (3.7.4.5) [Truncation of Complexes]. Let $\mathcal{A}$ be an Abelian category and $A^\bullet \subset \mathrm{Ch}^{\mathbb{Z}}(\mathcal{A})$, there are several ways to truncate $A^\bullet$:

- The **stupid truncation** $\sigma_{\leq n}A = \ldots \to A_{n-1} \to A_n \to 0 \to \ldots$. There is a morphism $A \to \sigma_{\leq n}A$.

- The stupid truncation $\sigma_{\geq n}A = \ldots \to 0 \to A_n \to A_{n+1} \to \ldots$. There is a morphism $\sigma_{\geq n}A \to A$.
- The **canonical truncation** $\tau_{\leq n}A = \ldots \to A_{n-1} \to \ker(d_n) \to 0 \to \ldots$. There is a natural morphism $\tau_{\leq n}A \to A$ that induces isomorphism on cohomology groups on degree$\leq n$.
- The canonical truncation $\tau_{\geq n}A = \ldots \to 0 \to \mathrm{Coker}(d_{n-1}) \to A_{n+1} \to \ldots$. There is a natural morphism $A \to \tau_{\geq n}A$ that induces isomorphism on cohomology groups on degree$\geq n$.

Cor. (3.7.4.6). There are exact sequences of complexes

$$0 \to \tau_{\leq n}A^\bullet \to A^\bullet \to \tau_{\geq n+1}A^\bullet \to 0$$

$$0 \to \sigma_{\geq n+1}A^\bullet \to A^\bullet \to \sigma_{\leq n}A^\bullet \to 0$$

Def. (3.7.4.7) [Cone & Cylinder]. The **mapping cone** of $f : K^\bullet \to L^\bullet$ is the complex $C(f)^\bullet$ that:

$$C(f) = K[1]^\bullet \oplus L^\bullet, \quad d(k^{i+1}, l^i) = (-d_K k^{i+1}, f(k^{i+1}) + d_L l^i)$$

The **mapping cylinder** of $f : K^\bullet \to L^\bullet$ is the complex $\mathrm{Cyl}(f)$ that:

$$\mathrm{Cyl}(f) = K^\bullet \oplus K[1]^\bullet \oplus L^\bullet, \quad d(k^i, k^{i+1}, l^i) = (d_K k^i - k^{i+1}, -d_K k^{i+1}, f(k^{i+1}) + d_L l^i)$$

It is a shame I haven't see clearly the similarity of this with the topological cone and cylinder, should study it further.

Def. (3.7.4.8) [Double Complexes]. A **double complex** over an Abelian category is a complex over $Comp(\mathcal{A})$(3.7.4.2).

Def. (3.7.4.9) [Totalization]. Given a double complex $K^{\bullet,\bullet}$ over an Abelian category $\mathcal{A}$, the associated **total complexes** is defined to be

$$(\mathrm{Tot}^\Pi(K))^n = \prod_{n=p+q} K^{p,q}, \quad d^n = \prod_{n=p+q} (d_1^{p,q} + (-1)^p d_2^{p,q})$$

$$(\mathrm{Tot}^\oplus(K))^n = \bigoplus_{n=p+q} K^{p,q}, \quad d^n = \sum_{n=p+q} (d_1^{p,q} + (-1)^p d_2^{p,q})$$

Def. (3.7.4.10) [Hom Complexes]. Let $\mathcal{A}$ be an Abelian category and $P^\bullet, Q^\bullet \in K(\mathcal{A})$, we define **Hom complex** $\mathrm{Hom}^\bullet(P^\bullet, Q^\bullet)$ to be

$$\mathrm{Hom}^n(P^\bullet, Q^\bullet) = \prod \mathrm{Hom}_i(P^i, Q^{n+i}),$$

with the differential giving by $d(\{f_k\})_i = \{df_i - (-1)^i f_{i+1} d\}$ and suitable signatures.

It is clear that $H^n(\mathrm{Hom}^\bullet(P^\bullet, Q^\bullet)) = \mathrm{Hom}_{K(\mathcal{A})}(P^\bullet, Q^\bullet[n])$.

Homotopy Category $K(\mathcal{A})$

Def. (3.7.4.11) [Homotopies of Complexes].

Def. (3.7.4.12) [$K(\mathcal{A})$]. Let $\mathcal{A}$ be an additive category, the **homotopy category of complexes** $K(\mathcal{A})$ is the category whose objects are complexes in $\mathcal{A}$ and whose morphisms are homotopy classes of morphism between complexes.

Prop. (3.7.4.13) [Distinguished Triangle of $K^*(\mathcal{A})$]. For any morphism $K^\bullet \to L^\bullet$, there exists a termwise-spliting exact sequence of Complexes commuting in $K(\mathcal{A})$.

$$\begin{array}{ccccccccc} & & K^\bullet & \longrightarrow & L^\bullet & & & & \\ & & \| & & \downarrow \alpha & & & & \\ 0 & \longrightarrow & K^\bullet & \longrightarrow & \mathrm{Cyl}(f) & \longrightarrow & C(f) & \longrightarrow & 0 \\ & & & & \downarrow \beta & & \| & & \\ & & 0 & \longrightarrow & L^\bullet & \longrightarrow & C(f) & \longrightarrow & K^\bullet[1] \longrightarrow 0 \end{array}$$

where $\beta\alpha = \mathrm{id}$ and $\alpha\beta \sim \mathrm{id}$. And $K^\bullet \to L^\bullet \to C(f) \to K^\bullet[1]$ is called a distinguished triangle. Any exact triple of complexes in $\mathrm{Kom}(\mathcal{A})$ is quasi-isomorphic to a distinguished triangle. In fact, we can define the distinguished triangle in $K(\mathcal{A})$ as that induced by a split exact sequence, Cf.[Sta]014L.

Notice all this can imitate the similar parallel construction in the category of topological spaces.

Proof: Cf.[Gelfand P157] □

Cor. (3.7.4.14) [Long Exact Sequences]. A distinguished triangle will induce a long exact sequence of cohomology groups, for this, just need to verify that the δ-homomorphism and the morphism $C(f) \to K^\bullet[1]$ induce the same map of cohomology groups.

Cor. (3.7.4.15). A morphism of complexes $f : K^\bullet \to L^\bullet$ is quasi-iso iff $C(f)$ is acyclic. It is homotopic to 0 iff f can be extended to a morphism $C(f) \to L$.

Prop. (3.7.4.16) [$K(\mathcal{A})$ is Triangulated]. If $\mathcal{A}$ is an additive category, then $K(\mathcal{A})$ is a triangulated category, with shifting functors defined in(3.7.4.4) and distinguished triangles defined in(3.7.4.13).

Proof: Cf.[Sta]014S. □

Prop. (3.7.4.17). An additive functor $F : \mathcal{A} \to \mathcal{B}$ between additive categories induces an exact functor $K(\mathcal{A}) \to K(\mathcal{B})$. Moreover, this functor maps quasi-isomorphisms to quasi-isomorphisms(3.7.5.1).

Proof: Cf.[Sta]014X. □

Def. (3.7.4.18) [Bounded Subcategories].

Prop. (3.7.4.19). Let $\mathcal{A}$ be an Abelian category,

- If $A^\bullet \subset K^+(\mathcal{A})$, then $\tau_{\leq n}(A^\bullet) \to A^\bullet$ is a quasi-isomorphism for n sufficiently large.
- If $A^\bullet \subset K^-(\mathcal{A})$, then $A^\bullet \to \tau_{\geq n}A^\bullet$ is a quasi-isomorphism for n sufficiently small.

Unbounded Complexes

Lemma (3.7.4.20) [Left Resolutions of Unbounded Complexes]. Let $\mathcal{A}$ be an Abelian category and $\mathcal{P}$ be a subset of objects of $\mathcal{A}$. Assume that every object of $\mathcal{A}$ is a quotient of an object of $\mathcal{P}$, then for any complex $\mathcal{K}^\bullet$, there exists a commutative diagram

$$\begin{array}{ccccc} P_1^\bullet & \longrightarrow & P_2^\bullet & \longrightarrow & \dots \\ \downarrow & & \downarrow & & \\ \tau_{\leq 1}K^\bullet & \longrightarrow & \tau_{\leq 2}K^\bullet & \longrightarrow & \dots \end{array}.$$

where the vertical arrows are quasi-isomorphisms, and each $P_n^\bullet$ is a bounded above complex with terms in $\mathcal{P}$, and each $P_n^\bullet \to P_{n+1}^\bullet$ are termwise-split injections and the cokernel is also a complex with terms in $\mathcal{P}$.

Proof: Cf.[Sta]06XX. □

5 Cohomology of Complexes

Def. (3.7.5.1) [Quasi-irosmoepwhiss].

Prop. (3.7.5.2) [Five lemma]. In an Abelian category, if there is a diagram

$$\begin{array}{ccccccccc} * & \longrightarrow & * & \longrightarrow & * & \longrightarrow & * & \longrightarrow & * \\ \downarrow{\scriptstyle s} & & \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle h} & & \downarrow{\scriptstyle i} \\ * & \longrightarrow & * & \longrightarrow & * & \longrightarrow & * & \longrightarrow & * \end{array}$$

Where the rows are exact and g, h are isomorphisms. If i is injective, then f is surjective; if s is surjective, then f is injective.

Proof: Rotate the diagram counterclockwise 90°. Then use the two different filtration both converge(3.9.7.8). □

Prop. (3.7.5.3) [Snake lemma]. In an Abelian category, if there is a diagram

$$\begin{array}{ccccccc} & & * & \xrightarrow{i} & * & \longrightarrow & * & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle h} & & \\ 0 & \longrightarrow & * & \longrightarrow & * & \xrightarrow{s} & * & & \end{array}$$

where the rows are exact, then there is a long exact sequence

$$\ker f \to \ker g \to \ker h \to \operatorname{Coker} f \to \operatorname{Coker} g \to \operatorname{Coker} h$$

And if i is injective, then the first one is injective; if s is surjective, then the last one is surjective.

Proof: Rotate the diagram counterclockwise 90°. Then use the two different filtration both converge(3.9.7.8). □

Cor. (3.7.5.4). In an Abelian category, if $f : A \to B, g : B \to C$, then there is a long exact sequence:

$$0 \to \ker f \to \ker gf \to \ker g \to \operatorname{Coker} f \to \operatorname{Coker} gf \to \operatorname{Coker} g \to 0.$$

Proof: Use snake lemma(as modules), there is a diagrams:

$$\begin{array}{ccccccc} & & A & \xrightarrow{f} & B & \longrightarrow & \operatorname{Coker} f & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle gf} & & \downarrow{\scriptstyle g} & & \downarrow & & \\ 0 & \longrightarrow & C & = & C & \longrightarrow & 0 & & \end{array}$$

So by Snake lemma,

$$\ker gf \to \ker g \to \operatorname{Coker} f \to \operatorname{Coker} gf \to \operatorname{Coker} g \to 0.$$

As Abelian category is dual, we can do this dually to get:

$$0 \to \ker f \to \ker gf \to \ker g \to \operatorname{Coker} f \to \operatorname{Coker} gf.$$

They splint together to get the desired long exact sequence. □

Prop. (3.7.5.5). For a 3×3 diagram of complexes, the connection homomorphism satisfies an anti-commutative diagram:

$$\begin{array}{ccc} H^{q-1}(Z'') & \xrightarrow{\delta} & H^q(X'') \\ \downarrow{\delta} & & \downarrow{-\delta} \\ H^q(Z) & \xrightarrow{\delta} & H^{q+1}(X) \end{array}$$

by(3.7.7.15) as the category $K(\mathcal{A})$ is triangulated.

Prop. (3.7.5.6) [Universal Coefficient Theorem]. Should be somewhere in [Weibel].

Def. (3.7.5.7) [Herbrand Quotient]. For a complex of R-modules cyclic of order 2, we define the **additive Herbrand quotient** as $\mathrm{length}_R(H^0) - \mathrm{length}_R(H^1)$, when both are definable and the **multiplicative Herbrand quotient** as $|H^0|/|H^1|$ when they are both finite.

Prop. (3.7.5.8). For an exact sequence $0 \to M \to N \to K \to$ of complexes of cyclic order 2, we have $h(N) = h(M) + h(K)$ and $h^*(N) = h^*(M)h^*(K)$ in the sense that if two of them are definable, then so is the third. This is an easy consequence of long exact sequence.

Prop. (3.7.5.9). If each term of this complex has finite length, then $h(M) = 0$. If each term is finite, then $h^*(M) = 0$. This is an consequence of isomorphism theorem. So we have, if a morphism of complexes has kernel and cokernel finite, then it induce an isomorphism on h or h^*.

Proof: □

6 Injectives & Projectives

Remark (3.7.6.1). The use of injection resolutions can be replaced by the use of ∞-categories.**??**

Def. (3.7.6.2) [Injective Objects]. An **injective object** in a Abelian category is a I s.t. $\mathrm{Hom}(-, I)$ is an exact functor, equivalently, maps to I can be extended along injections.

A **projective object** in a Abelian category is a I s.t. $\mathrm{Hom}(I, -)$ is an exact functor, equivalently, maps to I can be pulled back along surjections.

Prop. (3.7.6.3). Product of injective elements are injective, sums of projective elements are projective.

Prop. (3.7.6.4). In an Abelian category, the direct summand of a projective object is projective. (The summand has definition in an Abelian category).

Prop. (3.7.6.5). If a functor f between Abelian categories is left adjoint to an exact functor, then it preserves injectives. Dually for projectives.

Prop. (3.7.6.6). If A is an Abelian category, the chain complex category $Ch(A)$ is abelian by(3.7.3.8). A chain complex P is projective iff it is a split exact complex of projective objects. The same is true by dual argument for injectives.

Proof: If K is projective, use the surjection $C(\mathrm{id}_K) \to K[1]$, there is a homotopy between id_K and 0. Thus we have $x = dhx + hdx$. And if $dhx = hdy$, then $dhdy = 0$, thus $dy = 0$, so $K = dhK \oplus hdK$ and thus $K[n] = B_n \oplus B_{n+1}$. Thus K is a direct product of $0 \to B \to B \to 0$. And this one is projective if B is projective. □

Prop. (3.7.6.7) [Check Injectives]. In a Grothendieck Abelian category with generator U, an object is injective iff it is extendable over subobjects of U. (AB5 assures we can extend by Zorn's lemma. Then use GEN, Cf.[Sta]079G**?**). If it is a family of objects, it suffice to extend over each one of them.

Proof: □

Injective Resolutions

Prop. (3.7.6.8) [Horseshoe Lemma]. For a exact sequence $0 \to X_1 \to X \to X_2 \to 0$ and a injective resolution of X_1 and X_2, there is a injective resolution of X commuting with them. (Choose them one-by-one, in fact, $I_n = I_n^1 \oplus I_n^2$ using the injectivity of I_n^1. Snake lemma told us that the cokernel is an exact sequence, use that to define the next one.

Prop. (3.7.6.9). For two lifting of morphisms $X_1 \to Y_1$ and $X_2 \to Y_2$, there is a lifting of the morphism $X \to Y$ compatible with that. Cf.[Weibel P2.4.6].

Prop. (3.7.6.10)[Cartan-Eilenberg Resolution]. For a complex $K \in K^+(\mathcal{A})$, a **Cartan-Eilenberg resolution** of K consists of a 2-complex $I^{\bullet,\bullet}$ and a map of complexes $K \to I^{\bullet,0}$ that the induced complexes:

$$0 \to K^i \to I^{i,0} \to I^{i,2} \to \dots$$

$$0 \to B^i(K) \to B^i_x(I^{\bullet,0}) \to B^i_x(I^{\bullet,1}) \to \dots$$

$$0 \to Z^i(K) \to Z^i_x(I^{\bullet,0}) \to Z^i_x(I^{\bullet,1}) \to \dots$$

$$0 \to H^i(K) \to B^i_x(I^{\bullet,0}) \to H^i_x(I^{\bullet,1}) \to \dots$$

are all injective resolutions, and the exact sequences

$$0 \to B^i_x(I^{\bullet,j}) \to Z^i_x(I^{\bullet,j}) \to H^i_x(I^{\bullet,j}) \to 0$$

$$0 \to Z^i_x(I^{\bullet,j}) \to I^{\bullet,j} \to Z^i_x(I^{\bullet,j}) \to 0$$

split.

Then if $\mathcal{I}_{\mathcal{B}}$ is sufficiently large, for any K in $K(\mathcal{B})$ there is a Cartan-Eilenberg resolution.

Proof: Cf.[Gelfand P210],[Weibel P146].**?** □

Cor. (3.7.6.11). For a CE resolution of a complex $K \in K^+(\mathcal{B})$, the spectral sequence can be applied and shows $K \to \mathrm{Tot}(L)$ is a quasi-isomorphism, i.e. Tot(L) is a injective resolution of K.

Cor. (3.7.6.12) [Functoriality of Cartan-Eilenberg Resolution]. If $f : A \to B$ is a chain map and $A \to P, B \to Q$ are Cartan-Eilenberg resolutions, then there is a double complex map $\widetilde{f} : P \to Q$ extending f. And if f is homotopic to g, then $\widetilde{f}$ is homotopic to $\widetilde{g}$. In other words, we have a functor $K(\mathcal{A}) \to K(\mathcal{I}_{\mathcal{A}}^{\bullet\bullet})$

In particular, for any two Cartan-Eilenberg resolutions P, Q of A and an additive functor F, the chain complex $\mathrm{Tot}^{\Pi}(F(P))$ and $\mathrm{Tot}^{\Pi}(F(Q))$ are chain homotopy equivalent.

Def. (3.7.6.13)[Injective Amplitude]. Let $\mathcal{A}$ be an Abelian category with sufficiently injectives, then $K \in D(A)$ is said to have **finite injective dimension** if $K \subset D^b(\mathcal{I}_A)$. It is saied to have **injective amplitude** in $[a, b]$ iff $K \subset D^{[a,b]}(\mathcal{I}_A)$.

Prop. (3.7.6.14). Suppose $\mathcal{A}^\bullet \to \mathcal{I}^\bullet$ is an injective resolution of sheaves on $(\mathcal{C}, \mathcal{O})$, then the induced map of presheaves with values in $D_\infty(\mathbb{Z})$:

$$|\mathcal{A}^\bullet| \to |\mathcal{I}^\bullet|$$

identifies $|\mathcal{I}^\bullet|$ with the shifification of $|\mathcal{A}^\bullet|$.

Proof: **?** $\square$

7 Triangulated Categories

Def. (3.7.7.1)[Triangulated Categories]. A **triangulated category** is an additive category $\mathcal{D}$ with an additive automorphism T denoted by $X \mapsto X[1]$ and a set of distinguished triangles $\mathrm{Tri}(\mathcal{D})$ that is stable under isomorphism, and satisfying the following axioms:

(TR1): $X \xrightarrow{\mathrm{id}} X \to 0 \to X[1] \in \mathrm{Tri}(\mathcal{D})$. Any morphism $X \xrightarrow{u} Y$ can be completed to some $X \xrightarrow{u} Y \to C(u) \to X[1] \in \mathrm{Tri}(\mathcal{D})$.

(TR2): $X \to Y \to Z \to X[1] \in \mathrm{Tri}(\mathcal{D})$ iff $Y \to Z \to X[1] \to Y[1] \in \mathrm{Tri}(\mathcal{D})$.

(TR3): Any two consecutive morphisms of two distinguished triangles can be extended to a morphism of distinguished triangles.

(TR4): If $X \xrightarrow{f} Y \xrightarrow{g} Z$ are morphisms, then there are maps $C(f) \to C(gf)$, $C(gf) \to C(g)$ by TR3, Then $C(f) \to C(gf) \to C(gf) \to C(g) \to C(f)[1]$ is distinguished.

A **triangulated subcategory** is an additive subcategory $\mathcal{D}'$ stable under $[1]$ and $[-1]$ together with a subclass of triangles in $\mathcal{D}'$ that forms a triangulated category.

Def. (3.7.7.2) [Notations]. We use the tuple (X, Y, Z, f, g, h) to represent a distinguished triangle $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$.

Prop. (3.7.7.3). Given $(X, Y, Z, f, g, h), (X', Y', Z', f', g', h')$, they are both in $\mathrm{Tri}(\mathcal{D})$ iff $(X \oplus X', Y \oplus Y', Z \oplus Z', f \oplus f', g \oplus g', h \oplus h')$ is in $\mathrm{Tri}(\mathcal{D})$.

Proof: [Sta]05QS. $\square$

Cor. (3.7.7.4). $(X, X \oplus Y, Y, (1, 0), (0, 1), 0)$ is a distinguished triangle.

Prop. (3.7.7.5). There is a natural notation of a product of triangulated categories.

Def. (3.7.7.6) [Exact Functors]. A functor from a triangulated category to an Abelian category is called **(co)homological** iff it maps a distinguished triangle to a long exact sequence.

Conversely, a **δ-functor** is a functor from an Abelian category to a triangulated category together with a map from the category of exact sequences to the category of distinguished triangles.

A functor F between two triangulated category is called **exact** iff it maps distinguished triangles to distinguished triangles, and there is an isomorphism of functors $\xi : F \circ [1] \to [1] \circ F$.

Prop. (3.7.7.7). An exact functor of triangulated categories is additive.

Proof: Cf.[Sta]05QY. $\square$

Def. (3.7.7.8) [Bi-Exact Functors]. Let $\mathcal{D}, \mathcal{D}', \mathcal{E}$ be triangulated categories, a **bi-exact bifunctor** $F : \mathcal{D} \times \mathcal{D}' \to \mathcal{E}$ is a functor that for any $X \in \mathcal{D}$, $F(X, -) : \mathcal{D} \to E$ is an exact functor and for any $Y \in \mathcal{D}'$, $F(-, Y) : \mathcal{D} \to \mathcal{E}$ is an exact functor. By(3.7.7.7), any bi-exact functor is bi-additive.

Prop. (3.7.7.9). If $(F,G) : \mathcal{D} \rightleftharpoons \mathcal{D}'$ is an adjunction pair between triangulated categories and F is exact, then G is also an exact functor between triangulated categories.

Proof: Use adjunction, we can show that G commutes with $[1]$, and if $A \to B \to C \to A[1] \in \mathrm{Tri}(\mathcal{D}')$, choose a distinguished triangle $G(A) \to G(B) \to X \to G(A)[1] \in \mathrm{Tri}(\mathcal{D})$, then by (TR3) we get a map of distinguished triangles $(F(G(A)), F(G(B)), F(X)) \to (A, B, C)$, which by adjunction defines a map of distinguished triangles $(G(A), G(B), X) \to (G(A), G(B), G(C))$, which shows $X \cong G(C)$, and then $(G(A), G(B), G(C))$ is in $\mathrm{Tri}(\mathcal{D})$. □

Prop. (3.7.7.10). If $(F,G) : \mathcal{D} \rightleftharpoons \mathcal{D}'$ is an adjunction pair between triangulated categories and F, G are exact, F is fully faithful and $\ker(G) = 0$, then this is an equivalence of categories.

Proof: By(3.1.1.31), $u : \mathrm{id} \to gf$ is an isomorphism. Now for any $X \in \mathcal{D}'$, choose a distinguished triangle $(F(G(X)), X \to Y) \in \mathrm{Tri}(\mathcal{D}')$, which corresponds to $(G(F(G(X))), G(X), G(Y)) \in \mathrm{Tri}(\mathcal{D})$, and by(3.1.1.29), $G(X) \xrightarrow{u_X} GFG(X) \to G(X)$ is id_X, so we get an isomorphism of triangles $(G(F(G(X))), G(X), G(Y)) \cong (G(X), G(X), 0)$, so $G(Y) \cong 0$, and $Y = 0$ by hypothesis. So $v : FG \to \mathrm{id}$ is also an isomorphism, so (F,G) is an equivalence. □

Lemma (3.7.7.11). If (X, Y, Z, f, g, h) is a distinguished triangle, then $g \circ f = 0$.

Proof: By TR1 $(X, X, 0, \mathrm{id}, 0, 0)$ is a distinguished triangle, and by TR3 there is a map of distinguished triangles

$$\begin{array}{ccccccc} X & = & X & \longrightarrow & 0 & \longrightarrow & X[1] \\ \| & & \downarrow f & & \downarrow & & \| \\ X & \xrightarrow{f} & Y & \xrightarrow{g} & Z & \xrightarrow{h} & X[1] \end{array},$$

so $g \circ f = 0$. □

Prop. (3.7.7.12). Let $\mathcal{D}$ be a triangulated category and $C \in \mathcal{D}$ be any object, $\mathrm{Hom}_{\mathcal{D}}(-, C)$ and $\mathrm{Hom}_{\mathcal{D}}(C, -)$ is (co)homological.

Proof: By(3.7.7.3), for any distinguished triangle (X, Y, Z, f, g, h), $\mathrm{Hom}(C, X) \to \mathrm{Hom}(C, Y) \to \mathrm{Hom}(C, Z)$ is 0, and if $a \in \mathrm{Hom}(C, Y)$ is mapped to $0 \in \mathrm{Hom}(C, Y)$, then the morphism $(a, 0) : (C, 0) \mapsto (Y, Z)$ extends to a morphism of distinguished triangles $(b, a, 0) : (C, C, 0, \mathrm{id}, 0, 0) \to (X, Y, Z, f, g, h)$, thus $f \circ b = a$.

The converse case is dual. □

Cor. (3.7.7.13). If $(a, b, c) : (X, Y, Z, f, g, h) \to (X', Y', Z', f', g', h')$ is a morphism of distinguished triangles that two of a, b, c are isomorphisms, then this is an isomorphism of triangles.

In particular, the completion in TR1 is unique(may up to non-unique isomorphism) by TR3.

Proof: By 5-lemma, $\mathrm{Hom}(C, X) \to \mathrm{Hom}(C, X')$ is an isomorphism, then $X \to X'$ is an isomorphism by Yoneda lemma. □

Prop. (3.7.7.14). Let $\mathcal{D}$ be a triangulated category, then $f : X \to Y \in \mathcal{D}$ is an isomorphism iff $C(f) = 0$.

Proof: There is a morphism $(\mathrm{id}_X, f, 0) : (X, X, 0, \mathrm{id}, 0, 0) \to (X, Y, C(f), f, g, h)$ by (TR1) and (TR3). By(3.7.7.13), f is an isomorphism iff $0 \to C(f)$ is an isomorphism, which is equivalent to $Z = 0$. □

Prop. (3.7.7.15). In a triangulated category $\mathcal{D}$, any commutative diagram

$$\begin{array}{ccc} X & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X' & \longrightarrow & Y' \end{array}$$

can be extended to a diagram

$$\begin{array}{ccccccc} X & \longrightarrow & Y & \longrightarrow & Z & \longrightarrow & X[1] \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ X' & \longrightarrow & Y' & \longrightarrow & Z' & \longrightarrow & X'[1] \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ X'' & \longrightarrow & Y'' & \longrightarrow & Z'' & \longrightarrow & X''[1] \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ X[1] & \longrightarrow & Y[1] & \longrightarrow & Z[1] & \longrightarrow & X[2] \end{array}$$

where the lower right is anti-commutative.

Proof: Let $(X, Y, Z), (X', Y', Z'), (X, X', X''), (Y, Y', Y''), (X, Y, A)$ be distinguished triangles, then we can find maps $a : Z \to A, b : A \to Y', a' : X'' \to A, b' : A \to Z$ by TR3(3.7.7.1). Then TR4 says $(Z \to A, Y''), (X'' \to Z \to Z')$ is distinguished.

Now let (X'', Y'', Z'') be distinguished, then we use TR4 again to (X'', A, Y''), then $(Z', Z'', Z[1])$ is distinguished, thus so does $(Z \to Z' \to Z'')$.

Now it is left to verify the anti-commutativity of the righthdown square, for this, Cf.[Sta]05R0. □

Prop. (3.7.7.16)[Kernels are Saturated Triangulated Subcategories]. Let $\mathcal{D}, \mathcal{D}'$ be triangulated categories and $\mathcal{A}$ an Abelian category.

- Let $F : \mathcal{D} \to \mathcal{D}'$ be an exact functor, then the full subcategory of $\mathcal{D}$ consisting of objects X that $F(X) = 0$ is a strictly full saturated triangulated subcategory of $\mathcal{D}$, called the **kernel** of F.
- Let $H : \mathcal{D} \to \mathcal{A}$ be a (co)homological functor. then the full subcategory of $\mathcal{D}$ consisting of objects X that $F(X[n]) = 0$ for all n is a strictly full saturated triangulated subcategory of $\mathcal{D}$, called the **kernel** of H.

Proof: Cf.[Sta]05RC, 05RD. □

Prop. (3.7.7.17)[$K^*(\mathcal{A})$ is Triangulated]. For Abelian category A, the categories $K^*(A)$ with distinguished triangles(3.7.4.14) is triangulated, and they are all subcategories of $K(\mathcal{A})$. This is hard to verify, but it solves every problem. Cf[Gelfand P246][[Sta]014S]. And an additive functor will induce exact functor between K^* because distinguished is split.

Localizations of Triangulated Category

Def. (3.7.7.18) [Compatible Localizing Systems]. Let $\mathcal{D}$ be a triangulated category, a localizing system(3.1.1.54) S is said to be compatible with the triangulated structure if it satisfies the following axioms:

(LS4): For $s \in S, s[n] \in S$ for any $n \in \mathbb{Z}$.

(LS5): Any two consecutive morphisms of two distinguished triangle can be extended to a morphism of distinguished triangles by morphisms in S.

Cor. (3.7.7.19). Let $\mathcal{D}$ be a triangulated category. If a class of morphisms S satisfy (LS1), (LS5) and (LS6), then (LS2) holds as well.

Proof: Let $f : X \to Y \in \mathcal{D}$ and $s : X \to X' \in S$, we can use (TR1) and (TR2) to extend these to a morphism of distinguished triangles

$$\begin{array}{ccccccc} X & \xrightarrow{f} & Y & \longrightarrow & Z & \longrightarrow & X[1] \\ \downarrow{s} & & \downarrow{s'} & & \| & & \downarrow{s[1]} \\ X' & \longrightarrow & Y' & \longrightarrow & Z & \longrightarrow & X'[1] \end{array}.$$

The right extension is dual. □

Prop. (3.7.7.20)[Exact Functors and Saturated Localizing Systems]. Let $\mathcal{D}, \mathcal{D}'$ be triangulated categories and $\mathcal{A}$ an Abelian category.

- If $F : \mathcal{D} \to \mathcal{D}'$ is an exact functor and

$$S = \{f \in \mathcal{D} | F(f) \text{ is an isomorphism}\},$$

  then S is a saturated localizing system compatible with the triangulated structure(3.7.7.18).

- If $H : \mathcal{D} \to \mathcal{A}$ is a (co)homological functor and

$$S = \{f \in \mathcal{D} | H^i(f) \text{ is an isomorphism}\},$$

  then S is a saturated localizing system compatible with the triangulated structure(3.7.7.18).

Proof: Cf.[Sta]05R4, 05R6. □

Prop. (3.7.7.21) [Localed Triangulated Categories]. Let $\mathcal{D}$ be a triangulated category and S is a localizing system compatible with the triangulated structure, then there is a unique triangulated category structure on $S^{-1}\mathcal{D}$ that the localization functor $Q : \mathcal{D} \to S^{-1}\mathcal{D}$(3.1.1.53) is exact.

Moreover, $S^{-1}\mathcal{D}$ satisfies the following universal properties:

- If $\mathcal{A}$ is an Abelian category and $H : \mathcal{D} \to \mathcal{A}$ is a cohomological functor that $H(s)$ are isomorphisms for all $s \in S$, then the unique factorization $H' : S^{-1}\mathcal{D} \to \mathcal{A}$ s.t. $H' \circ Q = H$(3.1.1.57) is also a cohomological functor.

- If $\mathcal{D}'$ is a triangulated category and $F : \mathcal{D} \to \mathcal{D}'$ is an exact functor that $F(s)$ are isomorphisms for all $s \in S$, then the unique factorization $F' : S^{-1}\mathcal{D} \to \mathcal{A}$ s.t. $F' \circ Q = F$(3.1.1.57) is also an exact functor.

Proof: Cf.[Sta]05R6. □

Cor. (3.7.7.22) [Kernel of Localizing Functor]. An object $Z \in \mathcal{D}$ is in the kernel of the localizing functor $Q : \mathcal{D} \to S^{-1}\mathcal{D}$ iff it satisfies the following equivalent conditions:

- There exists Z' s.t. $0 : Z \to Z' \in S$.

- There exists Z' s.t. $0 :' \to Z \in S$.

- There exists Z' and a distinguished triangle $(X, Y, Z \oplus Z', f, g, h)$ that $f \in S$.

Proof: Cf.[Sta]05R8. □

Prop. (3.7.7.23) [Triangulated Subcategories of Localized Triangulated Categories]. Let $\mathcal{D}$ be a triangulated category and S is a localizing system compatible with the triangulated structure. Let $\mathcal{D}'$ be a full triangulated subcategory of $\mathcal{D}$ and S' is a localizing system of $\mathcal{D}'$. If either of the following holds:

- For any $s : X \to Y \in S$ and $X \in \mathcal{D}'$, there is a morphism $t : Y \to Z$ that $Z \in \mathcal{D}'$ and $t \circ s \in S'$.
- The same as in item1 but with arrows reversed.

Then the natural functor $(S')^{-1}\mathcal{D}' \to S^{-1}\mathcal{D}$ is fully faithful.

Proof: This is immediate from(3.1.1.60). □

Quotients of Triangulated Categories

Def. (3.7.7.24) [Saturated Triangulated Subcategories]. Let $\mathcal{D}$ be a triangulated category, then a full triangulated subcategory $\mathcal{D}'$ is called a **saturated triangulated subcategory** if whenever $X \oplus Y$ is isomorphic to an object of $\mathcal{D}'$, X, Y are all isomorphic to an object of $\mathcal{D}'$.

Prop. (3.7.7.25) [Full Triangulated Subcategories and Localizing Systems]. Let $\mathcal{D}$ be a triangulated category.

- If $\mathcal{D}'$ is a full triangulated subcategory, then

$$S = \{f : X \to Y \in \mathcal{D}' | \text{there exists a distinguished triangle } (X, Y, Z, f, g, h), Z \in \mathcal{D}'\}$$

  is a localizing system compatible with the triangulated structure of $\mathcal{D}$. And S is saturated iff $\mathcal{D}'$ is saturated.
- If S is a localizing system of $\mathcal{D}$, then $\mathcal{D}' = \ker(\mathcal{D} \to S^{-1}\mathcal{D})$(3.7.7.21)(3.7.7.16) is a saturated full triangulated subcategory of $\mathcal{D}$.

Proof: 1: Cf.[Sta]05RH. □

Def. (3.7.7.26) [Quotient Triangulated Categories]. Let $\mathcal{D}$ be a triangulated subcategory and $\mathcal{B}$ a full triangulated subcategory, define the **quotient triangulated category** $\mathcal{D}/\mathcal{B}$ as the localized triangulated category $S^{-1}\mathcal{D}$, where S is the localizing system associated to $\mathcal{B}$(3.7.7.25).

Moreover, $\mathcal{D}/\mathcal{B}$ satisfies the following universal properties:

- If $\mathcal{A}$ is an Abelian category and $H : \mathcal{D} \to \mathcal{A}$ is a cohomological functor that $\mathcal{B} \subset \ker(H)$, then H factors uniquely through $\mathcal{D}/\mathcal{B}$ by a functor H', and H' is also a cohomological functor.
- If $\mathcal{D}'$ is a triangulated category and $F : \mathcal{D} \to \mathcal{D}'$ is a cohomological functor that $\mathcal{B} \subset \ker(F)$, then F factors uniquely through $\mathcal{D}/\mathcal{B}$ by a functor F', and F' is also an exact functor.

Proof: The universal properties follow from the universal properties of localized triangulated categories(3.7.7.21) and the definition of S(3.7.7.25), using the long exact sequence or(3.7.7.14). □

Prop. (3.7.7.27)[Saturation]. Let $\mathcal{D}$ be a triangulated category and $\mathcal{D}'$ be a full triangulated subcategory, then the kernel of the quotient map $\mathcal{D} \to \mathcal{D}/\mathcal{D}'$(3.7.7.26) is a strictly full saturated subcategory consisting of objects $Z \in \mathcal{D}$ that $Z \oplus Z'$ is an object of $\mathcal{D}'$ for some object $Z' \in \mathcal{D}$. In particular, it is the smallest saturated triangulated subcategory containing $\mathcal{D}'$, called the **saturation** of $\mathcal{D}'$.

Proof: the kernel is a strictly full saturated subcategory by(3.7.7.16). The description of the objects of kernel follows from the definition(3.7.7.26)(3.7.7.25) amd(3.7.22). □

Prop. (3.7.7.28) [Kernel of Cohomological Functor is Saturated]. Let $\mathcal{D}$ be a triangulated category and $H : \mathcal{D} \to \mathcal{A}$ is a cohomological functor, then $\ker(H)$ is a saturated full triangulated subcategory(3.7.7.16) whose corresponding saturated localizing system(3.7.7.20) is the set

$$S = \{f | H^i(f) \text{ is an isomorphism in } \mathcal{A}\},$$

and H factors through the quotient $\mathcal{D} \to \mathcal{D}/\ker(H)$.

Proof: The description of S is clear from the definitions(3.7.7.16)(3.7.7.25) and a use of long exact sequences. The factorization follows from(3.7.7.26). □

K-Groups

Def. (3.7.7.29) [K-Groups of Triangulated Categories]. Let $\mathcal{D}$ be a triangulated categories, then the **K-group of** $\mathcal{D}$ is defined to be the quotient

$$\bigoplus_{X\to Y\to Z \text{ distinguished}} 1 \to \bigoplus_{X\in\mathcal{D}} \to K_0(\mathcal{D}) \to 0$$

where $e_{X\to Y\to Z}$ is mapped to $e_Y - e_X - e_Z$.

Prop. (3.7.7.30) [Naturality].

- An exact functor between triangulated categories induce a map of their corresponding K-groups,
- A bi-exact bifunctor $F : \mathcal{D} \times \mathcal{D}' \to \mathcal{E}$(3.7.7.8) induces a bilinear map $K_0(\mathcal{D}) \times K_0(\mathcal{D}') \to K_0(\mathcal{E})$ sending $([X], [X'])$ to $F(X, X')$.
- A δ-functor from an Abelian category to a triangulated category induces a map of their corresponding K-groups(Notice these two K-groups are defined differently).
- A functor from an exact category to a triangulated category that sends exact sequences to distinguished triangles induces a map of their corresponding K-groups.

Brown Representability

Def. (3.7.7.31) [Generators]. Let $\mathcal{D}$ be a triangulated category, a **generator of** $\mathcal{D}$ is an object of $\mathcal{D}$ s.t. for any object K of $\mathcal{D}$, there exists some integer n and a non-zero map $E[n] \to K$.

Prop. (3.7.7.32). Let $\mathcal{D}$ be a triangulated category, then the compact objects of $\mathcal{D}$ form a Karoubian, saturated, strictly full triangulated category of $\mathcal{D}$.

Proof: Cf.[Sta]09QH. □

Def. (3.7.7.33) [Compactly Generated]. Let $\mathcal{D}$ be a triangulated category with arbitrary direct sums, then $\mathcal{D}$ is said to be a **compactly generated triangulated category** if there exists a set of compact objects $\{E_i\}$ that $\oplus E_i$ is a generator of $\mathcal{D}$(3.7.7.31).

Prop. (3.7.7.34) [Brown Representability]. Let $\mathcal{D}$ be a triangulated category with direct sums that is compactly generated. Let H be a contravariant cohomological functor that transforms direct sums into products, then H is representable.

Proof: Cf.[Sta]018F. □

Cor. (3.7.7.35) [Adjointness Lemma]. Let $\mathcal{D}$ be a triangulated category with direct sums that is compactly generated and $F : \mathcal{D} \to \mathcal{D}'$ an exact functor of triangulated categories that transforms direct limits to direct limits, then F has an exact right adjoint.

Proof: By Brown representability, for any $Y \in \mathcal{D}'$, there is an object $G(Y) \in \mathcal{D}$ that represents the contravariant cohomological functor $\mathcal{D} \to \mathcal{A}\mathrm{b} : X \mapsto \mathrm{Hom}_{\mathcal{D}'}(F(X), Y)$(3.7.7.12). Then G is a functor by Yoneda lemma. It is exact by(3.7.7.9). □

8 Tensor Category Case

In this subsection we consider complexes over a tensor category(3.1.6.2) $\mathcal{A}$.

Lemma (3.7.8.1) [Koszul Sign Rule]. There is an isomorphism of complexes

$$\sigma : C^\bullet \otimes D^\bullet \to D^\bullet \otimes C^\bullet : \sigma(x \otimes y) = (-1)^{mn} y \otimes x$$

where $x \in C^m$ and $y \in D^n$.

Proof:

$$\partial(\sigma(x\otimes y)) = \partial((-1)^{mn} y\otimes x) = (-1)^{mn}(\partial y\otimes x) + (-1)^{mn+n}(y\otimes \partial x) = (-1)^n \sigma(x\otimes \partial y) + \sigma(\partial x\otimes y) = \sigma(\partial(x\otimes y))$$

□

Prop. (3.7.8.2) [Commutative Monoidal Structure on $\mathrm{Ch}^{\mathbb{Z}}(\mathcal{A})$]. The functor

$$\mathrm{Ch}^{\mathbb{Z}}(\mathcal{A}) \times \mathrm{Ch}^{\mathbb{Z}}(\mathcal{A}) \to \mathrm{Ch}^{\mathbb{Z}}(\mathcal{A}) : \quad (C^\bullet, D^\bullet) \mapsto \mathrm{Tot}^{\oplus}(C^\bullet \otimes D^\bullet)$$

endows $\mathrm{Ch}^{\mathbb{Z}}(\mathcal{A})$ with a (non-strict) commutative monoidal structure.

Proof: Commutativity follows from(3.7.8.1). Associality follows from the definition of totalization(3.7.4.9). □

Prop. (3.7.8.3) [Commutative Monoidal Structure on $K^*(\mathcal{A})$]. This monoidal functor descends to a strict monoidal structure on $K^*(\mathcal{A})$.

Proof: □

Prop. (3.7.8.4) [Tensoring is Exact]. Let $L^\bullet \in K(\mathcal{A})$, then tensoring functor $\mathrm{Tot}^{\oplus}(- \oplus L^\bullet)$ is an exact functor between triangulated categories.

Proof: □

Prop. (3.7.8.5). An R-module I is injective iff for any injective homomorphism from I to any R-module splits.

Proof: The critical point is that we can always embed I to an injective hull J by(3.7.3.23), then $J = I \oplus J'$, so I is clearly injective. □

Prop. (3.7.8.6) [K-Injective under Change of Rings]. If $R \to S$ is a ring map, then

1. If $R \to S$ is flat and $I^\bullet$ is a K-injective complex of S-modules, then $I^\bullet$ is K-injective as a complex of R-modules.

2. If $R \to S$ is surjective and $I^\bullet$ is a complex of S-modules that is K-injective as a complex of R-modules, then it is K-injective as a complex of S-modules.
3. If $I^\bullet$ is a K-injective complex of R-modules, then $\mathrm{Hom}_R(S, I^\bullet)$ is K-injective as a complex of S-modules.

Proof: 1: This is because $\mathrm{Hom}_{K(R)}(M^\bullet, I^\bullet) = \mathrm{Hom}_{K(S)}(M^\bullet \otimes_R S, I^\bullet)$ and(3.9.2.1), as tensoring S is exact.

2: This is because $\mathrm{Hom}_{K(R)}(N^\bullet, I^\bullet) = \mathrm{Hom}_{K(S)}(N^\bullet, I^\bullet)$ for a complex of S-modules $N^\bullet$ and(3.9.2.1).

3: This is because $\mathrm{Hom}_{K(S)}(N^\bullet, \mathrm{Hom}_R(S, I^\bullet)) = \mathrm{Hom}_{K(R)}(N^\bullet, I^\bullet)$, and(3.9.2.1). □

3.8 Stable ∞-Categories

References are [nLab], [Lur11]

Notation (3.8.0.1).

- Use notations defined in ∞-Categories.

1 Stable ∞-Categories

Def. (3.8.1.1) [Zero Objects]. A **zero object** in an ∞-category is an object that is both initial and final. A **pointed ∞-category** is an ∞-category with a zero object.

In a pointed ∞-category $\mathcal{C}$, the subcategory of zero objects is a trivial Kan complex. And for any $x, y \in \mathcal{C}$, $\mathrm{Map}(x, y)$(3.6.1.20) is a trivial Kan complex, by(3.4.8.3) and(3.6.1.21). So there is a **zero morphism** $0 : x \to y$ that is unique up to contractible choice.

Def. (3.8.1.2) [∞-Category of Pointed Objects]. For $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ with a final object $*$, denote $\mathcal{C}^{\mathrm{pt}} = \mathcal{C}_{*/}$, called the **∞-category of pointed objects** in $\mathcal{C}$. Then $\mathcal{C}_*$ is pointed, and there is a map $(-)_- : \mathcal{C}_* \to \mathcal{C}$, and there is also a map $(-)_+ : \mathcal{C} \to \mathcal{C}_*$ given by adding a final object. Then we have an adjunction between ∞-categories:

$$(-)_+ : \mathcal{C} \rightleftarrows \mathcal{C}^{\mathrm{pt}} : (-)_-.$$

Proof: □

Prop. (3.8.1.3). Let $\mathcal{C}$ be a pointed presentable ∞-category, then evaluation at $S^0 \in \mathcal{G}\mathrm{rpd}_\infty^{\mathrm{pt}}$ induces an equivalence of ∞-categories

$$\mathrm{Func}^L(\mathcal{G}\mathrm{rpd}_\infty^{\mathrm{pt}}, \mathcal{C}) \cong \mathcal{C}.$$

Proof: □

Def. (3.8.1.4) [Triangles in ∞-Categories]. A **triangle** is a pointed ∞-category $\mathcal{C}$ is a diagram

$$\tau : \Delta^1 \times \Delta^1 \to \mathcal{C} : \begin{array}{ccc} x & \longrightarrow & y \\ \downarrow & \searrow & \downarrow \\ 0 & \longrightarrow & z \end{array}$$

where 0 is a zero object. It is called a **fiber sequence** if this diagram is a pullback diagram, and called a **cofiber sequence** if this diagram is a pushout diagram. Denote $\mathrm{Tri}(\mathcal{C}) \subset \mathrm{Func}(\Delta^1 \times \Delta^1, \mathcal{C})$ the full sub-∞-category of triangles.

Def. (3.8.1.5) [Cofiber Maps and Fiber Maps]. If $\mathcal{C}$ is a pointed ∞-category which admits cofibers, then by(3.6.3.16) and(3.6.3.17), there is a **fiber sequence map**

$$\mathrm{Cof} : \mathrm{Func}(\Delta^1, \mathcal{C}) \to \mathrm{Func}(\Delta^1 \times \Delta^1, \mathcal{C}).$$

unique up to contractible choice. And its composition with $\mathrm{ev}_{(1,1)}$ is also denoted by $\Sigma : \mathrm{Func}(\Delta^1, \mathcal{C}) \to \mathcal{C}$. The dual is true for fibrations.

Prop. (3.8.1.6) [Cofiber Map Preserves Colimits]. If $\mathcal{C}$ is a pointed ∞-category which admits cofibers, choose a zero object 0, then any $\mathrm{Cof} : \mathrm{Func}(\Delta^1, \mathcal{C}) \to \mathcal{C}$ is left adjoint to a functor $\mathcal{C} \to \mathcal{C}_{0/} \to \mathrm{Func}(\Delta^1, \mathcal{C})$ which maps each $C \in \mathcal{C}$ to a morphism $0 \to C$. In particular, Cof preserves small colimits by(3.6.4.5). Dually, Fib preserves small limits.

Proof: □

Def. (3.8.1.7) [Suspension and Loop Diagrams]. For $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$, denote $\mathcal{C}^\Sigma \subset \mathrm{Func}(\Delta^1 \times \Delta^1, \mathcal{C})$ the full ∞-subcategory of cofiber sequences of the form

$$\tau : \Delta^1 \times \Delta^1 \to \mathcal{C} : \begin{array}{ccc} x & \longrightarrow & 0' \\ \downarrow & \searrow & \downarrow \\ 0 & \longrightarrow & z \end{array}$$

where $0, 0'$ are zero objects.

Dually, define $\mathcal{C}^\Omega \subset \mathrm{Func}(\Delta^1 \times \Delta^1, \mathcal{C})$ the full ∞-subcategory of exact triangles of the form

$$\tau : \Delta^1 \times \Delta^1 \to \mathcal{C} : \begin{array}{ccc} x & \longrightarrow & 0' \\ \downarrow & \searrow & \downarrow \\ 0 & \longrightarrow & z \end{array}$$

where $0, 0'$ are zero objects.

Def. (3.8.1.8) [Suspension Functors and Loop Functors]. If $\mathcal{C} \in \mathcal{C}\mathrm{at}_\infty$ is a pointed ∞-category with admits cofibers, then same argument as in(3.8.1.5) shows that $\mathcal{C}^\Sigma \to \mathcal{C}$ is a trivial Kan fibration, so there is a section $\Sigma : \mathcal{C} \to \mathcal{C}^\Sigma$, called a **suspension functor**. And its composition with $\mathrm{ev}_{(1,1)}$ is also denoted by $\Sigma : \mathcal{C} \to \mathcal{C}$.

Dually, if $\mathcal{C}$ is a pointed ∞-category which admits fibers, we can define **loop functors**. If $\mathcal{C}$ admits both fibers and cofibers, for $C \in \mathcal{C}$ and $n \in \mathbb{N}$, denote $X[n] = \Sigma^n(X), X[-n] = \Omega^n(X)$.

Def. (3.8.1.9) [Stable ∞-Category]. A **stable ∞-category** is a pointed ∞-category $(\mathcal{C}, 0)$ s.t.

- $\mathcal{C}$ admits cofibers and fibers.
- A triangle in $\mathcal{C}$ is a fiber sequence iff it is a cofiber sequence.

Notice that $\mathcal{C}$ is stable iff $\mathcal{C}^{\mathrm{op}}$ is stable.

Prop. (3.8.1.10). If $\mathcal{C}$ is a pointed category which admits both cofibers and fibers, then there is an adjunction

$$\Sigma : \mathrm{Ho}(\mathcal{C}) \rightleftarrows \mathrm{Ho}(\mathcal{C}) : \Omega.$$

And if $\mathcal{C}$ is stable, they are mutually inverse to each other.

Proof: □

Prop. (3.8.1.11) [HA.1.1.3.4]. A stable ∞-category is complete and cocomplete. And pullback squares and pushout squares coincide.

Prop. (3.8.1.12). Let $\mathcal{C}$ be a pointed ∞-category, then the following are equivalent:

- $\mathcal{C}$ is stable.
- $\mathcal{C}$ admits finite colimits, and the suspension functor $\Sigma : \mathcal{C} \to \mathcal{C}$ is an equivalence.
- $\mathcal{C}$ admits finite limits, and the loop functor $\Omega : \mathcal{C} \to \mathcal{C}$ is an equivalence.

Proof: Cf.[HA, 1.4.2.27]. □

Homological Algebra

Prop. (3.8.1.13) [Homotopy Groups]. Let $\mathcal{C}$ be a pointed ∞-category that admits cofibers, then for any $X, Y \in \mathcal{C}$, there is a bijection

$$\mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(\Sigma^n(X), Y) \cong \pi_n \mathrm{Map}_{\mathcal{C}}(X, Y).$$

Proof: **?** □

Def. (3.8.1.14) [Ext Groups]. For a pointed ∞-category $\mathcal{C}$ and $X, Y \in \mathcal{C}$, denote $\mathrm{Ext}^n(X,Y) = \mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(X[-n], Y)$, called the **Ext groups**.

Prop. (3.8.1.15). Let $\mathcal{C}$ be a pointed ∞-category that admits cofibers, then any diagram

$$\begin{array}{ccc} X & \xrightarrow{f} & 0 \\ \downarrow & & \downarrow f' \\ 0' & \longrightarrow & Y \end{array}$$

in $\mathcal{C}$ corresponds to a homotopy class of morphisms $\theta \in \mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(X[1], Y)$. Then in this way, the diagram diagram

$$\begin{array}{ccc} X & \xrightarrow{f'} & 0' \\ \downarrow & & \downarrow f' \\ 0 & \longrightarrow & Y \end{array}$$

corresponds to $-\theta \in \mathrm{Hom}_{\mathrm{Ho}(\mathcal{C})}(X[1], Y)$, where the group structure is given by(3.8.1.13).

Proof: Cf.[Lur11]P25. □

Lemma (3.8.1.16). Let $\mathcal{C}$ be a pointed ∞-category that admits cofibers, and the suspension functor Σ is an equivalence, then $\mathrm{Ho}(\mathcal{C})$ is an additive category(3.7.1.10).

Proof: It follows from(3.8.1.13) and the compatibility of group structures on π_n that $\mathcal{C}$ is preadditive. To show it is additive, Cf.[Lur11]P24.**?** □

Def. (3.8.1.17) [Distinguished Triangles]. Let $\mathcal{C}$ be a pointed ∞-category which admits cofibers, then a diagram $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]$ in $\mathrm{Ho}(\mathcal{C})$ is called a **distinguished triangle** if there exists a diagram $\Delta^1 \times \Delta^2 \to \mathcal{C}$ as shown:

$$\begin{array}{ccccc} X & \xrightarrow{\widetilde{f}} & Y & \longrightarrow & 0 \\ \downarrow & & \downarrow \widetilde{g} & & \downarrow \\ 0' & \longrightarrow & Z & \xrightarrow{\widetilde{h}} & W \end{array}$$

s.t.

- Both $0, 0'$ are zeros.
- both square are pushout squares.
- $\widetilde{f}$ lifts f, $\widetilde{g}$ lifts g.
- $h : Z \to X[1]$ equals $\widetilde{h}$ composed with an equivalence $W \cong X[1]$ determined by the outer rectangle.

Prop. (3.8.1.18) [Stable ∞-Categories and Triangulated Categories]. Let $\mathcal{C}$ be a stable ∞-category, then the translation functor defined(3.8.1.8) and distinguished triangles defined in(3.8.1.17) endow $\mathrm{Ho}(\mathcal{C})$ with the structure of a triangulated category(3.7.7.1).

Proof: Cf.[Lur11]P27. □

Def. (3.8.1.19) [Exact Functors]. An **exact functor** between stable ∞-categories is a functor $F : \mathcal{C} \to \mathcal{D}$ that is left and right exact and preserves fiber sequences.

Prop. (3.8.1.20). Let $\mathcal{C}\mathrm{at}_\infty^{\mathrm{Ex}} \subset \mathcal{C}\mathrm{at}_\infty$ be the subcategory of all stable ∞-categories and exact functors, then it admits all small limits and small filtered colimits, and they are preserved by the inclusion.

Proof: Cf.[HA1.1.4.4., 1.1.4.6.] □

Def. (3.8.1.21) [T-Structure]. A T-structure on a stable ∞-category $\mathcal{C}$ is a pair of full subcategories $\mathcal{C}_{\geq 0}.\mathcal{C}_{\leq 0}$ that

Prop. (3.8.1.22). For any $n \in \mathbb{Z}$, $\mathcal{C}_{\leq n} \subset \mathcal{C}$ is a localization, thus admits a left adjoint $\tau_{\leq n}$, called the **truncation functor**. Dually for $\tau_{\geq n}$.

Proof: Cf.[HA, P1.2.1.5]. □

Def. (3.8.1.23) [Heart]. The **heart** $\mathcal{C}^{\heartsuit} \subset \mathcal{C}$ is defined to be the full subcategory of $\mathcal{C}_{\leq 0} \cap \mathcal{C}_{\geq 0} \subset \mathcal{C}$.

Spectra Objects and Stabilization

Def. (3.8.1.24) [Spectra]. A **spectrum** is an object in the universal $(\infty, 1)$-category $\mathrm{Sp} = \mathrm{Sp}(\mathcal{T}\mathrm{op}) \cong \mathrm{Sp}(\mathcal{G}\mathrm{rpd}_\infty)$

Def. (3.8.1.25) [Homology Groups of Spectra].

Def. (3.8.1.26) [Connective Spectra]. A **connective spectrum** is a spectrum(3.8.1.24) that the negative homotopy groups vanish.

Prop. (3.8.1.27). There are equivalences between the following categories**?**:

- connected spectra.
- infinite loop spaces.
- group-like $\mathbb{E}_\infty$-spaces.

Proof: □

Def. (3.8.1.28) [$\mathbb{E}_\infty$-Rings]. An **$\mathbb{E}_\infty$-ring** is an object in $\mathcal{CM}\mathrm{on}_\infty(\mathrm{Sp}(\mathcal{G}\mathrm{rpd}_\infty))$(3.8.1.24).

Cor. (3.8.1.29). For $(\mathcal{C}, 0) \in \mathcal{C}\mathrm{at}_\infty^{\mathrm{pt}}$, the following are equivalent:

- $\mathcal{C}$ is stable.
- $\mathcal{C}$ admits finite finite colimits and the suspension functor $\Sigma : \mathcal{C} \to \mathcal{C}$ is an equivalence.
- $\mathcal{C}$ admits finite finite limits and the loop functor $\Sigma : \mathcal{C} \to \mathcal{C}$ is an equivalence.

Proof: Cf.[Lur11]P149. □

Presentable Stable ∞-Categories

2 Monoidal ∞-Categories

Def. (3.8.2.1) [Monoidal ∞-Categories]. A **monoidal** $(\infty,1)$**-category** is a tuple $(\mathcal{C},\otimes)$ where

- $\mathcal{C}$ is a simplicial set.
- $\otimes:\mathcal{C}\to N(\Delta)^{\mathrm{op}}$ is a coCartesian fibration.
- For $n\in\mathbb{N}$ and $0\le i\le n-1$, the induced $(\infty,1)$-functor $\mathcal{C}_{[n]}\to\mathcal{C}_{\{i,i+1\}}$ determines an equivalence of $(\infty,1)$-categories

$$\mathcal{C}_{[n]}\to\mathcal{C}_{\{0,1\}}\times\ldots\times\mathcal{C}_{\{n-1,n\}}\cong(\mathcal{C}_{[1]})^n$$

Def. (3.8.2.2) [$\mathbb{A}_\infty$-Rings]. Let $\mathcal{C}$ be a stable monoidal $(\infty,1)$-category(3.8.2.1) with the $(\infty,1)$-functor

$$p_\infty:\mathcal{C}\to N(\Delta)^{\mathrm{op}},$$

an $\mathbb{A}_\infty$**-Ring** is a lax monoidal section of $p_\otimes$.

Monoidal $(\infty,1)$-Categories

Def. (3.8.2.3) [Symmetric Monoidal $(\infty,1)$-Categories]. A symmetric monoidal $(\infty,1)$-category is an $(\infty,1)$-category which is ∞-tuply monoidal. Equivalently, it is a commutative algebra in the $(\infty,1)$-category of $(\infty,1)$-categories.

Or equivalently, it is a coCartesian fibration of simplicial sets

$$\pi:\mathcal{C}^\otimes\to N(\mathcal{F}\mathrm{in}\mathcal{S}\mathrm{et}_*)$$

s.t. for any $n\in\mathbb{N}$, the associated functor $\mathcal{C}^\otimes_{[n]}\to\mathcal{C}^\otimes_{[1]}$ determines an equivalence of $(\infty,1)$-categories.

Proof: ? □

Def. (3.8.2.4) [$\mathbb{E}_\infty$-Algebras(Commutative Monoids)]. Let $\mathcal{C}$ be a symmetric monoidal $(\infty,1)$-category, then an $\mathbb{E}_\infty$**-algebra** of a **commutative monoid** in $\mathcal{C}$ is a lax monoidal $(\infty,1)$-functor $*\to\mathcal{C}$?. The $(\infty,1)$-category of commutative monoids in $\mathcal{C}$ is denoted by $\mathcal{CM}\mathrm{on}_\infty(\mathcal{C})$.

Def. (3.8.2.5) [$\mathbb{E}_\infty$-Space]. An $\mathbb{E}_\infty$**-space** is a commutative ∞-monoid in $\mathcal{G}\mathrm{rpd}_\infty$(3.6.2.5), i.e.

$$\mathbb{E}_\infty\text{-Spa}=\mathcal{CM}\mathrm{on}_\infty(\mathcal{G}\mathrm{rpd}_\infty).$$

It is also denoted by $\mathcal{CM}\mathrm{on}_\infty$.

Def. (3.8.2.6) [Commutative Ring Spectra($\mathbb{E}_\infty$-Rings)]. An $\mathbb{E}_\infty$**-ring** or a **commutative ring spectra** is a commutative monoid in the stable $(\infty,1)$-category of spectra?.

Prop. (3.8.2.7) [∞-Abelianization]. There is an $(\infty,1)$-functor

$$\mathcal{A}\mathrm{b}_\infty:\mathcal{G}\mathrm{rpd}_\infty\to\mathcal{CM}\mathrm{on}_\infty\text{(3.8.2.5)}$$

that is left adjoint to the

3.9 Derived Categories

Main references are [G-M03] and [Sta]. Need to be refreshed by the language of ∞-categories **?**

1 Derived Category

Def. (3.9.1.1) [Derived Category]. Let $\mathcal{A}$ be an Abelian category. The full subcategory $Ac(\mathcal{A})$ of $K(\mathcal{A})$ consisting of acyclic complexes is a strictly full saturated triangulated subcategory, and its associated saturated localizing system is the class $\mathrm{QIso}(\mathcal{A})$ of quasi-isomorphisms.

Thus the kernel of the localizing functor $Q_{\mathcal{A}}: K(\mathcal{A}) \to \mathrm{QIso}(\mathcal{A})^{-1}K(\mathcal{A})$ is $Ac(\mathcal{A})$, and H^0 factors through $Q_{\mathcal{A}}$. Then the quotient triangulated category(3.7.7.26)

$$D(\mathcal{A}) = K(\mathcal{A})/Ac(\mathcal{A}) = \mathrm{QIso}(\mathcal{A})^{-1}K(\mathcal{A})$$

is called the **derived category** of $\mathcal{A}$.

Proof: As H^0 is a cohomological functor(3.7.4.14), these follows from(3.7.7.28) and(3.7.7.27). □

Cor. (3.9.1.2) [Universal Properties of Derived Categories]. Let $\mathcal{A}$ be an Abelian category,

- By(3.7.7.21), the derived category $D(\mathcal{A})$ of an Abelian category $\mathcal{A}$ has the universal property that any exact functor between Distinguished categories $F: K(\mathcal{A}) \to \mathcal{D}$ s.t. quasi-isomorphisms is mapped to isomorphisms uniquely factors through $D(\mathcal{A})$.
- Let $F: \mathcal{A} \to \mathcal{B}$ be an exact functor between Abelian categories, then F induces an exact functor $F: K(\mathcal{A}) \to K(\mathcal{B})$ of triangulated categories(3.7.4.17), and it maps quasi-isomorphisms to quasi-isomorphisms, so by item1 induces a morphism of categories $\mathcal{D}(\mathcal{A}) \to \mathcal{D}(\mathcal{B})$.

Prop. (3.9.1.3) [Universal δ-Functors]. The functor $Comp(\mathcal{A}) \to D(A)$ is a δ-functor.

Proof: Cf.[Sta]014Z.**?** □

Prop. (3.9.1.4) [Truncation Triangles]. Let $\mathcal{A}$ be an Abelian category and $K^\bullet \in K(\mathcal{A})$, then for any $a \in \mathbb{Z}$, the truncation is a distinguished triangle

$$\tau_{\leq a}K^\bullet \to K^\bullet \to \tau_{\geq a+1}K^\bullet \to \tau_{\leq a}K^\bullet[1].$$

Proof: This exact sequence comes from the exact sequence $0 \to \tau_{\leq a}K^\bullet \to K^\bullet \to K^\bullet/\tau_{\leq a}K^\bullet$ via the δ-functor(3.9.1.3) and the fact $K^\bullet/\tau_{\leq a} \to K^\bullet \to \tau_{\geq a+1}K^\bullet$ is a quasi-isomorphism thus an isomorphism in $D(\mathcal{A})$. □

Triangulated Subcategories of $D(\mathcal{A})$

Prop. (3.9.1.5). Let $\mathcal{A}$ be an Abelian category and $\mathcal{L}$ a full triangulated subcategory of $K(\mathcal{A})$, let $S = \mathcal{L} \cap \mathrm{QIso}(\mathcal{A})$, then S is the saturated localizing system compatible with the triangulated structure associated to the cohomological functor H^0 restricted to L(3.7.7.20), the we can form the localizing triangulated category $S^{-1}\mathcal{L}$(3.7.7.21) and there is a natural exact functor of triangulated categories $S^{-1}\mathcal{L} \to D(\mathcal{A})$ by the universal property(3.7.7.21).

Prop. (3.9.1.6) [Full Subcategories of $D(\mathcal{A})$]. Let $\mathcal{L} \subset \widetilde{\mathcal{L}}$ be full triangulated subcategories of $K(\mathcal{A})$, and $S = \mathcal{L} \cap \mathrm{QIso}(\mathcal{A})$, $\widetilde{S} = \widetilde{\mathcal{L}} \cap \mathrm{QIso}(\mathcal{A})$. If either of the following holds:

- For any $s : L_1 \to \widetilde{L}_1 \in \widetilde{S}$ and $L_1 \in \mathcal{L}$, there is a morphism $t : \widetilde{L}_1 \to L_2$ that $L_2 \in \mathcal{L}$ and $t \circ s \in \widetilde{S}$.
- The same as in item1 but with arrows reversed.

then the natural functor $S^{-1}\mathcal{L} \subset \widetilde{S}^{-1}\widetilde{\mathcal{L}}$ is fully faithful.

Proof: This follows immediately from(3.9.1.5) and(3.7.7.23). □

Cor. (3.9.1.7) [Bounded Derived Categories]. For $* = -, +, b$, the triangulated categories $D^*(\mathcal{A})$ are the localized category of $K^*(\mathcal{A})$ at the classes of isomorphism in $K^*(\mathcal{A})$(3.9.1.5). Then they are naturally full subcategories of $D(\mathcal{A})$, by(3.9.1.6), as the condition is satisfied by(3.7.4.19).

Def. (3.9.1.8)[Derived Category of Serre Subcategories]. If $\mathcal{B}$ is a Serre subcategory of an Abelian category $\mathcal{A}$, let $D^*_{\mathcal{B}}(\mathcal{A})$ be the full subcategory of $D^*(\mathcal{A})$ consisting of objects X that $H^n(X) \in \mathcal{B}$ for all n, then $D^*_{\mathcal{B}}(\mathcal{A})$ is a strictly full saturated triangulated subcategory of $D^*(\mathcal{A})$, as it is just the kernel of the cohomological functor $H^0 : D^*(\mathcal{A}) \to \mathcal{A} \to \mathcal{A}/\mathcal{B}$(3.7.3.14)(3.7.7.16).

Also there are natural exact functors $D^*(\mathcal{B}) \to D^*_{\mathcal{B}}(\mathcal{A})$, and $D^*(\mathcal{A})/D^*_{\mathcal{B}}(\mathcal{A}) \to D^*(\mathcal{A}/\mathcal{B})$(3.7.7.26).

Prop. (3.9.1.9). The map $D^*(\mathcal{A}) \to D^*(\mathcal{A}/\mathcal{B})$ is essentially surjective.

Proof: Cf.[Sta]06XL. □

Prop. (3.9.1.10). Let $\mathcal{B} \subset \mathcal{A}$ be a Serre subcategory and suppose that for any surjection $X \to Y \in \mathcal{A}$ with $Y \in \mathcal{B}$, there is a subobject $X' \subset X$ that $X' \to Y$ is surjective, then the exact functor $D^*(\mathcal{B}) \to D^*_{\mathcal{B}}(\mathcal{A})$ is an equivalence for $* = -$ or b.

Proof: Cf.[Sta]0FCL. □

Prop. (3.9.1.11). If $(\mathcal{C}, \mathcal{O})$ is a ringed site and $\mathcal{A} \subset \mathfrak{Mod}_{\mathcal{O}}$ is the Serre subcategory of torsion modules, then the functor $D(\mathcal{A}) \to D_{\mathcal{A}}(\mathcal{O})$ is an equivalence.

Proof: Cf.[Sta]0DD7. □

Prop. (3.9.1.12) [Embedding of $\mathcal{A}$ in $D(\mathcal{A})$]. The natural inclusion $i : \mathcal{A} \subset D(A)$ induces an equivalence of $\mathcal{A}$ with the subcategory of $D(\mathcal{A})$ consisting of complexes with cohomology concentrated at degree 0.

An object $K \in D(A)$ is called **discrete** if it is in the essential image of this inclusion.

Proof: The natural map $H^0 : D(\mathcal{A}) \to \mathcal{A}$ is inverse to i, so i is faithful. To show it is full, let (L, f, s^{-1}) be a morphism from $i(M)$ to $i(N)$, then we get a morphism $(H^0(L), H^0(f), H^0(s)^{-1})$, and these two morphisms are both dominated by the morphism $(\sigma^{\geq n}L, \sigma^{\leq n} \circ f, (\sigma^{\leq n} \circ s)^{-1})$, so they are equal morphisms in $D(\mathcal{A})$. But $(H^0(L), H^0(f), H^0(s)^{-1}) = i(s^{-1}f)$ is in the image of i, so i is full.

The assertion that any complex with cohomology groups concentrated at degree 0 is true by using truncation functors(3.7.4.19). □

Prop. (3.9.1.13) [K-Groups]. Let $\mathcal{A}$ be an Abelian category, then the embedding(3.9.1.12) induces an isomorphism of K-groups $K_0(\mathcal{A}) \cong K_0(D^b(\mathcal{A}))$(3.7.7.29).

Proof: The map $\mathcal{A} \to D^b(\mathcal{A})$ is a δ-functor by(3.9.1.3), thus by(3.7.7.30) induces a map $K_0(\mathcal{A}) \cong K_0(D^b(\mathcal{A}))$. There is a reverse map $K_0(D^b(\mathcal{A})) \to K_0(\mathcal{A}) : X \mapsto \sum_i (-1)^i H^i(X)$, which is inverse the the map above: one direction is clear, for the other, use induction and the truncation triangles(3.9.1.4). □

Def. (3.9.1.14) [Perfect Complex]. Let $\mathcal{A}$ be an Abelian category, a **perfect complex** in $D(\mathcal{A})$ is a complex that is equivalent to a bounded complex.

Operations on the Derived Category

Lemma (3.9.1.15) [Direct Sum]. If $\mathcal{A}$ is an Abelian category that has exact countable direct sums, then $D(\mathcal{A})$ has countable direct sums given by term-wise direct sums.

Proof: A system of morphisms $K_i^\bullet \to L^\bullet$ is a system of quasiisos $M_i^\bullet \to K_i^\bullet$ and $M_i \to L^\bullet$. Then by hypothesis $\oplus M_i^\bullet \to \oplus K_i^\bullet$ is a quasi-iso, thus defines a morphism $\oplus K_i^\bullet \to L^\bullet$. It can be verified that this morphism is unique?. □

Lemma (3.9.1.16) [Termwise Colimit as Hocolim]. Let $\mathcal{A}$ be an Abelian category, $L_n^\bullet$ be a system of complexes of $\mathcal{A}$. Assume colimits over $\mathbb{N}$ exists and are exact over $\mathcal{A}$, then the termwise colimit $L^\bullet$ is a derived colimit in $D(\mathcal{A})$.

Proof: We have an exact sequence

$$0 \to \oplus L_n^\bullet \to \oplus L_n^\bullet \to L^\bullet \to 0$$

and the termwise direct sum is the direct sum in $D(\mathcal{A})$ by(3.9.1.15), and then $L^\bullet$ is a derived colimit, by(3.7.4.13). □

Bounded (Co)Homological Dimensions

Def. (3.9.1.17) [Bounded Cohomological Dimensions]. An exact functor between two derived categories $F : D(\mathcal{A}) \to D(\mathcal{B})$ is called has **cohomological dimension bounded by** N if $F(D^{\leq m}(\mathcal{A})) \subset D^{\leq m+N}(\mathcal{B})$. Dually, it has **homological dimension bounded by** N if $F(D^{\geq m}(\mathcal{A})) \subset D^{\geq m-N}(\mathcal{B})$.

Prop. (3.9.1.18). If $(F, G) : D(\mathcal{A}) \to D(\mathcal{B})$ is an adjunction pair of exact functors, then F has cohomological dimension bounded by N iff G has homological dimension bounded by N.

Proof: If F has cohomological dimension bounded by N, let $K \in D^{\geq m}(\mathcal{B})$, then

$$\mathrm{Hom}_{D(\mathcal{A})}(\tau_{\leq m-N-1}GK, GK) = \mathrm{Hom}_{D(\mathcal{B})}(F\tau_{\leq m-N-1}GK, K) = 0.$$

The dual case is similar. □

2 K-injectives and K-Adapted Classes

Prop. (3.9.2.1) [K-injectives]. For an Abelian category $\mathcal{A}$, a complex $I^\bullet$ in $K(\mathcal{A})$ is called a **K-injective** object iff it satisfies the following equivalent conditions:

- $\mathrm{Hom}_{K(\mathcal{A})}(S^\bullet, I^\bullet) = 0$ for any acyclic $S^\bullet$ in $K(\mathcal{A})$.
- $\mathrm{Hom}_{K(\mathcal{A})}(N^\bullet, I^\bullet) \cong \mathrm{Hom}_{K(\mathcal{A})}(M^\bullet, I^\bullet)$ for quasi-iso $M^\bullet \to N^\bullet$.
- $\mathrm{Hom}_{K(\mathcal{A})}(X^\bullet, I^\bullet) \cong \mathrm{Hom}_{D(\mathcal{A})}(X^\bullet, I^\bullet)$ for every $X^\bullet$. In particular, a quasi-iso between two K-injective objects is an isomorphism in $K(\mathcal{A})$.
  Dually, we can define **K-projective** objects.

Proof: $1 \to 2$ is by(3.7.4.14); $2 \to 3$ use(3.9.1.7), for $3 \to 1$, notice any acyclic complex is quasi-iso to 0. □

Cor. (3.9.2.2). K-Injectives form a full triangulated subcategory of $K(\mathcal{A})$.

Cor. (3.9.2.3). If $I^\bullet$ is K-injective and quasi-isomorphic to an object in $K^+(\mathcal{A})$, then $I^\bullet \in K^+(\mathcal{A})$.

Cor. (3.9.2.4)[K-Injective Resolutions are Unique]. by item3 of the definition(3.9.2.1), K-injective resolutions are unique in $K(\mathcal{A})$.

Prop. (3.9.2.5)[Injectives and K-Injective]. Objects $K^+(\mathcal{I}_\mathcal{A})$ are all K-injectives. thus the injective resolution is unique in K^+. Dually $K^-(\mathcal{P})$ are all K-projectives.

Proof: Use the first definition of K-injectives(3.9.2.1), we prove any morphism $f : S^\bullet \to I^\bullet$ from an acyclic complex to a K-injective $I^\bullet$ is homotopic to 0 by a homotopy h. Let $I_k = 0$ for $k < n$, choose $h_k = 0$ for $k \leq n$, then $f_k = dh_k + h_{k+1}d$ for $k < n$. We use induction on n to find $h_k, k \leq n$ that $f_k = dh_k + h_{k+1}d$ for $k < n$ Suppose h_k are constructed for $k \leq n$, for $n+1$, $(f_n - dh_n)d = f_nd - df_{n-1} = 0$, thus $f_n - dh_n = h_{n+1}d$ for some h_{n+1} as I_n is injective. Then we are done. □

Prop. (3.9.2.6). If a functor f between Abelian categories is left adjoint to an exact functor, then it preserves K-injectives (use definition1).

Prop. (3.9.2.7) [Products of K-Injectives]. Let $\mathcal{A}$ be an Abelian category, I_t be K-injective complexes. If the termwise product of I_t exists, then it is also K-injective, and is the products of I_t in $D(\mathcal{A})$.

Proof: It is clearly K-injective by(3.9.2.1) item1 as it is the product in the category $K(\mathcal{A})$. Thus we can easily use the (3.9.2.1) item3 to see that $I^\bullet$ is also the product in the category $D(\mathcal{A})$. □

Lemma (3.9.2.8). [Sta]070M

Prop. (3.9.2.9) [Functorial K-injective Resolution]. If $\mathcal{A}$ is an Abelian category having enough injectives and exact countable products, then every complex is quasi-isomorphic to a K-injective complex that each term is injective.

Moreover, if $\mathcal{A}$ is a Grothendieck category, then the K-injective resolution can be chosen to be functorial.

Remark (3.9.2.10). Maybe this can be extended to any large enough class of elements, at least for $K^+(\mathcal{A})$.

Proof: By(3.9.2.8), it suffices to show that $K \to R\lim \tau_{\geq -n}K$ is a quasi-isomorphism for all complex K. But this is clear from the distinguished triangle

$$R\lim \tau_{\geq -n}K \to \prod \tau_{\geq -n}K \to \prod \tau_{\geq -n}K \to R\lim \tau_{\geq -n}K[1]$$

and the fact $H^p(\prod \tau_{\geq -n}K) = \prod_{p \geq -n} H^p(K)$.

For the second assertion, Cf.[Sta]079P.**?** □

K-Adapted Classes

Def. (3.9.2.11)[K-Adapted Classes]. Let $\mathcal{A}$ be an Abelian category, $\mathcal{D}$ a triangularized category and $F : K(\mathcal{A}) \to \mathcal{D}$ a triangularized functor, a **K-adapted class** for F is a full triangulated subcategory $\mathcal{R} \subset K(\mathcal{A})$ that

- If $I \to I'$ is a quasi-isomorphism in $\mathcal{R}$, then $F(I) \to F(I')$ is an isomorphism in $\mathcal{D}$.
- Every $A^\bullet \in K(\mathcal{A})$ admits some quasi-isomorphism $A^\bullet \to I^\bullet$ where $I^\bullet \in \mathcal{R}$.

Cor. (3.9.2.12) [K-Injective is K-Adapted]. If $\mathcal{A}$ has sufficiently many K-injectives, then the class of K-injectives is K-adapted to any left exact functor F, by(3.9.2.2) and(3.9.2.1).

3 Derived Functors

Def. (3.9.3.1) [Right Derived Functors]. Let $\mathcal{A}$ be an Abelian category, E a triangularized category and $F : K(\mathcal{A}) \to \mathcal{D}$ an exact functor between triangulated categories. Then a **right derived functor** of F is an exact functor $RF : D(\mathcal{A}) \to \mathcal{D}$ together with a natural transformation $\eta : F \to RF \circ Q_{\mathcal{A}}$ that satisfies the following universal property: For any exact functor $G : D(\mathcal{A}) \to \mathcal{D}$ and a natural transformation $\eta' : F \to G \circ Q_{\mathcal{A}}$, there is a natural transformation $\theta : RF \to G$ that $\eta' = (\theta \star Q_{\mathcal{A}}) \circ \eta$.

In particular, if RF exists, then it is unique up to unique isomorphism of exact functors.

Prop. (3.9.3.2) [Derived Functors via K-Adapted Classes]. Let $\mathcal{A}$ be an Abelian category, $\mathcal{D}$ a triangularized category and $F : K(\mathcal{A}) \to E$ an exact functor, if there exists a K-adapted class $\mathcal{R}$ for F, then RF exists. Moreover, for $I \in \mathcal{R}$, the morphism $\eta_I : F(I) \to RF \circ Q_{\mathcal{A}}(I)$ is an isomorphism in $\mathcal{D}$.

Proof: Let $S = \mathcal{R} \cap \mathrm{QIso}(\mathcal{A})$, then $\mathcal{R}, K(\mathcal{A})$ and the localizing systems $S, \mathrm{QIso}(\mathcal{A})$ satisfy the conditions in(3.9.1.6), so $\iota : S^{-1}\mathcal{R} \subset D(\mathcal{A})$ is a full triangulated subcategory, and it is also essentially surjective, thus it is an equivalence of categories. Let I be a right adjoint of the inclusion, then I is also an exact functor(3.7.7.9), and there is a natural isomorphism $\zeta : \mathrm{id}_{D(\mathcal{A})} \cong \iota \circ I$.

By the universal property, there is an exact functor $F_{\mathcal{R}} : S^{-1}\mathcal{R} \to \mathcal{D}$ extending $F|_{\mathcal{R}}$. Define

$$RF = F_{\mathcal{R}} \circ I : D(\mathcal{A}) \to \mathcal{D}.$$

To construct $\eta : F \to RF \circ Q_{\mathcal{A}}$, for any $X \in \mathrm{Ob}(K(\mathcal{A})) = \mathrm{Ob}(D(\mathcal{A}))$, the isomorphism ζ gives an isomorphism $X \cong \iota(I(X))$, which is represented by a roof $(R, f, s^{-1}), f, s \in \mathrm{QIso}(\mathcal{A})$, and we can assume $R \in \mathrm{Ob}(\iota(S^{-1}\mathcal{R})) = \mathrm{Ob}(\mathcal{R})$ by hypothesis, thus $s \in S$, and $F(s)$ is an isomorphism in E by hypothesis. Thus we get a morphism $\eta_X : F(s)^{-1} \circ F(f) : F(X) \to F(\iota(I(X))) = RF(Q_{\mathcal{A}}(X))$. This η_X is independent of the representation given, because if there is another dominant roof $(R', t \circ f, (t \circ s)^{-1})$, where $t : R \to R' \in S$, then $F(t \circ s)^{-1} \circ F(t \circ f) = F(s)^{-1} \circ F(f) \in E$.

And for a morphism $f : X \to Y \in K(X)$, ζ gives a commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{\zeta_X} & \iota(I(X)) \\ \big\downarrow{\scriptstyle f} & & \big\downarrow{\scriptstyle \iota(I(f))} \\ Y & \xrightarrow{\zeta_Y} & \iota(I(Y)) \end{array}$$

in $D(\mathcal{A})$ where ζ_X, ζ_Y are represented by $(R_X, f_X, s_X^{-1}), (R_Y, f_Y, s_Y^{-1})$, and $I(f)$ is represented (R_0, f_0, s_0^{-1}), then we can construct roof to realize this commutative diagram in $K(\mathcal{A})$ and show there is a commutative diagram

$$\begin{array}{ccc} F(X) & \xrightarrow{F(s_X)^{-1} \circ F(f_X)} & RF(Q_{\mathcal{A}}(X)) \\ \big\downarrow{\scriptstyle F(f)} & & \big\downarrow{\scriptstyle F(s_0)^{-1} \circ F(f_0) = RF \circ Q_{\mathcal{A}}(f)} \\ F(Y) & \xrightarrow{F(s_Y)^{-1} \circ F(f_Y)} & RF(Q_{\mathcal{A}}(Y)) \end{array}$$

in E, which means $\eta : F \to RF \circ Q_{\mathcal{A}}$ is a natural isomorphism.

Notice that η_I is an isomorphism for $I \in \mathcal{R}$, because in this case $F(f_I), F(s_I)$ are both isomorphisms.

It remains to show the universal properties of η: Given any exact functor $G : D(\mathcal{A}) \to E$ and a natural transformation $\eta' : F \to G \circ Q_{\mathcal{A}}$, for any $X \in \mathrm{Ob}(K(\mathcal{A})) = \mathrm{Ob}(D(\mathcal{A}))$, we get a morphism $\eta'_X : F(X) \to G(X)$ in E. Notation as before, because η' is a natural transformation, we get a commutative diagram in $K(\mathcal{A})$

$$\begin{array}{ccc} F(X) & \xrightarrow{\eta'_X} & G(X) \\ \downarrow{\scriptstyle F(f)} & & \downarrow{\scriptstyle G(Q_{\mathcal{A}}(f))} \\ F(R_X) & \xrightarrow{\eta'_{R_X}} & G(R_X) \\ \uparrow{\scriptstyle F(s)} & & \uparrow{\scriptstyle G(Q_{\mathcal{A}}(s))} \\ F(\iota(I(X))) & \xrightarrow{\eta'_{\iota(I(X))}} & G(\iota(I(X))) \end{array}$$

In E. As $\zeta_X = (R_X, f, s^{-1})$ is an isomorphism between X and $\iota(I(X))$, f, s are both quasi-isomorphisms, thus the vertical arrows are both isomorphisms, and we get a commutative diagram

$$\begin{array}{ccc} F(X) & \xrightarrow{\eta'_X} & G(X) \\ \downarrow{\scriptstyle \eta_X} & & \downarrow{\scriptstyle G(\zeta_X)} \\ RF(Q_{\mathcal{A}}(X)) & \xrightarrow{\eta'_{\iota(I(X))}} & G(\iota(I(X))) \end{array}.$$

So we can define
$$\theta_X = (G(\zeta_X))^{-1} \circ \eta'_{\iota(I(X))} : RF(Q_{\mathcal{A}}(X)) \to G(X),$$
then it is is functorial in X as both $\eta'_{\iota(I(X))}$ and $G(\zeta_X)$ are functorial in X, so defines a natural transformation $RF \circ Q_{\mathcal{A}} \to G$ that $(\theta \star Q_{\mathcal{A}}) \circ \eta = \eta'$.

For the uniqueness of η: For any $X \in \mathrm{Ob}(S^{-1}\mathcal{R}) = \mathrm{Ob}(\mathcal{R})$, η_X is an isomorphism, thus η_X is determined, but $\iota : S^{-1}\mathcal{R} \to D(\mathcal{A})$ is essentially surjective, so η_X is determined for any $X \in D(\mathcal{A})$. □

Cor. (3.9.3.3) [Derived Functors via K-Injective Classes]. Let $\mathcal{A}$ be an Abelian category, E a triangularized category and $F : K^*(\mathcal{A}) \to E$ an exact functor, if $K^*(\mathcal{A})$ has enough K-injectives, then the class of K-injectives is K-adapted to F(3.9.2.12), so $RF : D^*(\mathcal{A}) \to E$ exists. Moreover, for any K-injective $I^\bullet$, the morphism $\eta_{I^\bullet} : F(I^\bullet) \to RF \circ Q_{\mathcal{A}}(I^\bullet)$ is an isomorphism in E

Cor. (3.9.3.4) [Derived Functors via Injectives]. Let $\mathcal{A}, \mathcal{B}$ be Abelian categories s.t $\mathcal{A}$ has enough injective and countable products, and $F : \mathcal{A} \to \mathcal{B}$ an additive functor, then $K^*(F) : K^*(\mathcal{A}) \to D^*(\mathcal{A})$ is an exact functor by(3.7.7.17), and $K^*(\mathcal{A})$ has enough K-injectives by(3.9.2.9).

However, this is useless unless F is left exact in which case we see $R^0F(A) = F(A)$ for any $A \in \mathcal{A}$ by(3.9.3.3).

Cor. (3.9.3.5) [Naturality]. If $\eta : F \to F'$ is a natural transformation of left-exact functors, then by universal property(3.9.3.1), there is a natural transformation $R\eta : RF \to RF'$ inducing a long exact sequence about cohomology groups extending η.

Prop. (3.9.3.6) [Composition of Derived Functors]. $\mathcal{A}, \mathcal{B}$ be Abelian categories and $\mathcal{D}$ a triangulated category. If $F : K^*(\mathcal{A}) \to K^*(\mathcal{B}), G : K^*(\mathcal{B}) \to \mathcal{D}$ are exact functors between triangulated categories, and $\mathcal{R}_{\mathcal{A}}$ is K-adapted to F and $G \circ F$, $\mathcal{R}_{\mathcal{B}}$ is K-adapted to G, then the natural transformation $R(G \circ F) \to RG \circ RF$ is an isomorphism.

Proof: RF is isomorphic to F on $\mathcal{R}_{\mathcal{A}}$, so for any $A^\bullet \in K^*(\mathcal{A})$, choose some quasi-isomorphism $A^\bullet \to R$, where $R \in \mathcal{R}_{\mathcal{A}}$, then there is a commutative diagram

$$\begin{array}{ccccc} R(G\circ F)(A^\bullet) & \xrightarrow{\cong} & R(G\circ F)(R) & \xrightarrow{\cong} & G\circ F(R) \\ \downarrow & & \downarrow & & \downarrow \text{id} \\ RG\circ RF(A^\bullet) & \xrightarrow{\cong} & RG\circ RF(R) & \xrightarrow{\cong} & G\circ F(R) \end{array}$$

$$G\circ F(R) \cong G(F(R)) \to RG(F(I^\bullet)) \cong RG\circ RF(A^\bullet),$$

and we are done. □

Def. (3.9.3.7) [Universal δ-Functors]. A **universal δ-functor** between Abelian categories is one that any natural transformation from T^0 to another δ-functor will generate a δ-map. A **effaceable δ-functor** is one that for any $n > 0$ and any object A, there is an injection $A \to B$ that $T^n(A) \to T^n(B) = 0$.

Prop. (3.9.3.8) [Grothendieck]. A δ-functor is universal if it is effaceable.

Proof: We construct by induction on n. choose a $0 \to A \to B \to C \to 0$ such that $T^{n+1}(A) \to T^{n+1}(B) = 0$ then there is an isomorphism $T^{n+1}(A) \cong \mathrm{Coker}(T^n(B) \to T^n(C))$, and so we can construct the map on T^{n+1} induces by

$$\mathrm{Coker}(T^n(B) \to T^n(C)) \to \mathrm{Coker}(G^n(B) \to G^n(C)) \to G^{n+1}(A).$$

This can be verified to be a δ map. □

Prop. (3.9.3.9). The derived functors form a universal δ-functor (when it exists).

Proof: It is a δ functor by(3.9.1.1), it is universal by(3.9.3.8). □

Prop. (3.9.3.10). Derived functor commutes with filtered colimits on a Grothendieck Abelian category, this is by $AB5$.

Prop. (3.9.3.11) [Hypercohomology]. Given an Abelian category $\mathcal{A}$ with enough injectives, $\mathcal{B}$ a complete Abelian category, $F : \mathcal{A} \to \mathcal{B}$ a left exact functor, and $K \in \mathcal{K}(\mathcal{A})$, we can define the **right hyper-derived functor** of F at K as $\mathbb{R}F(K) = \mathrm{Tot}^\Pi F(P) \in K(\mathcal{B})$ where $K \to P$ is a Cartan-Eilenberg resolution of K. and the **hypercohomologies** of F at K as $R^n F(K) = H^n(\mathrm{Tot}^\Pi F(P))$. Dually we can define the left hyper-derived functor and hyperhomologies.

For complexes in $K^+(\mathcal{A})$, there is no restriction and the right derived-hyper functor descends to a functor from $D^+(\mathcal{A}) \to D^+(\mathcal{B})$.

When the Abelian category $\mathcal{A}$ satisfies AB3* and AB4*, i.e. the direct product is exact, then Tot^Π of the Cartan-Eilenberg resolution of any complex is a quasi-isomorphism to it by the dual of**??**. (Take horizontal filtration, AB4* assures it collapse).

Derived Bifunctors

Def. (3.9.3.12)[Right Derived Functors of Bi-Exact Bi-Functors]. Let $\mathcal{A}, \mathcal{B}$ be Abelian categories and $F : K(\mathcal{A}) \times K(\mathcal{B}) \to \mathcal{D}$ be bi-exact bifunctor between triangulated categories, a **right derived functor** of F is a bi-exact bifunctor $RF : D(\mathcal{A}) \times D(\mathcal{B}) \to \mathcal{D}$ together with a natural transformation $\eta : F \to RF \circ (Q_{\mathcal{A}} \times Q_{\mathcal{B}})$ that satisfies the following universal property: For any bi-exact bifunctor $G : \mathcal{D}(\mathcal{A}) \times \mathcal{D}(\mathcal{B}) \to \mathcal{D}$ and a natural transformation $\eta' : F \to G \circ (Q_{\mathcal{A}} \times Q_{\mathcal{B}})$, there is a natural transformation $\theta : RF \to G$ that $\eta' = (\theta \star (Q_{\mathcal{A}} \times Q_{\mathcal{B}})) \circ \eta$.

In particular, if RF exists, then it is unique up to unique isomorphisms of bi-exact bi-functors.

Prop. (3.9.3.13) [Deriving Bi-Exact Functors]. Let $\mathcal{A}_1, \mathcal{A}_2$ be Abelian categories and $F : K(\mathcal{A}_1) \times K(\mathcal{A}_2) \to \mathcal{D}$ be bi-exact bifunctor between triangulated categories, if $\mathcal{R}_i$ are full subcategories of $\mathcal{A}_i$ s.t.

- If $R_i \to R_i'$ are quasi-isomorphisms in $\mathcal{R}_i$, the induced map $F(R_1, R_2) \to F(R_1', R_2')$ is an isomorphism in $\mathcal{D}$.
- Any $A_i^\bullet \in K(\mathcal{A}_i)$ admits some quasi-isomorphism $A_i^\bullet \to \mathcal{I}_i^\bullet$ where $I_i^\bullet \in \mathcal{R}_i$.

Then the right derived functor(3.9.3.12) RF exists. Moreover, for any $R_i \in \mathcal{R}_i$, $\eta_{R_1,R_2} : F(R_1, R_2) \to RF \circ (Q_{\mathcal{A}_1} \times Q_{\mathcal{A}_2})(R_1, R_2)$ is an isomorphism.

Proof: Let $S_i = \mathcal{R}_i \cap \mathrm{QIso}(\mathcal{A}_i)$, then $\mathcal{R}_i, K(\mathcal{A}_i)$ and the localizing systems $S_i, \mathrm{QIso}(\mathcal{A}_i)$ satisfy the conditions in(3.9.1.6), so $\iota : S_i^{-1}\mathcal{R}_i \subset D(\mathcal{A}_i)$ is a full triangulated subcategory, and it is also essentially surjective, thus it is an equivalence of categories. Let I_i be a right adjoint of the inclusion, then I_i is also an exact functor(3.7.7.9), and there is a natural isomorphism $\zeta_i : \mathrm{id}_{D(\mathcal{A}_i)} \cong \iota_i \circ I_i$.

By hypothesis of universal properties, the functor F extends to an exact functor $F_\mathcal{R} : \prod_i S_i^{-1}\mathcal{R}_i \to \mathcal{D}$. Define

$$RF = F_\mathcal{R} \circ \prod_i \mathcal{I}_i : \prod_i D(\mathcal{A}_i) \to \mathcal{D}.$$

The rest of the proof is verbatim as that of(3.9.3.2). □

Remark (3.9.3.14). This proposition can be naturally extended to any multi-exact multi-functors. In fact, I suppose this can be deduced from the usual derived functors by considering the tensor product category $\mathcal{A} \otimes \mathcal{B}$, Cf.[Basic Concepts of Enriched Category Theory, Kelly].

Prop. (3.9.3.15) [Derived Functors of Adjunctions]. Let $\mathcal{A}_1, \mathcal{A}_2$ be Abelian categories and (F, G) be an adjunction between $K(\mathcal{A}_1)$ and $K(\mathcal{A}_2)$, and $\mathcal{R}_i$ are full subcategories of $\mathcal{A}_i$ s.t.

- If $R_i \to R_i'$ are quasi-isomorphisms in $\mathcal{R}_i$, the induced map $F(R_1', R_2) \to \mathrm{Hom}^\bullet_\mathcal{B}(R_1, R_2')$ is an isomorphism in $D(\mathcal{A}\mathrm{b})$.
- Any $A_1^\bullet \in K(\mathcal{A}_1)$ admits some quasi-isomorphism $A_1^\bullet \to I_1^\bullet$ where $I_1^\bullet \in \mathcal{R}_1$.
- Any $A_2^\bullet \in K(\mathcal{A}_2)$ admits some quasi-isomorphism $I_1^\bullet \to A_2^\bullet$ where $I_2^\bullet \in \mathcal{R}_2$.

then there is a functorial isomorphism

$$R\,\mathrm{Hom}(LF(A^\bullet), B^\bullet) \cong R\,\mathrm{Hom}(A^\bullet, RG(B^\bullet)) \in D(\mathcal{A}\mathrm{b})$$

for $A^\bullet \in K(\mathcal{A}), B^\bullet \in K(\mathcal{B})$. In particular,

$$\mathrm{Hom}(LF(A^\bullet), B^\bullet) \cong \mathrm{Hom}(A^\bullet, RG(B^\bullet)) \in \mathcal{A}\mathrm{b}$$

Proof: Regard both side as a right derived functor of the isomorphic bi-exact bi-functors

$$K(\mathcal{A})^{op} \times K(\mathcal{B}) \to D(\mathcal{A}\mathrm{b}) : (A^\bullet, B^\bullet) \mapsto \mathrm{Hom}^\bullet_\mathcal{B}(F(A^\bullet), B^\bullet) \cong \mathrm{Hom}_\mathcal{A}\bullet(A^\bullet, G(B^\bullet)) \in D(\mathcal{A}\mathrm{b}).$$

Then the functorial isomorphism follows from universal properties. □

Prop. (3.9.3.16). Situation as in(3.9.3.15), for any $K^\bullet \in K(\mathcal{A}_2)$, there is a commutative diagram of adjunction maps

$$\begin{array}{ccc} LF \circ G(K^\bullet) & \longrightarrow & F \circ G(K^\bullet) \\ \downarrow & & \downarrow \\ LF \circ RG(K^\bullet) & \longrightarrow & K^\bullet \end{array}$$

Proof: Cf.[Sta]0FPI. □

Internal Hom

Def. (3.9.3.17) [Internal Hom]. If $\mathcal{A}$ is an Abelian category and $K(\mathcal{A})$ has enough K-injectives or enough K-projectives, thus by(3.9.3.13), we can define the **internal Hom**

$$R\operatorname{Hom} : D(\mathcal{A})^{op} \times D(\mathcal{A}) \to D(\mathcal{A})$$

as the right derived functor of the bi-exact bifunctor $\operatorname{Hom}^\bullet : K(\mathcal{A})^{op} \times K(\mathcal{A}) \to D(\mathcal{A}\mathrm{b})$.

Prop. (3.9.3.18) [Ext Groups]. For $X, Y \in D(\mathcal{A})$, define the **ext groups**

$$\operatorname{Ext}^i_{\mathcal{A}}(X, Y) = H^i(R\operatorname{Hom}(X, Y)) = \operatorname{Hom}_{D(\mathcal{A})}(X[0], Y[i]).$$

Proof: To show $H^i(R\operatorname{Hom}(X, Y)) = \operatorname{Hom}_{D(\mathcal{A})}(X[0], Y[i])$, choose a K-injective resolution $Y \to I^\bullet$ of Y, then

$$H^i(R\operatorname{Hom}(X, Y)) = H^i(\operatorname{Hom}^\bullet(X, I^\bullet)) = \operatorname{Hom}_{K(\mathcal{A})}(X, I^\bullet[n]) = \operatorname{Hom}_{D(\mathcal{A})}(X, I^\bullet[n]) = \operatorname{Hom}_{D(\mathcal{A})}(X, Y[n])$$

by(3.7.4.10) and the definition(3.9.2.1). □

Prop. (3.9.3.19). If $P^\bullet \to X^\bullet$ is a projective resolution, then $\operatorname{Ext}^i(X^\bullet, Y^\bullet) = \operatorname{Hom}_{K(\mathcal{A})}(P^\bullet[-i], Y^\bullet)$. If $Y^\bullet \to I^\bullet$ is an injective resolution, then $\operatorname{Ext}^i(X^\bullet, Y^\bullet) = \operatorname{Hom}_{K(\mathcal{A})}(X^\bullet, I^\bullet)$.

Prop. (3.9.3.20). If $X \in D^{\leq a}(\mathcal{A})$ and $Y \in D^{\geq b}(\mathcal{A})$, then for $i < b - a$, $\operatorname{Ext}^i(X, Y) = 0$, and $\operatorname{Ext}^{b-a}(X, Y) = \operatorname{Hom}(H^a(X), H^b(Y))$.

In particular, for $A, B \in \mathcal{A}$, $\operatorname{Ext}^i(A, B) = 0$ for $i < 0$ and $\operatorname{Ext}^0(A, B) = \operatorname{Hom}(A, B)$.

Proof: This is because X can be represented by $K^{\leq a}(\mathcal{P})$ or Y can be represented by $K^{\geq b}(\mathcal{I})$. □

Prop. (3.9.3.21) [Long Exact Sequences]. Let $0 \to A_1 \to A_2 \to A_3 \to 0$ be an exact sequence in $\mathcal{A}$, then it is distinguished in $D(\mathcal{A})$, so by(3.7.7.12), for any $B \in \mathcal{A}$, there is a long exact sequence

$$0 \to \operatorname{Hom}(B, A_1) \to \operatorname{Hom}(B, A_2) \to \operatorname{Hom}(B, A_3) \to \operatorname{Ext}^1(B, A_1) \to \operatorname{Ext}^1(B, A_2) \to \ldots,$$

and similarly a long exact sequence

$$0 \to \operatorname{Hom}(A_3, B) \to \operatorname{Hom}(A_2, B) \to \operatorname{Hom}(A_1, B) \to \operatorname{Ext}^1(A_3, B) \to \operatorname{Ext}^1(A_2, B) \to \ldots.$$

Def. (3.9.3.22) [Yoneda Extensions]. Let $\mathcal{A}$ be an Abelian category and $A, B \in \mathcal{A}$, a **Yoneda extension** of B by A of degree d is an exact sequence

$$0 \to A \to Z_{d-1} \to \ldots \to Z_0 \to B \to 0.$$

One Yoneda extension is said to **dominate** another if there is a map of extensions s.t. restricts to id_A and id_B. Two Yoneda extensions of degree d is called **equivalent** if they are dominated by a common Yoneda extension.(Notice this is an equivalence relation by(3.9.3.23).

Prop. (3.9.3.23) [Ext and Yoneda Extensions]. There is a map from the equivalence classes of Yoneda extensions of degree d of B over A to $\operatorname{Ext}^d(B, A)$, which maps the exact sequence $0 \to A \to Z_{d-1} \to \ldots \to Z_0 \to B \to 0$ to $fs^{-1} \in \operatorname{Hom}_{D(\mathcal{A})}(B[0], A[d])$, where $f : (A \to Z_{d-1} \to \ldots \to Z_0) \to A[d]$, and $s : (A \to Z_{d-1} \to \ldots \to Z_0) \to B[0]$.

and corresponds to the set of i-term extensions of Y by X. There is a natural map

$$\operatorname{Ext}^i_{\mathcal{A}}(X, Y) \times \operatorname{Ext}^i_{\mathcal{A}}(Y, Z) \to \operatorname{Ext}^{i+j}_{\mathcal{A}}(X, Z)$$

by composition or equivalently the conjunction of extensions.

Proof: Cf.[Sta]06XU. □

Prop. (3.9.3.24)[Explicit Addition as Extensions]. In an Abelian category with enough injectives, the extension $\mathrm{Ext}^1(N, M)$ is equivalent with the Abelian group of extensions with Baer sum as addition.

Proof: We choose a projective resolution $0 \to K \to P \to N \to 0$, so $\mathrm{Hom}(K, M) \to \mathrm{Ext}^1(N, M)$ is surjective, so choose a lifting and the pushout $0 \to M \to L \to N \to 0$ with be the corresponding extension, Now the Baer sum is easy to define and verify. □

Prop. (3.9.3.25). If $\mathcal{A}$ is an Abelian category and $p \geq 0$ s.t. $\mathrm{Ext}^p(A, B) = 0$ for any $A, B \in \mathcal{A}$, then $\mathrm{Ext}^i(A, B) = 0$ for any $i \geq p$ and $A, B \in \mathcal{A}$.

Proof: Any Yoneda extension of degree i is a conjunction of extensions of degree p and degree $i-p$. □

Cor. (3.9.3.26). If $\mathcal{A}$ is an Abelian category s.t. $\mathrm{Ext}^2(A, B) = 0$ for any $A, B \in \mathcal{A}$, then each object of $D^b(\mathcal{A})$ is isomorphic to a direct sum of cohomologies.

Proof: Let K be represented by $K^\bullet \in D^{[a,b]}(\mathcal{A})$. We use induction on $b - a$. If $b - a > 0$, then there is a distinguished triangle $\tau_{\leq b-1}K \to K^\bullet \to H^b(K)[-b] \to \tau_{\leq b-1}K^\bullet[1]$(3.9.1.4). If we can prove $H^b(K)[-b] \to \tau_{\leq b-1}K^\bullet[1]$ is 0, then we finish by(3.7.7.4). But by induction and the hypothesis,

$$\mathrm{Hom}_{D(\mathcal{A})}(H^b(K)[-b], \tau_{\leq b-1}(K^\bullet)[1]) = \oplus_{i<b} \mathrm{Ext}_{\mathcal{A}}^{b-i+1}(H^b(K), H^i(K)),$$

which vanishes by hypothesis. □

Acyclic Objects

Prop. (3.9.3.27) [F-Acyclic Objects]. For a left exact functor F, an object X is (right)F-acyclic if RF is defined for X, and the natural map $F(X) \to RF(X)$ is an isomorphism, or equivalently $R^iF(X) = 0$ for all $i > 0$.

Then there is an adapted class of F iff the class of F-acyclic objects $Acy(F)$ is sufficiently large, and in this case adapted classes of F are exactly sufficiently large subclasses of $Acy(F)$, and $Acy(F)$ contains all injectives(But the class of injectives may not be sufficiently large!).

Proof: Cf.[Gelfand P195]. □

Prop. (3.9.3.28) [Leray's Acyclicity Lemma]. Let $F : \mathcal{A} \to \mathcal{B}$ be an additive functor and RF is everywhere defined, then for a complex $A^\bullet$ in $K^+(\mathcal{A})$ consisting of F-acyclic objects, the natural map $F(A^\bullet) \to RF(A^\bullet)$ is an isomorphism.

Proof: Cf.[Sta]015E. This may be equivalent to(3.9.3.27). □

Prop. (3.9.3.29) [Acyclic Criterion]. Let F be a left exact functor from an Abelian category $\mathcal{C}$ of enough injectives to another Abelian category, T is a class of objects of $\mathcal{C}$ that satisfies:

- T is sufficiently large.
- Cokernel of maps between elements of T is in T and $0 \to F(A) \to F(A') \to F(\mathrm{Coker}) \to 0$ is exact. (To use induction).

Then every object of T is F-acyclic.

Proof: Cf.[[Sta]05T8]. □

Prop. (3.9.3.30) [Injectives are adapted]. By(3.9.2.5), if $\mathcal{A}$ contains sufficiently many injectives, then injective objects are adapted to any left exact functor F. (Because id on acyclic injective complexes is homotopic to 0 by the lemma).

4 $D_\infty(R)$

5 (Co)Homological Dimension

Prop. (3.9.5.1). If $\mathcal{A}$ has enough projectives, then the projective dimension of an object X is the length of projective resolutions. (Use resolution and long sequence).

Prop. (3.9.5.2) [Hilbert Theorem]. For an Abelian category $\mathcal{A}$, the category $\mathcal{A}[T]$ is an Abelian category. If $\mathcal{A}$ has enough projectives and have infinite direct sum, then $\mathrm{dhp}_{\mathcal{A}[T]}(X,t) \leq \mathrm{dhp}_{\mathcal{A}}(X)+1$ and equality with $t=0$.

Cor. (3.9.5.3). The Categories $\mathcal{A}$b and $K[X]$-mod have homological dimension 1. $K[X_i,\ldots,X_k]$ has homological dimension k.

Def. (3.9.5.4)[Injective Amplitude]. Let $\mathcal{A}$ be an Abelian category with enough injectives, $K \in D(A)$ is said to have **finite injective dimension** if $K \in D^b(\mathcal{I})$. It is said to have **injective amplitude in** $[a,b]$ if $K \in D^{[a,b]}(\mathcal{I})$.

Prop. (3.9.5.5). Let $\mathcal{A}$ be an Abelian category and $K \in D(\mathcal{A})$,

- If $K \in D^b(\mathcal{A})$ and $H^i(K)$ all have finite injective dimensions, then K also has finite injective dimension.
- If K is represented by $K^\bullet \in K^b(\mathcal{A})$, and K^i all have finite injective dimensions, then K also has finite injective dimension.

Proof: 1 follows from the Grothendieck spectral sequence applied to the functor $\mathrm{Hom}(N,-)$ for any $N \in \mathcal{A}$ and the CE resolution of K(3.7.6.10).

2 follows from 1 as we can use induction to show all $H^i(K)$ has finite injective dimensions. □

6 Derived Limits and Colimits

Def. (3.9.6.1) [Derived (Co)Limits]. Let $\mathcal{D}$ be a triangulated category, and (K_n, f_n) is an inverse system of objects in $\mathcal{D}$, then an object K is called the **derived colimit** of it iff there $\oplus K_n$ exists and there is a distinguished triangle

$$\oplus K_n \to \oplus K_n \to K \to \oplus K_n[1]$$

where the first map is given by $(1-f_n)$. By TR1, the derived colimit exists as long as $\oplus K_n$ exists, and by TR3(3.7.7.12), the colimit is unique if it exists. And by TR3 again a morphism of systems induces a morphism of colimits.

The definition of **derived limit** is dual.

Prop. (3.9.6.2)[Cofinality of Hocolim]. Let $\mathcal{D}$ be a triangulated category and (K_n, f_n) be a system, if $0 \leq n_{i_0} < n_{i_1} < \ldots$ be a sequence of integers, then there is an isomorphism $ho\operatorname{colim} K_{n_i} \to ho\operatorname{colim} K_n$.

Proof: Cf.[[Sta]0CRJ]. □

Lemma (3.9.6.3). Let $\mathcal{A}$ be an Abelian category with countable products and enough injectives, then the derived limit $R\lim$ for any inverse system in $D^+(\mathcal{A})$ exists.

Proof: It suffices to show $\prod K_i^\bullet$ exists in $D(\mathcal{A})$. But every $K_n^\bullet$ has a K-injective resolution $I_n^\bullet$, by(3.7.6.10)(3.9.2.5). And then $\prod K_n^\bullet$ is represented by $\prod I_n^\bullet$, by(3.9.2.7). □

Def. (3.9.6.4) [Rlim]. Rlim on an Abelian category $\mathcal{A}$ with countable products and enough injectives is defined to be the right derived functor of $\lim : \mathcal{A}^{\mathbb{N}} \to \mathcal{A}$. Equivalently, it is just the derived limit(3.9.6.1)(3.9.6.3) in $D(\mathcal{A})$ restricted to the case where each K_n is discrete.

Prop. (3.9.6.5). Let $R\lim A$ exists on $\mathcal{A}$, if K_n, f_n is a system of objects in $D^+(\mathcal{A})$, then there are exact sequences

$$0 \to R^1 \lim(H^m(K_n), f_n) \to R^{m+1} \lim(K_n, f_n) \to \lim(H^m(K_n), f_n) \to 0.$$

Immediately from the definition(3.9.6.1).

7 Spectral Sequence

Reference for this section is [Weibel Ch5]. All the definition below is dual for homology and cohomology, just rotate the diagram 180 degree.

We work in an Abelian category.

Def. (3.9.7.1). A convergent **Spectral Sequence** is a three-dimensional arrange of entries $E_r^{p,q}$ that:

1. $d_r : E_r^{p,q} \to E_r^{p+r,q-r+1}$ that $d_r d_r = 0$.
2. $H^{p,q}(E_r^{p,q}) \cong E_{r+1}^{p,q}$. And $E_r^{p,q}$ has a direct limit $E_\infty^{p,q}$.
3. There is a complex $E^\bullet$ and a decreasing bounded filtration $F^p E^n$ on each E^n and $E_\infty^{p,q} \cong F^p E^{p+q}/F^{p+1}E^{p+q}$.

Def. (3.9.7.2) [Notations For Cohomological Spectral Sequence].

- The cohomology filtration is called **bounded below** $F^{n_s}E^n = 0$ for some n_s, it is called **bounded above** $F^{n_s}E_n = E^n$ for some n^s.
- The cohomology filtration is called **exhaustive** iff $\cup F^i E^n = E^n$.
- The spectral sequence is called **regular** iff $d^r_{pq} = 0$ for sufficiently large r.
- A spectral sequence is said to **weakly converges** to $E^\bullet$ if there is a filtration

$$\ldots \subset F^t H^n \subset F^{t-1} H^n \subset \ldots \subset F^s H^n \subset \ldots \subset H^n$$

  that $E_\infty^{pq} \cong F^p H^{p+q}/F^{p+1}H^{p+q}$.
- A spectral sequence **approaches** $E^\bullet$ if it weakly converges to $E^\bullet$.
- A spectral sequence **converges** to $E^\bullet$ if it approaches $E^\bullet$, it is regular, and $E^n = \varprojlim(E^n/F^p E^n)$.
- If a first quadrant spectral sequence converges to $E^\bullet$, then the morphisms $E_0^{n,0} \to E_\infty^{n,0} \subset E^n$ and $E^n \to E_\infty^{0,n} \to E_0^{0,n}$ are called the **edge morphisms**.

Prop. (3.9.7.3) [Notation for Filtrations on Homological Complexes]. Let $C_\bullet$ be a complex and $\ldots \subset F_{p-1}C \subset F_p C \subset \ldots \subset C$ be filtrations of complexes. Then it is called **exhaustive** if $C = \cup F_p C$. It is called **Hausdorff** if $\cap F_p C = 0$. It is called **complete** if $C = \varprojlim C/F_p C$.

Def. (3.9.7.4) [Spectral Sequence of a Filtered Complex]. For a complex $K^\bullet$ and a filtration $F^p K^n$ on K^n, we have a natural spectral sequence

$$E_1^{pq} = H^{p+q}(F^p E^{p+q}/F^{p+1}E^{p+q}), \quad E^n = H^n(K^\bullet), \quad F^p E^n = H^n(F^p K^\bullet).$$

For a morphism of filtered complexes that are isomorphism for some r, induction on the exact sequence $0 \to F^pE^n \to F^{p+1}E^n \to E_\infty^{p,n-p}$ and use five-lemma shows it induces isomorphism on H^*E.

Prop. (3.9.7.5) [Comparison Theorem]. For a morphism F between two convergent spectral sequences, if it is an isomorphism for some r, then it induce isomorphism on the infinite homologies.

Proof: Clearly F induces isomorphisms on $E_\infty^{p,q}$. Because there are exact sequence

$$0 \to F^{p+1}H^n \to F^pH^n \to E_\infty^{p,n-p} \to 0$$

we can use five lemma and induction to show that F induces isomorphisms on F^pH^n/F^sH^n. Then because $H^n = \cup F^pH^n$, we can take colimit to show F induces isomorphisms on H^n/F^sH^n, then take inverse limits, we are done. □

Prop. (3.9.7.6) [Classical Convergence]. If the filtration on a complex $C_\bullet$ is bounded below and exhaustive for all C_n, then there is a spectral sequence that is also bounded below and converges to $H_\bullet(C_\bullet)$.

Proof: Cf[Gelfand P203] for cohomological case and [Weibel P135] for homological case. □

Prop. (3.9.7.7) [Complete convergence]. If the filtration is complete, exhaustive and the spectral sequence is regular, then the spectral sequence weakly converges to $H_\bullet(C_\bullet)$. And if it is also bounded above, then it converges to $H_\bullet(C_\bullet)$.

Proof: Cf.[Weibel, P139]. □

There are two examples, the stupid filtration and the canonical filtration, the canonical filtration is natural and factors through $D(\mathcal{A})$.

Prop. (3.9.7.8) [Spectral Sequence of a Double Complex]. A double complex has two natural filtration of the total complex, they defines two spectral sequence, one has

$$E_{2,x}^{p,q} = H_x^p(H_y^{\bullet,q}(L^{\bullet,\bullet}))$$

and the other has

$$E_{2,y}^{p,q} = H_y^p(H_x^{q,\bullet}(L^{\bullet\bullet})).$$

Cf.[Gelfand P209]. In fact under reflection, there is only one spectral sequence. For the horizontal filtration, the differential goes vertical first, for the vertical filtration, the differential goes horizontal first. The differential goes one way, the convergence goes reversely.

If both the filtration is finite and bounded, in particular if E is in the first quadrant, then they both converges to $H^n(E)$, this will generate important consequences.

Cor. (3.9.7.9). If a double complex in the first quadrant has its all column acyclic (3rd-quadrant pointing), then the total complex is acyclic. Thus a morphism of double complex inducing quasi-isomorphism on each column induces a quasi-isomorphism on the total complex.

If a double complex has $H_p(C_{*,q}) = 0, \forall p > 0, q$, then

$$H_n(\mathrm{Tot}C_{*,*}) = H_n(\mathrm{Coker}(C_{1,*} \to C_{0,*})$$

Prop. (3.9.7.10) [Horizontal Filtration]. For a second-quadrant-free homology double complex, the filtration is bounded below and exhaustive for $\mathrm{Tot}^{\oplus}$, so the classical convergence(3.9.7.6) applies and there is a convergence

$$E^2_{p,q} = H^h_p H^v_q(C) \Rightarrow H_{p+q}\mathrm{Tot}^{\oplus}(C).$$

For a fourth-quadrant free homology double complex, the filtration is complete and exhaustive for Tot^{Π}, so the complete convergence(3.9.7.7) applies and there is a weak convergence

$$E^2_{p,q} = H^h_p H^v_q(C) \Rightarrow H_{p+q}\mathrm{Tot}^{\Pi}(C).$$

Cor. (3.9.7.11) [Grothendieck Spectral Sequence]. If $\mathcal{A},\mathcal{B},\mathcal{C}$ be Abelian categories, $\mathcal{B}$ have enough injectives and $F : K^+(\mathcal{A}) \to K^+(\mathcal{B}), G : K^+(\mathcal{B}) \to K^+(\mathcal{C})$ are exact functors between triangulated categories. If $\mathcal{R}_{\mathcal{A}}$ is adapted to $F, G\circ F$, then for any $X^\bullet \in K^+(\mathcal{A})$, there is a spectral sequence convergence(to upper left)

$$E_2^{p,q} = R^pG(R^qF(X)) \Longrightarrow E^n = R^n(G\circ F)(X).$$

And if $\mathcal{R}_{\mathcal{A}} = \mathcal{I}_{\mathcal{A}}$, this spectral sequence is functorial in $X^\bullet$.

In particular, this applies to the case that F is right adjoint to an exact functor and both $\mathcal{A},\mathcal{B}$ have enough injectives.

Proof: Choose a functorial injective resolution $X \mapsto I^\bullet_X$(3.9.2.9), let $K^\bullet = F(I^\bullet_X) = RF(X)$, and choose a functorial CE resolution of $K^\bullet$(3.7.6.10), because the resolutions for $B^i \to Z^i \to H^i$ and $Z^i \to K^i \to B^{i+1}$ split and G is additive, we have

$$H^{q,\bullet}_x(G(L^{\bullet,\bullet})) = G(H^{q,\bullet}_x(L^{\bullet,\bullet})) = RG(H^q(K))$$

So

$$E^{p,q}_{2,y} = H^p_y(H^{q,\bullet}_x(L^{\bullet\bullet})) = R^pG(H^q(K)) = R^pG(R^qF(X))$$

and

$$E^\bullet = RG(\mathrm{Tot}(L)) = G(\mathrm{Tot}(L)) = RG(K) = RG\circ RF(X) \cong R(G\circ F)(X)(3.9.3.6).$$

□

Cor. (3.9.7.12). The low degree parts read:

$$0 \to R^1G(F(A)) \to R^1(G\circ F)(A) \to G(R^1F(A)) \to R^2(G)(F(A)) \to R^2(G\circ F)(A).$$

(Check definition). More generally, if $R^pG(R^qF(A)) = 0, 0 < q < n$, then

$$R^mG(F(A)) \cong R^m(G\circ F)(A) \quad m < n$$

And

$$0 \to R^nG(F(A)) \to R^n(G\circ F)(A) \to G(R^nF(A)) \to R^{n+1}(G(F(A)) \to R^{n+1}(G\circ F)(A).$$

Remark (3.9.7.13). The Grothendieck spectral sequence is tremendously important.

Cor. (3.9.7.14) [Spectral Sequence for Hypercohomologies]. For chain complex K in $K^+(\mathcal{A})$ and a left exact functor F, the CE resolution will generate two spectral sequences by(3.9.7.10):

$$E^{p,q}_{2,x} = H^p_x(R^qF(A)) \Rightarrow \mathbb{R}^{p+q}(A), \text{when } A \text{ is bounded below}$$

$$E^{p,q}_{2,y} = (R^pF)(H^q(A)) \Rightarrow \mathbb{R}^{p+q}(A). \text{weakly convergent}$$

where the RHS is the hypercohomologies(3.9.3.11).

8 T-Structures

Examples

3.10 Differential Graded Algebras

Main references are [Ker] and [Sta].

Def. (3.10.0.1)[Differential Graded Algebras]. A **differential graded algebra** or *DGA* is a chain complex $A^\bullet$ of R-modules with R-linear maps $A^m \times A^n \to A^{m+n}$ that

$$d(ab) = d(a)b + (-1)^n ad(b).$$

that makes $\oplus A^n$ into an associative and unital R-algebra.

Notice the first condition is equivalent to giving a map $\mathrm{Tor}(A^\bullet \times_R A^\bullet) \to A$.

For a differential algebra $A^\bullet$, a right **differential module** is defined naturally. The tensor operation gives a closed symmetric monoidal structure $\mathcal{M}_A$.

Notice a usual R-algebra A can be seen as a differential graded algebra as $A^0 = A$ and $A^n = 0$ for $n > 0$.

And as in the case of chain complexes, the category of differential modules over A can be given a derived category.

Def. (3.10.0.2). A differential graded algebra $A^\bullet$ is called **commutative** if $ab = (-1)^{\deg(a)\deg(b)} ba$. It is called **strictly commutative** if moreover $a^2 = 0$ for $\deg(a)$ odd.

Def. (3.10.0.3). For two differential graded algebras A, B, the tensor graded algebra $A^\bullet \otimes B^\bullet$ is given by the $\mathrm{Tor}(A^\bullet \otimes_R B^\bullet)$.

1 dg-Categories

Def. (3.10.1.1) [dg-Categories]. Given a DGA A, a **dg-category** over A is a category enriched over the monoidal category $\mathcal{M}_A$(3.10.0.1). Let $dgCat_A$ denote the category of small dg-categories over A where morphisms are given by monoidal functors.

Def. (3.10.1.2) [Homotopy Categories]. Because H^0 and Z^0 are right-lax monoidal functors from $\mathrm{Ch}(R)$ to $\mathrm{Mod}(R)$, given a dg-category $\mathcal{C}$, by transferring, we can get categories $H^0(\mathcal{C})$ and $Z^0(C)$ enriched over Mod_{A^0}.

Def. (3.10.1.3) [Equivalences]. A morphism between dg-categories are called an **equivalence** if induces quasi-isomorphisms on all hom-complexes.

Prop. (3.10.1.4) [Model Category of dg-Categories]. There is a cofibrantly generated model category on $dgCat_A$, where weak equivalences are quasi-equivalences and the fibrations are morphisms $F : \mathcal{A} \to \mathcal{B}$ that:

- induces component-wise surjections on hom-complexes.
- given an isomorphism $g : F(X) \to Y \in H^0(\mathcal{B})$, there is an isomorphism in $H^0(\mathcal{A})$ lifting g.

This monoidal structure is induced from that of the case $A = R$ and the right-lax monoidal functor $Ch(R) \to \mathcal{M}(A)$ given by $M^\bullet \mapsto A \otimes M$.

Proof: Cf.[Tabuada, Gon calo. Une structure de catgorie de modles de Quillen sur la catgorie des dg- catgories. C. R. Acad. Sci. Paris Sr. I Math. 340 (1) (2005), 15-19. (2005), 3309?3339.] □

2 Sheaves of DGAs

3.11 Topology II

1 Topological Groups

Def. (3.11.1.1). A **topological group** is a group object in the category of groups(3.1.1.65).

Prop. (3.11.1.2). If U is a nbhd of 1 in a topological group, then there is a nbhd V of 1 that $VV \subset U$.

Proof: Consider the map $G \times G \to G$ continuous, and it maps $(1, 1)$ to $1 \in U$, so the preimage of U contains a nbhd of $(1, 1)$, thus some $V_1 \times V_2$, then choose $V = V_1 \cap V_2$. □

Prop. (3.11.1.3). Let G be a connected topological group, then for any nbhd U of e, $G = \bigcup_{n=1}^{\infty} (U \cup U^{-1})^n$. In particular, any open subgroup of G equals G.

Proof: This is because the RHS is an open subgroup of G, so all its cosets in G are also open, so it equals G as G is connected. □

Prop. (3.11.1.4) [Separating Axioms]. For a topological group G, the following are equivalent:

- e is a closed pt.
- G is T_1.
- G is Hausdorff(T_2).
- G is regular.
- G is completely regular

Proof: □

Prop. (3.11.1.5). Hausdorff topological group is completely regular.

Proof: Use a sequence of neighbourhood of identity to construct a uniform metric on G. Then set $\phi(x) = \min\{1, 2\sigma(a, x)\}$. Cf.[Abstract Harmonic Analysis Ross §8.4] □

Prop. (3.11.1.6). For a compact subset K and a nbhd U of e in a topological group, there exists a nbhd V of e that $xVx^{-1} \subset U$ for any $x \in K$.

Proof: For any x, there exists a nbhd W_x of x and a nbhd V_x of e that $txt^{-1} \in U$ for any $t \in W_x$ and $y \in V_x$. Let f.m. W_{x_i} cover K, then $V = \cap V_{x_i}$ satisfies the condition. □

Prop. (3.11.1.7). A compact open nbhd of e in a Hausdorff topological group contains an open subgroup of G.

Proof: Cf.[Etale Cohomology Fulei P147] □

Prop. (3.11.1.8)[Homogenous Space]. Let G be a topological group and H a closed subgroup. G/H is the quotient space in the quotient topology(3.3.1.8), then it is Hausdorff.

Proof: If $\overline{x} \neq y$, then consider a preimage $xy^{-1} \in G \backslash H$, then we can find some open subset V that $VV \subset G \backslash H$ by(3.11.1.2), thus $\overline{x} + \overline{V} \cap \overline{y} + \overline{V} = \varnothing$. Hence G/H is Hausdorff. □

Group Actions

Prop. (3.11.1.9) [Quotient by Group Action is Open]. Let $G \times X \to X$ be a group action, then the quotient map $\pi : X \to X/G$ is open.

Proof: This is because the $\pi^{-1}(\pi(U)) = \bigcup_{g \in G} gU$. □

Def. (3.11.1.10) [Regular Action]. An **regular action** is an action $\gamma : G \times X \to X$ that satisfies the following equivalent conditions:

- the graph of γ in $X \times X$ is closed.
- The diagonal $\Delta_{X/G} \subset X/G \times X/G$ is closed.
- X/G is Hausdorff.

Proof: $2 \iff 3$ is clear, for $1, 2$, notice $X/G \times X/G \cong (X \times X)/(G \times G)$, and the inverse image of Δ in $X \times X$ is just the graph of γ. □

Def. (3.11.1.11) [Proper Action]. A **proper action** is an action $\gamma : G \times X \to X$ that the graph map $\Gamma : G \times X \to X \times X$ is a proper map.

Prop. (3.11.1.12) [Proper Action is Regular]. A proper action of a group G on a locally compact Hausdorff space X is a regular action.

Proof: This follows from(3.3.2.12). □

Def. (3.11.1.13) [Proper Discontinuous Actions]. A group action is called **proper discontinuous** iff any elements $x, y \in H$ there are nbhds U_x, U_y that $\{g \in G | g(U_x) \cap U_y \neq \varnothing\}$ is finite.

Def. (3.11.1.14) [Covering Space Action]. A **covering space action** is action of a topological group G on a topological space Y is called if for any $y \in Y$, there is a nbhd U that $g(U) \cap U = \varnothing$ if $g \neq 1$.

Prop. (3.11.1.15) [Characterization of Proper Actions]. Let $\gamma : G \times X \to X$ be a group action that X is Hausdorff, then γ is a proper action iff any $K \subset X$ compact, the set $G_K = \{g \in G | g(K) \cap K \neq \varnothing\}$ is compact.

Proof: Let $\Gamma : G \times X \to X \times X$ be the graph.

$1 \to 2$: $G_K = \pi_1(\Gamma^{-1}(K \times K))$, thus it is compact.

$2 \to 1$: Let $L \subset M \times M$ be compact, then $L \subset \pi_1(L) \times \pi_2(L)$, and L is closed. Let $K = \pi_1(L) \cup \pi_2(L)$, then $\Gamma^{-1}(L) \subset \Gamma^{-1}(\pi_1(L) \times \pi_2(L)) \subset G_K \times K$, which is a closed subset of a compact set, so $\Gamma^{-1}(L)$ is compact, and Γ is a proper map. □

Prop. (3.11.1.16). If G is a compact topological group, then any group action $\gamma : G \times X \to X$ on a Hausdorff space X is proper.

Prop. (3.11.1.17) [Orbit of Proper Maps]. Let θ be a proper action of G on a Hausdorff space X, then each orbit map $\theta^{(p)}$ is proper. In particular, if X is locally compact, then the orbits are all closed(3.3.2.12).

Proof: For any compact subset $K \subset X$, $(\theta^{(p)})^{-1}(K)$ is closed by continuity and is contained in $G_{K \cup \{p\}}$, thus is compact. □

Prop. (3.11.1.18) [Properly Discontinuous Map is Proper]. If G acts proper discontinuously on a topological space H, then for any compact subsets $K_1, K_2 \in H$, $\{g \in G | K_2 \cap g(K_1) \neq \varnothing\}$ is finite. In particular, if H is Hausdorff, then it is a proper action.

Proof: Notice for any two points we can find nbhds that f.m. g intersects these two nbhds, so we can use the compactness to find f.m. pair of nbhds to cover K_2, and then use these nbhds to cover K_1 and finite the proof. □

Prop. (3.11.1.19) [Proper Free Action is a Covering Space Action]. Let $G \times X \to X$ be a proper free action on a locally compact Hausdorff space, then it is a covering space action.

Proof: For any $p \in X$, choose a precompact nbhd U of x, then $G_{\overline{U}}$ is finite, then shrink U. □

Prop. (3.11.1.20) [Continuity]. Let a topological group G acts freely and properly on a space X. If G and X/G are both connected, then X is connected.

Proof: If U, V are open subsets of X that $U \cap V = \varnothing, U \cup V = X$, then $\pi(U), \pi(V)$ are open by(3.11.1.9). Now $\pi(U) \cap \pi(V) = \varnothing$, because otherwise there is a G-orbit of X intersecting both U and V, contradiction the fact G is connected. Then $\pi_1(U) = \varnothing$ of $\pi(V) = \varnothing$, thus $U = \varnothing$ or $V = \varnothing$, and X is connected. □

Def. (3.11.1.21) [Constructible Action]. An action of a topological group G on a topological space X is called **constructible** if its graph is constructible in $X \times X$(3.11.3.10).

Prop. (3.11.1.22). Let $\gamma : G \times X \to X$ be an action

- γ is constructible iff the diagonal $\Delta_{X/G} \subset X/G \times X/G$ is constructible.
- If γ is constructible and X is non-empty, then there is a G-invariant open subset $U \subset X$ that G acts regularly.
- For a constructible action, each G-orbit is locally closed.

Proof: Cf.[Bernstein-Zelevinsky, P54]. □

Totally Disconnectedness

Prop. (3.11.1.23). A compact topological group is totally disconnected iff the intersection of all compact open nbhds of e equals $\{e\}$.

Proof: If it is totally disconnected, then $\{1\}$ is closed, so G is Hausdorff(3.11.1.4), so by(3.3.1.24), the assertion is true. Conversely, if the intersection of all compact open nbhds of e equals $\{e\}$, then $\{1\}$ is closed because G is a group. □

Prop. (3.11.1.24). A precompact nbhd of a e in a totally disconnected topological group contains a compact open subgroup.

Proof: Cf.[Etale Cohomology Fulei P147]. □

2 Hausdorff Geometry

Def. (3.11.2.1). The **Hausdorff distance** for two subset $Y_1, Y_2 \in X$ is the

$$d_X^H(Y_1, Y_2) = \inf\{\varepsilon | Y_2 \subset B(Y_1, \varepsilon), Y_1 \subset B(Y_2, \varepsilon)\}.$$

The **Gromov-Hausdorff metric** for two metric space is

$$d^{GH}(X_1, X_2) = \inf\{d_Z^H(i_1(X_1), i_2(X_2))\}$$

where i_1, i_2 are isometry of X_1, X_2 into a metric space Z.

This metric makes the set of all compact metric space into a complete Hausdorff space $\mathcal{MET}$.

Def. (3.11.2.2). A map from X to Y is called a ε **approximation** iff $B(f(X), \varepsilon) = Y$ and $|d(x, y) - d(f(x), f(y))| \leq \varepsilon$.

We have: if there is a ε approximation, then $d^{GH}(X, Y) \leq 3\varepsilon$, and if $d^{GH}(X, Y) \leq \varepsilon$, there is a 3ε approximation.

Prop. (3.11.2.3). The set of isometries of

3 Spaces from Algebraic Geometry

Noetherian Space

Def. (3.11.3.1)[Noetherian Spaces]. A **Noetherian space** is a space $X \in \mathfrak{Top}$ that any descending chain of closed subsets stabilizes. A **locally Noetherian space** is a space $X \in \mathfrak{Top}$ that every point has a nbhd U s.t. U is a Noetherian space.

Prop. (3.11.3.2). A Noetherian space is quasi-compact and all subsets of it in the induced topology is Noetherian hence quasi-compact.

Proof: Let $T \subset X$, for a chain of closed subsets $Z_i \cap T$ of T, $Z_1, Z_1 \cap Z_2, \ldots$ stabilize in X, hence the chain stabilize in T. □

Prop. (3.11.3.3). If X can be covered by f.m. Noetherian subspaces, then X is Noetherian.

Proof: □

Prop. (3.11.3.4) [Noetherian Space F.M. Irreducible Components]. A Noetherian space has only f.m. irreducible component, hence it has only f.m. connected components.

Proof: Let $\mathcal{C}$ be the family of closed subset that has infinitely many component, then there is a minimal object, but it is not irreducible, one of the component has infinitely many components and be smaller. □

Quasi-Separated

Def. (3.11.3.5) [Quasi-Separated]. A space X is called **quasi-separated** if the diagonal morphism is quasi-compact(3.3.2.2). If X has a basis consisting of quasi-compact open subsets, then this is equivalent to any intersection of two quasi-compact open subsets is quasi-separated open.

Specialization & Generalization

Def. (3.11.3.6)[Specializations and Generalizations]. Let $X \in \mathcal{T}\mathrm{op}$ then x is said to be a **specialization of** y if $x \in \overline{\{y\}}$. And in this case y is said to be a **generalization of** x.

And they are called **immediate specializations/generalizations** if there are no other points $z \in X$ s.t. $y \to z \to x$.

Def. (3.11.3.7)[Going Up and Down]. A map f of spaces is said to satisfy the **going-up property** iff specialization lifts along f. It is said to satisfy the **going-down property** iff generalization lifts along f.

Prop. (3.11.3.8). A closed map satisfies going-up.

Proof: If $y \to y'$, $f(x) = y$, consider $f(\overline{\{x\}})$, it is closed and contains y, so it contains y', thus the result. □

Constructible Set

Def. (3.11.3.9)[Retrocompact Subset]. A subset of X is called **retrocompact** if the inclusion map is quasi-compact(3.3.2.2).

Def. (3.11.3.10)[Constructible Subset]. A subset of X is called **constructible** if it is a finite union of sets of the form $U \cap V^c$ where U, V are open and retrocompact in X. In the case when X is Noetherian, by(3.11.3.2), all subsets are retrocompact hence constructible sets are just union of locally closed subsets of X.

A set of X is called **locally constructible** if locally it is constructible. If X is quasi-compact, then a locally constructible set is just a constructible set.

Prop. (3.11.3.11). Constructible subsets of X forms a Boolean algebra.

Proof: Cf.[Sta]005H. □

Prop. (3.11.3.12)[Constructible and Subsets].

- If U is open in X, then for any E constructible in X, $E \cap U$ is constructible in U.
- If U is retrocompact open and E is constructible in U, then E is constructible in X.

Proof: Easy. □

Prop. (3.11.3.13). Any constructible subsets of X is retrocompact.

Proof: It suffices to prove $U_i \cap V_i^c \cap W$ is quasi-compact for W quasi-compact, but this is because it is a closed subspace of the quasi-compact subspace $U_i \cap W$. □

Cor. (3.11.3.14). An open subset of X is constructible iff it is retrocompact, a closed subset of X is constructible iff its complement is retrocompact.((3.11.3.11) used).

Def. (3.11.3.15)[Constructible topology]. The **constructible topology** X_{cons} on a quasi-compact space X is generated by the open subsets U, U^c, where U is a quasi-compact open.

Notice that the space is quasi-compact, so the constructible topology is the coarsest topology that every constructible subset of X is both open and closed.

Prop. (3.11.3.16). Let X be quasi-compact and quasi-separated, then any constructible subset of X is quasi-compact. In particular, if Y is closed in X, then Y is constructible iff it is quasi-compact.

Proof: For $Y = \cup_{i=1}^n (U_i - V_i)$, with U_i, V_j quasi-compact open in X, then $U_i - V_i$ is closed in U_i thus quasi-compact, and then Y is quasi-compact. □

Prop. (3.11.3.17). Let E be a constructible subset of a space X, if E is dense in then E contains some open dense subset of its closure.

Proof: Let $Y = \cup_{i=1}^k Y_i$ where Y_i are locally closed. Denote $Z_i = \overline{Y}_i \backslash Y_i, Z = \cup Z_i$, $W = \overline{Y} \backslash Z$. Then $W \subset Y$, and we show that W is open dense in $\overline{Y}$: As Y_i are locally closed, Y_i is open in $\overline{Y}_i$, thus Z_i is closed, and Z is closed, so W is open in $\overline{Y}$. To show W is dense in $\overline{Y}$: If some open subset U of $\overline{Y}$ satisfies $U \cup Z_i$, then U cannot be contained in any Z_i, so we can inductively show $U \backslash Z_1, U \backslash (Z_1 \cup Z_2), \ldots$ are non-empty, which is a contradiction. □

Irreducible

Def. (3.11.3.18) [Irreducible Space]. A space is called **irreducible** iff there are no two nonempty nonintersecting open subsets. Thus an open subset of an irreducible set is dense and irreducible.

Prop. (3.11.3.19). If Y is irreducible in X, then $\overline{Y}$ is also irreducible.

Proof: Any two nonempty open sets of $\overline{Y}$ must intersect Y thus must intersect. □

Prop. (3.11.3.20). If $X \in \mathcal{T}\mathrm{op}$ and $U \subset X$ is open, then $Y \mapsto \overline{Y}$ is a order preserving bijection between irreducible closed subspaces of U and irreducible closed subspaces of X meeting U.

Jacobson Space

Def. (3.11.3.21). Let X be a space and X_0 the set of closed pts of X, then X is called **Jacobson** iff $\overline{Z \cap X_0} = Z$ for every closed subset Z of X. This is equivalent to every non-empty locally closed subset of X contains a closed pt.

Thus there is a correspondence between closed subsets of X_0 and closed subsets of X, so they have the same Krull dimension.

Prop. (3.11.3.22). Being Jacobson is local. And for an open covering U_i of X, $X_0 = \cup U_{i,0}$.

Proof: Firstly, if $X = \cup U_i$ where U_i are Jacobson, $X_0 \cap U_i = U_{i,0}$. One direction is trivial, for the other, let x be closed in U_i, then consider $\overline{\{x\}} \cap U_j$. If $x \notin U_j$, this is empty, if $x \in U_j$, consider $T = \overline{\{x\}} \cup (U_j - U_i \cap U_j)$, then T is closed in U_j, so by hypothesis, closed pts of U_j are dense in T, so x must be closed in U_j, so x is closed in X. Now clearly X is Jacobson.

Conversely, if X is Jacobson, for a closed subset Z of U_i, $X_0 \cap \overline{Z}$ is dense in $\overline{Z}$, so $X_0 \cap Z$ is dense in Z, then clearly U_i is Jacobson. □

Cor. (3.11.3.23). If X is Jacobson, then any locally constructible sets of X is Jacobson. And its closed pts are closed in X.

Proof: By the proposition, we only have to prove for constructible sets. For $T = \cup T_i$ where T_i is locally closed, then a locally closed set in T has a non-empty intersection $T \cap T_i$ which is also locally closed for some i.

Hence is has a closed pt in X hence in T, so T is Jacobson. The second assertion is implicit in the proof. □

Prop. (3.11.3.24). If X is Jacobson, then an open set U of X is compact iff $U \cap X_0$ is compact, hence an open set U is retrocompact iff $U \cap X_0$ is retrocompact.

Hence the constructible sets of X correspond to the constructible sets of X_0.

And Irreducible closed subsets correspond to irreducible subsets of X_0.

Krull Dimension

Def. (3.11.3.25). The **Krull dimension** of a topological space is the length of the longest chain of closed irreducible subsets.

The **local dimension** $\dim_x(X) = \min\{\dim U | x \in U \subset X \text{ open in X}\}$.

Prop. (3.11.3.26). If $Y \subset X$, then $\dim Y \leq \dim X$, because the closure of any chain of Y is a chain of X by(3.11.3.19).

For an open covering $\{U_i\}$ of X, $\dim X = \sup \dim U_i$, because for any chain of closed irreducible subsets, if U_i intersects the minimal one, then $\dim U_i =$ length of this chain.

Prop. (3.11.3.27). $\dim X = \sup \dim_x(X)$.

Proof: The right is smaller than the left by(3.11.3.26), and for any chain $Z_0 \subset Z_1 \subset \ldots \subset Z_n$ of irreducible closed subset of X, if I choose a point $x \in Z_0$, then $\dim_x(X) \geq n$. □

Prop. (3.11.3.28). In case $X = \operatorname{Spec} A$ for a Noetherian ring A, $\dim X = \sup \dim A_p$, because A is of finite?

Def. (3.11.3.29) [Codimensions]. Let $X \in \mathcal{T}op$ and $Y \subset X$ be an irreducible closed subspace, then the **codimension** of Y in X is defined to be the supremum of lengths e of chains $Y = Y_0 \subset Y_1 \subset \ldots \subset Y_e = X$, denoted by $\operatorname{codim}(Y, X)$.

Sober Spaces

Def. (3.11.3.30) [Sober Spaces]. A space X is called **sober** if every irreducible closed subset has a unique generic point.

Prop. (3.11.3.31). A sober space is T_1. Conversely, a finite T_0 space is sober.

Proof: The first assertion is because if $x \in \overline{\{y\}}$ and $y \in \overline{\{x\}}$, then $\overline{\{x\}} = \overline{\{y\}}$, and this irreducible closed subset has two generic point, contradiction.

If the space is finite, then for a closed irreducible subset $T = \{x_1, \ldots, x_n\}$, $T = \cup\overline{\{x_i\}}$, as it is irreducible, $T = \overline{\{x_i\}}$ for some x_i, and i is unique as it is T_1, so X is sober. □

Prop. (3.11.3.32) [Soberization]. There is a left adjoint t to the forgetful functor from the Sober spaces. $t(X)$ consists of irreducible closed subsets of X, and use $t(Y)$ for Y closed as closed subsets. for a map $f : X \to Z$ to a sober space Z, the extension maps the generic point of an irreducible Y to the generic point of the closure of $f(Y)$.

Def. (3.11.3.33) [Zariski Space]. A Noetherian Sober space is called a **Zariski space**.

Catenary spaces and Dimension Functions

Def. (3.11.3.34) [Catenary Space]. A space X is called **catenary** iff for any inclusion of irreducible closed subsets of X, their codimension is finite and every maximal chain of irreducible closed subsets has the same dimension. This is equivalent to $\operatorname{codim}(X, Y) + \operatorname{codim}(Y, Z) = \operatorname{codim}(X, Z)$.

Prop. (3.11.3.35). Catenary is a local property, by(3.11.3.20).

Def. (3.11.3.36) [Dimension Function]. For $X \in \mathcal{T}op$, consider the specialization relation(3.11.3.6), a **dimension function** is a function $\delta : |X| \to \mathbb{Z}$ that

- if y is a specialization of x in X, then $\delta(y) < \delta(x)$.
- if it is a direct specialization, then $\delta(y) = \delta(x) - 1$.

The dimension function is usually considered only when the space is sober.

Prop. (3.11.3.37). Let $X \in \mathcal{T}op$ be sober and catenary with a catenary function, then X is catenary, and if x is a specialization of x in X, then

$$\delta(x) - \delta(y) = \operatorname{codim}(\overline{\{y\}}, \overline{\{x\}}).$$

Proof: This is clear from the definitions(3.11.3.29). □

Prop. (3.11.3.38). If $X \in \mathcal{T}op$ be locally Noetherian and sober, and δ, δ' are two dimension functions on X, then $\delta - \delta'$ is locally constant on X.

Proof: We may assume X is Noetherian, so it has only f.m. irreducible components by(3.11.3.4), then $\delta - \delta'$ is locally constant on the X minus the irreducible components not passing through x by(3.11.3.37). □

Prop. (3.11.3.39) [Catenary and Sober]. Let $X \in \mathcal{T}op$ be locally Noetherian, sober, then X is catenary iff any point $x \in X$ has a nbhd U which has a dimension function.

Proof: Cf.[Sta]02IC.
The other direction follows from(3.11.3.37) and(3.11.3.35). □

Sober Spaces

Def. (3.11.3.40) [Sober Spaces]. A space X is called **sober** if every irreducible closed subset has a unique generic point.

Prop. (3.11.3.41). A sober space is T_1. Conversely, a finite T_0 space is sober.

Proof: The first assertion is because if $x \in \overline{\{y\}}$ and $y \in \overline{\{x\}}$, then $\overline{\{x\}} = \overline{\{y\}}$, and this irreducible closed subset has two generic point, contradiction.
. □

Prop. (3.11.3.42) [Catenary and Sober]. Let $X \in \mathcal{T}op$ be locally Noetherian, sober and catenary, then any point $x \in X$ has a nbhd U which has a dimension function.

Proof: Cf.[Sta]02IC. □

4 Spectral Spaces

References are [Sta]5.23 and [Adic Spaces].

Def. (3.11.4.1) [Spectral Space]. A space is called **spectral** iff it is quasi-compact, quasi-separated(3.11.3.5), sober and the quasi-compact opens form a basis for the topology.

A space is called **locally spectral** iff it has an open covering by spectral spaces.

A morphism $f : X \to Y$ between locally spectral spaces is called **spectral** if for any open spectral spaces $U \subset f^{-1}(V)$, $f : U \to V$ is quasi-compact.

Prop. (3.11.4.2) [Connected Components]. Let X be a spectral space, then any connected subset of X is an intersection of clopen subsets.

Proof: Let $x \in X$ and S be the intersection of all clopen subsets of X containing x, then it suffices to show S is connected. Suppose $S = B \coprod C$ with B, C closed, then B, C are compact, thus there exist quasi-compact opens $U, V \subset X$ that $B = U \cap S, C = V \cap S$. Then $U \cap V \cap S = \varnothing$. Now $U \cap V$ is quasi-compact also, so there exists some clopen Z_α containing x that $Z_\alpha \cap U \cap V = \varnothing$. Similarly, there exists some clopen Z_β containing x that $Z_\beta \subset U \cup V$. Then $Z_\gamma = Z_\alpha \cap Z_\beta$ is clopen and contained in $U \Delta V$, Then Both $Z_\gamma \cap U$ and $Z_\gamma \cap V$ is clopen, so $U = \varnothing$ or $V = \varnothing$. □

Cor. (3.11.4.3). Let X be a spectral space, then for a subset T of X, T is an intersection of clopen subsets of X iff T is closed in X and is a union of connected components of X.

Proof: If T is an intersection of clopen subsets, then T is clearly a union of connected components of X. Conversely, if T is a union of connected components of X, if $x \notin T$, let C be a connected components containing x. Then C is an intersection of clopen subsets, by(3.11.4.2). These subsets are closed under finite intersections, so by the compactness of T, there is a clopen subset containing T but not x, so we are done. □

Constructible Topology

Lemma (3.11.4.4). If X is a finite T_0 space, then it is spectral and every subset of X is constructible.

Proof: Cf.[Adic Space Morel, P26]. □

Prop. (3.11.4.5). If X is a spectral space, then the constructible topology(3.11.3.15) is Hausdorff, totally disconnected and quasi-compact.

Proof: The space is sober hence T_0(3.11.3.41), and then the constructible topology is Hausdorff and totally disconnected.

To show quasi-compactness, it suffices to show that the family $\mathcal{C}$ of quasi-compact open and complement quasi-compact open subsets has the finite intersection property(3.3.2.3). Notice elements in $\mathcal{C}$ are all quasi-compact. Now if there is a family that has the finite intersection property by has intersection 0, by Zorn's lemma, there is a maximal one of them, $\mathcal{B}$. Now let Z be the intersection of all the closed subsets in $\mathcal{B}$, then it is non-empty as X is quasi-compact. And we claim Z is irreducible: otherwise $Z = Z_1 \cup Z_2$, thus there are quasi-compact open sets U_1, U_2 that $U_1 \cap Z_1 \neq \varnothing, U_1 \cap Z_2 = \varnothing, U_2 \cap Z_2 \neq \varnothing, U_2 \cap Z_1 = \varnothing$. then let $B_i = X - U_i$, then B_1, B_2 cannot by added to $\mathcal{B}$ by maximality, so there is a finite intersection T_1, T_2 that $B_i \cap T_i = 0$. But then $Z \cap T_1 \cap T_2 = 0$, but Z is an intersection of closed subsets, thus some finite intersection of closed subsets in $\mathcal{B}$ will $\cap T_1 \cap T_2 = 0$, contradiction.

So now Z is irreducible, but then for every element $B \in \mathcal{B}$, $Z \cap B$ contains the generic point of Z, thus the intersection of B is not empty, contradiction. □

Cor. (3.11.4.6). Let X be a spectral space, then

- The constructible topology is finer than the original topology.
- A subset X is constructible iff it is clopen in the constructible topology of X.
- If U is open in X, then the constructible topology induces the constructible topology on U.

Proof:

1: Every open subset of X is a union of its quasi-compact open subsets, so it is open in the constructible topology.

2: Clearly constructible subset is clopen in the constructible topology. Conversely, if Y is clopen, then Y is a union of constructible subsets, but also it is quasi-compact, so it is a finite union of constructible subsets, thus constructible.

3: Cf.[Mor19] P28. □

Prop. (3.11.4.7). If $E \subset X$ is closed in the constructible topology, then it is a spectral space with the induced topology, and the inclusion map is spectral.

Proof: Cf. [Mor19]P34. □

Prop. (3.11.4.8). For a set E closed in the constructible topology in a spectral space,

- every point of $\overline{E}$ is a specialization of elements in E. Thus if E is stable under specialization, then it is closed.
- If E is open in the constructible topology and stable under generalization, then it is open.

Proof: Cf. [Sta]0903**?**. □

Prop. (3.11.4.9). For a map between spectral spaces $f : X \to Y$, the following are equivalent:

- f is spectral.
- f is quasi-compact.
- $f : X_{cons} \to Y_{cons}$ is continuous.

And if this is true, then $f : X_{cons} \to Y_{cons}$ is proper.

Proof: $1 \to 2 \to 3$ is trivial, an open subset of X is quasi-compact iff it is clopen in the constructible topology(3.11.4.6), so $3 \to 2$. For $2 \to 1$, notice that if $U \subset f^{-1}(V)$ are open spectrals, and $W \subset U$ is quasi-compact open, then $f^{-1}W \cap U$ is quasi-compact open, because X is quasi-separated.

Finally, f is proper because X_{cons}, Y_{cons} is compact Hausdorff(3.11.4.5), then use(3.3.2.10). □

Criterion of Spectralness

Lemma (3.11.4.10). Let X be a quasi-compact T_0 space that is has a subbasis consisting of quasi-compact open subsets that is stable under finite intersections. Let X' be the topology generated by the quasi-compact open subsets and their complements, then the following are equivalent:

- X is spectral.
- X' is compact Hausdorff, and its topology has a basis consisting of open and closed subsets.
- X' is quasi-compact.

Proof: Cf.[Adic Space Morel P30]. □

Prop. (3.11.4.11) [Hochster's Criterion of Spectrality]. Let $X' = (X_0, \mathcal{T}')$ be a quasi-compact topological space, and let $\mathcal{U}$ be the family of clopen subsets of $\mathcal{T}'$, let $\mathcal{T}$ be the topology generated by $\mathcal{U}$, let $X = (X_0, \mathcal{T})$.

Then if X is T_0, then it is spectral, and every element of $\mathcal{U}$ is quasi-compact open in X, and $X' = X_{cons}$.

Proof: Cf.[Adic Space Morel, P29]. □

Prop. (3.11.4.12) [Spectral and Inverse Limit]. A space is spectral iff it is a direct limit of finite sober(finite $T1$(3.11.3.41)) spaces.

Proof: Cf.[Sta]09XX. □

Prop. (3.11.4.13) [Spec and Spectral Space]. A spectral space is exactly the underlying space of spectrum of some ring.

Proof: The spectrum of a ring is qc: if $\cup D(f_i) = \operatorname{Spec} A$, then $(f_i) = (1)$, so f.m. of them generate (1). And similarly it is quasi-separable and $D(f) = \operatorname{Spec} A_f$ is quasi-compact. For the other direction, Cf.[M. Hochster. Prime ideal structure in commutative rings, Thm6]**?**. □

Cor. (3.11.4.14). Every quasi-compact irreducible scheme is homeomorphic to an affine scheme.

Cor. (3.11.4.15) [Characterization of Spectral Spaces]. The following are equivalent for a topological space T:

1. $T \cong \operatorname{Spec} R$ for some ring R.
2. $T \cong \varprojlim T_i$ where $\{T_i\}$ is an inverse system of finite T_0 spaces.
3. T is spectral.

Proof: This follows from(3.11.4.13) and(3.11.4.12). □

w-localness

Def. (3.11.4.16)[pro-Zariski Localization]. A map of spectral spaces $f : W \to V$ is called a **Zariski localization** if $W = \coprod_i U_i$ where $U_i \to V$ is a quasi-compact open immersion. A **pro-Zariski localization** is a cofiltered limit of Zariski localizations of V.

Def. (3.11.4.17)[w-Local]. A spectral space is called **w-local** if the set of closed pts of X is closed and any point of X specializes to a unique closed pt. A morphism of w-local spaces are called **w-local** if it is spectral and maps closed pts to closed pts.

Prop. (3.11.4.18). If X is w-local and $Y \subset X$ is a closed subset, then Y is also w-local.

Proof: Y is spectral by(3.11.4.7). Y_0 is closed because $Y_0 = Y \cap X_0$. And the second assertion is also trivial. □

Prop. (3.11.4.19). Let X be a spectral space and T profinite, then $Y = X \times_{\pi_0(X)} T$ is also spectral and $T = \pi_0(Y)$. If moreover X is w-local, then Y is also w-local and $Y \to X$ is w-local.

Proof: Cf.[Sta]096C. □

Def. (3.11.4.20) [Localization Along a Closed Set]. Given a closed set Z of a spectral set X, the pro-open subset of X consisting of all points that specializes to a point of Z is called the **localization of X along Z**. And X is called **local along** Z if $X_0 \subset Z$.

Prop. (3.11.4.21). A spectral space that is local along a closed w-local subset $Z \subset X$ with $\pi_0(Z) \cong \pi_0(X)$, is also w-local.

Proof: $X_0 = Z_0$ is clearly closed, and if a pt x of X specializes to two closed pts of Z, then the π_0 map is not injective, contradiction. □

3.12 Algebraic Topology I: Homotopies

Main references are [Hat02], [AGP02], [同调论, 姜伯驹], [May99], [https://ncatlab.org/nlab/show/Introduction+to+Homotopy+Theory#HomotopyGroupsOftopologicalSpaces].

Notation (3.12.0.1).

- Use notations defined in Topology I.
- All spaces are assumed to be compactly generated, and products and mapping spaces are assumed to be compact generated versions.

1 Homotopy Types

Def. (3.12.1.1) [Retraction]. A **retraction** of a space X to a subspace A is a map $r : X \to A$ that $r|_A = \mathrm{id}_A$.

Def. (3.12.1.2) [Homotopy]. A **homotopy** $f_t : X \to Y$ is a family of maps f_t for every $t \in I$ that $f : X \times I \to Y$ is continuous. For two homotopies $F : X \times I \to Y$ and $F' : X \times I \to Y$ s.t. $F_1 = F'_0$, we can define the **composite homotopy** $F' \cdot F : X \times I \to Y$.

Tow maps $f_0, f_1 : X \to Y$ are called **homotopic** is there is a homotopy $f_t : X \to Y$ connecting them. Homotopy relations are denoted by $f_0 \cong f_1$.

Let A be a subspace of X, then a **homotopy relative to** A is a homotopy $f_t : X \to Y$ whose restriction to A is fixed.

Let E_1, E_2 be spaces over B, then maps $f_0, f_1 : E_1 \to E_2$ over B are called **fiber homotopic** if there is a homotopy $f_t : E_1 \to Y$ connecting them that each f_t are maps over B. Homotopy relations over B are denoted by $f_0 \cong_B f_1$.

Def. (3.12.1.3) [Homotopy Equivalences]. A map $f : X \to Y$ is called a **homotopy equivalence** if there is a map $g : Y \to X$ that $f \circ g \cong \mathrm{id}$ and $g \circ f \cong \mathrm{id}$.

A space having the homotopy type of a point is called **contractible**.

A map $f : X \to Y$ over B is called a **fiber homotopy equivalence** if there is a map $g : Y \to X$ over B that $f \circ g \cong_B \mathrm{id}$ and $g \circ f \cong_B \mathrm{id}$.

Def. (3.12.1.4)[Deformation Retraction]. A **deformation retraction** of a space X onto a subspace A is a homotopy $f_t : X \to X, t \in I$ that $f_0 = \mathrm{id}, f_1(X) = A$ and $f_t|_A = \mathrm{id}_A$ for all t.

Prop. (3.12.1.5). A map $X \to Y$ is a homotopy equivalence iff the mapping cylinder deformation retracts onto X.

Proof: ? □

Def. (3.12.1.6) [Excisive Triads]. A **triad of spaces** is a triple $(X; A, B)$ s.t. $A \subset X, B \subset X$. An **excisive triad** is a triad $(X; A, B)$ s.t. $A^o \cup B^o = X$.

Relative Spaces

Def. (3.12.1.7) [Relative Spaces]. The category $\mathcal{CG}^{\mathrm{rel}}$ is the category of pairs (X, A) where $A \subset X \in \mathcal{CG}$, and morphisms in $\mathcal{CG}^{\mathrm{rel}}$ are equivariant maps.

Def. (3.12.1.8) [Smash Products]. **smash products** in $\mathcal{CG}^{\mathrm{rel}}$ are defined to be $(X, A) \wedge (Y, B) = (X \times Y, (X, A) \vee (Y, B))$, where $(X, A) \vee (Y, B) = X \times B \cup A \times Y \subset X \times Y$.

Def. (3.12.1.9) [Cones and Suspensions]. For $(X, A) \in \mathcal{T}\text{op}^{\text{rel}}$, the **cone** over (X, A) is defined to be $C(X, A) = (X, A) \wedge (\mathbb{I}, \{1\})$. The **suspension** of (X, A) is defined to be $\Sigma(X, A) = (X, A) \wedge \mathbb{S}^1$.

Prop. (3.12.1.10) [$\mathcal{CG}^{\text{rel}}$ is Closed]. For $(X, A), (Y, B), (Z, C) \in \mathcal{CG}^{\text{rel}}$, by(3.3.3.15) there is a homeomorphism

$$\text{Map}((X, A) \wedge (Y, B), (Z, C)) \cong \text{Map}((X, A), \text{Map}((Y, B), (Z, C))).$$

In particular, $\mathcal{CG}^{\text{rel}}$ is a closed symmetric monoidal category.

Def. (3.12.1.11) [Pointed Spaces]. The category $\mathcal{CG}^{\text{pt}}$ is the subcategory of $\mathcal{CG}^{\text{rel}}$ consisting of pairs (X, A) s.t. $A \cong \text{pt}$. It is stable under finite products.

We can define similarly homotopies of maps between pointed spaces, and denote $\langle X, Y \rangle$ the homotopy classes of maps from X to Y.

Def. (3.12.1.12) [Smash Products]. For $X, Y \in \mathcal{CG}^{\text{pt}}$, the **smash product** $X \wedge Y$ is defined to be $X \wedge Y = X \times Y / X \wedge Y$, where $X \vee Y = X \coprod_* Y$, called the **wedge sum** of X and Y. Similar to(3.12.1.9), we can define cones and suspensions of pointed spaces.

Then the smash product and wedge sums are commutative and associative, and they satisfy

$$(X \vee Y) \wedge Z = X \wedge Z \vee Z \wedge Z.$$

Because of(3.12.1.14), the smash product and wedge sums are also denoted by $X \otimes Y$ and $X \oplus Y$.

Proof: For the identities, use the fact product commutes with colimits(3.3.3.16). □

Prop. (3.12.1.13) [Smash Products, and Homotopy]. Suspensions preserves homotopy, as $\Sigma(X \wedge I) = X \wedge I \wedge \mathbb{S}^1 \cong (X \wedge \mathbb{S}^1) \wedge I$.

Prop. (3.12.1.14) [$\mathcal{CG}^{\text{pt}}$ is Closed]. For $X, Y, Z \in \mathcal{CG}^{\text{pt}}$, by(3.12.1.10), there is a bijection

$$\text{Map}(X \wedge Y, Z) \cong \text{Map}(X, \text{Map}(Y, Z)).$$

In particular, $\mathcal{CG}^{\text{pt}}$ is a closed symmetric monoidal category.

Def. (3.12.1.15) [Well-Pointed Spaces]. A pointed space $(X, *) \in \mathcal{CG}^{\text{pt}}$ is called a **well-pointed space** if $* \to X$ is a cofibration. The category of well-pointed spaces is denoted by $\mathcal{CG}^{\text{well-pt}}$.

Def. (3.12.1.16) [Augmentation]. There is a functor $\mathcal{CG} \to \mathcal{CG}^{\text{well-pt}} : X \mapsto X_+ = (X \coprod \text{pt}, \text{pt})$.

Prop. (3.12.1.17). The cone construction

$$\mathcal{T}\text{op}^{\text{rel}} \to \mathcal{T}\text{op} : (X, A) \mapsto C(A \to X)$$

preserves homotopy equivalence.

Prop. (3.12.1.18) [Path Spaces and Loop Spaces]. For $X \in \mathcal{CG}^{\text{pt}}$, define the **path space** $P(X) = \text{Map}((\mathbb{I}, \{0\}), X)$, and define the **loop space** $\Omega(X) = \text{Map}(\mathbb{S}^1, X)$.

Then by(3.12.1.14), there are homeomorphism of spaces

$$\text{Map}(\Sigma(X), Y) \cong \text{Map}(X, \Omega(Y)).$$

Thus also

$$\langle \Sigma(X), Y \rangle \cong \langle X, \Omega(Y) \rangle.$$

Def. (3.12.1.19) [Weak Products]. For $\{X_\alpha\}_\Sigma \in \mathcal{CG}^{\text{pt}}$, define the **weak product** $\prod' X_\alpha$ as

$$\prod{}' X_\alpha = \varinjlim_{S \subset \Sigma, \#S < \infty} \bigvee_{i \in S} X_i$$

with base point $\prod *$.

2 Isotopies

Prop. (3.12.2.1) [Alexander's Trick]. If $f, g : \mathbb{D}^n \to \mathbb{D}^n$ be two self-homeomorphisms that there is an isotopy $F : \mathbb{D}^n \times I \to \mathbb{D}^n$ between $f|_{\partial\mathbb{D}^n}$ and $g|_{\partial\mathbb{D}^n}$, then there exists an isotopy between f and g extending F.

Proof: Firstly, if $g = \mathrm{id}_{\mathbb{D}^n}$ and f fixes every points on the boundary, then an isotopy connecting f to the identity is given by

$$J(x,t) = \begin{cases} tf(x/t) & ,0 \le ||x|| < t \\ x & ,t \le ||x|| \le 1 \end{cases}.$$

In general, isotopy $g^{-1}F : \mathbb{D}^n \times I \to \mathbb{D}^n$ between $g^{-1}f|_{\partial\mathbb{D}^n}$ and $\mathrm{id}_{\partial\mathbb{D}^n}$ can be extended to an isotopy from $F' : \mathrm{Cone}(g^{-1}f|_{\partial\mathbb{D}^n})$ to $\mathrm{id}_{\mathbb{D}^n}$. Then $\mathrm{Cone}(g^{-1}f|_{\partial\mathbb{D}^n})$ and $g^{-1}f$ are identical on $\partial\mathbb{D}^n$, so by the argument above, they are isotopic. Then $g^{-1}f \cong \mathrm{id}_{\mathbb{D}^n}$, which gives an isotopy between f and g. □

Prop. (3.12.2.2). Any orientation-preserving self-homeomorphism f of $\mathbb{S}^d$ is isotopic to $\mathrm{id}_{\mathbb{S}^d}$.

Proof: By the decomposition of $\mathbb{S}^d$ into two hemispheres and using the annulus theorem(3.3.11.2), we see we can isotopy f to a map that fixes the equator. Then we can use Alexander's trick(3.12.2.1). □

3 CW Complexes

Def. (3.12.3.1)[CW Complexes]. A **CW complex** is a space X that $\varnothing \to X$ is cofibrantly generated by $\mathbb{S}^n \to \mathbb{D}^n$.

For a CW complex X, a **representation of** X is given as follows:

- $\mathrm{sk}_0 X$ is a discrete set, whose elements are regarded as 0-cells.
- Inductively, form the n**-skeleton** $\mathrm{sk}_n X$ from $\mathrm{sk}_{n-1} X$ by adding n**-cells** e^n_α via maps $\varphi_\alpha : \mathbb{S}^{n-1} \to \mathrm{sk}_{n-1} X$.
- Let $X = \cup \mathrm{sk}_n X$ be given the quotient topology from $\coprod_n \mathrm{sk}_n X$.

We will also call the image of e^n_α as an n-cell. The category of CW complexes is denoted by $\mathcal{CW}$. Any CW complex is compactly generated, by definition.

Def. (3.12.3.2) [Sub-CW Complexes]. For a CW complex X, a **subcomplex** $Y \subset X$ is a subspace $Y \subset X$ s.t. the cells with images in Y makes Y a CW complex.

Def. (3.12.3.3) [Finite CW Complexes].

- A **CW complex of finite dimension** is a CW complex X s.t. $X = \mathrm{sk}_n X$ for some $n \in \mathbb{N}$.
- A **CW complex of finite type** is a CW complex X that has only finitely many n-cells for each n.
- A **finite CW complex** is a CW complex that is both of finite dimensional and of finite type.
- A **locally finite CW complex** is a CW complex that each cell intersect only f.m. other cells.

Prop. (3.12.3.4) [Dimension of CW Complexes]. Given a representation of a CW complex of finite dimension X, $\dim X$ is defined to be the minimal n s.t. $X = \mathrm{sk}_n X$. Then this dimension is independent of the presentation given.

Proof: □

Prop. (3.12.3.5). Any compact subspace K of a CW complex X is contained in a finite subcomplex. In particular, a CW complex is compact iff it is finite.

Proof: Firstly K intersects with only f.m. interiors of cells of X(where we assume the interior of a point in $\mathrm{sk}_0 X$ is the point itself): otherwise take $S = \{x_1, x_2, \ldots\}$ be an infinite sequence of points lying in different cells, then $S \cap e_\alpha$ is closed for any cell e_α of X, so S is closed. But the same argument show any single point of S is also closed, so S is discrete, so S is finite, contradiction.

Then it suffices to show that any cell meets only f.m. cells: for this we can use induction on $\dim X$, and notice that for any cell e_α, the image of its attaching map is compact. □

Prop. (3.12.3.6) [Miyazaki]. Any CW complex is paracompact Hausdorff, thus also normal by(3.3.7.6).

Proof: To show it is Hausdorff, for any two points x, y, it is not hard to find disjoint precompact nbhds of x, y by induction on cells.

To show it is paracompact, Cf.[Rudolph Fritsch and Renzo Piccinini, Cellular Structures in Topology]Thm1.3.5.**?** □

Prop. (3.12.3.7). A CW complex is locally compact iff it is locally finite. A connected CW complex is metrizable iff it is locally finite.

Proof: Cf.[Rudolph Fritsch and Renzo Piccinini, Cellular Structures in Topology, Cambridge University Press, 1990.]Prop1.5.7. □

Prop. (3.12.3.8) [Product of CW Complexes]. For $X, Y \in \mathcal{CW}$, then the compactly generated product space $X \times_c Y$ admits a CW complex structure with

$$\mathrm{sk}_n X = \cup_{i+j=n} \mathrm{sk}_i X \times \mathrm{sk}_j Y.$$

And if either X or Y is locally compact or both X, Y have countably many cells, then $X \times_c Y = X \times Y$.

Proof: Given presentations of CW complexes of X, Y, we can define the CW complex structure on $X \times Y$ by choosing homeomorphisms of pairs

$$(\mathbb{D}^n, \mathbb{S}^n) \cong (\mathbb{D}^p \times \mathbb{D}^q, \mathbb{D}^p \times \mathbb{S}^{q-1} \cup \mathbb{S}^{p-1} \times \mathbb{D}^q),$$

where $p + q = n$. Then it is a CW structure on $X \times_c Y$ by(3.3.3.16).

For the last assertion, the case X is locally compact follows from(3.3.2.33). The case that X, Y both have countably many cells follow from [Hatcher, P524].**?** □

Prop. (3.12.3.9) [Cellular Maps]. Given $X, Y \in \mathcal{CW}$, a **cellular map** $f : X \to Y \in \mathcal{CW}$ is a map s.t. $f(\mathrm{sk}_n X) \subset \mathrm{sk}_n Y$ for any $n \in \mathbb{N}$. And a **cellular homotopy** between two cellular maps $f, g : X \to Y$ is a homotopy $F : X \times I \to Y$ between f and g s.t. F is a cellular map.

Prop. (3.12.3.10) [CW Structure on Compact Manifolds]. $\mathcal{M}\mathrm{ani}_{\mathrm{cpct}} \in \mathcal{CW}^{\mathrm{fin}}$.

Proof:

□

Def. (3.12.3.11) [Relative CW complexes]. A **relative CW complex** is a pair (A, X) s.t. $A \to X$ is cofibrantly generated by $\mathbb{S}^n \to \mathbb{D}^n$. The category of relative CW complexes is denoted by $\mathcal{CW}^{\mathrm{rel}}$. A **pointed CW complex** is a pointed space $(X, *) \in \mathcal{T}\mathrm{op}^{\mathrm{pt}}$ s.t. X has a presentation as a CW complex with $* \in X^0$. The category of pointed CW complexes is denoted by $\mathcal{CW}^{\mathrm{pt}}$.

Cellular maps in $\mathcal{CW}^{\mathrm{rel}}$ is defined similarly as that of(3.12.3.9).

Prop. (3.12.3.12)[Pathspace is CW Complex]. The homotopy fibers(3.3.3.18) of any map $f: A \to B$ between CW complexes are homotopic to a CW complex.

Proof: [Milnor, 1959]. or [Rudolph Fritsch and Renzo Piccinini, Cellular Structures in Topology]. □

Cor. (3.12.3.13)[Loop Space]. For $X \in \mathcal{CW}^{\mathrm{pt}}$, the loop space(3.3.3.19) ΩX is homotopic to a pointed CW complex. In particular, if X is of f.t., then so does ΩX.

Proof: This is a special case of(3.12.3.12) applied to $A = \{*\}$, by(3.3.3.20). □

Common CW complexes

Def. (3.12.3.14)[Infinite Vector Spaces]. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ or $\mathbb{H}$, then the **infinite vector space** $\mathbb{K}^\infty$ is the CW complex $\varinjlim_n \mathbb{K}^n$.

There can be given a norm map on $\mathbb{K}^\infty$, as the canonical embedding is norm preserving.

Prop. (3.12.3.15)[Grassmannian]. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ or $\mathbb{H}$, then the **Grassmannian** $\mathrm{Gra}(k, \mathbb{K}^n)$ admits a CW complex structure.

Proof: Cf.[Algebraic Topology Miller, P46] or [Characteristic Classes, Milnor].**?** □

Def. (3.12.3.16) [Infinite Grassmannian]. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ or $\mathbb{H}$, then the **infinite Grassmannian** $\mathrm{Gra}(k, \mathbb{K}^\infty)$ is the CW complex $\varinjlim_n \mathrm{Gra}(k, \mathbb{K}^n)$(11.7.2.12).

In particular, $\mathrm{Gra}(1, \mathbb{K}^\infty) \cong \varinjlim_n \mathbb{KP}^n$ is defined to be the **infinite projective space** $\mathbb{KP}^\infty$.

Def. (3.12.3.17)[Infinite Stiefel Manifold]. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ or $\mathbb{H}$, then the **infinite Stiefel Manifold** $V_k(\mathbb{K}^\infty)$ is the CW complex $\varinjlim_n V_k(\mathbb{K}^n)$ where $V_k(\mathbb{K}^n)$ is the set of orthonormal k-frames(11.7.2.12).

$V_1(\mathbb{K}^\infty) = \varinjlim_n S^n$ is called the **infinite sphere**. It is isomorphic to

$$\mathbb{S}^\infty = \varinjlim_k S^{2k+1} = \varinjlim_k \mathbb{C}^{2k+1} \backslash \{0\}/\mathbb{R}^+ = (\mathbb{C}^\infty \backslash \{0\})/\mathbb{R}_+^\times.$$

Prop. (3.12.3.18). $V_k(\mathbb{K}^\infty)$ is contractible.

Proof: We prove for $\mathbb{S}^\infty$, the proof for $V_k(\mathbb{K}^\infty)$ is verbatim, using Smith orthogonalization.

There is a map $H : \mathbb{S}^\infty \times I \to \mathbb{S}^\infty$ defined by

$$H((x_1, x_2, \ldots), t) = ((1-t)x_1, tx_2 + (1-t)x_1, tx_3 + (1-t)x_2, \ldots)/N$$

where N is the norm of the non-zero element $((1-t)x_1, tx_2 + (1-t)x_1, tx_3 + (1-t)x_2, \ldots)$. The image of H_1 is in the subspace $\mathbb{S}_1^\infty$ of elements $(x_1, x_2, \ldots)$ with $x_1 = 0$. Notice there is another map $H' : \mathbb{S}_1^\infty \times I \to \mathbb{S}^\infty$ defined by

$$H'((0, x_2, \ldots), t) = (t, (1-t)x_2, (1-t)x_3, \ldots)/N'$$

where N' is the norm of the non-zero element $(t, (1-t)x_2, (1-t)x_3, \ldots)$. Then the composition homotopy $(H' \circ H_1) \cdot H$ gives the desired homotopy from $\mathrm{id}_{\mathbb{S}^\infty}$ to a constant map. □

Prop. (3.12.3.19). $\mathbb{RP}^\infty = \mathbb{S}^\infty/\{\pm 1\} = (\mathbb{C}^\infty \backslash \{0\})/\mathbb{R}^\times$.

Def. (3.12.3.20)[James Reduced Product]. Let X be a space with a basepoint e, let the **James reduced product** space $J(X)$ be the quotient of $\coprod_n X^n$ under the identification $(x_1, \ldots, x_j, \ldots, x_n) \sim (x_1, \ldots, \widehat{x}_j, \ldots, x_n)$ if $x_j = e$.

$J(X)$ is a union of subspaces $J_m(X)$, where $J_m(X)$ is the quotient space of X^m under the identification $(x_1, \ldots, x_j, e, \ldots, x_n) \sim (x_1, \ldots, e, x_j, \ldots, x_n)$. If (X, e) is a CW-pair, then J_m is obtained from X^m by glueing together its m subcomplexes where one of the coordinates is e. It is then clear J is a CW complex.

Def. (3.12.3.21) [Infinite Symmetric Product]. Let X be a space with a basepoint e, define the **infinite symmetric product** as the quotient of $J(X)$ by permutations. If X is a simplicial complex, then $SP(X)$ is a CW-complex.

Proof: Cf.[Hat02]P482. □

4 Homotopy Groups

Def. (3.12.4.1) [Homotopy Groups]. For $(X, *) \subset \mathcal{T}\mathrm{op}^{\mathrm{pt}}$ and $n \in \mathbb{N}$, define the **homotopy groups** $\pi_n(X) = \pi_n(X, *) = \langle \mathbb{S}^n, X \rangle$, which is a pointed set.

And $\pi_1(X)$ is a group as $\mathbb{S}^1$ has a cogroup structure: $\mathbb{S}^1 \to \mathbb{S}^1 \wedge \mathbb{S}^1$. Similarly, $\pi_n(X) = \pi_1(\Omega^{n-1}X)$ are also groups, and the group structure are given by the cogroup structure $\mathbb{S}^n \to \mathbb{S}^n \wedge \mathbb{S}^n$.

Prop. (3.12.4.2) [Loop Spaces and Homotopy Groups]. $\pi_{i+1}(M) \cong \pi_i(\Omega(M))$.

Proof: This follows from the fact $\mathbb{S}^n = \Sigma^n(\mathbb{S}^0)$ and(3.12.1.18). □

Prop. (3.12.4.3) [Homotopy Groups are Abelian]. For $X \in \mathcal{CG}^{\mathrm{pt}}$, the homotopy group $\pi_n(X)$ is an Abelian group for $n \geq 2$.

Proof: By(3.12.4.2), it suffices to show for $n = 2$, and $\pi_2(X) = \pi_1(\Omega X)$ is Abelian by(3.13.2.30) and(3.13.2.24). □

Cor. (3.12.4.4). For any $X \in \mathcal{CG}$, $\langle \Sigma(X), Y \rangle$ is a group and $\langle \Sigma^2(X), Y \rangle$ is an Abelian group.

Prop. (3.12.4.5) [Homotopy Groups and Change of Basepoints]. Let $X \in \mathcal{CG}$ and $\gamma : \mathbb{I} \to X$ be a path from a to b, then for any $n \in \mathbb{Z}_+$, we can define a map $\gamma_\# : \pi_n(X, a) \to \pi_n(X, b)$ as follows: For any $f : (\mathbb{I}^n, \partial I^n) \to (X, a)$, identity $\mathbb{I}^n$ with the subspace of $\mathbb{R}^n$ consisting of vectors $\mathbf{x}$ s.t. $d(\mathbf{x}) \leq \frac{1}{2}$, where $d((x_1, \ldots, x_n)) = \min(|x_i|)$, and

$$\gamma_\#(f) : (\mathbb{I}^n, \partial I^n) \to X : \mathbf{x} \mapsto \begin{cases} f(2\mathbf{x}) & , ||\mathbf{x}|| \leq \frac{1}{4} \\ \gamma(4||\mathbf{x}|| - 1) & , \frac{1}{4} \leq ||\mathbf{x}|| \leq 1 \end{cases}$$

Then for any $x_0 \in X$, this defines an actions of $\pi_1(X, x_0)$ on $\pi_n(X, x_0)$ by group homomorphisms for any $n \in \mathbb{Z}_+$. And for $n = 1$, this is just the conjugation action.

Proof: It is a well-defined action because any homotopy between two maps $f_1, f_2 : (\mathbb{I}^n, \partial I^n) \to (X, a)$ can generate a homotopy between $\gamma_\#(f_1)$ and $\gamma_\#(f_2)$, and it is an action by group homomorphism because there is a homotopy between $\gamma_\#(f) \cdot \gamma_\#(g)$ and $\gamma_\#(f \cdot g)$, which is easy to write out. □

Def. (3.12.4.6) [Simple Spaces]. A space $X \in \mathcal{CG}$ is called a **simple topological space** if for any $x_0 \in X$, the action of $\pi_1(X, x_0)$ defined in(3.12.4.5) is trivial.

Def. (3.12.4.7) [Weak Homotopy Equivalences]. $f : X \to Y \in \mathcal{CG}$ is called a **weak homotopy equivalence** iff it induces isomorphism $\pi_n((X, x_0)) \cong \pi_n(Y, f(x_0))$ for any $n \in \mathbb{N}$ and $x_0 \in X$.

Prop. (3.12.4.8). Let $f_0, f_1 : X \to Y \in \mathcal{CG}$ be maps and $h : \mathbb{I} \times X \to Y$ be a homotopy $x_0 \in X$, then if $\gamma : \mathbb{I} \to Y : t \mapsto h(t, x_0)$, then

$$\gamma_\# \circ \gamma_\#(f_0)_* = (f_1)_*.$$

Proof: For $f : f : (\mathbb{I}^n, \partial I^n) \to (X, x_0)$ is easy to write out a homotopy between $\gamma_\#(f_0)_*(f)$ and $(f_1)_*(f)$. □

Cor. (3.12.4.9). Any homotopy equivalence is a weak homotopy equivalence.

Def. (3.12.4.10) [Relative Homotopy Groups]. For an inclusion $i : (A, *) \subset (X, *) \in \mathcal{T}\mathrm{op}^{\mathrm{pt}}$, $n \in \mathbb{Z}_+$, define the **relative homotopy groups** $\pi_n(X, A) = \pi_n(X, A, *) = \pi_{n-1}(P(X; *, A))$, where $P(X; *, A)$ is the homotopy fiber of i**?**. Equivalently, if we denote $\mathbb{J}^n = \partial \mathbb{I}^{n-1} \times \mathbb{I} \cup \mathbb{I}^{n-1} \times \{0\} \subset \mathbb{I}^n$ for $n \geq 2$ and $\mathbb{J}^1 = \{0\} \subset \mathbb{I}^1$, then

$$\pi_n(X, A) = [(\mathbb{I}^n, \partial \mathbb{I}^n, \mathbb{J}^n), (X, A, *)].$$

This is a pointed set for $n = 1$, a group for $n = 2$, and an Abelian group for $n \geq 3$.

Prop. (3.12.4.11) [Long Exact Sequence of Relative Homotopy Groups].

Proof: □

Cor. (3.12.4.12) [Covering Spaces and Homotopy Groups]. If $E \to B$ is a covering space, then $\pi_n(E) \to \pi_n(B)$ is an isomorphism for $n \geq 2$.

Prop. (3.12.4.13). If $X \in \mathcal{CG}^{\mathrm{pt}}$ is contractible, then $\pi_n(X) = 0$ for any $n \geq 0$.

Prop. (3.12.4.14) [Products and Homotopy Groups]. For $X, Y \in \mathcal{CG}^{\mathrm{pt}}$, $\pi_n(X \times Y) = \pi_n(X) \times \pi_n(Y)$ for any $n \in \mathbb{N}$.

Prop. (3.12.4.15) [Colimits and Homotopy Groups]. If $X = \varinjlim_i X_i \in \mathcal{CG}^{\mathrm{pt}}$ is a filtered colimits, there are natural isomorphisms

$$\varinjlim_i \pi_n(X_i) \cong \pi_n(X)$$

for each $n \in \mathbb{N}$.

Proof: This follows from the fact any compact subset of X is contained in some X_i**?**. □

Def. (3.12.4.16)[n-Connectedness]. For $n \in \mathbb{N}$, $(X, A) \in \mathcal{CG}^{\mathrm{rel,pt}}$ is called n**-connected** if $\pi_i(X, A) = *$ for any $i \leq n$. $X \in \mathcal{T}\mathrm{op}^{\mathrm{pt}}$ is called n-connected if $\pi_i(X) = *$ for any $i \leq n$.

Def. (3.12.4.17) [n-Equivalences]. For $n \in \mathbb{Z}_+$, $f : (X, A) \to (Y, B) \in \mathcal{T}\mathrm{op}^{\mathrm{rel}}$ is called an n-**equivalence** if $f_* : \pi_p(X, A) \to \pi_p(Y, B)$ are isomorphisms for $p < n$, and surjective for $p = n$.

Thm. (3.12.4.18) [Excision for Homotopy Groups]. if $m, n \geq 0, (X; A, B)$ is an excisive triad s.t. $(A, A \cap B)$ is m-connected and $(B, A \cap B)$ is n-connected, then $(A, A \cap B) \to (A \cup B, A)$ is an $m + n$-equivalence.

Proof: Cf.[Hatcher P360]. □

Cor. (3.12.4.19). For $n > 1$, $\pi_n(\bigvee_\alpha S^\alpha)$ is free Abelian with $\pi_n(S^n)$ as generators. This is because $(\prod_\alpha S^n, \bigvee_\alpha S^n)$ is $(2n-1)$-connected thus use excision, because $\pi_n(\prod_\alpha S^n)$ is easy to calculate.

Prop. (3.12.4.20). If $f : X \to Y$ is an n-equivalence between $(n-1)$-connected spaces, then the quotient map $\mathrm{pr} : (M(f), X) \to (C(f), *)$ is an $2n$-equivalence. And if X, Y are both n-connected, then pr is an $2n+1$-equivalence.

Proof: □

Cor. (3.12.4.21)[Quotients and Homotopy Groups]. For $n \in \mathbb{Z}_+$, if $i : A \to X$ is a cofibration that is a n-equivalence of $(n-1)$-connected space, then the map $(X, A) \to (X/A, *)$ is a $2n$-equivalence. And if A, X are n-connected, then this is a $2n+1$-equivalence.

Proof: This follows from the commutative diagram

$$\begin{array}{ccc} (M(i), A) & \longrightarrow & (C(i), *) \\ \downarrow & & \downarrow \\ (X, A) & \longrightarrow & (X/A, *) \end{array}$$

where the vertical maps are homotopy equivalences, by(3.12.6.7). □

Prop. (3.12.4.22) [Suspension and Homotopy Groups, Freudenthal]. For $X \in \mathcal{CG}^{\text{well-pt}}$, there are maps

$$\Sigma_* : \pi_p(X) \to \pi_{p+1}(\Sigma(X)) : f \in \langle \mathbb{S}^p, X\rangle \mapsto \Sigma(f) \in \langle \mathbb{S}^{p+1} \cong \Sigma(\mathbb{S}^p), \Sigma(X)\rangle(3.12.1.13).$$

Then if $n \in \mathbb{N}, X \in \mathcal{CG}^{\text{well-pt}}$ and X is n-connected, then Σ_* is bijective for $p \leq 2n$ and surjective for $p = 2n+1$.

In particular, $\Sigma^n(X)$ is $(n-1)$-connected.

Proof: Cf.[May, P85]. □

Def. (3.12.4.23)[Stable Homotopy]. For $X \in \mathcal{CG}^{\text{well-pt}}$, using the suspension(3.12.4.22), we can form the colimit

$$\pi_p^s(X) = \varinjlim_{n\in\mathbb{N}} \pi_{p+n}(\Sigma^n(X)).$$

Then by(3.12.4.22),

$$\pi_p^s(X) = \pi_{p+n}(\Sigma^n(X)), \quad n \geq p+2.$$

Prop. (3.12.4.24). The homotopic direct limit of a family of homotopy equivalence is a homotopy equivalence. Cf.[Morse Theory Milnor].

Fundamental Groups

Def. (3.12.4.25) [Simply Connected]. A space is called **simply connected** if it is connected and $\pi_1(X, x) = 0$ for some point $x \in X$.

Def. (3.12.4.26) [Semilocally Simply Connected]. A space is called **semilocally simply connected** if for any point $x \in X$, there is a nbhd U of x that the image of the inclusion-induced map $\pi_1(U, x) \to \pi_1(X, x)$ is trivial.

Prop. (3.12.4.27) [Van Kampen]. If X is a union of path-connected subsets A_α all containing x_0 that $A_\alpha \cap A_\beta$ and $A_\alpha \cap A_\beta \cap A_\gamma$ are all path-connected, then $*\pi_1(A_\alpha)/\sim$ where $\sim$ is generated by $i_*(\pi_1(A_\alpha \cap A_\beta)) \in \pi_1(A_\alpha) \sim i_*(\pi_1(A_\alpha \cap A_\beta)) \in A_\beta$ for every α, β.

Proof: Cf.[Hatcher P52]. □

Prop. (3.12.4.28) [Wedge Sums]. If $X_i \in \mathcal{CG}^{\text{well-pt}}$ and $X = \bigvee X_i$, then $\pi_1(X) = *_i\pi_1(X_i)$.

5 CW Approximations

Prop. (3.12.5.1) [CW Complex has Homotopy Extension Property]. For $(X, A) \in \mathcal{CW}^{\text{rel}}$, $X \times \{0\} \cup A \times I$ is a deformation retract of $X \times I$, thus (X, A) has the homotopy extension property(3.12.6.1).

Proof: Cf.[Hat02]P15. □

Lemma (3.12.5.2) [Compression and Homotopies]. For $n \in \mathbb{Z}_+, f : B \to Y \in \mathcal{CG}$, the following are equivalent:

- f_* induces an injection on π_n and a surjection on π_{n+1}.
- Any map $(\mathbb{D}^n, \mathbb{S}^n) \to (Y, B) \in \mathcal{T}\text{op}^{\text{rel}}$ is homotopic rel $\mathbb{S}^n$ to a map $\mathbb{D}^n \to B$.

Proof: Cf.[May, P70].**?** □

Thm. (3.12.5.3) [Compression Theorem]. If $n \in \mathbb{Z}_+, (X, A) \in \mathcal{CW}^{\text{rel}}$ has relative dimension$\leq n$ and $f : B \to Y$ an n-equivalence, then any map $(X, A) \to (Y, B) \in \mathcal{CG}^{\text{rel}}$ is homotopic rel A to a map $X \to B$.

In particular, (relative) homotopy doesn't depend on (2-degree)higher dimensional cells, (but might on lower one).

Proof: Use(3.12.5.2) on each cells. □

Thm. (3.12.5.4) [Whitehead]. If $f : Y \to Z \in \mathcal{CG}$ is an n-equivalence, then $[X, Y] \to [X, Z]$ is bijective for $X \in \mathcal{CW}^{\text{pt}}$ of dimension$\leq n-1$, and surjective for $\dim X = n$.

Proof: The surjectivity follows from the compression theorem for the pair $(\varnothing, X) \in \mathcal{CW}^{\text{rel}}$, and the injectivity follows from the compression theorem applied to $(X \times \mathbb{I}, X \times \partial\mathbb{I}) \in \mathcal{CW}^{\text{rel}}$. □

Cor. (3.12.5.5). If $Y \to Z \in \mathcal{T}\text{op}^{\text{pt}}$ is a weak-equivalence, then $\langle X, Y\rangle \to \langle X, Z\rangle$ is an equivalence for any $X \in \mathcal{CW}^{\text{pt}}$.

Cor. (3.12.5.6) [Whitehead]. For $n \in \mathbb{Z}_+$, an n-equivalence of CW complexes of dimension$\leq n-1$ is a homotopy equivalence.

A weak equivalence of CW complexes is a homotopy equivalence.

Proof: Let $e : Y \to Z \in \mathcal{CW}$ satisfies the hypothesis, then because $e_* : [Z, Y] \to [Z, Z]$ is a bijection by compression theorem(3.12.5.3), there exists $f : Z \to Y$ s.t. $e \circ f \cong \text{id}$. Thus $e \circ f \circ e \cong e$. Then since $e_* : [Y, Y] \to [Y, Z]$ is also a bijection by compression theorem, $f \circ e \cong \text{id}$. □

Cor. (3.12.5.7). If $X \in \mathcal{CW}^{\text{pt}}$ and $\pi_n(X) = 0$ for all n, then X is contractible.

Cor. (3.12.5.8) [Whitehead Combinatorial Homotopy Theorem I]. **?** If M and K is dominated by CW complexes, then any weak homotopy equivalence is an homotopy equivalence. If the map is an inclusion, then it is a deformation retract. In particular, if M is manifold, then it is dominated by its tubular nbhd, so this theorem is applied.

Proof: For inclusion, use compression, and in general use mapping cylinder and cellular approximation. □

Cellular and CW Approximations

Lemma (3.12.5.9). For $n \in \mathbb{Z}_+$, f $(X, A) \in \mathcal{CW}^{\text{rel}}$ has no m-cells for $m \leq n$, then (X, A) is n-connected. In particular, (X, X^n) is n-connected.

Proof: It suffices to show that any map $f : (\mathbb{I}^n, \partial\mathbb{I}^n, \mathbb{J}^n) \to (X, A, *)$ is homotopic to a map $(\mathbb{I}^n, \mathbb{J}^n) \to (A, *)$ rel $\mathbb{J}^n$(3.12.4.1). For this, notice that the image is compact, thus we can assume that (X, A) is finite**?**. Thus by doing one cell by one cell, it suffices to show for $X = A \coprod_{f, \mathbb{S}^n} \mathbb{D}^n$. In this case, notice that by simplicial approximation, we can find a homotopic map $f \cong f'$ that f' avoids some point in $(\mathbb{D}^n)^o$**?**. Then we can use projection to construct a homotopy. ☐

Thm. (3.12.5.10) [Cellular Approximationss]. Any map $f : (X, A) \to (Y, B) \in \mathcal{CW}^{\text{rel}}$ is homotopic rel A to a cellular map.

In particular, any $f : X \to Y \in \mathcal{CW}$ is homotopic to a cellular map.

Proof: This follows from(3.12.5.9). ☐

Remark (3.12.5.11). The cellular approximation makes the computation of homotopy theoretically easier, but the difficulty comes from the complexity of the homotopy group of the sphere.

Remark (3.12.5.12). In fact, all the rest of this subsubsection can be rewritten by the geometric realization functor $\Gamma(X) \to X$(3.5.3.8). It is functorial in the level of spaces.**?**

Prop. (3.12.5.13) [n-Connected CW Models]. For a pair (A, X), if A is CW complex, then there is a n-connected(3.12.4.16) CW pairs $(Z, A) \to (X, A)$ that is identity on A, and $\pi_i(Z) \to \pi_i(X)$ is isomorphism for $i > n$ and injection for $i = n$.

Such a pair (Z, A) is called a n-connected CW model of (X, A), and moreover it can be constructed from A by attaching cells of dimension greater than n.

Proof: Cf.[Hatcher P353]. ☐

Cor. (3.12.5.14). For an n-connected CW pair (X, A), there exist a homotopic $(Z, A) \cong (X, A)$ rel A that $Z \backslash A$ has only cells of dimension greater than n.

Proof: Choose the n-connected approximation as above. The map induce and isomorphism on $\pi_{>n}$ by definition and on $\pi_{<n}$ because $\pi_i(A) \to \pi_i(Z)$ and $\pi_i(A) \to \pi_i(X)$ are isomorphisms. And on π_n, it is injective by definition and surjective because $\pi_n(A) \to \pi_n(Z) \to \pi_n(X)$ is isomorphism. Hence we know that the collapsed mapping cylinder at is weak-homotopy equivalent to Z, thus it deforms into Z by(3.12.5.8), thus $Z \to X$ rel A by(3.12.1.5). ☐

Cor. (3.12.5.15)[Functorial CW Approximations]. A **CW approximation** of a space X is a CW complex Z and a weak homotopy equivalence $Z \to X$. A **CW approximation** of a pair (X, A) is pair of CW complexes (Z, Z_0) and a morphism $(Z, Z_0) \to (X, A)$ that induces isomorphisms on both relative and absolute homotopy groups.

Thus there exists a CW approximation for any space A, and also there exists a CW approximation for any pair (X, X_0).

Proof: Just choose A to be a set containing a point for each connected component of X, then $\pi_0(Z) \to \pi_0(X)$ is surjective hence injective.

For pairs, first approximate X_0 and use the mapping cylinder to get a embedding.**?** ☐

Prop. (3.12.5.16)[Functoriality of CW Models]. Given n-connected CW model $f:(Z,A)\to(X,A)$ and $f':(Z',A')\to(X',A')$, then any map of pairs $g:(X,A)\to(X',A')$ can be extended to a map of pairs $h:(Z,A)\to(Z',A')$ that $gf\cong f'h$ rel$A$. And such a map h is unique up to homotopy rel$A$.

Proof: Cf.[Hatcher, P355]. □

Cor. (3.12.5.17) [Uniqueness of CW approximation]. The CW approximation is unique up to homotopy.

Cor. (3.12.5.18) [Localizing Category]. Together with Whitehead combinatorial homotopy theorem(3.12.5.8) the homotopy category of spaces defined in(3.5.2.3) is the category of spaces $\mathcal{CG}$ localized by the class of weak homotopy equivalence classes.

Prop. (3.12.5.19)[CW Approximation of Excisive Triads]. Cf.[May, 79].

6 Fibrations and Cofibrations

Cofibrations

Def. (3.12.6.1)[Homotopy Extension Property]. $(X,A)\in\mathcal{T}\mathrm{op}^{\mathrm{rel}}$ is said to satisfy the **homotopy extension property** if every map $X\times\{0\}\coprod_{A\times\{0\}}A\times I\to Y$ can be extended to a map $X\times I\to Y$.

Def. (3.12.6.2) [Cofibrations]. A **cofibration** is a map $j:A\to X$ that for every map $X\times\{0\}\coprod_{A\times\{0\}}A\times I\to Y$ can be extended to a map $X\times I\to Y$.

This implies $X\times\{0\}\cup A\times\mathbb{I}\to X\times\mathbb{I}$ has a left inverse. And the converse is clearly true.

Then a cofibration is just a topological embedding with closed image that (X,A) has the homotopy extension property(3.12.6.1).

Cofibrations is stable under cobase change and coproducts.

Proof: ? □

Def. (3.12.6.3) [NDR-Pairs]. An neighborhood deformation retraction pair, or an **NDR-pair** is a pair $(X,A)\in\mathcal{T}\mathrm{op}^{\mathrm{rel}}$ s.t. there is a map $u:X\to\mathbb{I}$ s.t. $u^{-1}(0)=A$, and a homotopy $f_t:X\to X$ rel A s.t. $f_0=\mathrm{id}_X$, and $f_1(u^{-1}([0,1))\subset A$.

Prop. (3.12.6.4) [NDR Pairs and Cofibrations]. If $A\subset X$ is closed, then (X,A) is a NDR-pair(3.12.6.3) iff $A\to X$ is a cofibration.

Proof: Cf.[May, P45].? □

Prop. (3.12.6.5)[CW-Pairs are Cofibrations]. By compression theorem(3.12.5.3), for any CW-pair (A,X), $A\to X$ is a cofibration.

Def. (3.12.6.6) [Hurewitz Cofibration]. A **closed Hurewicz cofibration** $i:A\subset B$ is a closed inclusion of spaces that $B\times\{0\}\coprod A\times\mathbb{I}\to B\times\mathbb{I}$ has left extension property w.r.t any map $Y\to\mathrm{pt}$.

Prop. (3.12.6.7) [Quotient a Contractible Cofibration]. If $A\to X$ is a cofibration and A is contractible, then the quotient map $X\to X/A$ is a homotopy equivalence. In particular, this applies to $(X,A)\in\mathcal{CW}^{\mathrm{rel}}$, by(3.12.5.1).

Proof: Let $f_t : X \to X$ be a homotopy extending a contraction of A to a point, with $f_0 = \mathrm{id}$. Since $f_t(A) \subset A$, they descends to a homotopy $\overline{f}_t : X/A \to X/A$. Because $f_1(A)$ is a point, there is a map g in the following diagram

$$\begin{array}{ccc} X & \xrightarrow{f_1} & X \\ \downarrow \pi & \overset{g}{\nearrow} & \downarrow \pi \\ X/A & \xrightarrow{\overline{f}_1} & X/A \end{array}.$$

So g and π are inverse homotopy equivalences, because $f_1 \cong f_0 = \mathrm{id}$ and $\overline{f}_1 \cong \overline{f}_0 = \mathrm{id}$. □

Prop. (3.12.6.8). Let X be a normal space, then an inclusion $j : A \hookrightarrow X$ is a cofibration iff $A \hookrightarrow V$ is a cofibration for some open nbhd V of $j(A) \subset X$.

Proof: Cf.[AGP02]P92. □

Prop. (3.12.6.9) [Homotopic Glueing Functions]. Let $A \to X_1$ be a cofibration with X Hausdorff, and we have attaching maps $f, g : A \to X_0$ that is homotopic, then $X_0 \coprod_f X_1 \cong X_0 \coprod_g X_1$ rel X_0.

Proof: Now choose a homotopy $H : A \times I \to X_0$ connecting f and g, then H induces a quotient space $Z = X_0 \coprod_H (X_1 \times I)$. Let $X = X_0 \coprod_f X_1, Y = X_0 \coprod_g X_1$, then there are natural inclusion maps $i : X_1 \to Z, j : \quad Y \to Z$, and there are also deformation retractions $Z \to X, Z \to Y$ constructed as follows:

Choose a deformation retraction r of $X_1 \times I$ onto $X_1 \times \{0\} \coprod A \times I$(3.12.6.1), and H induces a map $\overline{H} : D^n \times \{0\} \coprod S^n \times I \to S^n \coprod_f D^n$, making the following diagram commutative

$$\begin{array}{ccc} A \times I & \longrightarrow & X_1 \times I \\ \Big\downarrow H & & \Big\downarrow r \\ & & A \times I \coprod X_1 \times \{0\} \\ & & \Big\downarrow \overline{H} \\ X_0 & \xrightarrow{\mathrm{id}} & X_0 \coprod_f X_1 \end{array}$$

which by definition defines a deformation retraction $r_1 : X_0 \coprod_H (X_1 \times I) \to X_0 \coprod_f X_1$. Similarly we have deformation retraction $r_2 : Z \to Y$. So $r_2 \circ i$ and $r_1 \circ j$ induce an homotopy equivalence between X and Y. □

Prop. (3.12.6.10). If $A \to X, A \to Y$ are cofibrations, and $f : X \to Y$ is a homotopy equivalence that $f|_A = \mathrm{id}_A$, then f is a homotopy equivalence rel A.

Proof: Cf.[Hatcher] P16. □

Cor. (3.12.6.11). If $j : A \to X$ is a cofibration which is also a homotopy equivalence, and X is Hausdorff, then A is a deformation retraction of X.

Serre Fibrations

Def. (3.12.6.12) [Serre Fibration]. A **Serre fibration** is the right lifting class of $D^n \times \{0\} \to D^n \times I$ for every n. This is equivalent to: for any homotopy of ∂D^n and a image D^n, there is a homotopy of D^n.

In particular, Serre fibrations are stable under base change, by(3.4.0.1).

Prop. (3.12.6.13). Being a Serre fibration is local on the target.

Proof: Cf.[Homotopical Point of View]P127. □

Prop. (3.12.6.14)[Long Exact Sequence of Serre Fibration]. Let $\pi : E \to X$ be a Serre fibration, let $b_0 \in B$ and $x_0 \in F = \pi^{-1}(b_0)$, then the map $\pi_* : \pi_n(E, F, x_0) \to \pi_n(B, b_0)$ is an isomorphism for all $n \geq 1$. In particular, there is a long exact sequence

$$\ldots \to \pi_n(F, x_0) \to \pi_n(E, x_0) \to \pi_n(B, b_0) \to \pi_{n-1}(F, x_0) \to \ldots \to \pi_0(B, b_0) \to 0.$$

by(3.12.4.11).

Proof: Cf.[Hat02]P376. [nLab]. □

Hurewicz Fibrations

Def. (3.12.6.15)[Hurewicz Fibrations]. A **Hurewicz fibration** is a map $p : X \to Y \in \mathcal{CG}$ that has right lifting property w.r.t maps $A \times \{0\} \to A \times [0, 1]$ for any $A \in \mathcal{CG}$. in particular, a Hurewicz fibration is a Serre fibration(3.12.6.12).

Hurewicz fibrations are stable under base change.

Prop. (3.12.6.16) [Comparing Fibers of a Hurewicz Fibration]. If $\pi : E \to B$ is a Hurewicz fibration, then for any arc γ in B with $\gamma(0) = a, \gamma(1) = b$, there is a homotopy equivalence $f_\gamma : \pi^{-1}(a) \cong \pi^{-1}B$, and the homotopy class of f_γ only depends on the homotopy class of γ.

In other words, a Hurewicz fibration over B determines a contravariant functor $\Pi_1(B) \to \mathrm{Ho}(\mathcal{CG})$.

Proof: This follows from the homotopy lifting property. □

Cor. (3.12.6.17). For a Hurewicz fibration $E \to B$, if B is contractible, then it is fiber homotopy equivalent to a trivial fiber bundle.

Prop. (3.12.6.18). Let $\pi : E \to B, \pi' : E' \to B$ be Hurewicz fibrations and $f : E \to E'$ be a map over B that is also a homotopy equivalence, then f is a fiber homotopy equivalence.

Proof: Cf.[Miller, P141]**?** □

Prop. (3.12.6.19) [Homotopy Invariance of Pullbacks]. Let $\pi : E \to X$ be a Hurewicz fibration and $f_0, f_1 : Y \to X \in \mathcal{CG}$ are two maps that are homotopic, then the two Hurewicz fibrations $f_0^*E/Y, f_1^*E/Y$ are fiber homotopy equivalent.

Proof: Cf.[Miller, P140]**?** □

Prop. (3.12.6.20) [Homotopy Fiber of Contractible Fibration]. Let $f : E \to B$ be a Hurewicz fibration with E contractible, then the homotopy fibers(3.3.3.18) F over b_0 is weak homotopy equivalent to $\Omega(B, b_0)$.

Proof: Let $x_0 \in \pi^{-1}(b_0)$. If we compose the contraction of E to x_0 with π, then we get for each $x \in E$ a path γ_x from $\pi(x)$ to b_0. Then these give a map $E \to PB : x \mapsto \pi\gamma_x^{-1}$, which is a lift of π. Then this map gives a commutative diagram

$$\begin{array}{ccccc} F & \longrightarrow & E & \longrightarrow & B \\ \downarrow & & \downarrow & & \| \\ \Omega(B, b_0) & \longrightarrow & PB & \longrightarrow & B \end{array}$$

that gives a map of their corresponding long exact sequences(3.12.6.14). Thus $F \to \Omega(B, b_0)$ is a weak homotopy equivalence because E, PB are both contractible(3.3.3.20). □

Prop. (3.12.6.21) [Pathspaces are Hurewicz Fibrations]. For any map $f : A \to B$, the map $\pi : E_f \to B : (a, \gamma) \mapsto \gamma(1)$ from the pathspace(3.3.3.18) is a Hurewicz fibration.

In particular, take $A = \{x_0\}$, then the path space $PB \to B$ is a Hurewicz fibration.

Proof: Firstly this map is continuous by(3.3.3.5). To verify the homotopy lifting property, let $g_t : X \to B$ be a homotopy and $\widetilde{g}_0 : X \to E_f$ be a lifting, let $\widetilde{g}_0(x) = (h(x), \gamma_x)$. Define a lift $\widetilde{g}_t : X \to E_f$ by $\widetilde{g}_t(x) = (h(x), \gamma_x \cdot g_{[0,t]}(x))$. The second term is concatenation, which can be defined because $g_0(x) = \pi\widetilde{g}_0(x) = \gamma_x(1)$.

To check this is a continuous homotopy, by(3.3.3.7), it suffices to show $A \times I \times I \to B : (x, s, t) \mapsto \gamma_x \cdot g_{[0,s]}(x)(t) = \begin{cases} \gamma(x, (1+t)s) & s \leq \frac{1}{1+t} \\ g_{(1+t)s-1}(x) & s \geq \frac{1}{1+t} \end{cases}$ is continuous. □

Cor. (3.12.6.22) [Homotopy Fibers]. We can embed A into E_f be mapping x to (x, γ_x), where γ_x is the trivial loop at x. Then A is a deformation contraction of E_f, by restricting to shorter and shorter initial segments: $H_t : E_f \to E_f : (a, \gamma) \mapsto (a, \gamma_t)$, where $\gamma_t(x) = \gamma(tx)$.

Then we factored f as a homotopy equivalence followed by a fibration: $A \to E_f \to B$.

If $x_0 \in X$ and F_f is the fiber of E_f over x_0, then a map $(I^{i+1}, \partial I^{i+1}, J^i) \to (A, B, x_0)$ is the same as a map $(I^i, \partial I^i) \to (F_f, \gamma_0)$, where γ_0 is the trivial loop at x_0. Thus $\pi_{i+1}(A, B, x_0) = \pi_i(F_f, \gamma_0)$.

Prop. (3.12.6.23) [Pathspace of a Hurewicz Fibration]. If $\pi : E \to B$ is a fibration, then the inclusion $E \to E_\pi$(3.12.6.22) is a fiber homotopy equivalence. In particular, the homotopy fibers of π are homotopy equivalent to the actual fibers.

Proof: □

Prop. (3.12.6.24) [Fibration Sequence]. Given a fibration $\pi : E \to B$ with $F = \pi^{-1}(b_0), x_0 \in F$, there is a sequence

$$\ldots \to \Omega^2(B, b_0) \to \Omega(F, x_0) \to \Omega(E, x_0) \to \Omega(B, b_0) \to F \to E \to B \to 0$$

where any two consecutive maps form a fibration, up to homotopy.

Proof: By(3.12.6.23), the inclusion i of F to the homotopy fiber F_π over π over p is a homotopy equivalence, and it extends to a map $i : F_p \to E : (x, \gamma) \mapsto x$, which is also a Hurewicz fibration, because it is the pullback of the fibration $PB \to B$(3.12.6.21).

Thus we can take the homotopy fiber F_i of $i : F_p \to E$ over x_0, and similarly there is a fibration $j : F_i \to F$, and F is naturally homotopic to the actual fiber of i, which is just $\Omega(B, b_0)$. □

Model Category Structures

Lemma (3.12.6.25)[Cofibrant Replacement]. Any map $f : X \to Y$ is a composition $X \to M_f \to Y$. Notice $M_f \to Y$ is a homotopy equivalence and $X \to M_f$ is cofibrant by(3.12.6.4).

Cor. (3.12.6.26) [Homotopy equivalence and mapping cylinder]. A map $f : X \to Y$ is a homotopy equivalence iff X is a deformation retraction of the mapping cylinder M_f. In particular, two spaces are homotopically equivalent iff there is a third space containing both of them as deformation retractions.

Proof: Cf.[Hatcher] P16. □

Lemma (3.12.6.27)[Fibrant Replacement]. Any map $f : X \to Y$ is a composition $X \to N(f) \to Y$, where $N(f) = X \times_Y Y^I$, where $Y^I \to Y$ is evaluation at $\{0\}$, and $X \to N(f)$ is given by $x \mapsto (x, c_{f(x)})$, where $c_{f(x)} \in Y^I$ is the constant map $f(x)$.

It is true that

Proof: $X \to N(f)$ is homotopy inverse to the projection map: We can use the homotopy $N(f) \times I \to N(f) : (\chi, a) \mapsto \chi_a : t \mapsto \chi(at)$.

To show that $N(f) \to Y$ is a fibration, Cf.[May, 50]**?**. □

Prop. (3.12.6.28)[Serre-Quillen]. The category $\mathcal{CG}$ can be given a **Serre-Quillen model structure** with

- Weak equivalences: weak homotopy equivalence,
- Fibrations: Serre fibrations,
- Cofibrations: Retracts of morphisms $X \to Y$ where Y is obtained from X by attaching cells.

Proof: Cf.[Homotopy Theories and Model Categories, Chap8]. □

Prop. (3.12.6.29). The homotopy category Ho($\mathcal{T}$op) of the Serre-Quillen model structure is equivalent to the homotopy category of spaces $\mathcal{H}$.

Proof:

□

Lemma (3.12.6.30). Every map can be decomposed as a homotopy equivalence followed by a fibration, by the construction of homotopy fibers.

Proof: □

Prop. (3.12.6.31) [Hurewicz-Str∅m]. The category $\mathcal{CG}$ can be given a **Hurewicz-Str∅m model structure** with

- Weak equivalences: homotopy equivalences.
- Cofibrations: closed Hurewicz cofibrations.
- Fibrations: Hurewitz fibrations.

Proof: Cf.[strum paper]. □

Prop. (3.12.6.32). The homotopy category of the Hurewicz-Str∅m model structure is equivalent to the usual category of homotopy types.

7 Calculations of Homotopy Groups

Prop. (3.12.7.1). For $0 < k < n \in \mathbb{Z}$, $\pi_k(\mathbb{S}^n) = 0$. And for $0 < n, \pi_0(\mathbb{S}^n) = *$.

Proof: This follows from cellular approximation(3.12.5.10) and the canonical CW structure on $\mathbb{S}^n$. □

Prop. (3.12.7.2). For $i \geq 2$, $\pi_1(\mathbb{RP}^i) \cong \mathbb{Z}/(2)$, and $\pi_n(\mathbb{RP}^i) \cong \pi_n(\mathbb{S}^i)$ for $n \neq 1$.

Proof: This follows from the fiber sequence $\mathbb{Z}/(2) \to \mathbb{S}^n \to \mathbb{RP}^n$ and(3.12.4.12). □

Lemma (3.12.7.3). There is a covering space $\mathbb{R} \to \mathbb{S}^1$ with fiber $\mathbb{Z}$, thus $\pi_1(\mathbb{S}^1) \cong \mathbb{Z}$.

Prop. (3.12.7.4) [Hopf Fibration]. By(3.14.1.12) and(3.12.6.14), there is a long exact sequence

$$\ldots \to \pi_i(\mathbb{S}^1) \to \pi_i(\mathbb{S}^3) \to \pi_i(\mathbb{S}^2) \to \pi_{i-1}(\mathbb{S}^1) \to \ldots \to \pi_0(\mathbb{S}^2) \to 1.$$

Thus $\pi_i(\mathbb{S}^3) \cong \pi_i(\mathbb{S}^2)$ for $i \geq 3$, and $\pi_2(\mathbb{S}^2) \cong \pi_1(\mathbb{S}^1) \cong \mathbb{Z}$(3.12.7.3).

Prop. (3.12.7.5) [Finiteness of Sphere Homotopy]. For $p > n > 1$, $\pi_p(\mathbb{S}^n)$ are all finite except for $\pi_{4n-1}(\mathbb{S}^{2n})$.

Proof: □

Prop. (3.12.7.6) [Basic Sphere Homotopy]. For $n \in \mathbb{Z}_+$, there are maps $\pi_i(S^n) \to \pi_{i+1}(S^{n+1})$ that is an isomorphism for $i < 2n - 1$ and surjective for $i = 2n - 1$.

In particular, $\pi_n(\mathbb{S}^n) \cong \pi_2(\mathbb{S}^2) \cong \mathbb{Z}$ for any $n \geq 2$.

Proof: This follows from Freudenthal suspension theorem(3.12.4.22). The last assertion follows from(3.12.7.3). □

Prop. (3.12.7.7). $\pi_4(\mathbb{S}^3) \cong \pi_4(\mathbb{S}^2) \cong \mathbb{Z}/(2)$.

Proof: □

Prop. (3.12.7.8). for $i \leq 2m$, $\pi_i G_m(\mathbb{C}^{2m}) \cong \pi_{i-1}U(m)$, and

$$\pi_{i-1}U(m) \cong \pi_{i-1}U(m+1) \cong \cdots .$$

and for $j \neq 1$, $\pi_j U(m) \cong \pi_j SU(m)$.

Similarly, $\pi_i \Omega_1(2m) \cong \pi_{i+1}O(2m)$ for $i \leq n - 4$.(11.3.1.12),Cf[Morse Theory Milnor Prop23.4].

Cor. (3.12.7.9) [Bott Periodicity theorem for Unitary Groups]. The stable homotopy group $\pi_i U$ has period 2. $\pi_{2k+1}U \cong 0$ and $\pi_{2k}U \cong \mathbb{Z}$.

Proof: Use the last proposition and long exact sequence to show that for $1 \leq i \leq 2m$,

$$\pi_{i-1}U = \pi_{i-1}U(m) \cong \pi_i G_m(\mathbb{C}^{2m}) \cong \pi_{i+1}SU(2m) \cong \pi_{i+1}U.$$

Notice that $U(m) \to U(2m)/U(m) \to G_m(\mathbb{C}^{2m})$ □

Prop. (3.12.7.10) [Bott Periodicity for O]. For the infinite dimensional orthogonal space O, $\Omega_8(16r) \cong O(r), \Omega_4(8r) \cong Sp(2r)$. So $\Omega_8 \cong O$ and $\Omega_4 O \cong Sp$. Thus by (3.12.4.2),

$$\pi_i(O) = \mathbb{Z}/(2), \mathbb{Z}/(2), 0, \mathbb{Z}, 0, 0, 0, \mathbb{Z} \ldots, \quad \pi_i(Sp) = 0, 0, 0, \mathbb{Z}, \mathbb{Z}/(2), \mathbb{Z}/(2), 0, \mathbb{Z} \ldots$$

respectively. (Use (11.3.1.13)) Cf.[Morse Theory Prop24.7].

Prop. (3.12.7.11). If a simply-connected finite complex X is not contractible, then infinitely many of its homotopy groups are non-zero.

Proof: Cf.[Jean-Pierre Serre, Cohomologie modulo 2 des complexes d'Eilenberg-Maclane] □

3.13 Algebraic Topology II: Homologies and Cohomologies

Notation (3.13.0.1).

- Use notations defined in Algebraic Topology I: Homotopies.

1 Homologies

Axiomatic Homologies

Def. (3.13.1.1) [Eilenberg-Steenrod Homology Theories, Eilenberg-Steenrod1945]. A **Eilenberg-Steenrod homology theory** is given by the following data:

- A functor $E_p(-) : \mathrm{Ho}(\mathcal{T}\mathrm{op}^{\mathrm{rel}}) \to \mathcal{A}\mathrm{b}$ for any $p \in \mathbb{Z}$. For $X \in \mathcal{T}\mathrm{op}$, denote $H_p(X, \varnothing)$ by $E_p(X)$.
- For any $p \in \mathbb{Z}$, an equivariant **boundary map** $\partial : E_p(X, A) \to E_{p-1}(A)$ for any $(X, A) \in \mathrm{Ho}(\mathcal{T}\mathrm{op}^{\mathrm{rel}})$.

that satisfies

Exact Sequence: For $(X, A) \in \mathcal{T}\mathrm{op}^{\mathrm{rel}}$, there is a natural long exact sequence

$$\cdots \to E_p(A) \to E_p(X) \to E_p(X, A) \xrightarrow{\partial} E_{p-1}(A) \to \cdots .$$

Excision: For any excisive triad $(X; A, B)$(3.12.1.6), the inclusion $(A, A \cap B) \to (X, B)$ induces an isomorphism

$$E_p(A, A \cap B) \cong E_p(X, B)$$

Additivity: If $(X, A) = \coprod_\alpha (X_\alpha, A_\alpha)$, then there are natural isomorphisms

$$\bigoplus_\alpha E_p(X_\alpha, A_\alpha) \cong E_p(X, A).$$

By functorial CW approximations on relative spaces(3.12.5.15), CW approximation of excisive triads(3.12.5.19) and Whitehead theorem(3.12.5.6), such a theory is equivalent to a theory restricted to all CW complexes with cellular maps as morphisms.

Prop. (3.13.1.2)[Cofibrations]. Given an Eilenberg-Steenrod homology theory E_*, for any cofibration $i : A \to X \in \mathcal{T}\mathrm{op}$, there is a natural isomorphism

$$E_*(X, A) \cong E_*(X/A, *).$$

Proof: As i is a cofibration, $C(A) \to C(i) = X \coprod_{A \times \{0\}} C(A)$ is also a cofibration. Consider the commutative diagram

$$\begin{array}{ccc} E_*(X \coprod_{A\times\{0\}} (A \times [0, 2/3]), A \times [1/3, 2/3]) & \longrightarrow & E_*(C(i), (A \times [1/3, 1])/(A \times \{1\})) \\ \downarrow & & \downarrow \\ E_*(X, A) & \longrightarrow & E_*(X/A, *) \end{array}.$$

Then the upper horizontal map is an isomorphism by excision, and the vertical maps are isomorphisms by homotopy invariance: The right vertical map is

$$(C(i), (A \times [1/3, 1])/(A \times \{1\})) \cong (C(i), C(A)) \cong (X/A, *)$$

by(3.12.6.7). Then the lower horizontal map is also an isomorphism. $\square$

Def. (3.13.1.3)[Reduced Homology Theories]. A **reduced Eilenberg-Steenrod homology theory** is given by the following data: A functor $\widetilde{E}_*(-) : \mathrm{Ho}(\mathcal{CG}^{\text{well-pt}}) \to \mathcal{A}\mathrm{b}$ for any $p \in \mathbb{Z}$ that satisfies

Exactness: For any cofibration $i : A \to X \in \mathcal{CG}^{\text{well-pt}}$, the sequences

$$\widetilde{E}_p(A) \to \widetilde{E}_p(X) \to \widetilde{E}_p(X/A)$$

are exact.

Suspension: For any $X \in \mathcal{CG}^{\text{well-pt}}$, there are natural isomorphisms

$$\Sigma_* : \widetilde{E}_p(X) \cong \widetilde{E}_{p+1}(\Sigma X).$$

Additivity: If $X = \bigvee_\alpha X_\alpha$, then there are natural isomorphisms

$$\bigoplus_\alpha \widetilde{E}_p(X_\alpha) \cong \widetilde{E}_p(X).$$

By functorial CW approximations on pointed spaces(3.12.5.15), such a theory is equivalent to a theory restricted to all CW complexes with cellular maps as morphisms.

Prop. (3.13.1.4)[Reduction to Reduced Homology Theories]. Giving an Eilenberg-Steenrod homology theory is equivalent to giving a reduced Eilenberg-Steenrod homology theory. Thus from now on we will not distinguish from a reduced ES-homology theory and an ES-homology theory.

Proof: Given an ES homology theory E_*, for $X \in \mathcal{T}\mathrm{op}^{\mathrm{pt}}$, define $\widetilde{E}_*(X) = E_*(X, *)$, then the maps $* \to X \to *$ induce a natural splitting $E_*(X) \cong \widetilde{E}_*(X) \oplus E_*(*)$. Then it is easy to show $\widetilde{E}_*$ is a reduced ES homology theory by(3.13.1.2): For suspension, because $C(X)$ is contractible and $X \to C(X)$ is a cofibration, the long exact sequence for $C(X)/X \cong \Sigma(X)$ and(3.13.1.2) implies the isomorphism

$$\Sigma^{-1} : \widetilde{E}_{p+1}(\Sigma(X)) \cong \widetilde{E}_{p+1}(C(X)/X) \cong E_{p+1}(C(X), X) \xrightarrow{\partial} \widetilde{E}_p(X).$$

Conversely, if $\widetilde{E}_*$ is a reduced ES homology theory, define $E_*(X, A) = \widetilde{E}_*(C(A \to X))$ where $C(A \to X)$ is pointed over the cone point. In particular, $E_*(X) = \widetilde{E}_*(X_+)$(3.12.1.16). We also define the boundary map as

$$\partial : E_*(X, A) \cong \widetilde{E}_*(C(i_+)) \xrightarrow{\partial} \widetilde{E}_*(\Sigma(A_+)) \xrightarrow{\Sigma^{-1}} E_{*-1}(A_+),$$

where ∂ comes from $\Sigma(A_+) \cong C(i_+)/X_+$.

To show E_* is a ES homology theory: additivity is clear. The homotopy invariance follows from(3.12.1.17). To show exactness**?**. To show excision**?**. Cf.[May, P110].

To show that these two constructions are inverse to each other, it suffices to show that the ∂ and Σ defined are inverse to each other**?**. □

Lemma (3.13.1.5). Let E be an ES-homology theory and $B \subset A \subset X$, then there is a functorial long exact sequence

$$\cdots \to E_p(A, B) \to E_p(X, B) \to E_p(X, A) \xrightarrow{\partial} E_{p-1}(A, B) \to \cdot,$$

where $\partial : E_p(X, A) \to E_{p-1}(A) \to E_{p-1}(A, B)$.

Proof: This follows from diagram chase or using the functorial CW approximations(3.12.5.15). □

Lemma (3.13.1.6). If E be an ES-homology theory and $(X;A,B)$ is an excisive triad, then the natural map

$$E_*(A,A\cap B)\oplus E_*(B,A\cap B)\to E_*(X,A\cap B)$$

is an isomorphism.

Proof: This is done by using the CW approximations for excisive triads(3.12.5.19). □

Prop. (3.13.1.7) [Mayer-Vietoris Sequences]. Let E be an ES-homology theory and $(X;A,B)$ be an excisive triad, then there is a long exact sequence

$$\cdots\to E_p(A\cap B)\xrightarrow{((i_1)_*,(i_2)_*)} E_p(A)\oplus E_p(B)\xrightarrow{(j_1)_*-(j_2)_*} E_p(X)\xrightarrow{\Delta} E_{p-1}(A\cap B)\to\cdots,$$

where Δ is the composite

$$E_p(X)\to E_p(X,B)\cong E_p(A,A\cap B)\xrightarrow{\partial} E_{p-1}(A\cap B).$$

Proof: Cf.[May, P112]. □

Prop. (3.13.1.8) [Relative Mayer-Vietoris Sequences]. The relative MV-sequence is related to the MV-sequence(3.13.1.7) by

$$\begin{array}{ccccccccc}\cdots\longrightarrow & E_p(Y,A\cap B) & \longrightarrow & E_p(Y,A)\oplus E_p(Y,B) & \longrightarrow & E_p(Y,X) & \longrightarrow & E_{p-1}(Y,A\cap B) & \longrightarrow\cdots\\ & \big\downarrow\partial & & \big\downarrow\partial\oplus\partial & & \big\downarrow\partial & & \big\downarrow\partial & \\ \cdots\longrightarrow & E_p(A\cap B) & \longrightarrow & E_p(A)\oplus E_p(B) & \longrightarrow & E_p(X) & \longrightarrow & E_{p-1}(A\cap B) & \longrightarrow\cdots\end{array}$$

Prop. (3.13.1.9) [Colimits]. If $X=\varinjlim_{i\in\mathbb{N}}X_i$, then there is a natural isomorphism

$$\varinjlim E_*(X_i)\cong E_*(X).$$

Proof: Cf.[May, P115]. □

Cor. (3.13.1.10). For a reduced ES-homology theory $\widetilde{E}_*$ and $(X_i)_{i\in\mathbb{N}}\in\mathcal{T}\mathrm{op}^{\mathrm{pt}}$, there are natural isomorphisms

$$\varinjlim\widetilde{E}_*(X_i)\cong\widetilde{E}_*(\prod_i{}' X_i)(3.12.1.19).$$

<u>**The Ordinary Homology Theory**</u>

Def. (3.13.1.11) [Ordinary Homology Theories]. For $\Lambda\in\mathcal{A}b$, an **ordinary homology theory** with coefficients in Λ is a generalized homology theory(3.13.2.1) that satisfies the additional axiom

Dimension: $E_p(\mathrm{pt})=\begin{cases}\Lambda & ,p=0\\ 0 & ,p\neq 0\end{cases}$.

Def. (3.13.1.12) [Ordinary Reduced Homology Theories]. For $\Lambda\in\mathcal{A}b$, an **ordinary reduced homology theory** with coefficients in Λ is a reduced homology theory(3.13.1.3) that satisfies the additional axiom

Dimension: $\widetilde{E}_p(S^0)=\begin{cases}\Lambda & ,p=0\\ 0 & ,p\neq 0\end{cases}$.

Def. (3.13.1.13)[Hurewicz Homomorphism]. For an ordinary homology theory H_*, if we denote the generator of $\widetilde{H}_0(\mathbb{S}^0)$ by a_0, and $a_n = \Sigma^n(a) \in \widetilde{H}_n(\mathbb{S}^n)$, then for any $X \in \mathcal{CG}^{\mathrm{pt}}$, define the **Hurewicz homomorphism**

$$\mathrm{Hur}_X : \pi_n(X) \to \widetilde{H}_n(X) : f \mapsto f_*(a_n).$$

Prop. (3.13.1.14). For $n \in \mathbb{Z}_+$, $X \in \mathcal{T}\mathrm{op}^{\mathrm{pt}}$, Hur_X is a homomorphism of groups.

Proof: Cf.[May, P117]. □

Prop. (3.13.1.15) [Generalized Hurewicz theorem]. If $n \geq 2$ and (X, A) is a $(n-1)$-connected pair of spaces, then the Hurewicz map induces an isomorphism

$$\pi_n(X, A)/\sim \pi_1(A) \cong H_n(X, A),$$

and $H_k(X, A) = 0, k < n$. Moreover, the Hurewicz map $\pi_{n+1}(X, A) \to H_{n+1}(X, A)$ is surjective.

Proof: Cf.[Hatcher P371 and 390Ex23].? □

Cor. (3.13.1.16)[Converse Whitehead]. If $f : X \to Y$ is a map of simple pointed spaces that induces isomorphisms on all homology groups, then f is a weak homotopy equivalence.

Proof: We may change Y to the mapping cylinder of f, then notice all the relative homology groups $H_n(Y, X)$ vanishes by long exact sequence, and then by the generalized Hurewicz theorem, $\pi_n(Y, X) = 0$, and then f is a weak homotopy equivalence, by(3.12.4.11). □

Thm. (3.13.1.17) [Hurewicz]. For $n \in \mathbb{Z}_+$, if $X \in \mathcal{CG}^{\mathrm{pt}}$ is $(n-1)$-connected, then $\mathrm{Hur}_X : \pi_n(X) \to \widetilde{H}_n(X)$ induces an isomorphism $\pi_n(X)^{\mathrm{ab}} \cong \widetilde{H}_n(X)$. In particular, if $n > 1$, $\pi_n(X) \cong \widetilde{H}_n(X)$(3.12.4.1).

Proof: Cf.[May, P118]. □

The Cellular and Singular Realizations

Def. (3.13.1.18) [Degree of Maps]. For any $f : \mathbb{S}^n \to \mathbb{S}^n \in \mathcal{T}\mathrm{op}$, we can choose a base point and use cellular approximation to make it homotopic to a cellular map $(\mathbb{S}^n, *) \to (\mathbb{S}^n, *)$, and define the **degree of** f to be the multiplying factor of $f_* : \pi_n(\mathbb{S}^n) \cong \mathbb{Z} \to \pi_n(\mathbb{S}^n) \cong \mathbb{Z}$(3.12.7.6).

Then this degree is independent of the base point chosen simply by rotation.

Prop. (3.13.1.19). The antipodal map $\mathbb{S}^n \to \mathbb{S}^n$ has degree $(-1)^{n-1}$.

Proof: This is because the antipodal map is a composition of $n+1$ reflections, and each reflection is an n-suspension of a reflection on $\mathbb{S}^1 \to \mathbb{S}^1$, which clearly has degree -1. Thus we finish by(3.12.7.6). □

Def. (3.13.1.20) [Cellular Complex on $\mathcal{CW}$]. Given $X \in \mathcal{CW}$ with presentation $X = \cup_i X^i$, we can define the **cellular homology groups** as follows: Let $C_\bullet(X)$ be the complex with $C_p(X)$ the free Abelian group generated by the p-cells of X, and the map $C_p(X) \to C_{p-1}(X)$ is given by $e_\alpha \mapsto a_{\alpha\beta} e_\beta$, where for any n-cell α and $n-1$-cell β, $a_{\alpha\beta}$ is the degree(3.13.1.18) of the map

$$S^{p-1} \xrightarrow{\alpha} X^{p-1} \to X^{p-1}/X^{p-2} \xrightarrow{\beta^{-1}} S^{p-1}.$$

Then $C_\bullet(X)$ is truly a complex. More generally, for any $\Lambda \in \mathcal{A}\mathrm{b}$, we can define $C_\bullet(X; \Lambda) = C_\bullet(X) \otimes \Lambda$.

Proof: Cf.[May, P99]**?**. □

Def. (3.13.1.21) [Cellular Homology Groups]. For $X \in \mathcal{CW}$ and a subcomplex $A \subset X$, there is an inclusion $C_*(A) \to C_*(X)$. If we define $C_*(X, A) = C_*(X)/C_*(A)$. Define the homology groups $H_p(X) = H_p(C_\bullet(X)), H_p(X, A) = H_p(C_\bullet(X, A))$.

then the long exact sequence associated to the exact sequence $0 \to C_*(A) \to C_*(X) \to C_*(X, A) \to 0$ gives a boundary map $\partial : H_p(X, A) \to H_{p-1}(A)$.

More generally, for any $\Lambda \in \mathcal{A}\mathrm{b}$, we can define $C_\bullet(X, A; \Lambda)$ and also $H_p(X; \Lambda), H_p(X, A; \Lambda)$.

Def. (3.13.1.22)[Cellular Complex of Products]. For $X, Y \in \mathcal{CW}$, with the CW structure on $X \times Y$ given in(3.12.3.8), then

$$C_\bullet(X) \otimes C_\bullet(Y) \cong C_\bullet(X \times Y).$$

Proof: The map $C_\bullet(X) \otimes C_\bullet(Y) \cong C_\bullet(X \times Y)$ is given by $e_\alpha \otimes e_\beta \mapsto (-1)^{|\alpha||\beta|} e_{\alpha\times\beta}$.

It is clear that this is an isomorphism up to sign. Fo the sign problem, see [May, P101]. □

Prop. (3.13.1.23). The cellular homology groups in(3.13.1.21) defines a ES-homology theory(3.13.2.1).

Proof: For homotopy invariance, notice a homotopy $X \times I \to Y$ between $f, g : X \to Y$ will induce a map

$$C_\bullet(X) \otimes C_\bullet(\mathbb{I}) \to C_\bullet(Y)$$

by(3.13.1.22), and with the canonical CW structure, $C_\bullet(\mathbb{I})$ is just $0 \to \mathbb{Z} \xrightarrow{(1,-1)} \mathbb{Z} \oplus \mathbb{Z} \to 0$. By writting it out, this gives exactly a homotopy between the two maps f_*, g_*. Additivity, excision and exactness is clear. □

Def. (3.13.1.24) [Singular Homologies]. For $X \in \mathcal{T}\mathrm{op}, \Lambda \in \mathcal{A}\mathrm{b}$, the **singular cohomology groups** with coefficients in R is defined to be $H_{\mathrm{sing},*}(X; \Lambda) = H_*(\Gamma(X); R)$(3.5.3.8). This is the just the homology on $\mathcal{T}\mathrm{op}^{\mathrm{rel}}$ corresponding to the cellular homology on CW-pairs.

Thm. (3.13.1.25) [Uniqueness of Ordinary Homology Theories]. There exists a unique ordinary homology theory, i.e. the one defined in(3.13.1.21).

Proof: Cf.[May, P119]. □

2 Cohomologies

Remark (3.13.2.1) [Eilenberg-Steenrod Cohomology Theories]. The whole basic theory of cohomologies is dual to that of homologies, so it is omitted here.

We only focus on new features appearing.

Def. (3.13.2.2) [Cohomological Operators]. Given reduced ES-cohomology theories $\widetilde{E}^*, \widetilde{F}^*$, $p, n \in \mathbb{Z}$, a **cohomological operator** of type p and degree n is a natural homomorphism $\widetilde{E}^p \to \widetilde{F}^{p+n}$.

A **stable cohomological operator** of degree n is a sequence of cohomological operators Φ_p^n of type p and degree n that commutes with the suspension isomorphism.

Ordinary Cohomology Theories

Thm. (3.13.2.3) [Uniqueness of Ordinary Homology Theories]. There exists a unique ordinary cohomology theory, i.e. the one give by cellular cohomology groups.

Proof: The proof is the same as that of(3.13.1.25). □

Prop. (3.13.2.4) [Universal Coefficient Theorem]. See (3.7.5.6).

Cor. (3.13.2.5). A map between topological spaces that induce isomorphism on arbitrary homology group induce isomorphisms on cohomology groups.

Def. (3.13.2.6) [Cup Product]. For $X, Y \in \mathcal{CW}$, as $C_\bullet(X) \otimes C_\bullet(Y) \cong C_\bullet(X \times Y)$(3.13.1.22), for any $R \in \mathcal{CA}\mathrm{lg}$, there is a chain homomorphism

$$\mathrm{Hom}^\bullet(C_\bullet(X), R) \otimes \mathrm{Hom}^\bullet(C_\bullet(Y), R) \to \mathrm{Hom}^\bullet(C_\bullet(X \times Y), R),$$

which induces a natural **cross product map**

$$H^*(X; R) \otimes H^*(Y; R) \to H^*(X \times Y; R).$$

And composing with the diagonal map $\Delta_X : X \to X \times X$ gives a **cup product map**

$$H^*(X; R) \times H^*(X; R) \to H^*(X \times Y; R)$$

that makes $H^*(X; R)$ into a unital commutative graded R-algebra.

Proof: Cf.[May, P139]. □

Def. (3.13.2.7) [Bockstein Homomorphism].

Prop. (3.13.2.8). the square of the Bockstein homomorphism $H^n(X, \mathbb{F}_p) \to H^{n+2}(X, \mathbb{F}_p)$ is trivial.

Proof: There is a commutative diagram of commutative rings

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathbb{Z} & \xrightarrow{\times m} & \mathbb{Z} & \longrightarrow & \mathbb{Z}/(m) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathbb{Z}/(m) & \xrightarrow{\times m} & \mathbb{Z}/(m^2) & \longrightarrow & \mathbb{Z}/(m) & \longrightarrow & 0 \end{array}$$

which induces commutative diagrams

$$\begin{array}{ccc} H^n(X, \mathbb{Z}/(m)) & \xrightarrow{\widetilde{\beta}} & H^{n+1}(X, \mathbb{Z}) \\ \| & & \downarrow \rho \\ H^n(X, \mathbb{Z}/(m)) & \xrightarrow{\beta} & H^n(X, \mathbb{Z}/(m)) \end{array}$$

so $\beta = \rho\widetilde{\beta}$, and $\beta^2 = \rho\widetilde{\beta}\rho\widetilde{\beta} = 0$, as $\widetilde{\beta}\rho = 0$ by long exact sequence. □

Prop. (3.13.2.9) [Lefschetz Fixed Point Theorem].

Prop. (3.13.2.10) [Wedge Sums]. For $M, N \in \mathcal{T}\mathrm{op}$, $\widetilde{H}^i(M \wedge N) = \widetilde{H}^i(M) \otimes \widetilde{H}^i(N)$.

Proof: □

Prop. (3.13.2.11) [Connected Sums]. Let $M, N \in \mathcal{M}\mathrm{ani}^d_{,\mathrm{cntd},\mathrm{cpct}}$, the cohomology of $M\#N$ is **?**

And if M, N are orientable, then $H^*(M\#N) = 1 \oplus [\widetilde{H}^*(M) \oplus \widetilde{H}^*(N)/([M]-[N])]$.

Proof: As $M\#N/S^{d-1} = M \vee N$, there is a long exact sequence

$$\ldots \to \widetilde{H}^i(M \vee N) \to \widetilde{H}^i(M\#N) \to \widetilde{H}^i(S^{d-1}) \to \widetilde{H}^{i+1}(M\#N) \to \ldots$$

Thus by(3.13.2.10), $\widetilde{H}^i(M\#N) = \widetilde{H}^i(M) \oplus \widetilde{H}^i(N)$ for $i \neq d-1, d$. And there is an exact sequence

$$0 \to \widetilde{H}^{d-1}(M \vee N) \to \widetilde{H}^{d-1}(M\#N) \to \mathbb{Z} \to \widetilde{H}^d(M \vee N) \to \widetilde{H}^d(M\#N) \to 0.$$

If M, N are both orientable, then so does $M\#N$, and the sequence looks like

$$0 \to \widetilde{H}^{d-1}(M \vee N) \to \widetilde{H}^{d-1}(M\#N) \xrightarrow{0} \mathbb{Z} \to \mathbb{Z} \otimes \mathbb{Z} \to \mathbb{Z} \to 0.$$

and $\widetilde{H}^{d-1}(M \vee N) \cong \widetilde{H}^{d-1}(M\#N)$.

If only one of M, N is orientable, then similarly, $\widetilde{H}^{d-1}(M \vee N) \cong \widetilde{H}^{d-1}(M\#N)$.

If neither M, N are orientable, then nor does $M\#N$, and the sequence looks like

$$0 \to \widetilde{H}^{d-1}(M \vee N) \to \widetilde{H}^{d-1}(M\#N) \to \mathbb{Z} \to 0 \otimes 0 \to 0 \to 0.$$

which splits**?**, so $\widetilde{H}^{d-1}(M\#N) \cong \widetilde{H}^{d-1}(M \vee N) \oplus \mathbb{Z}$. □

Cup and Cap Products

Main references are [Hat02]Chap3.2.

Prop. (3.13.2.12). The cup product will restrict to a relative version:

$$H^*(X, A) \times H^*(X, B) \to H^*(X, A \cup B),$$

This implies that if X is a union of n contractible open set, then the cup product of n-elements vanish. In particular, the cup product in a suspension vanishes.

Prop. (3.13.2.13) [Künneth Formula]. The cross product $H^*(X, \mathbb{R}) \otimes_R H^*(Y, \mathbb{R}) \to H^*(X \times Y, \mathbb{R})$ is an isomorphisms of rings if X, Y are CW complexes and $H^*(Y, \mathbb{R})$ are a finite free R-modules for any k.

Proof: Cf.[Hat02]P219. □

Def. (3.13.2.14) [Cap Products].

Cohomology of Fiber Bundles

Prop. (3.13.2.15) [Leray-Hirsch]. For a fiber bundle $F \to E \to B$ and a ring R s.t. $H^n(F, R)$ is f.g free for all n, and there exist classes c_j of $H^*(E)$ that constitute a basis for each fiber F, then

$$H^*(B, R) \otimes H^*(F, R) \to H^*(E, R)$$

is an isomorphism of $H^*(B, R)$-modules.

Proof: □

Cor. (3.13.2.16).
- $H^*(U(n);\mathbb{Z}) = \Lambda_{\mathbb{Z}}[x_1, x_3, \ldots, x_{2n-1}]$.
- $H^*(SU(n,\mathbb{R});\mathbb{Z}) = \Lambda_{\mathbb{Z}}[x_3, \ldots, x_{2n-1}]$.
- $H^*(Sp(n);\mathbb{Z}) = \Lambda_{\mathbb{Z}}[x_3, x_7, \ldots, x_{4n-1}]$.

Prop. (3.13.2.17). $H^*(\mathbb{G}(n,\mathbb{K}^\infty);\mathbb{Z})$ where $\mathbb{K} = \mathbb{R}, \mathbb{C}, \mathbb{H}$ is generated by the symmetric polynomials, where for $\mathbb{R}$ the coefficient is $\mathbb{Z}_2$.

Proof: Use the flag variety and first calculate for ∞. Then use Poincare duality to show it is mapped onto the symmetric polynomials. Cf.[Hatcher P435]. □

Prop. (3.13.2.18) [Leray-Serre]. For a Serre fibration, e.g. fiber bundle, $F \to E \to B$, that B is simply connected, then there is a spectral sequence

$$E_2^{pq} = H_p(B, H_q(F)) \Rightarrow H_{p+q}(E) \quad E_2^{pq} = H^p(B, H^q(F)) \Rightarrow H^{p+q}(E)$$

Cor. (3.13.2.19) [Wang Sequence]. When $B = S^n$, there is a long exact sequence:

$$\cdots \to H_q(F) \to H_q(E) \to H_{q-n}(F) \to H_{q-1}(F) \to H_{q-1}(E) \to \cdots$$

Cor. (3.13.2.20) [Gysin Sequence]. When $F = S^n$, there is a long exact sequence:

$$\cdots \to H_{p-n}(B) \to H_p(E) \to H_p(B) \to H_{p-n-1}(B) \to H_{p-1}(E) \to \cdots$$

H-Spaces

Def. (3.13.2.21) [H-Spaces]. An **H-space** is a unital magma object in $\mathrm{Ho}(\mathcal{CG}^{\mathrm{pt}})$. Equivalently, an H-space is a pointed space $X \in \mathcal{CG}^{\mathrm{pt}}$ with a map $\mu : X \times X \to X \in \mathrm{Ho}(\mathcal{CG}^{\mathrm{pt}})$ s.t. $X \to \{*\} \times X \to X$ and $X \to X \times \{*\} \to X$ is homotopic to id_X.

An **associative H-space** is an H-space s.t. μ_X is associative in $\mathcal{T}\mathrm{op}^{\mathrm{pt}} / \sim$. Similarly, we can define group-H-spaces and commutative H-spaces.

An H-space is called strictly associative(or a monoid space) if it comes from a unital associative object in the category of spaces.

Remark (3.13.2.22). The definition of a H-space structure can be modified when X is a CW complex. In fact, when (X, e) is a CW-pair, if there exists a map $\mu : X \times X \to X$ and a point $e \in X$ that $X \to \{e\} \times X \to X$ and $X \to X \times \{e\} \to X$ is homotopic to id_X, then μ can be homotoped that e is a strict identity.

Proof: ? □

Prop. (3.13.2.23). If H is an H-space, then for any $X \in \mathcal{T}\mathrm{op}^{\mathrm{pt}}$, $\langle X, H\rangle$ is a magma. Moreover, if H is a commutative associative group H-space, then $\langle X, H\rangle \in \mathcal{A}\mathrm{b}$.

Prop. (3.13.2.24) [Loop Spaces are H-Spaces]. For any $X \in \mathcal{T}\mathrm{op}^{\mathrm{pt}}$, $\Omega(X)$ is an associative group-H-space, and $\Omega^2(X)$ is a associative commutative group-H-space.

Proof: The multiplication is given by concatenation of loops. It is continuous by adjunction arguments. □

Prop. (3.13.2.25). $\mathbb{CP}^\infty$ can be given a commutative strictly associative H-space structure. More generally, $B(\mathbb{Z}/n) \cong (\mathbb{C}^\infty \backslash \{0\})/(\mathbb{R}^+ \times \mu_n)$(3.14.3.13) can be given a commutative strictly associative H-space structure. In particular this applies to $\mathbb{RP}^\infty$.

Proof: We can regard $\mathbb{C}^\infty$ as the space of polynomials with complex coefficients, then the polynomial multiplication gives a map $(\mathbb{C}^\infty \backslash \{0\}) \times (\mathbb{C}^\infty \backslash \{0\}) \to \mathbb{C}^\infty \backslash \{0\}$ that descends to a map $B(\mathbb{Z}/n) \times B(\mathbb{Z}/n) \to B(\mathbb{Z}/n)$. And $e = (1, 0, \ldots, 0, \ldots)$ is the unit. □

Prop. (3.13.2.26). The James reduced product $J(X)$**??**s a strictly associative H-space with multiplication given by $(x_1, \ldots, x_n)(y_1, \ldots, y_m) = (x_1, \ldots, x_n, y_1, \ldots, y_m)$, and the identity e. This H-space structure also descends to a H-space structure on $SP(X)$(3.12.3.21).

Prop. (3.13.2.27). The universal cover of a H-space is a H-space.

Proof: Take an arbitrary lift that maps $(\tilde{e}, \tilde{e})$ to $\tilde{e}$. Notice the homotopy can also be lifted. □

Prop. (3.13.2.28) [Cohomology Ring]. The cohomology ring of a H-space is a topologists' Hopf algebra, by Kunneth formula and naturality.

Cor. (3.13.2.29). $\mathbb{CP}^n$ is not a H-space.

Proof: This is because $H^*(\mathbb{CP}^n, \mathbb{Z}) = \mathbb{Z}[\alpha]/\alpha^n, |\alpha| = 2$, which is a not a topologist's Hopf algebra, by(2.9.1.14). □

Prop. (3.13.2.30). The fundamental group of an H-space is Abelian.

Proof: This is because π_1 preserves products, so takes unital magma space to unital magma objects(3.1.1.70). And the unital magma objects in the category of groups is the Abelian groups(3.1.1.69). □

Prop. (3.13.2.31) [Adam]. $\mathbb{S}^0, \mathbb{S}^1, \mathbb{S}^3, \mathbb{S}^7$ are the only spheres that have H-structures.

Proof: Firstly $S^1 \subset \mathbb{C}, S^3 \subset \mathbb{H}, S^7 \subset \mathbb{O}$ are submonoids, so they have H-structures. **?** □

Cor. (3.13.2.32). $\mathbb{RP}^n$ has a H-structure iff $n = 1, 3, 7$.

Proof: This is because the universal cover of a H-space is a H-space(3.13.2.27). Also $\mathbb{S}^1, \mathbb{S}^2, \mathbb{S}^3, \mathbb{S}^7$ are monoid spaces, and -1 are in their center, so the quotients are also monoid spaces. □

<u>**Examples of Calculations**</u>

Cor. (3.13.2.33).

$$H^*(\mathbb{RP}^n, \mathbb{F}_2) = \mathbb{Z}/(2)[a]/a^{n+1}, |a| = 1, \quad H^*(\mathbb{CP}^n, \mathbb{Z}) = \mathbb{Z}[\alpha]/\alpha^{n+1}, |\alpha| = 2$$

Proof: We prove for $\mathbb{RP}^n$, the $\mathbb{CP}^n$ case is similar. Use induction. For $n = 1$, this is clear. For $n > 1$, notice $\mathbb{RP}^n$ is the $n-1$-skeleton of $\mathbb{RP}^n$, thus the map of rings $H^*(\mathbb{RP}^n, \mathbb{F}_2) \to H^*(\mathbb{RP}^{n-1}, \mathbb{F}_2)$ maps the generator of $H^2(\mathbb{RP}^n, \mathbb{F}_2)$ to the generator a of $H^2(\mathbb{RP}^{n-1}, \mathbb{F}_2)$. Then by hypothesis $a^{n-1} \neq 0$. The $H^{n-1}(\mathbb{RP}^n, \mathbb{F}_2) \cong H_1(\mathbb{RP}^n, \mathbb{F}_2) \cong \mathbb{Z}/(2)$ is generated by α^{n-1}. Then the Poincaré duality shows that $\alpha \cup \alpha^{n-1} \neq 0$, so we are done. □

Cor. (3.13.2.34). For $n > 1$, the natural homomorphism $H^n(\mathbb{RP}^n, \mathbb{Z}/2\mathbb{Z}) \to H^n(\mathbb{S}^n, \mathbb{Z}/2\mathbb{Z})$ is 0.

Proof: Because the cohomology ring map maps $a \in H^1(\mathbb{RP}^n, \mathbb{Z}/2\mathbb{Z})$ to $0 \in H^1(S^n, \mathbb{Z}/2\mathbb{Z}) = 0$. □

Prop. (3.13.2.35) [$H^*(K, \mathbb{F}_2)$]**.** The cohomology ring of the Klein bottle K is $H^*(K, \mathbb{Z}/(2)) = \mathbb{F}_2[x, y]/(xy, x^2 - y^2, x^3, y^3)$.

Proof: Let $\varphi \in C^0(K, \mathbb{Z}/(2))$ be the dual of v, $\alpha, \beta, \gamma \in C^1(K, \mathbb{Z}/(2))$ be the dual of a, b, c, and $\mu, \lambda \in C^2(K, \mathbb{Z}/(2))$ be the dual of A, B, then

$$\partial(\varphi)(a) = \partial(\varphi)(b) = \partial(\varphi)(c) = 0$$

$$\delta(\alpha)(A) = \alpha(\partial(A)) = \alpha(a + b - c) = 1, \quad \delta(\alpha)(B) = \alpha(\partial B) = \alpha(b + c - a) = -1$$

$$\delta(\beta)(A) = \beta(\partial(A)) = \beta(a + b - c) = 1, \quad \delta(\beta)(B) = \beta(\partial(B)) = \beta(b + c - a) = 1$$

$$\delta(\gamma)(A) = \gamma(\partial(A)) = \gamma(a + b - c) = -1, \quad \delta(\gamma)(B) = \gamma(\partial(B)) = \gamma(b + c - a) = 1$$

So

$$H^0(K, \mathbb{Z}/(2)) = \mathbb{Z}/(2)\varphi, \quad H^1(K, \mathbb{F}_2) = \mathbb{F}_2(\alpha+\beta) \oplus \mathbb{F}_2(\alpha+\gamma), \quad H^2(K, \mathbb{F}_2) = (\mathbb{F}_2\mu \oplus \mathbb{F}_2\lambda)/(\mu+\lambda).$$

Now we calculate the cup product:

$$(\alpha + \beta) \cup (\alpha + \beta)(A) = (\alpha + \beta)(a) \cdot (\alpha + \beta)(b) = 1$$

$$(\alpha + \beta) \cup (\alpha + \gamma)(A) = (\alpha + \beta)(a) \cdot (\alpha + \gamma)(b) = 0$$

$$(\alpha + \gamma) \cup (\alpha + \gamma)(A) = (\alpha + \gamma)(a) \cdot (\alpha + \gamma)(b) = 0$$

$$(\alpha + \beta) \cup (\alpha + \beta)(B) = (\alpha + \beta)(b) \cdot (\alpha + \beta)(c) = 0$$

$$(\alpha + \beta) \cup (\alpha + \gamma)(B) = (\alpha + \beta)(b) \cdot (\alpha + \gamma)(c) = 1$$

$$(\alpha + \gamma) \cup (\alpha + \gamma)(B) = (\alpha + \gamma)(b) \cdot (\alpha + \gamma)(c) = 0$$

Then $(\alpha + \beta) \cup (\alpha + \beta) = (\alpha + \beta) \cup (\alpha + \gamma) = \mu \in H^2(K, \mathbb{Z}/(2))$. Now if we set $\alpha + \beta = x, \beta + \gamma = y$, then the cohomology ring

$$H^*(K, \mathbb{Z}/(2)) = \mathbb{Z}/(2)[x, y]/(xy, x^2 - y^2, x^3, y^3).$$

□

Prop. (3.13.2.36) [$H^*(L, \mathbb{Z}/(m))$]**.** Let L be the Lens space, then the cohomology ring is calculated at [**?**]P304.

Proof: □

3 Manifolds

Orientations

Prop. (3.13.3.1). Let $d \in \mathbb{Z}_+, R \in \mathcal{CAlg}, M \in \mathcal{M}\mathrm{ani}^d, X \subset M$, then for any $x \in M$, choose a nbhd U of $x \in M$ s.t. $U \cong \mathbb{R}^n$, then by excision and exactness,

$$H_d(M, M\backslash x) \cong H_d(U, U\backslash x) \cong \widetilde{H}_{d-1}(U\backslash\{x\}) \cong \widetilde{H}_{d-1}(\mathbb{S}^{d-1}) \cong R.$$

Prop. (3.13.3.2) [Vanishing]. For $M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cpct,cntd},\partial}, \Lambda \in \mathcal{A}b$, $H_i(M;\Lambda) = 0$ for $i > d$, and $\widetilde{H}_d(M;\Lambda) = 0$ unless M is compact without boundary.

Proof: □

Def. (3.13.3.3) [R-Fundamental Class]. Let $R \in \mathcal{CAlg}, M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cntd}}, X \subset M$, an R-**fundamental class** of M at X is an element $z \in H_d(M, M\backslash X)$ s.t. for any $x \in X$, the map

$$H_d(M, M\backslash X) \to H_d(M, M\backslash\{x\})$$

maps z to a generator of $H_d(M, M\backslash\{x\}) \cong R$(3.13.3.1).

Def. (3.13.3.4) [R-Orientation]. Let $R \in \mathcal{CAlg}, M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cntd}}, X \subset M$, an R-**orientation** of M is an open cover $\{U_i\}$ of M and R-fundamental classes z_i of M at U_i s.t. z_i, z_j restricts to the same element in $H_d(M, M\backslash(U_i \cup U_j))$.

For $M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cntd},\partial}$, an R-orientation is an R-orientation of M^o.

Prop. (3.13.3.5) [R-Fundamental Classes and R-Orientations]. For $R \in \mathcal{CAlg}, M \in \mathcal{M}\mathrm{ani}^d$ and $K \subset M$ compact, then

- $H_i(M, M\backslash K, R) = 0$ for $i > d$.
- Any R-orientation of M defines an R-fundamental class of M at K that is compatible for $x \in K$.

In particular, if M is compact, then an R-orientation is equivalent to an R-fundamental class.

Proof: Firstly, if $K \subset U$ and $U \cong \mathbb{R}^n$ is a coordinate chart on which the R-orientation is defined, then by excision and exactness,

$$H_i(M, M\backslash K, R) \cong H_i(U, U\backslash K, R) \cong H_{i-1}(U\backslash K, R)$$

which vanishes for $i > n$ by vanishing theorem(3.13.3.2). And the R-orientation restricts to K.

In general, K can be written as a sum of compact subsets each contained in a coordinate char on which the R-orientation is defined. Then using induction, it suffices to show that if the results hold for $K, L, K \cap L$, then it holds for $K \cup L$: item1 follows from the MV-sequence

$$H_{i+1}(M, M\backslash(K \cup L)) \to H_i(M, M\backslash(K \cup L)) \to H_i(M, M\backslash K) \oplus H_i(M, M\backslash L) \to H_i(M, M\backslash(K \cap L)).$$

For item2, the same MV-sequence with R-coefficients and $i = d$ together with the definition of R-orientation classes(3.13.3.4) shows there exists a fundamental class at $K \cap L$ that restricts to the fundamental classes at K and L. □

Prop. (3.13.3.6)[Orientation Dichotomy]. For $d \in \mathbb{Z}_+, M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cntd,cpct}}$, there are only two cases:

- M is non-orientable, and $H_d(M) = 0$.

- M is orientable, and the map $H_d(M) \to H_d(M, M\backslash\{x\}) \cong \mathbb{Z}$(3.13.3.1) is an isomorphism for any $x \in M$.

Proof: For any $R \in \mathcal{CA}\mathrm{lg}$, as $M\backslash\{x\}$ is connected and non-compact, $H_d(M\backslash\{x\}; R) = 0$ by(3.13.3.2), thus
$$H_d(M, R) \to H_d(M, M\backslash\{x\}; R) \cong R$$
is injective. Thus $H_d(M) \cong 0$ or $\mathbb{Z}$. In particular, by universal coefficients theorem,
$$H_d(M) \otimes \mathbb{F}_p \to H_d(M, M\backslash\{x\}) \otimes \mathbb{F}_p$$
is injective for any $p \in \mathbf{P}$. Then it is clear to see that $H_d(M) \to H_d(M, M\backslash\{x\})$ is an isomorphism for any $x \in M$. □

Prop. (3.13.3.7)[Fundamental Classes on Manifolds with Boundaries]. For $M \in \mathcal{M}\mathrm{ani}_\partial^d$, $\partial M \neq 0$, an R-orientation on M determines an R-orientation of ∂M. Moreover, the fundamental class $[\partial M]_R$ defined by(3.13.3.5) comes from the partial of a unique element $[M]_R \in H_d(M, \partial M; R)$, called the **$R$-fundamental class determined the orientation**.

Proof: By collar nbhd theorem, $M \cong M^o$, and by vanishing theorem, $H_d(M) \cong H_d(M^o) = 0$, thus $H_d(M, \partial M; R) \to H_{d-1}(\partial M; R)$ is injective. Let N be an open collar of ∂M, then $H_d(M^o, M^o \cap N; R) \cong H_n(M, \partial M; R)$. Also, $M\backslash N$ is compact, so the orientation on M^o defines a fundamental class in $H_d(M, M^o \cap N; R) \cong H_n(M, \partial M; R)$. Then this class determined the orientation on every point of M^o, and determines the orientation on ∂M, Cf.[May, P170]**?**. □

Prop. (3.13.3.8)[Orientation Coverings].

Proof: □

Cor. (3.13.3.9). If $M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cntd}}$, then if M is orientable, it has exactly two orientations. And if M is simply connected or $\pi_1(M)$ has no subgroup of index 2, then M is orientable.

Def. (3.13.3.10)[Connected Sums]. For $M, N \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cntd,cpct}}$, define the **connected sum** $M\#N$ as follows: Take a subset $D \subset M, D' \subset N$ that are contained in coordinate charts(orientable coordinates charts if M, N are oriented). $\varphi : U \cong \mathbb{R}^d, \varphi' : U' \cong \mathbb{R}^d$ s.t. $\varphi(D) \cong \mathbb{D}^d \cong \varphi(D')$. Then define
$$M\#N = (M\backslash D) \coprod_{\partial D \cong \partial D'} (N\backslash D')$$
where $\partial D \cong \partial D'$ is an orientation-reversing homeomorphism when M, N are both orientable. This is independent of D, D' and the homeomorphism $\partial D \cong \partial D'$ chosen.

Proof: Firstly we show that $M\backslash D$ is independent of D chosen: As M is locally path connected and connected, it is path connected, Then we can consider a chain of charts isomorphic to $\mathbb{R}^d$ that connects any two such subsets D, D'. Then reducing to affine charts, it suffices to show for the case $M \cong \mathbb{R}^d$. In this case, we can use isotopy of M to make $D \subset D'$, and then use the coordinate charts and annulus theorem(3.3.11.2) to show that $D'\backslash D$ is isomorphic to $\mathbb{S}^{d-1} \times \mathbb{I}$. Then the homeomorphism $M\backslash D \cong M\backslash D'$ can be easily given.

Now we show the connected sum is independent of the homeomorphism chosen: ∂D and $\partial D'$ are given orientations by the coordinate charts, and in the non-orientable case, use the argument above on the orientation covering of M(3.13.3.8), we know there exists a self-homeomorphism of M that is isotopic to id_M that reverses the orientation on ∂D. Thus in both cases, we can assume $\partial D \cong \partial D'$ is orientation-preserving. Now(3.12.2.2) shows any such homeomorphism is isotopic, and using the coordinate charts, we can extend the isotopy to a nbhd of nbhd of ∂D. Thus the connected sum is well-define. □

Remark (3.13.3.11). WARNING: The connected sum may be different in the orientable case if we change one of the orientations: $\mathbb{CP}^2\#\mathbb{CP}^2$ is not homeomorphic to $\mathbb{CP}^2\#\overline{\mathbb{CP}^2}$.

Proof:

□

Poincaré Duality

Lemma (3.13.3.12) [Poincaré Duality]. For $R \in \mathcal{CA}\mathrm{lg}$, if $M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cntd,cpct}}$ is R-oriented, then for any $p \in \mathbb{Z}$, there is an isomorphism

$$D = - \cap [M]_R : H^p(M;R) \cong H_{n-p}(M;R).$$

In particular, $H^n(X,\mathbb{F}_2) \cong \mathbb{Z}/(2)$, and the non-trivial element is called the **fundamental homology class mod 2**, denoted by $[M]_2$.

Proof: which follows immediately from(5.8.6.30) and(5.3.5.9). (Should also attain the compact cohomology case if we know the relation of compact sheaf cohomology better). □

Prop. (3.13.3.13) [Relative Poincaré Duality]. Let $R \in \mathcal{CA}\mathrm{lg}, M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cpct},\partial}$ be R-orientable with fundamental class $[M]_R \in H_d(M,\partial M;R)$, then for any $\Lambda \in \mathcal{M}\mathrm{od}_R$, capping with $[M]_R$ defines isomorphisms

$$H^p(M,\partial M;\Lambda) \cong H_{d-p}(M), \quad H^p(M;\Lambda) \cong H_{d-p}(M,\partial M;\Lambda).$$

Proof: Cf.[May, P170]?. □

Cor. (3.13.3.14). For $M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cntd,cpct,orntd}}$, for any $p \in \mathbb{Z}$, there is a perfect pairing

$$H^p(M)_{\mathrm{lf}} \times H^{n-p}(M)_{\mathrm{lf}} \to \mathbb{Z} : (\alpha,\beta) \mapsto \langle \alpha \cup \beta, [M]\rangle.$$

Proof: By universal coefficient theorem?, $H^p(M)_{lf} \cong \mathrm{Hom}(H_p(M),\mathbb{Z})$. So if $\alpha \in H^p(M)$ is non-zero in $H^p(M)_{\mathrm{lf}}$, there exists $a \in H_p(M)$ s.t. $\langle a,\alpha\rangle = 1$. Then by Poincaré duality(3.13.3.12), there exists $\beta \in H^{d-p}(M)$ s.t. $\beta \cap [M] = a$. Thus $\langle \alpha \cup \beta, [M]\rangle = \langle \alpha, \beta \cap [M]\rangle = 1$. □

Def. (3.13.3.15) [Intersection Pairing]. Let $k \in \mathbb{N}, M \in \mathcal{M}\mathrm{ani}^{2k}_{\mathrm{cpct,orntd,cntd}}$, The Poincaré duality(3.13.3.14) shows the cup product pairing

$$H^k(M;\mathbb{Q}) \times H^k(N;\mathbb{Q}) \to \mathbb{Q} : (\alpha,\beta) \mapsto \langle \alpha \cup \beta, [M]\rangle$$

is non-degenerate, called the **intersection pairing** of M. Notice if k is odd, it is skew-symmetric, and if k is even, it is symmetric.

Def. (3.13.3.16) [Index]. For $M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cpct,orntd,cntd}}$, define the **index of** M as the index of the symmetric intersection pairing of M if $d = 4k$, and 0 otherwise. The index of M is denoted by $I(M)$.

Prop. (3.13.3.17). For $M, N \in \mathcal{M}\mathrm{ani}_{\mathrm{cpct,orntd,cntd}}$, $I(M \times N) = I(M)I(N)$.

Proof: Cf.[May, P167]. □

Prop. (3.13.3.18). For $k \in \mathbb{N}, k \in \mathtt{Field}, M \in \mathcal{M}\mathrm{ani}^{2k+1}_{\mathrm{cpct},\partial}$, then

$$\dim_k H_k(\partial M; k) = 2\dim\ker(H_k(\partial M; k) \xrightarrow{i_*} H_k(M; k)) = 2\dim\mathrm{Im}(H^k(\partial M; k) \xrightarrow{i^*} H^k(M; k)).$$

Proof: There is a commutative diagram

$$\begin{array}{ccccc} H^k(\partial M; k) & \xrightarrow{i^*} & H^k(M; k) & \xrightarrow{\partial} & H^{k+1}(M, \partial M; k) \\ \downarrow D & & \downarrow D & & \downarrow D \\ H_{k+1}(M, \partial M; k) & \xrightarrow{\partial} & H_k(M; k) & \xrightarrow{i_*} & H_k(\partial M; k) \end{array}$$

where the vertical arrows are isomorphisms and i_* is the vector dual of i^* by universal coefficient theorem. Thus the theorem follows. □

Prop. (3.13.3.19) [Gysin Sequence]. Cf.[姜伯驹同调论].

Euler Characteristic

Def. (3.13.3.20)[Euler Characteristic]. For any $X \in \mathcal{T}\mathrm{op}$ with finite $\mathbb{Z}$-homologies, define the **Euler character** of X to be

$$\chi(X) = \sum_i (-1)^i H_i(X; \mathbb{Z}).$$

Then by universal coefficients theorem(3.13.2.4),

$$\chi(X) = \sum_i (-1)^i H_i(X; k)$$

for any $k \in \mathtt{Field}$.

The condition holds for $X \in \mathcal{CW}^{\mathrm{fin}}$, in particular any $X \in \mathcal{M}\mathrm{ani}_{\mathrm{cpct}}$(3.12.3.10).

Prop. (3.13.3.21). For any $i \in \mathbb{N}, X \in \mathcal{M}\mathrm{ani}^{2i+1}_{\mathrm{cpct,cntd}}$, $\chi(X) = 0$.

Proof: This follows from Poincaré duality for $\mathbb{F}_2$-coefficients. □

Prop. (3.13.3.22) [Euler Characteristic and Boundary]. For $i \in \mathbb{N}, M \in \mathcal{M}\mathrm{ani}^{2i+1}_{\mathrm{cpct},\partial}$, then $\chi(\partial M) = 2\chi(M)$.

Proof: Consider the "double" $\widetilde{M}$ of M along ∂M, then $\widetilde{M} \in \mathcal{M}\mathrm{ani}^{2i+1}_{\mathrm{cpct}}$. It is clear by excision and collar neighborhood theorem that $\chi(\widetilde{M}) + \chi(\partial M) = 2\chi(M)$. Then we use(3.13.3.21). □

Cor. (3.13.3.23). If $N \in \mathcal{M}\mathrm{ani}_{\mathrm{cpct}}$ is a boundary of some other $M \in \mathcal{M}\mathrm{ani}_{\mathrm{cpct},\partial}$, then $\chi(N) = 0$.

Proof: If $\dim N$ is odd, this is(3.13.3.21). If $\dim N$ is even, this is(3.13.3.22). □

Prop. (3.13.3.24). For any $i \in \mathbb{N}$, $M \in \mathcal{M}\mathrm{ani}^{4i+2}_{\mathrm{cpct,orntd}}$, $\chi(M)$ is even.

Proof: The parity of $\chi(M)$ is the same as $H^{2i+1}(M, \mathbb{Q})$, which is odd by(3.13.3.15) and(2.3.8.7). □

Prop. (3.13.3.25) [Morse Inequality]. For any $X \in \mathcal{CW}$,

$$\chi(X) \leq \sum(-1)^i c_i(X),$$

where $c_i(X)$ is the number of I-dimensional cells. (Use the dimension counting of the long exact sequence).

Prop. (3.13.3.26). For $M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cpct,orntd,cntd}}$, $I(M) \equiv \chi(M) (\mathrm{mod}\ 2)$.

Proof: If d is odd, $I(M) = 0 = \chi(M)$ is even by(3.13.3.21). If $d = 4k+2$, then $I(M) = 0$ and $\chi(M)$ is even by(3.13.3.24). if $d = 4k$, then $I(M) \equiv \chi(M) \equiv \dim H^{2k}(M, \mathbb{Q})$. □

deRham Cohomology

Prop. (3.13.3.27) [de Rham Comparison]. For $X \in \mathcal{M}\mathrm{ani}_{\mathrm{sm}}, G \in \mathcal{A}\mathrm{b}$, by(5.3.5.11).

$$H^*_{\mathrm{dR}}(X, G) \cong H^*(X, \underline{G}).$$

Prop. (3.13.3.28)[Homotopy Axiom for deRham Cohomology]. For two homotopic map between two smooth manifold, they induce the same map on deRham Cohomology.

Proof: We only have to prove the case of $M \times \mathbb{R} \to M$, where any constant section map induces an isomorphism $H^*_{\mathrm{dR}}(M \times I) \cong H^*_{\mathrm{dR}}(M)$. Because any homotopy is a morphism $M \times I \to N$ where f and g are the sections 0 and 1.

For the zero section, we define $K : a + bdt \mapsto \int_0^t b$. This is the desired homotopy, Cf.[Differential Forms in Algebraic Topology Bott Tu]. □

4 Applications

Prop. (3.13.4.1) [No Contraction to the Boundary]. For $M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cpct},\partial}$, there are no retraction from M onto ∂M.

Proof: We may assume ∂M is connected and non-empty, otherwise clearly there are no retraction. If it has a retraction, $H_{d-1}(\partial M, \mathbb{F}_2) \to H_{d-1}(M, \mathbb{F}_2)$ has a left inverse. Thus It suffices to show that $H_{d-1}(\partial M, \mathbb{Z}/(2)) \to H_{d-1}(M, \mathbb{Z}/(2))$ is 0. So it suffices to show that $H_d(M, \partial M, \mathbb{Z}/(2)) \to H_{d-1}(\partial M, \mathbb{Z}/(2))$ is surjective. And this follows from(3.13.3.7) and(3.13.3.6) as the image of $[M]_2$ is $[\partial M]_2$, which generates $H_{d-1}(\partial M, \mathbb{F}_2)$. □

Prop. (3.13.4.2) [Brouwer Fixed Point Theorem]. For any $f : \mathbb{D}^n \to \mathbb{D}^n \in \mathcal{T}\mathrm{op}$, $\mathrm{Fix}(f) \neq \varnothing$.

Proof: If $\mathrm{Fix}(f) = \varnothing$, consider the intersection of the ray $f(x)x$ with S^{n-1}, then it depends continuously on x, and this defines a function from D^n to S_n that is identity on S^n, but then this is a retraction from $\mathbb{D}^n \to \mathbb{S}^n$, which is impossible by(3.13.4.1). □

Prop. (3.13.4.3). If $M \in \mathcal{M}\mathrm{ani}^d_{\mathrm{cntd},\partial}$, then if M is contractible and $\partial M \neq \varnothing$, ∂M is a homotopy sphere.

Proof: As $M^o \sim M$ is contractible, it is orientable by(3.13.3.9). Then by relative Poincaré duality(3.13.3.13) and the long exact sequence,

$$H_p(\partial M) \cong H_{p+1}(M, \partial M) \cong H^{d-p-1}(M) = 0.$$

□

Lemma (3.13.4.4). If $m > n \in \mathbb{Z}_+$, any map $f : \mathbb{RP}^m \to \mathbb{RP}^n$ induces $f_* = 0 : \pi_1(\mathbb{RP}^m) \to \pi_1(\mathbb{RP}^n)$.

Proof: As $\pi_1(\mathbb{RP}^m) = \begin{cases} \mathbb{Z}/(2) & ,m > 1 \\ \mathbb{Z} & ,m = 1 \end{cases}$. The assertion is clearly true for $n = 1$. And if $n \in \mathbb{Z}_+, f_* \neq 0$, then by the naturality of Hurewicz homomorphism(3.13.1.17), $f_* \neq 0 : H_1(\mathbb{RP}^m) \to H_1(\mathbb{RP}^n)$. Then by universal coefficient theorem, so is $f^* \neq 0 : H^1(\mathbb{RP}^n, \mathbb{F}_2) \to H^1(\mathbb{RP}^m, \mathbb{F}_2)$. But f^* is a ring homomorphism and $H^*(\mathbb{RP}^m)$ is generated by $a = f^*(a') \in H^1(\mathbb{RP}^m)$(3.13.2.33), so $a^{n+1} = f^*((a')^{n+1}) = 0$, contradiction. □

Lemma (3.13.4.5). If $m > n \geq 1$, there are no antipodal maps: $f : \mathbb{S}^m \to \mathbb{S}^n$, i.e. $f(x) = -f(-x)$.

Proof: Any such map induces a map $\mathbb{RP}^m \to \mathbb{RP}^n$, which induces 0 on π_1, so by covering space theory, there exists a lifting $\mathbb{RP}^m \to \mathbb{S}^n$. The composition $\mathbb{S}^m \to \mathbb{RP}^m \to \mathbb{S}^n$ is the original map, by the theory of covering spaces, as $\mathbb{S}^n$ is connected and they agree at least on one point. But then f takes antipodal maps to the same point, contradiction. □

Thm. (3.13.4.6) [Borsuk-Ulam]. For ant map $f : \mathbb{S}^n \to \mathbb{R}^n$, there exists $x \in \mathbb{S}^n$ s.t. $f(x) = f(-x)$.

Proof: If $f(x) \neq f(-x)$ for any $x \in \mathbb{S}^n$, then we can define a map $\mathbb{S}^n \to \mathbb{S}^{n-1}$ that maps x to the intersection of the ray $0, f(x) - f(-x)$ with $\mathbb{S}^n$. Then this map is antipodal, which contradicts(3.13.4.5). □

5 Obstruction Theory & General Cohomology Theory

Towers

Prop. (3.13.5.1) [Towers]. There are Whitehead Towers and Postnikov Towers for a CW complex X.

$$\cdots \to Z_2 \to Z_1 \to Z_0 \to X \to \cdots \to X_2 \to X_1 \to X_0$$

Z_n annihilate $\pi_{\leq n}(X)$, X_n remains only $\pi_{\leq n}(X)$. The towers can be chosen to be fibrations, with fibers $K(\pi_n X, n)$ by(3.12.6.30).

Prop. (3.13.5.2). There is a Postnikov towers of :

$$B\mathrm{String}(n) \to B\mathrm{Spin}(n) \to BSO(n) \to BO(n)$$

with corresponding obstructions $w_1(X), w_2(X)$ and $p_1(X)/2$.

Prop. (3.13.5.3) [Obstructions]. If a connected abelian CW complex X ($\pi_1(X)$ abelian and action on higher homotopy trivial) and (W, A) satisfies $H^{n+1}(W, A; \pi_n X) =$ for all n, then $A \to X$ can extend to a map $M \to X$.

Proof: Cf.[Hatcher P417]. □

Cor. (3.13.5.4). A map between Abelian CW complexes that induce isomorphisms on homology is a homotopy equivalence.

Proof: Notice that $\pi_1(X)$ acts trivially on $\pi_1(Y, X)$ and use Hurewicz. □

6 Brown Representability

Prop. (3.13.6.1). For any $Z \in \mathcal{T}\mathrm{op}^{\mathrm{pt}}$, the functor

$$\langle -, Z\rangle : \mathcal{CW}^{\mathrm{pt}} \to \mathcal{S}\mathrm{et}^{\mathrm{pt}}$$

satisfies:

Exactness: If $A \subset X$ is a subcomplex, then there is an exact sequence

$$\langle X/A, Z\rangle \to \langle X, Z\rangle \to \langle A, Z\rangle.$$

Additivity: If $X = \bigvee_i X_i \in \mathcal{CW}^{\mathrm{pt}}$, then

$$\langle X, Z\rangle \cong \prod_i \langle X_i, Z\rangle.$$

Proof: 1 follows from the fact that $A \to X$ is a cofibration(3.12.6.5). 2 is trivial. □

Spectrum

Def. (3.13.6.2) [Prespectrums]. A **prespectrum** is a sequence of pointed spaces $(T_n)_{n\in\mathbb{Z}}$ together with maps $\sigma_n \in \langle \Sigma T_n \to T_{n+1}\rangle \cong \langle T_n, \Omega T_{n+1}\rangle$.

An **Ω-Spectrum** is an prespectrum $(T_n)_{m\in\mathbb{Z}}$ s.t. σ_n are all weak-homotopy equivalences.

Def. (3.13.6.3) [Suspension Prespectrums]. For $X \in \mathcal{T}\mathrm{op}^{\mathrm{pt}}$, the sequence of pointed spaces $(\Sigma^n(X))_{n\in\mathbb{Z}}$(where we define $\Sigma^{-1} = \Omega$) is a prespectrum, called the **suspension prespectrum** of X. If $X = S^0$, this is called the **sphere spectrum**.

Prop. (3.13.6.4) [Prespectrum and Homotopy Theories]. Let $(T_n)_{n\in\mathbb{N}}$ be a prespectrum consisting of pointed CW complexes s.t. T_n is $(n-1)$-connected for any $n \in \mathbb{N}$, then

$$\widetilde{E}_p(X) = \varinjlim_n \pi_{p+n}(X \wedge T_n)$$

is a reduced homology theory on $\mathcal{CW}^{\mathrm{pt}}$.

Proof: Cf.[May, P176]. □

Prop. (3.13.6.5) [Ω-Prespectrum and ES-Cohomology theories]. If K_n is an Ω-spectrum, i.e. $K_n \cong \Omega K_{n+1}$ weak equivalence, then the functors $X \mapsto \langle X, K_n\rangle$ define a reduces ES-cohomology theory on $\mathcal{CW}^{\mathrm{pt}}$

Proof: By(3.13.6.1), these functors satisfy the additivity and exactness. The natural suspension isomorphism is given by

$$\Sigma : \langle X, T_n\rangle \to \langle \Sigma(X), \Sigma T_n\rangle \cong \langle \Sigma(X), \Sigma T_n\rangle,$$

which is an isomorphism by(3.12.5.5). □

Thm. (3.13.6.6) [Brown Representability]. Any reduced ES-cohomology theory on $\mathcal{CW}^{\mathrm{pt}}$ is represented by a Ω-prespectrum.

Proof: **?** □

Eilenberg-Maclane Spaces

Def. (3.13.6.7) [Eilenberg-Maclane Spaces]. For $\Lambda \in \mathcal{A}\mathrm{b}$, an **Eilenberg-Maclane space** is defined to be a pointed CW complex $K(\Lambda, n) \in \mathcal{CW}^{\mathrm{pt}}$ s.t. $\pi_k(K(\Lambda, n)) = \begin{cases} \Lambda & , k = n \\ 0 & , \text{otherwise} \end{cases}$.

Prop. (3.13.6.8) [Eilenberg-Maclane Spaces and Homologies]. For $X \in \mathcal{CW}^{\mathrm{pt}}, \Lambda \in \mathcal{A}\mathrm{b}$, there are isomorphisms

$$\widetilde{H}_p(X; \Lambda) \cong \varinjlim_{p+n} \pi_{p+n}(X \wedge K(\Lambda, n)).$$

Proof: Cf.[May, P176]. □

Prop. (3.13.6.9) [Eilernberg-Maclane Spaces and Cohomologies]. For $\Lambda \in \mathcal{A}\mathrm{b}, X \in \mathcal{CW}^{\mathrm{pt}}, n \in \mathbb{N}$, $K(\Lambda, n)$ are unique up to weak homotopy, and there are natural isomorphisms

$$\widetilde{H}^n(X; \Lambda) \cong \langle X, K(\Lambda, n) \rangle.$$

Proof: Given a $K(\Lambda, n)$, if we define $K(\Lambda, m) = \Sigma^{m-n}(K(\Lambda, n))$, then these are all CW complexes by(3.12.3.13), and it defines an ordinary cohomology theory: The dimension axiom follows from the definition of $K(\Lambda, n)$, and it is a reduced ES-cohomology theory by(3.12.5.5) and(3.13.6.10). Thus the asserted isomorphism follows from(3.13.2.3).

This shows in particular that $K(\Lambda, n)$ are unique up to homotopy by Yoneda lemma. □

Cor. (3.13.6.10) [Uniqueness of Eilenberg-Maclane Spaces]. $K(\Lambda, n)$ is unique up to homotopy, and $\Omega(K(\Lambda, n)) \sim K(\Lambda, n-1) \in \mathcal{CW}^{\mathrm{pt}}$.

Prop. (3.13.6.11) [Eilenberg-Maclane Spaces Exist]. Take $K(\Lambda, n) = \Gamma(B(\Lambda, n))$(3.14.3.7), where Λ is regarded as a discrete subgroup.

Note $K(G, 1)$ is constructed the same as by(3.5.8.1).

Proof: □

Prop. (3.13.6.12) [Cohomology Operators]. Cohomological operators $\widetilde{H}^p(-; \Lambda) \to \widetilde{H}^{p+n}(-; \Lambda')$ are in bijection with elements in $\widetilde{H}^{p+n}(K(\Lambda, p); \Lambda')$, by(3.13.6.9) and Yoneda lemma.

Prop. (3.13.6.13) [Examples].

- $K(\mathbb{Z}, 1) = S^1 = U(1)$.
- $K(\mathbb{Z}, 2) = \mathbb{CP}^\infty$.
- $K(\mathbb{Z}/(2), 1) = \mathbb{RP}^\infty$.

Proof: 1 is clear.

2: This is because by(3.14.1.17), $\mathbb{S}^\infty \to \mathbb{CP}^\infty$ is a locally trivial bundle with fiber S^1, and $\mathbb{S}^\infty$ is contractible by(3.12.3.18) thus by(3.12.6.14), $\pi_2(\mathbb{CP}^\infty) = \mathbb{Z}$ and $\pi_n(\mathbb{CP}^\infty) = 0$ for $n \neq 2$.

3: This is because by(3.14.1.17), $\mathbb{S}^\infty \to \mathbb{CP}^\infty$ is a locally trivial bundle with fiber $\{\pm 1\}$, and $\mathbb{S}^\infty$ is contractible by(3.12.3.18) thus by(3.12.6.14), $\pi_2(\mathbb{CP}^\infty) = \mathbb{Z}/2\mathbb{Z}$ and $\pi_n(\mathbb{CP}^\infty) = 0$ for $n \neq 2$. □

Steenrod Powers

Prop. (3.13.6.14) [Steenrod Powers]. There are stable cohomology operators

$$\mathrm{Sq}: H^*(X,\mathbb{F}_2)\to H^*(X,\mathbb{F}_2): x\in H^k(X,\mathbb{F}_2)\mapsto \sum_{i\in\mathbb{N}}\mathrm{Sq}^i(x),\quad \mathrm{Sq}^i(x)\in H^{k+i}(X,\mathbb{F}_2)$$

called **Steenrod Powers** that satisfies

- $\mathrm{Sq}(\alpha\cup\beta)=\mathrm{Sq}(\alpha)\cup\mathrm{Sq}(\beta)$.
- $\mathrm{Sq}^i(\alpha)=\alpha^2$ if $i=|\alpha|$, and 0 if $i>|\alpha|$.

For $p\in\mathbf{P}$, the total Steenrod powers P is a similar map from $H^n(X,\mathbb{F}_p)\to H^{n+*}(X,\mathbb{F}_p)$ that $\mathrm{P}^i(\alpha)=\alpha^p$ if $2i=|\alpha|$ and 0 if $2i>\alpha$.

Proof: Cf.[Hatcher P497].? □

Prop. (3.13.6.15) [Adam Relations]. For $0<i<2j\in\mathbb{Z}$,

$$\mathrm{Sq}^i\,\mathrm{Sq}^j=\sum_{0\le k\le\lfloor\frac{i}{2}\rfloor}\binom{j-k-1}{i-2k}\mathrm{Sq}^{i+j-k}\,\mathrm{Sq}^k\in\mathrm{End}(H^*(-,\mathbb{F}_2))$$

There are Adam relation calculators in terms of Serre-Cartan basis at`https://math.berkeley.edu/~kruckman/adem/`.

Proof: □

Cor. (3.13.6.16). The subalgebra of $\mathrm{End}(H^*(-,\mathbb{F}_2)$ generated by $\{\mathrm{Sq}^{\mathbb{Z}}\}$ is generated respectively by elements Sq^{2^k}.

and for $p\in\mathbf{P}$ The subalgebra of $\mathrm{End}(H^*(-,\mathbb{F}_p))$ generated by $\{\mathrm{P}^{\mathbb{Z}}\}$ is generated by elements P^{p^k} and β.

Proof: ? □

Prop. (3.13.6.17) [$H^*(K(\mathbb{F}_2,p),\mathbb{F}_2)$]. $H^*(K(\mathbb{F}_2,p),\mathbb{F}_2))$ can be calculated, Cf,[May, P185].

Proof:

□

7 Stable Homotopy Theory

3.14 Fiber Bundles & K-Theory

Main references are [Ati64], [AGP02] and [M-S74].

Remark (3.14.0.1). Any base space B in this section is assumed to be paracompact. Instead, we may require in the definition of locally trivial bundles s.t. there exists a trivialization that is dominated by a partition of unity on B.

1 Fiber Bundles

Def. (3.14.1.1) [Fiber Bundles]. $\pi : E \to X \in \mathcal{CG}$ is called a **fiber bundle** with fiber F if every fiber $\pi^{-1}(x)$ is homeomorphic to F. If any $x \in X$ has a nbhd U together with a homeomorphism $\pi^{-1}(U) \cong U \times F$ over U, then it is called a **locally trivial bundle**. And a **numerical locally trivial bundle** is a locally trivial bundle $\pi : E \to X$ s.t. their there is a numerical covering $\{U_i \to X\}$ s.t. there are homeomorphisms $\pi^{-1}(U_i) \cong U_i \times F$ over U_i for each i.

Prop. (3.14.1.2) [Dold]. If $\pi : E \to X \in \mathcal{CG}$ and there is a numerical covering $\{U_i \to X\}$ s.t. $\pi^{-1}(U_i) \to U_i$ are Hurewicz fibrations, then π is a Hurewicz fibration.

Proof: Cf.[Tammo tom Dieck, Algebraic Topology]Chap13**?** □

Cor. (3.14.1.3) [Fiber Bundles are Hurewicz Fibrations]. Every numerical locally trivial bundle is a Hurewicz fibration.

Prop. (3.14.1.4) [Pullback Bundle]. Let $\pi : E \to X$ be a fiber bundle with fiber F and $f : Y \to X$ a map, then the pullback space $f^*E \to Y$(3.3.1.7) is also a fiber bundle over Y with fiber F, called the **pullback bundle**.

Prop. (3.14.1.5). If $E \to B, E' \to B'$ are fiber bundles both with compact Hausdorff fibers/or both with discrete fibers/, and $f : E/B \to E'/B'$ is a bundle map that induces isomorphisms on the fibers, then $E \cong f^*E'$ over B.

Proof: □

Lemma (3.14.1.6). Suppose $\pi : E \to B \times I$ is a fiber bundle whose restriction to $B \times [0, a]$ and $B \times [a, 1]$ are all trivial for some $a \in I$, then $E \to B \times I$ is a trivial bundle.

Proof: Choose trivializations $\varphi_1 : B \times [0, a] \times B \times F \to \pi^{-1}(B \times [0, a])$, and $\varphi_2 : B \times [a, 1] \times B \times F \to \pi^{-1}(B \times [a, 1])$, then these induces a map

$$B \times \{a\} \times F \xrightarrow{\varphi_1|} \pi^{-1}(B \times \{a\}) \xrightarrow{\varphi_2^{-1}|} B \times \{a\} \times F,$$

of the form $(b, a, v) \mapsto (b, a, g(b)v)$, where $g : B \to \mathrm{Homeo}(F)$ is continuous. Then we get a trivialization

$$B \times I \times F \to E : \varphi(b, t, v) = \begin{cases} \varphi_1(b, t, v) & t \le a \\ \varphi_2(b, t, g(b)v) & t \ge a \end{cases}.$$

□

Lemma (3.14.1.7). Let $E \to B \times I$ be a fiber bundle, then there exists a covering $\{U_i\}$ of B that E is trivial on each $U_i \times I$.

Proof: For each $b \in B$, we can find a nbhd U_b and a division $0 = s_0 < s_1 < \ldots < s_n = 1$ that E is trivial on each of $U_b \times [s_i, s_{i+1}]$. Then by(3.14.1.6), E is trivial on $U_b \times I$. Then these $\{U_b\}$ is a covering of X that E is trivial on each $U_b \times I$. □

Lemma (3.14.1.8). Let $\pi : E \to B \times I$ be a fiber bundle, where B is a paracompact space, and $r : B \times I \to B \times I$ defined by $r(b, x) = (b, 1)$, then there exists a bundle morphism f over r that induces an isomorphism $r^*E \cong E$ over $B \times I$.

Proof: By(3.14.1.7), we can choose a covering $\{U_\alpha\}$ of B that is E is trivial over each $U_\alpha \times I$, and let ψ_α be a partition of unity $1 = \sum \psi_i$ that $\mathrm{Supp}(\psi_i) \subset U_i$ and $\{\mathrm{Supp}(\psi_i)\}$ is locally finite. We also define $\mu_\alpha(x) = \frac{\psi_\alpha(x)}{\max\{\psi_\beta(x)\}}$, then μ_α are all continuous and subordinate to $\{U_\alpha\}$, and for each $x \in B, \max\{\mu_\alpha(x)\} = 1$.

Let $\varphi_\alpha : U_i \times I \times F \to \pi^{-1}(U_i \times I)$ be the local trivializations. We define a bundle map $f_\alpha : E/B \times I \to E/B \times I$ by identity outside $\pi^{-1}(U_i \times I)$ and $f_\alpha(\varphi_\alpha(b, t, v)) = \varphi_\alpha(b, \max(\mu_\alpha(x), t), v)$, then f_α is continuous and induces an isomorphism $f_\alpha^*E \cong E$ over $B \times I$. Now choose a well-ordering on α, by local finiteness, for each $v \in E$, there is a nhhd $W_v \times I$ of $\pi(v) \in B \times I$ that $W_v \cap U_\alpha \neq \varnothing$ for only α in a finite set $\{\alpha_1, \ldots, \alpha_m\}$ with $\alpha_1 < \alpha_2 \ldots < \alpha_m$. Then we define a bundle map $f : E \to E$ that $f|_{\pi^{-1}(W_v \times I)} = f_{\alpha_m} \circ \ldots \circ f_{\alpha_1}$. Then this is well-defined, and it is a bundle map over r that induces an isomorphism $f^*E \cong E$. □

Prop. (3.14.1.9) [Homotopy Invariance of Fiber Bundles]. Let $E' \to B'$ be fiber bundles. If $f, g : B \to B'$ are two homotopic maps with B paracompact, then there is a bundle isomorphism $f^*E' \cong g^*E'$.

Proof: Let $F : B \times I \to B'$ be a homotopy from f to g, and let $i_v : B \to B \times I : i_v(b, x) = (b, v)$ for $v = 0, 1$. Let $r : B \times I \to B \times I$ be the retraction defined by $r(b, x) = (b, 1)$, then by(3.14.1.8), there is an isomorphism of fiber bundles

$$f^*E' \cong (F \circ i_0)^*E' \cong i_0^*F^*E' \cong i_0^*r^*F^*E' \cong i_1^*F^*E' \cong g^*E'.$$

□

Prop. (3.14.1.10) [Cone Bundles]. Let E/X be a fiber bundle with fiber F, then we can construct a new fiber bundle $Cone(E)/X$ with bundle $C(F)$.

Cor. (3.14.1.11). This is because we can use the transformation characterization to extend maps $U_i \cap U_j \to \mathrm{Aut}(F)$ to maps $U_i \cap U_j \to \mathrm{Aut}(C(F))$.

Prop. (3.14.1.12) [Hopf Fibration]. There is a locally trivial fiber bundle $S^3 \to S^2$ with fiber S^1, called the **Hopf fibration**.

Proof: Cf.[AGP02]P129. □

Prop. (3.14.1.13) [Ehresmann]. Let $f : E \to B \in \mathcal{M}\mathrm{ani}_{\mathrm{sm}}$ be a proper submersion, then it is a locally trivial bundle.

Proof: Cf.[Björn Dundas, A Short Course in Differential Topology].**?** □

Cor. (3.14.1.14). There is a locally trivial bundle $S^{2n-1} \to \mathbb{CP}^n$ with fiber S^1.

Proof:

□

Cor. (3.14.1.15). There is a locally trivial bundle $\mathbb{RP}^{2n-1} \to \mathbb{CP}^n$ with fiber S^1.

Proof: □

Prop. (3.14.1.16) [Classifying Space Bundles]. There is a locally trivial bundle $U(n, \mathbb{K}) \to V_n(\mathbb{K}^\infty) \to \mathrm{Gra}(n, \mathbb{K}^\infty)$. for $\mathbb{K} = \mathbb{R}, \mathbb{C}$ or $\mathbb{H}$.

Proof: □

Cor. (3.14.1.17). There is a locally trivial bundle $\mathbb{S}^\infty \to \mathbb{CP}^\infty$ with fiber S^1.

Prop. (3.14.1.18). There is a locally trivial bundle $S^n \to \mathbb{RP}^n$ with fiber $\{\pm 1\}$.

Proof: □

Prop. (3.14.1.19). There is a locally trivial fiber bundle $\mathbb{S}^\infty \to \mathbb{RP}^\infty$ with fiber $\{\pm 1\}$.

Proof: Cf.[AGP02]P335. □

Covering Space

Def. (3.14.1.20) [Covering Space]. A **covering space** is a fiber bundle $E \to X$ with discrete fibers.

Prop. (3.14.1.21). if X and Y are Hausdorff spaces, $f : X \to Y$ is a local homeomorphism, X is compact, and Y is connected, then f a covering map.

Proof: First, f is surjective (using the connectedness), and that for each $y \in Y$, $f^{-1}(y)$ is finite. Because X is compact, there exists a finite open cover of X by $\{U_i\}$ such that $f(U_i)$ is open and $f|_{U_i} : U_i \to f(U_i)$ is a homeomorphism. For $y \in Y$, let $\{x_1, \dots, x_n\} = f^{-1}(y)$ (the x_i all being different points). Choose pairwise disjoint neighborhoods $U_1, \dots, U_n$ of $x_1, \dots, x_n$, respectively (using the Hausdorff property).

By shrinking the U_i further, we may assume that each one is mapped homeomorphically onto some neighborhood V_i of y.

Now let $C = X \setminus (U_1 \cup \dots \cup U_n)$ and set

$$V = (V_1 \cap \dots \cap V_n) \setminus f(C)$$

V should be an evenly covered nbhd of y. □

Prop. (3.14.1.22). If $\pi : \tilde{B} \to B$ is a local onto homeomorphism with the property of lifting arcs. Let $\tilde{B}$ be arcwise connected and B simply connected, then π is a homomorphism.

Proof: only need to prove injective. If p_1 and p_2 map to the same point, then they can be connected, and the image is a loop thus contractable, contradiction. □

Cor. (3.14.1.23). If $\tilde{B}$ is locally arcwise connected and B is locally simply connected, then π is a covering map.

Proof: Choose the connected components of a simply connected nbhd of a point p and use(3.14.1.22). □

Prop. (3.14.1.24) [Homotopy Lifting Property]. Given a covering space $\pi : \widetilde{X} \to X$, and a homotopy $f_t : Y \to X$, and a map $\widetilde{f_0} : Y \to \widetilde{X}$ lifting X, then there is a unique homotopy $\widetilde{f_t} : Y \to \widetilde{X}$ of $\widetilde{f_0}$ lifting f_t.

Proof: Let U_α be a covering of X that the We first construct a lift $\widetilde{F} : N \times I \to \widetilde{X}$ for N a nbhd near some point $y_0 \in Y$. Because f is continuous, there is a nbhd N of y_0 and a partition $0 = t_0 < t_1 < \ldots < t_m = 1$ of I that each $N \times [t_i, t_{i+1}]$ is mapped into some U_α. Then we can construct a lifting $\widetilde{F} : N \times I \to \widetilde{X}$ by induction using the local homeomorphism property of covering space.

Next we show the uniqueness in the special case that Y is a point. This can also be done using a partition of I and induction.

Finally we can construct lifting near every point $y \in Y$, and also they coincide on the overlap because of the uniqueness we just proved. So these liftings glue together to give a lifting $\widetilde{f_t} : Y \to \widetilde{X}$. □

Cor. (3.14.1.25). The map $\pi_* : \pi_1(\widetilde{X}, \widetilde{x}_0) \to \pi_1(X, x_0)$ induced by the covering map is injective. And the image of this map consists of homotopy types of loops that based at x_0 whose lift starting at $\widetilde{x}_0$ are also loops.

Proof: This is because a homotopy of a the image of a loop to trivial loop in $\widetilde{X}$ can be lifted to a homotopy of the loop itself to trivial loop. And this homotopy also fixes the endpoint, because the lifting of a trivial loop must be a trivial loop.

For the second assertion, one direction is easy, for the other, if a loop is a homotopic to the image of a loop of $\widetilde{X}$, then it is itself the image of a loop of $\widetilde{X}$. □

Prop. (3.14.1.26) [Degree of a Covering]. Let $\pi : \widetilde{X} \to X$ be a covering map, then the cardinality of $\pi^{-1}(x)$ is a a locally constant function of x. Thus if X is constant, this cardinality is fixed for any $x \in X$, and it is called the degree of the covering.

The number of sheets of a covering with $\widetilde{X}$ path-connected equals the index of $\pi_*(\pi_1(\widetilde{X}, \widetilde{x}_0))$ in $\pi_1(X, x_0)$.

Proof: For a loop g in X based at x_0, let $\widetilde{g}$ be its lift to $\widetilde{X}$ starting at $\widetilde{x}_0$. Now if $h \in \pi_*(\pi_1(\widetilde{X}, \widetilde{x}_0))$, then the loop $h \cdot g$ has lift that has the same ending as $\widetilde{g}$. So we get a map from the quotient set $\pi_1(X, x_0)/\pi_*(\pi_1(\widetilde{X}, \widetilde{x}_0))$ to $p^{-1}(x_0)$ mapping $\pi_*(\pi_1(\widetilde{X}, \widetilde{x}_0))[g]$ to $\widetilde{g}(1)$. This map is injective, and it is surjective because $\widetilde{X}$ is path-connected. Then we are done. □

Prop. (3.14.1.27) [Unique Lifting Property]. Let $\pi : (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ be a covering space and $f : (Y, y_0) \to (X, x_0)$ be a map with Y path-connected and locally path-connected, then a lift $\widetilde{f} : (Y, y_0) \to (\widetilde{X}, \widetilde{x}_0)$ exists iff $f_*(\pi_1(Y, y_0)) \subset \pi_*(\pi_1(\widetilde{X}, \widetilde{x}))$. And when Y is connected, this lifting is unique.

In particular, a covering space has unique path lifting property.

Proof: One direction is clear, for the other, to construct a lifting, choose a path γ from y_0 to y, the path $f\gamma$ has a unique lifting $\widetilde{f\gamma}$ starting from $\widetilde{x}_0$. Define $\widetilde{f}(y) = \widetilde{f\gamma}$. This is a well-defined map: if γ' is another path from y_0 to y, then $f\gamma^{-1}f\gamma'$ is a loop that is homotopic to the image of a loop at $\widetilde{x}_0$. Now we can lift this homotopy, and then $f\gamma^{-1}f\gamma'$ is also the image of a loop at $\widetilde{x}_0$, which must be $\widetilde{f\gamma}^{-1}\widetilde{f\gamma'}$ by uniqueness. So $\widetilde{f}$ is well-defined.

It can be verified that $\widetilde{f}$ is continuous.

The uniqueness is clear, because if there are two lifts, the points that they are equal and the points that they are not are both open in Y. □

Prop. (3.14.1.28)[Galois Theory of Covers]. Let X be a path-connected and locally path-connected and semilocally simply-connected space(3.12.4.26), then

- there is a connected and simply-connected covering space $\widetilde{X}$ of X, called a **universal cover** of X.
- Thee fundamental group acts continuously and properly on $\widetilde{X}/X$.
- For any subgroup H of $\pi_1(X, x_0)$, there is a connected covering space $\pi : X_H \to X$ that $\pi_*(\pi_1(X_H, \widetilde{x}_0)) = H$ for a suitably chosen base point $\widetilde{x}_0$. And this covering space is unique up to isomorphism over (X, x_0). Thus by(3.14.1.27), there is an inclusion-preserving bijection between isomorphism classes of covering spaces over X and the the set of conjugacy classes of subgroups of $\pi_1(X, x_0)$.

Proof: Cf.[Hat02]P64, P67.**?** □

Def. (3.14.1.29) [Normal Covering Spaces]. A **normal covering space** is a covering space $\pi : \widetilde{X} \to X$ that for any $x \in X$ and two elements $\widetilde{x}, \widetilde{x}' \in \pi^{-1}(x)$, there is a covering isomorphism of $\widetilde{X}/X$ taking $\widetilde{x}$ to $\widetilde{x}'$.

Prop. (3.14.1.30). Let $\pi : (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ be a path-connected covering space of a path-connected, locally path-connected space X, and let H be the subgroup $\pi_*(\pi_1(\widetilde{X}, \widetilde{x}_0)) \subset \pi_1(X, x_0)$, then

- The covering space is normal iff H is normal in $\pi_1(X, x_0)$.
- The group $G(\overline{X})$ of covering transformations of $\widetilde{X}$ is isomorphic to $N(H)/H$.

Proof: 1: Let $\widetilde{x}_1, \widetilde{x}_2 \in \pi^{-1}(x_0)$ and γ a path from $\widetilde{x}_1$ to $\widetilde{x}_2$ corresponding to an element of $\pi_1(X, x_0)$, then H is normal is equivalent to $\pi_*(\pi_1(\widetilde{X}, \widetilde{x}_1)) = \pi_*(\pi_1(\widetilde{X}, \widetilde{x}_2))$. Then the lifting criterion shows there is a covering transformation taking $\widetilde{x}_1$ to $\widetilde{x}_2$. The converse is also true.

2: From the above argument, we can define a map $N(H) \to G(\widetilde{x})$ by mapping a $\gamma \in N(H)$ to a covering transformation mapping $\widetilde{x}_0$ to $\widetilde{x}_1$. And the kernel of this map is exactly those γ lifting to a loop at $\widetilde{x}_0$, which are exactly the elements of H. □

Prop. (3.14.1.31) [Covering Space Action]. If G is a discrete group and $G \times Y \to Y$ is a covering space action(3.11.1.14), then the quotient map $Y \mapsto Y \backslash G$ is a normal covering space. And if Y is path-connected, G is the group of covering transformations.

Proof: The condition on the action shows it is locally a homeomorphism, thus it is a covering space. And it is a normal covering space because $g_1 g_2^{-1}$ takes any $g_1(x)$ to $g_2(x)$. The group of covering transformations is just G, because the covering transformation on a path-connected space is determined by its action on a single point. □

2 Vector Bundles

Basics

Def. (3.14.2.1) [Vector Bundle]. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$, a $\mathbb{K}$-**vector bundle** of dimension n over a topological space X is a fiber bundle over X with fiber $\mathbb{K}^n$ that each trivialization φ_α restricts to $\mathbb{K}$-linear isomorphisms on the fibers. The category of vector bundles over X is denoted by $\mathcal{V}\mathrm{ect}_{\mathbb{K}}(X)$.A **vector bundle homomorphism** $E \to F$ is a map of spaces over X that the maps on the fibered are all $\mathbb{K}$-linear.

Then a $\mathbb{K}$-vector bundle of dimension n over X is just an associated $\mathrm{GL}(n, \mathbb{K})$-bundle with fiber $\mathbb{K}^n$ over X. In particular, there is a bijection $\mathcal{V}\mathrm{ect}^n_{\mathbb{K}}(X) \cong \mathcal{P}_{\mathrm{GL}(n,\mathbb{K})}(X)$ by(3.14.3.4).

Def. (3.14.2.2) [Trivial Vector Bundles]. For any $n \in \mathbb{N}$, the **trivial vector bundle** of rank n is denoted by e^n.

Prop. (3.14.2.3) [Constructions of Vector Bundles]. Let $T : (\mathcal{V}\mathrm{ect}^f/\mathbb{K})^{\otimes n} \to \mathcal{V}\mathrm{ect}^f/\mathbb{K}$ be a functor that is either covariant or contravariant for each of its factor that $T : \prod_i \mathrm{Hom}(V_i, W_i) \to \mathrm{Hom}(T(V_i), T(W_i))$ is continuous, then we have a functor $T : Vect(X)^n \to Vect(X)$ that is either covariant or contravariant for each of its factor.

Proof: Cf.[Ati64]P6. □

Cor. (3.14.2.4). In this way, given a vector bundles E, F on X, we can construct

$$E \oplus F, \quad E \otimes F, \quad \mathrm{Hom}(E, F) \cong E^* \otimes F, \quad E^*, \quad T^n E, \quad \wedge^i E.$$

Prop. (3.14.2.5) [Existence of Hermitian Metric]. There exists a Hermitian(Riemannian) metric on any bundle E over a paracompact space X. In this way, $E^* \cong E(\overline{E})$.

Proof: Choose a metric on each trivialization open subset and use partition of unity to glue. □

Cor. (3.14.2.6). A vector bundle over a paracompact space can have its transform maps $\in O(n)$ (or $U(n)$).

Proof: We can choose the metric on it compatible with the given metric. In this way, the transform map is $\in O(n)$ (or $U(n)$). □

Cor. (3.14.2.7) [Semisimplicity of $\mathcal{V}\mathrm{ect}(B)$]. Any exact sequence of vector bundles over a paracompact space B splits.

Proof: Because we can take the orthogonal complement. □

Cor. (3.14.2.8). If $f : X \to Y$ is a homotopy equivalence, then $f^* : \mathcal{V}\mathrm{ect}(Y) \to \mathcal{V}\mathrm{ect}(X)$ is an isomorphism.

In particular, if X is contractible, then every bundle over X is trivial.

Def. (3.14.2.9) [Orientations of Vector Bundles]. Let $\pi : E \to X$ be a vector bundle of rank n over a space X and $\mathbb{R} \cong \mathbb{Z}$ or $\mathbb{Z}/2\mathbb{Z}$, then a **orientation of** E with coefficient R is a functions that assigns a generator u_x of $H^n(E_x, 0, R) \cong R$ for any $x \in X$ s.t. for any $x \in X$, there is a nbhd U of $x \in X$ and an element $u \in H^n(\pi^{-1}N, \pi^{-1}(N)_0, R)$ s.t. u pulls back to u_x via $(E_x, 0) \subset (\pi^{-1}N, \pi^{-1}(N)_0)$ for any $x \in U$. In particular, any vector bundle is $\mathbb{F}_2$-orientable.

Prop. (3.14.2.10) [Orientation of Complex Vector Bundles]. For $E/X \in \mathcal{V}\mathrm{ect}_{\mathbb{C}}(X)$, the underlying real bundle has a preferred orientation, which is compatible with direct sums.

In particular, the tangent bundle of a complex manifold gives rise to a unique orientation of the underlying real manifold.

Proof: Let $a_1, \ldots, a_n$ be a complex basis for E, then take the real basis to be $a_1, ia_1, \ldots, a_n, ia_n$. This orientation is stable under $GL(n, \mathbb{C})$ transformation, as $GL(n, \mathbb{C})$ is connected. □

Prop. (3.14.2.11). If E is a complex vector bundle over X, then $E \otimes_{\mathbb{R}} \mathbb{C} \cong E \oplus \overline{E}$ as complex vector bundles.

Lemma (3.14.2.12). Suppose $\pi : E \to B \times I$ is a fiber bundle whose restriction to $B \times [0, a]$ and $B \times [a, 1]$ are all trivial for some $a \in I$, then $E \to B \times I$ is a trivial bundle.

Proof: The proof is similar to that of(3.14.1.6) □

Lemma (3.14.2.13). Let $E \to B \times I$ be a fiber bundle, then there exists a covering $\{U_i\}$ of B that E is trivial on each $U_i \times I$.

Proof: The proof is similar to that of(3.14.1.7) □

Lemma (3.14.2.14). Let $\pi : E \to B \times I$ be a fiber bundle, where B is a paracompact space, and $r : B \times \mathbb{I} \to B \times I$ defined by $r(b, x) = (b, 1)$, then there exists a bundle morphism f over r that induces an isomorphism $r^*E \cong E$ over $B \times \mathbb{I}$.

Proof: The proof is similar to that of(3.14.1.8) □

Prop. (3.14.2.15) [Homotopy Invariance of Vector Bundles]. Let $E' \to B'$ be a vector bundle. If $f, g : B \to B'$ are two homotopic maps with B paracompact, then there is a bundle isomorphism $f^*E' \cong g^*E'$.

Proof: The proof is similar to that of(3.14.1.9) □

Bundles of Finite Type

Def. (3.14.2.16) [Bundles of Finite Type]. Let X be a paracompact Hausdorff space, then a **vector bundle of finite type** over X is a vector bundle over X that has a covering by f.m. trivialization maps. The category of k-dimensional vector bundles over X of f.t. is denoted by $\mathcal{V}\mathrm{ect}_k^{\mathrm{ft}}(X)$. Trivially, any vector bundle over a compact space is of f.t..

Prop. (3.14.2.17) [Vector Bundles on the Quotient]. Let Y be a closed subspace of X, E a vector bundle over X, then a trivialization $\alpha : E|_Y \cong Y \times V$ defines a bundle E/α over X/Y. The isomorphism class of E/α only depends on the homotopy type of α.

Proof: To show it is a vector bundle, notice the trivialization α extends to a □

Prop. (3.14.2.18) [Splitting Principle]. For a vector bundle $E \to X$, there is a space $Y \to X$ that p^* is injective on $H^*(-, \mathbb{Z})$ and p^*E splits as a sum of line bundles. This proposition is useful when proving theorems about characteristic classes.

Proof: It suffice to find a Y that p^*E has a subbundle, then choose its orthogonal part, and use induction. For this, choose $Y = P(E)$, then Y has a tautological bundle, which is a subbundle of p^*E, and Y is fibered over X with fiber $\mathbb{P}^n$, and we want to use Leray-Hirsch, so check the fact $H^*(\mathbb{P}^n)$ is free and generated by the first Chern class, by(3.14.4.16) and(5.7.2.1). And Chern class is functorial, so the powers of Chern class of f^*E will generate the cohomology ring of any stalks. □

Prop. (3.14.2.19). For any bundle E over a compact Hausdorff space X, there is a surjective bundle map $X \otimes \mathbb{R}^n \to E$ for some $m \geq 0$.

Proof: Choose a finite cover of trivialization of E, then we can glue these maps together via a partition function. □

Cor. (3.14.2.20) [Negation of Bundles]. For any vector bundle E on a compact space X, there is a vector bundle F that $E \oplus F$ is a trivial bundle.

Proof: Choose a bundle map $\mathbb{R}^n \times X \to E$ that is surjective, then the kernel of this map is a bundle F, such that $E \oplus F \cong \mathbb{R}^n$(By taking a Hermitian metric(3.14.2.5) and taking the orthogonal bundle). □

Cor. (3.14.2.21) [Global Transversal Sections]. For a vector bundle over a compact manifold, there exists a global section transversal to the zero section, in particular, if $\dim E > M$, then it has no zero.

Proof: Choose a bundle map $\mathbb{R}^n \times X \to E$ that is surjective, and then use parametric transversality theorem(11.1.4.5) to prove there is a section that is transversal. □

Cor. (3.14.2.22) [Vector Fields with Isolated Zeros]. There is a vector field on compact manifold of only isolated zeros. And a vector bundle over a k dimensional curve splits to components of dimension no bigger than k. Determined by its Chern class.

Prop. (3.14.2.23) [Constructing Vector Bundles].

Cor. (3.14.2.24). There is a natural isomorphism $\mathcal{V}\mathrm{ect}_n(S(X)) \cong [X, GL(n, \mathbb{C})]$.

Proof: Write $\Sigma(X) = C^+(X) \coprod C^-(X)$, and $C^\pm(X)$ are both contractible, thus E are trivial restricted to them(3.14.2.8). Let $\alpha^\pm$ be the trivialization isomorphism, then $\alpha^+ \circ \alpha^-$ is a bundle map of $X \times \mathbb{R}^n$, which is equivalent to a map $\alpha : X \to GL(n, \mathbb{C})$. The homotopy type of α is determined because $C^\pm(X)$ are both contractible, and vise versa. □

Prop. (3.14.2.25) [Vector Bundles as Modules]. Γ induces an equivalence between the category of vector bundles over X and the category of finitely projective modules over $C(X)$.

Proof: Clearly a bundle induces a module over $C(X)$. And it is a fully faithful functor. Now the image is the subcategory of finite projective modules, because every bundle is a direct summand of a trivial bundle, and a trivial bundle corresponds to a finite free $C(X)$-modules. □

Thom isomorphism

Prop. (3.14.2.26) [Thom Class]. Let $R = \mathbb{Z}$ or $\mathbb{F}_2$ and an R-orientable vector bundle E over base B of rank n.

Then there exists uniquely **Thom class** $u_E \in H^n(E, E \backslash B, R)$ that induce the preferred generator $H^n(E_x, E_x \backslash \{0\}, R)$(3.14.2.9) on every fiber. Then the relative Leray-Hirsch will give an isomorphism

$$\varphi_R : H^i(B, R) \cong H^{i+n}(E, E \backslash B, R) : x \mapsto \pi^*(x) \cup u_E.$$

For $\mathbb{F}_2$ coefficient there exists a Thom class, and for orientable bundle there exists a $\mathbb{Z}$-Thom class. Notice that fiber bundle over a simply connected base is orientable.

Proof: □

Cor. (3.14.2.27) [Naturality].

- Let $B' \to B$ be a map and E/B be an R-orientable vector bundle, which induces a map $f^* : H^n(E, E_0, R) \to H^n(f^*(E), E_0', R)$. Then $f^* u_E \cong u_{f^*(E)}$.
- The Thom class u_E maps to $u_{E,2}$ under the change of coefficients $\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$.

Prop. (3.14.2.28). Similarly, for a orientable fiber bundle $S^{n-1} \to E \to B$, make it a $D^n \to E' \to B$ bundle, then E' is homotopy equivalent to B so there is a Gysin sequence

$$\to H^{i-n}(B) \xrightarrow{\smile e} H^i(B) \to H^i(E) \to H^{i-n+1}(B) \to$$

Where the Euler class e is chosen to commute with the Thom isomorphism.

Examples of Vector Bundles

Def. (3.14.2.29) [n-Universal k-Vector Bundle]. Let $K = \mathbb{R}$ or $\mathbb{C}$, endow $\mathbb{K}^n$ with the canonical Hermitian metric, define $E_k(\mathbb{K}^n)$ be the subspace of $\mathrm{Gra}(k, \mathbb{K}^n) \times \mathbb{K}^n$ consisting of pairs (W, v) that $v \in W$. Then this is a vector bundle over the Grassmannian $\mathrm{Gra}(k, \mathbb{K}^n)$(11.7.2.12), called the **n-universal k-vector bundles**, or the **tautological bundles**.

Proof: We construct localization maps: endow $\mathbb{K}^n$ with the natural metric. For $W_0 \in G_k(\mathbb{K}^n)$, then the subspace U of $G_k(\mathbb{K}^n)$ consisting of W that $W \cap W_0^\perp = \varnothing$ is a nbhd of W_0, and it is naturally homeomorphic to $\mathrm{Hom}(W_0, W_0^\perp)$. There is an isomorphism

$$\pi^{-1}(U) \cong U \times W_0 : (f, (f + \mathrm{id})w_0) \mapsto (f, w_0).$$

□

Prop. (3.14.2.30) [Universal Vector Bundle]. Because by(3.14.3.20) $E_k(\mathbb{K}^\infty)/\,\mathrm{Gra}(k, \mathbb{K}^\infty)$ is the universal bundle, there is a map $i_k : \mathrm{Gra}(k, \mathbb{K}^n) \to \mathrm{Gra}(k + 1, \mathbb{K}^n)$ s.t. $i_k^*(E_{k+1}(\mathbb{K}^\infty))$ is the bundle $E_k(\mathbb{K}^\infty) \oplus \mathbb{K}$. Then it can be shown

$$BU(\mathbb{K}) = \mathrm{colim}_k(\mathrm{Gra}(k, \mathbb{K}^\infty) \xrightarrow{i_k} \mathrm{Gra}(k + 1, \mathbb{K}^\infty))$$

is a CW complex.

Moreover, there are maps $w_{k,l} : \mathrm{Gra}(k, \mathbb{K}^\infty) \times \mathrm{Gra}(l, \mathbb{K}^\infty) \to \mathrm{Gra}(k + l, \mathbb{K}^\infty)$ that corresponds to the bundle $E_k(\mathbb{K}^\infty) \times E_l(\mathbb{K}^\infty)$, and these maps induces an H-space structure on BU.

Proof: □

Prop. (3.14.2.31)[Tautological Line Bundles]. For $\mathrm{Gra}(1, \mathbb{R}^{n+1}) \cong \mathbb{RP}^n$, the line bundle $E_1(\mathbb{R}^{n+1})$ is denoted by γ_n^1.

Then the tangent bundle τ_n of $\mathbb{RP}^n$ is isomorphic to $\mathrm{Hom}(\gamma_n^1, \gamma_n^\perp)$, where $\gamma_n^\perp$ is the orthogonal complement of γ_n^1 in $e^{n+1}_{\mathbb{RP}^n}$(with the canonical norm).

Proof: This is because a tangent vector at $x \in \mathbb{RP}^n$ is equivalent to a homomorphism $[x]$ to $[x]^\perp$.
? How to prove this rigorously. □

Cor. (3.14.2.32). $\tau_n \oplus e^1 \cong (\gamma_n^1)^{n+1}$.

Proof: By(3.14.2.31), $\tau_n \oplus e^1 \cong \mathrm{Hom}(\gamma_n^1, \gamma_n^1) \oplus \mathrm{Hom}(\gamma_n^1, \gamma_n^\perp) = \mathrm{Hom}(\gamma_n^1, \mathbb{R}^n) = (\gamma_n^1)^{*n}$. Then we are done because γ_n^1 is self-dual because it has a Euclidean metric(3.14.2.5). □

Prop. (3.14.2.33)[Pullback the Universal Bundle]. For $V \in \mathcal{V}\mathrm{ect}/\mathbb{K}$, for any continuous map $\varphi : X \to \mathrm{Gra}(k, V)$, we get a subspace $E_\varphi = \{(x, v) \in X \times V | v \in \varphi(x)\} \subset X \times V$. This is a vector bundle over X, and it is a subbundle of the trivial bundle $X \times V \to X$. In fact, $E_\varphi \cong f^* E_k(V)$(3.14.2.29).

Cor. (3.14.2.34). Let $f : X' \to X$ and $\varphi : X \to Pr(V)$, then $f^*(E_\varphi) = E_{\varphi \circ f}$.

Prop. (3.14.2.35) [Infinite Universal k-Vector Bundle]. The n-universal k-vector bundles $E_k(\mathbb{K}^n)$(3.14.2.29) for various n gets together to a bundle $E_k(\mathbb{K}^\infty)$ on $\mathrm{Gra}(k, \mathbb{K}^\infty)$ that the pull-back of $E_k(\mathbb{K}^\infty)$ via $i : \mathrm{Gra}(k, \mathbb{K}^n) \to \mathrm{Gra}(k, \mathbb{K}^\infty)$ is $E_k(\mathbb{K}^n)$.

Def. (3.14.2.36) [Hopf Bundle]. Define a map $\varphi : \mathbb{C}P^n \to G_1(\mathbb{C}^{n+1})$ that $\varphi([z]) = [z]$, then this defines a vector bundle on $\mathbb{C}P^n$ by(3.14.2.33), called the **dual of Hopf bundle**. The **Hopf bundle** is defined to be the dual of the dual of Hopf bundle.

3 Principal Bundles

Main reference is [Principal Bundles and Classifying Space].

Def. (3.14.3.1) [Principal Bundles]. For $G \in \mathcal{T}op\,\mathcal{G}rp$, a **principal G-bundle** is a bundle P with G-fibers that the transition function is right G-map, i.e. left multiplication by some $g_{\alpha\beta}$. a associated bundle of a representation $G \to \mathrm{End}(V)$ is the total space of $P \times V$ module the equivalence $[gg_0, v] = [g, g_0 v]$. The corresponding transition function is just the left action by $g_{\alpha\beta}$.

For $B \in \mathcal{T}op$, denote $\mathscr{P}_G(B)$ the isomorphism classes of vector bundles on B.

Prop. (3.14.3.2) [Homogenous Space]. For $G \in \mathcal{L}ie\mathcal{G}rp$ and $H \leq G$ is a closed subgroup, then the quotient $H\backslash G$ can be given a structure of a G-homogenous space and $G \to H\backslash G$ is a principal H-bundle.

Proof: □

Prop. (3.14.3.3). The projection $\mathbb{S}^{2n+1} \to \mathbb{CP}^n$ is a principal $\mathbb{S}^1$-bundle.

Proof: □

Prop. (3.14.3.4) [Associated Bundles]. If $G \in \mathcal{T}op\,\mathcal{G}rp$ and G acts freely on $F \in \mathcal{T}op$, then an **associated G-bundle with fiber F** is a locally trivial F-bundles with a G-action**?**.

Then the isomorphism classes of associated G-bundles with fiber F over B is in bijection with $\mathscr{P}_G(B)$.

Proof: **?** □

Classifying Space

Def. (3.14.3.5) [Classifying Spaces]. For $G \in \mathcal{T}op\,\mathcal{G}rp$, a **classifying space** of G is a space $B(G) \in \mathcal{T}op$ together with a principal G-bundle $E(G) \to B(G)$ s.t. $E(G)$ is contractible.

Notice $\pi_{n+1}(BG) = \pi_n(G)$ by**??**.

Thm. (3.14.3.6) [Classifying Spaces and Principal Bundles]. If $G \in \mathcal{T}op\,\mathcal{G}rp$ and $E(G) \to B(G)$ is a classifying space for G, then for any $B \in \mathcal{T}op$ that is paracompact, the pullback induces a bijection

$$[B, B(G)] \cong \mathscr{P}_G(B).$$

In particular, the classifying spaces is uniquely defined ique up to homotopy, if it exists.

Proof: **??** □

Prop. (3.14.3.7) [Classifying Spaces Exist]. For $G \in \mathcal{T}op\,\mathcal{G}rp$, define

$$E_*(G) \in s\,\mathcal{T}op : E_n(G) = G^{n+1}$$

$$d_i((g_1, \ldots, g_{n+1})) = \begin{cases} (g_2, \ldots, g_{n+1}) & , i = 0 \\ (g_1, g_{i-1}, g_i g_{i+1}, g_{i+2}, \ldots, g_{n+1}) & , 1 \leq i \leq n \end{cases}$$

$$s_i((g_1, \ldots, g_n)) = (g_1, \ldots, g_i, e, g_{i+1}, \ldots, g_n), \quad 0 \leq i \leq n$$

And

$$B_*(G) \in s\,\mathcal{T}op : B_n(G) = G^n$$

$$d_i((g_1,\ldots,g_n)) = \begin{cases} (g_2,\ldots,g_n) & ,i=0 \\ (g_1,g_{i-1},g_ig_{i+1},g_{i+2},\ldots,g_n) & ,1\le i\le n-1 \\ (g_1,\ldots,g_n) & i=n \end{cases}$$

$$s_i((g_1,\ldots,g_{n-1})) = (g_1,\ldots,g_i,e,g_{i+1},\ldots,g_{n-1}), \quad 0\le i\le n.$$

Then there is a map

$$\mathrm{pr}: E_*(G)\to B_*(G)\in s\mathcal{T}\mathrm{op} : (g_1,\ldots,g_{n+1})\in E_n(G)\mapsto (g_1,\ldots,g_n)\in B_n(G).$$

Denote $E(G)=|E_*(G)|, B(G)=|B_*(G)|$, then pr induces a map $\mathrm{pr}: E(G)\to B(G)$. $B(G)$ is called the **classifying space** of G.

Cor. (3.14.3.8). Any group G is a fundamental group of a topological space.

Prop. (3.14.3.9). Situation as in(3.14.3.7), there is a right action of G on $E_*(G)$ on the last coordinates, which induces an action of G on $E(G)$, and $B(G)\cong E(G)/G$. Then if (G,e) is well-pointed, $E(G)\to B(G)$ is a locally trivial bundle with fiber G, and $E(G)$ is contractible. In particular, $G\cong\Omega(BG)$, by(3.12.6.20).

Proof: ?. Cf.[Milnor, Construction of Universal Fiber Bundles, I, II]. □

Cor. (3.14.3.10). For $G,G'\in\mathcal{T}\mathrm{op}\,\mathcal{G}\mathrm{rp}$,

$$E(G\times G')\cong E(G)\times E(G'),\quad B(G\times G')\cong B(G)\times B(G').$$

Cor. (3.14.3.11). If G is commutative, then $G\times G\to G$ is a homomorphism that makes $B(G)$ a commutative topological group. Then we can define for any $n\in\mathbb{N}$,

$$B(G,n)=B^{\circ n}(G).$$

Prop. (3.14.3.12). $[X,BG]\cong G$-bundles on X. And BG is Abelian if G is Abelian. Thus the classifying space BG is unique up to homotopy equivalence because they all represent the functor from the CW homotopy category to the set of G-bundles on it.

Proof: Cf.[Principal Bundles and Classifying Space P13]. □

Prop. (3.14.3.13) [Examples of Classifying Spaces].

- $B(\mathbb{Z}/n\mathbb{Z})\cong\mathbb{S}^\infty/(\mathbb{Z}/n)=(\mathbb{C}^\infty\backslash\{0\})/(\mathbb{R}^+\times\mu_n)$(3.12.3.17). In particular, $B(\mathbb{Z}/2)\cong\mathbb{RP}^\infty$(3.12.3.19).
- $BSU(2,\mathbb{R})=\mathbb{HP}^\infty$.
- $B(\mathbb{Z}^g)=\mathbb{T}^g$ because $\mathbb{R}\to\mathbb{T}^1$ is a universal cover, this can be seen observing only has to satisfy the sum of inner angle is π.
- $BO(n),BU(n),BSp(n)$ are respectively the infinite Grassmannians $\mathrm{Gra}(n,\mathbb{R}^\infty),\mathrm{Gra}(n,\mathbb{C}^\infty),\mathrm{Gra}(n,\mathbb{H}^\infty)$, because there is a locally trivial fiber bundle(3.14.1.16) $U(n,\mathbb{K})\to V_n(\mathbb{K}^\infty)\to\mathrm{Gra}(n,\mathbb{K}^\infty)$, and $V_n(\mathbb{K}^\infty)$ is contractible(3.12.3.18). In particular, $B(\mathbb{Z}/2)=\mathbb{RP}^\infty$ and $BS^1=\mathbb{CP}^\infty$.

Proof: □

Def. (3.14.3.14)[Admissible Subgroups]. A subgroup of a topological group G is called **admissible** if $G \to G/H$ is a principal H-bundle. In particular, this is the case for $G \in \mathcal{L}ie\mathcal{G}rp$ and $H \leq G$ closed, by(3.14.3.2).

Prop. (3.14.3.15). If H is an admissible subgroup of G, then there is a homotopy fiber sequence $G/H \to BH \to BG$.

Proof: Cf.[Principal Bundles and Classifying Space P22]. □

Cor. (3.14.3.16). There are homotopy equivalences $\Omega BK \cong K$ and $B\Omega K \cong K$.

Prop. (3.14.3.17). If H is an admissible normal subgroup of G, then there is a homotopy fiber sequence $BH \to BG \to B(G/H)$.

Proof: □

Cor. (3.14.3.18).

- there are fiber bundles $\mathbb{S}^0 \to BSO(n) \to BO(n)$ and similarly for $BSU(n)$ and $BSp(n)$.
- there are fiber bundles $\mathbb{S}^n \to BO(n) \to BO(n+1)$.
- there are fiber bundles $U(n)/T^n \to (\mathbb{CP}^\infty)^n \to BU(n)$, where $U(n)/T^n$ is the variety of complete flags in $\mathbb{C}^n$.
- for a discrete group $H \subset G$, $BH \to BG$ is a covering map.
- there are fiber bundles $BSO(n) \to BO(n) \to \mathbb{RP}^\infty$ and similarly for $\mathbb{C}$ and $\mathbb{H}$.
- there are fiber bundles $\mathbb{RP}^\infty \to B\,\mathrm{Spin}(n) \to BSO(n)$.

Proof: These are all classifying spaces of Lie groups. □

Prop. (3.14.3.19) [Classifying Line Bundles]. Note that $K(\mathbb{Z},2) = \mathbb{CP}^\infty = B(K(\mathbb{Z},1)) = BU(1)$(3.14.3.13), thus we have a bijection $H^2(X,\mathbb{Z}) \cong [X, K(\mathbb{Z},2)] \cong \mathcal{V}\mathrm{ect}^1_{\mathbb{C}}(X)$. Similarly, we have a bijection $H^1(X,\mathbb{Z}/2\mathbb{Z}) \cong \mathcal{V}\mathrm{ect}^1_{\mathbb{R}}(X)$.

Classifying Spaces

Prop. (3.14.3.20)[Universal Real Bundle]. Let X be paracompact, then there is a natural bijection

$$[X, \mathrm{Gra}(k, \mathbb{K}^\infty)] \to \mathcal{V}\mathrm{ect}^k_{\mathbb{K}}(X) : f \mapsto f^* E_k(\mathbb{K}^\infty).$$(3.14.3.13)(3.14.2.35)

Proof: Because E is of f.t., we can find a f.d. vector space W with a metric and a vector bundle epimorphism $\varphi : X \times W \to E$ via partition of unity. Then we can take the map $\varphi : X \to G_k(W) : x \mapsto \ker(\varphi_x)^\perp$. Then $f^* E_k(\mathbb{K}^\infty) \cong E$ via restriction of φ. The last assertion follows from the definition of $E_k(\mathbb{K}^\infty)$(3.14.2.35) and(3.14.2.15).

Cf.[AGP02]P284.? □

Cor. (3.14.3.21). By(3.13.6.13), there are isomorphisms

$$\mathcal{V}\mathrm{ect}^{\mathbb{R}}_1(X) \cong [X, \mathrm{Gra}(1, \mathbb{R}^\infty)] = [X, K(\mathbb{Z}/(2), 1)] = H^1(X, \mathbb{F}_2).$$

$$\mathcal{V}\mathrm{ect}^{\mathbb{C}}_1(X) \cong [X, \mathrm{Gra}(1, \mathbb{C}^\infty)] = [X, K(\mathbb{Z}, 2)] = H^2(X, \mathbb{Z}).$$

Cohomology of Classifying Spaces

Prop. (3.14.3.22). $H_*(\mathbb{B}G,\mathbb{Z})\cong H_*(\Lambda,\mathbb{Z})$ and $H^*(\mathbb{B}G,\mathbb{Z})\cong H^*(G,\mathbb{Z})$.

Proof: Because EG is weakly contractible, $S_*(EG)$ is a free $\mathbb{Z}[G]$-module resolution of $\mathbb{Z}$ and $S_*(EG)_G$ is identified with $S_*(BG)$. The rest is easy. □

Def. (3.14.3.23) [Whitney Sums].

Prop. (3.14.3.24). The diagonal map $O(1)^n\to O(n)$ induces a map

$$\omega:(\mathbb{RP}^\infty)^n\cong(\mathbb{B}O(1))^n\to\mathbb{B}O(n).$$

The conjugation by permutation matrices preserves $O(1)^n$, thus induces a covariant action on this map. The action on $\mathbb{B}O(n)$ is identity**?**, and the action on $(\mathbb{B}O(1))^n$ is by permutation.

Then it induces a map

$$H^*(\mathbb{B}O(n))\to H^*((\mathbb{B}O(1))^n)^{\mathcal{S}_n}\cong\mathbb{F}_2[\sigma_1,\sigma_2,\ldots,\sigma_n]$$

where σ_i are the elementary symmetric functions. This is injective and thus surjective when tensoring any field, thus it is a bijection**?**.

Denote the inverse image of σ_i by w_i, then

$$H^*(\mathbb{B}O(n))\cong\mathbb{F}_2[w_1,\ldots,w_n],\quad |w_i|=i$$

and these elements satisfy

- $c_0=1$.
- $i_1^*(c_1)$ is the canonical generator of $H^2(\mathbb{B}U(1))$.
- $i_n^*(w_i)=c_i$.
- $p^*(w_i)=\sum_{j=0}^i w_j\otimes w_{i-j}$.

Proof: Cf.[Cohomology of Classifying Space Toda P82]. □

Prop. (3.14.3.25)[$H^*(\mathbb{B}SO(n),\mathbb{F}_2)$]. $\mathrm{pr}:\mathbb{B}SO(n)\to\mathbb{B}O(n)$ is the universal covering with fiber $\mathbb{Z}/(2)$, and

$$H^*(\mathbb{B}SO(n),\mathbb{F}_2)\cong\mathbb{F}_2[\mathrm{pr}^*\omega_2,\ldots,\mathrm{pr}^*\omega_n].$$

Proof:

□

Prop. (3.14.3.26). The diagonal map $U(1)^n\to U(n)$ induces a map

$$\omega:(\mathbb{CP}^\infty)^n\cong(\mathbb{B}U(1))^n\to\mathbb{B}U(n).$$

The conjugation by permutation matrices preserves $U(1)^n$, thus induces a covariant action on this map. The action on $\mathbb{B}U(n)$ is identity**?**, and the action on $(\mathbb{B}U(1))^n$ is by permutation.

Then it induces a map

$$H^*(\mathbb{B}U(n))\to H^*((\mathbb{B}U(1))^n)^{\mathcal{S}_n}\cong\mathbb{Z}[\sigma_1,\sigma_2,\ldots,\sigma_n]$$

where σ_i are the elementary symmetric functions. This is injective and thus surjective when tensoring any field, thus it is a bijection**?**.

Denote the inverse image of σ_i by c_i, then

$$H^*(\mathbb{B}U(n)) \cong \mathbb{Z}[c_1, \ldots, c_n], \quad |c_i| = 2i$$

and these elements satisfy

- $c_0 = 1$.
- $i_1^*(c_1)$ is the canonical generator of $H^2(\mathbb{B}U(1))$.
- $i_n^*(c_i) = c_i$.
- $p^*(c_i) = \sum_{j=0}^i c_j \otimes c_{i-j}$.

Proof: Cf.[Cohomology of Classifying Space Toda P81]. □

Prop. (3.14.3.27).

$$H^*(BO(2n), \mathbb{Z}[\frac{1}{2}]) \cong H^*(BO(2n+1), \mathbb{Z}[\frac{1}{2}]) \cong H^*(BSO(2n+1), \mathbb{Z}[\frac{1}{2}]) = \mathbb{Z}[\frac{1}{2}][p_1, p_2, \ldots, p_n], \quad |p_i| = 4i$$

$$H^*(BSO(2n), \mathbb{Z}[\frac{1}{2}]) = \mathbb{Z}[\frac{1}{2}][p_1, p_2, \ldots, p_n, e], e^2 = p_n, \quad |p_i| = 4i$$

Cf.[Cohomology of Classifying Space Toda P81].

Prop. (3.14.3.28)[Complexifications]. As $\mathbb{B}SO(n)$ is the set of oriented real n-planes in $\mathbb{R}^\infty$, $BU(n)$ is the set of complex n-planes in $\mathbb{C}^\infty$, regarding a complex n-plane as an oriented real $2n$-plane induces a map

$$r : \mathbb{B}U(n) \to \mathbb{B}SO(2n).$$

And complexification of a real plane induces a map

$$\mathfrak{c} : \mathbb{B}O(n) \to \mathbb{B}U(n).$$

Then

$$p_k = (-1)^k \mathfrak{c}^*(c_{2k}) \in H^{4k}(\mathbb{B}O(n)), \quad \mathfrak{c}^*(c_k) = w_k^2 \in H^{2k}(\mathbb{B}O(n), \mathbb{F}_2), \quad p_k = w_{2k}^2 \in H^{4k}(\mathbb{B}O(n), \mathbb{F}_2)$$

$$r^*(w_{2k}) = c_k \in H^{2k}(\mathbb{B}U(n), \mathbb{F}_2), \quad r^*(e) = c_n \in \mathbb{H}^{2n}(BU(n)).$$

$$Bk^*(p_k) = \sum_{i+j=k} (-1)^i c_i c_j, \quad .$$

Cf.[Cohomology of Classifying Space Toda P81].

4 Characteristic Classes

References are [Cohomology of Classifying Space, Toda], [May99] and [M-S74].

Def. (3.14.4.1) [Characteristic Classes]. For an ES-cohomology theory E^*, $p \in \mathbb{Z}, n \in \mathbb{N}$, a **characteristic class** functor of degree p for n-dimensional $\mathbb{K}$-bundles is a natural assignment $c : \mathcal{V}\mathrm{ect}_{\mathbb{K}}^n(X) \to E^p(X)$ for any $X \in \mathcal{T}\mathrm{op}$ paracompact that is functorial w.r.t. pullbacks.

By(3.14.3.20), there is a bijection between characteristic class functors of degree p with elements in $E^p(BO(n))$.

Stiefel-Whitney Classes

Def. (3.14.4.2) [Stiefel-Whitney Classes]. A **Stiefel-Whitney class** functor w for real bundles is a total characteristic class functor for real bundles for the ordinary cohomology theory with $\mathbb{F}_2$ coefficients $H^*(-,\mathbb{F}_2)$ that satisfies:

- $w(E) = 1 + w_1(E) + \ldots + w_n(E) \in H^*(X,\mathbb{F}_2), \quad |w_i| = i, n = \mathrm{rank}(E)$.
- $f^*(w(E)) = w(f^*(E))$.
- $w(E \oplus F) = w(E)w(F)$.
- On the tautological bundle γ_1^1 over $\mathbb{RP}^1$, $w(\gamma_1^1) = 1 + w_1(\gamma_1^1)$ and $w_1(\gamma_1^1)$ is the unique non-trivial element in $H^1(\mathbb{RP}^1,\mathbb{F}_2)$.

Prop. (3.14.4.3) [Existence and Uniqueness of Stiefel-Whitney Classes]. There exists uniquely a Stiefel-Whitney class functor, and they can be defined using the Thom isomorphism

$$\varphi_E : H^i(B;\mathbb{F}_2) \cong H^{i+n}(E, E\backslash B;\mathbb{F}_2)(3.14.2.26)$$

as

$$w(E) = \varphi_E^{-1}\,\mathrm{Sq}(\varphi_E(1)) \in H^*(B;\mathbb{F}_2) = \varphi^{-1}\,\mathrm{Sq}(u_E).$$

Proof: Cf.[May, P191] and [Milnor, P92].**?** □

Prop. (3.14.4.4). For $B \in \mathcal{T}\mathrm{op}$ paracompact, $E, E' \in \mathcal{V}\mathrm{ect}_{\mathbb{R}}(B)$, then

- If E is trivial, $w(E) = 1$.
- If $E \oplus E'$ is trivial, then
$$w(E') = w(E)^{-1} = 1 + w_1 + (w_1^2 + w_2) + (w_1^3 + w_3) + (w_1^4 + w_1^2 w_2 + w_2^2 + w_4) + \ldots.$$
- Let γ_n^1 be the tautological line bundle over $\mathbb{RP}^n$(3.14.2.31), then $w(\gamma_n^1) = 1 + a$.
- Let ξ, η be vector bundles on M, N, then
$$w(\xi \times \eta) = \pi_1^* w(\xi) \cup \pi_2^* w(\eta) = w(\xi) \times w(\eta)$$
in $H^*(M \times N, \mathbb{F}_2)$.

Proof: 1: A trivial bundle is the pullback of a bundle over pt, thus $w(f^*(E)) = w^*(e(E)) = 1$.
2 is trivial.
3: This is because $E_1(\mathbb{R})/\mathbb{RP}^1 \to E_1(\mathbb{R}^n)/\mathbb{RP}^n$ is a bundle map, thus $w_1(E_1(\mathbb{R}^n))$ pulls back to $w_1(E_1(\mathbb{R})) \neq 0$, thus $w_1(E_1(\mathbb{R}^n)) = a$.
4: This follows from the definition that $\xi \times \eta = \pi_1^*\xi \oplus \pi_2^*\eta$ and Künneth formula(3.13.2.13). □

Cor. (3.14.4.5) [Tangent and Normal Bundles]. Let M be a submanifold of a smooth manifold N, let $\mathcal{T}_M, \mathcal{T}_N$ be the tangent bundles and ν the normal bundle, then

$$w(\mathcal{N}_{M/N}) = w(\mathcal{T}_N) w(\mathcal{T}_M)^{-1}$$

Proof: This follows form the smooth nbhd theorem**?**. □

Prop. (3.14.4.6) [Wu Formula]. For $E \in \mathcal{V}\mathrm{ect}_B$,

$$\mathrm{Sq}^i(w_j) = \sum_{t=0}^{i} \binom{j+t-i-1}{t} w_{i-t} w_{i+t}$$

Proof: Use splitting principal. □

Def. (3.14.4.7) [Characteristic Classes of Smooth Manifolds]. For $M \in \mathcal{M}\text{ani}_{\text{sm}}$, denote $w(M) = w(TM)$.

Prop. (3.14.4.8) [Wu Formula]. For $M \in \mathcal{M}\text{ani}^d_{\text{sm,cpct}}$, define the **Wu class** $v = \sum v_i \in H^*(M, \mathbb{F}_2)$ s.t.

$$\langle \nu(M) \cup x, [M]_2 \rangle = \langle \text{Sq}(x), [M]_2 \rangle$$

for any $x \in H^*(M, \mathbb{F}_2)$. In particular, $\nu_k(M)_k \cup x = \text{Sq}^k(x)$ for any $x \in H^{d-k}(M, \mathbb{F}_2)$. Notice such a class exists by Poincaré duality.

Then the Stiefel-Whitney class of M is given by the Wu class:

$$w(M) = \text{Sq}(\nu(M))(3.13.6.14).$$

Proof: Cf.[Milnor, P132]. □

Cor. (3.14.4.9) [Homotopy Invariance of Stiefel-Whitney Classes of Manifolds]. The Stiefel-Whitney classes only depends on the homotopy type of M, and pullbacks of Stiefel-Whitney classes along smooth maps between smooth manifolds only depends on the homotopy type of the map.

Def. (3.14.4.10) [Stiefel-Whitney Numbers]. Let M be a closed smooth manifold of dimension n, then for each tuple $(i_1, \ldots, i_k)$ with $i_1 + \ldots + i_k = n$, define the **Stiefel-Whitney number**

$$w_{i_1,\ldots,i_k}(M) = (w_{i_1}(TM) \cup \ldots \cup w_{i_k}(TM), [M]) \in \mathbb{Z}/2\mathbb{Z}.$$

Euler Classes

Def. (3.14.4.11) [Euler Classes]. Axioms for **Euler classes** for orientable real bundles E/B:

- $e(e^1) = 0$.
- For any map $f : B' \to B$, $f^*(e(E)) = e(f^*(E))$.
- $e(E \oplus F) = e(E)e(F)$.
- for the opposite orientation $-E$, $e(-E) = -e(E)$.

Prop. (3.14.4.12) [Existence of Euler Classes]. For any oriented $E/B \in \mathcal{V}\text{ect}_{\mathbb{R}}(B)$, let $e(E)$ be defined as the image of the Thom class(3.14.2.26) under the maps

$$\varphi_E^{-1} : H^n(E, E_0, \mathbb{Z}) \to H^n(E, \mathbb{Z}) \cong H^n(B, \mathbb{Z}).$$

or equivalently, $e(E) = \varphi^{-1}(u_E \cup u_E)$ where u_E is the Thom class and $\varphi_{\mathbb{Z}}$ is the Thom isomorphism(3.14.2.26). then it is the desired Euler class.

Proof: **?**

1: If E has a non-zero section $s : B \to E_0$, then $B \xrightarrow{s} E_0 \subset E \to B$ is identity, thus

$$H^n(B) \xrightarrow{\pi^*} H^n(E) \to H^n(E_0) \xrightarrow{s^*} H^n(B)$$

is the identity. But $H^n(B) \xrightarrow{\pi^*} H^n(E) \to H^n(E_0)$ equals the restriction of u_E to E_0, which is 0.

2: This $e(E)$ is compatible with base change by(3.14.2.27) and the definition.

3: For products, Cf.[Milnor, P100].

4: If the orientation is reversed, then $u_{-E} = -u_E$. □

Cor. (3.14.4.13).

- For a trivial line bundle, $e(E) = 0$.
- For an odd dimensional vector space E/B, $2e(E) = 0$.

Proof: 1: A trivial bundle is the pullback of a bundle over pt, thus $e(f^*(E)) = f^*(e(E))$ is trivial.

2: This is because their is an orientation preserving isomorphism $(-1) : E/B \cong (-E)/B$ that is isomorphism on the base, so $e(-E) = e(E)$. □

Cor. (3.14.4.14) [Euler classes and Whitney Classes]. For a vector bundle E/B of rank n, the natural map $H^n(B, \mathbb{Z}) \to H^n(B, \mathbb{Z}/2\mathbb{Z})$ maps the Euler class $e(E)$ to the top Whitney class $w_n(E)$.

Proof: $e(E) = \varphi^{-1}(u_E \times u_E)$, which maps to $\varphi_2^{-1}(u_{E,2} \cup u_{E,2}) = \varphi_2^{-1}(Sq^n(u_{E,2})) = w_n(E)$ by(3.14.2.27). □

Prop. (3.14.4.15) [Euler Class and Euler Characteristic]. For $M \in \mathcal{M}\mathrm{ani}_{\mathrm{cpct,sm,orntd}}$, then

$$\langle e(\mathcal{T}_M), [M] \rangle = \chi(M).$$

Proof: ? □

Chern Classes

Def. (3.14.4.16) [Chern Classes]. Axioms for **Chern classes** for complex bundles:

- $c(E) = 1 + c_1(E) + \ldots + c_n(E) \in H^*(X, \mathbb{Z}), \quad |c_i| = 2i, n = \deg(E)$.
- $f^*(c(E)) = c(f^*(E))$.
- $c(E \oplus F) = c(E)c(F)$.
- For the tautological bundle η over $\mathbb{CP}^\infty$, $c_1(\eta)$ corresponds to the element id $\in [\mathbb{CP}^\infty, \mathbb{CP}^\infty] \cong H^2(\mathbb{CP}^\infty)$.

Prop. (3.14.4.17). There exists uniquely a natural transformation $c : Vect_{\mathbb{C}}(X) \to H^*(X, \mathbb{Z})$ satisfying these axioms. (For this, it suffice to calculate the cohomology ring of $BGL_n(\mathbb{C})$, Cf.[Cohomology of Classifying Space Toda]).

Cor. (3.14.4.18). For a trivial bundle $E = \underline{\mathbb{C}}$, $c_i(E) = 0$ for $i > 0$, because E is a pullback from a bundle on pt.

In particular, for any complex vector bundle E, $c(E \oplus \underline{\mathbb{C}}) = c(E)$.

Prop. (3.14.4.19) [First Chern Class Map]. A complex line bundle can be seen as an element of $H^1(X, \underline{\mathbb{C}}^*)$, by(5.3.2.14), by the exact sequence

$$0 \to \underline{\mathbb{Z}} \to \underline{\mathbb{C}} \xrightarrow{exp(2\pi i -)} \underline{\mathbb{C}^*} \to 0$$

($\mathbb{C}$ is sheaf of smooth functions from X to $\mathbb{C}$)which gives a map $H^1(X, \mathbb{C}^*) \to H^2(X, \mathbb{Z})$, called the **first Chern class map**. It is called so because it gives the first Chern class of this complex line bundle. It is also an isomorphism because $\mathbb{C}$ is fine sheaf so acyclic.

Proof: Only have to prove they are equal in $H^2(X, \mathbb{C})$. We choose a totally convex covering U_i of X by(11.2.3.21), then it is a fine cover, so by(5.3.2.15) the Čech cohomology and sheaf cohomology equal.

Use the Chern-Weil map definition of the Chern class, a connection on a line bundle satisfies $\nabla e_\alpha = \omega_\alpha e_\alpha$, and if $e_\beta = e_\alpha g_{\alpha\beta}$, then $\omega_\beta = g_{\alpha\beta}^{-1}\omega_\alpha g_{\alpha\beta} + g_{\alpha\beta}^{-1} dg_{\alpha\beta} = \omega_\alpha + d(\log g_{\alpha\beta})$. So $\Omega_\alpha = d\omega_\alpha$ locally, and the first Chern class is giving by Ω_α in $H^2(X,\mathbb{C})$.

Then we need to understand the deRham isomorphism. For the exact sequence $0 \to \underline{\mathbb{C}} \to \mathcal{A}^0 \to \mathcal{A}^1 \to \ldots$, it has a splitting: $0 \to \underline{\mathbb{C}} \to \mathcal{K}^1 \to 0$ and $0 \to \mathcal{K}^1 \to 0 \to \mathcal{A}^1 \to \mathcal{K}^2 \to 0$, this gives

$$0 \to H^1(X,\mathcal{K}^1) \xrightarrow{\delta} H^2(X,\underline{\mathbb{C}}) \to 0, \quad \mathcal{A}^1(X) \to \mathcal{K}^2(X) \xrightarrow{\delta} H^1(X,\mathcal{K}^1) \to 0.$$

because $\mathcal{A}^k$ are fine sheaves. The composite of them is just the de Rham isomorphism(Here we are identifying $H^2(X,\underline{\mathbb{C}})$ to $H^2(X,\mathbb{C})$ by(5.3.5.9)). Tracking the lifting, we notice Ω is mapped to the cocycle $\{\log g_{\alpha\beta} + \log g_{\beta\gamma} - \log g_{\alpha-\beta}\}$, which is exactly the image of the first Chern class map. □

Cor. (3.14.4.20). Complex line bundles are characterized by the first Chern class up to smooth isomorphism, because $H^1(X,\mathbb{C}^*) \to H^2(X,\mathbb{Z})$ is an isomorphism.

Pontryagin Classes

Def. (3.14.4.21) [Pontryagin Classes]. The Pontryagin classes are defined as $p_k(E) = (-1)^k c_{2k}(E_{\mathbb{C}}) \in \mathrm{H}^{4k}(X,\mathbb{Z})$.

Def. (3.14.4.22) [Pontryagin Number]. Let M be a closed manifold of dimension $4n$, then for each tuple $I = (i_1,\ldots,i_k)$ with $i_1+\ldots+i_k = n$, define the **Pontryagin numbers**

$$p_I(M) = (p_{i_1}(TM) \cup \ldots \cup p_{i_k}(TM), [M]) \in \mathbb{Z}.$$

Prop. (3.14.4.23)[Pontryagin Number of Product Manifolds]. Let M,N be closed submanifolds of dimension $4m, 4n$ resp., then for any tuple $I = (i_1,\ldots,i_k)$ with $i_1+\ldots+i_k = m+n$,

$$p_I(M\times N) = \sum_{I_1,I_2 | I_1 \coprod I_2 = I} p_{I_1}(M) p_{I_2}(N)$$

where the summation is over all partitions I_1, I_2 of m,n resp..

Proof: Cf.[Milnor, P193]. □

Combinatorial Pontryagin Classes

See [Milnor]Chap20.

Calculations and Applications

Prop. (3.14.4.24). $w(\mathbb{RP}^n) = (1+a)^{n+1}$. In particular, $w(\mathbb{RP}^n) = 1$ iff $n = 2^k - 1$ for some k.

Proof: This follows from(3.14.2.32). □

Cor. (3.14.4.25). Let $n = 2^k - 1 - r$, where $r \le 2^{k-1} - 1$, then $\mathbb{RP}^n$ can be immersed into $\mathbb{R}^{n+d}$ iff $d \ge r$.

Proof: By(3.14.4.5), the normal bundle ν satisfies $w(\nu) = (1+a)^r$, and $r < n$, thus $d = \mathrm{rank}(\nu) \ge r$. □

Cor. (3.14.4.26). If $n+1=2^r m$, then there doesn't exist 2^r-linearly independent vector fields on $\mathbb{RP}^n$.

Proof: This is because if their is, then $w(\mathbb{RP}^n)$ has degree$\leq n-2^r=2^r(m-1)-1$, but in fact it equals $(1+a^{2^r})^m$ has leading term $a^{2^r(m-1)}$. □

Remark (3.14.4.27). By considering irreducibility, we can prove stronger results, like $\tau_{\mathbb{RP}^4}$ doesn't contain a subbundle of rank2.

Prop. (3.14.4.28) [Non-Vanishing Vectors]. $\mathbb{RP}^n$ admits a non-vanishing vector field iff n is odd.

Proof: If $n=2k+1$, consider the non-vanishing vector field on $\mathbb{S}^{2k+1}:(x_1,\ldots,x_{2k+2})\mapsto(x_2,-x_1,x_4,-x_3,\ldots,x_{2k+2},-x_{2k+1})$. Then This descends to a non-vanishing vector field on $\mathbb{RP}^{2k+1}$. Conversely, if $n=2k$, by(3.14.4.26), there doesn't exists a non-vanishing vector field on $\mathbb{RP}^{2k}$. □

5 K-Theory

Def. (3.14.5.1) [Topological K-Groups]. For $X\in\mathcal{T}\mathrm{op}_{\mathrm{cpct}}$, the **K-group** $K(X)$ is defined to be $K_0(\mathcal{V}\mathrm{ect}(X))$(3.7.2.9), which is a ring under sum and tensor. Two vector bundles E,F are called **stably equivalent** if $[E]=[F]$.

There is a degree map $\deg K(X)\to\mathbb{Z}$, and the kernel is denoted by $\widetilde{K}(X)$. There is a canonical splitting $K(X)\cong\widetilde{K}(X)\oplus\mathbb{Z}$.

Prop. (3.14.5.2). A continuous map $f:X\to Y$ induces a group morphism $f^*:K(Y)\to K(X)$. By(3.14.1.9), this map only depends on $f\in[X,Y]$.

Prop. (3.14.5.3). By(3.14.2.20), over a compact Hausdorff space, E,F is stably equivalent iff $E\oplus\mathbb{R}^n\cong F\oplus\mathbb{R}^n$ for some n.

Thm. (3.14.5.4) [Periodicity Theorem]. Let L be a line bundle over X, then as a $K(X)$-algebra, $K(P(L\oplus 1))$ is generated by $[H]$, and is subject to the single relation $([H]-[1])([L][H]-[1])=0$.

Proof: Cf.[K theory, Atiyah, P46]. □

Cor. (3.14.5.5). $K(S^2)$ is generated by $[H]$ as a $K(\mathrm{pt})$-module, and is subject to the single relation $([H]-[1])^2=0$.

Cor. (3.14.5.6). There is an isomorphism $\mu:K(X)\otimes K(S^2)\to K(X\times S^2)$, where $\mu(a\otimes b)=(\pi_1^*a)(\pi_2^*b)$.

Def. (3.14.5.7) [Setup for Proof of Periodicity Theorem]. Given a line bundle E over X, we can associate a projective bundle $P(E)$ that $P(E)_x=P(E_x)$. Now denote P^0 the subspace of $P(E)$ consisting of all vectors of length≤ 1 and P_∞ the subspace consisting of all vectors of length≥ 1 together with the infinity section. There are projections $\pi_0:P_0\to X$ and $\pi_\infty:P_\infty\to X$, which are homotopy equivalences.

Now by(3.14.2.8),

6 Adam Operators

7 Cobordism

Def. (3.14.7.1) [Bordism Groups]. If X is a topological space, define the **bordism group** $\Omega_n(X)$ to be the set of pairs (M,f) where M is a closed smooth manifold of dimension n and $f:M\to X$ is a continuous map, under the equivalence relation that $(M_0, f_0) \sim (M_1, f_1)$ iff there is an $n+1$ manifold N and a map $F : N \to X$ that $\partial F = f_1 \coprod f_2$. This is a vector space over $\mathbb{F}_2$.

Let $\Omega_n = \Omega_n(\mathrm{pt})$, then for any m, n, there is a map $\Omega_m \times \Omega_n \to \Omega_{m+n} : (M, N) \mapsto M \times N$, so Ω_* is a graded commutative ring.

Prop. (3.14.7.2) [Thom]. If $N \in \mathcal{M}\mathrm{ani}^{n+1}_{\mathrm{sm,cpct},\partial}$ and $\partial(N) = M$, then all the Stiefel-Whitney numbers of M vanish.

Conversely, if $M \in \mathcal{M}\mathrm{ani}^{n}_{\mathrm{sm,cpct}}$ with all Stiefel-Whitney numbers 0, then it is the boundary of a compact smooth manifold with boundary.

Proof: Let $[N] \in H_{n+1}(N, M)$ be the fundamental homology class of the pair, then $\partial([N]) = [M]$. Let τ_N, M be the tangent bundle of N, M, then $\tau_N|_M = \tau_M \oplus \mathbb{R}^1$, because there is an outward pointing normal bundle. Thus the Stiefel-Whitney classes of M comes from restriction of that of N. Now the composite $H^n(N) \to H^n(M) \xrightarrow{\delta} H^n(N, M)$ is 0, so $\delta(w_{i_1,\ldots,i_k}(M)) = 0$. thus

$$\langle w_{i_1,\ldots,i_k}(M), [M]\rangle = \langle \delta(w_{i_1,\ldots,i_k}(M)), [N]\rangle = 0.$$

Conversely, Cf.[Stong, Notes on Cobordism Theory].? □

Prop. (3.14.7.3). For $m \in \mathbb{Z}_+$, $\mathbb{RP}^{2m-1}$ is a boundary and $\mathbb{RP}^{2m}$ is not a boundary.

Proof: Consider the fiber bundle $S^1 \to \mathbb{RP}^{2n-1} \to \mathbb{CP}^n$, its cone bundle is $D^1 \to M^n \to \mathbb{CP}^{2n-1}$, which has boundary $\mathbb{RP}^{2n-1}$.

$\mathbb{RP}^{2m}$ is not a boundary by(3.14.7.2) and the fact its top Stiefel-Whitney class is non-zero. □

Thm. (3.14.7.4) [Thom].

$$\Omega_* = \mathbb{F}_2[t_2, t_4, t_5, \ldots,]$$

is a graded polynomial algebra where there's one generator $t_n \in \Omega_n$ for each $n \neq 2^k - 1$.

Also $\Omega_*(X) = H_*(X, \Omega_*) \cong H_*(X, \mathbb{F}_2) \otimes_{\mathbb{F}_2} \Omega_*$.

Proof:

□

Cor. (3.14.7.5). A map $f : X \to Y$ induces a map $f_* : \Omega_n(X) \to \Omega_n(Y)$. This map only depends on the homotopy type of f.

Oriented Cobordism

Def. (3.14.7.6)[Oriented Bordism Groups]. When X is an orientable manifold, define the **oriented bordism group** $\Omega^{so}_n(X)$ to be the set of pairs (M, f) where M is an oriented smooth manifold of dimension n and $f : M \to X$ is a continuous map preserving orientation, under the equivalence relation that $(M_0, f_0) \sim (M_1, f_1)$ iff there is an $n + 1$ manifold N and a map $F : N \to X$ that $\partial F = (-f_1) \coprod f_2$.

Let $\Omega^{so}_n = \Omega^{so}_n(\mathrm{pt})$, then for any m, n, there is a map $\Omega^{so}_m \times \Omega^{so}_n \to \Omega^{so}_{m+n} : (M, N) \mapsto M \times N$, and $M \times N \cong (-1)^{mn} N \times M$, so Ω^{so}_* is a graded anti-commutative ring.

Prop. (3.14.7.7). The relation of (oriented) bordism is truly an equivalence class. It suffices to show transitivity, and this is because we can piece together two manifold with boundaries by collar neighborhood theorem(11.1.1.2).

Prop. (3.14.7.8). If $N \in \mathcal{M}\mathrm{ani}^{n+1}_{\mathrm{sm,cpct,orntd},\partial}$ and $\partial(N) = M$, then all the Pontryagin numbers of M vanish.

Proof: Let $[N] \in H_{n+1}(N, M)$ be the fundamental homology class of the pair, then $\partial([N]) = [M]$. Let τ_N, M be the tangent bundle of N, M, then $\tau_N|_M = \tau_M \oplus \mathbb{R}^1$, because there is an outward pointing normal bundle. Thus the Stiefel-Whitney classes of M comes from restriction of that of N. Now the composite $H^n(N) \to H^n(M) \xrightarrow{\delta} H^n(N, M)$ is 0, so $\delta(w_{i_1,\ldots,i_k}(M)) = 0$. thus

$$\langle w_{i_1,\ldots,i_k}(M), [M]\rangle = \langle \delta(w_{i_1,\ldots,i_k}(M)), [N]\rangle = 0.$$

□

Prop. (3.14.7.9) [Mayer-Vitories]. Let $X = U \cup V$ where U, V are open subsets of X, ?

Thm. (3.14.7.10) [Thom].

$$\Omega^{so}_* \otimes_{\mathbb{Z}} \mathbb{Q} \cong \mathbb{Q}[u_1, \ldots, u_n, \ldots],$$

where $u_i \in \Omega^{so}_{4i}$ and is represented by $[\mathbb{CP}^{2i}]$. Moreover,

- $\Omega^{so}_0 = \mathbb{Z}$.
- $\Omega^{so}_1 = 0$.
- $\Omega^{so}_2 = 0$.
- $\Omega^{so}_3 = 0$.
- $\Omega^{so}_4 = \mathbb{Z}$, generated by $\mathbb{CP}^2$.
- $\Omega^{so}_5 = \mathbb{Z}/2\mathbb{Z}$, generated by Y^5.
- $\Omega^{so}_6 = 0$.
- $\Omega^{so}_7 = 0$.
- $\Omega^{so}_8 = \mathbb{Z} \oplus \mathbb{Z}$, generated by $\mathbb{CP}^4$ and $\mathrm{CP}^2 \times \mathbb{CP}^2$.
- $\Omega^{so}_9 = \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$, generated by Y^9 and $Y^5 \times \mathbb{CP}^2$.
- $\Omega^{so}_{10} = \mathbb{Z}/2\mathbb{Z}$, generated by $Y^5 \times Y^5$.
- $\Omega^{so}_{11} = \mathbb{Z}/2\mathbb{Z}$, generated by Y^{11}.
- $\Omega^{so}_n \neq 0$ for $n \geq 8$.

Proof: Cf.[Milnor, P203].

By (3.14.7.8), for any partition I of k, there is a map $\Omega_{4k} \to \mathbb{Z} : M \mapsto p_I(M)$. These maps can be used to show that the products $\{\mathbb{CP}^{2i_1} \times \mathbb{CP}^{2i_r} | \sum i_r = k\}$ are linearly independent in Ω_{4k} by(3.14.4.23). □

Prop. (3.14.7.11) [Index and Oriented Cobordism]. If $k \in \mathbb{N}, W \in \mathcal{M}\mathrm{ani}^{4k+1}_{\mathrm{cntd,orntd,cpct}}$, then the index $I(M) = 0$.

Proof: This follows from the fact the image of $H^{2k}(W) \xrightarrow{i^*} H^{2k}(M)$ is a half-dimensional subspace(3.13.3.18) that the intersection product is trivial:

$$\langle i^*\alpha \cup i^*\beta, \partial[W]\rangle = \langle \alpha \cup \beta, i_*\partial[W]\rangle = 0.$$

Then it is by linear algebra? that the signature of this pairing is 0. □

Def. (3.14.7.12) [Stably Framed Manifold]. A **stably framed manifold** is a smooth manifold M of dimension n together with an isomorphism $TM \oplus \mathbb{R}^N \cong \mathbb{R}^{N+n}$ for some N.

Def. (3.14.7.13) [Framed Bordism Groups]. Because $T(\partial N) \oplus \mathbb{R} \cong TN|_{\partial N}$, we have the notion of a stably framed bordism $\Omega_n^{fr}(X)$. Denote $\Omega_n^{fr} = \Omega_n^{fr}(\mathrm{pt})$.

Prop. (3.14.7.14). $S^3 \cong SU(2)$ is naturally framed, and this generates $\Omega_3^{fr} \cong \mathbb{Z}/24$.

Thm. (3.14.7.15) [Pontryagin]. $\Omega_n^{fr} \cong \pi_{n+N}(S^N)$.

8 Applications

Prop. (3.14.8.1). A simply connected manifold is orientable. (Use the orientable double cover).

4 Commutative Algebras

4.1 Commutative Algebra I

Main References are [A-M69], [Mat80], [Sta]Chap10, [Commutative Algebra with a View Towards Algebraic Geometry] and [Wei94]Chap4.

Commutative rings are studied in this subsection.

Notation (4.1.0.1).
- All rings and algebras in this section is assumed to be commutative.

1 Basics

Def. (4.1.1.1) [Ideals]. For $R \in \mathcal{CR}\mathrm{ing}$, an **ideal** of R is a subgroup $I \leq R$ that is a left ideal. The category of ideals of R is denoted by $\mathrm{Ideal}(R)$.

Prop. (4.1.1.2) [Quotients]. For $R \in \mathcal{CR}\mathrm{ing}, I \in \mathrm{Ideal}(R)$, there is a **quotient ring** $R/I \in \mathcal{CR}\mathrm{ing}_R$ with the universal propertie: any $f : R \to R' \in \mathcal{CR}\mathrm{ing}$ that vanishes on I factors through R/I.

Proof: □

Prop. (4.1.1.3). The quotient map induces an order-preserving bijection of ideals of A/I and ideals of A containing I.

Prop. (4.1.1.4) [Prime Avoidance]. Let $R \in \mathcal{CR}\mathrm{ing}, I \in \mathrm{Ideal}(R)$, and $\mathfrak{p}_i$ are f.m. prime ideals that $I \not\subseteq \mathfrak{p}_i$ for any i, then $I \not\subseteq \cup\mathfrak{p}_i$.

Proof: Use induction on the number of primes n. For $n = 1$ this is trivial. For $n > 2$, let $z_i \in I \backslash \cup_{j \neq i} P_j$. Now consider $z = z_1 \cdot z_{n-1} + z_n$. If $z \in P_i$ for some $i < n$, then $z_n \in P_i$, contradiction. If $z \in P_n$, then some $z_i, i < n$ is in P_n because P_n is a prime ideal, contradiction. □

Prop. (4.1.1.5) [Existence of a Maximal Ideal]. Any non-zero commutative ring has a maximal ideal.

Proof: Use Zorn's lemma, the union of a chain of ideals is an ideal. □

Cor. (4.1.1.6). Any non-trivial ideal is contained in a maximal ideal.

Proof: If $I \subset A$ is a non-trivial ideal, then A/I is a non-zero ring, thus A/I has a maximal ideal, which corresponds to a maximal ideal of A containing I(4.1.1.3). □

Prop. (4.1.1.7). If $r(I)$ and $r(J)$ are coprime, then I, J are coprime.

Proof: As $a + b = 1$, and $a^m \in I, b^n \in J$, $1 = (a + b)^{m+n} \in I + J$. □

Def. (4.1.1.8) [Local Ring]. A **local ring** is a commutative ring R that has only one maximal ideal. Equivalently, there is a prime ideal $\mathfrak{m}$ that any element in $R\backslash\mathfrak{m}$ is invertible.

Proof: If $\mathfrak{m}$ is the maximal ideal, then for any $x \in R$, if (x) is not all of R, then x is contained in a maximal ideal by(4.1.1.5), which can only be $\mathfrak{m}$. Conversely, if there is a prime ideal $\mathfrak{m}$ that any element in $R\backslash\mathfrak{m}$ is invertible, then clearly every non-trivial ideal is included in $\mathfrak{m}$. □

Prop. (4.1.1.9). Any quotient of a local ring is also a local ring.

Def. (4.1.1.10) [Local Ring Map]. A map between two local rings are called **local ring map** iff it maps non-invertible elements to non-invertible elements, equivalently, $f^{-1}(\mathfrak{m}_S) = \mathfrak{m}_R$.

Def. (4.1.1.11) [Ideal of Definition]. In a Noetherian local ring $(R, \mathfrak{m})$, an ideal $I \subset R$ is called an **ideal of definition** if $\sqrt{I} = \mathfrak{m}$.

Prop. (4.1.1.12)[Ideals of Products and Filters]. If $F_i, i \in I$ is a collection of fields, then the prime ideals in the ring $\prod F_i$ is in bijection with the ultrafilters on I, where the ultrafilter $\mathcal{F}$ corresponds to the ideal $p_{\mathcal{F}} = \{(a_i)|\text{the set of coordinates that } a_i = 0 \text{ is in } \mathcal{F}\}$. And in the same way, ideals of $\prod F_i$ corresponds to the filters on I.

Proof: Clearly $p_{\mathcal{F}}$ is an ideal, and if $\mathcal{F}$ is an ultrafilter, let $Z(a)$ be the coordinates that a is zero on, and notice $Z(ab) = Z(a) \cup Z(b)$, then $ab \in p$ iff $a \in p$ or $b \in p$, by(1.2.10.7), so it is a prime ideal.

Conversely, notice that any two a, b with $Z(a) = Z(b)$ differs by a unit, so $\mathcal{F}_p = \{Z(a)|z \in p\}$ is easily checked to be a filter. And if p is a prime, then for any $A \subset I$, let $a, b \in \prod F_i$ be that $Z(a) = A, Z(b) = I - A$, then $ab = 0 \in p$, so $a \in p$ or $b \in p$. □

Def. (4.1.1.13)[Torsion-Free Modules]. Let $S \subset A$ be a set in a commutative ring, then an A-module M is called S**-torsion-free** if for any $\{x \in M|Sx = 0\} = 0$.

Prop. (4.1.1.14) [Maximal Torsion-Free Quotient]. Let $S \subset A$ be a set, the functor from the category of torsion-free A-modules to the category of A-modules has a left adjoint, called the **maximal** S**-torsion-free quotient**.

Proof: A quotient of M is determined by the kernel. It suffices to prove if $M/N_1, M/N_2$ are both S-torsion-free, then $M/N_1 \cap N_2$ is also S-torsion-free: This is easy. □

Prop. (4.1.1.15). Let A be a ring and B a finite A-algebra. if $A \to B$ is epimorphism in the category of rings, then $A \to B$ is surjective.

Proof: Notice that $h^B \to h^A$ is injective iff $h^B \times_{h^A} h^B \cong h^B$, or equivalently, $B \times_A B \to B$ is an isomorphism. Now we can localize A at maximal ideals, thus we can assume A is local, with maximal ideal $\mathfrak{m}$ and residue field k. And then use Nakayama lemma, it suffices to show that $k \to B/\mathfrak{m} = C$ is surjective. But $C \times_k C \cong C$, so $\dim_k C = 1$ or 0, which means $k \to C$ is surjective. □

Def. (4.1.1.16) [Locally Nilpotent]. A **locally nilpotent ideal** is an ideal consisting of nilpotent elements.

Prop. (4.1.1.17). If I is a locally nilpotent ideal of A, then $1 + I \to 1 + I : x \mapsto x^n$ is an isomorphism.

Proof: The converse is given by $x \mapsto (1+x)^{1/n} = 1 + \binom{1/n}{1}x + \binom{1/n}{2}x^2 + \ldots$. □

Cor. (4.1.1.18). If I is a locally nilpotent ideal of A, then a unit in A is an n-th power iff it is an n-th power in A/I.

Proof: If $a =\equiv b^n \mod I$, then b is also a unit, and $ab^{-n} = c^n$ for some n by(4.1.1.17), thus a is a n-th power. □

Tensor Product, Limits and Colimits

Remark (4.1.1.19) [Tensor Product]. Tensor product is defined in(2.2.4.13). Notice that in case the rings are all commutative, there are no need to distinguish between left and right modules.

Def. (4.1.1.20) [Tensor Algebras]. For a module M over a commutative ring R, we define the

- **tensor algebra** operator from $\mathcal{M}\mathrm{od}_R$ to graded algebras over R that is left adjoint to the forgetful functor. It can be defined as follows:
$$T(M) = \bigoplus_{n\geq 0} \otimes^n M$$
as the module, and the algebra structure determined by the canonical map $\otimes^m M \times \otimes^n M \to \otimes^{m+n} M$.
- **exterior product** $\wedge^k M$ as the module with the universal property that $\mathrm{Hom}_B(\wedge^k M, N)$ is the set of all morphisms $M^n \to N$ that vanishes on all elements that have two equal coordinates.
- **exterior algebra** operator $\wedge$ from $\mathcal{M}\mathrm{od}_R$ to the category of strict graded commutative algebras over R that is left adjoint to the forgetful functor. It can be defined as follows: $\wedge(M) = T(M)/(x\otimes x)$, where $x \in M$, or equivalently $\wedge(M) = \bigoplus_{k\geq 0} \wedge^k(M)$.
- **symmetric algebra** operator S from $\mathcal{M}\mathrm{od}_R$ to $\mathcal{CR}\mathrm{ing}_R$ that is left adjoint to the forgetful functor. It can be defined as follows: $\wedge(M) = T(M)/(x\otimes y - y\otimes x)$ where $x, y \in M$.

Cor. (4.1.1.21). The construction of $T(M), \wedge M$ and $\mathrm{Sym}(M)$ commutes with all colimits, because they are all left adjoints.

Prop. (4.1.1.22) [Tensor Product and Quotient]. Let R be a commutative ring and I, J be ideals of R, then $R/I \otimes_R R/J \cong R/(I+J)$.

Proof: This follows from the universal property of quotient and tensoring. □

Prop. (4.1.1.23). There is a pullback square

$$\begin{array}{ccc} R/I\cap J & \longrightarrow & R/I \\ \downarrow & & \downarrow \\ R/J & \longrightarrow & R/(I+J) \end{array}$$

Proof: The pullback is just the elements in $R/I \times R/J$ that mapsto the same element in $R/(I+J)$. If $(x+I, y+J)$ maps to the same element $z+I+J$, then $x = y+i+j$, so $x-i = y+j$, and the pullback lies in the image of $\Delta : R \mapsto R/I \times R/J$. Now the kernel is just $I\cap J$. □

Prop. (4.1.1.24) [Filtered Colimits of Modules are Exact]. Let $\mathcal{I}$ be an index category that each connected components of $\mathcal{I}$ is filtered, then taking colimits over $\mathcal{I}$ is exact in the category $\mathcal{M}\mathrm{od}_R$ of modules over a ring R.

Proof: It is clearly right exact. To check left exactness, Cf.[Sta]04B0.**?** □

Cor. (4.1.1.25) [Filtered Colimits of Abelian Groups are Exact]. Filtered colimits are exact in $\mathcal{A}\mathrm{b}$.

Prop. (4.1.1.26). Let k be a field and A, B be k-algebras and let $\mathfrak{b} \subset A\otimes_k B$ be an ideal. Then among the ideals $\mathfrak{a} \subset A$ that $\mathfrak{b} \subset \mathfrak{a}\otimes_k B$, there exists a smallest one.

Proof: Choose a k-basis of B, then the smallest ideal $\mathfrak{a}$ is just the ideal generated by all the A-coefficients of elements of $\mathfrak{b}$. □

Localization

Def. (4.1.1.27) [Localization as Filtered Colimit]. Let A be a commutative ring and S be a multiplicatively closed subset of A containing 1 and not containing 0, the localization $S^{-1}A$ is defined to be a ring over A that any ring map $A \to B$ that maps elements of S to units factors through $S^{-1}A$.

$S^{-1}A$ can be constructed as

$$\varinjlim_{s \in S} A$$

where the ordering is defined to be $s < t$ if $t = sr$ for some $r \in S$, and if $t = sr$, there is a map from A_s to A_t defined by multiplying by r. This is easily seen to be a filtered colimit. There is easily seen to be the localization.

Prop. (4.1.1.28) [Localization is exact]. S^{-1} is an exact functor from $\mathcal{M}od_R$ to $\mathcal{M}od_R$. Because it is a filtered colimit(3.7.3.28)(4.1.1.24).

Cor. (4.1.1.29). $(R/I)_{\bar{P}} \cong R_P/IR_P$, in particular, $k(R/P) \cong R_P/PR_P$.

Def. (4.1.1.30) [Total Ring of Fractions]. For any ring R, the set of non-zerodivisors in R is a multiplicatively closed set S, and the localization $Frac(R) = S^{-1}R$ is called the **total ring of fractions** of R.

Prop. (4.1.1.31) [Localization Along an Ideal]. Let I be an ideal of A, then the localization of A along I is the ring $\widetilde{A}$ that $\operatorname{Spec}\widetilde{A}$ is the localization of $\operatorname{Spec} A$ along $V(I)$ as defined in(3.11.4.20)(because $\operatorname{Spec} A$ is spectral, by(3.11.4.13)).

Equivalently, it can be defined as $\widetilde{A} = S^{-1}A$, where $S = A \backslash (\cup_{\mathfrak{p} \in V(I)} \mathfrak{p})$. (It can be checked that S is multiplicatively closed).

Notice then $I \subset \operatorname{rad}\widetilde{A}$.

For $f \in A$, we call the localization of A along f the **f-localization** of A. In fact, it is the universal A-algebra that $f \in \operatorname{rad}\widetilde{A}$.

Prop. (4.1.1.32). Let R be a commutative ring, $f_1, \ldots, f_n \in R$, and M an R-module, then $M \to \oplus_i M_{f_i}$ is injective iff $M \to \oplus_i M : m \mapsto (mf_1, \ldots, mf_n)$ is injective.

Proof: Cf.[Sta]0565. □

Prop. (4.1.1.33). For any ring A, $A \to \prod A_{\mathfrak{m}}$ is injective, where $\mathfrak{m}$ are maximal ideals of A.

For a domain A, $A = \bigcap A_{\mathfrak{m}}$ inside the fraction field of A, where $\mathfrak{m}$ are maximal ideals of A.

Proof: if $g \in \operatorname{Frac}(A)$ is in the RHS, then $I = \{x \in A | xg \in A\}$ is an ideal of A not contained in any maximal ideal, thus $I = 1$(4.1.1.6), and thus $g \in A$. □

Lemma (4.1.1.34). Let R be a ring and $\mathfrak{p}$ be a prime, then there exists an $f \in R, f \notin \mathfrak{p}$ that $R_f \subset R_{\mathfrak{p}}$, if any of the following holds:

- R is a domain.
- R is Noetherian.
- R is reduced and has f.m. irreducible components.

Proof: Cf.[Sta]0BX1. □

Def. (4.1.1.35) [Identifying Local Rings]. A ring map $A \to B$ is said to **identify local rings** if for every prime $\mathfrak{q} \subset B$, the map $A_{\varphi^{-1}(\mathfrak{q})} \to B_{\mathfrak{q}}$ is an isomorphism.

Prop. (4.1.1.36). The property of identifying local rings is stable under base change and composition. (This is immediate from(4.1.1.37)).

Prop. (4.1.1.37) [Tensor Product and Localization]. For a ring map $R \to S$, let $q \subset \operatorname{Spec} S$, $p = q \cap R$, then $(M \otimes_R S)_q = M_p \otimes_{R_p} S_q$ for any R-module M.

Proof: $(M \otimes_R S)_q = M \otimes_R S_q = M \otimes_R R_p \otimes_{R_p} S_q = M_p \otimes_{R_p} S_q$. □

Noetherian

Def. (4.1.1.38) [Noetherian Module]. Let R be a commutative ring and M an R-module, then M is called **Noetherian** iff every ascending chain of submodules stablizes.

R is called a **Noetherian ring** iff R is Noetherian over itself.

Prop. (4.1.1.39). Let $R \in \mathcal{CR}\mathrm{ing}$ and $0 \to M_1 \to M \to M_2$ be an exact sequence in $\mathcal{M}\mathrm{od}_R$, then M is Noetherian iff M_1, M_2 are both Noetherian.

Prop. (4.1.1.40)[Hilbert Basis Theorem, Hilbert1888]. Let A be a Noetherian ring, then quotient ring, f.g. module, f.g. algebra, localization and power series of A are Noetherian. Hence graded algebra of a Noetherian ring A by an ideal I is Noetherian. Products of Noetherian rings are Noetherian.

Proof: Only need to prove $A[X]$ and $A[[X]]$, localization and others are quotients of these. For an ascending chain of ideal I_j of $A[X]$, we consider the coefficients ideal $I_{i,j}$ of X^i of I_j, then there are only f.m. different $I_{i,j}$s, so we have I_j stabilize as well.

Similarly for $A[[X]]$, we prove any ideal I is f.g. Consider the lowest terms coefficient ideal at degree i, then it is ascending and stabilize, then a set of generators as a whole generate I. □

Remark (4.1.1.41). The subring of a Noetherian ring is NOT necessarily Noetherian, by the example of $k[X_1, \ldots, X_n, \ldots] \subset k(X_1, \ldots, X_n, \ldots)$.

Prop. (4.1.1.42). When A is Noetherian and is quipped with I-adic topology, then I is f.g., and there is a surjective ring map $A[[X]] \to A^\wedge$, mapping to the generators of I, hence the completion is Noetherian. (It is surjective can be seen by the Cauchy sequence construction of completion).

Prop. (4.1.1.43). If $R \to R'$ is ring map of f.t., then if $S \in \mathcal{CR}\mathrm{ing}\,/R$ and S is Noetherian, then $S \otimes_R R'$ is Noetherian, because $S \times_R R'$ is of f.t. over S, and use(4.1.1.40).

Cor. (4.1.1.44). For $k \in$ `Field`, $S \in \mathcal{CR}\mathrm{ing}\,/k$, then for any f.g. field extension K/k, $S \otimes_k K$ is Noetherian. (Because there is a f.g. algebra B over k that K is the localization of B, and use(4.1.1.40)).

Prop. (4.1.1.45). If R is Noetherian and M is a f.g. R-module, then there is a filtration $\{M_i\}$ of M that the quotients are all isomorphic to $R_{\mathfrak{p}_i}$ where $\mathfrak{p}_i$ are primes.

Proof: M is generated by x_i, so $(x_1) \cong R/I_i$, and so we modulo x_i, then the result follows by induction. So we may assume $M = R/I$. We use Noetherian condition to choose a maximal element J that is a counterexample, then J is not a prime, so there are $a, b \notin J$ that $ab \in J$. Then we have a filtration $0 \subset aR/(J \cap aR) \subset R/J$. Notice $R/(J + bR) \to aR/(J \cap aR) \to 0$, and the second quotient is $R/(J + aR)$, so they all can be factorized. □

Prop. (4.1.1.46). A Noetherian ring has only f.m. minimal prime ideals.

Proof: This is a consequence of(5.4.1.20)(5.4.1.21) and(3.11.3.4). □

Prop. (4.1.1.47) [Cohen]. If $R \in \mathcal{CR}$ing and every prime ideal is f.g., then R is Noetherian.

Proof: Suppose P is not Noetherian. Firstly the set of non-finitely generated ideals has the chain property: if I_i is a chain of non-f.g. ideals of R, then $I = \cup_{i\in\Phi} I_i$ is non-f.g., otherwise there are $(f_i) = I$, but $\{f_i\} \in I_h$ for some h, thus I_h is f.g.. Then we use the Zorn's lemma to find a maximal non-f.g. ideal I. We show that I is a prime ideal:

$I \neq R$ because $R = (1)$. So if $a, b \in R\backslash I$ that $ab \in I$, then $I + (a)$ and $I + (b)$ is f.g. by $p_i + r_i a$, by maximality, and let $K = (P : a)$, then $I \subset I + (b) \subset K$, thus K is f.g., so does aK.

Now I claim $I = (p_1) + \ldots + (p_n) + aK$: one direction is clear, and if $r \in I \subset I + (a)$, then $r = \sum c_i(p_i + r_i a)$, thus $(\sum c_i r_i)a = r - \sum c_i p_i \in I$, thus $\sum c_i r_i \in K$, thus $r = \sum c_i p_i + (\sum c_i r_i)a \in (p_1) + \ldots + (p_n) + aK$.

So now I is f.g., contradiction, which shows I is a prime, but this contradicts the hypothesis. □

Prop. (4.1.1.48) [Modules over Noetherian Ring are Noetherian]. Let R be a Noetherian ring, then any submodule of a finite module M over R is finite. Thus any module over R is a Noetherian module(4.1.1.38). In particular, any module over R is of f.p.

Proof: it suffices to prove the first assertion: we use induction on the minimal number of generators of M: if it is generated by 1 element, then $M \cong R/I$ for some ideal I, thus $N \subset M$ is isomorphic to some J/I, so it is finite because J is finite. If the minimal number of generators of M is greater than 1, then there exists an exact sequence

$$0 \to M' \to M \to M'' \to 0$$

where M', M'' has fewer number of generators. Now there is also an exact sequence

$$0 \to N \cap M' \to N \to \overline{N} \to 0,$$

and the minimal number of generators of N is smaller than the sum of that of M' and M'', thus it is also finite. □

Prop. (4.1.1.49) [Artin-Tate]. Let R be a Noetherian ring and S a f.g. R-algebra. If $T \subset S$ is an R-subalgebra that S is a finite module over T, then T is f.g. over R.

Proof: Cf.[Sta]00IS. □

Prop. (4.1.1.50) [Krull-Akizuki]. If R is a Noetherian domain of dimension 1 with fraction field K, L/K a finite extension of fields, then for any ring A s.t. $R \subset A \subset L$, A is Noetherian.

Proof: Cf.[Sta]00PG. □

2 Lengths

Def. (4.1.2.1) [Lengths]. The **length** of a R-module M is the supremum of lengths of chains of submodules of M, denoted by $\text{length}_R(M)$.

Prop. (4.1.2.2). Length is an additive function on $\mathcal{M}\text{od}_R$.

Proof: Cf.[Sta]00IV. □

Prop. (4.1.2.3). If $\text{length}_R(M) < \infty$, then any maximal chain of submodules has the same length.

Proof: Let $l(M)$ be the minimal length of a maximal chain, then if $M \subsetneq N$, then firstly $l(M) < l(N)$, because a maximal chain of M restricts to a maximal chain of N, and if the length is the same, then each term is in M, so $N \subset N$, contradiction. Now any chain has length $l(M)$, because if there is a chain M_i, then $l(M_0) < l(M_1) < \ldots < l(M)$. □

Prop. (4.1.2.4). Let $R \in \mathcal{CR}\text{ing}$ and S a multiplicative set of R, then $\text{length}_R(M) \geq \text{length}_{S^{-1}R}(S^{-1}M)$.

Proof: This is because any $S^{-1}R$-submodule of $S^{-1}M$ is of the form $S^{-1}N$ where N is a R-submodule of M. □

Prop. (4.1.2.5). If R is a ring with a maximal ideal $\mathfrak{m}$, M is an R-module that $\mathfrak{m}M = 0$, then $\text{length}_R(M) = \dim_{k(\mathfrak{m})}(M)$.

Prop. (4.1.2.6) [Length over a Local Ring]. Let $(R, \mathfrak{m})$ be a local ring, and $M \in \mathcal{M}\text{od}_R$ is of finite length, then $\mathfrak{m}^n M = 0$ for some $n \in \mathbb{N}$.

Conversely, if $\mathfrak{m}$ is f.g. and M is a finite R-module, and $\mathfrak{m}^n M = 0$ for some $n \in \mathbb{N}$, then $\text{length}_R(M) < \infty$.

Proof: M is clearly a finite module over R. Take $n = \text{length}_R(M)$. If $f_1, \ldots, f_n \in \mathfrak{m}$ and $x \in M$ s.t. $f_1 \ldots f_n x \neq 0$, then by Nakayama the submodules

$$0 \subset (f_1 \ldots f_n)x \subset (f_2 \ldots f_n)x \subset (f_n)x \subset M$$

are all different, so $\text{length}_R(M) \geq n$, contradiction.

For the converse, use additivity on the filtration $0 = \mathfrak{m}^m M \subset \mathfrak{m}^{n-1} M \subset \ldots \subset M$, where each quotient is finite over R and annihilated by $\mathfrak{m}$, so we conclude by(4.1.2.5). □

Prop. (4.1.2.7). If $(A, \mathfrak{m})$ is a local ring and B is a ring over A with f.m. maximal ideals $\mathfrak{m}_i$ s.t. each $\mathfrak{m}_i$ is over $\mathfrak{m}$ and $k(\mathfrak{m}_i)/k(\mathfrak{m})$ is finite, then there for any $M \in \mathcal{M}\text{od}_B$ with $\text{length}_B M < \infty$,

$$\text{length}_A M = \sum_i [k(\mathfrak{m}_i) : k(\mathfrak{m})] \,\text{length}_{B_{\mathfrak{m}_i}} M_{\mathfrak{m}_i}.$$

Prop. (4.1.2.8). Let $A \to B$ be a flat local maps of local rings, then for any $M \in \mathcal{M}\text{od}_A$,

$$\text{length}_A(M)\,\text{length}_B(B/\mathfrak{m}_A B) = \text{length}_B(M \otimes_A B).$$

Proof: Cf.[Sta]02M1.**?** □

Cor. (4.1.2.9). Let $A \to B \to C$ be local maps of local rings, C/B is flat, and $\mathfrak{m}_A$ the maximal ring of A, then

$$\text{length}_B(B/\mathfrak{m}_A B)\,\text{length}_C(\mathfrak{m}_B C) = \text{length}_C(C/\mathfrak{m}_B C).$$

Prop. (4.1.2.10) [Order of Vanishing]. If R is a semi-local Noetherian domain of dimension 1 and a, b are not zero-divisors, then $f(a) = \text{length}(R/(a))$ satisfies $f(a) + f(b) = f(ab) < \infty$.

So this $R \subset K$ and has fraction field K, then f extends to an additive function on K^*, denoted by $\text{ord}_R(f)$.

Proof: It is finite by[Sta]00PF. It is additive because length is additive(4.1.2.1) and $0 \to R/(a) \to R(ab) \to R(b) \to 0$. □

3 Artinian Ring

Def. (4.1.3.1) [Artinian Rings]. A ring A is called **Artinian** if any descending chain of ideals of A stablizes.

For example, a f.g. k-algebra that is a finite k-module is an Artinian ring.

Lemma (4.1.3.2). Let A be an Artinian ring, then A has f.m. maximal ideals.

Proof: Consider $\mathfrak{m}_1 \supset \mathfrak{m}_1 \cap \mathfrak{m}_2 \ldots \supset$, then it is a descending chain, by Chinese remainder theorem. So it has f.m. maximal ideals. □

Lemma (4.1.3.3). If A is an Artinian ring, then the Jacobson radical is nilpotent.

Proof: Consider the Jacobson radical I, $I^n = I^{n+1}$ for some n, let $J = \mathrm{Ann}(I^n)$, it suffices to show $J = A$. If not, choose a minimal J' that contains J but not J(exists by Artinian property), then $J' = J + Ax$, and $IJ' \subset J$ by Nakayama, so $xI^{n+1} \subset JI^n = 0$, so $x \in J$, contradiction. □

Prop. (4.1.3.4) [Characterization of Artinian Rings]. The following are equivalent:

1. A is Artinian.
2. A is Noetherian of dimension 0.
3. $\mathrm{length}_A A < \infty$.
4. A is a finite product of local Artinian rings.
5. A is Noetherian, Jacobson(4.2.6.4), and has f.m. maximal ideals.

Proof: $1 \iff 3$: if $\mathrm{length}_A A < \infty$, then A is clearly Artinian. Conversely, if A is Artinian, then by(4.1.3.2)(4.1.3.3)(4.2.6.7) A a finite product of its localization of maximal ideals, so we may assume A is local with maximal ideal $\mathfrak{m}$. Then $\mathfrak{m}^n = 0$ for some n by(4.1.3.3), and $\mathfrak{m}^i/\mathfrak{m}^{i+1}$ has length the same as their dimension as a $A/\mathfrak{m}$ vector space, by(4.1.2.5), which is finite because A is Artinian, so $\mathrm{length}_A A < \infty$.

$1 + 3 \to 5$: A has f.m. maximal ideals by(4.1.3.2). It is Jacobson by(4.1.3.3). $\mathrm{length}_A A < \infty$ clearly implies A is Noetherian.

$5 \to 2$: By(4.2.6.7).

$2 \to 5$: all prime ideals are maximal, so $\mathrm{Spec}\, A$ is discrete, so A has f.m. maximal ideals, and it is clearly Jacobson.

$5 \to 3$: By(4.2.6.7), R is a product of its local rings, and the local rings are all Noetherian and Jacobson(4.2.6.6), so by Nakayama, they have finite lengths. So also R has finite length.

$5 \to 4$: By lemma(4.2.6.7) below, A is a product of its localization, and its localizations also satisfies 5, and by $5 \to 3 \to 1$, they both have descending conditions.

$4 \to 5$: An Artinian ring is Noetherian and Jacobson by $1 + 3 \to 5$, then so does their product. □

Cor. (4.1.3.5) [Reduced Artinian Ring]. A reduced local Artinian ring is a field. In particular, A reduced Artinian ring is a product of fields.

Proof: An Artinian local ring A is Jacobson(4.1.3.4) so the maximal ideal $\mathfrak{m} = 0$ as A is reduced. □

Prop. (4.1.3.6). For an Artinian local ring A, the following are equivalent:

1. A is a PID.

2. the maximal ideal $\mathfrak{m}$ is principal.
3. $\dim_k(\mathfrak{m}/\mathfrak{m}^2) \leq 1$.

Proof: It suffices to prove $3 \to 1$: If $\mathfrak{m} = \mathfrak{m}^2$, then $\mathfrak{m} = 0$ by Nakayama, so A is a field. If $\dim_k(\mathfrak{m}/\mathfrak{m}^2) = 1$, then $\mathfrak{m}$ is principle by Nakayama. And $\mathfrak{m}$ is nilpotent by(4.1.3.4), so for any ideal a there is a minimal n that $a \subset \mathfrak{m}^n$. Now choose $y \in a - \mathfrak{m}^{n+1}$, then $y = ux^r$, and $u \notin (x)$, so u is a unit, thus $x^r \in a$, meaning $a = \mathfrak{m}^n$ hence principal. □

4 Local Properties

Def. (4.1.4.1) [Local properties]. A property P of rings or modules over a ring is called **local property** iff X has P iff X_{f_i} all has P for a covering $(f_1, \ldots, f_n) = 1$.

A property of morphisms of rings is called **local on the target** iff $R \to S$ has P iff $R_{f_i} \to S_{f_i}$ has P for a covering $(f_1, \ldots, f_n) = 1$ in R.

Prop. (4.1.4.2) [Stalkwise Properties]. For a commutative ring R, a property P is called stalkwise if A satisfies P iff all $A_\mathfrak{m}$ satisfies P where $\mathfrak{m}$ are maximal ideals, and iff all $A_\mathfrak{p}$ satisfies P where $\mathfrak{p}$ are prime ideals of A.

1. Trivial is stalkwise for modules over R. Hence so does injectivity and surjectivity because localization is exact.
2. Torsion-free is stalkwise for modules over R if R is integral.
3. Flatness for modules over R.
4. Flatness for rings over R on the source.
5. Formal unramifiedness for rings over R, both on the target and source.
6. (universally)catenary is stalkwise.
7. reducedness is stalkwise.
8. Integral+integrally closed is stalkwise.
9. normal is stalkwise.
10. regular is stalkwise.

Proof:

1. It suffice to prove an element is trivial on every localization then it is 0. For this, consider the annihilator $\mathrm{Ann}(x)$, it is not contained in any maximal ideal so it contains 1.
2. if $xf = 0$ but $f \neq 0$, then $x \in Ann(f) \neq (1)$, so $Ann(f) \subset \mathfrak{m}$ maximal, so f is torsion in $M_\mathfrak{m}$ over $R_\mathfrak{m}$. Conversely, if f is torsion in $R_\mathfrak{m}$, then it is clearly torsion over R.
3. We use the definition(4.4.1.2). Notice $(IM)_\mathfrak{p} = I_\mathfrak{p} M_\mathfrak{q}$ and every ideal of $R_\mathfrak{p}$ is of the form $I_\mathfrak{p}$. Then use the fact injective is stalkwise(4.1.4.2).
4. We use the definition(4.4.1.2). Notice $(I \otimes_R S)_\mathfrak{q} = I_\mathfrak{p} \otimes_{R_\mathfrak{p}} S_\mathfrak{q}$ for all primes $\mathfrak{q}$ of S and $\mathfrak{p} = \mathfrak{q} \cap R$. And every ideal of $R_\mathfrak{p}$ is of the form $I_\mathfrak{p}$. Then use the fact injective is stalkwise(4.1.4.2)
5. Because formally unramified is equivalent to $\Omega_{R/S} = 0$(4.4.6.1), so we get the result by functorial properties of $\Omega_{S/R}$(4.4.3.6) and triviality is stalkwise(4.1.4.2).
6. For any two prime ideals $\mathfrak{p} \subset \mathfrak{q}$, we can choose a maximal ideal containing them.

7. use(4.1.1.33).
8. If A is integrally closed, then clearly any localization of A is integrally closed. Conversely, if $r \in K(A)$ is integral over A but $r \notin A$, let $I = \{s \in A | rs \in A\}$, then $I \neq A$, so $I \subset \mathfrak{m}$ for some maximal ideal $\mathfrak{m}$, then $r \notin A_\mathfrak{m}$, so $A_\mathfrak{m}$ is not integrally closed, contradiction.
9. By definition.
10. By definition.

□

Remark (4.1.4.3). Our main technique of proving local properties are using affine communication theorem(5.4.1.2).

Prop. (4.1.4.4) [Local Properties]. For a fixed ring R,

1. Every property that is stalkwise is a local property.(4.1.4.2) The properties listed below should be not stalkwise.
2. Every property that satisfies faithfully flat descent is a local property. The properties listed below should not satisfy faithfully flat descent.
3. Noetherian.
4. F.t. ring maps on the source.
5. F.p. ring maps on the source.
6. N-1 and N-2 and universally Japanese for rings.
7. Nagata for rings.

Proof:

1.
2.
3. If A is Noetherian, then A_{f_i} are Noetherian by(4.1.1.40). Conversely, if A_{f_i} are all Noetherian and $I_1 \subset I_2 \subset \ldots$ is an ascending chain of ideals of A, consider $A \to \prod A_{f_i}$ faithfully flat, thus $I_1 \otimes_A (\prod A_{f_i}) \subset I_2 \otimes_A (\prod A_{f_i}) \subset \ldots$ is an ascending chain of $\prod A_{f_i}$. Now $\prod A_{f_i}$ are Noetherian by(4.1.1.40), so this chain stabilizes. But this ring map is faithfully flat, so the original chain must also stablizes.
4. Let $(g_1, \ldots, g_n) = 1$, choose $\sum h_i g_i = 1$, and let $x_{ij} = y_{ij}/g_i^{n_{ij}}$ generates S_{g_i}. Now let S' be the sub-R-algebra of S generated by y_{ij}, g_i, h_j. Then $(S')_{f_i} \to S_{f_i}$ is surjective for any i, so $S' \to S$ is also surjective, by(4.1.4.2). Then $S' = S$, and S is f.g. over R.
5. Cf.[Sta]00EP.
6. If A is N-1, then A_{f_i} are N-1 because taking integral closure commutes with localization. The same for N-2. Conversely, if all A_{f_i} are N-1 or N-2, so is A because finiteness is local(4.1.4.4). The universal Japanese case follows from the N-2 case.
7. This follows from the localness of Noetherian and N-2(4.1.4.4).

□

5 Miscellaneous

Fitting Ideals

Def. (4.1.5.1)[Fitting Ideals]. Let $R \in \mathcal{CR}\text{ing}$ and M be a finite R-module, then for any presentation

$$\oplus_{j\in J} R \to R^{\oplus n} \to M \to 0$$

given by a $n \times J$ matrix A, the ideal generated by the $(n-k)\times(n-k)$ matrices of A is independent of the presentation chosen, called the k-th **Fitting ideal of** A, denoted by $\mathrm{Fit}_k(M)$.

6 Rings and Categories

Quotient by Equivalence Relations

Prop. (4.1.6.1) [Quotients by Equivalence Relations]. Let $u_0, u_1 : A_0 \to A_1$ be an equivalence in the dual category of $\mathcal{CR}\text{ing}_{R_0}$(3.1.1.23). If u_0 is locally free of constant rank r, then a quotient $u : A \to A_0$ exists, and u is locally free of constant rank r.

Proof: Cf.[Mil17b]P592. □

Morita Equivalence

Basic References are [Morita Equivalence] and [Fuller Rings and Categories of Modules].

Def. (4.1.6.2). Two ring R, S are called **Morita equivalent** if the category of mod-R is equivalent to the category of mod-S.

Prop. (4.1.6.3). For an Abelian category $\mathcal{A}$ satisfying AB3 (i.e arbitrary sum exists), An object P of $\mathcal{A}$ is a **progenerator** if the functor $h' : X \mapsto \mathrm{Hom}_{\mathcal{A}}(P, X)$ is exact and and strict: $h'(X) = 0$ implies $X = 0$. Then h' determines an equivalence from $\mathcal{A}$ to mod-R, where $R = \mathrm{Hom}_{\mathcal{A}}(P, P)$.

Similarly, if $\mathcal{A}$ is an Abelian Noetherian category and P is a progenerator, then R is Noetherian and $\mathcal{A}$ is equivalent to the category of finitely generated R-categories.

Proof: Essentially surjective: construct using direct limit and cokernel.

Notice that $h'(X) \cong h'(X') \to X \cong X'$ by strictness and A4 axiom. So let $X = \mathrm{Coker}(P^{\oplus I}, P^{\oplus J})$,

$$\begin{aligned}
\mathrm{Hom}(h'(X), h'(Y)) &= \mathrm{Hom}(\mathrm{Coker}(h'(P^{\oplus J}), h'(P^{\oplus I})), h'(Y)) \\
&= \ker(\mathrm{Hom}(h'(P^{\oplus J}), h'(Y)) \to \mathrm{Hom}(h'(P^{\oplus I}), h'(Y))) \\
&= \ker(h'(Y^{\Pi I}) \to h'(Y^{\Pi J})) \\
&= \mathrm{Hom}(X, Y)
\end{aligned}$$

□

Prop. (4.1.6.4). In the case when A is the category mod-R, P is a generator $\iff$ $h' : X \mapsto \mathrm{Hom}_R(P, X)$ is faithful $\iff$ every M is a quotient of direct sums of P. And a **progenerator** is a f.g. projective generator.

Prop. (4.1.6.5). Let P be a (A, B)-bimodule, iff P is a progenerator as a right B module, then it is a progenerator as a left A module.

Prop. (4.1.6.6). Let P be a progenrator as a

Prop. (4.1.6.7) [Morita]. The following are equivalent:
- categories A-mod and B-mod are equivalent.
- categories mod-A and mod-B are equivalent.
- There exist a finitely generated progenerator P of mod-A that $B \cong \operatorname{End}_A P$.

Proof: $2 \to 3$:A is a progenerator in mod-A, thus when $A \sim B$, F : mod-$A \to$ mod-B, $A \cong \operatorname{End}_A A = \operatorname{End}_B F(A)$, and $F(A)$ is a left A module as well as a progenerator of B. Thus there is a (A, B)-bimodule P that $A \cong \operatorname{End}_B P$, and a (B, A)-bimodule Q that $B \cong \operatorname{End}_A Q$. □

Prop. (4.1.6.8). There can be defined another Morita invariance that $R \sim S$ iff there are (R, S)-bimodule P and (S, R)-bimodule Q that $P \otimes_S Q \cong R$ as a (R, R)-bimodule and $Q \otimes_R P \cong S$ as a (S, S)-bimodule. This will immediately generate equivalence between R-mod and S-mod as well as equivalence between mod-R and mod-S by tensoring. And P and Q are projective modules respectively, because equivalence is a kind of adjoint.

Prop. (4.1.6.9). Let D be a division ring over k of finite degree and $A = M_r(D)$. Let $S = D^r$ with A acting by left multiplication and D acting by right multiplication, then there S is a simple A-module, and every A-module is a direct sum of copies of S. This means that $S \otimes_D -$ induces an equivalence from $\mathcal{M}\mathrm{od}_D$ to $\mathcal{M}\mathrm{od}_A$.

Prop. (4.1.6.10) [Properties Preserved under Morita Invariance]. Cf.[Rings and Categories of Modules P54].

7 Spectra

Lemma (4.1.7.1). In $\operatorname{Spec} A$, a subset U is retrocompact iff it is quasi-compact iff it is a finite union of standard opens $D(f_i)$. In particular, any constructible subset of $\operatorname{Spec} A$ is a finite union of morphisms of the form $D(f_i) \cap V(g_1, \ldots, g_m)$.

Proof: Retrocompact is quasi-compact because $\operatorname{Spec} A$ is quasi-compact. A quasi-compact subset is equivalent to a finite union of $D(f_i)$. Now for any quasi-compact subset $V = \cup_j D(g_j)$, $U \cap V = \cup_{ij} D(f_i g_j)$ is also quasi-compact, so $\cup_i D(f_i)$ is retrocompact. □

Lemma (4.1.7.2). Let R be a ring, then
- the image of any standard open subsets of $\operatorname{Spec} R[X]$ is qc open in $\operatorname{Spec} R$.
- for $g, f \in R[X]$ with g monic, the image of $D(f) \cap V(g)$ is qc open in $\operatorname{Spec} R$.

Proof: 1: For any prime $\mathfrak{p}$ of R, the primes mapping to $\mathfrak{p}$ has a minimal one, $\mathfrak{p}[X]$, so $\mathfrak{p}$ is in the image of $\operatorname{Spec} R[X] \to \operatorname{Spec} R$ iff $f \in \mathfrak{p}[X]$, which means the image is $D(a_0, a_1, \ldots, a_n)$, where $f = a_0 + a_1 X + \ldots + a_n X^n$.

2: $R[X]/g$ is finite free over R, let $P(T) = T^d + r_{d-1} T^{d-1} + \ldots + r_0$ be the characteristic polynomial of f acting on $R[X]/g$ by left multiplication, then $\mathfrak{p} \in V(r_0, \ldots, r_{d-1})$ iff f acts nilpotently on $R[X]/g \otimes_R k(\mathfrak{p})$, which is equivalent to $\mathfrak{p}$ being in the image of $D(f) \cap V(g)$(by base change to $k(\mathfrak{p})$ argument). □

Lemma (4.1.7.3) [Affine Chevalley]. The Spec map of a f.p. ring map maps constructible sets to constructible sets.

Proof: Suppose $S = R[X_1,\ldots,X_n](f_1,\ldots,f_m)$, then it suffices to show for the case $S = R/(f_1,\ldots,f_m)$ and $S = R[X]$.

If $S = R/(f_1,\ldots,f_m) = R/I$, it suffices to show the image of $D(\overline{g})\cap V(\overline{h}_1,\ldots,\overline{h}_m)$ is retrocompact in $\operatorname{Spec} R$: in fact its image is just $D(g)\cap V(h_1,\ldots,h_m)\cap V(I)$, where g, h_i are any inverse images in R.

For the second case, we first prove some localizing result: If $S = R_f$, then the compact open subsets of $\operatorname{Spec} S$ are compact open subsets of $\operatorname{Spec} R$, so $\operatorname{Spec} S \to \operatorname{Spec} R$ maps constructible sets to constructible sets. Now for any $c \in R$, $\operatorname{Spec} R = \operatorname{Spec} R/c \coprod \operatorname{Spec} R_c$, so to prove the proposition for R, it suffices to prove for R_c and R/c.

Let $D(f)\cap V(g_1,\ldots,g_n) \subset \operatorname{Spec} R[X]$, where f, g_i are polynomials, We can use induction on the degree series $\deg(g_1) \leq \deg(g_2) \leq \ldots \leq \deg(g_n)$. If the leading coefficient of g_1 is invertible, then we can use reduction to R/c and R_c to either reduces the degree of g_1 or reduce to the case it is invertible. If it is invertible, then we can use Euclidean division. Eventually, it can be reduced to the case $D(f)\cap V(g)$ where g is monic, or $D(f)$. This is proved in the above lemma(4.1.7.2). □

Lemma (4.1.7.4). For a Noetherian local ring $(A,\mathfrak{m})$, $\operatorname{Spec} A - \mathfrak{m}$ is affine iff $\dim A \leq 1$.

Proof: if $\dim A = 0$, this is true, if $\dim A = 1$, let $f \in m$ not in any other minimal primes of A, then $\operatorname{Spec} A - m = \operatorname{Spec} A_f$.

Conversely, Cf.[[Sta]0BCR]. □

Idempotents

Prop. (4.1.7.5) [Clopen Subsets]. The clopen subsets of $\operatorname{Spec} A$ corresponds to idempotents in A.

Proof: This is all equivalent to the fact that there exists $e + f = 1, ef = 0$:

If $A = U\coprod V$, then both U, V are closed hence qc, so $\operatorname{Spec} A = \cup V(f_i)\coprod \cup V(g_j)$, then $f_i g_j$ is nilpotent by(4.2.6.2). Denote $I = (f_i), J = (g_j)$, then $(IJ)^N = 0$ and $I + J = A$, there are $1 = x + y$, $x \in I^N, y \in J^N$.

For uniqueness, if $e_1 \neq e_2$, then $0 \neq e_1 - e_2 = e_1(e_2 + f_2) - e_2(e_1 + f_1) = e_1 f_2 - e_2 f_1$, so may assume $e_1 f_2 \neq 0$, and it is not nilpotent, so there is a $e_1 f_2 \subset \mathfrak{p}$, which is a contradiction. □

Cor. (4.1.7.6). A local ring has no non-trivial idempotents, and then an idempotent is defined by the maximal ideals that it vanishes.

Cor. (4.1.7.7). If I is an ideal of R that $I = I^2$, and I is f.g., then $V(I)$ is open and closed in $\operatorname{Spec} R$, and $V(I) = R_e$ for some idempotent e.

Proof: By Nakayama, there is a a $f = 1 - e$ with $e \in I$ that $fI = 0$. So $e - e^2 = 0$ and $f^2 = f$. $V(I) = D(f) = D(e)$. □

Lemma (4.1.7.8). If I is a locally nilpotent ideal, then $R \to R/I$ induces a bijection on idempotents.

Proof: Because $R \to R/I$ induces a homeomorphism on the spectra, and clopen subsets of the spectrum corresponds to the idempotents(4.1.7.5). □

Lemma (4.1.7.9). Let R be a ring and $T \subset \operatorname{Spec} R$ is a set. Then the following are equivalent:

- T is closed and is a union of connected components of $\operatorname{Spec} R$.
- T is an intersection of clopen subsets.
- $T = V(I)$ where I is generated by idempotents.

Proof: 1 and 2 are equivalent by(3.11.4.3), and $2 \to 3 \to 1$ are easy. □

Prop. (4.1.7.10). Let R be a ring, then any connected component of $\operatorname{Spec} R$ is of the form $V(I)$, where I is an ideal generated by idempotents that any idempotent of R maps to either 0 or 1 in R/I.

Proof: By(3.11.4.2) and(3.11.4.13), a connected component of $\operatorname{Spec} R$ is an intersection of clopen subsets, so it is of the form $V(I)$ where I is generated by idempotents. The last assertion is equivalent to $V(I)$ being connected. □

Going-up and down

Def. (4.1.7.11) [Going-up and Going Down]. Going-up and down for topological spaces is defined in(3.11.3.7). A ring map $R \to S$ is said to satisfy the going-up property iff its Spec map does, equivalently, for any prime ideal $\mathfrak{q} \subset S$ and prime ideal $\mathfrak{p} \subset \mathfrak{q} \cap R$, there exists a prime ideal $\mathfrak{q}' \subset \mathfrak{q}$ that $\mathfrak{q}' \cap R = \mathfrak{p}$.

It is said to satisfy the going-down property iff its Spec map does, equivalently, for any prime ideal $\mathfrak{q} \subset S$ and prime ideal $\mathfrak{q} \cap R \subset \mathfrak{p}$, there exists a prime ideal $\mathfrak{q} \subset \mathfrak{q}'$ that $\mathfrak{q}' \cap R = \mathfrak{p}$.

Prop. (4.1.7.12). Going-up and Going-down are stable under composition, trivially.

Prop. (4.1.7.13) [Integral Map satisfies Going-Up]. Integral ring map satisfies going-up(4.2.1.5). Flat ring map satisfies going-down(4.4.1.19).

Lemma (4.1.7.14). If the image of the Spec map of a ring map is closed under specialization, then this image is closed.

Proof: Let it be $R \to S$, let I be the kernel, then the image is contained in $V(I)$, so we may replace R be R/I, then $R \subset S$. Now we show the image contains all the minimal primes of R: for a minimal prime $\mathfrak{p}$, $A_{\mathfrak{p}} \subset B_{\mathfrak{p}}$, thus $B_{\mathfrak{p}}$ is not-empty, and thus has a maximal ideal, whose intersection with $A_{\mathfrak{p}}$ can only be $\mathfrak{p}$ by hypothesis, thus $\mathfrak{p}$ is in the image of Spec. Then the image is all of $\operatorname{Spec} R$ by hypothesis, thus closed. □

Cor. (4.1.7.15) [Going-up and Spec Closed]. Going-up is equivalent to Spec map closed.

Proof: If going-up holds, then Spec map is closed by(4.1.7.14). Conversely, a closed map satisfies going-up, by(3.11.3.8). □

Prop. (4.1.7.16). If $R \to S$ is a ring map that satisfies going-up, and $P \subset S$ is a maximal ideal, then $P \cap R$ is also a maximal ideal.

Prop. (4.1.7.17) [Krull]. If $A \subset B$ is an integral extension of integral domains, and A is normal, then going-down holds.

Proof: Let L_1, K be the fraction fields of B, A resp., and let L be the normal extension of K contained in L_1, C the integral closure of A in L. Let $P \in \operatorname{Spec} B$ and $\mathfrak{p} = P \cap A$, $\mathfrak{p}' \subset \mathfrak{p}$. Take a prime ideal $Q' \in \operatorname{Spec} C$ lying over p, and by going-up applied to $A \subset C$(4.1.7.13), there is a prime ideal Q_1 lying over $\mathfrak{p}$ that $Q' \subset Q_1$. Take $Q \in \operatorname{Spec} C$ lying over P, then by(4.3.5.12) there is a $\sigma \in G_{L/K}$ that $\sigma(Q_1) = Q$. Set $P' = \sigma(Q') \cap B$, then $P' \subset P$ is a prime of B lying over $\mathfrak{p}'$, so going-down holds for $A \subset B$. □

Prop. (4.1.7.18) [Going-down and Spec Open]. If Spec map is open, then going-down holds.

Proof: □

Minimal Primes and Irreducible Components

Prop. (4.1.7.19) [Minimal Primes Exists]. Every nonzero ring contains a minimal prime ideal.

Proof: Firstly prime ideal exists, by(4.1.1.5), and we use Zorn's lemma to find a minimal prime ideal: it suffices to show the intersection of a chain of prime ideals is a prime ideal, this is not hard. □

Lemma (4.1.7.20). If $\mathfrak{p}$ is a minimal prime of R, then $\mathfrak{p}R_{\mathfrak{p}}$ is locally nilpotent by(4.2.6.1). In particular, if R is reduced, then $R_{\mathfrak{p}}$ is a field.

Prop. (4.1.7.21) [Zerodivisors in a Reduced Ring]. Let R be a reduced ring, then

- $R \to \prod_{\mathfrak{p} \text{ minimal}} R_{\mathfrak{p}}$ is an embedding into a product of fields.
- $\cup_{\mathfrak{p} \text{ minimal}} \mathfrak{p}$ is the set of zerodivisors of R.

Proof: 1: By(4.1.7.20), $R_{\mathfrak{p}}$ are fields. In particular, the kernel of $R \to R_{\mathfrak{p}}$ is $\mathfrak{p}$. Then the kernel of the map $R \to \prod_{\mathfrak{p} \text{ minimal}} R_{\mathfrak{p}}$ is $\cap_{\mathfrak{p} \text{ minimal}} \mathfrak{p} = 0$ by(4.2.6.1).

2: If $xy = 0$ and $x \neq 0$, then $x \notin \mathfrak{p}$ for some minimal prime $\mathfrak{p}$ by(4.2.6.1), thus $y \in \mathfrak{p}$. Conversely, if $y \in \mathfrak{p}$ for some minimal prime p, then y is mapped to $0 \in R_{\mathfrak{p}}$, which means there are some $x \notin \mathfrak{p}$ that $xy = 0$. □

Prop. (4.1.7.22). If R is a ring with f.m. minimal primes $\mathfrak{q}_i$ and $\cup_i \mathfrak{q}_i$ is the set of zerodivisors of R, then the ring of fractions of R(4.1.1.30) is equal to $\prod_i R_{\mathfrak{q}_i}$.

Proof: Cf.[Sta]02LX. □

Prop. (4.1.7.23) [Irreducible Components of Spectrum]. The irreducible closed subsets of $\operatorname{Spec} R$ are exactly the sets of the form $V(\mathfrak{p})$ for some prime $\mathfrak{p} \subset R$. The irreducible components of $\operatorname{Spec} R$ are exactly the sets of the form $V(\mathfrak{p}_i)$ for some minimal prime $\mathfrak{p}_i$.

Prop. (4.1.7.24). If R be a ring and $\mathfrak{p}$ a minimal prime of R. If $W \subset \operatorname{Spec} R$ is a quasi-compact open subset of $\operatorname{Spec} R$ not containing $\mathfrak{p}$, then there exists some $f \in R$ that $\mathfrak{p} \subset D(f)$ and $D(f) \cap W = \varnothing$.

Proof: W is of the form $\cup_{i=1}^r D(f_i)$. As $\mathfrak{p} \notin D(f_i)$, $f_i \in \mathfrak{p}$ for each i. Then(4.1.7.20) says f_i are nilpotent in $R_{\mathfrak{p}}$, so there is some $g \in R$ that gf_i are nilpotent in R for any i, which means g satisfies the requirement. □

Prop. (4.1.7.25). For $R \subset S$, all the minimal primes of R are in the image of the Spec map of a minimal prime of S.

Proof: Localize w.r.t. to the minimal prime $\mathfrak{p}$, then it is a local ring with only one prime. And $S_{\mathfrak{p}}$ is nonzero because localization is exact, so it has a maximal ideal $\mathfrak{q}$. Now we choose a minimal prime of S contained in $\mathfrak{q}$, then it is also mapped to $\mathfrak{p}$. □

Universal Homeomorphism

Cf.[Sta]10.45 and [Sta]28.44.

Prop. (4.1.7.26). If $\varphi : R \to S$ is a ring map and p is a prime number that satisfies:

- S is generated over R by elements x that there is n that $x^{p^n} \in \varphi(R)$ and $p^n x \in \varphi(x)$.
- $\ker(\varphi)$ is locally nilpotent.

then $\operatorname{Spec} S \to \operatorname{Spec} R$ is a homeomorphism, and any base change of φ satisfies the above conditions, so it is a universal homeomorphism.

In particular, this applies to any base change of a field extension k'/k that is purely inseparable, because it is f.f. hence injective.

Proof: Cf.[Sta]0BRA. □

4.2 Commutative Algebra II

Main references are [Sta].

1 Integral Extensions

Def. (4.2.1.1)[Totally Integrally Closed]. For two rings $A \to B$, $f \in B$ is called **almost integral**(or totally integral when almost mathematics is performed:)) over A if $f^{\mathbb{N}}$ lies in a f.g. A-module of B. It is clear that the elements of totally integral elements of B is a subring. And A is called **totally integrally closed** in B iff any $f \in B$ totally integral over A is in A.

Prop. (4.2.1.2). For a ring map $\varphi : A \to B$, an element x is integral over A iff x is contained in a finite A-module in B. In particular, the elements of B that are integral over A is a ring containing $\varphi(A)$.

Proof: If x is integral, then $\varphi(A)[x]$ is finite. If $\varphi(A)[x]$ is finite, then there is a set of generators of polynomials in x. Then for m large, $x^m = \sum a_i f_i(x)$, so x is integral over A. □

Prop. (4.2.1.3) [Integral Extension of Field]. For $A \subset B$, if B is integral over A, then A is a field iff B is a field.

Proof: If A is a field, $y^{-1} = -a_n^{-1}(y^{n-1} + \ldots + a_{n-1}) \in B$. If B is a field, $x^{-1} = -(b_1 + b_2 x + \ldots + b_m x^{m-1}) \in A$. □

Cor. (4.2.1.4). If B is integral over A, then a prime $\mathfrak{p} \subset B$ is maximal iff $\mathfrak{p} \cap A$ is maximal.

Proof: Look at the integral extension $A/(\mathfrak{p} \cap A) \to B/\mathfrak{p}$. □

Prop. (4.2.1.5) [Going-Up]. Let $A \to B$ integral. Then:

1. There is no inclusion relation between prime ideals of B lying over a fixed prime ideal of A.
2. if $A \subset B$, then thee Spec map is surjective. In particular, for any $\mathfrak{p} \subset A$, $\mathfrak{p}B \cap A = \mathfrak{p}$.
3. The going-up holds. In particular, the Spec map of an integral ring map is closed, by(4.1.7.15).

Proof:

1. If $p \cap A = p' \cap A = q$, Localize at q, then p, p' are both maximal ideals of B_q by(4.2.1.4), they cannot contain each other.
2. For any prime $\mathfrak{p}$ of A, since $A_\mathfrak{p} \subset B_\mathfrak{p}$, $B_\mathfrak{p} \neq 0$, so it has a maximal ideal(4.1.1.5), and use(4.2.1.4).
3. for any prime ideal $\mathfrak{q}$ of B and $\mathfrak{p} = \mathfrak{q} \cap A$, replace $A \to B$ by $A/\mathfrak{p} \subset B/\mathfrak{q}$, then we can use2.

□

2 Graded Rings

Cf.[Matsumura Ch11].

Def. (4.2.2.1)[Graded Rings]. A **graded ring** is a ring $A = \bigoplus_{n\in\mathbb{Z}} A_n$ that $A_m A_n \subset A_{m+n}$. A **graded module** over a graded ring A is a module $M = \bigoplus_{n\in\mathbb{Z}} M_n$ that $A_m M_n \subset M_{m+n}$.

Notice that often we mean $\mathbb{Z}^{\geq 0}$-graded rings when we say graded rings. For a $\mathbb{Z}^{\geq 0}$-graded ring A, the subset $A_+ = \bigoplus_{n=1}^{\infty} A_n$ is an ideal of A, called the **irrelevant ideal**.

Def. (4.2.2.2) [Twisted Modules]. Let A be a graded ring and M a graded A-module, denote $M(n)$ the graded A-module s.t. $M(n)_m = M_{m+n}$.

Lemma (4.2.2.3). Let $A = \bigoplus_0^\infty A_n$ be a graded ring, then a set of homogenous elements $f_i \in A_+$ generate A as an algebra over A_0 iff they generate A_+ as an ideal of A.

Proof: If f_i generate A as algebra over A_0, then every element of A_+ is a polynomial in f_i with constant coefficients in A_0, thus f_i generates A_+ as an ideal. Conversely, if f_i generate A_+ as a ideal, then for any homogenous element f we can use induction on the degree of f to show that f is a polynomial in f_i. □

Prop. (4.2.2.4) [Noetherian Graded Rings]. A graded ring $A = \bigoplus_{n=0}^\infty A_n$ is Noetherian iff A_0 is Noetherian and A_+ is f.g. as an ideal of A.

Proof: If A is Noetherian, then clearly A_+ is f.g. and $A_0 = A/A_+$ is Noetherian. Now if A_+ is f.g. as an ideal of A, then it is generated by f.m. homogenous elements f_i, so we see f_i generates A as an algebra over A_0, which means A is a quotient of a polynomial ring over A_0, thus Noetherian by(4.1.1.40). □

Def. (4.2.2.5) [Homogenous Ideals]. Let $A_\bullet$ be a graded ring, then a **homogenous ideal** $I_\bullet$ of $A_\bullet$ is a ring that is generated by homogenous elements.

Prop. (4.2.2.6) [Equivalent definition of Homogenous Ideals]. Let $S_\bullet$ be a graded ring, then

- an ideal I of $S_\bullet$ is homogenous iff it contains the degree n part of each of its element for any n.
- The set of homogenous ideals of $S_\bullet$ is stable under sum, product, intersection and radical.
- A non-trivial homogenous ideal I of $S_\bullet$ is a prime ideal iff for any homogenous elements a, b, if $ab \in I$, then $a \in I$ or $b \in I$.

Proof: 1: If I contains the degree n part of each of its element for any n, then clearly it is generated by homogenous elements. Conversely, if it is generated by homogenous elements, then any element $f = \sum a_i f_i$, where f_i is homogenous. Then we can see $[f]_n = \sum [a_i]_{n-\deg f_i} f_i$ is also in I.

2: Use 1 and the definition. For radicals, we show $\sqrt{I}$ contains all its homogenous parts: if $f \in \sqrt{I}$, then $f^n \in I$ for some n, then we see that the minimal degree part $[f]_m$ of f also satisfies $[f]_m^n \in I$, because I contains the homogenous parts of each of its elements. Then we can use induction to show that all the homogenous parts of f is in $\sqrt{I}$.

3: One direction is trivial, for the other, if $a = \sum a_i, b = \sum b_i$ satisfies $ab \in I$, and $a \notin I, b \notin I$, and a_i, b_j homogenous. Let i_0, j_0 be the minimal numbers that $a_{i_0} \notin I$, $b_{j_0} \notin I$, then $a_{i_0} b_{j_0}$ is not in I, contradicting the fact I is homogenous. □

Prop. (4.2.2.7). Let $R \to S$ be a homomorphism of graded rings, then the integral closure of R in S is a homogenous ideal of S.

Proof: consider the base change $\varphi : R \otimes_{R_0} R_0[t, t^{-1}] \to S \otimes_{S_0} S_0[t, t^{-1}]$, where $\deg(t) = 0$, and the integral closure is denoted by A. Then there is an automorphism of φ: $s \mapsto t^{\deg s} s$. This automorphism thus preserves the integral closure. if $s = s_n + s_{n+1} + \ldots + s_m \in S$ is integral over R, to show each s_i are integral over S. We may assume $n > 0$ because s_0 is clearly integral over R_0. Now we use induction on m. If $m > n$, consider $t^n s_n + \ldots + t^m s_m$ is also in A, we see $(t^m - t^i) s_i \in A$ by induction hypothesis.

Notice $S \subset S[t, t^{-1}]/(t^m - t^i - 1) = S[t]/(t^m - t^i - 1)$ is injective, and the image of $(t^m - t^i) s_i$ is s_i, which is integral over $R[t]/(t^m - t^i - 1)$, and this ring is finite over R, so s_i is also integral over R. □

Prop. (4.2.2.8). Let A be a graded ring that is f.g. over A_0 and M be a f.g. graded A-module, then each M_n is a finite S_0-module.

Def. (4.2.2.9) [Reductions of Graded Rings]. Let S be a graded ring and $d \geq 1$, define $S^{(d)}$ the graded ring $\oplus_{n\geq 0} S_{nd}$. And for a graded S-module M, define $M^{(d)} = \oplus_{n\in\mathbb{Z}} M_{nd}$.

Prop. (4.2.2.10). If S is a graded ring that is f.g. over S_0, then for d sufficiently divisible, $S^{(d)}$ is generated by the degree 1 part over S_0.

Proof: Let S be generated by homogenous elements $f_1, \ldots, f_r$. Let $M = lcm(\deg(f_1), \ldots, \deg(f_r))$, then for any $f \in S_{Nm}$ and $N \geq r$, by pigeonhole principle, there are some i s.t. $f_i^{M/\deg(f_i)} | f$. Thus any monomials of degree nrM is a product of polynomials of degree rM. So $d = rM$ satisfies the hypothesis. ☐

Topology Defined by Ideals

Def. (4.2.2.11) [Filtrations on Graded Modules]. Let A be a ring, M a graded A-module, and $\mathfrak{a}$ be an ideal of A, an **$\mathfrak{a}$-filtration** of M is a descending sequence of submodules $M = M_0 \supset M_1 \supset \ldots$ that $\mathfrak{a}M_n \subset M_{n+1}$. It is called a **stable filtration** iff there is an N that $\mathfrak{a}M_n = M_{n+1}$ for $n \geq N$.

For an ideal $\mathfrak{a} \subset A$, there can be associated a graded ring $A^* = \oplus \mathfrak{a}^n$, and an $\mathfrak{a}$-filtration M can be associated a graded module over $A^* : M^* = \oplus M_n$. When A is Noetherian, then so is A^*, because it is a quotient of a polynomial ring over A(4.1.1.40).

Lemma (4.2.2.12). If A is a Noetherian ring and M is a f.g. A-module that has a $\mathfrak{a}$-filtration M_n, then M^* is f.g. over A^* iff M_n is a stable filtration.

Proof: As every M_n is finite over A, if it is stable, then M^* is generated over A^* by all the generator of $M_n, n \leq N$, so it is f.g.. Conversely, if it is f.g., then it is clear that M_n is a stable filtration. ☐

Prop. (4.2.2.13) [Artin-Rees]. For A Noetherian and I an ideal, let $N \subset M$ be finite A-modules, then if M_n is a stable filtration of M, then $M_n \cap N$ is a stable filtration of N.

In particular, let $M_n = I^n M$, then $I^n M \cap N = I^{n-r}(I^r M \cap N)$, hence the I-adic topology on M induce the I-adic topology on N.

Proof: This is immediate from the lemma above, as N^* is an A^*-submodule of M^*, and A^* is Noetherian(4.2.2.11). ☐

Cor. (4.2.2.14) [Krull's Intersection Theorem]. Notation as in(4.2.2.13), let $N = \bigcap^{\infty} I^n M$, then the I-adic topology on N is trivial, by Artin-Rees, thus $IN = N$. So Nakayama tells us there is an element $a \in 1 + I$ that $aN = 0$. Thus if $I \subset \mathrm{rad}(A)$ or A is an integral domain, $N = 0$. This can be used to use induction to prove some theorem.

In particular, for any prime ideal $\mathfrak{p}$ containing I, use the above on $R_{\mathfrak{p}}$ shows $N_{\mathfrak{p}} = 0$. But also N is f.g., so there exists an element $g \notin \mathfrak{p}$ that $N_g = 0$.

Cor. (4.2.2.15) [Krull]. For A Noetherian, if $I \subset \mathrm{rad}(A)$ or A is a domain, then $\bigcap^{\infty} I^n = 0$.

Prop. (4.2.2.16). Notice for any ring A and a non-zero-divisor f, if $I = \cap_n f^n A$, then $fI = I$, needless of the Noetherian property.

Proof: If $x \in I$, $x = fy$, because $x \in f^n A$, $fy = f^n t$ for some t, so $y = f^{n-1} t$, so $f \in I$. Thus $I = fI$. ☐

Def. (4.2.2.17) [Hilbert-Serre]. Let A be a Noetherian graded ring with A_0 Artinian that A_+ is generated by A_1. For a f.g. graded A-module $M = \oplus M_n$, we have $l(M_n)$ is a numerical polynomial of n(24.1.3.10) for n sufficiently large, called the **Hilbert Polynomial**. Its degree is the dimension of $\mathrm{Supp}\, M \subset \mathrm{Proj}(A)$.

Proof: We prove by induction on the minimal number of generators of A_1(it is finite by(4.2.2.4)). If it is 0, then $M_n = 0$ for n large and the result holds. Now choose $x \in S_1$ as one of the minimal set of generators, then the induction hypothesis applies to $S/(x)$.

Firstly, if x acts nilpotently on M, then we do induction on the minimal number r that $x^r M = 0$. If $r = 1$, then M is a module over $S/(x)$ and the assertion holds. If $r > 1$, then we can find an exact sequence $0 \to M' \to M \to M'' \to 0$ that M', M'' has smaller r, then we have the desired result, because l is additive.

Next, if x doesn't act nilpotently on M, let $M' \subset M$ is the largest submodule that x acts nilpotently, then there is an exact sequence $0 \to M' \to M \to M/M' \to 0$. So we can assume multiplication by x is injective on M.

Let $\overline{M} = M/xM$, then for any d, there are exact sequences

$$0 \to M_d \xrightarrow{x} M_{d+1} \to \overline{M}_{d+1}.$$

so $l(M_{d+1}) - l(M_d) = l(\overline{M}_{d+1})$. Then we finish by(24.1.3.11). □

Cor. (4.2.2.18). Let k be a field, $I \subset k[X_1, \ldots, X_n]$ be a non-zero graded ideal, and $M = k[X_1, \ldots, X_n]/I$, then the numerical polynomial $n \mapsto \dim_k(M_n)$ has degree $< d - 1$.

Proof: The numerical polynomial associated to $k[X_1, \ldots, X_n]$ is $n \mapsto \binom{n-1+d}{d-1}$, and for any non-zero homogenous element $f \in I$ of degree e, $f \cdot k[X_1, \ldots, X_n]_{d-e} \subset I_d$, thus $\dim_k(M_n) < \binom{n-1+d}{d-1} - \binom{n-e-1+d}{d-1}$, which means the numerical polynomial has degree$< d - 1$. □

Prop. (4.2.2.19) [Hilbert Polynomial and Dimension]. For a Noetherian local ring A, the Hilbert polynomial of a f.g. module M w.r.t $\mathfrak{m}$ has degree $\dim M$. And $\dim M$ is the smallest integer r s.t. there exists $x_1, \ldots, x_r$ that $l(M/x_1 M + \ldots, x_r M) < \infty$.

Proof: Cf.[Mat P76]. □

3 Completions

This subsubsection should be combined with the derived completion.

Prop. (4.2.3.1). Let the topology on a A-module be defined by countable filtration of submodules, then iff M is complete, then M/N is complete in the quotient topology.

Proof: Write $x_{i+1} - x_i = y_i + z_i$ with $y_n \in M_n$ and $z_n \in N$, then the image of the limit of $\sum y_i$ is the limit of $\overline{x_i}$. □

Def. (4.2.3.2) [Completeness]. Let I be an ideal of R, the ***I*-adic completion** of a R-module is a functor $\varphi : M \mapsto \widehat{M} = \lim M/I^n M$. An R-module is called ***I*-adically complete** if the natural map $M \to \widehat{M}$ is an isomorphism.

This is compatible with the general notion of completion of a topological Abelian groups(10.3.1.5).

Prop. (4.2.3.3). Let R be a ring and $I \subset R$ be an ideal, $\varphi : M \to N$ be a map of R-modules. Then

- If $M/IM \to N/IN$ is surjective, then $\widehat{M} \to \widehat{N}$ is surjective. In particular, this holds for $M \to N$ surjective.
- If $0 \to K \to M \to N \to 0$ is exact and N is flat, then $0 \to \widehat{K} \to \widehat{M} \to \widehat{N} \to 0$ is exact.
- $M \otimes_R \widehat{R} \to \widehat{M}$ is surjective for any finite R-module M.

Proof: Cf.[Sta]0315. □

Prop. (4.2.3.4). Let I be a f.g. ideal of A and M an A-algebra, then $\widehat{M}$ is I-adically complete and $I^n\widehat{M} = \ker(\widehat{M} \to M/I^nM) = (I^nM)^\wedge$.

Proof: Because I is f.g., so does I^n. If $I^n = (f_1, \ldots, f_r)$. Applying(4.2.3.3) to $(f_1, \ldots, f_r) : M^r \to I^nM$ shows

$$\widehat{M}^r \to (I^nM)^\wedge = \varprojlim_{m \geq n} I^nM/I^mM = \ker(\widehat{M} \to M/I^nM)$$

but the image is clearly $I^n\widehat{M}$, so $\widehat{M}/I^n\widehat{M} \cong M/I^nM$. Taking inverse limit yields $(M^\wedge)^\wedge = M^\wedge$. □

Cor. (4.2.3.5) [Completion is Complete]. Let I be a f.g. ideal of A and (M_n) an inverse system of A-modules that $I^nM_n = 0$, then $M = \lim M_n$ is I-adically complete.

Proof: We have maps $M \to M/I^n \to M_n$, taking limit, we get $M \to \widehat{M} \to M$, so M is a direct summand of $\widehat{M}$. Since $\widehat{M}$ is I-adically complete by(4.2.3.4), so does M. □

Prop. (4.2.3.6). If I is a f.g. ideal of A and (M_n) is an inverse system of A-modules that $M_n = M_{n+1}/I^nM_{n+1}$, then $M = \lim M_n$ is I-adically complete and $M/I^nM = M_n$.

Proof: $\widehat{M}$ is I-adically complete by(4.2.3.5), and $M \to M_n$ are all surjective because the transition maps are surjective. Consider the inverse system $N_n = \ker(M \to M_n)$. Since $M_n = M_{n+1}/I^nM_{n+1}$, the map $N_{n+1} + I^nM \to N_n$ is surjective, and thus $N_{n+1}/(N_{n+1} \cap I^{n+1}M) \to N_n/(N_n \cap I^nM)$ is surjective.

Taking the inverse limit of the exact sequences

$$0 \to N_n/(N_n \cap I^nM) \to M/I^nM \to M_n \to 0,$$

we get an exact sequence

$$0 \to \varprojlim N_n/(N_n \cap I^nM) \to \widehat{M} \to M.$$

As M is I-adically complete, $\widehat{M} = M$, thus $\varprojlim N_n/(N_n \cap I^nM) = 0$, thus $N_n/(N_n \cap I^nM) = 0$ for any n as n the transition maps are surjective. Then $M/I^nM = M_n$, as desired. □

Cor. (4.2.3.7) [Spectrum Map of Completions]. $\operatorname{Spec} R^\wedge \to \operatorname{Spec} R$ has image $\operatorname{Spec} R/I \subset \operatorname{Spec} R$. This follows from(4.2.3.18) and $R/I \cong R^\wedge/I$.

Prop. (4.2.3.8). If I is an ideal of R and $0 \to M \to N \to Q \to 0$ is an exact sequence that Q is annihilated by a power of I, then completion produces an exact sequence

$$0 \to \widehat{M} \to \widehat{N} \to Q \to 0$$

Proof: If $I^cQ = 0$, then $Q/I^nQ = Q$ cor $n \geq c$, and $I^nM \subset M \cap I^nN \subset I^{n-c}M$ because of this. Then $\widehat{M} = \varprojlim M/(M \cap I^nN)$ by(3.1.1.41), and we apply(4.9.3.2) to the inverse system of exact sequences

$$0 \to M/(M \cap I^nN) \to N/I^nN \to Q \to 0$$

to conclude. □

Cor. (4.2.3.9). If A is a ring with a nonzero-divisor t and there is an exact sequence $0 \to M \to N \to Q \to 0$ of A-modules that $IQ = 0$, then M is I-adically complete iff N is I-adically complete.

Proof: Use snake lemma. □

Cor. (4.2.3.10). Take $I = (f)$ and $M = N = R$, then we see that if t is a nonzero-divisor in R then t is a nonzero-divisor in $\widehat{R}$.

Prop. (4.2.3.11). The completion of a submodule $N \subset M$ is the closure of $\varphi(N)$ (By direct construction). The completion of M/N is M^*/N^* because it is right exact.

Cor. (4.2.3.12). If N is open in M then $M/N \cong M^*/N^*$ because M/N is discrete hence complete.

Prop. (4.2.3.13). When A is Noetherian and M is finite A-module, then the natural map $M \otimes_A A^* \to M^*$ is an isomorphism (use M is finite presentation and tensor & completion is right exact), and five lemma.

Cor. (4.2.3.14). When A is Noetherian, $A \to A^\wedge$ is flat (because flatness is check for finite module).

And when A is complete Hausdorff, any finite module M is complete Hausdorff and hence any its submodule is complete thus closed in it. Hence the the completion of a submodule $N \subset M$ is $\varphi(N)A^*$ in $M^* = MA^*$. In fact this implies complete Hausdorff adic-ring is Zariski.

Remark (4.2.3.15). WARNING: If A is not Noetherian, in general $A \to A^\wedge$ is not flat, Cf.[Sta]0AL8.

Lemma (4.2.3.16). Let A be a ring and $I = (f_1, \ldots, f_r)$ be a f.g. ideal. If $M \to \varprojlim M/f_i^n M$ is surjective for each i, then $M \to \varprojlim M/I^n M$ is also surjective.

Proof: Note that $\varprojlim M/I^n M = \varprojlim M/(f_1^n, \ldots, f_r^n)M$, as $I^{rn} \subset (f_1^n, \ldots, f_r^n) \subset I^n$, and elements in $\varprojlim M/(f_1^n, \ldots, f_r^n)M$ can be written as an infinite sum $\xi = \sum_n \sum_i f_i^n x_{n,i}$. There is an element x_i mapping to $\sum_n f_i^n x_{n,i}$ for any i, thus $\sum_i x_i$ maps to ξ. □

Lemma (4.2.3.17). Let A be a ring and $I \subset J$ be ideals, if M is J-adically complete and I is f.g., then M is I-adically complete.

Proof: It is clearly I-adically Hausdorff, and for completeness, by(4.2.3.16) it suffices to show for $I = (f)$: Let $x_n \in M$ with $x_n - x_{n+1} \in f^n M$, then $\{x_n\}$ is J-adically Cauchy, thus there is an element x that $x - x_n \in J^n$, and we can replace x_n by $x_n - x$ to assume $x_n \in J^n$. Now we prove $x_n \in (f^n)$: assume $x_n - x_{n+1} = f^n z_n$, then

$$x_n = f^n(z_n + f z_{n+1} + \ldots).$$

This equation is true because it is J-adically Cauchy. □

Properties of Complete Rings

Prop. (4.2.3.18). If A is I-adically complete, then $I \subset \operatorname{rad} A$.

Prop. (4.2.3.19). Let A be a ring with a non-zero-divisor t, then any limit of t-adically complete algebras is t-adically complete.

Proof: Check the definition directly. □

Prop. (4.2.3.20) [Zariski Rings]. A Noetherian I-adic ring is called **Zariski ring** if it satisfies the following equivalent conditions:

- Every finite module is Hausdorff in the I-adic topology.
- Every submodule in a finite module is closed in the I-adic topology.
- Every ideal is closed.
- $I \subset \mathrm{rad}A$.
- $A^\wedge/A$ is f.f.

Hence every complete Hausdorff ring is Zariski.

Proof: $1 \to 2$: Apply it to the submodule M/N.

$3 \to 4$: If $I \not\subseteq m$, then $I^n + m = A$, thus $\overline{M} = A$, contradiction.

$4 \to 1$: by intersection theorem(4.2.2.14).

$4 \to 5$: for any maximal ideal m, $I \subset m$ so it is open, thus $A^*/mA^* = A/m \neq 0$ by(4.2.3.12) thus f.f. by(4.4.1.5).

$5 \to 1$:by(4.4.1.21), for any m maximal, there is a maximal ideal m' lying over m, so $IA^* \subset m^*$ by(4.2.3.14), thus $I \subset m$, hence $I \subset \mathrm{rad}A$. □

Cor. (4.2.3.21). In a Zariski ring A, maximal ideals are open, thus $A/m \cong A^*/mA^*$ by(4.2.3.12), thus $\mathrm{Spec}\, A^* \to \mathrm{Spec}\, A$ is bijection on closed pt.

Prop. (4.2.3.22) [Cohen Structure Theorem]. If A is a complete local ring containing a field k that the residue field is separably generated over k, then there is a field K containing k that is a Cohen ring, i.e. complete local ring with a prime number as a uniformizer, that has the same residue field as A.

Proof: □

Lemma (4.2.3.23) [Complete Interchanging Lemma]. If R is a commutative ring, $x, y \in R$, if x is not a zero-divisor in R and R is x-adically complete, and y is not a zero-divisor in R/x and R/x is y-adically complete, then the same is true with x, y interchanged.

Proof: ? □

4 Dimension

Def. (4.2.4.1) [Dimensions and Heights]. For a A-module M, $\dim(M)$ is defined as $\dim(A/\mathrm{Ann}(M))$.

The **height** of an ideal I in A is defined as the infimum of heights of the prime ideals over I.

The **dimension** of a ring R is defined to be the supremum of heights of prime ideals of R.

Prop. (4.2.4.2). For any ring A $\dim A = \sup \dim A_{\mathfrak{p}}$.

Def. (4.2.4.3) [Catenary Rings]. $A \in \mathcal{CA}\mathrm{lg}$ is called **catenary** if for any pair of primes $\mathfrak{p} \subset \mathfrak{q} \subset A$, any maximal chain of primes $\mathfrak{p} = \mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_e = \mathfrak{q}$ has the same length. A Noetherian ring is called **universally catenary** if all f.g. algebras over it are catenary.

Prop. (4.2.4.4). $A \in \mathcal{CA}\mathrm{lg}$ is catenary iff $\mathrm{Spec}\, A$ is a catenary space(3.11.3.34).

Prop. (4.2.4.5). Any quotient ring and localization of a (universally)catenary ring is catenary. Any quotient of a Noetherian universally catenary ring is universally catenary. Catenary and universally catenary are stalkwise properties(4.1.4.2).

Prop. (4.2.4.6). If $(A, \mathfrak{m})$ is a Noetherian local ring, then A is catenary iff $\mathfrak{p} \to \dim(A/\mathfrak{p})$ is a dimension function on Spec A.

Proof: This follows from(3.11.4.13)(3.11.3.39) and(3.11.3.37). □

Example (4.2.4.7) [Universally Catenary Rings]. The following are same examples of universally catenary Rings:

- A f.g. algebra over a universally catenary ring.
- A Noetherian C.M. rings.
- 1-dimensional Noetherian domains,
- Fields.

Proof: Cf.[Sta]00NM.**?** □

Def. (4.2.4.8) [Hilbert Polynomials]. Let $(A, \mathfrak{m})$ be a Noetherian local ring, I an ideal of definition, then

Dimension of Noetherian Local Rings

Prop. (4.2.4.9). For a Noetherian local ring R, the following three numbers are equal:

- $\dim R$.
- $d(R)$.
- the minimal number of elements needed to generate an ideal of definition of R(4.1.1.11).

A **system of parameters** is d elements $g_1, \ldots, g_d$ that generate an ideal of definition of R, where $d = \dim R$.

Proof: Cf.[Sta]00KQ.**?** □

Cor. (4.2.4.10). The dimension of a Noetherian local ring is finite, by item3. Thus the codimension of a subscheme in a Noetherian scheme is finite.

Cor. (4.2.4.11). If A is a Noetherian local ring with maximal ideal $\mathfrak{m}$, then $\dim A \leq \dim_k \mathfrak{m}/\mathfrak{m}^2$.

Proof: By Nakayama, if $x_1, \ldots, x_d \in \mathfrak{m}$ generate $\mathfrak{m}/\mathfrak{m}^2$, then $(x_1, \ldots, x_d) = \mathfrak{m}$. □

Dimension and Ring Extensions

Prop. (4.2.4.12) [Dimension and Going-Up(Down)]. If $A \to B$ is a ring map that Spec map is surjective and $A \to B$ satisfies either going-up or going-down, then $\dim B \geq \dim A$.

Proof: The hypothesis implies any chain of primes in A can lifted to a chain of primes in B. □

Prop. (4.2.4.13) [Dimensions and Noetherian Ring Extensions]. Let $A \to B$ be a map between Noetherian rings, P a prime ideal of B, $\mathfrak{p} = P \cap A$, then:

- $\operatorname{ht}(P) \leq \operatorname{ht}(\mathfrak{p}) + \operatorname{ht}(P/pB)$,in other words $\dim(B_P) \leq \dim(A_p) + \dim(B_P/\mathfrak{p}B_P)$.

- equality holds if going-down holds. For example, if it is flat(4.1.7.13).

Proof: 1: Localize at p and P, we may assume A, B are local rings with maximal ideals $\mathfrak{p}$ and P, then use the characterization(4.2.4.9) of dimension, if $x_1, \dots, x_d$ generate an ideal of definition of $A_\mathfrak{p}$ and $y_1, \dots, y_e$ generate an ideal of definition of $B_P/\mathfrak{p}B_P$, then $x_1, \dots, x_d, y_1, \dots, y_e$ generate an ideal of definition of B_P.

2: If going down holds, for any chain of primes in B_P containing $\mathfrak{p}B_P$, we can lift the chain of primes in $A_\mathfrak{p}$ to a chain of primes in B_P to get a longer chain, thus we get the other direction of inequality.

□

Prop. (4.2.4.14) [Dimension of Integral Extensions]. Let $A \to B$ be an integral ring map, then:

1. Spec maps closed points to closed points, and $\dim(A) \geq \dim(B)$, which equality if $A \subset B$.
2. If A, B is Noetherian, $\mathrm{ht}(P) \leq \mathrm{ht}(P \cap A)$
3. If A, B is Noetherian and going down holds, then $\mathrm{ht}(J) = \mathrm{ht}(J \cap A)$ for any ideal $J \subset B$.

Proof: 1:By(4.2.1.5), there is no inclusion relation between prime over a fixed prime, so $\dim(B) \leq \dim(A)$. On the other hand, if $A \subset B$, then Spec map is surjective going-up holds(4.2.1.5), so $\dim(B) \geq \dim(A)$(4.2.4.12).

2: Follows from (4.2.4.13)(1) since $\mathrm{ht}(P/(P \cap A)B) = 0$ by(4.2.1.5).

3: In this case, $\mathrm{ht}(P) = \mathrm{ht}(P \cap A)$ holds by(4.2.4.13)(2), then use the surjectiveness of Spec for the integral extension $A/J \cap A \subset B/J$(4.2.1.5). □

Cor. (4.2.4.15). if $A \to B$ is integral and faithfully flat, then $\dim A = \dim B$.

Proof: This follows from(4.2.4.14) and(4.4.1.28). □

Prop. (4.2.4.16) [Dimension and Completion]. For a local ring A, $\dim A = \dim \widehat{A}$.

Proof: □

Noetherian Normalization

Prop. (4.2.4.17). For a Noetherian ring A, $\dim A[X] = \dim A + 1$.

Proof: Let $\mathfrak{p}$ be a prime ideal of A and let $\mathfrak{q}$ be a prime ideal of $A[X]$ maximal among primes lying over $\mathfrak{p}$, then $\mathrm{ht}(\mathfrak{q}/\mathfrak{p}A[X]) = 1$. In fact, by localizing, we can assume $\mathfrak{p}$ is a maximal ideal, then $A[x]/\mathfrak{p}A[x]$ is a polynomial ring over a field thus a PID and $\mathrm{ht}(\mathfrak{q}/\mathfrak{p}A[X]) = 1$. Thus $\mathrm{ht}(\mathfrak{q}) = \mathrm{ht}(\mathfrak{p}) + 1$ by(4.2.4.13). Now we are done, because $\mathrm{Spec}\, A[X] \to \mathrm{Spec}\, A$ is surjective. □

Prop. (4.2.4.18) [Krull's Height Theorem]. In a Noetherian domain R, the height of an ideal generated by n elements is at most n.

Proof: Let $\mathfrak{p}$ be a minimal ideal containing $(f_1, \dots, f_n)$, then it suffices to show $\dim(R_\mathfrak{p}) \leq n$ In this case, $(f_1, \dots, f_n)$ is an ideal of definition of $R_\mathfrak{p}$, thus we can use(4.2.4.9). □

Prop. (4.2.4.19) [Number of Generators]. To show an ideal $I \subset A$ cannot be generated by smaller than n element, choose a maximal ideal $\mathfrak{m}$, then show that $\dim_{A/\mathfrak{m}} I/\mathfrak{m}I \geq n$.

Cor. (4.2.4.20).

- (x, z) is not principal in $k[x, y, z]$.

- $(wz - xy)$ is not principal in $k[x, y, z]$.
- (xy, yz, xz) is not generated by two elements in $k[x, y, z]$.

Lemma (4.2.4.21). Let $A = k[X_1, \ldots, X_n]$ be a polynomial ring over a field k, and I is an ideal of A of height r, then we can choose $Y_1, \ldots, Y_n \in A$ that A is integral over $k[Y_1, \ldots, Y_n]$ and $I \cap k[Y_1, \ldots, Y_n] = (Y_1, \ldots, Y_r)$.

Proof: We use induction on r. $r = 0$ is easy. For $r = 1$, let $f(X)$ be any non-zero polynomial in I, then we can assign suitable integral weights $d_1 = 1, d_2, \ldots, d_n$ to X_i that monomials of f have different weights. Put $Y_i = X_i - X_1^{d_i}$ for $i \geq 2$, and

$$Y_1 = f(X) = f(X_1, Y_2 + X_1^{d_2}, \ldots, Y_n + X_1^{d_n}) = a_1 X_1^N + g(X_1, Y_2, \ldots, Y_n)$$

where g has degree in X_1 lower that N. Then X_1 is integral over $k[Y_1, \ldots, Y_n]$, and hence $X_i = Y_1 + X_1^{d_i}$ is also integral over $k[Y]$.

Now (Y_1) is a prime ideal in $k[Y]$ of height 1 and $(Y_1) \in I \cap k[Y]$. Also notice $I \cap k[Y]$ has height 1 by(4.2.4.14)(Because going-down holds by(4.1.7.17)), so $(Y_1) = I \cap k[Y]$.

For $r \geq 2$, let $J \subset I$ be an ideal with height $r - 1$, let J be an ideal of $k[X]$ contained in I that $\mathrm{ht}(J) = r - 1$.(This is possible by choosing f_i out of all minimal primes containing $(f_1, \ldots, f_{r-1})$ and use Krull's Height Theorem). By induction hypothesis, there exists $Z_1, \ldots, Z_n$ that $k[X]$ is integral over $k[Z]$, and $J \cap k[Z] = (Z_1, \ldots, Z_{r-1})$. Now $ht(I \cap k[Z]) = r$ by the same argument above, thus there exist $f \in I \cap k[Z] \backslash (Z_1, \ldots, Z_{r-1})$, and do the same for $r = 1$ again, we can find the desired Y_i that $Y_k = Z_k$ for $k \leq r - 1$. □

Prop. (4.2.4.22) [Noetherian Normalization Theorem]. If A is a f.g. algebra over a field. then there are r alg. independent elements y_i that A is integral over $k[y_i]$.

Proof: Let $A = k[X_1, \ldots, X_n]/I$ and height$(I) = n - r$, then by the lemma we can choose $Y_1, \ldots, Y_n$ that $k[X_1, \ldots, X_n]$ is integral over $k[Y_1, \ldots, Y_n]$(so $Y_1, \ldots, Y_n$ are algebraically independent) and $I \cap k[Y_1, \ldots, Y_n] = (Y_{r+1}, \ldots, Y_n)$. Now we can just choose $y_i = Y_i$ for $i \leq r$. □

Cor. (4.2.4.23) [Dimension and Transcendental Degree]. If A is a f.g. integral ring over a field k, then $\dim A = \mathrm{tr.deg}_k A$.

Proof: This is because integral extensions of integral Noetherian rings have the same dimensions(4.2.4.14) and their fraction fields have the same transcendental degrees. □

Cor. (4.2.4.24). Let A, B be f.g. algebras over a field k, then $\dim(A \otimes_k B) = \dim A + \dim B$.

Cor. (4.2.4.25) [Dimension and Field Base Change]. Let K/k be a field extension and S a f.g. algebra over k, then $\dim S = \dim S \otimes_k K$.

Proof: By Noetherian normalization, there exists a finite injective map $k[d_1, \ldots, d_n] \to S$ where $n = \dim S$. Then there exists a finite injective map $K[d_1, \ldots, d_n] \to S_K$, so $\dim S \otimes_k K = n$, by(4.2.4.14) and(4.2.4.17). □

Prop. (4.2.4.26) [Codimensions and Field Base Change]. Let K/k be a field extension and S a f.g. k-algebra. Let $\mathfrak{q}$ be a prime of S and q_K be a prime of S_K lying over $\mathfrak{q}$, then

$$\dim(S_K \otimes_S k(\mathfrak{q}))_{\mathfrak{q}_K} = \dim(S_K)_{\mathfrak{q}_K} - \dim S_{\mathfrak{q}} = \mathrm{tr.deg}_k\, k(\mathfrak{q}) - \mathrm{tr.deg}_K\, k(\mathfrak{q}_K).$$

Moreover, for any $\mathfrak{q}$, we can choose q_K so that this number is 0.

Proof: Cf.[Sta]0CWE. □

Local Dimension over Fields

Prop. (4.2.4.27) [Local Dimension]. Let Let S be an algebra f.g. over a field k, $X = \operatorname{Spec} S$ and $x \in X$, then the following three numbers are equal:

- the local dimension(3.11.3.25) $\dim_x(X)$.
- $\max \dim(Z)$ where Z runs through irreducible components of X passing through x.
- $\min \dim(S_\mathfrak{m})$, where $\mathfrak{m}$ are maximal ideals containing $\mathfrak{p}_x$.

Proof: Cf.[Sta]00OT. □

Lemma (4.2.4.28). Let k be a field and S a f.g. k-algebra, $X = \operatorname{Spec} S$, $x \in X$, then

$$\dim_x(X) = \dim S_\mathfrak{p} + \operatorname{tr.deg}_k k(\mathfrak{p}).$$

Proof: Cf.[Sta]00P1. □

Cor. (4.2.4.29). Let $S' \to S$ be a surjection of f.g. algebras over a field k, $\mathfrak{p}$ a prime ideal of S and $\mathfrak{p}'$ its inverse image in S', corresponding to x, x' in $X = \operatorname{Spec} S, X' = \operatorname{Spec} S'$ resp., then

$$\dim_{x'}(X') - \dim_x(X) = \operatorname{ht}(\mathfrak{p}') - \operatorname{ht}(\mathfrak{p}).$$

Def. (4.2.4.30) [Relative Dimension]. Let $R \to S$ be a ring map of f.t., and $\mathfrak{q} \subset S$ be a prime over $\mathfrak{p} \subset R$, then we define the **relative dimension** of S/R at $\mathfrak{q}$ to be $\dim_\mathfrak{q}(\operatorname{Spec} S)_\mathfrak{p}$. The supremum of all these numbers over $\mathfrak{q} \subset \operatorname{Spec} S$ is called the relative dimension of S/R, denoted by $\dim(S/R)$.

Lemma (4.2.4.31) [Local Dimension and Field Extension]. Let K/k be a field extension, S be a f.g. k-algebra, and $X = \operatorname{Spec} S$. Now if $\mathfrak{p}_K$ is an element of S_K lying over $\mathfrak{p} \subset S$, then $\dim_\mathfrak{p}(S) = \dim_{\mathfrak{p}_K}(S_K)$.

Proof: The proof is by reduction to polynomial ring. Let $S = k[X_1, \ldots, X_n]/I$, let $\mathfrak{p}'_K, \mathfrak{p}'$ be primes of $k[X_1, \ldots, X_n]$ and $K[X_1, \ldots, X_n]$ that is the image of x and x_K, then there is a commutative diagram

$$\begin{array}{ccc} K[X_1, \ldots, X_n]_{\mathfrak{q}'_K} & \longrightarrow & (S_K)_{\mathfrak{q}_K} \\ \downarrow & & \downarrow \\ k[X_1, \ldots, X_n]_{\mathfrak{q}'} & \longrightarrow & S_\mathfrak{q} \end{array}.$$

The vertical arrows are flat because they are local morphisms of flat maps, and their fibers are the same, so by(5.6.3.17), $\operatorname{ht}(\mathfrak{q}'_K) - \operatorname{ht}(\mathfrak{q}') = \operatorname{ht}(\mathfrak{q}_K) - \operatorname{ht}(\mathfrak{q})$. Also use(4.2.4.29) on the horizontal maps, then we get the desired assertion. □

Prop. (4.2.4.32) [Semicontinuity of Dimensions]. Let $f : R \to S$ be a ring map of f.t., then the map $\mathfrak{q} \mapsto \dim_\mathfrak{q}(S/R)$ is a upper-semicontinuous function on $\operatorname{Spec}(S)$.

Moreover, if f is of f.p., then the set $\{\mathfrak{q} | \dim_\mathfrak{q}(S/R) \leq n\}$ is quasi-compact open in $\operatorname{Spec}(S)$.

Proof: Cf.[Sta]00QH, 00QJ. □

5 Support and Associated Primes

Def. (4.2.5.1) [Support of a Module]. The **support** $\mathrm{Supp}(M)$ of a module M is the set of all p that $M_p \neq 0$. When M is f.g., $\mathrm{Supp}(M) = V(\mathrm{Ann}(M))$.

Prop. (4.2.5.2) [Support is Non-Empty]. The support of a nonzero module is not empty, because triviality is stalkwise by(4.1.4.2).

Prop. (4.2.5.3). If $0 \to N \to M \to Q \to 0$, then we have $\mathrm{Supp}(M) = \mathrm{Supp}(N) \cup \mathrm{Supp}(Q)$, this is because localization is exact.

Cor. (4.2.5.4).

Prop. (4.2.5.5). Let $(R, \mathfrak{m})$ be a Noetherian local ring and M a finite R-module, $f \in \mathfrak{m}$, then

$$\dim \mathrm{Supp}(M) - 1 \leq \dim(\mathrm{Supp}(M/fM)) \leq \dim(\mathrm{Supp}(M))$$

Proof: Cf.[Sta]0B52. □

Prop. (4.2.5.6). Let $0 = M_0 \subset M_1 \subset \ldots \subset M_n = M$ be a filtration of M that $M_i/M_{i-1} \cong R/\mathfrak{p}_i$ where $\mathfrak{p}_i$ are primes, by(4.1.1.45), then $\mathrm{Supp}(M) = \cup_i V(\mathfrak{p}_i)$.

In particular, the minimal primes in $\{\mathfrak{p}_i\}$ are the same as the minimal primes of $\mathrm{Supp}(M)$. Moreover, the multiplicity of a prime $\mathfrak{p}_i$ equals $\mathrm{length}_{R_\mathfrak{p}} M_\mathfrak{p}$.

Proof: Cf.[Sta]00L7. □

Prop. (4.2.5.7). Let $(R, \mathfrak{m})$ be a Noetherian local ring and M a non-zero finite R-module, then $\mathrm{Supp}(M) = V(\mathfrak{m})$ iff $\mathrm{length}_R(M) < \infty$.

Proof: Cf.[Sta]00L5.? □

Prop. (4.2.5.8). Let A be Noetherian and I be an ideal, then $I^n M = 0$ for some n iff $\mathrm{Supp}(M) \subset V(I)$.

Proof: If $I^n M = 0$, then if $I \not\subseteq P$, then $M_P = 0$. Conversely, we have a filtration of M, and by(4.2.5.3) we have all the P_i include I, so I^n annihilate M. □

Prop. (4.2.5.9). If R is a ring and M is a f.p. R-module, then $\mathrm{Supp}(M)$ is a closed subset of $\mathrm{Spec}\, R$ whose complement is quasi-compact.

Proof: Let $R^m \to R^n \to M \to 0$, then the support of M is just the the locus that some minor of the linear map from $R^m \to R^n$ doesn't vanish. Then its complement is quasi-compact. □

Prop. (4.2.5.10). Let $(R, \mathfrak{m})$ be a Noetherian local ring and M is a finite R-module, then $d(M) = \dim(\mathrm{Supp}(M))$.

Proof: Cf.[Sta]00L8. □

Prop. (4.2.5.11). Let R be a Noetherian ring and $0 \to M' \to M \to M'' \to 0$ be an exact sequence of finite R-modules, then $\dim \mathrm{Supp}(M) = \max(\dim \mathrm{Supp}(M'), \dim \mathrm{Supp}(M''))$.

Proof: Cf.[Sta]0B51. □

Associated Primes of a Module

Def. (4.2.5.12) [Associated Primes of a Module]. The **weakly associated primes** $\mathrm{Ass}(M)$ of an A-module M is the set of minimal primes of $A/\mathrm{Ann}(m)$ for some $m \in M$.

The **associated primes** $\mathrm{Ass}(M)$ is the set of primes $\{p = \mathrm{Ann}(m)\}$ where $m \in M$.

Prop. (4.2.5.13). $Ass_R(M) \subset WeakAss_R(M)$, and if R is Noetherian, the converse is also true.

Proof: Cf.[Sta]058A. □

Prop. (4.2.5.14) [Associated Primes and Exact Sequence]. For an exact sequence $0 \to M_1 \to M \to M_2 \to 0$, $\mathrm{WeakAsso}(M) \subset \mathrm{WeakAsso}(M_1) \cup \mathrm{WeakAsso}(M_2)$ and $\mathrm{WeakAsso}(M_1) \subset \mathrm{WeakAsso}(M)$.

Proof: Cf.[Sta]0548.**?** □

Cor. (4.2.5.15) [F.M. Associated Primes]. For a finite module M over a Noetherian ring A, $\mathrm{Ass}_A(M)$ is finite by(4.1.1.45).

Prop. (4.2.5.16) [Associated Primes and Support]. $\mathrm{WeakAsso}(M) \subset \mathrm{Supp}\, M$, and their minimal elements are the same.

If $M \neq 0$, $\mathrm{WeakAsso}(M) \neq \varnothing$ by(4.2.5.2), and $\mathrm{WeakAsso}(A/I)$ contains all the minimal primes over I.**?**

Proof: If $\mathfrak{p} = \mathrm{Ann}(m)$, then m is nonzero in $M_{\mathfrak{p}}$, so $M_{\mathfrak{p}}$ is nonzero, i.e. $\mathfrak{p} \in \mathrm{Supp}(M)$.

For the second assertion, we first prove for M finite, and then write any module as sum of finite submodules, and use the fact Supp and ass are all unions of those of the submodules. Cf.[Sta]05C4 0588.**?** □

Prop. (4.2.5.17) [Weakly Associated Primes and Zero-divisors]. Let M a R-module, then the union of the weakly associated primes of M is the set of zero-divisors in M.

Proof: Elements in associated points are zero-divisors obviously, and conversely, if $xm = 0$, then $x \in \mathrm{Ann}(m)$ and $\mathrm{Ann}(m)$ has an associated point $\mathfrak{q}$ by(4.2.5.16). Now x must be in $\mathfrak{q}$ and $\mathfrak{q}$ is also an associated point of M by(4.2.5.16). Cf.[Sta]05C3**?** □

Cor. (4.2.5.18). Use the prime avoidance(4.1.1.4), we can prove if R is Noetherian and M is a finite R-module, then $I \subset \mathfrak{p}$ for some $\mathfrak{p} \in WeakAss(M)$ iff I consists of zero-divisors.

Prop. (4.2.5.19) [Associated Primes and Maps]. For a ring map $\varphi : R \to S$ and a S-module M, then

$$\mathrm{Spec}(\varphi)(Ass_S(M)) \subset Ass_R(M) \subset WeakAss_R(M) \subset \mathrm{Spec}(\varphi)(WeakAss_S(M)).$$

Equalities hold if S is Noetherian. Also $WeakAss_R(M) = \mathrm{Spec}(\varphi)(WeakAss_S(M))$ if φ is a finite ring map.

Proof: Cf.[Sta]05C7, 05E1.

We prove it is equal. If $\mathfrak{p} = \mathrm{Ann}_R(m)$, then we let $I = \mathrm{Ann}_S(m)$, then $R/\mathfrak{p} \subset S/I \subset M$, so by(4.1.7.25), there is a minimal prime of S over I that are mapped to $\mathfrak{p}$, now this prime is in $Ass(S/I)$ by(4.2.5.16) and also in $Ass_S(M)$ by(4.2.5.14). □

Prop. (4.2.5.20) [Associated Primes and Localization]. Let $\varphi : \operatorname{Spec} S^{-1}A \to \operatorname{Spec} A$ and M an A-module, then

$$\mathrm{Ass}_A(S^{-1}M) = \mathrm{Spec}(\varphi)(\mathrm{WeakAsso}_{S^{-1}A}(S^{-1}M)) = \mathrm{WeakAsso}_A(M) \cap \varphi(\mathrm{Spec}(S^{-1}R)).$$

Proof: Cf.[Sta]05C9**?**.

The first equality is by(4.2.5.19). For the second, if $\mathrm{Ann}_A(x) = \mathfrak{p}$ and $\mathfrak{p} \cap S = \varnothing$, then $\mathrm{Ann}_{S^{-1}A}(x/1) = S^{-1}(\mathfrak{p})$. Conversely, if $\mathrm{Ann}_{S^{-1}A}(x/s) = S^{-1}\mathfrak{p}$, then $\mathfrak{p} \cap S = \varnothing$, and $\mathrm{Ann}_A(x) \subset S^{-1}\mathfrak{p} \cap A = \mathfrak{p}$. □

Cor. (4.2.5.21) [Associated Primes are Stalkwise]. Let R be a ring and M an R-module, $\mathfrak{p} \subset R$, then the following are equivalent:

- $\mathfrak{p} \subset WeakAss(M)$.
- $\mathfrak{p}R_{\mathfrak{p}} \subset WeakAss(M_{\mathfrak{p}})$.
- $M_{\mathfrak{p}}$ contains some element m that $\sqrt{Ann(m)} = \mathfrak{p}R_{\mathfrak{p}}$.

Proof: $1 \to 2$: $\mathfrak{p}$ is a minimal prime of $I = Ann(m)$ for some $m \in M$, so $I_{\mathfrak{p}}$ is the minimal prime of $Ann(m) \subset R_{\mathfrak{p}}$.

$2 \to 3$: As $\mathfrak{p}R_{\mathfrak{p}}$ is the maximal prime, it is the only prime over $Ann(m)$, so $\mathfrak{p}R_{\mathfrak{p}} = \sqrt{Ann(m)}$.

$3 \to 1$: This means there are some $m \in M$ that $\sqrt{I_{\mathfrak{p}}} = \mathfrak{p}R_{\mathfrak{p}}$, which means that $\mathfrak{p}$ is a minimal prime over $Ann(m)$. □

Prop. (4.2.5.22). If M is an R-module, then $M \to \prod_{\mathfrak{p} \subset WeakAss(M)} M_{\mathfrak{p}}$ is injective.

Proof: Cf.[Sta]05CB.

If $m \neq 0 \in M$, there is an associated prime $\mathfrak{p}$ of Rm(4.2.5.16), then it is an associated prime of M, and then $(x)_{\mathfrak{p}} \subset M_{\mathfrak{p}}$ is not zero. □

Def. (4.2.5.23) [Embedded Primes]. A non-minimal prime in $Ass_R(M)$ is called a **embedded prime**. Equivalently, it is an associated point that is not a generic point of $\mathrm{Supp}(M)$.

Prop. (4.2.5.24). For a reduced ring R, $WeakAss_R(R)$ is just the set of minimal primes of R.

Proof: Cf.[Sta]0EMA. □

Cor. (4.2.5.25) [Reduced Ring No Embedded Primes]. A reduced ring has no embedded primes, because it has no nilpotent elements. Hence all its associated primes are just the minimal primes.

Def. (4.2.5.26) [Unmixed Ideals]. I is called **unmixed** if primes in $\mathrm{Ass}(A/I)$ all have the same height. In particular, they don't contain each other.

Primary Decomposition

Def. (4.2.5.27). For R Noetherian, a R-module M is called **coprimary** iff it has only one associated primes. A submodule N of M is called p**-primary** iff $Ass(M/N) = \{p\}$. A ring is called p**-primary** iff (0) is p-primary.

Notice coprimary is equivalent to the following: if $a \in A$ is a zero divisor for M, then for each $x \in M$, there is a n that $a^n x = 0$, i.e. **locally nilpotent**. And for ideals in a Noetherian ring, this is equivalent to $r(I)$ is a prime.

Proof: If M is p-primary, if $x \in M$ is nonzero, then $Ass(Rx) = \{p\}$, so p is the unique minimal element of $\mathrm{Supp}(Rx) = V(\mathrm{Ann}(x))$ by(4.2.5.16). So p is the radical of $\mathrm{Ann}(x)$, i.e. $a^n x = 0$ for some n(4.2.6.2).

Conversely, we know the ideal p of locally nilpotent elements equals the union of the associated primes(4.2.5.17), so if $q \in AssM = \mathrm{Ann}(x)$, then by definition, $p \subset q$. So $p = q$, and thus $AssM = \{p\}$. □

Lemma (4.2.5.28). A primary ring has no nontrivial idempotent element, because e and $1-e$ will all belong to the same minimal ideal p.

Lemma (4.2.5.29). The intersection of p-primary submodules are p-primary. (Because there is a injection $M/Q_1 \cap Q_2 \to M/Q_1 \oplus M/Q_2$).

Lemma (4.2.5.30) [Associated Prime and Primary Decomposition]. If $N = \cap Q_i$ is an irredundant primary decomposition and if Q_i belongs to p_i, then we have $Ass(M/N) = \{p_1, \ldots, p_r\}$.

Proof: There is a injection $M/N \to M/Q_1 \oplus \ldots M/Q_r$ which shows $Ass(M/N) \subset \{p_1, \ldots, p_r\}$. And for the inverse, notice $Q_2 \cap \ldots \cap Q_r/N$ is a submodule of M/Q_1, which shows $Ass(Q_2 \cap \ldots \cap Q_r/N) = \{p_1\}$ by(4.2.5.16). □

Prop. (4.2.5.31). If N is a p-primary submodule of a R-module M, and p' is a prime ideal, then

- $N_{p'} = M_{p'}$ if $p \not\subset p'$.
- $N = M \cap N_{p'}$ if $p \subset p'$.

Proof: $M_{p'}/N_{p'} = (M/N)_{p'}$, and $Ass((M/N)_{p'}) = Ass(M/N) \cap \{\text{primes contained in } p'\} = \varnothing$ by(4.2.5.20). So $M_{p'} = M_{p'}$ by(4.2.5.16).

For the second, notice it suffices to show $M/N \to M_{p'}/N_{p'}$ is injective. But this is because $A - p'$ contains no nonzero-divisor, by(4.2.5.17). □

Cor. (4.2.5.32) [Second Uniqueness of Primary Decomposition]. For an irredundant primary decomposition $N = \cap Q_i$, if Q_1 corresponds to p_1 and p_1 is minimal in $Ass(M/N)$, then $Q_1 = M \cap N_{p_1}$. In particular, the minimal prime part of a irredundant primary decomposition is uniquely determined.

Proof: By the above proposition, there are elements u_i of Q_i, i$\neq 1$ that are mapped to units in M_{p_1}, so $Q_1 \cdot u_2 u_3 \ldots u_r$ is mapped onto the image of $Q_1 \to M_{p_1}$. Then $Q_1 = M \cap (Q_1)_{p_1} = M \cap N_{p_1}$. □

Prop. (4.2.5.33). If R is Noetherian and M is a R-module, there are p-primary submodules $Q(p)$ for each $p \in \mathrm{Ass}M$ that $(0) = \bigcap_{p \in \mathrm{Ass}M} Q(p)$.

Proof: For a $p \in AssM$, we seek $Q(p)$ to be the maximal submodule N that $p \notin AssN$. This has a maximal ideal because of Zorn and the fact $Ass(\cup N_\lambda) = \cup Ass(N_\lambda)$. Then We have $\mathrm{Ass}(M/Q(p)) = \{p\}$, otherwise there is another p', then there is a $Q'/Q(p) \cong A/p'$. Now Q' is bigger than $Q(p)$. Finally, $(0) = \bigcap_{p \in \mathrm{Ass}M} Q(p)$ because it has no associated primes. □

Cor. (4.2.5.34)[Primary Decomposition]. If M is f.g. over a Noetherian ring R, then any submodule has a primary decomposition. (Notice M has only f.m. associated primes).

Def. (4.2.5.35) [Symbolic Power]. For a prime ideal $\mathfrak{p}$ in a Noetherian ring, The n-th **symbolic power** $\mathfrak{p}^{(n)}$ is defined to be the $\mathfrak{p}$-primary component of $\mathfrak{p}^n$, who has only one minimal prime(hence one associated prime). The symbolic power is giving by $\mathfrak{p}^n A_\mathfrak{p} \cap A$ by(4.2.5.32).

6 Jacobson Radical and Nilradical

Nilradical

Def. (4.2.6.1)[Nilradical]. The **nilradical** of a commutative ring R is defined to be the ideal consisting of nilpotent elements.

Prop. (4.2.6.2). The nilradical $\mathfrak{n}$ of a ring A(4.2.6.1) is the intersection of all prime ideals.

Proof: Every nilpotent element is contained in every prime, and if a is not nilpotent, then the localization A_a is nonzero, hence there is a maximal ideal, i.e. there is a prime of A not containing a. □

Cor. (4.2.6.3). In particular, $\operatorname{Spec} A/\mathfrak{n} \to \operatorname{Spec} A$ is a homeomorphism, and $A \to A/\mathfrak{n}$ induces a bijection on idempotents and units.

Jacobson Ring

Def. (4.2.6.4) [Jacobson Ring]. A commutative ring is called **Jacobson** if every prime ideal is an intersection of maximal ideals. In particular, the Jacobson radical equals the nilradical. This is equivalent to every radical ideal is an intersection of maximal primes.

Prop. (4.2.6.5). R is Jacobson iff $\operatorname{Spec} R$ is Jacobson space(3.11.3.21). In particular, the closed pts are dense in any closed subsets (Hilbert's Nullstellensatz satisfied).

Proof: We need to show that a locally closed subset contains a closed pt, we assume this set is of the form $V(I) \cap D(f)$, I is radical, then $f \notin I$, then by the condition, there is a $I \subset \mathfrak{m}$ that $f \notin \mathfrak{m}$, thus the result.

Conversely, for a radical ideal, let $J = \cap_{I \subset \mathfrak{m}} \mathfrak{m}$, then J is radical and $V(J)$ is the closure of $V(I) \cap X_0$, $V(I) = V(J)$, and because they are both radical, $I = J$. □

Cor. (4.2.6.6). Being Jacobson is a local property, and quotient of Jacobson ring is Jacobson, and maximal ideals of R_f are maximal in R. (Immediate from(4.2.6.5)(3.11.3.22) and(3.11.3.23)).

Prop. (4.2.6.7). If a Jacobson ring A has f.m. maximal ideals, then it is the product of its localizations at maximal primes and $\dim A = 0$.

Proof: Any prime ideal $\mathfrak{p}$ is a finite intersection of maximal ideals, so it equals one of them, so $\dim A = 0$. Now $A/I = \oplus A/\mathfrak{m}_i$ by Chinese remainder theorem, so $\operatorname{Spec} A/I$ is discrete with n pts, so by(4.1.7.8) there are n idempotents e_i that $e_i \equiv \mathfrak{d}_{ij} \mod \mathfrak{m}_j$, $\sum e_i = 1$. Thus $R = \prod Re_i$. And Re_i is just the localization at a maximal prime. □

Lemma (4.2.6.8). If R is a Jacobson domain and $R \subset K$ where K is a field, and K is f.g. over R, then R is a field and K/R is a finite field extension.

Proof: By induction, it suffices to consider the monogenic case $A = R[a]$. So a is algebraic over quotient field of R because A is a field. Let $\sum r_i t^i$ be a polynomial satisfied by a, and let $\mathfrak{m}$ be a maximal ideal of R that $r_n \notin R$(exists because $\operatorname{rad} R = 0$). Then Nakayama says $\mathfrak{m}A \not\subset A$. Then $\mathfrak{m} = 0$ because A is a field, hence R is a field. □

Lemma (4.2.6.9). Let $R \subset A$ be commutative domains s.t. A is f.g. over R, then $\operatorname{rad} A = 0$ if $\operatorname{rad} R = 0$.

Proof: By induction, it suffices to consider the case $A = R[a]$. If a is transcendental over quotient field of R, then we finish by(2.4.2.12). Now assume a is algebraic over quotient field of R, let $\sum r_i t^i, \sum s_i t^i$ be the polynomials satisfied by a, b of minimal degrees, then $s_0 = -\sum_{i=1}^m s_i b^i \neq 0 \in \operatorname{rad} A$, and $r_n s_0 \neq 0$.

From the fact $\operatorname{rad} R = 0$, we can find a maximal ideal $\mathfrak{m}$ that $r_n s_0 \notin \mathfrak{m}$. Then Nakayama says

$$\mathfrak{m} \cdot S^{-1}A \subsetneq S^{-1}A.$$

In particular, $\mathfrak{A} \subsetneq A$. Choose a maximal ideal of A containing $\mathfrak{m}A$, then it cannot contain s_0, contradicting $s_0 \in \operatorname{rad} A$. □

Prop. (4.2.6.10) [Generalized Nullstellensatz]. If R is Jacobson and S is a finitely generated R-algebra, then:

- S is Jacobson.
- The maximal ideal of S intersect with R a maximal ideal, and the quotient ring extension is finite, (in particular algebraic).

In particular, a f.g. algebra over a ring of dimension 0, (e.g. Artinian ring or field) is Jacobson.

Proof: To show S is Jacobson, consider for any prime $\mathfrak{p} \subset A$, $A/\mathfrak{p}$ is a f.g. domain over $R/\mathfrak{p} \cap R$. Because R is Jacobson, $\operatorname{rad}(R/\mathfrak{p} \cap R) = 0$, so $\operatorname{rad}(A/\mathfrak{p}) = 0$, by(4.2.6.9). And this shows A is Jacobson.

If $\mathfrak{m}$ is maximal in S, then $R/\mathfrak{m} \cap R \to S/\mathfrak{m}$ satisfies the condition of(4.2.6.8), by(4.2.6.6), so the first two assertions are proved. □

Cor. (4.2.6.11). If R is Jacobson and $S \in \mathcal{CA}\mathrm{lg}^{\mathrm{fg}}(R)$ is reduced, then $\cap_{\mathfrak{m} \subset R \text{ maximal}} \mathfrak{m}S = 0$.

Proof: This is because

$$\bigcap_{\mathfrak{m} \subset R \text{ maximal}} \mathfrak{m}S \subset \bigcap_{\mathfrak{M} \subset S \text{ maximal}} (\mathfrak{M} \bigcap R)S \subset \bigcap_{\mathfrak{M} \subset S \text{ maximal}} \mathfrak{M} = 0.$$

□

Zariski Pairs

Def. (4.2.6.12)[Zariski Pairs]. A pair (A, I) is called a **Zariski pair** iff I is contained in the Jacobson radical of A.

Prop. (4.2.6.13). If (A, I) is a Zariski pair, then the map $A \to A/I$ induces a bijection between the idempotents.

Proof: idempotents are determined by the maximal ideals that it vanishes(4.1.7.6), and $A \to A/I$ induces a bijection on the maximal ideals. □

7 Dedekind Domains

Def. (4.2.7.1)[Dedekind Domain]. A **Dedekind domain** is an integrally closed Noetherian domain of dimension 1. A UFD is a Dedekind domain by(4.3.5.2).

Prop. (4.2.7.2) [Characterizing]. For a domain R, the following are equivalent:

1. R is a Dedekind domain.

2. R is Noetherian and each $R_{\mathfrak{m}}$ is DVR for any maximal ideal $\mathfrak{m}$.
3. each ideal of R can be written as a product of prime ideals uniquely.

Proof: $1 \iff 2$ as normal is a stalkwise and(4.3.5.20).

$3 \to 2$: If 3 is true, then $\mathfrak{p} \neq \mathfrak{p}^2$ for each prime $\mathfrak{p}$, so choose $x \in \mathfrak{p} - \mathfrak{p}^2$, then for each $y \in \mathfrak{p}$, $(x, y) = \prod p_i$, then exactly one p_i(may assume p_1) is contained in p, so $(x, y)R_p = p_1 R_p$. Now in fact $(x)R_p = p_1 R_p$, because $(x, y^2)R_p$ is also a prime, so $y = ax + by^2$ in R_p, $(1 - by)y = ax \in (x)R_p$ is a prime, so $y \in (x)R_p$. This is for all $y \in p$, so $(x)R_p = p_1 R_p$.

Now if $(x) = \mathfrak{p}_1 \cdots p_r$, then $p_1 R_p = pR_p$, so $p_1 = p$, and p is f.g. by the lemma(4.2.7.3) below. $\mathfrak{p}$ is arbitrary, so R is Noetherian and $R_{\mathfrak{m}}$ is DVR for $\mathfrak{m}$ maximal, by(4.3.5.20).

$1 \to 3$: if 1 is true, then any ideal is a unique intersection of primary ideals, and primary ideals are their radical are different, so they are coprime(4.1.1.7), so this is in fact a unique decomposition into products of primary ideals. And any primary ideal is a power of its radical, because this is the case after localization. □

Lemma (4.2.7.3). I, J be ideals in a ring A and $IJ = (f)$ where f is a non-zero-divisor, then I, J are f.g. and finitely locally free of rank 1 as A-modules.

Proof: The second assertion implies the first, by(4.3.1.7). $f = \sum x_i y_i$, and $x_i y_i = a_i f$, so $\sum a_i = 1$ as f is non-zero-divisor. Now we show I_{a_i} as J_{a_i} is free of rank 1. Now after localization, $f = xy$, so x, y are non zero divisors. Now if $x' \in I$, then $x'y = af = axy$ for some a, so $x' = ax$. □

Fractional Ideals

Def. (4.2.7.4) [Fractional Ideals]. For A an integral domain and K its quotient field, then an A-submodule M of K is called a **fractional ideal** if $xM \subset A$ for some $x \neq 0$.

Every f.g. submodule in K is a fractional ideal, and if A is Noetherian, then the converse is true, because it is of the form $x^{-1}\mathfrak{a}$.

Prop. (4.2.7.5). An A-submodule M of K is called an **invertible ideal** if there is a submodule N that $MN = A$. It follows that M, N are f.g., because there are $\sum x_i y_i = 1$, so M is generated by x_i and N is generated by y_i.

Prop. (4.2.7.6). Invertibility is a stalkwise property.

Proof: Notice $(A : M)_{\mathfrak{p}} = (A_{\mathfrak{p}} : M_{\mathfrak{p}})$, and M is invertible iff $M(A : M) = A$. Then use the fact isomorphism is stalkwise(4.1.4.2). □

Prop. (4.2.7.7). A local domain is a DVR iff every non-zero fractional ideal of A is invertible.

Proof: If is a DVR, let $\mathfrak{m} = (x)$, for any fractional ideal $M<$ let $yM \subset A = (x^r)$, then $M = (x^{r-s})$, where $v(y) = s$. Conversely, if every non-zero fractional ideal of A is invertible, then they are all f.g.(4.2.7.5), so A is Noetherian. Now it suffices to prove that every ideal of A is a power of $\mathfrak{m}$, by(4.3.5.20). If this is not true, choose a maximal element $\mathfrak{a}$ in the set of ideals that is not a power of $\mathfrak{m}$(by Noetherian), then $\mathfrak{m}^{-1}\mathfrak{a} \subset \mathfrak{m}^{-1}\mathfrak{m} = A$, and $\mathfrak{m}^{-1}\mathfrak{a} \supset \mathfrak{a}$, but it is not $\mathfrak{a}$, so $\mathfrak{m}^{-1}\mathfrak{a} = \mathfrak{m}^k$ for some k, so $\mathfrak{a} = \mathfrak{m}^{k+1}$, contradiciton. □

Cor. (4.2.7.8) [Dedekind Domain Fractional Ideals are Invertible]. An integral domain is a Dedekind domain iff every non-zero fractional ideal is invertible.

Proof: Immediate from the proposition and(4.2.7.2)(4.2.7.6). □

Def. (4.2.7.9) [Class Group]. Let $\mathcal{O}$ be a Dedekind domain, we denote $\mathrm{Cl}(\mathcal{O})$ the Abelian group of fractional ideals of $\mathcal{O}$ modulo principal fractional ideals, called the **class group** of $\mathcal{O}$.

Prop. (4.2.7.10) [Localizations of Dedekind Domains]. Let $(\mathcal{O}, F)$ be a Dedekind domain and $S \subset \operatorname{Spec} \mathcal{O}$ be a finite subset of maximal ideals of $\mathcal{O}$, let $\mathcal{O}_S$ denote the localization of $\mathcal{O}$ at all such $\mathfrak{p}_i$. Then there is an exact sequence of Abelian groups:

$$1 \to \mathcal{O}^* \to \mathcal{O}_S^* \to \bigoplus_{\mathfrak{p}\in S} F^\times/\mathcal{O}_\mathfrak{p}^* \to \mathrm{Cl}(\mathcal{O}) \to \mathrm{Cl}(\mathcal{O}_S) \to 1.$$

Proof: The only non-trivial map is the map $\bigoplus_{\mathfrak{p}\in S} F^*/\mathcal{O}_\mathfrak{p}^* \to \mathrm{Cl}(\mathcal{O})$ given by $(\overline{a_\mathfrak{p}})$ mapsto $\prod_{x\in S} \mathfrak{p}^{v_\mathfrak{p}(a_v)}$. □

Extensions of Dedekind Domains

References are[Neu99]Chap1.8..

Prop. (4.2.7.11) [Krull-Akizuki]. If A is a Noetherian domain of dimension 1 with fraction field K and L/K is a finite field extension, then the integral closure B of A in L is a Dedekind domain with fraction field L, and $\operatorname{Spec} B \to \operatorname{Spec} A$ is surjective, and have finite fibers and induces finite residue field extension.

Proof: Cf.[Sta]09IG or [Neu99]P77.**?** □

Cor. (4.2.7.12). The integral closure of a Dedekind domain in a finite extension fields of its quotient fields is again a Dedekind domain.

Def. (4.2.7.13) [Situation]. Let $\mathcal{O}_K$ be a Dedekind domain with quotient field K, L/K a finite field extension, and $\mathcal{O}_L$ the integral closure of $\mathcal{O}_K$ in L, which is also a Dedekind domain by(4.2.7.11).

Prop. (4.2.7.14). In situation(4.2.7.13), if $\alpha_1, \ldots, \alpha_n$ is a basis of L/K that is contained in $\mathcal{O}_L$, and $d = d(\alpha_1, \ldots, \alpha_n)$, then

$$d\mathcal{O}_L \subset \mathcal{O}_K\{\alpha_1, \ldots, \alpha_n\}.$$

Proof: For any $\alpha = a_1\alpha_1 + \ldots + a_n\alpha_n \in \mathcal{O}_L, a_i \in K$, α satisfies the following equations

$$\mathrm{tr}_{L/K}(\alpha_i\alpha) = \sum_j \mathrm{tr}_{L/K}(\alpha_i\alpha_j)a_j$$

for any i. Notice $\mathrm{tr}(\alpha_i\alpha) \in \mathcal{O}_K$, so $da_j \in \mathcal{O}_K$ by linear algebra. □

Prop. (4.2.7.15). In situation(4.2.7.13), if L/K is separable and $\mathcal{O}_K$ is a PID, then every f.g. $\mathcal{O}_L$-module in L is a free $\mathcal{O}_K$-module of rank $[L : K]$. In particular, $\operatorname{rank}_{\mathcal{O}_K} \mathcal{O}_L = [L : K]$.

Proof: Let $\alpha_1, \ldots, \alpha_n$ be a basis of L/K that is contained in $\mathcal{O}_L$, and let $d = d(\alpha_1, \ldots, \alpha_n) \neq 0$ by(2.2.5.34), then by(4.2.7.14), $d\mathcal{O}_L \subset \mathcal{O}_K\{\alpha_1, \ldots, \alpha_n\}$. Notice any generator of the torsion-free module $\mathcal{O}_L$ over $\mathcal{O}_K$ is a generator of the field L/K, so $\operatorname{rank}_{\mathcal{O}_K} \mathcal{O}_L \geq [L : K]$. Now if $M \subset L$ is a free $\mathcal{O}_L$-module with a set of generators $\mu_1, \ldots, \mu_r$, then we can take $a \in \mathcal{O}_K$ s.t. $a\mu_i \in \mathcal{O}_L$. Then

$$adM \subset d\mathcal{O}_L \subset \mathcal{O}_K\{\alpha_1, \ldots, \alpha_n\}.$$

And then

$$[L : K] \leq \operatorname{rank}_{\mathcal{O}_K} \mathcal{O}_L \leq \operatorname{rank}_{\mathcal{O}_K} M = \operatorname{rank}_{\mathcal{O}_K}(adM) \leq [L : K].$$

and the assertion follows. □

Prop. (4.2.7.16) [Integral Basis of Joins]. In situation(4.2.7.13), if $L/K, L'/K$ are two Galois extensions in $\overline{K}$ s.t. $L\cap L' = K$, and let $\omega_1,\ldots,\omega_n$(resp. $\omega_1',\ldots,\omega_{n'}'$) be an integral basis of L/K(resp. L'/K) with discriminants d(resp. d'). Suppose that $(d,d') = \mathcal{O}_K$, then $\omega_i\omega_j'$ is an integral basis of LL'/K with discriminant $d^{n'}(d')^n$.

Proof: The hypothesis implies that $[LL':K] = nn'$, so $\{\omega_i\omega_j'\}$ is a basis of LL'/K that is integral. To show it is an integral basis, if $\alpha = \sum_{i,j} a_{ij}\omega_i\omega_j' \in \mathcal{O}_{LL'}$, we need to show that $a_{ij}\in\mathcal{O}_K$. Let $\beta_i = \sum a_{ij}\omega_i$, and let $\mathrm{Gal}(LL'/L') = \{\sigma_1,\ldots,\sigma_n\}, \mathrm{Gal}(LL'/L) = \{\sigma_1',\ldots,\sigma_{n'}'\}$,

$$T = (\sigma_i'\omega_j')_{i,j},\quad \underline{a} = (\sigma_1'\alpha,\ldots,\sigma_{n'}'\alpha)^t,\quad \underline{b} = (\beta_1,\ldots,\beta_{n'})^t,$$

then $\det(T)^2 = d'$, and $\underline{a} = T\underline{b}$. So $\det(T)\underline{a} = T^*\underline{b}$ has integral entries, and $d'b$ is integral. Thus $d'a_{ij}\in\mathcal{O}_K$ for each i,j. Dually, $da_{ij}\in\mathcal{O}_K$. Thus by hypothesis, $a_{ij}\in\mathcal{O}_K$.

To calculate the discriminant,

$$d = d(\{\omega_i\omega_j'\}) = \det(\{\sigma_k\sigma_l'\omega_i\omega_j'\}_{k,\ell,i,j})^2 = \det((\sigma_k\omega_i)_{k,i}\otimes(\sigma_l'\omega_j')_{l,j})^2 = \det((\sigma_k\omega_i)_{k,i})^{2n'}\det((\sigma_l'\omega_j')_{l,j})^{2n} = d^{n'}(d')^n.$$

□

Def. (4.2.7.17) [Conductors]. Let $R\subset S\in \mathcal{CR}\mathrm{ing}$ the **conductor of** R in S is defined to

$$\mathfrak{c} = \{\alpha\in R|\alpha S\subset R\}.$$

And if (R,K) is an integral domain, the **conductor of** R is defined to be the conductor of R in the integral closure of R w.r.t. K.

Prop. (4.2.7.18). Let R be a Noetherian integral domain with integral closure S, then the conductor of R in S is nonzero iff S is f.g. as a R-module.

Proof: This follows from(4.2.7.4). □

Def. (4.2.7.19) [Conductors of an Element]. In situation(4.2.7.13) and $\alpha\in\mathcal{O}_L$, then the **conductor of** α w.r.t K is the conductor of $\mathcal{O}_K[\alpha]$ in $\mathcal{O}_L$, denoted by $\mathfrak{d}(\alpha)$. It is non-zero by(4.2.7.4) as $\mathcal{O}_L$ is f.g. over $\mathcal{O}_K[\alpha]$.

Prop. (4.2.7.20) [Inertia and Ramification]. Situation as in(4.2.7.13), let $\mathfrak{p}$ be a maximal prime of $\mathcal{O}_K$, then $\mathfrak{p}\mathcal{O}_L\cap\mathcal{O}_L$ by(4.2.1.5). Let $\mathfrak{p}\mathcal{O} = \prod_i \mathfrak{P}_i^{e_i}$ be a decomposition. Denote e_i the **ramification degree** of $\mathfrak{P}_i$ over $\mathfrak{p}$, and $f_i = [\mathcal{O}_L/\mathfrak{P}_i : \mathfrak{O}_K/\mathfrak{p}]$ the **inertia degree** of $\mathfrak{P}_i$ over $\mathfrak{p}$.

Prop. (4.2.7.21) [Fundamental Identity]. Situation as in(4.2.7.13), if $\mathcal{O}_L$ is a finite $\mathcal{O}_K$-module, then for any $\mathfrak{p} = \prod_i \mathfrak{P}_i^{e_i}$,

$$\sum e_i f_i = [L:K].$$

In particular, this applies to the case that L/K is separable.

Proof: By hypothesis, $\mathcal{O}_{L,\mathfrak{p}}$ is a finite $\mathcal{O}_{K,\mathfrak{p}}$-module of rank $[L:K]$, thus $\mathcal{O}_L/\mathfrak{p}$ is an $\mathcal{O}_K/\mathfrak{p}\mathcal{O}_L$-module of rank n. Notice there is an isomorphism $\mathcal{O}_L/\mathfrak{p}\mathcal{O}_L\cong\prod_i \mathcal{O}_L/\mathfrak{P}_i^{e_i}$, thus

$$[L:K] = \sum_i \dim_{\mathcal{O}_L/\mathfrak{p}}\mathcal{O}_L/\mathfrak{P}_i^{e_i} = \sum_i e_i f_i.$$

If L/K is separable, let $\{\alpha_1,\ldots,\alpha_n\}$ be a basis of L/K with $\alpha_i\in\mathcal{O}_K$, then as $d(\alpha_1,\ldots,\alpha_n)\neq 0$ by(2.2.5.34), $\mathcal{O}_L\subset d^{-1}(\alpha_1\mathcal{O}_K+\ldots+\alpha_n\mathcal{O}_K)$ by(4.2.7.14). So it is a finite $\mathcal{O}_K$-module, as $\mathcal{O}_K$ is Noetherian. □

Prop. (4.2.7.22) [Decompositions in a Galois Extension]. Situation as in(4.2.7.13), if L/K is Galois, then for any $\mathfrak{p} \in \mathrm{Spec}(\mathcal{O}_K)$, $\mathrm{Gal}(L/K)$ acts transitively on the set of primes over $\mathfrak{p}$.

Proof: If $\mathfrak{P}, \mathfrak{P}'$ are two primes over $\mathfrak{p}$ but $\mathfrak{P}' \neq \sigma\mathfrak{P}$ for any $\sigma \in \mathrm{Gal}(L/K)$, then by Chinese remainder theorem, there exists $x \in \mathcal{O}_L$ s.t.

$$x \equiv 0 \mod \mathfrak{P}', \quad x \equiv 1 \mod \sigma\mathfrak{P}, \forall \sigma \in \mathrm{Gal}(L/K).$$

But then $\mathrm{Nm}_{L/K}(x) = \prod_{\sigma \in \mathrm{Gal}(L/K)} \sigma(x) \in \mathfrak{P}' \cap \mathfrak{O}_K = \mathfrak{p}$, but none of $\sigma(x)$ is in $\mathfrak{P}$, so $\prod_{\sigma \in \mathrm{Gal}(L/K)} \sigma(x) \notin \mathfrak{P} \cap \mathcal{O}_K = \mathfrak{p}$, contradiction. □

Thm. (4.2.7.23) [Dedekind-Kummer]. Situation as in(4.2.7.13), suppose $L = K(\theta)$, where $\theta \in \mathcal{O}_L$ has minimal polynomials $p(X) \in \mathcal{O}_K[X]$(such a θ exists if L/K is separable, by(2.2.5.20)). Let $\mathfrak{d}$ be the conductor of θ, then for any prime ideal $\mathfrak{p}$ of $\mathcal{O}_K$ prime to $\mathfrak{d}$, let

$$\overline{p}(X) = \prod_i \overline{p}_i(X)^{e_i}$$

be the decomposition of $\overline{p}(X)$ into irreducible factors in $\mathcal{O}_K/\mathfrak{p}[X]$, where $\mathfrak{p}_i(X) \in \mathcal{O}_K[X]$ are monic polynomials, then

- $\mathfrak{P}_i = \mathfrak{p}\mathcal{O} + p_i(\theta)\mathcal{O}_L$ are different primes ideals in $\mathcal{O}_L$.
- $\mathfrak{p}\mathcal{O}_L = \prod_i \mathfrak{P}_i^{e_i}$.
- The inertia degree f_i equals $\deg(\overline{p}_i(X))$.

Proof: Cf.[Neu99]P48. □

Def. (4.2.7.24) [Ramification Notations]. Situation as in(4.2.7.20), let $\mathfrak{p}\mathcal{O} = \prod_i \mathfrak{P}_i^{e_i}$, then

- **splits completely in** L if $r = [L : K]$.
- $\mathfrak{p}$ is **non-split in** L if $r = 1$.
- $\mathfrak{P}_i$ is **unramified over** $\mathfrak{p}$ if $e_i = 1$ and the residue fields extension $(\mathcal{O}_L/\mathfrak{P}_i)/(\mathcal{O}_K/\mathfrak{p})$ is separable.
- $\mathfrak{P}_i$ is **ramified in over** $\mathfrak{p}$ if it is not unramified over $\mathfrak{p}$.
- $\mathfrak{P}_i$ is **totally ramified over** $\mathfrak{p}$ if it is ramified over $\mathfrak{p}$ and $f_i = 1$.
- $\mathfrak{p}$ is called **unramified in** L if all $\mathfrak{P}_i$ are unramified over $\mathfrak{p}$.
- L/K is called a **unramified extension** if all primes of $\mathcal{O}_K$ are unramified.

Prop. (4.2.7.25) [Almost Every Prime is Unramified]. Situation as in(4.2.7.23), then a.e. prime $\mathfrak{p}$ of $\mathcal{O}_K$ is unramified in L, by(4.2.7.39).

Prop. (4.2.7.26). Situation as in(4.2.7.13), $\mathcal{O}_L \otimes_{\mathcal{O}_K} \mathcal{O}_{K,\mathfrak{p}} = \prod_i \mathcal{O}_{L,\mathfrak{P}_i}$.

Proof: Cf.[MIT notes, 11.7]. □

Prop. (4.2.7.27). If a prime $\mathfrak{p}$ splits completely in two separable extension LM of K, then it also splits completely in the composite LM.

Proof: We use the language of valuation. The extension of a valuation v of K corresponds to the set of equivalent classes of algebra map from L to $\overline{K_v}$ module conjugacy over K_v. So We only need to show that two different maps of LM are not conjugate over K_v. But the restrict of them to L or M is different, thus not conjugate over K_v by the assumption. □

Cor. (4.2.7.28). A prime splits completely in a separable extension L if it splits completely in the Galois closure N of L.

Proof: This is because the Galois closure is the composite of the conjugates of L. □

Differents and Discriminants

Def. (4.2.7.29) [Differents]. Let L/K be a finite separable field extension with separable residue field extension, and $\mathcal{O}_K$ is a Dedekind domain with integral closure $\mathcal{O}_L$ in L, there is a **trace form** on L: $(x,y)\to \mathrm{tr}(xy)$, which is non-degenerate.

We define the **dual module** for a fractional ideal I as $I^\vee = \{x\in L \,|\, \mathrm{tr}(xI)\in \mathcal{O}_K\}$. This is truly a fractional ideal because if $\alpha_i\in\mathcal{O}_L$ is a basis of L/K, and let $d=\det(\mathrm{tr}(\alpha_i\alpha_j))$, then for any $a\in I\cap\mathcal{O}_L$, $ad\cdot I^\vee\in\mathcal{O}_L$, because if $x=\sum x_i\alpha_i\in I^\vee$, then $\sum ax_i\,\mathrm{tr}(\alpha_i\alpha_j)=\mathrm{tr}(xa\alpha_j)\in\mathcal{O}_K$, so solve the equation shows $dax_i\in\mathcal{O}_K$.

The **different of** K/L is defined to be $\mathfrak{D}_{L/K}=((\mathcal{O}_L)^\vee)^{-1}$.

Prop. (4.2.7.30) [Properties of Differents]. Different is compatible with composition, localization w.r.t. a prime ideal and completion.

Proof: Cf.[Neu99]P195. □

Cor. (4.2.7.31). $\mathfrak{D}_{L/K}=\prod_{\mathfrak{P}}\mathfrak{D}_{L_{\mathfrak{P}}/K_{\mathfrak{p}}}$.

Prop. (4.2.7.32). If $\mathcal{O}_L=\mathcal{O}_K[\alpha]$, then $\mathfrak{D}_{L/K}=(f'(\alpha))$, where $f(X)=\mathrm{Irr}(\alpha,K;X)$.

Proof: By(2.2.5.30), if $f(X)/(X-\alpha)=\beta_0+\beta_1X+\ldots+\beta_{n-1}X^{n-1}$, then $\mathcal{O}_L^\vee = f'(\alpha)^{-1}(\beta_0,\ldots,\beta_{n-1})$. Now the result follows if $(\beta_0,\ldots,\beta_{n-1})=\mathcal{O}_L$, which is easy to see if we write β_i as polynomials of α. □

Cor. (4.2.7.33). If L/K is finite separable extension of local fields, then

$$v_L(\mathfrak{D}_{L/K})=\sum_{\sigma\in G,\sigma\neq 1} i_{L/K}(\sigma)=\int_{-1}^{\infty}(|G(L/K)_t|-1)dt.$$

Notation as in(12.2.2.22).

Prop. (4.2.7.34) [Different as Annihilator of Kähler Differential]. The different $\mathfrak{D}_{L/K}$ is the annihilator of $\Omega_{\mathcal{O}_L/\mathcal{O}_K}$.

Proof: It suffices to show the exact sequence

$$0\to\mathfrak{D}_{L/K}\to\mathcal{O}_L\to\Omega_{\mathcal{O}_L/\mathcal{O}_K},$$

but because exactness is stalkwise(4.1.4.2), we can localized at a maximal ideal, then by(12.2.2.2), $\mathcal{O}_L=\mathcal{O}_K[x]$ is monogenous, thus $\Omega_{\mathcal{O}_L/\mathcal{O}_K}$ is cyclic, and the annihilator of dx is $f'(x)$. So by(4.2.7.32) we are done. □

Prop. (4.2.7.35)[Ramification and Different]. A prime ideal $\mathfrak{P}$ of L is ramified over K iff $\mathfrak{P}\mid\mathfrak{D}_{L/K}$.

Let e be the ramification of $\mathfrak{P}$, then the power s of $\mathfrak{P}$ in $\mathfrak{D}_{L/K}$ is

$$\begin{cases} s=e-1 & \mathfrak{P}\text{ tamely ramified}\\ e\leq s\leq e-1+v_{\mathfrak{P}}(e) & \mathfrak{P}\text{ wildly ramified}\end{cases}.$$

Proof: Cf.[Neu99]P199. □

Def. (4.2.7.36)[Discriminants]. Let the situation the same as in(4.2.7.29), the **discriminant of** L/K is defined to be the set $\mathfrak{d}_{L/K}$ consisting of discriminants $d(\alpha_1,\ldots,\alpha_n)$(2.2.5.33) where α_i is a basis of L/K that $\alpha_i\in\mathcal{O}_L$.

Because $d(\alpha_1,\ldots,\alpha_n)\subset\mathcal{O}_K$ and $\mathrm{tr}_{L/K}$ is $\mathcal{O}_K$-linear, $\mathfrak{d}_{L/K}$ is an ideal of $\mathcal{O}_K$.

Prop. (4.2.7.37) [Differents and Discriminants].

$$\mathfrak{d}_{L/K}=N_{L/K}\mathfrak{D}_{L/K}.$$

Proof: Cf.[Neu99]P201. □

Cor. (4.2.7.38) [Compositions and Discriminants]. For a tower of fields $K\subset L\subset M$, we have

$$\mathfrak{d}_{M/K}=\mathfrak{d}_{L/K}^{[M:L]}N_{L/K}(\mathfrak{d}_{M/L}).$$

Proof: Apply $N_{M/K}=N_{L/K}N_{M/L}$ to the equation $\mathfrak{D}_{M/K}=\mathfrak{D}_{M/L}\mathfrak{D}_{L/K}$(4.2.7.30), we get

$$\mathfrak{d}_{M/K}=N_{L/K}(\mathfrak{d}_{M/L})N_{L/K}(\mathfrak{D}_{L/K}^{[M:L]})=N_{L/K}(\mathfrak{d}_{M/L})\mathfrak{d}_{L/K}^{[M:L]}.$$

□

Cor. (4.2.7.39) [Ramification and Discriminant]. Let L/K be a separable finite field extension, then a prime ideal $\mathfrak{p}$ of K ramifies in L iff $\mathfrak{p}|\mathfrak{d}_{L/K}$.

In particular, only f.m. primes are ramified in L/K, and the extension is unramified iff $\mathfrak{d}_{L/K}=1$.

Proof: This follows from(4.2.7.35) and(4.2.7.37). □

Cor. (4.2.7.40). $\mathfrak{d}_{L/K}=\prod_{\mathfrak{P}}\mathfrak{d}_{L_{\mathfrak{P}}/K_{\mathfrak{p}}}$.

Proof: This follows from(4.2.7.31) and(4.2.7.37). □

4.3 Commutative Algebra III

1 Projective

References are [Projective Modules], [Sta]and[Vak17].

Def. (4.3.1.1) [Projective Modules]. A module P over a ring R is called **projective** iff $\mathrm{Hom}(P,-)$ is exact, or equivalent, for any surjective map of modules $F \to Q \to 0$, $\mathrm{Hom}(P,F) \to \mathrm{Hom}(P,Q)$ is surjective.

Prop. (4.3.1.2). Localization and tensor product preserves projective because they are left adjoints.
And when tensoring f.f. map, then the converse is also true(4.4.2.1).

Prop. (4.3.1.3). A module over a ring is projective iff it is a direct summand of a free module, in particular, it is flat. Moreover, there is a free module Q that $P \oplus Q = F$ free.

Proof: For the second assertion, we can choose an arbitrary Q that $P \oplus Q$ free, and see $\bigoplus_{\mathbb{N}}(P \oplus Q)$ is free. □

Lemma (4.3.1.4). A projective module is a direct sum of countably generated projective modules.

Proof: This follows from(2.2.4.28). □

Prop. (4.3.1.5) [Projective over Local Ring]. A projective module P over a local ring R or a PID is free.

Proof: Local ring case: By(4.3.1.4) and(2.2.4.29), it suffices to show that any element x of P is contained in a free direct summand of P. Because P is projective, it is a direct summand of a free module F, $F = P \oplus Q$. Let B be a basis of F that the number of basis element in the expression of x is minimal. Let $x = \sum a_i e_i$. Then no a_i is contained in the ideal generated by other a_j, otherwise we can choose another basis to show this is minimal. Let $e_i = y_i + c_i$ be decompositions into P and Q components, and write $y_i = \sum a_{ij} e_i + t_i$, where t_i is combination of elements in B other than e_i. Now it suffices to show $\det(a_{ij})$ is invertible, because in this way $\{y_i\} \cup (B \backslash \{x_1\})$ is a basis of F and $x = \sum a_i y_i$ because $x \in P$. And $N = \mathit{span}\{y_i\}$ is a summand of P because $N \subset P$ and both N, P are summands of F.

To show $\det(a_{ij})$ is invertible, notice that by plugging $y_i = \sum b_{ij} e_j + t_i$ into $\sum a_i e_i = \sum a_i y_i$ shows $a_j = \sum a_i a_{ij}$, thus by the argument before, a_{ij} are non-invertible for $i \neq j$ and $1 - a_{ii}$ is non-invertible, so a_{ii} is invertible. Because R is a local ring, we can easily see $\det(a_{ij})$ is invertible.

PID case: directly from(2.2.4.21). □

Prop. (4.3.1.6). If R is a ring and I is nilpotent ideal and $\overline{P}$ is a projective R/I-module, then there exists a projective R-module P that $P/IP \cong \overline{P}$.

Proof: Cf.[Sta]P07LV. □

Finite Projective Modules

Prop. (4.3.1.7) [Finite Projective Modules]. Let M be a R-module, the following are equivalent:

1. M is finite projective.
2. M is f.p. and flat.

3. M is f.p. and all its localizations at (maximal)primes are free.
4. M is finite locally free.
5. M is finite and locally free.
6. M is finite and all its localizations at primes are free and the function $p \to \dim_{k(p)} M \otimes_R k(p)$ is a locally constant function on $\operatorname{Spec} R$.

Proof: $1 \to 2$: $M \otimes K = R^m$ for some K and m, so K is finite and $M = R^m/K$ is f.p. And M is flat because it is a summand of R^n(4.4.1.4).

$2 \to 4$: For any prime p, choose a basis for the $k(p)$-vector space $M \otimes k(p)$, then by Nakayama, their inverse image generate M_g for some $g \notin p$(2.2.4.8), and the kernel K of this generation is finite because M_g is f.p. And $K \otimes k(p) = 0$ by the flatness of M_g. Then by Nakayama again there is a $g' \notin p$ that $M_{gg'} = 0$(2.2.4.8).

$4 \to 3$: Because f.p. is local(4.1.4.4).

$3 \to 2$: Because flatness is trivial.

$4 \to 5$: Because finite is local(4.1.4.4).

$5 \to 4, 4 \to 6$: Trivial.

$6 \to 4$: Cf.[Sta]00NX.?

$2 + 3 + 4 + 5 + 6 \to 1$: Cf.[Sta]00NX.?

Consider the stalk, it is all free by(4.3.1.2) and(4.3.1.5), thus by(5.5.1.38), it is locally free. □

Cor. (4.3.1.8) [Partially Stalkwise]. If P is fo f.p., then finite projectiveness is a stalkwise property for P.

Cor. (4.3.1.9) [Projective and Flat]. A finite module over a Noetherian ring is projective iff it is flat.

Cor. (4.3.1.10). If M is finite projective, then the canonical map $\operatorname{Hom}(M, N) \otimes L \to \operatorname{Hom}(M, N \otimes L)$ is an isomorphism.

Proof: By proposition above M is f.p. and finite locally free, so by(4.3.7.7) and tensor commutes with localization, we can check locally, where M is finite free so the isomorphism is obvious. □

Def. (4.3.1.11) [Characteristic Polynomials for Finite Projective Modules]. Let M be a finite projective module over a ring A. then we can define a characteristic polynomial in $A[X]$ for any map of A-modules $M \to M$: if M is free, then this map is defined as usual. In general, we can find an open covering $\operatorname{Spec} A_{f_i}$ of $\operatorname{Spec} A$ that M_{f_i} is free over A_{f_i}. Thus we can define the characteristic polynomial locally and glue them together to get a characteristic polynomial in $A[X]$.

In particular, we can also define trace and norm of a A-module map $M \to M$. And when B is a locally free A-algebra, then there are trace and norm maps $\operatorname{tr} : B \to A$ and $Nm : B \to A$.

Prop. (4.3.1.12). Let R be a ring and I be a locally nilpotent ideal. If $\overline{P}$ is a finite projective module over R/I, then there exists a finite projective R-module P that $P/IP \cong \overline{P}$.

Proof: Cf.[Sta]0D47. □

Prop. (4.3.1.13). Let M be a R module and I a nilpotent ideal of R. If M/IM is a projective R/I-module and M is flat over R, then M is a projective R-module.

Proof: Cf.[Sta]05CG. □

Thm. (4.3.1.14) [Serre-Suslin]. Every finite projective module over the polynomial ring $k[x_1, \dots, x_n]$ is free.

Proof: Cf.[Lan05]P850.? □

Duality of Projective Modules

Prop. (4.3.1.15) [Basis Criterion of Projectiveness]. An A-module P is projective iff there are elements x_i in P and f_i in P^* that for any x, $f_i(x) = 0$ a.e. i, and $\sum f_i(x)x_i = x$. Moreover, P is finite projective iff there are f.m. of them.

Proof: If P is projective, as a summand of a free module, then we can choose the coordinates of the inclusion map as f_i, and choose the image of the quotient map of the coordinate as x_i. The converse is verbatim. □

Cor. (4.3.1.16) [Finite Projective Duality]. If P is projective, then $P \to P^{**}$ is injective, and if P is finite projective, then it is an isomorphism.

Proof: If $f(x) = 0$ for all $f \in P^*$, then the proposition says $x = 0$. And if P is finite projective, it can be seen x_i, f_i forms a "basis" of P^*(finiteness used), so f_i generate P^*, and similarly x_i generate P^*, so $P \to P^{**}$ is surjective. □

Cor. (4.3.1.17). If P is projective over R, then $P^* \neq 0$.

Cor. (4.3.1.18). In the meanwhile of the proof, we already get: if P is finite projective, then P^* is finite projective, by(4.3.1.15).

Cor. (4.3.1.19). If P is finite projective, the the map $P \otimes M \to \mathrm{Hom}(P^*, M)$ is an isomorphism.

Proof: In(4.3.1.10), let $N = R$ and let $M = P^*$, then use the fact $P \cong P^{**}$. □

Thm. (4.3.1.20) [Quillen-Suslin]. For $k \in \texttt{Field}$, any finite projective module over $k[X_1, \ldots, X_k]$ is free. (Highly nontrivial).

Proof: Cf.[Lan05]P850. □

Prop. (4.3.1.21). $\prod^{\mathbb{N}} \mathbb{Z}$ is not free over $\mathbb{Z}$, by(2.1.4.4).

2 Injective

Prop. (4.3.2.1) [Baer's Criterion]. A right $R-$module I is injective iff for every right ideal J of R, every map $J \to I$ can be extended to a map $R \to I$. (Directly from (3.7.6.7)).

Cor. (4.3.2.2). A module over a PID is injective iff it is divisible.

Cor. (4.3.2.3). A is injective iff $\mathrm{Ext}^1(R/I, A) = 0$ for every ideal I of R.

Cor. (4.3.2.4) [Rank]. Let M a finite projective R-module, then M is said to have rank n if $M/\mathfrak{m}M$ is of rank n over the field $R/\mathfrak{m}$ for any arbitrary maximal ideal $\mathfrak{m}$ of R.

Prop. (4.3.2.5). The category of R-mod has enough injectives by(3.7.3.28), and it has enough projectives trivially.

Prop. (4.3.2.6). If I is an injective A-module, then for any ideal α of A, $\Gamma_\alpha(I) = \{m | \alpha^n m = 0\}$ for some n is injective.

Proof: Use Baer criterion, for any ideal b of A, it is f.g. so there is a n that $\phi(\alpha^n b) = 0$, and Artin-Rees tells us that $\phi(\alpha^N \cap b) = 0$ for some N. So we have an extension of ϕ over $b/b \cap \alpha^N$ to $A/\alpha^N \to I$, and this obviously factor through $\Gamma_\alpha(I)$, so it is done. □

Prop. (4.3.2.7). For an injective module A-module I, $I \to I_f$ is surjective.

Proof: we have the sheaf of modules $\widetilde{I}$ is flabby(5.7.1.5), thus the map to the stalk is surjective. □

Pontryagin Duality

Basic references are [Weibel Homological Algebra].

Def. (4.3.2.8). The **Pontryagin dual** $M^\vee$ of a left R-module M is the right R-module $\mathrm{Hom}_{Ab}(M, \mathbb{Q}/\mathbb{Z})$, where $(fr)(b) = f(rb)$.

It is easily verified that if $A \neq 0$, then $A^\vee \neq 0$, and $\mathbb{Q}/\mathbb{Z}$ is an injective $\mathbb{Z}$-module, thus the Pontryagin dual is faithfully exact.

Prop. (4.3.2.9). M is flat R-module iff $M^\vee$ is an injective right R-module (Because $\mathrm{Hom}(-, \mathbb{Q}/\mathbb{Z})$ is exact).

3 Homological Dimension

Def. (4.3.3.1). For a R-mod A, the **projective dimension** $\mathrm{pd}(A)$ is the minimal length of a projective resolution of A. The **injective dimension** $\mathrm{id}(A)$ is the minimal length of a injective resolution of A. The **flat dimension** $\mathrm{fd}(A)$ is the minimal length of a flat resolution of A.

Prop. (4.3.3.2). If R is Noetherian, then $fd(A) = pd(A)$ for every f.g. module A.

Proof: Use(4.3.3.3), we see that if we choose a syzygy and look at the n-th term, then it is f.p and flat, so we have it is projective by(4.4.1.14). □

Lemma (4.3.3.3) [pd]. If $\mathrm{Ext}^{d+1}(A, B) = 0$ for every B, then for every resolution

$$0 \to M \to P_{d-1} \to \ldots, P_1 \to P_0 \to A \to 0$$

where P_k is projective, then M is projective. Hence we have $pd(A) \leq d$. (Use dimension shifting, the following two are the same).

Lemma (4.3.3.4) [id]. If $\mathrm{Ext}^{d+1}(A, B) = 0$ for every A, then for every resolution

$$0 \to B \to P_0 \to \ldots, P_{n-1} \to M \to 0$$

where P_k is injectives, then M is injective. Hence we have $id(B) \leq d$

Lemma (4.3.3.5) [fd]. If $\mathrm{Tor}_{d+1}(A, B) = 0$ for every B, then for every resolution

$$0 \to M \to F_{d-1} \to \ldots, F_1 \to F_0 \to A \to 0$$

where F_k is flat, then M is flat. Hence we have $fd(A) \leq d$

Prop. (4.3.3.6)[Global Dimension Theorem]. The following are the same for any ring R and called the **left global dimension** of R:

1. $\sup\{id(B)\}$
2. $\sup\{pd(A)\}$
3. $\sup\{pd(R/I)\}$
4. $\sup\{d : \mathrm{Ext}^d_R(A, B) \neq 0$ for some module A,B.

Proof: This follows from(4.3.3.3),(4.3.3.4) and (4.3.2.3). □

Prop. (4.3.3.7). A $\mathbb{Z}$ has global dimension 1 because injective is equivalent to divisible, and this shows that a quotient of an injective is injective.

Prop. (4.3.3.8) [Tor Dimension Theorem]. The following are the same for any ring R and called the **Tor dimension** of R:

1. $\sup\{fd(A)\}$ for A a left module.
2. $\sup\{fd(B)\}$ for B a right module.
3. $\sup\{pd(R/I)\}$ for I a left ideal.
4. $\sup\{pd(R/J)\}$ for J a right ideal.
5. $\sup\{d : \mathrm{Tor}_d^R(A,B) \neq 0$ for some module A,B.

Proof: This follows from(4.3.3.5) applied to R and R^{op} and also(4.4.1.2). □

Prop. (4.3.3.9)[Change of Rings]. Let $S \to R$ be a ring map, let $A \in \mathrm{Mod}_R$, then we have $pd_S(A) \leq pd_R(A) + pd_S(R)$.

Proof: Use the Cartan-Eilenberg resolution and the total complex has length $pd_R(A)+pd_S(R)$. □

4 Depth

Regular sequences

Def. (4.3.4.1) [Regular Sequences]. If R is a commutative ring and M is an R-module, then a sequence $(f_1,\dots,f_n)$ of elements of R is called a **M-regular sequence** if f_k is a nonzero-divisor of $M/(f_1,\dots,f_{k-1})$ and $M/(f_1,\dots,f_n) \neq 0$. If $M = R$, then it is simply called a **regular sequence**.

Prop. (4.3.4.2). If R is a **local ring**, M a finite R-module, and $(f_1,\dots,f_n)$ is a M-regular sequence, then a permutation of this sequence is also an M-regular sequence.

Proof: By transposition of adjacent indices, we can assume $n = 2$. Then x is a non-zero-divisor, and $x \in \mathfrak{m}$, so Now (x,y) is an M-regular sequence iff $M \otimes_R^L R/x$ is discrete and $M \otimes^L R/x \otimes_R^L R/y$ is discrete. Then it suffices to prove y is injective on M: If $ym = 0$, then $m = xm'$ for some m', because y is injective on M/x, and then $ym' = 0$ also because x is injective on M. Then x is surjective on $\ker(y)$, thus $\ker(y) = 0$ by Nakayama. □

Prop. (4.3.4.3). Let R be a ring and $0 \to M_1 \to M_2 \to M_3 \to 0$ be an exact sequence of R-modules. Then if a sequence $(f_1,\dots,f_r) \in R^r$ is both M_1-regular and M_3-regular, then it is also M_2-regular.

Proof: Use the snake lemma, $\ker(f_1|_M) = 0$, and $0 \to M_1/fM_1 \to M_2/fM_2 \to M_3/fM_3 \to 0$, then use induction. □

Prop. (4.3.4.4). For any integers $e_i \geq 1$, $(f_1,\dots,f_n)$ is a M-regular iff $(f_1^{e_1},\dots,f_n^{e_n})$ is M-regular.

Proof: Use induction on n. $n = 1$ is trivial, and it suffices to show that $(f_1^e, f_2,\dots,f_n)$ is M-regular. Then we use induction on e: There is an exact sequence $0 \to M/f_1M \to M/f_1^eM \to M/f^{e-1}M \to 0$, so by(4.3.4.3), if $(f_1,\dots,f_n)$ is a M-regular, then $(f_1^e, f_2,\dots,f_n)$ is M-regular. Conversely, if $(f_1^e, f_2,\dots,f_n)$ is M-regular, then f_2 is injective on M/f_1^eM, so also injective on M/f_1M, thus injective on $M/f^{e-1}M$ by induction hypothesis, and also there is a further exact sequence $0 \to M/(f_1,f_2)M \to M/(f_1^e,f_2)M \to M/(f^{e-1},f_2)M \to 0$, so we can consider f_3, and then so on, thus show $(f_1^e, f_2,\dots,f_n)$ is M-regular. □

Prop. (4.3.4.5). Let R be a ring, then the following are equivaletn:

- any permutation of $(f_1,\ldots,f_r)$ is a regular sequence.
- Any subsequence of $(f_1,\ldots,f_r)$ is a regular sequence.
- $(f_1X_1,\ldots,f_rX_r)$ is a regular sequence of $R[X]$.

Proof: $1\to 2$: Trivial. $2\to 1$: Use induction on r: If $r=2$ and (x,y) is regular, we have $M\otimes^L_R R/x, M\otimes^L_R R/y$ are both discrete, and $M\otimes^L_R R/x\otimes^L R/y$ is also discrete, thus $M\otimes^L_R R/y\otimes^L_R R/x$ is also discrete and (y,x) is regular. For $r>2$, it suffices to show $f_{\sigma(r)}$ is regular in $M/(f_{\sigma(1)},\ldots,f_{\sigma(r-1)})$. If $\sigma(r)=r$, then we are done, otherwise, f_r and $f_{\sigma(r)}$ are both injective on $M/(f_1,\ldots,\widehat{f_{\sigma(r)}},\ldots,f_{r-1})$ by induction hypothesis, and $(f_{\sigma(r)},f_r)$ is a regular sequence for this ring, then so is $(f_r,f_{\sigma(r)})$ by the $r=2$ case, thus we are done.

$3\iff 2$: Notice as a R-module, $R[X_1,\ldots,X_r]/(f_1X_1,\ldots,f_iX_i)$ is a direct sum of the modules $R/I_E X_1^{e_1}\ldots X_r^{e_r}$, where I_E is generated by those f_j that $j\leq i$ and $e_j>0$. Then $f_{i+1}X_{i+1}$ is injective on this iff f_{i+1} is injective on R/I_E for any E. Then it is clear that this is equivalent to 2. □

Def. (4.3.4.6) [Quasi-Regular Sequence]. Let $f_1,\ldots,f_c\in R$ and $J=(f_1,\ldots,f_c)$, let M be a R-module, then there is a canonical map $M/JM\otimes_{R/J}R/J[X_1,\ldots,X_c]\to\otimes_{n\geq 0}J^nM/J^{n+1}M$. Then $(f_1,\ldots,f_c)$ is called M**-quasi-regular sequence** iff this is an isomorphism.

Depth

Prop. (4.3.4.7) [Rees]. For a f.g. module M and $IM\neq M$,

$$\mathrm{depth}_I(M)=\min\{i|\operatorname{Ext}^i_A(A/I,M)\neq 0\}=\min\{i|\operatorname{Ext}^i_A(N,M)\neq 0\}$$

where $\mathrm{depth}_I(M)$ is the length of the maximal M-regular sequence in I, N is a finite A-module with $\mathrm{Supp}(N)\subset V(I)$.

Proof: If No elements of I are M-regular, then $i\subset\cup\mathrm{Ass}(M)$ thus in one of them, so $\operatorname{Hom}_{A_p}(k,M_p)\neq 0$, and we have $N_p/PN_p=N\otimes_A k_p$ nonzero by Nakayama, thus $\operatorname{Hom}_k(N\otimes_A k_p,k_p)\neq 0$, thus $\operatorname{Hom}_{A_p}(N_p,M_p)=(\operatorname{Hom}_A(N,M))_p\neq 0$, so $\operatorname{Ext}^0_A(N,M)\neq 0$. Other dimensions follows by induction, consider the cokernel of $M\xrightarrow{a_1}M$.

Conversely, use induction, then we have an injection $\operatorname{Ext}^i_A(N,M)\xrightarrow{a_1}\operatorname{Ext}^i_A(N,M)$ for $i<n$. And the condition shows that $I\subset\sqrt{\mathrm{Ann}(M)}$, so $a_1^rN=0$, thus the result. □

Cor. (4.3.4.8). Two maximal regular sequence in a f.g. module have the same length.

Cor. (4.3.4.9). For a module M over a Noetherian ring A, we know $\Gamma_I(M)=\{m|I^nm=0\text{ for some }n\}$, and H^n_I is its right derived functor, then we have $\mathrm{depth}_I(M)\geq n\iff H^i_I(M)=0$ for $i<n$. (Because derived functor commutes with colimits, consider $N=A/I^k$).

Lemma (4.3.4.10) [Ischebeck]. For a Noetherian local ring A, if M,N are finite modules, then we have $\operatorname{Ext}^i_A(N,M)=0$ for $i<\mathrm{depth}(M)-\dim N$.

Proof: □

Prop. (4.3.4.11). Let A be a local ring and M is finite A-module, then $\mathrm{depth}(M)\leq\dim A/P\leq\dim M$ for every $P\in\mathrm{Ass}(M)$. (Because $\operatorname{Hom}(A/P,M)\neq 0$.)

Proof: □

Prop. (4.3.4.12) [Auslander-Buchsbaum Formula]. For a local ring R, if M is a finitely generated R-mod, if $pd(M)<\infty$, then we have $\mathrm{depth}(R)=\mathrm{depth}(M)+\mathrm{pd}(M)$.

Proof: Cf.[Weibel P109]. □

Cohen-Macaulay

Def. (4.3.4.13) [Cohen-Macaulay Modules]. For A Noetherian local, a f.g. A-module M is called **Cohen-Macaulay** if $\mathrm{depth}(M) = \dim M$. In view of(4.3.4.11), this is equivalence to $\mathrm{depth}(M) = \dim A/P$ for all $P \in \mathrm{Ass}(M)$. A **Cohen-Macaulay ring** is a ring A that is Cohen-Macaulay over itself.

A localization of a C.M local ring is C.M, so we call a ring **Cohen-Macaulay** if all its localization at primes are C.M.

Prop. (4.3.4.14) [Gorenstein Ring]. A ring R is called **Gorenstein** iff $id_R R < \infty$. A Gorenstein local ring is C.M. In this case, $\mathrm{depth}(R) = id_R R = \dim R$, and $\mathrm{Ext}^q_R(R/m, R) \neq 0 \iff q = \dim R$.

Proof: Cf.[Weibel P107]. □

Prop. (4.3.4.15). A ring is C.M. iff for all ideals, the associated primes of A/I all have the same height as I, i.e. unmixed.

Proof:

□

Prop. (4.3.4.16). If a local ring is C.M. and $I = (x_1, \ldots, x_r)$ is a regular sequence, then $(x_1, \ldots, x_r)$ is .

Proof: ? Isn't this always true? □

Prop. (4.3.4.17). Let A is a Noetherian local ring and M a f.g. module, if a set of elements $(x_1, \ldots, x_r)$ forms a regular sequence for M, then $\dim M/(x_1, \ldots, x_r) = \dim M - r$. The converse is also true when A is C.M. If this is the case, then $A/(x_1, \ldots, x_r)$ is also C.M.

Proof: By(4.2.2.19), we have $<$, for the converse, $\mathrm{Supp}(M/fM) = \mathrm{Supp}(M) \cap \mathrm{Supp}(A/fA) = \mathrm{Supp}(M) \cap V(f)$, and when f is M-regular, $V(f)$ doesn't contain any $\mathrm{Ass}(M)$ thus no minimal elements of $\mathrm{Supp}(M)$, so $\dim(M/fM) < \dim M$, thus we have $>$.

When A is C.M.:? □

Prop. (4.3.4.18). Let $R \to S$ be a local homomorphism of Noetherian local rings, if R is C.M. and S is finite flat over R or S is flat over R and $\dim S \leq \dim R$, then S is C.M., and $\dim R = \dim S$.

Proof: Cf.[Sta]00R5. □

5 Normal & Regular Rings

Normal Ring

Def. (4.3.5.1)[Normal Rings]. A **normal domain** is a domain and is integrally closed in its fraction field.

A domain is normal iff all its localizations are normal, so we can define a **normal ring** to be a ring that all its stalks are normal local rings. In particular, a normal ring is reduced.

Proof: The localization of a normal domain is normal, and the converse follows from $A = \cap A_{\mathfrak{m}}$(4.1.1.33). □

Prop. (4.3.5.2) [UFD is Normal]. A UFD is a normal domain.

Proof: If A is a UFD, then for any $x \in \mathrm{Frac}(A)$ integral over A, checking the primes dividing the coefficients, we see $x \in A$. □

Prop. (4.3.5.3). A normal ring R is integrally closed in its ring of fractions.

Proof: Let $x \in Q(R)$ be integral over R, and $I = \{f \in R | fx \in R\}$, then for any prime $\mathfrak{p}$ of R, $R \to R_\mathfrak{p}$ is injective, so $R_\mathfrak{p} \subset \mathrm{Frac}(R) \otimes_R R_\mathfrak{p}$, and $x \otimes 1$ is integral over $R_\mathfrak{p}$, thus $x \otimes 1 \subset R_\mathfrak{p}$, which means $x \otimes 1 = 1 \otimes a/f$ for some $a, f \in R, f \notin \mathfrak{p}$. This means $f'(fx - a) = 0 \in Q(R)$ for some $f' \notin \mathfrak{p}$, so $ff' \in I$, and thus I is not contained in any prime ideal, so $I = 1$ and $x \in R$. □

Prop. (4.3.5.4). Let R be a reduced ring with f.m. minimal prime ideals, then the following are equivalent:

- R is a normal ring.
- R is integrally closed in its ring of fractions.
- R is a finite product of normal domains.

In particular, a Noetherian normal domain is a finite product of normal domains(4.1.1.46).

Proof: $3 \to 1$ is trivial, $1 \to 2$ is by(4.3.5.3), for $2 \to 3$: let $\mathfrak{p}_i$ be the minimal prime ideals of R, then $\mathrm{Frac}(R) = \prod_{i=1}^r Q_{\mathfrak{p}_i}$(4.1.7.22), with each $Q_{\mathfrak{p}_1}$ field because R is reduced. Denote the idempotents of $\mathrm{Frac}(R)$ by e_i. Then e_i is integral thus in R. These idempotents make R into a product of domains, which are just $R/\mathfrak{p}_i$, because the kernel of the map $R \to R_{\mathfrak{p}_i}$ is $\mathfrak{p}_i$. Now R is integrally closed in $Frac(R)$ implies each $R/\mathfrak{p}_i$ is integrally closed in $R_{\mathfrak{p}_i}$, thus R is a finite product of normal domains. □

Def. (4.3.5.5) [Normalization]. The **normalization** of an integral domain is the alg.closure of it in its quotient field. It commutes with localization.

Def. (4.3.5.6)[Completely Normal Domains]. A domain is called **completely normal** iff all almost normal elements are in A, i.e. $\{u | \exists a, au^n \in A\ \forall n\} \in A$. For Noetherian ring, completely normal is equivalent to normal.

Proof: Cf.[Sta]00GX. □

Prop. (4.3.5.7). A is a normal domain, then so does $A[X]$. If A is Noetherian normal domain, then so does $A[[X]]$.

Proof: Cf.[Sta]030A, 0BI0. □

Prop. (4.3.5.8). Direct limits of normal rings are normal.

Proof: Let $\mathfrak{p}$ be an ideal of $R = \varinjlim R_i$, $\mathfrak{p}_i = \mathfrak{p} \cap R_i$, then $R_\mathfrak{p} = \varinjlim (R_i)_{\mathfrak{p}_i}$, so it suffices to prove for normal domains, the rest is easy. □

Prop. (4.3.5.9)[Closure in Separable Extension]. Let R be a Noetherian normal domain with field of fraction K and L/K is a finite separable field extension, then the integral closure S of R in L is finite over R.

Proof: Let $\mathrm{tr} : L \times L \to K : (x, y) \mapsto \mathrm{tr}(xy)$ be the trace pairing, then as L/K is finite separable, this is non-degenerate. Now if $x \in L$ is integral over R, then $\mathrm{tr}(x) \in R$. So if $x_1, \ldots, x_n$ are integral and form a basis of L over K, then $M = \{y \in L | \langle x_i, y\rangle \in R\}$ is an R-module and $M \cong R^n$, and $S \subset M$, so S is finite over R as R is Noetherian. □

Prop. (4.3.5.10) [Field Extension]. Let A be a K-algebra, and L/K is a field extension, then if A_L is a normal integral domain, so is A. And the converse is also true if L/K is separable.

Prop. (4.3.5.11) [Algebraic Hartogs's Lemma]. Principal ideals in a Noetherian normal domain is unmixed and $A = \cap_{\mathrm{ht}\, p=1} A_p$.

Proof: Cf.[Matsumura P124].**?** [Rising Sea, P320], [Sta]031T. □

Prop. (4.3.5.12) [Krull]. If A is a normal domain with fraction field K, L is a normal extension field of K and B is the integral closure of A in L that $A \subset B$ is integral, then any two prime ideals of B lying over a prime in A are conjugate by an action of $G_{L/K}$.

Proof: Firstly if $G_{L/K}$ is finite, and P, P' be primes of B that $P \cap A = P' \cap A$. Let $P_i = \sigma_i(P)$. If $P' \neq P_i$ for any i, then $P' \not\subseteq P_i$ for any i by(4.2.1.5), so there is some $x \in P'$ not in any of P_i. Now let $y = (\prod_i \sigma_i(x))^q$ where $q = 1$ if $\mathrm{char}(K) = 0$ and $q = p^r$ for r large if $char(K) = p$, then $y \in K$ thus in A because A is normal, and it is not in P by hypothesis. But $y \in P' \cap A = P \cap A$, contradiction.

For the infinite field extension case, let K' be the fixed field of $G_{L/K}$ so that K'/K is purely inseparable, then there is clearly exactly one prime of K' over any prime of A. So we can assume L/K is Galois, then use profinite group technique to find a $\sigma \in G_{L/K}$ that $\sigma(P) = P'$. □

Prop. (4.3.5.13) [Hironaka]. Let A be a local Noetherian domain that is a localization of an algebra of f.t. over a field k. Let $t \in A$ that

- tA has only on eminimal associated prime ideal p.
- t generate the maximal ideal of A_p.
- A/p is normal.

Then $p = tA$ and A is normal.

Proof: Cf.[Hartshorne P264]. □

Prop. (4.3.5.14) [Quadratic Extension is Normal]. If A is a UFD that 2 is invertible in A and $f \in A \backslash A^2$, then $A[Z]/(Z^2 - f)$ is integral and normal.

Proof: It is integral by(2.2.3.13). To show it is normal, assume $F(T) \in B[T]$ that $f(\alpha) = 0$, where $\alpha \in K(B) \backslash B$, then by replacing F by $\overline{F}F$, we can assume $F(T) \in A[T]$. We can assume $\alpha \notin K(A)$, thus $\alpha = g + hZ$, then the minimal polynomial of α is $Q(T) = T^2 - 2gT + (g^2 - h^2 f) \in K(A)[T]$. Then $F(T) = P(T)Q(T)$ in $K(A)[T]$. By Gauss's lemma, $2g, g^2 - h^2 f \in A$, so $g, f \in A$ by hypothesis. □

Cor. (4.3.5.15). If k is a field of characteristic$\neq 2$, then

- $k[x_1, \ldots, x_n]/(x_1^2 + \ldots + x_m^2)$ is integral normal for $n \geq m \geq 3$.
- $k[x, y, z, w]/(wz - xy)$ is normal.(Diagonalize).

Prop. (4.3.5.16). $\mathbb{Z}[\sqrt{n}]$ is integrally closed for $n \equiv 3 \mod 4$, and $\mathbb{Z}[\frac{1+\sqrt{n}}{2}]$ is integrally closed for $n \equiv 1 \mod 4$, by(12.4.3.6).

Regular Ring

Def. (4.3.5.17) [Regular Rings]. A Noetherian local ring $(A, \mathfrak{m}, k)$ is called **regular local** iff it $\mathrm{rank}_k\, \mathfrak{m}/\mathfrak{m}^2 = \dim A$. This is equivalent to $\mathrm{rank}_k\, \mathfrak{m}/\mathfrak{m}^2 \leq \dim A$, or $\mathrm{gr}\ A \cong k[X_1, \ldots, X_d]$ by(4.2.2.19).

Localization of a regular local ring at primes are regular local, Cf.[Sta]0AFS. Hence we define a **regular ring** to be a Noetherian ring that all its localization at primes are regular local.

Proof: Cf.[Matsumura P139]. □

Prop. (4.3.5.18). If A is regular, then $A[X_1, \ldots, X_n]$ is regular, and $A[[X_1, \ldots, X_n]]$ is regular.

Proof: Cf.[Matsumura P176]. □

Prop. (4.3.5.19) [Auslander-Buchsbaum]. A regular local ring is UFD. In particular it is a normal domain. Thus a regular ring is normal and thus reduced(4.3.5.1).

Proof: Cf.[Matsumura P142],[Weibel P106]. □

Cor. (4.3.5.20). A regular local ring of dimension 0 is a field, and a regular local ring of dimension 1 is a DVR.

Prop. (4.3.5.21). A regular local ring is Gorenstein hence C.M..

Proof: □

Prop. (4.3.5.22)[Regular Local Ring and Regular Sequences]. Let $(R, \mathfrak{m})$ be a regular local ring of dimension d,

- If $x_1, \ldots, x_c$ be a sequence that maps to linearly independent elements in $\mathfrak{m}/\mathfrak{m}^2$, then $(x_1, \ldots, x_c)$ is a regular sequence, and $R/(x_1, \ldots, x_c)$ is a regular local ring of dimension $d - c$.
- If $I \subset \mathfrak{m}$ and R/I is a regular local ring, then $I = (x_1, \ldots, x_c)$ where $(x_1, \ldots, x_c)$ is a regular sequence.
- If $(x_1, \ldots, x_c)$ is a regular sequence in $\mathfrak{m}$ and $R/(x_1, \ldots, x_c)$ is a regular local ring, then R is also a regular local ring.

Proof: 1: We can complete it to a sequence $(x_1, \ldots, x_d)$ that $(x_1, \ldots, x_d)$ generate $\mathfrak{m}/\mathfrak{m}^2$, then by Nakayama $(x_1, \ldots, x_d) = \mathfrak{m}$. Now by Krull's height theorem(4.2.4.18), $R/(x_1)$ has dimension$\geq d - 1$ and $(x_2, \ldots, x_d)$ generate the maximal ideal, so $R/(x_1)$ is a regular local ring by definition. Now $x_1 \neq 0$ because R is a domain(4.3.5.19), thus we can use induction to show $(x_1, \ldots, x_c)$ is a regular sequence.

2: Let $\dim(R/I) = d - c$, then the hypothesis shows $(I + \mathfrak{m}^2)/\mathfrak{m}^2 \cong I/\mathfrak{m}I$ has rank c, thus we can choose $(x_1, \ldots, x_c) \in I$ that generate $I/\mathfrak{m}I$. Thus by Nakayama $I = (x_1, \ldots, x_c)$, and $(x_1, \ldots, x_c)$ is a regular sequence by item1.

3: By induction, it suffices to prove the $c = 1$ case, then any lift of x_1 together with $d-1$ generator of the maximal ideal of $R/\mathfrak{m}$ is a set of generator of $\mathfrak{m}$. □

Cor. (4.3.5.23). A regular local ring is C.M., by item1.

Prop. (4.3.5.24). If a quotient of a Noetherian local ring by a non-zerodivisor is regular, then it is itself regular.

Prop. (4.3.5.25) [Serre]. A Noetherian local ring A is regular iff the global dimension of A is finite.

Proof: Cf.[Mat P139]. □

Prop. (4.3.5.26). For A a regular local ring and M a f.g. A-module,

$$pd(M) + \text{depth } M = \dim A.$$

Cf.[Hartshorne P237].

Cor. (4.3.5.27). For a f.g. module M over a regular local ring A, $pd(M) \leq n$ iff $\text{Ext}^i(M, A) = 0$ for all $i > n$.

Proof: This is because we can use dimension shifting to show $\text{Ext}^i(M, N) = 0$ for all N f.g., then(4.3.3.3) says that $pd(M) \leq n$. □

Prop. (4.3.5.28) [Regular and Regular Sequence]. Let

Prop. (4.3.5.29). Let $R \to S$ be a flat local homomorphism of Noetherian local rings that R is regular, $S/\mathfrak{m}_S$ is regular, then S is also regular.

Proof: Cf.[Sta]031E. □

Serre Conditions R_k & S_k

Def. (4.3.5.30). A ring is called R_k iff for all prime p of height $\leq k$, A_p is regular.
A ring is called S_k iff $\text{depth}(A_p) \geq \min(k, \text{ht}(p))$ for all prime p.
A module M is called S_k iff $\text{depth}(M_p) \geq \min(k, \dim \text{Supp } M_p)$ for all prime p.

Prop. (4.3.5.31).

- M is S_1 iff M has no associated embedded primes. Cf.[Sta]031Q.
- A Noetherian ring is reduced iff it is R_0 and S_1. Cf.[Sta]031R.
- (Serre Criterion)A Noetherian ring is normal iff it is R_1 and S_2. Cf.[Sta]031S.
- A ring is C.M. iff it is $S_{\mathbb{N}}$.

Proof: □

Cor. (4.3.5.32) [Regular and Normal]. A regular ring is normal, and normal ring is regular in codimension 1.

Proof: By(4.3.5.31), it suffices to prove that a regular ring satisfies R_1 and S_2. A regular ring is C.M.(4.3.5.21) so it is S_2 by(4.3.5.31), it is R_1 by(4.3.5.17) □

Cor. (4.3.5.33) [Normal and Regular Dimension 1]. A Noetherian local ring of dim 1 is normal iff it is regular. i.e. integral domain and integrally closed iff maximal ideal is principal.

6 Geometric Properties

Def. (4.3.6.1).

- A k-algebra S is called **geometrically reduced/integral/connected**... over a field k iff for any field extension k'/k, $\text{Spec } S_{k'}$ is reduced/integral/connected....
- A Noetherian k-algebra S is called **geometrically regular** iff for any f.g. field extension K/k, S_K is regular(Notice $A \otimes_k k'$ is Noetherian(4.1.1.44), so this makes sense).

Prop. (4.3.6.2) [Geometrically reduced]. If S is a k-algebra, the following are equivalent.

1. S is geometrically reduced.
2. $S \otimes_k \overline{k}$ is reduced.
3. $S \otimes_k k^{per}$ is reduced.
4. $S \otimes_k k'$ is reduced for any finite purely inseparable field extension k'/k.
5. $S \otimes_k k^{1/p}$ is reduced.
6. residue fields of S at maximal points are reduced.
7. $S \otimes_k R$ is reduced for every reduced k-algebra R.

Proof: 1 $\to$ 7: We can assume R is f.g., thus R is contained in a finite product of fields Cf.[Sta]030V?, and then we can assume R is a product of fields, and we are done.

1 $\to$ 2 $\to$ 3 $\to$ 4 is clear. 3 $\to$ 5 is clear.

4 $\to$ 1: For any field extension K/k, we can assume WLOG K/k is f.g., thus?

5 $\to$ 1: ? 6:? Cf.[Sta]030V and [Gortz 135]. □

Prop. (4.3.6.3) [Geometrically Irreducible]. Let S be a k-algebra, the following are equivalent:

1. S is geometrically irreducible.
2. For any finite separable field extension k'/k, the spectrum of $S_{k'}$ is irreducible.
3. The spectrum of $S_{k^{sep}}$ is irreducible.
4. The spectrum of $S_{\overline{k}}$ is irreducible.

Proof: Cf.[Sta]037K.? □

Prop. (4.3.6.4). Let S be a geometrically irreducible k-algebra and R is a k-algebra, then the map

$$\operatorname{Spec}(R \otimes_k S) \to \operatorname{Spec} R$$

induces a bijection on irreducible components.

Proof: Cf.[Sta]037O.? □

Prop. (4.3.6.5) [Geometrically Integral]. Let S be a k-algebra, the following are equivalent:

1. S is geometrically integral.
2. For any finite separable field extension k'/k, $S_{k'}$ is an integral domain.
3. $S_{\overline{k}}$ is an integral domain.
4. $S \otimes_k R$ is an integral domain for any integral domain R over k.

Proof: This follows from(4.3.6.3)(4.3.6.2) and(4.3.6.4). □

Prop. (4.3.6.6). It suffices to check geometrically regular for k'/k finite purely inseparable.

Proof: Cf.[Sta]0381.? □

7 Finitely Presentedness

Finite Presented Modules

Def. (4.3.7.1) [Finitely Presented Modules]. A **finitely presented module** is a module of the form R^m/R^n.

Finite presentation is stable under base change because tensoring is right exact.

Prop. (4.3.7.2). Given an exact sequence of R-modules $0 \to M_1 \to M_2 \to M_3 \to 0$,

- If M_1, M_3 are f.p., then so does M_2.
- If M_3 is f.p. and M_2 is f.g., then M_1 is f.g.
- If M_2 is f.p. and M_1 is f.g., then M_3 is f.p.

Proof: 1: e can find an commutative diagram $\begin{array}{ccccccccc} 0 & \longrightarrow & R^m & \longrightarrow & R^{m+n} & \longrightarrow & R^m & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & M_1 & \longrightarrow & M_2 & \longrightarrow & M_3 & \longrightarrow & 0 \end{array}$ and use the snake lemma to see the kernel is f.g..

2: Use the diagram $\begin{array}{ccccccccc} & & R^m & \longrightarrow & R^n & \longrightarrow & M & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle\alpha} & & \downarrow & & \downarrow{\scriptstyle\mathrm{id}} & & \\ 0 & \longrightarrow & M_1 & \longrightarrow & M_2 & \longrightarrow & M_3 & \longrightarrow & 0 \end{array}$. and snake lemma, then image and cokernel of α are all finite, so M_1 is finite.

3: Choose a presentation $R^m \to R^n \to M_2$ and a surjection $f: R^k \to M_1$, then we can lift f to $R^k \to R^n$, and then M_3 can be written as a quotient $R^{m+k} \to R^n \to M_3$. □

Cor. (4.3.7.3). A direct summand of a f.p. module is f.p..

Prop. (4.3.7.4). If $R \to S$ is a f.g. ring map and a S-module M is f.p. over R, then it is f.p. over S.

Proof: Let $S = R[x_1, \ldots, x_n]$, and $M = R[y_1, \ldots, y_m]/(\sum a_{ij} y_j), 1 \le i \le t$, then as M is a S-module, we let $x_i y_j = \sum a_{ijk} y_k$, and forms a quotient $S^{mn+t} \to S^m \to N \to 0$, where S^{mn+t} corresponds to the relations $\sum a_{ij} y_j$ and $x_i y_j - \sum a_{ijk} y_k$. Then there is a surjective A-module map $N \to M$, and we check it is injective: if $z = \sum b_j y_j$ are mapped to 0, where $b_j \in S$, then we can transform z into the shape $\sum c_j y_j$, where $c_j \in R$ by relations $x_i y_j - \sum a_{ijk} y_k$. Thus it is zero by definition. □

Prop. (4.3.7.5)[Direct Limits of F.P. Modules]. Any module is a direct limit of f.p. modules. This can be seen by considering all finite submodules and f.m relations between them.

Prop. (4.3.7.6) [Characterizing Finite and F.P. Modules]. Let N be an R-module, then

- N is finite R-module iff for any filtered colimits $M = \varinjlim M_i$ of R-modules, the map $\varinjlim \mathrm{Hom}(N, M_i) \to \mathrm{Hom}(N, \varinjlim M_i)$ is injective.
- N is a f.p. R-module iff for any filtered colimits $M = \varinjlim M_i$ of R-modules, the map $\varinjlim \mathrm{Hom}(N, M_i) \to \mathrm{Hom}(N, \varinjlim M_i)$ is a bijection.

Proof: 1: If N is generated by x_i and a map $f: N \to M_i$ maps to $0 \in \mathrm{Hom}(N, \varinjlim M_i)$, then there is a j that $f: M \to M_i \to M_j$ is 0. Thus $f = 0$. Conversely, N is the sum of its f.g. submodules N', thus $N \to \varinjlim N/N_i = 0$, which implies the identity map $N \to N$ vanishes for some N/N' where N' is a finite submodule of N, so $N = N'$ and N is a finite.

2: If M is f.p., we can get the assertion by writing M as a quotient of free modules and use the fact filtered colimit is exact(4.1.1.24). Conversely, write N as a filtered colimits of f.p. modules(4.3.7.5), then $\mathrm{id}: M \to M$ factors through some f.p. module, so it is a direct summand of a f.p. module, thus f.p. by(4.3.7.3). □

Cor. (4.3.7.7)[FP and Localization]. For M f.p., $S^{-1}\operatorname{Hom}_R(M,N) = \operatorname{Hom}_{S^{-1}R}\operatorname{Hom}(S^{-1}M, S^{-1}N)$ for any R-module N. (Use the presentation and Hom is left exact).

Proof: $\operatorname{Hom}_{S^{-1}R}\operatorname{Hom}(S^{-1}M, S^{-1}N) \cong \operatorname{Hom}_R(M, S^{-1}N)$ by duality, and then we can use(4.3.7.6), as localization is a filtered colimit. □

Finitely Presented Ring Map

Def. (4.3.7.8) [Finitely Presented Ring Map]. A ring map is called **of finite presentation** iff it is a quotient of a free algebra by a free algebra.

Prop. (4.3.7.9). Finite presentation is stable under composition(choose a presentation form to see) and base change because tensoring is right exact.

It is local on the source and target by(4.1.4.4).

Prop. (4.3.7.10). For S f.p. over R, then the kernel of any surjective ring map $R[X_1,\ldots,R_n] \xrightarrow{\alpha} S$ is f.g..

Proof: Let $S = R[Y_1,\ldots,Y_m]/(f_1,\ldots,f_k)$, then if $\alpha(X_i) \cong g_i(Y)$, then $\alpha : R[X_1,\ldots,R_n] \to R[X_1,\ldots,X_m,Y_1,\ldots,Y_m]/(f_1,\ldots,f_k,X_i - g_i)$. And the Y_i are in the image, thus we let Y_i are mapped onto by $h_j(X)$, then $\ker\alpha = (f_i(h_j(X)), X_i - g_i(X))$. □

Prop. (4.3.7.11). If $g \circ f : R \to S' \to S$ is of finite presentation and f is of finite type, then g is of finite presentation.

Proof: Let $S' = R[y_1,\ldots,y_a]$ and $S = R[X_1,\ldots,X_n]/(f_1,\ldots,f_m)$, then let $h_i(X) \cong y_i$ in S, then $S = S'[X_1,\ldots,X_n]/(f_1,\ldots,f_m,h_i - y_i)$. □

Prop. (4.3.7.12) [Normal Form of F.P.]. If S is f.p. over R that S has a presentation $S = R[X_1,\ldots,X_n]/I$ that I/I^2 is free over S, then S has a presentation $R[X_1,\ldots,X_m]/(f_1,\ldots,f_c)$ that $(f_1,\ldots,f_c)/(f_1,\ldots,f_c)^2$ is freely generated by $f_1,\ldots,f_c$.

Proof: Cf.[Sta]07CF. □

Prop. (4.3.7.13)[Finite Type Locally of Finite Presentation]. If $R \to S$ is a injective map of f.t. of domains, then there are $f \neq 0 \in R, g \neq 0 \in S$ that $R_f \to S_{fg}$ is of f.p.

Proof: Use induction on the number of generators of S/R. If $S = R[x]$, then $S = R[X]/\mathfrak{q}$. If $q = 0$, then S is of f.p.. If $g = fx^d + a_{d-1}x^{d-1} + \ldots a_0$ be a polynomial of minimal degree in $\mathfrak{q}$, then $R \to S_f$ is of f.p.

The more generator case can be reduced to the single generator case, because f.p. ring map is stable under composition(4.3.7.9). □

Lemma (4.3.7.14) [Filtered Colimits and F.P.]. Let $R \to A$ be a ring map, then the category of f.p. R-algebras A' with an R-algebra map $A' \to A$ is filtered, and the colimit is just A.

Proof: Cf.[0BUF]. □

8 Nagata & Excellent Rings

Def. (4.3.8.1) [Japanese & Nagata Rings]. Let R be a domain with quotient field K, then R is called **N-1** iff the integral closure of R in K is a finite R-module.

R is called **N-2** or **Japanese** iff for any finite field extension L/K, its integral closure in L is a finite R-module.

A ring R is called **universally Japanese** if for any domain S of f.t. over R, S is Japanese.

A ring R is called **Nagata** if it is Noetherian and for any prime p, R/p is Japanese.

All these properties are local properties(4.1.4.4). And they are in fact stable under any localizations.

Prop. (4.3.8.2) [Nagata]. Let R be a ring, the following are equivalent:

- R is Nagata,
- any f.g. R-algebra is Nagata.
- R is universally Japanese and Noetherian.

Proof: Cf,[Sta]0334. □

Prop. (4.3.8.3)[Nagata and Formal Fibers]. Let $(A, \mathfrak{m})$ be a Noetherian local ring, then A is Nagata iff the formal fibers of A are geo.reduced.

Proof: Cf.[Sta]0BJ0. □

<u>**Excellent Rings**</u>

Def. (4.3.8.4) [G-Rings]. A **G-ring** is a Noetherian ring s.t. for any prime $\mathfrak{p} \subset R$, the map $R_\mathfrak{p} \to R_\mathfrak{p}^\wedge$ is regular.

Def. (4.3.8.5) [Excellent Rings]. A **quasi-excellent ring** is a ring that is Noetherian, G-ring and J-2. A **excellent ring** is a quasi-excellent ring that is universally catenary.

Prop. (4.3.8.6). Quasi-excellent rings are Nagata.

Proof: Cf.[Sta]07QV. □

Prop. (4.3.8.7) [Examples]. The following rings and f.g. algebras over them are excellent rings:

- fields.
- Noetherian complete local rings
- Dedekind domain with fraction field of characteristic 0.

In particular, ring of integers in all local fields and number fields are excellent.

Proof: Cf.[Sta]0335. □

Cor. (4.3.8.8). The above rings are all Nagata, by(4.3.8.6).

9 Separability

Main references are [Matsumura Ch10], [Weibel Chap P309] and [Sta]10.41, 10.43.

Def. (4.3.9.1) [Separable Algebra]. A f.d semisimple algebra R over a field k is called **separable** iff for every field extension K/k, $R \otimes_k K$ is semisimple.

Def. (4.3.9.2). A field extension K/k is called **separably generated** iff it K is a separable algebraic extension of a purely transcendental field L/k.

A field extension K/k is called **separable** iff all f.g. subextensions are separably generated.

An algebra A/k is called **separable** iff $A \otimes_k k'$ is reduce for any k'/k algebraic.

Prop. (4.3.9.3). If $k \subset K$ is a f.g. field extension, then there is a finite purely inseparable field extension $k \subset k'$ that $k' \subset k'K$ is separable.

Proof: □

Prop. (4.3.9.4) [Separable and Geo.Reduced]. Let K/k be a field extension, then K/k is separable iff K/k is geometrically reduced.

Proof: Cf.[Sta]030W.? □

Cor. (4.3.9.5). If K/k is a separable field extension and S is a reduced k-algebra, then $S \otimes_k K$ is reduced.

Proof: Cf.[Sta]030U. □

Cor. (4.3.9.6). A separably generated field extension is separable.

10 Henselian Ring

Main References are [Sta]Chap10.148.

Def. (4.3.10.1). A local ring $(R, \mathfrak{m}, k)$ is called **Henselian** iff for every $f \in R[X]$ and $a_0 \in k$ that $\overline{f}(a_0) = 0$ and $\overline{f}'(a_0) \neq 0$, then there is a root α of f lifting a_0. It is called **strict Henselian** if moreover its residue field is separably closed.

Henselian Pairs

Def. (4.3.10.2). A **Henselian pair** is a pair (A, I) that is Zariski and for any f, g in $A[T]$ monic and $\overline{f} = \overline{g}\overline{h} \in A/I[T]$ that is coprime and monic, there is a factorization $f = gh$ lifting the decomposition.

In particular, if f has a simple root $\overline{x}$ in A/I, then it has a root $x \in A$ lifting $\overline{x}$.

Prop. (4.3.10.3). Filtered limits of Henselian pairs is Henselian, this is clear from the definition(4.3.10.2).

Lemma (4.3.10.4). If A is a ring with ideal I, if $\overline{f} = \overline{g}\overline{h}$ be a factorization of a polynomial $f \in A[T]$ in $A/I[T]$, then there is an étale ring map $A \to A'$ that $A/IA \cong A'/IA'$, and a factorization $f = g'h' \in A'[T]$ lifting the factorization.

Proof: Cf.[Sta]0ALH? □

Prop. (4.3.10.5) [Topological Invariance of Étale Sites]. If I is locally nilpotent, then (A, I) is Henselian, in particularly $A_{ét} \cong (A/I)_{ét}$(4.3.10.9).

Proof: First if $A \to S$ is étale, then $A/I \to S/IS$ is étale by base change(4.4.7.5) and the map is essentially surjective by(4.4.7.15). And any map $B/IB \to B'/IB'$ can be lifted to $B \to B$ because étale is smooth and use(4.4.5.16). And the lifting is unique, otherwise if f, g are two lifting, because étale is unramified, so if we choose an idempotent e generating the kernel of $B \otimes_A I \to B \to B$(4.4.6.10), then $f \otimes g(e) \in IB'$, which is locally nilpotent, thus $f \otimes g(e) = 0$, thus $f = g$.

For then Henselian, I is clearly contained in the Jacobson radical, and for the decomposition, by(4.3.10.4) these is an étale map $A \to A'$ that $A/IA \cong A'/IA'$ that lifts the factorization, but $A = A'$, by what we have seen above. □

Cor. (4.3.10.6) [Complete Pair is Henselian]. If (A, I) is a pair that A is I-adically complete, then (A, I) is Henselian.

Proof: I is in the Jacobson radical because $1 + I$ consists of units, and by(4.3.10.5) and(4.3.10.4) we can lift the decomposition to A/I^n inductively. As $A = \lim A/I^n$, we are done. □

Prop. (4.3.10.7) [Equivalent Definitions of Henselian Pair]. The following are all equivalent to (A, I) being Henselian:

- Given any étale ring map $A \to A'$, then any $A' \to A/I$ lifts to an A-algebra map $A' \to A$.
- For any finite/integral A-algebra B, the map $B \to B/IB$ induces a bijection on idempotents.
- (Gabber) (A, I) is Zariski and every monic polynomial $f(T) \in A[T]$ of the form $T^n(T-1) + a_nT^n + \ldots + a_1T + a_0$ with $a_i \in I$ has a root $\alpha \in 1 + I$.

Moreover, root in item3 is unique.

Proof: Cf.[Sta]09XI. □

Cor. (4.3.10.8). if (A, I) is Henselian and $A \to B$ is integral, then (B, IB) is also Henselian.

Prop. (4.3.10.9) [Henselian Lifting]. If (A, I) is a Henselian pair, then there is a natural equivalence of categories: $A_{ét} \cong (A/I)_{ét}$.

Proof: Cf.[Sta]09ZL.? □

Prop. (4.3.10.10). A Zariski pair (R, I) is Henselian iff the pair $(\mathbb{Z} \oplus I, I)$ is Henselian. In particular, the property of being Henselian only depends on the non-unital ring I.

Proof: Cf.[Almost Ring Theory, 5.1.9]. □

4.4 Commutative Algebra IV

1 Flatness

Def. (4.4.1.1) [Flatness]. A modules M over a ring R is called **flat** if $M\otimes_R - : \mathcal{M}od_R \to \mathcal{M}od_R$ is an exact functor. This is compatible with the definition(5.2.2.15).

Prop. (4.4.1.2). Flatness need only be checked for finite modules, and it is equivalent to $\mathrm{Tor}_1(M, A/I) = 0$ for any f.g. ideal I(i.e $I\otimes M \to M$ is injective).

Proof: This is because of(5.3.3.12) and the fact tensor product commutes with colimit. □

Cor. (4.4.1.3). If $0 \to M' \to M \to M'' \to 0$, then M' and M'' flat implies M is flat.

Prop. (4.4.1.4). If M is flat then $\mathrm{Tor}_i^A(M,N) = 0$ for all $i > 0$, because we have: if $0 \to M_1 \to M_2 \to M_3 \to 0$ M_2, M_3 flat, then M_1 is flat (Use 9 entry sequence and the fact that Tor is symmetric(4.9.2.5)). So $\mathrm{Tor}_{n+1}(M_3,N) = \mathrm{Tor}_n(M_1,N) = 0$ by induction.

And a direct summand of a flat module is flat. Thus we have the class of flat modules is adapted $-\otimes N$ for all N (because free is flat).

Prop. (4.4.1.5) [Faithfully Flatness]. The following are equivalent:

- M is flat and for any $N\neq 0$, $N\otimes_R M \neq 0$.
- M is flat and for any (maximal)prime ideal $\mathfrak{m}$ of R, $k(\mathfrak{m})\otimes_R M \neq 0$. (When $\mathfrak{m}$ is maximal, which means $\mathfrak{m}M \neq M$).

And such a M is called **faithfully flat** over R.

Proof: $1\to 2$ is easy. $2 \to 1$: any nonzero module has a submodule R/I, choose a maximal ideal $\mathfrak{m}$ containing I, then $(A/I)\otimes_A M \subset N\otimes_A M$ surjects to $k(\mathfrak{m})\otimes_A M \neq 0$. □

Prop. (4.4.1.6) [Flatness and Base Change].

- (Faithfully)Flatness is stable under base change.
- Flatness satisfies f.f. descent(4.4.2.1).
- Flatness is stable under filtered colimit because filtered colimit commutes with tensoring(2.2.4.13) and is exact(4.1.1.24). In particular, $S^{-1}A$ is flat(4.1.1.27).
- Let $S \to S'$ be a map of R-algebras, M is an S-module, $M' = M\otimes_S S'$, then if M is flat over R, so does M'. The converse also holds if $S\to S'$ is f.f..
- If $R\to S$, and a S-module M is R-flat and S-f.f., then $R \to S$ is flat.

Proof:

4: For any injection of R-modules $N \to N'$, use the fact $\ker(N\otimes_R M \to N'\otimes_R M)\otimes_S S' = \ker(N\otimes_R M' \to N'\otimes_R M')$.

5: For any injection of R-modules $N \to N'$, use the fact $\ker(N\otimes_R S \to N'\otimes_R S)\otimes_S M = \ker(N\otimes_R M \to N'\otimes_R M)$. □

Prop. (4.4.1.7)[Equational Criterion of Flatness]. For a R-module M, a relation $\sum f_i x_i = 0$ where $f_i\in R, x_i \in M$ are called **trivial** iff $\overrightarrow{x} = A\overrightarrow{y}$ for some $A\in M_{n\times n}(R)$, $\overrightarrow{y}\in M^n$, and $\overrightarrow{f}^t A = 0$. Then M is flat iff all relations of elements of M is trivial.

Proof: Assume M if flat over R, and $\sum_i f_i x_i = 0$ is a relation in M, Let $I = (f_1, \ldots, f_n)$ and let $K = \ker(R^n \to I : (x_i) \mapsto \sum x_i f_i)$, then $\sum f_i \otimes x_i = 0 \in I \otimes_R M$ by flatness, then $\sum e_i \otimes x_i \in K \otimes_R M$. Let $\sum e_i \otimes x_i = \sum k_j \otimes y_j$, and $k_j = \sum_i a_{ij} e_i$, then this is the desired relations.

Conversely, suppose every relation is trivial, and I is an ideal of R, let $x = \sum f_i \otimes x_i \subset I \otimes M$ be an element mapping to $0 \in R \otimes M = M$, then $\sum f_i x_i$ is a relation, so it is trivial, and then $x = \sum f_i \otimes x_i = \sum f_i \otimes (a_{ij} y_j) = \sum (f_i a_{ij}) y_j = 0$. □

Prop. (4.4.1.8) [Gororov-Lazard]. Any flat A-module is isomorphic to a direct limit of finite free modules.

Proof: Cf.[Sta]058G. □

Prop. (4.4.1.9). Flat module is torsion-free.

Proof: If $x \in R$ is a nonzero-divisor, $R \xrightarrow{x} R$ is injective, thus $M \xrightarrow{x} M$ is also injective. □

Prop. (4.4.1.10) [Flat over Local Rings]. A finite module M over a local ring A is flat iff it is free. In particular, finite modules over a field are all flat.

Proof: Let $A/\mathfrak{m} = k$, choose a k-basis x_i of $M/\mathfrak{m}M$, then they generate M by Nakayama. It suffices to prove that x_i are independent over R. For this, use equational criterion of flatness(4.4.1.7), we prove that if x_i is independent over k, then they are independent over A. Use induction, if $x \neq 0$ in $M/\mathfrak{M}$, if $fx = 0$ for some $f \in A$, then $x = \sum a_j y_j$ that $f a_j = 0$, but then some a_j is a unit, so $f = 0$.

If $\sum f_i x_i = 0$, then by hypothesis, $f_i \in \mathfrak{m}$, and there are y_j that $x_i = \sum a_{ij} y_j$, $\sum f_i a_{ij} = 0$. As $x_n \notin \mathfrak{m}M$, there is a $a_{nj} \notin \mathfrak{m}$, so $f_n = \sum(-a_{ij}/a_{nj}) f_i$. then $\sum_{i \neq n} f_i (x_i - a_{ij}/a_{nj} x_n) = 0$, but $x_i - a_{ij}/a_{nj} x_n$ is also independent over k, so by induction, $f_i = 0$, also does f_n, so we are done. □

Prop. (4.4.1.11) [Flat over Bézout Domains]. A module M over a Bézout domain R is flat iff it is torsion-free.

Proof: One direction is clear by(4.4.1.9). If it is torsion-free, we use the equational criterion of flatness(4.4.1.7):

Let $\sum a_i x_i = 0$ where $a_i \in R^*, x_i \in M$, then consider $(a_1, \ldots, a_n) = (a)$, thus $a_i = a b_i$ for some $b_i \in R$, and $\sum c_i b_i = 1$ for some $c_i \in R$ as R is a domain. Because M is torsion-free, $\sum_i b_i x_i = 0$. Notice $\overrightarrow{x} = (1 - \overrightarrow{c}\overrightarrow{b}^t)\overrightarrow{x}$, so we can take $\overrightarrow{y} = \overrightarrow{x}$, $A = 1 - \overrightarrow{c}\overrightarrow{b}^t$. Then $\overrightarrow{b}^t A = \overrightarrow{b}^t - \overrightarrow{b}^t \overrightarrow{c}\overrightarrow{b}^t = 0$. □

Cor. (4.4.1.12) [Flat over Valuation Rings]. A module over a valuation ring is flat iff it is torsion free. In particular, if $(A, \mathfrak{m})$ is a DVR with a uniformizer t, then $M \in \mathcal{M}od_A$ is flat iff t is injective on M.

Proof: Because valuation ring is Bézout (10.3.2.8), we can use(4.4.1.11). □

Cor. (4.4.1.13) [Flat Module over a Dedekind Domain]. If A is a Dedekind domain, then an A-module is flat iff it is torsion-free.

Proof: Because flatness and torsion-freeness is stalkwise(4.1.4.2), so it suffices to prove for its localization, which is DVR(4.2.7.2), so the result follows from(4.4.1.12). □

Prop. (4.4.1.14) [Finite Flat is Locally Free]. Finitely presented flat module is equivalent to finite projective and equivalent to finite locally free. (Immediate from(4.3.1.7)).

Prop. (4.4.1.15). if M is a flat R-module, then $IM \cap JM = (I \cap J)M$ for ideals of A.

Proof: Tensoring the exact sequence $0 \to I \cap J \to I \oplus J \to J \cup J \to 0$ with M. □

Prop. (4.4.1.16) [Local & Infinitesimal Criterion of Flatness]. Let $(A, \mathfrak{m}) \to (B, \mathfrak{n})$ be a local homomorphism of Noetherian local rings, and M is a finite B-module, then the following are equivalent:

- M is flat over A.
- $\mathrm{Tor}_1^A(M, A/\mathfrak{m}) = 0$.
- $M/\mathfrak{m}^n M$ is flat over $A/\mathfrak{m}^n$ for sufficiently large n.

Proof: $1 \to 2, 1 \to 3$ is trivial. For the converse, we need to prove $\mathrm{Tor}_A^1(M, A/I) = 0$ for any ideal $I \subset A$, or $I \otimes M \to M$ is injective.

If 2 holds, then $\mathrm{Tor}_1^A(M, N) = 0$ for any A-module of finite length, because by devissage we can reduce N to $A/\mathfrak{m}$.

Tensoring the exact sequence $0 \to \mathfrak{m}^n \cap I \to I \to I/I \cap \mathfrak{m}^n \to 0$ with M, we get

$$\mathfrak{m}^n \cap I \otimes M \to I \otimes M \to (I/I \cap \mathfrak{m}^n) \otimes M \to 0$$

and also the exact sequence $0 \to I/I \cap \mathfrak{m}^n \to R/\mathfrak{m}^n \to R/(I + \mathfrak{m}^n) \to 0$ gives

$$0 \to (I/I \cap \mathfrak{m}^n) \otimes M \to M/\mathfrak{m}^n M \to M/(I + \mathfrak{m}^n)M \to 0$$

by the fact $R/(I + \mathfrak{m}^n)$ has finite length in case2 or the fact they are all $R/\mathfrak{m}^n M$ modules in case3.

Thus the kernel of $I \otimes M \to M$ is contained in $(\mathfrak{m}^n \cap I) \otimes M$ for any n, which means it is contained in $\mathfrak{m}^n(I \cap M)$ for any n by Artin-Rees(4.2.2.13). Thus the kernel is trivial by Krull's intersection theorem(4.2.2.14) as $I \otimes M$ is finite over S. □

Prop. (4.4.1.17).

Flat ring extension

Prop. (4.4.1.18)[Flatness is Local]. Flatness is stalkwise both on the target and source, thus flatness is local both on the target and the source(4.1.4.2).

Cor. (4.4.1.19) [Going-down]. Going-down holds for flat ring map.

Proof: The ring map $R_{\mathfrak{p}'} \to S_{\mathfrak{q}'}$ is flat by(4.4.1.18), thus it is f.f. by(4.4.1.23). Then(4.4.1.21) says $\mathfrak{p} \subset \mathfrak{p}'$ is in the image. □

Prop. (4.4.1.20). if rings $A \subset B \subset C$ and $C/A, C/B$ is flat, then B/A is flat.

Proof: Cf.[GAGA Serre P26]. □

Prop. (4.4.1.21). The following are equivalent:

- $A \to B$ is f.f.
- It is flat and $\mathrm{Spec}\, B \to \mathrm{Spec}\, A$ is surjective.
- It is flat and Spec map contains all the closed pts.

Proof: This follows form(4.4.1.5) as we see that $\mathfrak{p}$ is in the image of Spec map iff $k(\mathfrak{p}) \otimes_A B \neq 0$. □

Cor. (4.4.1.22). Integral flat injective ring extension is f.f., by(4.2.1.5).

Cor. (4.4.1.23). Flat local ring map of local rings is f.f..

Cor. (4.4.1.24). Filtered colimits of f.f. rings over R is f.f.

Proof: If is flat by(4.4.1.6), and for a maximal ideal $\mathfrak{m}$ of R, $S_i/\mathfrak{m}S_i$ is non-zero, hence there direct limit is non-zero because 1 is contained. So $\mathfrak{m}$ is in the image, hence it is f.f. by(4.4.1.21). □

Cor. (4.4.1.25)[Filtered Colimit of Flat Ring Maps]. If I is filtered and $R_i \to S_i$ are (faifhfully)flat ring maps, then $\operatorname{colim}_I R_i \to \operatorname{colim}_I S_i$ is (faithfully)flat.

Proof: For any colim R_i-module M, $(\operatorname{colim} S_i) \otimes_{\operatorname{colim} R_i} M = \operatorname{colim}(S_i \otimes_{R_i} M)$, so it is flat, because colim is exact. For the faithfully flatness, for any maximal ideal $\mathfrak{m}$ of colim R_i, let $\mathfrak{m}_i = \mathfrak{m} \cap R_i$, then $S_i/\mathfrak{m}_i S_i \neq 0$, thus the direst limit is also $\neq 0$, so $\mathfrak{m}$ is in the image, hence it is f.f. by(4.4.1.21). □

Prop. (4.4.1.26). If $R \to S$ is (faithfully)flat ring map and M is a (faithdully)flat S-module, then M is a (faithfully)flat R-module. In particular, (faithfully) flatness is stable under composition. Also (faithfully)flatness is stable under base change.

Prop. (4.4.1.27). If B is flat over A, then

$$\operatorname{Tor}_i^A(M, N) \otimes B = \operatorname{Tor}_i^B(M_{(B)}, N_{(B)}), \quad \operatorname{Ext}_i^A(M, N) \otimes B = \operatorname{Ext}^B(M_{(B)}, N_{(B)}).$$

Prop. (4.4.1.28) [Faithfully Flat Ring Map is Injective]. A f.f. ring map $R \to S$ is universally injective. In particular, tensoring with R/I, we get $R \cap IS = I$ for an ideal I of R.

Proof: Because $R \to S$ is f.f., we only need to show that $N \otimes_R S \to N \otimes_R S \otimes_R S$ is injective for any N, but this is true because it has a left inverse. □

Prop. (4.4.1.29). A f.f. map between valuation rings is equivalent to an injective local homomorphism.

Prop. (4.4.1.30). A flat ring map maps a non-zero-divisor to a non-zero-divisor, because if we consider the principal ideal generated by it, then(4.4.1.2) shows the ideal in M is also injective, so it is not a zero-divisor.

Prop. (4.4.1.31) [Noetherian Completion is Flat]. If A is Noetherian and I is an ideal, the the I-adic completion $A^\wedge$ is flat over A by(4.2.3.14).

Prop. (4.4.1.32) [Flat Map is Open]. The Spec map of a ring map $R \to S$ of f.p. that satisfies going-down(e.g. flat), is open.

Proof: $S \to S_f$ satisfies going-down and is of f.p, so we see that $R \to S_f$ satisfies going down. It suffice to prove the image of this map is open. By Chevalley, the image is constructible, and it is stable under generalization. So it is open by(3.11.4.8). □

Cor. (4.4.1.33). The Spec map f of a f.f. ring map is an quotient map.

Prop. (4.4.1.34) [Generic Freeness+F.P.]. Let R be a reduced ring, S a f.g. R-algebra, M a finite S-module, and R is reduced, then there exists an open dense subset $U \subset \operatorname{Spec} R$ that there is a covering of U by standard opens $D(f)$ s.t.

- M_f and S_f are free over R_f.
- S_f is a f.p. R_f-algebra.

- M_f is a f.p. S_f-module.

In particular, it is generically flat.

Proof: Cf.[Sta]051Z.? □

Prop. (4.4.1.35) [Miracle Flatness]. Let $f: A \to B$ be a local map of local Noetherian rings s.t.

- A is regular.
- B is Cohen-Macauley.
- $\dim B = \dim A + \dim(A/f(\mathfrak{m}_A)B)$.

Then f is flat.

Proof: Cf.[Sta]00R4. □

Prop. (4.4.1.36) [Slicing Criterion for Flat Modules on the Target]. Let $R \to S$ be a local homomorphism of local rings s.t.

- S is essentially of f.p. over R,
- M is of f.p. over S,
- $\mathrm{Tor}_1^R(M, R/I) = 0$.
- M/IM is flat over R/I.

Then M is flat over R.

Proof: Cf.[Sta]0471.? □

Prop. (4.4.1.37) [Slicing Criterion for Flatness on the Source]. Let $(R, \mathfrak{m}) \to (S, \mathfrak{n})$ be a local homomorphism of local rings s.t.

- S is essentially of f.p. over R,
- S is flat over R,
- t is a non-zero divisor of $S/\mathfrak{m}S$.

Then S/fS is flat over R, and f is a non-zero divisor in S.

Proof: Cf.[Sta]046Z. □

Prop. (4.4.1.38) [Fibral Criterion of Flat Modules]. Let $R \to S \to S'$ be local homomorphisms of local rings and $\mathfrak{m}$ is the maximal ideal of R. If

- $R \to S'$ is essentially of f.p.
- $R \to S$ is essentially of f.t.
- $M \neq 0 \in \mathcal{M}od(S')$ is of f.p. over S.
- $M/\mathfrak{m}M$ is flat over $S/\mathfrak{m}S$.
- M is flat over R.

Then S is essentially of f.p. and flat over R and M is flat over S.

Proof: [Sta]05UV. □

2 Faithfully Flat Descent

Prop. (4.4.2.1) [Faithfully Flat Descent]. List of properties that descent through faithfully flat morphism. Let $R \to R'$ be a f.f. ring map.

1. Finiteness for modules over a ring.
2. F.p. for modules over a ring.
3. Flatness for modules over a ring.
4. Finite locally freeness and invertibility for modules over a ring.
5. Mittag-Leffler for modules over a ring.
6. Projectiveness for modules over a ring.
7. F.g. for ring maps.
8. F.p. for ring maps, both on the target and source.
9. (Formal)Smoothness for ring maps.
10. Noetherian for rings.
11. Reducedness for rings.
12. Normal for rings.
13. Regular for rings.
14. Being Noetherian and has property (R_k) for rings.
15. Local Complete Intersection ring maps.

Proof:

1. Cf.[Sta]03C4.
2. Cf.[Sta]03C4.
3. Let M be a R-module, and $M' = M \otimes_R R'$, if M' is R-flat, then for any R-module N, $(N \otimes_R M) \otimes_R S = (N \otimes_R S) \otimes_S M'$, so as $\cdot \otimes_R S$ is exact and reflects exactness, $\cdot \otimes_R M$ is exact, so M is R-flat.
4. This follows from f.f. descent for f.p. and flatness and(4.3.1.7).
5. Cf.[Sta]05A5.
6. Cf.[Sta]05A9.
7. Cf.[Sta]00QP.
8. Cf.[Sta]00QQ, 00EP.
9. Use criterion(4.4.5.3), we see by flatness that the sequence $I/I^2 \to \Omega_{P/R} \otimes_P S \to \Omega_{S/R} \to 0$ commutes with flat base change, and when it is f.f., then use(4.4.3.6) and descent for projectiveness(4.4.2.1) that $\Omega_{S/R}$ is projective, so it is a split exact sequence. The smooth case follows from definition(4.4.5.12) as f.p. can descend.
10. Because for $S \to S'$ faithfully flat and a chain of ideals I_k in S, $I_k S' = I_k \otimes_S S'$, and $I_k S'$ is stable if S' is Noetherian, so also I_k is stable because it is faithfully flat.
11. $S \to S'$ is f.f. hence injective(4.4.1.28).

12. Normality is stalkwise, so it suffices to assume $R \to S$ is f.f. and R, S are both local. Then S is normal integral thus by(4.4.1.28), R is also normal integral. Now if $a/b \in R$, then $a/b \in S$, $a \in bS$, thus $a \in bS \cap R = bR$ by(4.4.1.28), so $a/b \in R$.
13. Cf.[Sta]07NG.?
14. Cf.[Sta]0353.
15. flatness and f.p. both satisfies f.f. descent, so it suffices to show that if $\mathfrak{p}' \subset R'$ is a prime lying over $\mathfrak{p} \subset R$, then $S \otimes_R k(\mathfrak{p})$ is a local complete intersection iff $S' \otimes_{R'} k(\mathfrak{p}') = S \otimes_R k(\mathfrak{p}) \otimes_{k(\mathfrak{p})} k(\mathfrak{p}')$ is a local complete intersection, and this follows from [Sta]00SI.

□

Prop. (4.4.2.2) [fpqc-Poincaré Lemma]. If a ring map $A \to B$, either has a section $B \to A$, or it is faithfully flat, then the Amitsur complex $s(M)$ for the canonical descent datum (with augmentation):

$$0 \to M \to B \otimes_A M \to B \otimes_A B \otimes_A M \to \dots$$

with Čech-like maps, is exact.

Proof: In the case $A \to B$ has a section s, It suffices to construct a nullhomotopy of the case $M = A$. Then we can just let $h(e_0 \otimes e_1 \otimes \dots \otimes e_r) = s(e_0)e_1 \otimes \dots \otimes e_r$.

The f.f. case can be reduced to the first case by tensoring B to consider $B \to B \otimes_A B$, because it has a section. □

Cor. (4.4.2.3) [Glueing Functions]. Let R be a commutative ring, M a R-module, and $(f_1, \dots, f_n) = (1)$, then there is an exact sequence

$$0 \to M \to \prod_i M_{f_i} \rightrightarrows \prod_{i,j} M_{f_i f_j}.$$

In particular this holds for $M = R$.

Proof: This is just(4.4.2.2) applied to $A \to \prod_i A_{f_i}$, which is faithfully flat. □

Formal Glueing of Modules

Main references are [Sta]Chap15.80 and 15.81.

Lemma (4.4.2.4). Let $R \to S$ be a ring map and $I = (f_1, \dots, f_r) \subset R$ be an ideal, then for any R-module M we can define a complex

$$0 \to M \xrightarrow{\alpha} M \otimes_R S \times \prod M_{f_i} \xrightarrow{\beta} \prod (M \otimes_R S)_{f_i} \times \prod M_{f_i f_j}$$

where $\alpha(m) = (m \otimes 1, m, \dots, m)$, $\beta(m', m_1, \dots, m_t) = (m' - m_1 \otimes 1, m' - m_2 \otimes 1, \dots, m' - m_t \otimes 1, m_1 - m_2, \dots, m_{t-1} - m_t)$.

Assume that $R \to S$ is flat and $R/I \to S/IS$ is an isomorphism, then this complex is exact.

Proof: Cf.[Sta]05EK. □

Def. (4.4.2.5) [Category of Gluing Data]. Let $R \to S$ be a ring map and $I = (f_1, \dots, f_r) \subset R$ be an ideal, then we define the category $Glue(R \to S, f_1, \dots, f_r)$ of gluing data $Glue(R \to S, f_1, \dots, f_t)$ consisting of objects $M = (M', M_i, \alpha_i, \alpha_{ij})$ where M' is a S-module, M_i are R_{f_i}-modules, α_i : $(M')_{f_i} \to M_i \otimes_R S$ and $\alpha_{ij} : (M_i)_{f_j} \to (M_j)_{f_i}$ are isomorphisms that

- $\alpha_{ij}\circ\alpha_i=(\alpha_j)_{f_i}$.
- $\alpha_{jk}\circ\alpha_{ij}=\alpha_{ik}$.

There is a canonical functor $Can:\mathcal{M}\mathrm{od}_R\to Glue(R\to S,f_1,\ldots,f_r)$ and also a morphism $H^0:Glue(R\to S,f_1,\ldots,f_r)\to\mathcal{M}\mathrm{od}_R$ where

$$H^0(M)=\ker(M'\times\prod M_i\to\prod M'_{f_i}\times\prod(M_i)_{f_j}).$$

H^0 is a left inverse of Can, by(4.4.2.4).

Lemma (4.4.2.6). If $R\to S$ is flat, then $Glue(R\to S,f_1,\ldots,f_r)$ is an Abelian category, and Can is an exact functor that commutes with arbitrary colimits.

If moreover $(f_1,\ldots,f_r)=R$, then Can and H^0 induces an equivalence of categories.

Proof: The kernels and cokernels can be constructed because $-\otimes_R S$ is exact, and Can is exact because R_{f_i} and S are flat over R, and also tensoring commutes with taking colimits.

For the last assertion, by(4.4.2.5) it suffices to show that Can is essentially surjective. For this, just use(4.4.2.3) on both R and S. □

Prop. (4.4.2.7). In the setting of(4.4.2.5), if $R/I\to S/IS$ is an isomorphism, then Can and H^0 induces an equivalence of categories.

Proof: Cf.[Sta]05ER. □

Cor. (4.4.2.8). If $R\to S$ is a flat ring map and $f\in R$ that $R/fR\cong S/fS$ is an isomorphism, then there is a pullback diagram of categories:

$$\begin{array}{ccc}\mathcal{M}\mathrm{od}_R & \longrightarrow & \mathcal{M}\mathrm{od}_{R_f}\\ \downarrow & & \downarrow\\ \mathcal{M}\mathrm{od}_S & \longrightarrow & \mathcal{M}\mathrm{od}_{S_f}\end{array}$$

and we can also restrict to the category of f.g./f.p/flat/projective(any property satisfying f.f. descent) modules.

Proof: For the last assertion, notice $R\to R^\wedge\times\prod R_{f_i}$ is f.f. by(4.2.3.7), then use f.f. descent(4.4.2.1). □

Cor. (4.4.2.9). If R is a Noetherian ring, $f\in R$ and $R^\wedge$ the f-adic completion of R, then there is an pullback of categories:

$$\begin{array}{ccc}\mathcal{M}\mathrm{od}_R & \longrightarrow & \mathcal{M}\mathrm{od}_{R_f}\\ \downarrow & & \downarrow\\ \mathcal{M}\mathrm{od}_{R^\wedge} & \longrightarrow & \mathcal{M}\mathrm{od}_{R^\wedge_f}\end{array}$$

and we can also restrict to the category of f.g./f.p/flat/projective(any property satisfying f.f. descent) modules.

Proof: This satisfies the hypothesis of(4.4.2.7) by(4.2.3.14). □

Def. (4.4.2.10) [Gluing Pairs]. Let $R \to R'$ be a ring map and $f \in R$ that induces an isomorphism $R/f^n R \cong R'/f^n R'$ for any $n > 0$, then $(R \to R', f)$ is called a **gluing pair** if the sequence

$$0 \to R \to R' \oplus R_f \to R'_f \to 0$$

is exact. The pair (R, f) is called a gluing pair if $(R \to \widehat{R}, f)$ is a gluing pair(This makes sense by(4.2.3.6)).

This is equivalent to $R[f^\infty] \to R'[f^\infty]$ is bijective.

Let M be an R-module, then M is called a **glueable module** for $(R \to R^\wedge, f)$ if the sequence

$$0 \to M \to M_{R'} \oplus M_{R_f} \to M_{R'_f} \to 0$$

is exact.

This is equivalent to $M[f^\infty] \to M_{R'}[f^\infty]$ is a bijection. And when $(R \to R', f)$ is a gluing pair, this is equivalent to $M[f^\infty] \to M_{R'}[f^\infty]$ is injective.

Proof: Cf.[Sta]0BNR, 0BNW. □

Prop. (4.4.2.11) [Flatness and Gluing]. $(R \to R', f)$ is a gluing pair when $R \to R^\wedge$ is flat. In particular (R, f) is a gluing pair then R is Noetherian or f is a nonzero-divisor(4.2.3.10), Cf.[Sta]0BNT.

If $(R \to R', f)$ is gluing, then M is glueable if $\mathrm{Tor}_1^R(M, R')$ is f-power torsion, or equivalently $\mathrm{Tor}_1^R(M, R'_f) = 0$. In particular this is the case when M is flat R-module or f is not a zero-divisor. And when $R \to R'$ is flat, any R-module M is glueable, in particular this is the case for (R, f) when R is Noetherian. Cf.[Sta]0BNX.

Prop. (4.4.2.12) [Beauville-Laszlo]. Let A be a commutative ring and $f \in A$ is a nonzero-divisor, let $\widehat{A}$ be the f-adic completion, then there is a pullback diagram of categories:

$$\begin{array}{ccc} \mathcal{M}\mathrm{od}_A & \longrightarrow & \mathcal{M}\mathrm{od}_{A[\frac{1}{f}]} \\ \downarrow & & \downarrow \\ \mathcal{M}\mathrm{od}_{\widehat{A}} & \longrightarrow & \mathcal{M}\mathrm{od}_{\widehat{A}[\frac{1}{f}]} \end{array}$$

Proof: Cf.[Sta]Ch15.81. □

3 Kähler Differentials

Def. (4.4.3.1) [Derivations]. A **derivation** over S from an S-algebra R to an S-module M is a morphism of S-modules $\delta : R \to M$ that $\delta(ab) = a\delta(b) + b\delta(a)$. The set of all derivatives from R to M is denoted by $\mathrm{Der}_S(R, M)$

Def. (4.4.3.2) [$A \ltimes_R M$]. For any R-algebra A, there is a functor $A \ltimes -$ from $\mathcal{M}\mathrm{od}_R$ to $(Alg_R)_{/A}$ that $A \ltimes_R M = A \otimes M$ with the algebra given by

$$(a, x)(b, y) = (ab, ay + bx).$$

Then there is a bijection of sets

$$(\mathcal{C}\mathcal{A}\mathrm{lg}_R)_{/A}(X, A \ltimes_R M) \cong \mathrm{Der}_R(X, M).$$

Def. (4.4.3.3) [Kähler Differential]. Let $S \to R$ a ring map, Then the **Kahler Differential** $\Omega_{R/S}$ is defined as a R-module that $\mathrm{Der}_S(R, M) \cong \mathrm{Hom}_S(\Omega_{R/S}, M)$. In particular, $\mathrm{Der}_S(R, R)$ is the R-dual of $\Omega_{R/S}$.

Prop. (4.4.3.4). One construction is by the free group generated by elements of R module some relations.

It can also be constructed as follows: there are two ring maps λ_i from S to $R \otimes_R S$, and one map ε from $S \otimes_R S$ to S. Let $I = \ker \varepsilon$ as a R module by λ_1, then $I/I^2 \cong \Omega_{S/R}$ by (4.4.3.8) that

$$0 \to I/I^2 \to \Omega_{S\otimes_R S/S} \otimes_{S\otimes_R S} S \to \Omega_{S/S} \to 0.$$

So $I/I^2 \cong \Omega_{S/R} \otimes_S (S \otimes_R S) \otimes_{S\otimes_R S} S \cong \Omega_{S/R}$. And it can be verified that $a \otimes 1 - 1 \otimes a$ corresponds to da.

Prop. (4.4.3.5) [Adjointness]. The functor $X \to A \otimes_X \Omega_{X/R}$ is left adjoint to the functor $A \ltimes_R -$ defined in(4.4.3.2) as a functor from $(\mathcal{CA}\mathrm{lg}_R)_{/A} \to \mathcal{M}\mathrm{od}_A$.

Proof: Because they are both equivalent to $\mathrm{Der}_R(X, M)$. □

Cor. (4.4.3.6) [Functoriality]. From the first construction, we can see directly that for a family of morphisms $R_i \to S_i$,

$$\Omega_{\operatorname{colim} S_i/\operatorname{colim} R_i} = \operatorname{colim} \Omega_{S_i/R_i}.$$

In particular, we have:

$$T^{-1}\Omega_{B/A} = \Omega_{T^{-1}B/A}, \quad \Omega_{S^{-1}B/S^{-1}A} = S^{-1}\Omega_{B/A}.$$

Moreover, we have

$$\Omega_{S/R} \otimes_R R' = \Omega_{S\otimes_R R'/R'}, \quad (S \otimes_R \Omega_{T/R}) \oplus (T \otimes_R \Omega_{S/R}) \cong \Omega_{S\otimes_R T/R}$$

by universal properties.

Proof: We prove for the localization: it suffices to show the following two assertions:

1. $S^{-1}\Omega_{A/B} \cong \Omega_{S^{-1}A/B}$.
2. If $T \subset B$ is a multiplicatively closed subset that $i(t)$ are all invertible in A, then $\Omega_{A/T^{-1}B} \cong \Omega_{A/B}$.

We check the universal properties: For any $S^{-1}A$-module M,

$$\mathrm{Hom}_{S^{-1}A}(S^{-1}\Omega_{A/B}, M) \cong \mathrm{Hom}_{S^{-1}A}(S^{-1}A \otimes_A \Omega_{A/B}, M) \cong \mathrm{Hom}_A(\Omega_{A/B}, M) \cong \mathrm{Der}_B(A, M),$$

$$\mathrm{Hom}_{S^{-1}A}(\Omega_{S^{-1}A/B}, M) \cong \mathrm{Der}_B(S^{-1}A, M)$$

There is a map $\mathrm{Der}_B(S^{-1}A, M) \to \mathrm{Der}_B(A, M)$ by restriction, and the converse is given by

$$d \mapsto d(\frac{a}{s}) = \frac{sda - ads}{s^2}.$$

This is well-defined as

$$d(\frac{at}{st}) = \frac{std(at) - atd(st)}{s^2t^2} = \frac{sda - ads}{s^2},$$

and it satisfies

$$\begin{aligned}
d(\frac{a_1}{t_1}+\frac{a_2}{t_2}) &= d(\frac{a_1t_2+a_2t_1}{t_1t_2})\\
&= \frac{(a_1d(t_2)+t_2d(a_1)+a_2d(t_1)+t_1d(a_2))t_1t_2-(a_1t_2+a_2t_1)(t_1d(t_2)-t_2d(t_1))}{t_1^2t_2^2}\\
&= \frac{t_1t_2^2d(a_1)+t_1^2t_2d(a_2)-a_2t_1^2d(t_2)+a_1t_2^2d(t_1)}{t_1^2t_2^2}\\
&= d(\frac{a_1}{t_1})+d(\frac{a_2}{t_2})
\end{aligned}$$

$$\begin{aligned}
d(\frac{a_1a_2}{t_1t_2}) &= \frac{(a_1d(a_2)+a_2d(a_1))t_1t_2-a_1a_2(t_1d(t_2)+t_2d(t_1))}{t_1^2t_2^2}\\
&= \frac{a_1(t_2d(a_1)-a_2d(t_2))}{t_1t_2^2}+\frac{a_2(t_1d(a_2)-a_1d(t_1))}{t_2t_1^2}\\
&= \frac{a_1}{t_1}d(\frac{a_2}{t_2})+\frac{a_2}{t_2}d(\frac{a_1}{t_1})
\end{aligned}$$

Thus this d is an extension of the derivative to $S^{-1}A$. Thus we get the desired isomorphism by Yoneda lemma. □

Prop. (4.4.3.7) [Jacobi-Zariski Sequences]. For a sequence of commutative rings: $A \to B \to C$, there is an exact sequence

$$C\otimes_B \Omega_{B/A}\to\Omega_{C/A}\to\Omega_{C/B}\to 0$$

of C-modules. It has a left inverse and splits iff any derivation over A from B to a C-module can be extended to a derivation over A from C to M. This is trivially true when $B\to C$ has a retraction, and true when C/B is formally smooth by(4.4.5.5).

Proof: Taking Hom with an arbitrary C-module M, by universal property, we need to check the exactness of $0\to \mathrm{Der}_B(C,M)\to\mathrm{Der}_A(C,M)\to\mathrm{Der}_A(B,M)$, which is easy. □

Prop. (4.4.3.8) [Second Exact Sequence]. (This is a special case of(6.1.1.5)). If $S'=S/I$, then there is an exact sequence of R'-modules:

$$I/I^2\to\Omega_{S/R}\otimes_S S'\to\Omega_{S'/R}\to 0.$$

Where $f\in I$ is mapped to $df\otimes 1$ and it has a left inverse and splits iff $S/I^2\to S'$ has a right inverse.
And in fact $\Omega_{S/R}\otimes S'\cong\Omega_{(S/I^2)/R}\otimes S'$.

Proof: For a S/I-module M, we check:

$$0\to\mathrm{Der}_R(S/I,M)\to\mathrm{Der}_R(S,M)\to\mathrm{Hom}_{S/I}(I/I^2,M)$$

To prove $\Omega_{S/R}\otimes S'\cong\Omega_{(S/I^2)/R}\otimes S'$, we apply Hom for a S'-module M.

So to prove the left exactness, we may assume $I^2=0$. If we have an inverse $\Omega_{S/R}\otimes_S S'\to I$. then it gives a derivation $D: A\to I$ that is identity on I, so $a-D(a)$ gives a R-ring map $S\to S$ that is trivial on I(because $I^2=0$). Hence it gives a $S/I\to S$ that is inverse to the projection.

For the converse, if $d: S/I\to S$ is a right inverse, then $a-d(\overline{a})$ is a derivation $S\to I$, which is identity on I, so it gives a inverse map $\Omega_{S/R}\otimes_S S'\to I$ by universal property. □

Cor. (4.4.3.9). If $R \to S$ is of f.p., then $\Omega_{S/R}$ is of f.p. over S. If $R \to S$ is of f.t., then $\Omega_{S/R}$ is of f.t. over S. (Follows from the second exact sequence(4.4.3.8) and(4.4.3.10)).

Cor. (4.4.3.10) [Examples].

1. $\Omega_{A[X_1,\ldots,X_n]/A} = A[X_1,\ldots,X_n]\{dX_1,\ldots,dX_n\}$.
2. If $S = A[X_i]/\{f_j\}$, then $\Omega_{S/A} = S[dX_i]/\{df_j\}$.
3. $\Omega_{A[X_i]/k} = \Omega_{A/k} \otimes_A A[X_i] \oplus A[X_i]\{dX_1 \ldots, dX_n\}$.
4. (Standard Étale Algebra)For $A = R[x]_g/(f)$, where f' has image invertible in $A, \Omega_{A/R} = 0$.
5. The differential for the inclusion $k[y^2, y^3] \to k[y]$ is $k[y]/(2y, 3y^2)\{dy\}$.

Cor. (4.4.3.11). 1: Use the differential operator and universal property.

2: Use item1 and(4.4.3.8).

3: Use item1 and the fact(4.4.3.8) splits because any derivative of A/k can be extended to derivative of B/k by acting on the coefficients.

4:

5: Use definition.

Cor. (4.4.3.12). If S/I is a field k that embeds in S, then $I/I^2 \cong \Omega_{S/k} \otimes_S k$.

Prop. (4.4.3.13). Let $k \subset K \subset L$ be fields, and L/K f.g., then

$$\dim_L \Omega_{L/k} \geq \dim_K \Omega_{K/k} + \operatorname{tr.deg}(L/K).$$

Equality holds if L/K is separably generated, i.e. separable over a transcendental basis. If $K = k$, then the equality hold iff L/k is separably generated. In particular, L/k is separable algebraic extension iff $\Omega_{L/k} = 0$.

Proof: Take a subfield $K \subset K(t_1,\ldots,t_n) \subset L$ that L is separable algebra over $K(t_1,\ldots,t_n)$. Then it suffices to add one element a time, so we may assume $L = K(\alpha)$.

1: If α is transcendental over K, then $\Omega_{K[\alpha]/t} \cong \Omega_{K/k} \otimes K[\alpha] \oplus K[\alpha]dt$ by(4.4.3.10), and by localization(4.4.3.6) we get $\Omega_{L/K} \cong \Omega_{K/k} \otimes_K L \oplus Ldt$, thus $\operatorname{rank}\Omega_{L/k} = \operatorname{rank}\Omega_{K/k} + 1$.

2: If α is separable over K, then there is a monic polynomial $f \in K[X]$ that $K[\alpha] \cong K[X]/(f)$. Then f' is invertible in $K[\alpha]$, and by(4.4.3.10) $\Omega_{K[\alpha]/k} = \Omega_{K/k} \otimes_K L \oplus LdX/(d(f) + f'dX) \cong \Omega_{K/k} \otimes_K L$. Thus $\operatorname{rank}\Omega_{L/k} = \operatorname{rank}\Omega_{K/k}$.

3: If K has characteristic p and $L = K[X]/(X^p - a)$ and $d_{K/k}(a) = 0$, then $\Omega_{K[\alpha]/k} = \Omega_{K/k} \otimes_K L \oplus LdX/(d(a)) \cong \Omega_{K/k} \otimes_K L \oplus LdX$. Thus $\operatorname{rank}\Omega_{L/k} = \operatorname{rank}\Omega_{K/k} + 1$.

4: If K has characteristic p and $L = K[X]/(X^p - a)$ and $d_{K/k}(a) \neq 0$, then $\Omega_{K[\alpha]/k} = \Omega_{K/k} \otimes_K L \oplus LdX/(d(a))$ has rank $\operatorname{rank}\Omega_{K/k}$.

Thus the assertion is clear. □

Prop. (4.4.3.14) [Differential and Regularity]. Let B be a Noetherian local ring containing its residue field k and k is perfect, then $\Omega_{B/k}$ is a free B-module of rank $\dim B$ iff B is regular. [Hartshorne Ex.2.8.1] has a generalization of this fact.

Proof: One way is by(4.4.3.12). Conversely, if B is regular, then it is integral(4.3.5.19), so $\Omega_{B/k} \otimes_B K = \Omega_{K/k}$(4.4.3.6) is of K-dimension $tr.\deg K/k = \dim B$, where K is the quotient field of B, and $\Omega_{B/k} \otimes k \cong m/m^2$ is of k-dimension $\dim B$ once again. These two facts shows that $\Omega_{B/k}$ is free B-module of rank $\dim B$ by(4.4.8.1). □

Prop. (4.4.3.15). The Kähler differential $\Omega_{\mathcal{O}_L/\mathcal{O}_K}$ for an extension of number fields is cyclic.

Proof: Because it is locally cyclic**?**(4.2.7.34). □

4 Complete Intersections

Koszul Complex

Prop. (4.4.4.1) [Koszul Complex]. The complex of $\mathbb{Z}[X_1,\ldots,X_n]$-modules $K_\bullet$, where

$$K_r = \wedge^{r+1}\mathbb{Z}[dX_1,\ldots,dX_n]\otimes_{\mathbb{Z}}\mathbb{Z}[X_1,\ldots,X_n]$$

and the morphism is given linearly by

$$\iota : dX_{i_0}\wedge dX_{i_1}\wedge\ldots\wedge dX_{i_r}\mapsto\sum_k X_{i_k}dX_{i_0}\wedge\ldots\wedge dX_{i_{k-1}}\wedge dX_{i_{k+1}}\wedge\ldots\wedge dX_{i_r}$$

Then this is a free resolution of $\mathbb{Z}$ over $\mathbb{Z}[X_1,\ldots,X_n]$.

Proof: We can use induction. If $r=1$, then this is clear. For the induction process, if $\iota(dX_1\wedge\alpha+\beta)=0$, and $\beta\in K_i$, where β,α has no dX_1 involved. Notice if $dX_1\wedge\alpha\in K_0$, then we may assume α has no constant coefficient, because this is impossible.

then $X_1\alpha-dX_1\wedge\iota(\alpha)+\iota(\beta)=0$. Then we see that $\iota(\alpha)=0$. We can write $\alpha=\alpha_0+X_1\alpha_1+X_1^2\alpha_2+\ldots$, where α_i has no X_i involved, then we see that $\iota(\alpha_i)=0$, then by induction hypothesis $\alpha=\iota(\alpha')$(notice α_0 has no constant coeffienct), and $\iota(\beta)+X_1\iota(\alpha')=0$. If $\beta=X_1\beta_1+\beta_2$, where β_2 has no X_1 involved, then $\iota(\beta_2)=0$, so $\beta_2=\iota(\beta_2')$, and $\iota(\beta_1+\alpha')=0$, so $\beta_1+\alpha'=\iota(\beta_1')$. So

$$dX_1\wedge\alpha+\beta=dX_1\wedge\iota(\alpha')+\iota(X_1\beta_1'+\beta_2')-X_1\alpha'=\iota(X_1\beta_1'+\beta_2'-dX_1\wedge\alpha').$$

And in degree0, this is clear. □

Def. (4.4.4.2) [Koszul Complex]. Let A be a ring and $I=(f_1,\ldots,f_n)\in A$ is an ideal, then the **Koszul complex** for $Kos(A,f_1,\ldots,f_n)$ is an object in $D(A)$ defined by

$$Kos(A,f_1,\ldots,f_n)=A\otimes^L_{\mathbb{Z}[X_1,\ldots,X_n]}\mathbb{Z},$$

where A is a $\mathbb{Z}[X_1,\ldots,X_n]$-algebra by mapping $X_i\to f_i$. If M is an A-module, then we define $Kos(M,f_1,\ldots,f_n)=M\otimes^L_A Kos(A,f_1,\ldots,f_n)$.

Prop. (4.4.4.3). If $f_1,\ldots,f_n\in R$, then $I=(f_1,\ldots,f_n)$ annihilates $H^*(K(f_1,\ldots,f_n))$. In particular, $Kos(A,f_1,\ldots,f_n)$ is in the image of $D(A/I)\subset D(A)$.

Proof: This is because every $H^i(A\otimes^L_{\mathbb{Z}[X_1,\ldots,X_n]}\mathbb{Z})$ is an $H^0(A\otimes^L_{\mathbb{Z}[X_1,\ldots,X_n]}\mathbb{Z})=A/I$-algebra, because it is a simplicial algebra. □

Prop. (4.4.4.4). $K(A,f_1,\ldots,f_n,g_1,\ldots,g_m)=K(A,f_1,\ldots,f_n)\otimes_A K(A,g_1,\ldots,g_m)$. (Easy).

Prop. (4.4.4.5). The cone of the map

$$f_n : K(f_1,\ldots,f_{n-1})\to K(f_1,\ldots,f_{n-1})$$

is isomorphic to $K(f_1,\ldots,f_n)$.

Proof: This is because $\mathbb{Z}[X]\xrightarrow{X}\mathbb{Z}[X]\to\mathbb{Z}$ is an exact triangle, so $A\xrightarrow{f_n}A\to A\otimes^L_{\mathbb{Z}[X]}\mathbb{Z}$ is an exact triangle, so $Kos(A,f_1,\ldots,f_{n-1})\xrightarrow{f_n}K(A,f_1,\ldots,f_{n-1})\to K(A,f_1,\ldots,f_n)$ is an exact triangle. □

Prop. (4.4.4.6). Let A be a ring and M be an A-module. Let $f_1,\dots,f_{r-1},f,g$ be elements of A, then there is a natural distinguished triangle

$$Kos(M,f_1,\dots,f_{r-1},f)\to Kos(M,f_1,\dots,f_{r-1},fg)\to Kos(M,f_1,\dots,g).$$

Proof: We use(4.4.4.5) to consider $Kos(M,f_1,\dots,f_{r-1},f)$ as a cone of $f_n: Kos(M,f_1,\dots,f_{r-1})\to Kos(M,f_1,\dots,f_{r-1})$. Then this distinguished triangle is given by(3.7.7.15) applied to the diagram

$$\begin{array}{ccc} Kos(M,f_1,\dots,f_{r-1}) & = & Kos(M,f_1,\dots,f_{r-1}) \\ \downarrow f & & \downarrow fg \\ Kos(M,f_1,\dots,f_{r-1}) & \xrightarrow{g} & Kos(M,f_1,\dots,f_{r-1}) \end{array}$$

□

Prop. (4.4.4.7) [Koszul Complex and Čech Complex]. Let A be a commutative ring and $I=(f_1,\dots,f_n)\subset A$, $K_n^\bullet=Kos(A,f_1^n,\dots,f_r^n)=A\otimes^L_{\mathbb{Z}[X_1,\dots,X_r]}\mathbb{Z}$. Then there are natural maps

$$\dots\to K_3^\bullet\to K_2^\bullet\to K_1^\bullet$$

compatible with the inverse system $H^0(K_n^\bullet)=A/(f_1^n,\dots,f_r^n)$. Then there is a description of $R\operatorname{colim}K_n^\vee$(4.9.5.6) as the alternating Čech complex

$$R\to\bigoplus_{i_0}R_{f_{i_0}}\to\bigoplus_{i_0<i_1}R_{f_{i_0}f_{i_1}}\to\dots\to R_{f_1f_2\dots f_r}$$

where R sits in degree 0.

Proof: Cf.[Sta]0913, which is not hard. □

Def. (4.4.4.8)[Koszul-Regular Sequence]. Let A be a ring and $(f_1,\dots,f_n)\in A$ be a sequence, then $f_1,\dots,f_n$ is called M**-Koszul-regular** iff $Kos(M,f_1,\dots,f_n)=0$. It is called **Koszul-regular** iff $Kos(A,f_1,\dots,f_n)=0$.

Prop. (4.4.4.9). If $(f_1,\dots,f_r)$ is (M-Koszul)regular and $n_i>0$, then $(f_1^{n_1},\dots,f_r^{n_r})$ is also (M-Koszul)regular.

Proof: This follows from(4.4.4.6). □

Prop. (4.4.4.10) [Regular and Koszul-Regular]. A M-regular sequence(4.3.4.1) is M-Koszul-regular. A regular sequence is Koszul-regular.

Proof: Let $(f_1,\dots,f_r)$ be a regular sequence. The assertion is clear when $r=1$. For the induction:

$$\begin{aligned} Kos(M,f_1,\dots,f_n) &= Kos(M,f_2,\dots,f_n)\otimes^L_{\mathbb{Z}[X]}\mathbb{Z}=Kos(A,f_2,\dots,f_n)\otimes^L_A M\otimes^L_{\mathbb{Z}[X]}\mathbb{Z}\\ &= Kos(A/f_1,f_2,\dots,f_n)\otimes^L_{A/f_1}M/f_1M=Kos(M/f_1M,f_2,\dots,f_n)\end{aligned}$$

so we can use induction. □

Complete Intersections

Def. (4.4.4.11)[Global Complete Intersections]. A ring map $R \to S$ is called **global intersection** if $S = R[x_1, \dots, x_n]/(f_1, \dots, f_c)$ that every non-empty fiber of $\operatorname{Spec} S \to \operatorname{Spec} R$ has dimension $n - c$.

Prop. (4.4.4.12). Global intersection is stable under base change and composition. And $S \to S_f$ a global intersection, so it is stable under localization.

Proof: Base change: this is because flatness, f.p. is stable under base change, and the fibers are the same.

Localization: $S_f = S[X]/(fX - 1)$ has trivial fibers.

Composition: It suffices to assume R is a field and calculate the dimension of the fibers, which is true by dimension formula(4.2.4.13). □

Prop. (4.4.4.13)[Noetherian Approximation]. Let R be a ring and $S = R[X_1, \dots, X_n]/(f_1, \dots, f_c)$ is a global intersection over R, then there is a f.g. $\mathbb{Z}$-algebra $R_0 \subset R$ that $f_i \in R_0[X_1, \dots, X_n]$, and $S_0 = R_0[X_1, \dots, X_n]/(f_1, \dots, f_c)$ is a global intersection over R.

Proof: Cf.[Sta]00SU. □

Prop. (4.4.4.14) [Complete Intersection is Regular]. Let R be a ring and $S = R[X_1, \dots, X_n]/(f_1, \dots, f_c)$ be a global complete intersection, then $\operatorname{Spec} S \to \operatorname{Spec} R[X_1, \dots, X_n]$ is a regular embedding(5.6.8.1), and S is flat over R.

Proof: Cf.[Sta]00SV. □

Local Complete Intersections

Def. (4.4.4.15)[Local Complete Intersections]. Let S be a R-algebra, then S is a **local complete intersection** over R iff S is locally a global complete intersection over R. Local complete intersection is flat, by(4.4.4.14).

Prop. (4.4.4.16). Local complete intersection is local on the source and target. In fact satisfies f.f. descent(4.4.2.1).

Lemma (4.4.4.17). If S is a f.t. k-algebra and K/k is a field extension, then S is a local complete intersection iff S_K is a local complete intersection.

Prop. (4.4.4.18) [Global Intersections and Fibers]. Let $R \to S$ be a ring map and $\mathfrak{q} \subset S$ be a prime lying over $\mathfrak{p} \subset R$, then the following are equivalent:

- $R \to S$ is a global complete intersection around $\mathfrak{q}$.
- $R \to S$ is a f.p. around $\mathfrak{q}$, $S_\mathfrak{q}/R_\mathfrak{p}$ is flat, and (the fiber)$S_\mathfrak{q}/\mathfrak{p}S_\mathfrak{q}$ is a local complete intersection ring over $k(\mathfrak{p})$.

Proof: $1 \to 2$ follows from(4.4.4.14). For $2 \to 1$, Cf.[Sta]00SY. □

Prop. (4.4.4.19) [Local Complete Intersection over Fields is Stalkwise]. For a f.g. k-algebra S, S is a local complete intersection iff all localization at (maximal)primes are complete intersection local rings over k. In particular, being local complete intersection is a stalkwise property.

Proof: This is because over field everything is f.p. and flat, and use(4.4.4.18). □

Prop. (4.4.4.20). If S is a f.g. local complete intersection over a field k, then it is a CM ring.

Proof: Cf.[Sta]00SB. □

Def. (4.4.4.21) [Complete Intersection Local Rings]. Let A be a local ring essentially of f.t. over a field k, then A is called a **complete intersection local ring** over k if there exists a surjection $R \to A$ from a regular local ring essentially of f.t. over k that the kernel is generated by a regular sequence.

Prop. (4.4.4.22). When A is f.g. local ring over a field k, then A is a complete intersection local ring iff A is local complete intersection over k(4.4.4.11).

Proof: Cf.[Sta]00SC. □

See more in [Sta]Chap 23.8.

5 Smoothness

Formally Smoothness

Def. (4.4.5.1). A ring map $R \to S$ is called **formally smooth** if has right lifting property w.r.t all ring maps $A \to A/I$ where $I^2 = 0$.

Formal smooth is stable under base change and composition, by universal arguments. A polynomial algebra is formally smooth.

Prop. (4.4.5.2). Giving a presentation $S = P/J$ where P is formally smooth(e.g. polynomial algebra), S is formally smooth iff there is a map $S \to P/J^2$ that is right converse to the obvious projection.

Proof: One way is from the definition of formally smooth applied to P/J^2 and J. Conversely, for any A and I, we notice the map $P \to S \to A/I$ can be lifted to $P \to A$, and J is mapped to I, so J^2 is mapped to 0, so we have a map $P/J^2 \to A$. Then $S \to P/J^2 \to A$ is the lifting. □

Cor. (4.4.5.3). If $P \to S$ is a presentation of S/R by polynomial algebra with kernel I, then S/R is formal smooth iff

$$0 \to I/I^2 \to \Omega_{P/R} \otimes_P S \to \Omega_{S/R} \to 0$$

is split exact as in(4.4.3.8).

Proof: This sequence is split exact iff $P/J^2 \to S$ has a right converse, by(4.4.3.8). □

Now we consider the relation of Formal Smoothness and Kahler Differentials.

Cor. (4.4.5.4) [Equivalence Definition]. S/R is formally smooth iff $NL_{S/R}$ is quasi-isomorphic to a projective S-module at degree 0.

Proof: If S/R is formally smooth, then choose a presentation will suffice by(4.4.5.3). The converse is also true by projectiveness and(4.4.5.3). □

Cor. (4.4.5.5). If C/B is formally smooth, then the Jacobi-Zariski sequence

$$0 \to C \otimes_B \Omega_{B/A} \to \Omega_{C/A} \to \Omega_{C/B} \to 0$$

as in(4.4.3.7) is split exact, by(6.1.1.5). In particular, any derivation of B to a C-module can be extended to a derivation C to a C-module.

Cor. (4.4.5.6). If $A \to B \to C$ with $A \to C$ formally smooth and $B \to C$ surjective with kernel I, then there is an split sequence

$$0 \to I/I^2 \to \Omega_{B/A} \otimes_B C \to \Omega_{C/A} \to 0$$

by(6.1.2.6).

Standard Smooth Algebra

Def. (4.4.5.7). A **standard smooth algebra** over R is a algebra $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)$, where $c \leq n$ and $J(\frac{f_1,\ldots,f_c}{X_1,\ldots,X_c})$ is invertible in S.

Prop. (4.4.5.8) [Standard Smooth Localization]. If $R \to S$ is standard smooth, then $R \to S_g$ is standard smooth, and $R_f \to S_f$ is standard smooth(because stable under base change(4.4.5.9)).

Proof: For localization at $g \in S$, let h be an inverse image of g in $R[X_1, \ldots, X_n]$, then $S_g = R[X_1, \ldots, X_n, X_{n+1}]/(f_1, \ldots, f_c, X_{n+1}h - 1)$, and it is standard smooth. □

Prop. (4.4.5.9). Standard smoothness is stable under base change and composition.

Proof: For base change, notice the Jacobi matrix is the base change of the Jacobi matrix, so it is also invertible. For composition, write out the presentation, the determinant is the product of the presentation. □

Lemma (4.4.5.10) [Kähler Differential of Smooth Algebra is Free]. The Kähler differential of a standard smooth algebra S over a field k is free of rank $\dim S$, and $(f_1, \ldots, f_c)/(f_1, \ldots, f_c)^2$ is free over S with basis $f_1, \ldots, f_c$. Moreover, S is pure dimensional.

Proof: The naive cotangent complex for S/R is

$$d : (f_1, \ldots, f_c)/(f_1, \ldots, f_c)^2 \to S[dX_1, \ldots, dX_n].$$

By hypothesis and linear algebra it is a split injection, and $\Omega_{S/R} = S[dX_{c+1}, \ldots, dX_n]$, so it is free of rank $n - c = \dim S$, because S is a global complete intersection(4.4.5.11). □

Prop. (4.4.5.11) [Standard Smooth and Complete Intersection]. A standard smooth algebra $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)$ is a global complete intersection(4.4.4.11).

Proof: It suffices to show any fiber of S has dimension $n - c$. For this, notice $S \otimes_R k(\mathfrak{p})$ is also standard smooth, then we reduce to the field case. Now $I = (f_1, \ldots, f_c)$ satisfies $I/I^2 \to \oplus S dx_i$ is a split injection. For any maximal ideal $\mathfrak{m}$ containing I, tensoring $k(\mathfrak{m})$, we get an injection $I/\mathfrak{m}I \to \oplus k(\mathfrak{m}) dx_i$. Notice there is a commutative diagram

$$\begin{array}{ccc} I & \longrightarrow & S/\mathfrak{m} \otimes I \cong I/\mathfrak{m}I \\ \downarrow{\scriptstyle d} & & \downarrow{\scriptstyle incl} \\ \oplus S dx_i & \xrightarrow{dx_i \mapsto 1 \otimes x_i} & S/\mathfrak{m} \otimes \mathfrak{m} \cong \mathfrak{m}/\mathfrak{m}^2 \end{array}.$$

And the lower horizontal map is an isomorphism by Hilbert's Nullstellensatz, so the image of f_i in $\mathfrak{m}_i/\mathfrak{m}_i^2$ are linearly independent over $k(\mathfrak{m})$, thus we can use(4.3.5.22) to show that $\dim S = n - c$. □

Smoothness

Def. (4.4.5.12) [Smooth Ring Map]. A ring map $R \to S$ is called **smooth** if it satisfies the following equivalent conditions:

- It is of f.p. and the naive cotangent complex $NL_{S/R}$ is quasi-isomorphic to a finite locally free S-module placed at degree 0. In other words,

$$0 \to I/I^2 \to \Omega_{P/R} \otimes_P S \to \Omega_{S/R} \to 0$$

is exact and $\Omega_{S/R}$ is finite locally free. By(6.1.1.1), we only need to prove for a single presentation of S.

- It is locally standard smooth.
- It is formally smooth and of f.p..

We say S is smooth at x if it is smooth on a nbhd of x.

Proof: $1 \to 3$: by(4.4.5.4). $3 \to 1$: By(4.4.5.4), $\Omega_{S/R}$ is f.p. and projective, so it is finite projective.

At this point we already know that the first definition is stable under base change and composition, because f.p. and formally smoothness both do(4.4.5.1)(4.3.7.9).

And also the first definition is local on source because f.p. does(4.1.4.4) and NL commutes with localization(6.1.1.6) so we can use the local properties of triviality(4.1.4.2) and finite projectiveness(4.3.1.7).

Now it is also local on the source because it is stable under base change and composition and $R \to R_{f_i}$ does by locality on the source.

$2 \to 1$:Now the property are all local on source. It suffices to prove a standard smooth map is smooth. This follows from(4.4.5.10).

$1 \to 2$:We need to prove, assuming the first definition, it is locally standard smooth. For this, Cf.[Sta]00TA**?**. □

Cor. (4.4.5.13). Smoothness is stable under composition and base change. Smoothness is local on the source and target(In particular, $R \to R_f$ is smooth). (Already proved in the proof of(4.4.5.12)).

Prop. (4.4.5.14). A smooth map is a local complete intersection(4.4.4.15), hence flat.

Proof: Clear from(4.4.5.12). □

Prop. (4.4.5.15) [Noetherian Descent]. A smooth ring map $R \to S$ is a base change of smooth ring map over a ring f.g. over $\mathbb{Z}$.

Proof: Use the equivalence definition(4.4.5.2), we know that there is a map

$$S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c) \to R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)^2,$$

which if we write $\sigma(X_i) = h_i$, then must satisfy

$$f_i(h_1, \ldots, h_n) = \sum a_{ijk} f_j f_k.$$

Then we consider the subalgebra generated by f_i, h_i, a_{ijk}, then by the same reason, they form a smooth algebra over $\mathbb{Z}$, and its tensor with R gives out S. □

Cor. (4.4.5.16) [Strong Lifting Property]. For a smooth ring map, the lifting property is true for $A \to A/I$, where I is locally nilpotent.

Proof: By(4.4.5.15), $R \to S$ is a base change of a smooth ring map $R_0 \to S_0$ where R_0 is f.g. over $\mathbb{Z}$. Now if S_0 is generated by $x_1, \ldots x_n$ and $a_1, a_n \in A$ maps to the image of $x_1, \ldots, x_n$ in A/I, then consider the subring A_0 generated by R_0 and a_i, and let $I_0 = A_0 \cap I$, then it suffices to prove this case followed by base change. But now A_0 is f.g. over $\mathbb{Z}$, so it is Noetherian, and then I is nilpotent, thus we have a desired lifting. □

Prop. (4.4.5.17) [Stalkwise]. If $R \to S$ is f.p., then it is smooth iff it is S_q/R_p is smooth for every (maximal)prime q of S and p under it.

Proof: Because of f.p., we only need to check triviality of $H_1(NL)$ and finite projectivity of $\Omega_{S/R}$(4.4.5.12). But both triviality and finite projectivity is stalkwise(4.1.4.2). (Notice $R \to R_p$ is smooth). □

Cor. (4.4.5.18) [Smooth Locus and Flat Base Change]. If $R \to S$ is of f.p. and $R \to R'$ is flat. Then the smooth locus of $S' = S \otimes_R R'/R'$ is the inverse image of smooth locus of S/R.

Proof: One direction is because smooth is stable under base change. Conversely, the local ring map is f.f., so $H_1(NL_{S'/R',q}) = H_1((NL_{S/R} \otimes_S S')_q) = H_1(NL_{S/R,p} \otimes_{S_p} S'_q)$. Then the result follows as S'_q/S_p is f.f. and triviality and finite projective descents for f.f. map(4.4.2.1). □

Lemma (4.4.5.19). A global complete intersection $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)$ is smooth at a point $\mathfrak{p}$ iff the Jacobian has rank $\geq n - \dim_{\mathfrak{q}}(S)$ at $\mathfrak{q}$, i.e. $J(\frac{f_1,\ldots,f_c}{X_1,\ldots,X_c})$ is not in $\mathfrak{q}$ for some permutation of $X_1, \ldots, X_n$.

Proof: This is a special case of(4.4.5.24). However, we need to prove it first here. If it is smooth at $\mathfrak{q}$, then $\Omega_{S/R}$ is locally free of dimension $\geq n - \dim_{\mathfrak{q}}(S)$ at $\mathfrak{q}$ by(4.4.5.10), so the Jacobian has rank $\geq n - \dim_{\mathfrak{q}}(S)$. Conversely, if $g = J(\frac{f_1,\ldots,f_c}{X_1,\ldots,X_c}) \notin \mathfrak{q}$, then $S_g = R[X_1, \ldots, X_n, X_{n+1}]/(f_1, \ldots, f_c, gX_{n+1}-1)$ is a standard smooth map. □

Prop. (4.4.5.20) [Fiberwise]. For a ring map $R \to S$ and $\mathfrak{q}$ is a prime of S over $\mathfrak{p}$. Then S/R is smooth at $\mathfrak{q}$ iff S/R is of f.p. around $\mathfrak{q}$ and $S_{\mathfrak{q}}/R_{\mathfrak{p}}$ is flat and $S \otimes_R k(\mathfrak{p})/k(\mathfrak{p})$ is smooth at $\mathfrak{q}$.

Proof: One direction is because smooth is flat, f.p. and stable under base change. Conversely, by(4.4.5.14) and(4.4.4.18), change R to R_g for some $g \notin \mathfrak{p}$, we may assume $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)$ is a global complete intersection. Then we may use(4.4.5.19) to see the map is smooth on the standard open subset defined by the product of Jacobians of f_i. □

Prop. (4.4.5.21). If $A \to A[X_1, \ldots, X_n] \to R$ is smooth, then $A[X_1, \ldots, X_n] \to R$ is smooth.

Proof: The desired map is firstly of f.p. by(4.3.7.11), and it can be verified to be formally smooth, because $A[X_1, \ldots, X_n]$ is free. □

Smooth over Fields

Lemma (4.4.5.22). Let S be f.g. over a alg.closed field k and $\mathfrak{m}$ a maximal ideal, then the following are equivalent:

- $S_{\mathfrak{m}}$ is regular.
- $\dim_k \Omega_{S/k} \otimes_S k \leq \dim S_{\mathfrak{m}}$
- $\dim_k \Omega_{S/k} \otimes_S k = \dim S_{\mathfrak{m}}$
- S/k is smooth at $\mathfrak{m}$.

Proof: Cf.[Sta]00TS. □

Prop. (4.4.5.23) [Differential Criterion of Smoothness]. For a ring S f.g. over a field k, S is smooth in a nbhd of $\mathfrak{q}$ iff $\dim_{k(\mathfrak{q})} \Omega_{S/k} \otimes k(\mathfrak{q}) \leq \dim_{\mathfrak{q}}(S)$.

And in this case, equality hold, and $S_{\mathfrak{q}}$ is regular.

Proof: Cf.[Sta]00TT.

If S is smooth at x, then $\Omega_{S/R}$ is finite free on a nbhd of x of rank equals to the dimension(4.4.5.10), so the equation holds.

Conversely, if $\dim_{k(x)} \Omega_{S/k} \otimes k(x) \leq \dim_x(X)$, then □

Cor. (4.4.5.24)[Jacobian Criterion of Smoothness]. For a f.p. ring $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)$ and $\mathfrak{q} \subset S$, S is smooth at $\mathfrak{q}$ iff the Jacobian has rank$\geq n - \dim_{\mathfrak{q}}(S)$ at $\mathfrak{q}$ iff the Jacobian has rank$= n - \dim_{\mathfrak{q}}(S)$ at $\mathfrak{q}$.

Lemma (4.4.5.25). Let k be a field and $(R, \mathfrak{m}, \kappa)$ be a Noetherian local ring containing k. If the residue field of R is a f.g. field extension of k, then the derivation map

$$\mathfrak{m}/\mathfrak{m}^2 \to \Omega_{R/k} \otimes_R \kappa$$

is injective.

Proof: Cf.[Sta]00TU. □

Prop. (4.4.5.26) [Smooth and Regular at Geometric Points]. Let S be f.g. over a field k, if $k(\mathfrak{q})/k$ is separable(e.g. char 0) for $\mathfrak{q}$ a prime of S, then S is smooth at $\mathfrak{q}$ iff it is regular at $\mathfrak{q}$.

Proof: Let $R = S_{\mathfrak{q}}$ with maximal ideal $\mathfrak{m}$. By(4.4.5.25) and(4.4.3.8) there is an exact sequence

$$0 \to \mathfrak{m}/\mathfrak{m}^2 \to \Omega_{R/k} \otimes_R k(\mathfrak{q}) \to \Omega_{k(\mathfrak{q})/k} \to 0.$$

Since $k(\mathfrak{q})/k$ is separable, $\dim_{k(\mathfrak{q})} \Omega_{k(\mathfrak{q})/k} = \operatorname{tr.deg}(k(\mathfrak{q})/k)$. So

$$\dim_{k(\mathfrak{q})}(\Omega_{R/k} \otimes_R k(\mathfrak{q})) = \dim_{k(\mathfrak{q})} \mathfrak{m}/\mathfrak{m}^2 + \operatorname{tr.deg}(k(\mathfrak{q})/k) \geq \dim R + \operatorname{tr.deg}(k(\mathfrak{q})/k) = \dim_{\mathfrak{q}}(S)$$

with identity iff R is regular(The last identity comes from(5.6.3.7)). So we are done by differential criterion of smoothness(4.4.5.23). □

Prop. (4.4.5.27) [Smooth over Fields and Geo.Regular]. Let S be f.g. over a field k, then S is smooth over k iff S is geo.regular(4.3.6.1).

Proof: If S is smooth at x, then all its base change is smooth at x(4.4.5.13), and the stalk is regular by(4.4.5.23), so it is geometrically regular at x.

Conversely, if X is geometrically regular, then for any point $x \in X$, $k(x)$ is f.g. over k, so by(4.3.9.3) there is a finite purely inseparable extension k'/k that the compositum $k'k(x)$ is separable over k'. Then by(4.1.7.26), $\operatorname{Spec} A \otimes_k k'$ is homeomorphic to $\operatorname{Spec} A$, so there is a unique prime p' of $X_{k'}$ over X, and its residue field is $k'k(x)$. So by(4.4.5.26), as $k'k(x)/k'$ is separable, $X_{k'}$ is smooth over k' at p'. And f.f. descent for smoothness(4.4.2.1) says X is also smooth over k at p. □

Cor. (4.4.5.28) [Differential and Smoothness]. Let k be a field of characteristic 0 and S a f.g. algebra over k, and $\mathfrak{q}$ a prime ideal of S, if $\Omega_{S/k,\mathfrak{q}}$ is free over $S_{\mathfrak{q}}$, then S is smooth in a nbhd of $\mathfrak{q}$.

Proof: Cf.[Sta]00TX. □

Prop. (4.4.5.29) [Generic Smoothness]. Let $R \to S$ be an injective ring map of f.t. with R, S domains, then it is smooth at (0) iff the quotient field map is separable.

Proof: If S is smooth at 0, then replacing S by S_g for some g, we can assume $R \to S$ is smooth. Then $K \to S \otimes_R K$ is also smooth(4.4.5.13), and also for any field extension K' of K. Then $S \otimes_R K'$ is regular, by(4.4.5.23), a priori reduced(5.4.1.5). Thus $S \otimes_R K$ is geometrically reduced. Hence also L is geometrically reduced over K, thus separable, by(4.3.9.4).

Conversely, by(4.4.1.34), we may assume $R \to S$ is of f.p., thus to show it is smooth at (0), it suffices to show $S \otimes_R K$ is smooth at (0), by(4.4.5.20). Then this follows from(4.4.5.26). □

Smoothing Ring Maps

Prop. (4.4.5.30). A regular homomorphism of Noetherian rings is a filtered colimit of smooth ring maps.

Proof: Cf.[Sta]07GC. □

6 Unramified

Formally Unramified

Def. (4.4.6.1). A ring map $R \to S$ is called **formally unramified** if for every R-ring A and an ideal I of A that $I^2 = 0$, a map $S \to A/I$ has at most one extension to a map $S \to A$.

Formally unramified is equivalent to $\Omega_{S/R} = 0$. So it is stable under composition by Jacobi-Zariski sequence(4.4.3.7).

Proof: Let $J = \ker(S \otimes_R S \to S)$, let $A_{univ} = S \otimes_R S/J^2$, then $J/J^2 \cong \Omega_{S/R}$(4.4.3.4), so we have two natural map from S to A_{univ}, they differ by the universal differential $S \to \Omega_{S/R}$. If S/R is unramified, then $ds = 0$ for all $s \in S$, so $\Omega_{S/R} = 0$.

Conversely, if there is a A and A/J that there are two liftings τ_1, τ_2, then we let $A_{univ} \to A$ defined by $s_1 \otimes s_2 \to \tau_1(s_1)\tau_2(s_2)$, this is well-defined, and because $A_{univ} \cong S$, this map descends to S, so $\tau_1(s_1 s_2) = \tau_2(s_1 s_2)$. □

Prop. (4.4.6.2) [Formally Unramified Stalkwise]. Formally unramified is stalkwise both on the source and target(4.1.4.2).

Prop. (4.4.6.3). Colimits of formally unramified rings over R is formally unramified. (Trivial as one renders on the diagram in the definition of formally unramified).

Unramified Map

Def. (4.4.6.4) [Unramified Maps]. A ring map is called **unramified** iff it is formally unramified and f.g..

A ring map is called G-**unramified** iff it is formally unramified and of f.p.. In particular, an étale map is G-unramified.

These two notions are stable under composition and base change. These two notions are local on the source and target. $R \to R_f$ is G-unramified.(4.4.6.1)(4.1.4.2)

Prop. (4.4.6.5). $R \to R/I$ is unramified, and if I is f.g., then it is G-unramified. (Trivial).

Prop. (4.4.6.6) [Stalkwise and Fiberwise]. If $R \to S$ is of f.t(f.p.), then it is unramified(G-unramified) at a prime q of S iff $(\Omega_{S/R})_q = 0$ iff $\Omega_{S/R} \otimes_S k(q) = 0$ iff $(\Omega_{S\otimes k(p)/k(p)})_q = 0$ iff $\Omega_{S\otimes k(p)/k(p)} \otimes k(q) = 0$.

Proof: By Nakayama, two pair of them are equivalent, and if $\Omega_{S/R,q} = 0$, then $\Omega_{S/R,g} = 0$ for some $g \notin q$(because support of finite module is open), so $R \to S_g$ is (G-)unramified. And notice in fact $\Omega_{S/R} \otimes_S k(q) = \Omega_{S\otimes k(p)/k(p)} \otimes_{k(p)} k(q)$. □

Prop. (4.4.6.7) [Equivalent Definition of Unramifiedness]. A f.g. ring map $R \to S$ is unramified at a prime q of S over p iff $pS_q = qS_q$ and $k(q)/k(p)$ is finite separable.

Proof: Suppose $R \to S_g$ is unramified, then $S \otimes k(p)$ is unramified over $k(p)$, hence by(4.4.5.23), it is also smooth, so it is étale, and(4.4.7.9) gives the result.

For the converse, Cf[Sta]02FM]. □

Prop. (4.4.6.8). A ring map is unramified iff it is locally a quotient of a standard étale map.

Proof: Cf.[Sta]0395]. □

Prop. (4.4.6.9). Any G-unramified map is a base change of a G-unramified map over a ring R_0 f.g. over $\mathbb{Z}$. And similarly any unramified map is a quotient of a base change of a G-unramified map over a ring R_0 f.g. over $\mathbb{Z}$.

Proof: Let $S = R[X_1, \ldots, X_n]/(g_1, \ldots, g_c)$, then we have $dX_i = \sum a_{ij} dg_j + a_{ijk} g_j dX_k$, so we let R_0 be generated by g_i, a_{ij}, a_{ijk}, so $S_0 = R_0[X_1, \ldots, X_n]/(g_1, \ldots, g_c)$ is G-unramified. □

Prop. (4.4.6.10) [Unramifiedness and Idempotent]. If $R \to S$ is of f.t., then it is unramified iff $S \times_R S \to S$ is isomorphic to $S \otimes_R S \to (S \otimes_R S)_e$ for some diagonal idempotent $e \in S \otimes_R S$ that $e \ker(\mu) = 0$, i.e. $S \otimes_R S \cong S \times S'$.

Proof: If it is G-unramified, the kernel I satisfies $I/I^2 = 0$, and I is f.g.(by $x_i \otimes 1 - 1 \otimes x_i$) so we can use(4.1.7.7).

Conversely, the existence of the diagonal idempotent e implies that $I = I^2$. □

7 Étale

Formally Étale

Def. (4.4.7.1). A ring map $R \to S$ is called **formally étale** iff it is formally smooth and formally unramified.

Prop. (4.4.7.2). Colimits of formally étale rings over R is formally étale. (The lifting are compatible because of uniqueness).

Prop. (4.4.7.3). $R \to S^{-1}R$ is formally étale.

Proof: It suffice to prove that if $\varphi(s)$ is invertible modulo I, then $\varphi(s)$ is invertible, but this is true because I is nilpotent. □

Étale Map

Def. (4.4.7.4). A ring map $R \to S$ is called **étale** if it is of f.p. and the naive cotangent complex is exact, i.e. $I/I^2 \cong \Omega_{P/R} \otimes_P S$.

In particular, étale is equivalent to smooth+formally unramified($\Omega_{R/S} = 0$).

Cor. (4.4.7.5) [Properties of Étale].

1. Étale map is stable under base change and composition.
2. Étale map is local on the source and target. In particular, $R \to R_f$ is étale.
3. If $R \to S$ is of f.p. and $R \to R'$ is flat. Then the set of primes in $S' = S \otimes_R R'$ that has a nbhd that is étale over R' is the inverse image of set of primes in S that has a nbhd that is étale over R. (The same as(4.4.5.18)).

4. Étale map is syntomic, hence flat.
5. Any Étale map is a base change of an étale map over a ring R_0 f.g. over $\mathbb{Z}$. (Cf.[Sta]00U2).

Cor. (4.4.7.6)[Étale Localness of Differential]. For ring morphisms $A \to R \to S$, if $R \to S$ is étale, then $\Omega_{S/A} = \Omega_{R/A} \otimes_R S$.

Proof: This follows from(4.4.7.4) and(4.4.5.5). □

Prop. (4.4.7.7) [Jacobson Criterion]. Any étale map is equivalent to a standard smooth ring map $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_n)$ that $J(\frac{f_1,\ldots,f_n}{X_1,\ldots,X_n})$ is invertible in S.

Proof: $I/I^2 \cong \Omega_{P/R} \otimes_P S$, so I/I^2 is free, so by(4.3.7.12), there is a presentation of S that $f_1, \ldots, f_c$ freely generate I/I^2, then obviously $c = n$ and $J(\frac{f_1,\ldots,f_c}{X_1,\ldots,X_n})$ is invertible in S, i.e. S is standard smooth. □

Cor. (4.4.7.8)[Example of Étale Maps]. The ring

$$S = R[X_1, \ldots, X_n, X_{n+1}]/(f_1, \ldots, f_n, X_{n+1} \det(\frac{f_1, \ldots, f_n}{X_1, \ldots, X_n}) - 1)$$

is étale over R.

Prop. (4.4.7.9). If $R \to S$ is étale at a nbhd of a prime q of S over p, then $pS_q = qS_q$, and $k(q)/k(p)$ is finite separable.

Proof: We can replace S by S_g so S_g/R is étale. Then $S \otimes k(p)/k(p)$ is étale, that is S_p/pS_p is a finite product of finite separable fields, so $S_q/pS_q = (S_p/pS_p)_q =$ some separable closed field. □

Lemma (4.4.7.10). If $R \to S$ is an étale map and q is a prime of S over p, then S/R is étale in a nbhd of q if

- $R \to S$ is of f.p.
- $R_p \to S_q$ is flat.
- $pS_q = qS_q$.
- $k(q)/k(p)$ is a finite separable field extension.

Proof: Cf.[Sta]00U6. □

Prop. (4.4.7.11) [Equivalent Definition of Étale]. A ring map $R \to S$ is **étale** iff it is flat, of f.p. and $\Omega_{S/R}$ vanishes.

Proof: One direction is by definition, and the converse is by(4.4.7.10) and(4.4.6.7). □

Prop. (4.4.7.12). A ring map of f.p. is formally étale iff it is étale. (Because in this case, formally smooth is equivalent to smooth(4.4.5.12).)

Prop. (4.4.7.13). If S/R and S'/R are étale, then any R-algebra map $S \to S'$ is étale.

Proof: $S \to S'$ is of f.p. by(4.3.7.11), the rest Cf.[Sta]00U7. □

Prop. (4.4.7.14) [Étale Algebra seen explicitly as Finite Projective Modules]. Étale algebras are finite projective, by(4.3.1.7). And we can see this clearly as follows: There is an diagonal idempotent as it is unramified(4.4.6.10), If $e = \sum a_i \otimes b_i$, then we can realize S as a direct command of R^n through maps

$$S \xrightarrow{\alpha} R^n \xrightarrow{\beta} S$$

where $\alpha(f) = (\mathrm{tr}_{S/R}(fa_i))$, and $\beta((g_i)) = \sum g_i b_i$.

Proof: We check that $\beta \circ \alpha = \mathrm{id}$: Notice first that $\mathrm{tr}_{i_2}(e) = \mathrm{tr}_{S/S}(1) = 1$, following from the decomposition above, so $\sum \mathrm{tr}_{S/R}(a_i)b_i = 1$, thus shows that $\beta\alpha(1) = 1$.

Now for general f, using the formula $(f \otimes 1)e = (1 \otimes f)e$, we get $\sum \mathrm{tr}(fa_i)b_i = \sum \mathrm{tr}(a_i)b_i f = f$. □

Prop. (4.4.7.15). If R is a ring and I is an ideal, then any étale ring map $R/I \to \overline{S}$ comes from an étale ring map $R \to S$.

Proof: Use(4.4.7.7), an étale map is of the form $\overline{S} = R/I[X_1, \ldots, X_n]/(\overline{f}_1, \ldots, \overline{f}_n)$ that $\delta = J(\frac{f_1,\ldots,f_n}{X_1,\ldots,X_n})$ is invertible in S, then we take $S = R[X_1, \ldots, X_n, X_{n+1}]/(f_1, \ldots, f_n, X_{n+1}\delta - 1)$, then it is étale by(4.4.7.8) and maps to $\overline{S}$. □

Standard Étale

Def. (4.4.7.16). A ring map $R \to R' = R[X]_g/(f)$ is called **standard étale** iff f is monic and the derivative f' is invertible in R'.

Standard étale is stable under base change and principal localization, but not stable under composition.

Prop. (4.4.7.17) [Étale and Standard Étale]. A ring map is étale iff it is locally standard étale.

Proof: For a standard étale algebra $R[X]_g/(f) = R[X, Y]/(f, gY - 1)$ which is standard smooth and $\Omega_{R'/R} = 0$(4.4.3.10), so it is étale. To prove if it is locally standard étale then it is étale, Cf.[Sta]00UE. □

Prop. (4.4.7.18). Giving any ring R and a prime p, if there is a finite separable extension $L/k(p)$, then there is a standard étale map $R \to R'$ that for some q', $k(q') \cong L$ over k.

Proof: $L = k(p)[\alpha]$ by primitive element theorem, so the minimal polynomial of α is separable, and if we change α to $c\alpha$ for some $c \in k(p)$, we can assume f can be lifted to a $f \in R[X]$. Now $f'(\alpha)$ is invertible in L, so there is a map from $R[X]_{f'}/(f)$ to L, whose kernel gives the desired prime q. □

Étale over Fields

Prop. (4.4.7.19) [Étale over Fields]. An algebra over a field k is étale iff it is a finite product of finite separable extensions of k.

Proof: If k'/k is finite separable, then $k' = k(\alpha)$ for some α by primitive element theorem, thus $k' = k[X]/(f)$ that f' is invertible in k', thus it is étale by(4.4.7.7).

Conversely, Cf.[Sta]00U3. □

Cor. (4.4.7.20) [Étale over Perfect Fields]. Let k be a perfect field. If R is a k-algebra that is a finite as a k-module, then it is étale over k iff it is reduced.

Proof: If it is étale , then it is reduced, by(4.4.7.19). Conversely, if it is finite and reduced, then it is a reduced Artinian ring(4.1.3.4), so a product of fields over k, so étale as k is perfect. □

Prop. (4.4.7.21) [Étale and Trace Form]. Let A be a f.d. k-algebra, then A is étaleover k iff the trace form: $A \times A \to k : (a, b) \mapsto \mathrm{tr}_{A/k}(ab)$ is non-degenerate.

Proof: If it is étale, then the trace form is non-degenerate by(4.4.7.19) and(2.2.5.32). Conversely, if the trace form is non-degenerate, then A is reduced, because if $a \in A$ is nilpotent, then ab are nilpotent for any $b \in A$, and $\mathrm{tr}_{A/k}(ab) = 0$. Then as a reduced Artinian ring, A is isomorphic to a product of fields, then by(2.2.5.32), all the fields are separable over k. □

Prop. (4.4.7.22) [Étale and Unramified over Fields]. For $k \in \mathtt{Field}$, a f.g. k-algebra is étale iff it is (G-)unramified over k, by(4.4.5.23).

Prop. (4.4.7.23) [Maximal Étale Subalgebra]. Let A be an algebra of f.t. over a field k, then there is a maximal étale k-subalgebra of A. Also this subalgebra commutes with arbitrary field base change.

Proof: If R is an étale subalgebra of A, then $R_{\overline{k}}$ is étale over $\overline{k}$, thus isomorphic to $(\overline{k})^n$ for some n. Now n is smaller than the number of connected components of $\mathrm{Spec}\, A_{\overline{k}}$, which is finite. So it suffices to show the composite of two étale subalgebras of A is étale. For this, notice RR' is a quotient of $R \otimes_k R'$, which is a finite product of finite separable fields over k, thus its quotient is also a finite product of finite separable fields over k, which is étale.

□

8 Local Algebras

Main references are [Local Algebra, Serre].

Prop. (4.4.8.1). If A is a Noetherian local integral domain with residue field k and quotient field K, if M is a f.g. A-module that $\dim_k M \otimes_A k = \dim_K M \otimes_A K = r$, then M is free of rank r.

In other words, if the rank of M at the generic point and closed pt of B are the same, then M is free.

Proof: First M is generated by r elements by Nakayama and the kernel R of $A^r \to M$ vanishes when tensoring K, thus vanish because it is torsion-free. □

Prop. (4.4.8.2). Let $A \to B$ be a local ring map of local rings that

- B is finite as an A-module.
- $\mathfrak{m}_B$ is a f.g. ideal.
- $A/\mathfrak{m}_A \cong B/\mathfrak{m}_B$.
- $\mathfrak{m}_A/\mathfrak{m}_A^2 \cong \mathfrak{m}_B/\mathfrak{m}_B^2$.

Then $A \to B$ is surjective.

Proof: By Nakayama, to show it is surjective, it suffices to show $A/\mathfrak{m}_A \to B/\mathfrak{m}_A B$ is surjective, then it suffices to show $\mathfrak{m}_A \otimes_A B \to \mathfrak{m}_B$ is surjective. For this, use Nakayama again on B to reduce to the fact $\mathfrak{m}_A \otimes_A B/\mathfrak{m}_B \to \mathfrak{m}_B \otimes B/\mathfrak{m}_B$ is surjective, which is satisfied because this is just $\mathfrak{m}_A/\mathfrak{m}_A^2 \to \mathfrak{m}_B/\mathfrak{m}_B^2$. □

4.5 p-adic Commutative Algebras

1 $\mathbb{F}_p$-Algebras

Def. (4.5.1.1) [relative Frobenius]. Let $S \to R$ be a ring map, then the **relative Frobenius** $\varphi_{R/S}$ is the map $R \otimes_{S,\mathrm{Frob}} S \to R$ induced by universal property.

Def. (4.5.1.2) [Perfect Rings]. A ring of characteristic p is called **perfect** iff the Frobenius $\mathrm{Frob}/\varphi : P \to P$ is an isomorphism. It is called **semi-perfect** iff Frob is surjective.

Prop. (4.5.1.3) [Perfection and Coperfection]. If R is of char p, we define $R_{\mathrm{perf}} = \varinjlim_{\varphi} R$ and $R^{\mathrm{perf}} = \varprojlim_{\varphi} R$.

The $(\cdot)_{\mathrm{perf}}$ and $(\cdot)^{\mathrm{perf}}$ are respectively the left and right adjoint to the forgetful functor from the category of perfect rings to the category of rings of characteristic p.

In particular, the category of perfect rings admits limits and colimits, and it equals the limits and colimits in the category of rings.

Proof: First both R_{perf} and R^{perf} are perfect: for R_{perf}, every element in R_{perf} is represented by an element $a_n \in R_n$, and this element is equivalent to $a_n^p \in R_{n+1}$, so its p-th root is $a_n \in R_{n+1}$. For R^{perf}, an element $(\ldots, x_n, \ldots, x_0)$ has p-th root $(\ldots, x_{n+1}, \ldots, x_1)$.

Second it is easily checked to be a functor because Frob is natural. The universal property is easy. □

Prop. (4.5.1.4) [Perfection Kills Nilextensions]. If $f : R \to S$ is a map of rings of characteristic p that is surjective with nilpotent kernel, then $R_{\mathrm{perf}} \to S_{\mathrm{perf}}$ and $R^{\mathrm{perf}} \to S^{\mathrm{perf}}$ are both isomorphisms.

Proof: $-_{\mathrm{perf}}$ map is clearly surjective, and it is injective because if a maps to 0, then $\mathrm{Frob}^k(a) \in \ker f$ for some k, so it is nilpotent, so $\mathrm{Frob}^{k+n}(a) = 0$.

$-^{\mathrm{perf}}$ is clearly injective, and it is surjective because: suppose $\ker f^n = 0$, then for a $(s_n) \in S$, let t_m be the inverse image of s_{mn}, for each m, and let $x = (x_n), x_{mn-k} = \mathrm{Frob}^k t_m$, then $(x) \in R^{\mathrm{perf}}$ and x maps to s. □

Def. (4.5.1.5) [Perfectly Finitely Presented]. A map of perfect $\mathbb{F}_p$-algebras $B \to A$ are called **perfectly finitely presented** if $A = (A_0)_{\mathrm{perf}}$ for some f.p. B-algebra A_0.

Prop. (4.5.1.6) [Aberbach-Hochster]. Let R be a perfect $\mathbb{F}_p$-algebra, $f_1, \ldots, f_r \in R$, and consider the ideal $I = \sqrt{(f_1, \ldots, f_r)} \in R$. Then R/I has flat dimension$\leq r$ as an R-module.

Proof: We only prove for $r = 1$.

We show $I = \varinjlim_{f^{1/p^n - 1/p^{n+1}}} R$. The map is given by $(a_n) \mapsto f^{1/p^n} a_n$. This is injective because if $f^{1/p^n} a = 0$, then $f^{1/p^{n+1}} a = 0$ by perfectness, thus a is killed by the transition map $f^{1/p^n - 1/p^{n+1}}$. □

Prop. (4.5.1.7) [Perfect Algebras are Tor Independent]. For any two perfect A-algebras B, C where A is a perfect $\mathbb{F}_p$-algebra, $\mathrm{Tor}_i^A(B, C) = 0$ for $i > 0$.

Proof: $A \to B$ can be written as a composition of a perfection of a free A-algebra and a quotient. The perfection of free algebra is flat, thus we can assume $B = A/I$. By a filtered colimit argument again, we can assume $I = (f_1^{\frac{1}{p^\infty}}, \ldots, f_r^{\frac{1}{p^\infty}})$ is perfectly f.p. By induction, we can assume $r = 1$. Now the lemma(4.5.1.6) applied to $R = C$ shows that $IC = \varinjlim_{f^{1/p^n - 1/p^{n+1}}} C = I \otimes_A^L C$, so $B \otimes_A^L C = C/IC$ is discrete. □

Prop. (4.5.1.8). If R is a perfect $\mathbb{F}_p$-algebra, I is a radical ideal, and $J = R[I] \subset R$, then J and $I + J$ are both radical, and the square

$$\begin{array}{ccc} R & \longrightarrow & R/I \\ \downarrow & & \downarrow \\ R/J & \longrightarrow & R/I+J \end{array}$$

is both a fiber pullback and pushout square of commutative rings.

Proof: J is clearly a radical, and notice that $I + J$ is the kernel of the map $R \to R/I \otimes_R R/J = R/I + J$(4.1.1.22), and the target is a colimit of perfect rings thus perfect, by(4.5.1.3). Thus $I + J$ is also perfect, thus a radical ideal.

By(4.1.1.23), to show the map is a pullback square, it suffices to show that $I \cap J = 0$. If $x \in I \cap J$, then $x^2 = 0$, thus $x^p = 0$, so $x = 0$. □

Tilting

Def. (4.5.1.9) [Tilting]. For any $R \in \mathcal{CR}\text{ing}$, the ($p$-adic)**tilting** of R is defined to be $R^\flat = (R/(p))^{\mathrm{perf}}$, endowed with the profinite topology.

Prop. (4.5.1.10). If R is a f.g. algebra over an alg.closed field k of char$p$, then $R^\flat \cong k^{\pi_0(\operatorname{Spec} R)}$.

Proof: It suffice to prove for $\operatorname{Spec} R$ connected and reduced, because by(4.5.1.4). We first prove the case $\operatorname{Spec} R$ is irreducible, i.e. R is integral:

In this case, choose a closed point x, then there is a map $R \to \widehat{R_x}$, where $\widehat{R_x}$ is the $\mathfrak{m}_x$-adic completion. By Krull(4.2.2.15) and the fact R is integral, this map is injective, so it suffices to show that $0 = (\widehat{R_x})^{\mathrm{perf}} = \varinjlim (R_x/\mathfrak{m}_x^n)^{\mathrm{perf}}$. But $(-)^{\mathrm{perf}}$ is a right adjoint so commutes with colimits and $\widehat{R_x} = \varinjlim R_x/\mathfrak{m}_x^n$. But $(R_x/\mathfrak{m}_x^n)^{\mathrm{perf}} = (R_x/\mathfrak{m}_x)^{\mathrm{perf}} = k^{\mathrm{perf}} = k$, by(4.5.1.4) again.

If R is not irreducible, **?** □

Prop. (4.5.1.11) [Examples of Tilting].

- $\mathbb{F}_p[t]_{\mathrm{perf}} = \mathbb{F}_p[t^{\frac{1}{p^\infty}}]$, $\mathbb{F}_p[t]^\flat = \mathbb{F}_p[t]^{\mathrm{perf}} = \mathbb{F}_p$.
- $(\mathbb{Z}_p)^\flat = \mathbb{F}_p$.
- If R is a perfect ring of char$p$ and $f \in R$ is a non-zerodivisor, then $(R/f)^{\mathrm{perf}}$ is the f-adic completion of R. In particular, $(\mathbb{F}_p[t^{\frac{1}{p^\infty}}]/(t))^{\mathrm{perf}} \cong \widehat{\mathbb{F}_p[t^{\frac{1}{p^\infty}}]}$.
- $(\widehat{\mathbb{Z}_p[p^{\frac{1}{p^\infty}}]})^{\mathrm{perf}} \cong \widehat{\mathbb{F}_p[t^{\frac{1}{p^\infty}}]} \cong \widehat{\mathbb{F}_p[t]_{\mathrm{perf}}} \cong (\mathbb{F}_p[t]_{\mathrm{perf}}/(t))^{\mathrm{perf}}$.

Proof: The first two are trivial, for the third, notice $\widehat{R_f} = \varprojlim_n R/f^n = \varprojlim_n R/f^{p^n}$, and there are commutative diagram
$$\begin{array}{ccc} R/f & \xrightarrow{\varphi} & R/f \\ \downarrow{\scriptstyle \varphi^{k+1}} & & \downarrow{\scriptstyle \varphi^k} \\ R/f^{p^{k+1}} & \xrightarrow{i} & R/f^{p^k} \end{array}$$
, so $\varprojlim_n R/f^{p^n} \cong (R/f)^{\mathrm{perf}}$.

For the fourth, only the first equivalence needs proving, the others are consequences of the first three items. Then notice

$$(\widehat{\mathbb{Z}_p[p^{\frac{1}{p^\infty}}]})^\flat \cong \varprojlim (\widehat{\mathbb{Z}_p[p^{\frac{1}{p^\infty}}]}/p^k)^{\mathrm{perf}} \cong (\widehat{\mathbb{Z}_p[p^{\frac{1}{p^\infty}}]}/p)^{\mathrm{perf}} \cong (\mathbb{F}_p[t^{\frac{1}{p^\infty}}]/t)^{\mathrm{perf}} \cong \widehat{\mathbb{F}_p[t^{\frac{1}{p^\infty}}]}$$

The last isomorphism by item3. □

Prop. (4.5.1.12). If $R \in \mathcal{CR}\mathrm{ing}$ is a p-adically complete, $\pi \in R^\times, p \in (\pi)$, then the map $R \to R/p$ induces an homeomorphism of monoids:

$$\varprojlim_{x \to x^p} R \cong \lim_{\varphi} R/\pi \overset{(4.5.1.4)}{=} \lim_{\varphi} R/p = R^\flat$$

Proof: Injectivity: if $(a_n), (b_n) \in \lim_{x \to x^p} R$ satisfies $a_n \equiv b_n \mod \pi$ for all n, then applying power lifting(24.1.3.4), $a_n \cong b_n \mod \pi^{n+k}$ for all k, so $a_n = b_n$.

Surjectivity: for $(\overline{a_n}) \in R^\flat$, choose arbitrary lifting a_n, then $a_{n+k+1}^p \equiv a_{n+k} \mod \pi$ for all $n+k$, so $k \mapsto a_{n+k}^{p^k}$ is a Cauchy sequence by power lifting(24.1.3.4) again, thus converging to some point b_n. then it's easily checked that $b_{n+1}^p = (\lim a_{n+1+k}^{p^k})^p = \lim a_{n+1+k}^{p^{k+1}} = b_n$. so (b_n) maps to $(\overline{a_n})$.

For the topology: it is clearly continuous, and for the reverse, if $(a_i), (b_i)$ satisfies that $a_i \equiv b_i \mod \pi$ for $i < k$, then the image in $\varprojlim_{x \to x^p} R$ satisfies $x_i \equiv y_i \mod p^{k-i}$ for $i < k$, thus it is open. □

Cor. (4.5.1.13) [Sharp Map]. From this proposition, we get a multiplicative **sharp map**:

$$\sharp : R^\flat \to R : (\overline{a}_n) \mapsto \lim_{k \to \infty} a_k^{p^k},$$

and its image is just the elements that has a compatible system of p^k-th roots $x^{\frac{1}{p^k}}$. These elements are also called **perfect**.

Cor. (4.5.1.14) [Addition in $R^\flat$]. From the isomorphism(4.5.1.12) above, we can read what the addition looks like in the presentation $\varprojlim_\varphi R$: if $(f_n), (g_n)$ are two elements, then their addition is given by (h_n), where $h_n = \lim_k (f_{n+k} + g_{n+k})^{p^k}$.

Cor. (4.5.1.15) [Fontaine's Functor]. By(6.1.4.4), the natural map $R^\flat \to R/p$ induces a map $\theta_R : W(R^\flat) \to R$ of rings, called the **Fontaine's functor**, which writes as $\sum [a_i] p^i \mapsto \sum a_i^\sharp p^i$. And we denote $A_{\mathrm{inf}}(R) = W(R^\flat)$ the **infinitesimal Fontaine's ring** of R.

Prop. (4.5.1.16). If R is p-complete, the Fontaine's functor θ_R is surjective iff R/p is semiperfect.

Proof: As R is p-complete, θ is surjective iff it is surjective modulo p. Because its reduction modulo p is $R^\flat \to R/p$ is surjective as $\varphi : R/p \to R/p$ does. □

Prop. (4.5.1.17) [Tilting as a Valuation Ring]. If R is a domain or a valuation ring, then the same is true for $R^\flat$. In the valuation case, the valuation of $R^\flat$ can in fact be chosen to be $|\cdot| \circ \sharp$, so in particular, the rank of $R^\flat$ is no more than the rank of R.

Proof: Use the isomorphism $\varprojlim_{x \to x^p} R \cong \lim_\varphi R/p = R^\flat$(4.5.1.12).

For the domain case, if $(a_n)(b_n) = 0$, then $a_n b_n = 0$, so $a_0 = 0$ or $b_0 = 0$, so $(a_n) = 0$ or $(b_n) = 0$. Similarly, if R is a valuation ring, then $R^\flat$ is firstly a domain, and it suffices to prove that for any $(a_n), (b_n) \in R^\flat$, the quotient of one by another is in $R^\flat$, by(10.3.2.3). For this, because R is valuation ring, we may assume $a_0/b_0 \in R$, so a_n/b_n is also in R, because their power do, and R is normal(10.3.2.6), thus $(a_n)/(b_n) \in R^\flat$.

For the valuation given, notice in the above proof, $|(a_n)| \leq |(b_n)|$ iff $|a_0| \leq |b_0|$, so the valuation are equivalent to $|\cdot| \circ \sharp$ by(10.3.3.14), so it can be chosen to be so. □

Prop. (4.5.1.18) [Tilting and Completion]. If $R = A/I$ with A/p perfect, then $R^\flat$ identifies with the I-adic completion of A/p.

Proof: $R^\flat = \varprojlim_\varphi R/p = \varprojlim_\varphi A/(p,I)$. But there are commutative diagrams

$$\begin{array}{ccc} A/(p,I) & \xrightarrow{\varphi} & A/(p,I) \\ \downarrow{\varphi^{n+1}} & & \downarrow{\varphi^n} \\ A/(p,I^{p^{n+1}}) & \longrightarrow & A/(p,I^{p^n}) \end{array}$$

where the vertical arrows are isomorphisms because A/p is perfect. So the conclusion follows. □

2 p-Local Rings

Def. (4.5.2.1) [p-Local Rings]. A commutative ring is called p-local if $p \in \operatorname{rad} A$.

Prop. (4.5.2.2). Let A be a p-adically complete ring, then A is p-local, by(4.2.3.18).

Prop. (4.5.2.3). If A is p-adically complete and has bounded p-torsions, the p-completion of a smooth A-algebra is p-completely smooth.

Proof: This follows from(4.9.7.4) and(4.9.6.16). □

Def. (4.5.2.4) [p-Normal Rings]. A p-torsion-free ring R is called **p-normal** if R is p-root closed in $R[\frac{1}{p}]$.

Complete Discrete Valuation Rings

Structure of complete p-local DVRs will be studied in this subsubsection.
Main references are [Ser79], [Integral p-adic Hodge, BMS].

Def. (4.5.2.5) [Strict p-Ring]. A **p-ring** A is a ring which is complete Hausdorff in the topology defined by the decreasing chain of ideals $\mathfrak{a}_1 \supset \mathfrak{a}_2 \supset \cdots$ such that $\mathfrak{a}_m\mathfrak{a}_n \subset \mathfrak{a}_{m+n}$ that $k = A/\mathfrak{a}_1$ is a perfect ring of characteristic p.

It is called a **strict p-ring** if moreover $\mathfrak{a}_n = (p^n)$ and p is a non-zero divisor of A.

Prop. (4.5.2.6) [Teichmüller Lifts]. For a p-ring, there exists a unique section map $[\cdot] : k \to A$ that is multiplicative, called the **Teichmüller lifts**.

If $\operatorname{char} A = p$, then the Teichmüller lift is also additive(but not in general). And an element is in the image of f iff it is a p^n-th power for any n.

Proof: For any $\lambda \in k$, the $\lambda^{p^{-n}}$ is unique in k, and if we consider U_n the set of all x^{p^n} where x is a lift of $\lambda^{p^{-n}}$, then U_n is a descending set. Moreover, the diameter converges to 0, because $a \equiv b \mod \mathfrak{a}_1$ implies $a^{p^n} \equiv b^{p^n} \mod \mathfrak{a}_{n+1}$ as $p \in \mathfrak{a}_1$. So it converses to a unique point $f(\lambda)$ in A. And we see that any other f' maps λ to a p^n-th root hence in U_n for any n, hence it map be equal to $f(\lambda)$. The rest is easy. □

Cor. (4.5.2.7) [Equal Characteristic case]. If A is a complete discrete valuation ring with residue field k. If k and A have the same characteristic and k is perfect, then $A \cong k[[T]]$.

Def. (4.5.2.8) [$(0,p)$-type case]. When A is a complete DVR with residue field k and quotient field K. If $\operatorname{char}K = 0$ and $\operatorname{char}k = p$, then p goes to 0 in k, so $e = v(p) \geq 1$, called the **absolute ramification index** of A. It is called **absolutely unramified** iff $e = 1$.

Remark (4.5.2.9) [Universal Strict p-Ring]. The canonical strict p-ring is the ring $\widehat{S} = \widehat{\mathbb{Z}}[X_\alpha^{p^{-n}}]$. Its residue ring is $\mathbb{F}_p[X_\alpha^{p^{-n}}]$ which is perfect. X_i are all Teichmüller lifts, as they has all p^n roots.

Now we consider the $* = + - \times$ in $\widehat{S}$. then there are elements $Q_i^* \in \mathbb{F}_p[X_\alpha^{p^{-n}}, Y_\alpha^{p^{-n}}]$ that $x * y = \sum f(Q_i^*)p^i$ where f is the Teichmüller lift.

Prop. (4.5.2.10) [Universal Law of p-Rings]. For any p-ring A with residue ring k, the calculation in A is dominated by Q_i^* defined in(4.5.2.9), i.e.

$$\left(\sum f(\alpha_i)p^i\right) * \left(\sum f(\beta_i)p^i\right) = \sum f(\gamma_i)p^i$$

where $\gamma_i = Q_i^*(\alpha_0, \alpha_1, \ldots, \beta_0, \beta_1, \ldots)$.

Proof: There is a map θ from $\widehat{S} = \widehat{\mathbb{Z}}[X_i^{p^{-n}}, Y_i^{p^{-n}}]$ to A induced by $f(\alpha_i), f(\beta_i)$ as they all has p^{-n}-th roots. Then notice θ induce a $\overline{\theta}$ on residue ring and these two θ commutes with Teichmüller lift, as seen by the definition of the latter. Then the theorem follows immediately. □

Prop. (4.5.2.11) [Universal Properties of Strict p-Rings]. For two p-ring A, A' that A is strict, then any map φ of their residue ring induces a unique ring homomorphism $A \to A'$. In particular, two strict p-ring with the same residue ring is canonically isomorphic.

Proof: We have already seen that ring homomorphism commutes with Teichmüller lift. Now we define

$$g(a) = \sum g(f(\alpha_i))p^i = \sum f(\varphi(\alpha_i))p^i$$

and this is the unique choice. It is a ring homomorphism by universal law of(4.5.2.10). □

3 Witt Theory

References are [Michiel Hazewinkel, Formal Groups and Applications] and [Rab14].

Witt Vectors

Def. (4.5.3.1) [Divisor Stable Subsets]. A non-empty subset $P \subset \mathbb{Z}_+$ is called **divisor-stable** if it is stable under taking divisors.

For a divisor-stable subset P and $n \in \mathbb{Z}_+$, define $P(n) = \{m \in P | m \leq n\}$.

Def. (4.5.3.2) [Witt Polynomials]. For $n \in \mathbb{N}$, the n-th **Witt polynomial** is defined to be

$$W_n = \sum_{d|n} dX_d^{n/d} \in \mathbb{Z}[\{X_d : d|n\}].$$

For example,

$$W_{p^k} = X_1^{p^k} + pX_p^{p^{k-1}} + \ldots + p^n X_{p^n}.$$

Prop. (4.5.3.3) [Commutative Coalgebra Δ_P]. For a divisor-stable set P, let $\Delta_P = \mathbb{Z}[\{X_n | n \in P\}]$, then there is a unique commutative ring scheme structure on $\operatorname{Spec}\Delta_P$ s.t. the map

$$W_* : \mathbb{Z}[X_P] \to \Delta_P : n \mapsto W_n \in \Delta_P$$

induces a homomorphism of ring schemes $\operatorname{Spec}\Delta_P \to \operatorname{Spec}\mathbb{Z}[X_P]$, where the ring structure on $\operatorname{Spec} Z[X_P]$ is given by

$$\times : \mathbb{Z}[X_P] \to \mathbb{Z}[X_P] \otimes \mathbb{Z}[Y_P] : X_n \mapsto X_n \otimes Y_n, \quad + : \mathbb{Z}[X_P] \to \mathbb{Z}[X_P] \otimes \mathbb{Z}[Y_P] : X_n \mapsto X_n \otimes 1 + 1 \otimes Y_n.$$

Then for another divisor-stable set $P' \subset P$, there is a natural map $\Delta_{P'} \to \Delta_P$ that induces a homomorphism of ring schemes.

If $P = \mathbb{Z}_+$, denote $\Delta_P = \Delta$, if $P = \{1, p, p^2, \ldots\}$, denote $\Delta_P = \Delta_p$, and if $P = \{1, p, \ldots, p^k\}$, denote $\Delta_P = \Delta_{p,k}$.

Proof: □

Cor. (4.5.3.4). S_n is of the form $S_n(X_P, Y_P) = X_n + Y_n + f_n(X_{P(n-1)}, Y_{P(n-1)})$.

Proof: □

Def. (4.5.3.5) [Witt Vectors]. For a divisor-stable set P, consider the functor

$$W_P : \mathcal{CA}\mathrm{lg} \to \mathcal{CA}\mathrm{lg} : A \mapsto W_P(A) = \mathrm{Hom}(\Delta_P, A),$$

then it is an exact functor, and by(4.5.3.3), there are natural ring homomorphism

$$W_* : W_P(A) \to \prod_P A : f \mapsto (f(W_n))_W$$

For $x \in W_P(A)$, $W_n(x)$ are called the **ghost components** of x, and $W_*(x)$ is called the **Witt coordinate** of x.

If $P = \mathbb{Z}_+$, $W_P(A)$ is denoted by $W(A)$, if $P = \{1, p, p^2, \ldots\}$, $W_P(A)$ is denoted by $W_p(A)$, and if $P = \{1, p, \ldots, p^k\}$, denote $W_P(A) = W_{p,k}(A)$.

Prop. (4.5.3.6) [Natural Coordinates]. There is another map

$$\varphi_* : W_P(A) \to \prod_P A : f \mapsto (f(X_i))$$

which is an isomorphism of sets, whose components are maps of sets $\varphi_n : W_P(A) \to A, n \in P$. WARNING: it is not an isomorphism of groups. For $x \in W_P(A)$, $\varphi_n(x)$ are called the **ghost components** of x, and $\varphi_*(x)$ is called the **Witt coordinate** of x. All coordinates of elements in x will be assumed to be in the natural coordinates by default.

Then the map $W_*\varphi_*^{-1}$ is given by

$$W_*\varphi_*^{-1} : \prod_P A \to \prod_P A : (x_n)_\varphi \mapsto (W_n(\{x_P\}))_W.$$

Cor. (4.5.3.7) [Witt Coordinates are Injective]. $W_* : W_P(A) \to \prod_P A$ is injective if A is n-torsion-free for any $n \in P$, and an isomorphism iff n is invertible in A for any $n \in P$.

This is very useful because it can prove equations by checking on each W_n. Also when checking universal equations, it is even not necessary that A is n-torsion-free, because any ring A is a quotient of a free $\mathbb{Z}$-algebra.

Proof: It suffices to prove for $W_*\varphi_*^{-1}$. Using the Witt polynomials and prove inductive on $n \in P$ s.t. if $x = (x_n)$ is mapped to 0, then $x_n = 0$ for any $n \in P$.

In case n is invertible in A for any $n \in P$, solve x_n out of $W_*(x)$ inductively. □

Def. (4.5.3.8)[Topology on $W_P(A)$]. Let P be a divisor-stable set, then for any $A \in \mathcal{CA}\mathrm{lg}$, the natural map

$$W_P(A) \to \varprojlim_{n \in \mathbb{Z}_+} W_{P(n)}(A)$$

is an isomorphism of rings, so we can define the **natural topology** on $W_P(A)$ is as the profinite topology.

Then this topology makes $W_P(A)$ a topological ring, and it is discrete iff $\#P < \infty$, and W_P is a functor from $\mathcal{CA}\mathrm{lg}$ to the category of profinite rings.

Prop. (4.5.3.9). Let P be a divisor-stable set and $A \in \mathcal{CA}\mathrm{lg}$, then for $x = (x_n), y = (y_n) \in W_P(A)$, if $x_n y_n = 0$ for any $n \in P$, then

$$x + y = (x_n + y_n) \in W_P(A).$$

Proof: It suffices to prove on Δ_P. By(4.5.3.7), it suffices to prove $W_n((x_n + y_n)) = W_n(x) + W_n(y)$ for any $n \in P$. This is true because

$$W_n((x_n + y_n)) = \sum_{d|n} d(x_d + y_d)^{n/d} = \sum_{d|n} dx_d^{n/d} + \sum_{d|n} dy_d^{n/d} = W_n(x) + W_n(y).$$

□

Prop. (4.5.3.10) [Teichmüller Lifts]. Let P be a divisor-stable set and $A \in \mathcal{CA}\mathrm{lg}$, for $a \in A$, denote $[a] = (a, 0, \ldots) \in W_P(A)$. Then for any $x = (x_n) \in W_P(A)$,

$$[a]x = (a^n x_n).$$

In particular, $[\cdot] : A \to W_P(A)$ is multiplicative, called the **Teichmüller lifts** of A.

Proof: It suffices to prove on Δ_P. By(4.5.3.7), it suffices to prove $W_n((a^n x_n)) = W_n([a]x)$ for any $n \in P$. This is because

$$W_n((a^n x_n)) = \sum_{d|n} d(a^d x_d)^{n/d} = a^n \sum dx_d^{n/d} = W_n([a])W_n(x) = W_n([a]x).$$

□

Frobenius and Verschiebung Maps

Def. (4.5.3.11) [Verschiebung Maps].

Def. (4.5.3.12) [Frobenius Maps].

Prop. (4.5.3.13) [Frobenius and Verschiebung]. Let $n \in \mathbb{Z}_+$ and P is a divisor-stable subset s.t. $nP \subset P$. Let $A \in \mathcal{CA}\mathrm{lg}$, let $x, y \in W_P(A)$, then

- $F_n \circ V_n = n \cdot \mathrm{id}$.
- $V_n(F_n(x)y) = xV_n(y)$.
- If $(m, n) = 1$, then $V_m \circ F_n = F_n \circ V_m$.
- For $m \in \mathbb{Z}_+$, $(V_n(x))^m = n^{m-1}V_n(X^m)$.

Proof: Cf.[Rab14]P18. □

p-Typical Witt Vectors

Prop. (4.5.3.14) [Structure of Δ_p]. The ring structure on Spec Δ_p is given by

$$\times : \Delta_p \to \Delta_p \otimes \Delta_p : X_{p^k} \mapsto S_k(X_P, Y_P), \quad + : \Delta_p \to \Delta_p \otimes \Delta_p : X_{p^k} \mapsto Z_k(X_P, Y_P)$$

where

$$S_1 = X_1 + Y_1, \quad S_2 = X_p + Y_p + \sum_{i=1}^{p-1} \frac{1}{p}\binom{p}{i} X_1^i Y_1^{p-i},$$

$$Z_1 = X_1 Y_1, \quad Z_2 = X_1^p Y_p + X_p Y_1^p + pX_p Y_p.$$

Proof: □

Cor. (4.5.3.15) [W_2]. Let $W_2 = W_P$ where $P = \{1, p\}$, then $W_2(A)$ is the set $A \times A$(as the natural coordinates) with the addition and multiplication given by

$$(x_0, x_1)+(y_0, y_1) = (x_0+y_0, x_1+y_1+\frac{x_0^p + y_0^p - (x_0 + y_0)^p}{p}), \quad (x_0, x_1)(y_0, y_1) = (x_0 y_0, x_0^p y_1+y_0^p x_1+px_1 y_1)$$

There are two natural morphism of rings $\varepsilon_1, \varepsilon_2 : W_2(A) \to A$:

$$\varepsilon_1((x_0, x_1)) = x_0, \quad \varepsilon_2((x_0, x_1)) = x_0^p + px_1.$$

Prop. (4.5.3.16). For $k \geq 1$ and $A \in \mathcal{CA}\mathrm{lg}$, the kernel of $W_1 : W_{p,k}(A) \to A$ is a nilpotent ideal.

Proof: Cf.[Basic Algebra 2, Jacobson]P508.? □

Cor. (4.5.3.17). An element $x \in W_{p,k}(A)$ is a unit iff $W_1(x) \in A$ is a unit.

Example (4.5.3.18) [p-Typical Witt Vectors].

- $W_p(\mathbb{F}_q)$ is the unramified extension of $\mathbb{Z}_p$ of degree $\log_p q$.
- $W_p(\overline{\mathbb{F}}_p)$ is the completion of the maximal unramified extension of $W_p(\mathbb{F}_p)$.

Proof:

□

Lemma (4.5.3.19) [Formula for p-Rings]. For $* = +$ or $\times$, there are integral polynomials $S_*(X_i, Y_i)$ that

$$\Big(\sum f(\alpha_i)p^i\Big) * \Big(\sum f(\beta_i)p^i\Big) = \sum f(\gamma_i)p^i$$

where $\gamma_i = Q_i^*(\alpha_0, \alpha_1, \ldots, \beta_0, \beta_1, \ldots)$. And for $+$, when reduced to $\mathbb{F}_p$, Q_i^+ are polynomials in $X_i^{p^{-n}}, Y_i^{p^{-n}}$ for $i \leq n$ and homogenous of degree 1. And

$$Q_i^+ = (X_n + Y_n) + (X_{n-1}^{p^{-1}} + Y_{n-1}^{p^{-1}})R_{n,n-1} + \ldots + (X_0^{p^{-n}} + Y_0^{p^{-n}})R_{n,0}.$$

Proof: We solve S_n by induction. Notice for any lift $\widehat{S}_i$ of S_i,

$$f(S_i) \equiv \widehat{S}_i(X^{1/p^{n-i}}, Y^{1/p^{n-i}})^{p^{n-i}} \mod p^{n-i+1}$$

so we mod p^{n+1} to solve S_n:

$$S_n \equiv 1/p^n\Big(X_0 + Y_0 + \ldots + p^n X_n + p^n Y_n - \widehat{S}_0(X^{1/p^n}, Y^{1/p^n})^{p^n} - \ldots - p^{n-1}\widehat{S}_{n-1}(X^{1/p}, Y^{1/p})^p\Big)$$

The rest follows by induciton. □

Lemma (4.5.3.20). If k is a perfect field of characteristic p and R is a strict p-ring with residue field k, then the map

$$f: W_p(k) \to R: (x_1, x_p, x_{p^2}, \ldots) \mapsto \sum_{n=0}^{\infty} [x_{p^n}^{1/p^n}] p^n$$

is an isomorphism of topological rings.

Proof: We need to prove this is a ring homomorphism. That on $W(A)$ is to make φ a ring homomorphism, and that on the right is usual. It suffice to prove for the canonical strict p-ring, as seen by the universal law(4.5.2.10).

For this, we let $(\sum X_i^{p^{-i}} p^i) * (\sum Y_i^{p^{-i}} p^i) = \sum f(\psi_i(X_i, Y_i))^{p^{-i}} p^i$, and $W_n(a_i) * W_n(b_i) = W_n(\varphi_i)$, where $\psi_i \in \mathbb{F}_p[X_i, Y_i]$ and $\varphi_i \in \mathbb{Z}[X_i, Y_i]$, they both exist, the latter because of(4.5.4.7).

Then we mod p^{n+1}, and let $X_i = X_i^{p^n}$, $Y_i = Y_i^{p^n}$, so

$$W_n(\varphi_i) = W_n(X_i) * W_n(Y_i) \equiv \sum_{i \le n} f(\psi_i(X_i^{p^n}, Y_i^{p^n}))^{p^{-i}} p^i \equiv W_n(\psi_i) \mod p^{n+1}$$

Now induction, $\varphi_i \equiv \psi_i \mod p$, then $p^n \varphi_n \equiv p^n \psi_n \mod p^{n+1}$ so this is true for n, too.

Cf.[Rab14]P8, 20.? □

Prop. (4.5.3.21) [W_p For Perfect Rings]. For any perfect ring k of char p, there exists uniquely a strict p-ring $W(k)$ that has residue ring k, which is just the ring of Witt vectors $W_p(k)$.

Then W_p is a faithful functor from the category of perfect rings to the category of p-rings with perfect residue fields that is left adjoint to the functor mapping a p-ring with perfect residue fields to its residue field, by(4.5.2.11).

Proof: For a canonical ring $\mathbb{F}_p[X_\alpha^{p^{-n}}]$, $\widehat{\mathbb{Z}}[X_\alpha^{p^{-n}}]$ is a strict p-ring. Now arbitrary perfect p-ring is a quotient of $\mathbb{F}_p[X_\alpha^{p^{-n}}]$, so we can construct its strict p-ring $W(k)$ as the quotient of $\widehat{\mathbb{Z}}[X_\alpha^{p^{-n}}]$. Uniqueness is by(4.5.2.11).

Notice it is nothing mysterious, it is just the set of all formal sum $\sum f(x_i) p^i$ under the operation defined in(4.5.2.9). See also(4.5.3.20). □

Cor. (4.5.3.22). $W_{p,k}(\mathbb{F}_p) \cong \mathbb{Z}/(p^k)$.

Def. (4.5.3.23)[Witt Vectors over Valued Rings]. If a perfect ring R itself has a complete valuation v, then we can endow $W(R)$ with a finer topology: we let $w_k(x) = \inf_{i \le k} v(x_i)$, where $x = \sum p^i f(x_i)$. Now $w_k(x+y) \ge \inf(w_k(x), w_k(y))$ by(4.5.3.19). The **weak topology** of $W(R)$ is defined by the semi-valuations w_k.

Prop. (4.5.3.24). If $a, b \in \mathcal{O}_R + p^{n+1} W(R)$, then

$$p^n v(a_n - b_n) \ge w_n(a - b) \ge \inf_{k \le n} p^{-k} v(a_{n-k} - b_{n-k}).$$

So we see that a sequence is Cauchy in $W(R)$ if each coordinate is Cauchy in R, so $W(R)$ is complete in the weak topology.

Proof: Firstly the last proposition follows from the first because we can always multiply by a $f(\alpha)$ to make the first n coordinate in $\mathcal{O}_R$.

The first is nearly an immediate consequence of(4.5.3.19). □

Prop. (4.5.3.25). $\mathcal{O}_{\mathcal{E}} = W(K^{\frac{1}{p^\infty}})$ is a complete ring with maximal ideal $p\mathcal{O}_{\mathcal{E}}$. And $\mathcal{O}_{\mathcal{E}}[\frac{1}{p}] = \mathcal{E}$ is complete ring of character p. And the same construction of $\overline{K^{\frac{1}{p^\infty}}}$ yields the completion of maximal unramified extension of $\mathcal{O}_{\mathcal{E}}$, and the Galois group is the same as G_K.

Prop. (4.5.3.26) [van Der Kallen]. If $A \to B$ is an étale morphism, then $W_r(A) \to W_r(B)$ is also étale. Moreover, if $A \to A'$ is any ring map with $B' = B \otimes_A A'$, then the natural map

$$W_r(A') \otimes_{W_r(A)} W_r(B) \to W_r(B')$$

is also an isomorphism.

Proof: Cf.[Integral p-adic Hodge, BMS]. □

Cohen Rings

Def. (4.5.3.27)[Cohen Rings]. For any $k \in \texttt{Field}^p$, there exists a unique absolutely unramified DVR of characteristic 0 and residue field k, denoted by $\mathrm{Coh}(k)$.

Proof: Cf.[Fontaine-OuYang]P185.? □

Cor. (4.5.3.28). If $k_0 = k^{\mathrm{perf}}$, then $W(k_0) \subset \mathrm{Coh}(k) \subset W(k)$.

4 δ-Rings

Def. (4.5.4.1) [δ-Ring]. A δ-ring structure on R characterize the deficit in lifting the Frobenius action on R/p. i.e. $\varphi(x) = x^p + p\delta(x)$. A **$\delta$-ring** is a pair (R, δ) where R is a commutative ring and $\delta : R \to R$ is a map that $\delta(0) = \delta(1) = 0$, and satisfies:

$$\delta(xy) = x^p\delta(y) + y^p\delta(x) + p\delta(x)\delta(y), \quad \delta(x+y) = \delta(x) + \delta(y) - \frac{(x+y)^p - x^p - y^p}{p}.$$

δ-rings naturally form a category, denoted by $\mathcal{CA}\mathrm{lg}^\delta$. And in case A is p-torsionfree, a δ-structure on A is the same as a lifting of the Frobenius on A/p.

Def. (4.5.4.2) [δ-Pairs]. The category of **δ-pairs** consists of pairs (A, I) where A is a δ-ring and I is an ideal of A that morphisms $\varphi : (A, I) \to (B, J)$ are δ-ring maps $A \to B$ that $\varphi(I) \subset J$.

Prop. (4.5.4.3) [δ-Rings and W_2]. A δ-ring structure on A is the same as a section of the map $W_1 : W_2(A) \to A$, and a morphism of δ-rings is a commutative diagram of sections.

Proof: By the description of W_2 in(4.5.3.15), this is clear, the morphism is given by $A \to W_2(A) : x \mapsto (x, \delta(x))$. □

Lemma (4.5.4.4) [Initial δ-Algebra]. We usually work with δ-algebras over $\mathbb{Z}_{(p)}$. Then there is an initial object in the category of δ-rings, given by $Z_{(p)}$ with $\delta(x) = \frac{x-x^p}{p}$.

Prop. (4.5.4.5). For a δ-ring A, φ commutes with δ.

Proof: We need to check $\delta(x^p + p\delta(x)) = \delta(x)^p + p\delta(\delta(x))$. This is hard to check, but we can check $\varphi(\frac{\varphi(x)-x^p}{p}) = \frac{\varphi(\varphi(x))-\varphi(x)^p}{p}$, so the conclusion is true when A is p-torsion-free. But by(4.5.4.10), every δ-ring is a quotient of a free thus p-torsionfree ring, thus the equation is also true for arbitrary A. □

Def. (4.5.4.6) [Commutative Coalgebra $\mathbb{Z}[\delta]$]. Denote $\mathbb{Z}[\delta] = \mathbb{Z}[e, \delta_1, \ldots, \delta_n, \ldots]$. Using the formulas in(4.5.4.1), we can write $\delta^{\circ n}(xy)$ and $\delta^{\circ n}(x+y)$ as functions of $\delta^{\circ i}(x), \delta^{\circ i}(y)$ for $0 \leq i \leq n$, i.e.

$$\delta^n(xy) = M_n(x, \delta(x), \delta^{\circ 2}(x), \ldots, \delta^{\circ n}(x), y, \delta(y), \ldots, \delta^{\circ n}(y))$$

$$\delta^n(x+y) = S_n(x, \delta(x), \delta^{\circ 2}(x), \ldots, \delta^{\circ n}(x), y, \delta(y), \ldots, \delta^{\circ n}(y))$$

Then we can change $\delta^{\circ n}$ to δ_n to define a commutative ring scheme structure on $\operatorname{Spec} \mathbb{Z}[\delta]$:

$$\times : \mathbb{Z}[\delta] \to \mathbb{Z}[\delta] \otimes \mathbb{Z}[\delta] : \delta_n \mapsto M_n, \quad + : \mathbb{Z}[\delta] \to \mathbb{Z}[\delta] \otimes \mathbb{Z}[\delta] : \delta_n \mapsto S_n.$$

it is easily prove by induction that if we denote $\mathbb{Z}[\varphi] = \mathbb{Z}[e, \varphi, \varphi_2, \ldots, \varphi_n, \ldots]$, and $\operatorname{Spec} \mathbb{Z}[\varphi]$ the commutative ring scheme with the ring structure given by

$$\times : \mathbb{Z}[\varphi] \to \mathbb{Z}[\varphi] \otimes \mathbb{Z}[\varphi] : \varphi_n \mapsto \varphi_n \otimes \varphi_n, \quad + : \mathbb{Z}[\varphi] \to \mathbb{Z}[\varphi] \otimes \mathbb{Z}[\varphi] : \varphi_n \mapsto \varphi_n \otimes 1 + 1 \otimes \varphi_n,$$

then the map

$$Z[\varphi] \to \mathbb{Z}[\delta] : \varphi_n \mapsto \text{expansion of } \varphi^{\circ n} \in \mathbb{Z}[e, \delta_1, \ldots, \delta_n]$$

induces a homomorphism of ring schemes $\operatorname{Spec} \mathbb{Z}[\delta] \to \operatorname{Spec} \mathbb{Z}[\varphi]$.

There is a natural functor:

$$[\delta] : \mathbb{Z}[\delta] \to \mathbb{Z}[\delta] : \delta_i \mapsto \delta_{i+1}$$

Lemma (4.5.4.7) [δ-Component]. Let $\varphi = e^p + p\delta$ be a polynomial in e, δ, then there are polynomials $\Theta_n \in \mathbb{Z}[e, \delta_1, \delta_2, \ldots, \delta_n]$ s.t.

$$\varphi^{\circ n} = \Theta_0^{p^n} + p\Theta_1^{p^{n-1}} + \cdots + p^n \Theta_n = W_{p^n}(\Theta_0, \ldots, \Theta_n), \forall n$$

In particular, $\Theta_0 = e, \Theta_1 = \delta$.

Moreover, $\mathbb{Z}[\Theta_0, \Theta_1, \ldots, \Theta_n] = \mathbb{Z}[e, \delta_1, \delta_2, \ldots, \delta_n]$ for any n.

Proof: Use equation $\varphi \circ \varphi^n = \varphi^n \circ \varphi$ and module $p^n \mathbb{Z}[\Theta_0, \Theta_1, \ldots, \Theta_n]$.**?** □

Prop. (4.5.4.8) [Witt Vectors as δ-Rings]. By(4.5.4.7), there is an isomorphism of algebras

$$\Delta_p \cong \mathbb{Z}[\delta] : X_{p^n} \mapsto \Theta_n,$$

but it is also an isomorphism of ring schemes because of the uniqueness property of(4.5.3.3).

Then for any $A \in \mathcal{CA}\mathrm{lg}$, every element of $W_p(A)$ has a δ-coordinates:

$$f \in W_p(A) = \operatorname{Hom}(\Delta_p, A) \mapsto (f(e), f(\delta_1), f(\delta_2), \ldots)_\delta.$$

Let $W_p(A)$ be defined as in(4.5.3.5), then $[\delta] : \mathbb{Z}[\delta] \to \mathbb{Z}[\delta]$ induces a homomorphism $\delta : W_p(A) \to W_p(A)$ that can be checked to be a δ-functor from our definition of coalgebra structure on $\mathbb{Z}[\delta]$. Thus W_p is a functor $\mathcal{CA}\mathrm{lg} \to \mathcal{CA}\mathrm{lg}^\delta$.

Prop. (4.5.4.9) [Witt Vectors as an Right Adjoints]. W_p is right adjoint to the forgetful functor $\mathcal{CA}\mathrm{lg}^\delta \to \mathcal{CA}\mathrm{lg}$.

Proof: Given a ring homomorphism $f : B \to A$, let

$$f^\delta : B \to W_p(A) : x \mapsto (f(x), f(\delta(x)), f(\delta^{\circ 2}(x)), \ldots)_\delta,$$

Then f^δ is a δ-ring homomorphism: It is a homomorphism by our definition of the ring structure on $\operatorname{Spec} \mathbb{Z}[\delta]$(4.5.4.6), and it is a δ-ring homomorphism by our definition δ-ring structure(4.5.4.8).

And it is easy to see f^δ is the unique δ-ring homomorphism $B \to W(A)$ that restricts to $f : B \to A$, thus

$$\mathrm{Hom}^\delta(B, W(A)) \cong \mathrm{Hom}(B, A).$$

□

Prop. (4.5.4.10) [Free δ-Rings]. The ring $\mathbb{Z}\{x_i\}$ is a ring on the free generators $\{x, \delta(x_i), \delta^2(x_i), \ldots\}$ and the Frobenius morphism defined by asserting $\varphi(\delta^i(x)) = \delta^i(x)^p + p\delta^{i+1}(x)$.

Generally we can define the **free δ-ring** generated by $\{x_i\}$ over a δ-ring A as the tensor $A \otimes \mathbb{Z}\{x_i\}$, and it satisfies the universal property.

Then the Frobenius action is f.f..

Proof: It is easily verified that for any δ-ring R over A and a map of sets $\{x_i\} \to R$, there is a unique morphism $\mathbb{Z}_{(p)}\{x_i\} \to R$ sending x to f, thus verifying the universal property.

For the f.f., notice it is a colimit of $\varphi_n : \mathbb{Z}[x, \delta(x), \ldots, \delta^n(x)] \to \mathbb{Z}[x, \delta(x), \ldots, \delta^{n+1}(x)]$, so by(4.4.1.25), it suffices to show φ_n are all f.f.. We decompose this map as n maps:

$$\mathbb{Z}[x, \delta(x), \ldots, \delta^n(x)] \cong \mathbb{Z}[x, \delta(x), \ldots, (\delta^i(x))^p, \ldots, \delta^n(x)] \subset \mathbb{Z}[x, \delta(x), \ldots, \delta^n(x)]$$

which are all f.f., so it is f.f. □

Cor. (4.5.4.11) [Frobenius is Fpqc locally Surjective]. For a δ-ring A and an element $x \in A$, there is a faithfully flat morphism of δ-rings $A \to B$ that the image of x in B is of the form $\varphi(y)$ for some $y \in B$.

Cor. (4.5.4.12). Set B as the pushout of the diagram $\mathbb{Z}_{(p)}\{s\} \leftarrow \mathbb{Z}_{(p)}\{t\} \to A$, where the arrows sends t to $\varphi(s)$ and x. B exists by(4.5.4.13) and the underlying ring is the same as the ring pushout, thus $A \to B$ is faithfully flat by(4.5.4.10).

Prop. (4.5.4.13) [Limits and Colimits of δ-Rings]. $\mathcal{CA}\mathrm{lg}^\delta$ admits limits and colimits, and their underlying rings are just the ring-theoretical limit and colimit, as the forgetful functor $\mathcal{CA}\mathrm{lg}^\delta \to \mathcal{CA}\mathrm{lg}$ has both left and right adjoints (4.5.4.9)(4.5.4.10).

Proof: Use(4.5.4.3), the construction of limits is straightforward, as W_2 commutes with limits. To construct colimits, notice the morphisms $A_i \to W_2(A_i)$ induces a morphism

$$\varinjlim A_i \to \varinjlim W_2(A_i) \to W_2(\varinjlim A_i)$$

and clearly this map is a section of $W_2(\varinjlim A_i) \to \varinjlim A_i$, thus given a δ-ring structure on $\varinjlim A_i$.

It is a colimit because any commutative diagrams $\varphi_i : (A_i \to W_2(A_i)) \to (B \to W_2(B))$ induces a unique commutative diagram

$$\begin{array}{ccccc}
\varinjlim_i A_i & \longrightarrow & \varinjlim W_2(A_i) & \xrightarrow{\varinjlim W_2(\varphi_{ij})} & W_2(\varinjlim A_i) \\
\downarrow{\scriptstyle \varinjlim \varphi_i} & & \downarrow & \swarrow{\scriptstyle W_2(\varinjlim \varphi_i)} & \\
B & \longrightarrow & W_2(B) & &
\end{array}.$$

□

Extension of δ-Structures

Lemma (4.5.4.14) [Quotients]. Let A be a δ-ring and I be an ideal, then if I is stable under δ, then there is a natural δ-structure on A/I compatible with A. In general, if J is an ideal of A, then there is a universal δ-A-algebra $B = A/J$, where $J = \cup_{n\geq 0}\delta^n(I)$. It is the universal δ-A-algebra that the image of I is 0.

Lemma (4.5.4.15) [Localization]. Let A be a δ-ring and S be a multiplicative set of A that $\varphi(S) \in S$, then there is a unique δ-structure on $S^{-1}A$, and it satisfies the universal property.

Proof: Firstly if A is p-torsionfree, in this case a δ-structure is the same as a lifting of the Frobenius on A/p, thus the proposition is clear because $\varphi_{S^{-1}A} : S^{-1}A \to S^{-1}A$ is uniquely determined.

Generally, we choose a free δ-ring F and a surjection $\alpha : F \to A$, then $T = \alpha^{-1}S$ is multiplicative, and $T^{-1}F$ admits a unique δ-structure. But now $S^{-1}A = T^{-1}F \otimes_F A$, so there is a δ-structure on $S^{-1}A$ as the colimit, so compatible with that of $S^{-1}A$. Then it's also the unique one(because if there is another one, the colimit properties gives a morphism of δ-rings above $\mathrm{id}_{S^{-1}A}$, which must by identity). □

Lemma (4.5.4.16) [p-adic Localization]. If A is a δ-ring with $p \in \mathrm{rad}(A)$, then the formula $\varphi(f) = f^p + p\delta(f)$ shows if f is a unit, then $\varphi(f)$ is also a unit(2.4.2.2), so $S^{-1}A = T^{-1}A$, where $T = \{S, \varphi(S), \varphi^2(S), \ldots\}$.

Thus for any δ-ring A and a multiplicative set S, the p-localization(4.1.1.31) $(S^{-1}A)_{(p)}$ is the same as the p-localization of $T^{-1}A$. Then(4.5.4.15) shows that $(S^{-1}A)_{(p)}$ carries a unique δ-structure compatible with that of A.

Lemma (4.5.4.17) [Completions]. For a δ-ring A and a f.g. ideal I, the I-adic completion of A has a unique δ-structure compatible with that of A.

Proof: Let $A \to W_2(A)$ corresponds to the δ-structure by(4.5.4.3), then there is a natural map $A \to W_2(A) \to W_2(\widetilde{A})$, then by the universal property of complete, it extends to a map $\widetilde{A} \to W_2(\widetilde{A})$, which is a ring map and is a section, all by universal properties. □

Lemma (4.5.4.18) [Derived Completion]. If A is a δ-ring and $I \subset A$ is an ideal containing p, then the derived I-completion ring $\widehat{A}$ of A admits a unique δ-structure extending that of A.

Proof: The proof is similar as(4.5.4.17). □

Prop. (4.5.4.19) [Étale Extension]. Let A be a δ-ring with a f.g. ideal I containing p. Assume B is a derived I-complete and I-completely étale A-algebra, then B admits a unique δ-structure compatible with that of A.

In particular, any δ-structure on an algebra A passes uniquely to its derived I-completion for any ideal $I \subset A$ containing p.

Proof: By Elkik's algebraization(4.9.7.9), we can write B as derived I-completion of some étale A-algebra B'. Then $W_2(A) \to W_2(B')$ is étale by van der Kallen's theorem(4.5.3.26). Then $W_2(B)$ is the derived I-completion of $W_2(B')$, with the A-algebra structure given by $A \to W_2(A) \to W_2(B')$. For the rest, Cf.[Scholze, Prism, 2.18]. □

Distinguished Elements

Def. (4.5.4.20) [Distinguished Elements]. In a δ-ring A, an element d is called a **distinguished element** if $\delta(d)$ is a unit in A. A distinguished element is preserved by a δ-ring map.

Lemma (4.5.4.21) [Distinguished up to units]. If A is a δ-ring, d is distinguished and u is a unit, then ud is also distinguished, if $d, p \in \mathrm{rad}(A)$.

Proof: $\delta(ud) = u^p\delta(d) + d^p\delta(u) + p\delta(u)\delta(d)$ is a unit. □

Lemma (4.5.4.22) [Irreducibility of Distinguished Elements]. Let A be a δ-ring and d be distinguished element in A. If $d = fh$ for some $f, h \in A$ that $f, p \in \mathrm{rad}(A)$, then f is also distinguished and h is a unit.

Proof: Notice that $\delta(d) = f^p\delta(h) + h^p\delta(f) + p\delta(f)\delta(h)$, $\delta(d)$ is a unit, $f^p\delta(h) + p\delta(f)\delta(h) \in \mathrm{rad}(A)$, thus $h^p\delta(f)$ is a unit, so we are done. □

Prop. (4.5.4.23) [Characterization of Distinguished Elements]. Fix a δ-ring A and an element d that $d, p \in \mathrm{rad}(A)$, then d is distinguished iff $p \in (d, \varphi(d))$. In particular, distinguished elements is stable under units.

Proof: If d is distinguished, then $\delta(d)$ is a unit, thus $\varphi(d) = d^p + d^p + p\delta(d)$ shows immediately $p \in (d, \varphi(d))$. Conversely, if $p = ad + b\varphi(d)$, we show $\delta(d)$ is invertible. It suffices to show it is invertible modulo (d, p) as $d, p \in \mathrm{rad}(A)$, or equivalently $(p, d, \varphi(d)) = A$. If it is not the case, then we may take a $(p, d, \varphi(d))$-adic completion to assume $p, d, \varphi \in \mathrm{rad}(A)$, thus the equation simplifies to $p(1 - b\delta(d)) = cd$. The left side is distinguished, by(4.5.4.21), and then d is also distinguished, by(4.5.4.22), so truly $(p, d, \varphi(d)) = A$. □

Prop. (4.5.4.24) [Examples of Distinguished Elements]. The element d is distinguished in the following cases:

- (Crystalline cohomology)Take $A = \mathbb{Z}_{(p)}$ and $d = p$, then $\delta(p) = 1 - p^{p-1}$ is a unit.
- (q-de Rham cohomology) Take $A = \mathbb{Z}_p[[q-1]]$ and $d = [p]_q = \sum_{i=0}^{p-1} q^i \in A$, with the δ-structure determined by $\varphi(q) = q^p$.
- (Breuil-Kisin cohomology)Fix a discretely valued field K/Q_p with uniformizer π, W the maximal unramified subring of $\mathcal{O}_K$. Take $A = W[[u]]$ with $\delta(u) = u^p$, then any generator of the kernel of the map of $A \to \mathcal{O}_K : u \mapsto \pi$ is distinguished**?**.
- (A_{inf}-cohomology)Let A be the $(p, q-1)$-completion of $\mathbb{Z}_p[q^{\frac{1}{p^\infty}}]$. Then A is p-torsion free and $\varphi(q) = q^p$ gives a δ-structure. Then $d = [p]_q$ defined in item2 is also distinguished. And $\varphi^n(d)$ is distinguished for any $n \in \mathbb{Z}$ by(4.5.4.5).

Proof: 2: It is clear φ is continuous and δ stablizes $(q-1)$, and d is distinguished because the image of $\delta(d)$ in $A/(q-1) \cong \mathbb{Z}_q$ is $\delta(p) = 1 - p^{p-1}$ is a unit, thus it is also a unit in A. □

Perfect δ-Ring

Def. (4.5.4.25) [Perfect δ-Ring]. A **perfect δ-ring** is a δ-ring that φ is an isomorphism.

Prop. (4.5.4.26) [Perfections]. The inclusion of the category of perfect δ-rings to the category of δ-rings admits left and right adjoints, A_{perf} and A^{perf} with definition similar to(4.5.1.9).

Proof: We use(4.5.4.3), the map $A \to W_2(A) \to W_2(A_{\text{perf}})$ extends uniquely to a map $A_{\text{perf}} \to W_2(A_{\text{perf}})$ lifting the δ-action of A. Similarly, because $(-)^{\text{perf}}$ is a limit and $W_2(-)$ is a right adjoint, then $W_2(-)$ commutes with $(-)^{\text{perf}}$. In particular, there is a natural map $A^{\text{perf}} \to W_2(A^{\text{perf}})$. □

Lemma (4.5.4.27) [Frobenius Kills p-Torsion]. If A is a δ-ring and $x \in A$ satisfies $px = 0$, then $\varphi(x) = 0$. In particular, if A is perfect, then A is p-torsionfree.

Proof: Applying δ to $px = 0$, we have $0 = p^p\delta(x) + x^p\delta(p) + p\delta(x)\delta(p) = p^p\delta(x) + \varphi(x)\delta(p)$. As $\delta(p)$ is a unit, and $p^p\delta(x) = p^{p-1}(\varphi(x) - x^p) = \varphi(p^{p-1}x) - p^{p-1}x^p = 0$, thus $\varphi(x) = 0$. □

Prop. (4.5.4.28) [Perfect p-Complete δ-Rings]. The following categories are equivalent:

- The category of perfect p-adically complete δ-rings.
- The category p-adically complete and p-torsionfree rings A with A/p perfect.
- The perfect $\mathbb{F}_p$-algebras.

In particular, every perfect p-complete δ-ring is of the form $W(k)$ thus has Teichmuller expansions.

Proof: 2 and 3 are equivalent by Witt vector construction, by(6.1.4.3), noticing that there is a natural lifting on $W(k)$ lifting the Frobenius of $k/\mathbb{F}_p$ that induces a δ-functor?. There is a forgetful functor from 1 to 2, by(4.5.4.27)(notice A/p is also perfect because if $\varphi(x) \in (p)$, then $x \in \varphi^{-1}(p) = (p)$ as $\varphi(p) = p\varphi(1) = p$) and it is faithful. Now there is an equivalence from $3 \to 1 \to 2$, thus $1 \to 2$ is essentially surjective thus is an equivalence. □

Prop. (4.5.4.29) [Perfect Element has Rank 1]. Fix a δ-ring A and an element $x \in A$, then $\delta(x^{p^n}) \in p^nA$ for any n. In particular, if A is p-adically separated and y is perfect in A, then $\delta(y) = 0$.

Proof: By formal calculation, it suffices to show that $p\delta(x^{p^n}) \in p^{n+1}A$, which is equivalent to $\varphi(x^{p^n}) \equiv x^{p^{n+1}} \mod p^{n+1}A$, which is true by(24.1.3.4). □

Prop. (4.5.4.30) [Distinguished Elements in Perfect δ-Rings]. Let A be a perfect p-complete δ-ring(or perfect $\mathbb{F}_p$-algebra by(4.5.4.28)), and $d \in A$, then d is distinguished iff its coefficient of p in the Teichmuller expansion(4.5.4.28) is a unit.

If d is distinguished, then it is a nonzero-divisor, and $A/d[p^\infty] = A/d[p]$.

Proof: Let $d = \sum_{i\geq 0}[a_i]p^i$, then

$$\delta(d) = \frac{1}{p}(\sum_{i\geq 0}[a_i^p]p^i - (\sum_{i\geq 0}[a_i]p^i)^p) \equiv [a_1^p] \mod pA$$

thus it is a unit iff a_1 is a unit, because A is p-complete.

Now if d is distinguished, and $fd = 0$. If $f \neq 0$, we may assume $p \nmid f$, because A is p-torsionfree and p-adically complete(4.5.4.28). Now

$$\varphi(f)\delta(fd) = \varphi(f)(f^p\delta(d) + \delta(f)\varphi(d)) = \varphi(f)f^p\delta(d) = 0,$$

so $f^p\varphi(f) = 0$, and $f^{2p} \equiv 0 \mod p$. Hence $f \equiv 0 \mod p$, but then $p|f$, contradiction.

For the last assertion, it suffices to show that $A/d[p^2] = A/d[p]$. If $p^2f = dg$, then $\varphi(g)\delta(gd) = \varphi(g)(\delta(d)g^p + \varphi(d)\delta(g)) = \varphi(g)\delta(d)g^p + \varphi(dg)\delta(g) \in pA$, thus $\varphi(g)g^p \in pA$, hence $g^{2p} \in pA$, and hence $g \in pA$, showing $pf \in dA$. □

4.6 Divided Power Algebras

Basics

Def. (4.6.0.1)[PD-Structures]. Let I be an ideal of a commutative ring A, a **devided power structure** or **pd-structure** on I is a collection of maps $I_n : I \to A, n \geq 0$ that

- $\gamma_0(x) = 1, \gamma_1(x) = x, \gamma_n(x) \in I \forall n$.
- $\gamma_n(x+y) = \sum \gamma_{n-i}(x)\gamma_i(y)$.
- $\gamma_n(\lambda x) = \lambda^n \gamma_n(x), \lambda \in A, x \in I$.
- $\gamma_m(x)\gamma_n(x) = \binom{m+n}{n}\gamma_{m+n}(x)$.
- $\gamma_n(\gamma_m(x)) = \frac{(mn)!}{(m!)^n n!}\gamma_{mn}(x)$.

It is a simulation of the divided power $\gamma_n(x) = \frac{x^n}{n!}$ in case $n!$ is definable.

A **divided power ring** is a triple (A, I, γ) where I is an ideal of a commutative ring A and γ is a pd-structure on I. A morphism of divided power rings is a morphism of pairs (A, I) that preserves pd-structures.

For a pd-structure (A, I), denote $I^{[n]}$ the ideal generated by $\prod_i \gamma_{n_i}(x_i)$ where $x_i \in I$ and $\sum n_i \geq n$.

Prop. (4.6.0.2)[Limits and Colimits]. The category of divided power rings has all limits and colimits, the limits commute with forget functors but the colimits don't. However, the colimit always commutes with the functor taking (A, I) to A/I. This can be seen from the universal property of colimit applied to the pd-structures that $I = 0$.

Proof: The construction of the limit is clear. For the colimits, we use representability criterion(3.1.1.27), Cf.[[Sta]07GX]**?**. ☐

Prop. (4.6.0.3). Let A be a ring and I an ideal of A, then if γ is a pd-structure on I, then $n!\gamma(x) = x^n$.

Proof: If γ is a pd-structure, then we have $n\gamma_n(x) = \gamma_1(x)\gamma_{n-1}(x)$, so we can use induction. ☐

Prop. (4.6.0.4). If I, J are two ideals of A and γ a pd-structure on I and δ a pd-structure on J, then

- γ, δ agree on IJ.
- If γ, δ agree on $I \cap J$, then they extends to a pd-structure on $I + J$.

Proof: 1: for $x \in I, y \in J$, $\gamma_n(xy) = y^n\gamma_n(x) = n!\delta_n(y)\gamma_n(x) = \delta(xy)$.
2: direct calculation. ☐

Prop. (4.6.0.5)[p-Nilpotent and Thickening]. Let p be a prime and (A, I, γ) a pd-structure. Assume p is nilpotent in A/I, then I is locally nilpotent iff p is nilpotent in A, equivalently (A, I, γ) is a pd-thickening.

Proof: If $p^N = 0 \in A$, then for any $x \in I$, $x^{pN} = (pN)!\gamma_{pN}(x) = 0$. Then converse is trivial. ☐

Constructing PD-Structures

Prop. (4.6.0.6) [$\mathbb{Z}_{(p)}$-Algebras]. Cf.[[Sta]07GN].

Prop. (4.6.0.7). Let A be a $\mathbb{Z}_{(p)}$-algebra and I is an ideal, then two pd-structures γ, γ' on γ are equal iff $\gamma_p = \gamma'$. Moreover, given a map $\delta : I \to I$ that

- $p!\delta(x) = x^p$,
- $\delta(ax) = a^p\delta(x)$ for any $a \in A, x \in I$,
- $\delta(x+y) = \delta(x) + \delta(y) + \sum_{i+j=p,i>0,j>0} \frac{1}{i!j!}x^iy^j$.

Then there exists a unique pd-structure on I that $\gamma_p = \delta$.

Proof: Just notice that $\gamma_n(x) = dx\gamma_{n-1}(x)$ for some c invertible in $\mathbb{Z}_{(p)}$, and also $\gamma_{pm}(x) = c\gamma_m(\gamma_p(x))$ for some c invertible in $\mathbb{Z}_{(p)}$, thus γ is uniquely determined, and we can also define γ_n inductively in this way, and the verification of axioms in in[[Sta]07GS]. □

Prop. (4.6.0.8). Let A be a $\mathbb{Z}$-torsion-free ring and I an ideal of A, then:

- I has at most one pd-stuucture.
- if $\gamma_n : I \to I$ are maps, then γ is a pd-structure iff $n!\gamma_n(x) = x^n$.
- I has a pd-structure iff there is a set of generators $\{x_i\}$ of I that $x_i^n \in n!I$.

Proof: 1 is clear from(4.6.0.3).

2: because $A \subset A \otimes_{\mathbb{Z}} \mathbb{Q}$, we can verify in $A \otimes_{\mathbb{Z}} \mathbb{Q}$, then the verifications are trivial.

3: Use the axioms to extend linearly and additively. □

Prop. (4.6.0.9) [DVR]. If R is a DVR in char 0 with residue field of char p and ramification p and maximal ideal $\mathfrak{m}$, then $\mathfrak{m}$ has a pd-stucture iff $e \le p-1$.

Proof: As R has char0, it has at most one pd-structure by(4.6.0.8), and we need to show that $x^n/n!$ is in $\mathfrak{m}$ for any $x \in \mathfrak{m}$. And using(24.1.3.17), we are done. □

Extending PD-Structure

Def. (4.6.0.10) [Extending PD-Structure]. Let (A, I, γ) be a pd-structure and B is an A-algebra, we say that γ extends to B if $A \to B$ extends to a morphism of pd-structures $(A, I, \gamma) \to (B, IB, \gamma')$.

Let $(A, I), (B, J)$ be two pd-structures and B is an A-algebra, then these two pd-structures are said to be compatible iff the pd-structure on A extends to B and the pd-structure on J and IB coincides, or equivalently, there is a pd-structure on $IB + J$ compatible with IB and J, by(4.6.0.4).

Prop. (4.6.0.11) [Extendability]. Let (A, I) is a pd-structure and B an A-algebra, if any of the following holds:

- $IB = 0$,
- I is principal,
- $B[I] = 0$, (e.g. $A \to B$ is flat).

then γ extends to B.

Proof: 1 is trivial.

2: if $I = (x)$, we define $\gamma_n(bx) = b^n\gamma_n(x)$. This is well defined: if $(b-b')x = 0$, then $(b^n - (b')^n)\gamma_n(x) = 0$ because $\gamma_n(x) \in (x)$. Verifications of axioms is routine.

3: The condition shows $I \otimes_A B \cong IB$, thus it suffices to define γ on $I \otimes_A B$. For this we define on $I \times B$ and descend: let $\gamma_n((x, b)) = b^n\gamma_n(x)$ and extend by freeness and axioms in(4.6.0.1), then it is easy to show it is bi-additive and A-linear, so descend to $I \otimes B$ by(2.2.4.13). □

Prop. (4.6.0.12) [PD-Structure and Completions]. Let (A, I, γ) be a pd-structure that p is nilpotent in A/I, then each γ_n is continuous in the p-adic topology and extends to a pd-structure $\widehat{\gamma}$ on $\widehat{I}$.

If moreover A is a $\mathbb{Z}_{(p)}$-algebra, then for e large, $p^e A \in I$ is preserved by γ and

$$(\widehat{A}, \widehat{I}, \widehat{\gamma}) = \mathrm{colim}_e (A/p^e A, I/p^e A, \gamma).$$

Proof: Let $p^t \in I$, then 1 follows from(4.2.3.8). γ_n is clearly continuous, and γ_n preserves $p^e A$ because

$$\gamma_n(p^e a) = p^n \gamma_n(p^{e-1} a) = \frac{p^n}{n!} p^{n(e-1)} a^n \in p^e A.$$

The limit equation follows from(4.6.0.2). □

Prop. (4.6.0.13) [Quotient]. Let (A, I, γ) be a pd-structure and $\mathfrak{a} \subset A$ is an ideal, and $I' = I \cap \mathfrak{a}$, then the following are equivalent:

- δ extends to $A/\mathfrak{a}$.
- I' is preserved by γ.
- There is a set of generator x_i of I' that $\gamma_n(x_i) \in I'$ for all n, i.

Proof: $1 \to 2 \to 3$ is clear. $2 \to 1$: we can just define $\gamma(x + I) = \gamma(x) + I$, which is well defined by axiom2 of(4.6.0.1). $3 \to 2$ is clear. □

Def. (4.6.0.14) [Free PD-Algebra]. For a pd-structure (A, I, δ), the **free pd-algebra** $A\langle t_1, \ldots, t_n \rangle$ is defined to be the A-algebra generated by symbols $t_i^{[n_i]}$, where $n_i > 0$, modulo the algebraic relations $t_i^{[m]} t_i^{[n]} = \binom{m+n}{n} t_i^{[m+n]}$. Denote by $A\langle t_1, \ldots, t_n \rangle_+$ the ideal generated by $t_i^{[n_i]}$ where $n_i > 0$.

Then the ideal J generated by I and $A\langle t_1, \ldots, t_n \rangle_+$, where $n_i > 0$ has a unique pd-structure that $\gamma_n(t_i) = t_i^{[n]}$ and $(A, I, \delta) \to (A\langle t_1, \ldots, t_n \rangle, J, \gamma)$ is a morphism of pd-structures.

It has a universal property that $\mathrm{Hom}(((A\langle t_1, \ldots, t_n \rangle, J, \gamma), (C, K, \varepsilon)$ is the same as $\mathrm{Hom}((A, I, \delta), (C, K, \varepsilon))$ with specified n elements in K.

Proof: Because $IA\langle t_i \rangle \cap A\langle t_1, \ldots, t_n \rangle_+ = IA\langle t_i \rangle + A\langle t_1, \ldots, t_n \rangle_+$, by(4.6.0.4), it suffices to construct pd-structures on $IA\langle t_i \rangle$ and $A\langle t_1, \ldots, t_n \rangle_+$. The former is by(4.6.0.11) and for the latter: if A is torsion-free, then we can use(4.6.0.8) because $\gamma_m(x)^n = n! \gamma_n(\gamma_m(x)) = \frac{(mn)!}{(m!)^n} \gamma_{mn}(x) \in n! A\langle t_1, \ldots, t_n \rangle_+$. In general, we write $A = R/\mathfrak{a}$ where R is a torsion-free pd-structure(can choose $\mathbb{Z}\langle A \rangle$), so there is a pd-structure on $R\langle t_i \rangle$, and $R\langle t_i \rangle / \mathfrak{a}\langle t_i \rangle = A\langle t_i \rangle$, then we can use(4.6.0.13) to construct a pd-structure on $A\langle t_i \rangle$ compatible with that of A.

The verification of universal property is omitted. □

PD-Envelopes

Prop. (4.6.0.15) [PD-Envelope]. Let (A, I, γ) be a pd-structure, then there is a **pd-envelope** functor $(B, J) \to (D_B(J), \overline{J}, \overline{\delta})$ from the the category of pairs over (A, I) to the category of pd-structures over (A, I, γ) that is left adjoint to the forgetful functor.

In particular, by the universal property of pd-envelope, there is a morphism $(B, J) \to (D_B(J), \overline{J}) \to (B/J, 0)$ of pairs, so in particular $D/\overline{J} \to B/J$ is surjective.

Proof: We use adjoint functor theorem(3.1.1.34), the forgetful functor preserves limit by(4.6.0.2), and it satisfies the set-theoretical condition: for any pair (B,J) over (A,I) and a morphism $\psi: (B,J)\to(C,K)$ over (A,I) where $\varphi:(A,I,\gamma)\to(C,K,\delta)$ is a pd-morphism, then we can consider the subring $C'\subset C$ generated by all $\varphi(A),\psi(B)$ and $\delta_m(J)$, and $K'\subset K\cap C'$ the ideal of C' generated by $\varphi(I),\delta_n(\psi(J))$, then $|C'|<|A|\otimes|B|^{\aleph_0}$ and its type is bounded by a cardinal, so does (C,I). □

Prop. (4.6.0.16) [PD-Envelope of Quotients]. Let (A,I,γ) be a pd-structure and $\varphi: B'\to B$ be a surjection of A-algebras with kernel K. Let $IB\subset J\subset B$ an ideal and $J'=\varphi^{-1}(J)$ and $D_{B',\gamma}(J')=(D',\overline{J}',\overline{\gamma})$, then $D_{B,\gamma}(J)=(D'/K',\overline{J}'/K',\overline{\gamma})$ where K' is the ideal generated by all $\overline{\gamma}_n(k)$ for $n\geq 0$ and $k\in K$.

Proof: There is a pd-structure on $(D'/K',\overline{J}'/K',\overline{\gamma})$ by(4.6.0.13). A map of pais $(B,J)\to(T,I',\gamma)$ is equivalent to a map of pairs $(B',J')\to(T,I',\gamma)$ that vanishes on K, or a map of pd-structures $(D',\overline{J}',\overline{\gamma})\to(T,I',\gamma)$ that vanishes on $\gamma_n(K)$, thus this is clearly represented by $(D'/K',\overline{J}'/K',\overline{\gamma})$. □

Prop. (4.6.0.17). If (A,I) is a pd-structure and (B,J) is a pair over (A,I), then

$$D_{B[X_i],\gamma}(JB[X_i]+(X_i))\cong D_{B,\gamma}(J)\langle X_i\rangle$$

Proof: This follows from the universal property of free pd-structure(4.6.0.14). □

PD-Structures and δ-Rings

Lemma (4.6.0.18). If A is a p-torsionfree $\mathbb{Z}_{(p)}$-δ-ring, denote $\gamma_n(z)=\frac{z^n}{n!}$. If $z\in A$ satisfies $\gamma_p(z)\in A$, then $\gamma_n(z)\in A$ for any n.

Proof: WARNING: this is not an easy consequence of power counting. We first prove for $n=p^2$: as A is a δ-ring, $\delta(\frac{z^p}{p})\in A$

$$\delta(\frac{z^p}{p})=\frac{1}{p}(\frac{\varphi(z)^p}{p}-\frac{z^{p^2}}{p^p})=\frac{(z^p+p\delta(z))^p}{p^2}-\frac{z^{p^2}}{p^{p+1}}\in A.$$

The first term is in A by assumption, thus the second term is also in A, proving the case for $n=p^2$.

Now for general n, it suffices to prove for $n=kp$. But it can be checked that $\gamma_{nk}(z)=u\gamma_k(\gamma_p(z))$ where u is a unit. Now by what we just proved, we can use induction hypothesis for $z=\gamma_p(z)$, and conclude that $\gamma_{nk}(z)\in A$. □

Prop. (4.6.0.19). The ring $C=\mathbb{Z}_{(p)}\{x,\frac{\varphi(x)}{p}\}$(4.5.4.10) identifies with the pd-envelope $D=D_{\mathbb{Z}_{(p)}\{x\}}(x)=\mathbb{Z}_{(p)}\{x\}[\{\gamma_n(x)\}]$ where $\gamma_n(x)=\frac{x^n}{n!}$. Moreover, it also equals to $\mathbb{Z}_{(p)}[X_1,X_2,\ldots]/(pX_1-x^p,pX_2-X_1^p,\ldots)$.

Proof: It suffices to show that the smallest δ-ring of $\mathbb{Z}_{(p)}\{x\}[\frac{1}{p}]$ containing $\mathbb{Z}_{(p)}\{x\}$ and $\frac{\varphi(x)}{p}$ is the same as the smallest ring of $\mathbb{Z}_{(p)}\{x\}[\frac{1}{p}]$ containing $\mathbb{Z}_{(p)}\{x\}$ and $\frac{\varphi(x)}{n!}$.

$D\subset C$ is immediate from(4.6.0.18). To show $C\subset D$, notice $\frac{x^p}{p}\in D$, it suffices to show φ preserves D, or equivalently, $\varphi(y)-y^n\in pD$ for any $y\in D$. Now

$$\varphi(\frac{x^n}{n!})=\frac{(x^p+p\delta(x))^n}{n!}=\frac{\sum_{i=0}^n\binom{n}{i}(pi)!p^{n-i}\frac{x^{pi}}{(pi)!}\delta(x)^{n-i}}{n!}$$

The coefficients

$$\frac{\binom{n}{i}(pi)!p^{n-i}}{n!}$$

are all in $p\mathbb{Z}_{(p)}$, thus $\varphi(\frac{x^n}{n!}) \in pD$. On the other hand,

$$(\frac{x^n}{n!})^p = \gamma_p(\gamma_n(x)) = u\gamma_{pn}(x)\cdot p! \in pD$$

where u is a unit in $\mathbb{Z}_{(p)}$ by(4.6.0.1), thus we are done. ☐

Lemma (4.6.0.20). If A is a p-torsionfree (equivalently, flat) $\mathbb{Z}_{(p)}$-algebra and (a,p) is a regular sequence in A, then $D_A((a)) \cong A\otimes_{\mathbb{Z}_{(p)}\{x\}} D_{\mathbb{Z}_{(p)}}((x)) = A[X_1,X_2,\ldots]/(pX_1 - a^p, pX_2 - X_1^p,\ldots)$.

Proof: By(4.6.0.19),

$$A\otimes_{\mathbb{Z}_{(p)}\{x\}} D_{\mathbb{Z}_{(p)}}((x)) = A\otimes_{\mathbb{Z}_{(p)}\{x\}}[\{\gamma_n(x)\}] = A[X_1,X_2,\ldots]/(a^p - pX_1, X_1^p - pX_2, X_2^p - pX_3,\ldots)$$

thus there is a natural map from $A\otimes_{\mathbb{Z}_{(p)}\{x\}} D_{\mathbb{Z}_{(p)}}((x))$ to $D_A((a))$ given by

$$X_k \mapsto \frac{a^{p^k}}{p^{\mathrm{ord}_p(n!)}} = \frac{a^{p^k}}{p^{1+p+\ldots+p^{k-1}}} \in D_A((a)).$$

It is surjective, and it is an isomorphism when inverting p. Thus the kernel are all p^∞-torsions. Then to show it is an isomorphism, it suffices to show $A[X_1,X_2,\ldots]/(a^p - pX_1, X_1^p - pX_2, X_2^p - pX_3,\ldots)$ is p-torsion-free. It is a filtered colimit, so it suffices to show $A[X_1,\ldots,X_n]/(a^p - pX_1, X_1^p - pX_2,\ldots,X_{n-1}^p - pX_n)$ is p-torsionfree.

For this, it suffices to prove $A' = A[X_1,\ldots,X_k]/(px_1 - a^k, px_2 - x_1^k,\ldots,px_k - x_{k-1}^p)$ is p-torsionfree. If we denote $K(R) = K(R[X_1,\ldots,X_n], px_1 - a^k, px_2 - x_1^k,\ldots,px_k - x_{k-1}^p)$ for any ring R, then we have a distinguished triangle

$$K(A)\xrightarrow{p} K(A)\to K(Kos(A[X_1,\ldots,X_k],p)) = K(A/p)$$

as A is p-torsionfree. Now we can consider the spectral sequence associated to this distinguished triangle. Notice first that $(px_1 - a^k, px_2 - x_1^k,\ldots,px_k - x_{k-1}^p)$ is a regular sequence in A'/p, which is clear. So the E_1 page looks like

$$\begin{array}{ccccc} A' & \xrightarrow{p} & A' & \longrightarrow & A'/p \\ \uparrow & & \uparrow & & \uparrow \\ * & \longrightarrow & * & \longrightarrow & 0 \\ \uparrow & & \uparrow & & \uparrow \\ * & \longrightarrow & * & \longrightarrow & 0 \\ \uparrow & & \uparrow & & \uparrow \\ \ldots & \longrightarrow & \ldots & \longrightarrow & \ldots \end{array}$$

and the E_2 page is of the form

$$\begin{array}{ccccc} A'[p] & \xrightarrow{p} & 0 & \longrightarrow & 0 \\ \uparrow & & \uparrow & & \uparrow \\ * & \longrightarrow & * & \longrightarrow & 0 \\ \uparrow & & \uparrow & & \uparrow \\ * & \longrightarrow & * & \longrightarrow & 0 \\ \uparrow & & \uparrow & & \uparrow \\ \ldots & \longrightarrow & \ldots & \longrightarrow & \ldots \end{array}$$

This spectral sequence converges to 0, so $A'[p]=0$, we win. □

Prop. (4.6.0.21) [PD-Envelope for Regular Sequence]. Let A be a p-torsionfree δ-ring and $p, f_1, \ldots, f_r$ define a regular sequence in A, then $A\{\frac{\varphi(f_1)}{p}, \ldots, \frac{\varphi(f_r)}{p}\}$ identifies with the pd-envelope $D_A(I)$ of $I=(f_1,\ldots,f_r)$ as a subring of $A[\frac{1}{p}]$.

Proof: In case $r=1$, $A\{\frac{\varphi(f_1)}{p}\} = A\otimes_{\mathbb{Z}_{(p)}\{x\}}\mathbb{Z}_{(p)}\{x,\frac{\varphi(x)}{p}\} = A\otimes_{\mathbb{Z}_{(p)}\{x\}} D_{\mathbb{Z}_{(p)}}((x)) \cong D_A((f_1))$ by(4.6.0.20).

The general case follows from this, by considering the tower

$$\begin{aligned}(A,(f_1)) &\to (D_A(f_1),(f_2)) = (A\{\frac{\varphi(f_1)}{p}\},(f_2))\\ &\to (D_{A\{\frac{\varphi(f_1)}{p}\}}(f_2),(f_3)) = (A\{\frac{\varphi(f_1)}{p},\frac{\varphi(f_2)}{p}\},(f_3))\\ &\to \ldots = A\{\frac{\varphi(f_1)}{p},\ldots,\frac{\varphi(f_r)}{p}\}\end{aligned}$$

The equations are true because (p,f_k) are regular in $A\{\frac{\varphi(f_1)}{p},\ldots,\frac{\varphi(f_{k-1})}{p}\}$:

$$\begin{aligned}A\{\frac{\varphi(f_1)}{p},\ldots,\frac{\varphi(f_{k-1})}{p}\}/p =& A/p[X_{11},X_{12},\ldots,X_{21},X_{22},\ldots,\ldots,X_{k-1,1},X_{k-1,2},\ldots]/\\ &(f_1^p,f_2^p,\ldots,f_{k-1}^p,X_{11}^p,X_{12}^p,\ldots,X_{21}^p,X_{22}^p,\ldots,\ldots,X_{k-1,1}^p,X_{k-1,2}^p,\ldots)\end{aligned}$$

and f_k is a nonzero-divisor in it because it is a non-zero divisor in $A/(p,f_1^p,\ldots,f_{k-1}^p)$, as $(p,f_1^p,\ldots,f_k^p)$ is also a regular sequence by(4.3.4.4). then a map of pairs of rings $(A,I)\to(C,J)$ will lift through this tower uniquely by the universal property of pd-envelop.

then we see $A\{\frac{\varphi(f_1)}{p},\ldots,\frac{\varphi(f_r)}{p}\}$ is just the pd-envelop of (A,I), by the universal property. □

Lemma (4.6.0.22). Let A be an $\mathbb{F}_p$-algebra and B an A-algebra. If $(x_1,\ldots,x_n)\in B$ is regular w.r.t. A(4.8.3.7), then $D_B((x_1,\ldots,x_n))$ is A-flat.

Proof: By(4.6.0.19) and base change, it is clear that $D_B(I)$ is a free B/I^p-algebra. Thus we need to show that B/I^p is a flat A-module. And this is true as the sequence $x_1^p,\ldots,x_n^p$ is also regular w.r.t. A(4.8.3.8). □

Prop. (4.6.0.23) [Flatness of PD-Envelope]. If $A\to B$ is a map of simplicial rings, A is naturally a simplicial pd-structure with $I_\bullet = pA_\bullet$, and B is p-completely flat over A(4.8.3.5), and $(x_1,\ldots,x_n)\in\pi_0(B)$ is p-completely regular w.r.t A(4.8.3.7), then the completed pd-envelope $D=D_B((x_1,\ldots,x_n))^\wedge$ is p-completely flat over A.

Proof: By definition(4.8.3.5), to check it is p-completely flat, it suffices to check

$$Kos(A,p)\to Kos(A,p)\otimes_A^L D$$

is flat. and by(4.8.3.4) it suffices to check that

$$\pi_0(Kos(A,p))\to\pi_0(Kos(A,p))\otimes_A^L D$$

is flat. The formation of pd-envelope commutes with derived base change by universal property, and tensor with A/p-algebra undoes the completions, so we are reduced to the the case $A' = \pi_0(Kos(A,p))$ and $B' = A' \otimes_A^L B$ is flat over A' and to show that

$$A' \to D_{B'}((x_1,\ldots,x_n))$$

is flat. Notice B' is a discrete flat A'-algebra by definition(4.8.3.5), and $(x_1,\ldots,x_n)$ is a sequence in B' that $Kos(B,x_1,\ldots,x_n)$ is a sequence regular w.r.t. A':

$$\begin{aligned} Kos(B,x_1,\ldots,x_n) &= Kos(B' = A' \otimes_A^L B, x_1,\ldots,x_n) = A' \otimes_A^L Kos(B,x_1,\ldots,x_n) \\ &= A' \otimes^L_{Kos(A,p)} Kos(A,p) \otimes_A Kos(B,x_1,\ldots,x_n) \\ &= A' \otimes^L_{Kos(A,p)} Kos(B,p,x_1,\ldots,x_n) \end{aligned}$$

is flat because $Kos(A,p) \to Kos(B,p,x_1,\ldots,x_n)$ does by definition(4.8.3.7) and(4.8.3.3). So we are done by(4.6.0.22). □

Cor. (4.6.0.24). If A is a p-complete simplicial δ-ring and B is a p-completely flat simplicial δ-A-algebra, and if $x_1,\ldots,x_r \in \pi_0(B)$ is p-completely regular w.r.t. A, then

$$C_\bullet = B_\bullet\{\frac{x_1}{p},\ldots,\frac{x_r}{p}\}$$

is p-completely flat over A.

Proof: Let $C'_\bullet = B_\bullet\{\frac{\varphi(x_1)}{p},\ldots,\frac{\varphi(x_r)}{p}\}^\wedge$, then $C'_\bullet$ is p-completely flat over A, by(4.6.0.21)(? why B is p-torsionfree and $(p,x_1,\ldots,x_n)$ is regular sequence) and(4.6.0.23). Now there is a commutative diagram

$$\begin{array}{ccccccccc} A & \longrightarrow & A\{x_1,\ldots,x_r\} & \longrightarrow & B & \longrightarrow & B\{\frac{x_1}{p},\ldots,\frac{x_r}{p}\} & \longrightarrow & C_\bullet \\ \| & & \downarrow{\scriptstyle\psi} & & \downarrow{\scriptstyle\psi_B} & & \downarrow{\scriptstyle\psi'} & & \downarrow{\scriptstyle\psi_C} \\ A & \longrightarrow & A\{\varphi(x_1),\ldots,\varphi(x_r)\} & \longrightarrow & B' & \longrightarrow & B'\{\frac{\varphi(x_1)}{p},\ldots,\frac{\varphi(x_r)}{p}\} & \longrightarrow & C'_\bullet \end{array}$$

where ψ is the relative Frobenius and ψ_B, ψ_C is the derived base change and completed derived base change. Then ψ is f.f. as it is the base change of the Frobenius on the free δ-ring $\mathbb{Z}\{x_1,\ldots,x_r\}$(4.5.4.10), thus so does ψ'. Then ψ_C is p-completely flat, because it is the completion(use(4.9.7.2)(4.9.7.4)). Now the conclusion follows, by completely f.f. descent(4.9.7.2). □

1 de Rham Complex

Def. (4.6.1.1) [PD-Differentials]. Let B be an A-algebra and (B,J,δ) be a pd-structure and M a B-module, then a **pd-A-derivation** from B to M is a an element θ of $\mathrm{Der}_A(B,M)$ that $\theta(\delta_n(x)) = \delta_{n-1}(x)\theta(x)$ for $n \geq 1$ and $x \in J$.

As in(4.4.3.4), there is a **pd-differential** $\Omega_{B/A,\delta}$ that

$$\mathrm{Hom}_B(\Omega_{B/A,\delta}, M)$$

is isomorphic to the set of pd-A-derivations of B to M, functorially in M.

Prop. (4.6.1.2) [PD-Differential of PD-Envelope]. Let (A,I,γ) be a pd-structure and (B,J) be a pair over (A,I), and let $D_{B/A,\gamma}(J) = (D,\overline{J},\overline{\gamma})$ be the pd-envelope, then $\Omega_{D/A,\overline{\gamma}} = \Omega_{B/A} \otimes_B D$.

Proof: It suffices to show that for any D-module M, the set of A-derivations $B \to M$ is isomorphic to the set of pd-A-derivations $D \to M$.

Let $D \otimes M$ be the ring that $M^2 = 0$ and a pd-structure on $\overline{J} \oplus M$ is given by $\delta_n(x+m) = \delta_n(x) + \delta_{n-1}(x)m$. Then a pd-$A$-derivations $D \to M$ is equivalent to a pd-ring map $(D, \overline{J}) \to (D \oplus M, \overline{J} \oplus M)$, and an A-derivations $B \to M$ is also equivalent to a map of pairs $(B, J) \to (D \oplus M, \overline{J} \oplus M)$, thus we are done by the universal property of D. □

Prop. (4.6.1.3). Let B be an A-algebra and (B, J, δ) be a pd-structure, then

- if $(B[X], JB[X], \delta')$ is the δ-structure extended from that of (B, J, δ) as in(4.6.0.11), then
$$\Omega_{B[X]/A,\delta'} = \Omega_{B/A,\delta} \otimes_B B[X] \oplus B[X]dx.$$
- Let $B\langle x\rangle$ be the free pd-algebra over B(4.6.0.14), then
$$\Omega_{B\langle x\rangle/A,\delta'} = \Omega_{B/A,\delta} \otimes_B B\langle x\rangle \oplus B\langle x\rangle dx.$$
- Let $K \subset J$ be an ideal preserved by δ and then consider the quotient $(B' = B/K, \overline{J} = J/K, \overline{\delta})$, then $\Omega_{B'/A,\overline{\delta}}$ is quotient of the module $\Omega_{B/A,\overline{\delta}} \otimes_B B'$ by the B'-submodule generated by dk where $k \in K$.

Proof: These are all somewhat trivial. □

Prop. (4.6.1.4) [PD-Differential and Completion]. Let A be a $\mathbb{Z}_{(p)}$-algebra, B be an A-algebra and (B, J, δ) be a pd-structure and p is nilpotent in B/J, then
$$\lim_e \Omega_{B_e/A,\overline{\delta}} = (\Omega_{B/A,\delta})^\wedge = (\Omega_{\widehat{B}/A,\widehat{\delta}})^\wedge.$$
where $B_e = B/p^e$.

Proof: By(4.6.0.12), the terms make sense. Now by(4.6.1.3) and the observation $d(p^e) = 0$, we have $\Omega_{B_e/A,\overline{\delta}} = \Omega_{B/A,\delta}/p^e = \Omega_{\widetilde{B}/A,\widetilde{\delta}}/p^e$, thus we are done. □

Def. (4.6.1.5) [PD-de Rham Complex]. Let $\Omega^i_{B/A,\delta} = \wedge^i \Omega_{B/A,\delta}$, then the surjection $\Omega_{B/A} \to \Omega_{B/A,\delta}$ satisfies the condition of(7.2.1.2), thus there is a **pd-de Rham complex** $\Omega^\bullet_{B/A,\delta}$.

PD-Poincaré Lemma

Lemma (4.6.1.6) [PD-Poincaré Lemma]. Let A be a ring, $P = A\langle X_i\rangle$ is the free PD-algebra over A, then for any A-module, the complex
$$0 \to M \to M \otimes_A P \to M \otimes_A \Omega^\wedge_{P/A,\delta} \to \ldots$$
is exact. And if $D = \widehat{P}$ and let $\Omega^n_D = \Omega^n_{P/A,\delta}$, then for any p-complete A-module M, the complex
$$0 \to M \to M \widehat{\otimes}_A P \to M \widehat{\otimes}_A \Omega^\wedge_{P/A,\delta} \to \ldots$$
is exact.

Proof: It suffices to show that $0 \to M \to M \otimes_A P \to M \otimes_A \Omega^1_{P/A,\delta} \to \ldots$ is homotopic to 0. For this, notice every element of $\Omega^n_{P/A,\delta}$ is of the form $\sum P \prod_{j=0}^n dx_{i_0} dx_{i_1} \ldots dx_{i_n}$, so we can let
$$f(\omega) = f(\gamma_{n_{i_0}}(x_{i_0}) dx_{i_0} \wedge \omega) = \gamma_{n_{i_0}+1}(x_{i_0})\omega$$
where ω doesn't divides dx_k for $k < i_0$. Then it can be checked that $df + fd = \mathrm{id}$, so we are done. □

Prop. (4.6.1.7). If A is a ring and (B, J, δ) is a is a pd-structure, and let $P = B\langle X_i\rangle$ be the free pd-structure(4.6.0.14). Let M be a B-module endowed with an integrable connection $\nabla : M \to M \otimes_B \Omega^1_{B/A,\delta}$, then the map of de Rham complexes

$$M \otimes_B \Omega^*_{B/A,\delta} \to M \otimes_B \Omega^*_{P/A,\delta}$$

is a quasi-isomorphism. And if we denote D, D' the p-adic completions of B, P, and $\Omega_D, \Omega_{D'}$ the p-adic completion of $\Omega_{B/A,\delta}, \Omega_{P/A,\delta}$, and M is a p-complete B-module endowed with an integrable connection $\nabla : M \to M \otimes_D \Omega_D$, then the map of de Rham complexes

$$M \otimes_D \Omega^*_D \to M \otimes_{D'} \Omega^*_{D'}$$

is a quasi-isomorphism.

Proof: Consider the filtration F^* on $\Omega^\bullet_{B/A,\delta}$ given by the stupid truncation $\sigma_{\geq i}\Omega^\bullet_{B/A,\delta}$, and consider the filtration on $\Omega^\bullet_{P/A,\delta}$ given by

$$F^*(\Omega^\bullet_{P/A,\delta}) = F^*(\Omega^\bullet_{B/A,\delta}) \wedge \Omega^\bullet_{P/A,\delta}.$$

Notice that we have a split exact sequence

$$0 \to \Omega^1_{B/A,\delta} \otimes_B P \to \Omega^1_{P/A,\delta} \to \Omega^1_{P/B,\delta} \to 0$$

and $\Omega^1_{P/B,\delta}$ is free on X_i over B(pondering the universal property, this is for the same reason as(4.4.3.7).

Then we see that $F^i(\Omega^\bullet_{P/A,\delta}) \to \Omega^\bullet_{P/A,\delta}$ is termwise split injection for any i, and the graded is $\Omega^i_{B/A,\delta} \otimes_B \Omega^\bullet_{P/B,\delta}$. Thus if we let $F^i(M \otimes_B \Omega^\bullet_{P/A,\delta}) = M \otimes F^i(\Omega^\bullet_{P/A,\delta})$, then the graded is $M \otimes_B \Omega^i_{B/A,\delta} \otimes_B \Omega^\bullet_{P/B,\delta}$, which is quasi-isomorphic to $M \otimes_B \Omega^i_{B/A,\delta}$ by(4.6.1.6). Then the original map is a filtered complexes that induces quasi-isomorphism on gradeds, so it induces a quasi-isomorphism, because it induces an morphism between two convergent spectral sequences, by(3.9.7.6) and(3.9.7.5).
□

4.7 Almost Ring Theory

References are [Almost Ring Theory Gabber/Ramero] and [Almost Ring Theory Foundations Gabber/Ramero].

Def. (4.7.0.1). The setup of most mathematics is an flat ideal $I \subset R$, that $I^2 = I$. This implies that $I \otimes I \cong I^2 = I$.

Denote $i : R \to R/I$. Then there is a map $i_* : M \mapsto M_R$, which has a left adjoint $i^* : N \mapsto N \otimes_R R/I$, and a right adjoint $i^! : N \mapsto \mathrm{Hom}(R/I, N)$.

1 Homological Theory

Almost Modules

Prop. (4.7.1.1) [Examples].

- If K is a perfectoid field, $R = K^0, I = K^{00}$, then I is flat over R, because if π is a pseudo-uniformizer of K(10.3.8.9), then $I = (\pi^{\frac{1}{p^\infty}})$, which is a colimit of free modules thus flat, and $I^2 = I$ clearly.
- Let R be a ring and f is an arbitrary element with compatible p^n-th roots, let $I = (f^{\frac{1}{p^\infty}})$, then $I^2 = I$. To show I is flat, consider:

$$M_0 \xrightarrow{f^{1-\frac{1}{p}}} M_1 \xrightarrow{f^{\frac{1}{p}-\frac{1}{p^2}}} M_2 \to \ldots \to M_n \xrightarrow{\frac{1}{p^n}-\frac{1}{p^{n+1}}} M_{n+1} \to \ldots$$

where $M_i \cong R$, and $M = \operatorname{colim} M_i$, then M is flat, and there is a map $M \to I : 1 \in M_n \to f^{\frac{1}{p^n}}$, then this map is surjective, and it is injective: if α maps to 0, then $\alpha f^{\frac{1}{p^n}} = 0$, so $\alpha^{p^m} f = 0$ for all $m \geq n$, and by perfectness of R, $\alpha f^{\frac{1}{p^m}} = 0$, so in particular, $\alpha = 0 \in M_{n+1}$.

Prop. (4.7.1.2)[The Category of Almost R-Modules in disguise]. Let $\mathcal{A} \subset \mathrm{Mod}_R$ be the category of all R-modules M that the action $I \otimes M \to M$ is an isomorphism(By $I \otimes I = I$ this is equivalent to $M = I \otimes N$ for some N) then:

- The inclusion $j_! : \mathcal{A} \to \mathrm{Mod}_R$ is exact, i.e. the cokernel, kernel of objects in $\mathcal{A}$ are also in $\mathcal{A}$.
- $j_!$ has a right adjoint $j^* : M \mapsto I \otimes M$, and the unit map $N \to j^* j_! N$ is an isomorphism on $\mathcal{A}$.
- j^* has its right adjoint $j_*(M) = \mathrm{Hom}(I, M)$, and the counit $j^* j_* M \to M$ is an isomorphism on $\mathcal{A}$.

Proof: 1: an easy consequence of five-lemma.

2: We need to show for $N \in \mathcal{A}$, $\mathrm{Hom}(N, I \otimes M) \cong \mathrm{Hom}(N, M)$. Notice there is a distinguished triangle

$$I \otimes M \to M \to M \otimes R/I,$$

as $- \otimes^L_R M$ is a derived functor and I is flat. So it suffices to show

$$R\,\mathrm{Hom}_R(N, M \otimes^L_R R/I) = 0 = R\,\mathrm{Hom}_{R/I}(N \otimes^L_R R/I, M \otimes^L_R R/I).$$

And in fact $N \otimes^L_R R/I = 0$, because $N \otimes^L_R R/I = N \otimes^L_R I \otimes^L_R R/I$, and $I \otimes^L_R R/I = I \otimes_R R/I = I/I^2 = 0$ by flatness and hypothesis.

$N \cong j^* j_! N$ is an easy consequence of $I \otimes I = I$.

3: The adjointness is just Tor-Hom-adjunction, and for the isomorphism $I\otimes \mathrm{Hom}(I,M)\cong M$, as I is flat, it suffices to prove the stronger result that $I\otimes^L_R R\mathrm{Hom}(I,M)=M[0]$. As there is an exact triangle

$$R\mathrm{Hom}(R/I,M)\to M\to R\mathrm{Hom}(I,M),$$

so it suffices to show $I\otimes^L R\mathrm{Hom}(R/I,M)=0$, because $I\otimes^L M=M$. But this is because $I\otimes^L R\mathrm{Hom}(R/I,M)=I\otimes^L R/I\otimes^L R\mathrm{Hom}(R/I,M)$, and $I\otimes^L R/I=0$ as before. □

Prop. (4.7.1.3) [Category of Almost R-modules].

- The image of the functor $i_*:\mathrm{Mod}_{R/I}\to\mathrm{Mod}_R$ is a Serre subcategory of Mod_R, so the quotient $\mathrm{Mod}^a_R=\mathrm{Mod}_R/\mathrm{Mod}_{R/I}$ exists by(3.7.3.14),
- The quotient $q:\mathrm{Mod}_R\to\mathrm{Mod}^a_R$ admits fully faithful left and right adjoints. In particular, q preserves all limits and colimits.
- The image of i is a 'tensor ideal' of Mod_R, so the quotient Mod^a_R inherits a natural symmetric monoidal $\otimes$-product structure.
- There is a functor $\mathrm{alHom}:(\mathrm{Mod}^a_R)^{op}\times\mathrm{Mod}^a_R\to\mathrm{Mod}^a_R:(X,Y)\to\mathrm{alHom}(X,Y)$ that $\mathrm{alHom}(X,-)$ is right adjoint to $-\otimes X$:

$$\mathrm{Hom}(Z\otimes X,Y)\cong\mathrm{Hom}(Z,\mathrm{alHom}(X,Y)).$$

Proof: 1: the image of i_* is just the category of modules killed by I, if M is killed by I, then subobjects and quotients of M is killed by I, and if M is an extension of two elements killed by I, then $IM=I^2M=0$.

2: In fact we show that the category $\mathcal{A}$ in(4.7.1.2) and the functor j^* is just equivalent to Mod^a_R: First: $j^*(\mathrm{Mod}_{R/I})=0$, because $I\otimes M=I\otimes_R R/I\otimes_{R/I}M=I/I^2\otimes_{R/I}M=0$ as $I=I^2$, and j^* is exact because I is flat.

And for any R-module M, consider $I\otimes M\to M$, it has kernels and cokernels, then tensoring I, it becomes $I\otimes M\to I\otimes M$(4.7.0.1). as I is flat, the kernel and cokernels are killed by I, so for any functor q to another category that kills $\mathrm{Mod}_{R/I}$, $q(M)=q(I\otimes M)=qj_!j^*(M)$, so q factors through M, uniquely, as j^* is surjective.

Now the left/right adjoints exist by(4.7.1.2).

3: if $IM=0$, then $IM\otimes N=0$, so the tensor products pass to the quotient, and j^* is a map between symmetric monoidal categories.

4: alHom is defined by $\mathrm{alHom}(j^*M,j^*N)=j^*(\mathrm{Hom}(M,N))=\mathrm{Hom}(M,N)^a$. This is well defined, because if $IM=0$ or $IN=1$, then $I\mathrm{Hom}(M,N)=0$. □

Cor. (4.7.1.4).

- $i^*j_!=0$.
- $i^!j_*=0$.
- $j^*i_*=0$, and the kernel of j^* is just $i_*(\mathrm{Mod}_{R/I})$.

Proof: 1: $R/I\otimes I\otimes M=0$, because $I\otimes R/I=0$.

2: $\mathrm{Hom}(R/I,\mathrm{Hom}(I,M))=0$, because $I\otimes R/I=0$.

3: This is by 2 of the proposition(4.7.1.3). □

Remark (4.7.1.5). The construction above can be summarized as the following diagram:

$$\mathrm{Mod}_{R/I}\ \underset{\overset{\xleftarrow{i^!}}{}}{\overset{\xleftarrow{i^*}}{\xrightarrow{i_*}}}\ \mathrm{Mod}_R\ \underset{\overset{\xleftarrow{j_*}}{}}{\overset{\xleftarrow{j_!}}{\xrightarrow{j^*}}}\ \mathrm{Mod}^a_R$$

with four adjoint pair and three vanishing. This should be seen as an analogy of the case of topology: X is a space and $i : U \to X$ is open in X, and $j : Z \to X$ is closed, $Z = X - U$, then the defined sheaf operations are the same as written above.

However, one should not consider Mod_R^a as the sheaf of modules on the open subscheme $\mathrm{Spec}\, R_f$ for some pseudo uniformizer, because the map $M \to M \otimes R_f$ factors through Mod_R^a as it vanishes on $\mathrm{Mod}_{R/I}$, but it is not $\mathrm{Mod}_{R/I}^a$. For example, if k is a perfect field, and consider $R = k[t^{\frac{1}{p^\infty}}]$, then the module $M = R/(t)$ is also killed by $\otimes R_f$, but it is not killed by I.

Then one may consider it is the category of Qco sheaves on $D(I)$, but first this is not an affine scheme, and second this is false, anyway. And we should imagine an non-existent open subscheme $\overline{U}$ bigger than U, as it contains any affine opens of U.

Remark (4.7.1.6). Notice j^* is both left exact and right exact, so it preserves both arbitrary limits and colimits, so almostification nearly loses anything. In particular, the category Mod_R^a has all colimits and limits.

Def. (4.7.1.7) [Almost Commutative Algebras]. As Mod_R^a has a symmetric monoidal structure, it is possible to define the category of **almost commutative algebras** as the category of commutative unitary monids in Mod_R^a, denoted by $CAlg(\mathrm{Mod}_R^a)$. Notice that its unit object is $I = R^a$.

There is an obvious map
$$(-)^a : \mathrm{Alg}(\mathrm{Mod}_R) \to \mathrm{Alg}(\mathrm{Mod}_R^a),$$
and yet another functor
$$(-)_* : \mathrm{Alg}(\mathrm{Mod}_R^a) \to \mathrm{Alg}(\mathrm{Mod}_R),$$
because $M \to M_*$ is lax symmetric monoidal, i.e. there are natural map $M_* \otimes N_* \to (M \otimes N)_*$. This is a right adjoint of $(-)^a$, as j^* and j_* is adjoint.

Finally there is a functor
$$(-)_{!!} : \mathrm{Alg}(\mathrm{Mod}_R^a) \to \mathrm{Alg}(\mathrm{Mod}_R),$$
whose construction is a little complicated, first notice the functor $(-)_!$ preserves multiplication but it has no units, so in order to give it a unit, consider the module pushout: $(A_! \oplus V)/I$, which has a natural multiplicative structure that can be made into a R-module, and $(-)_{!!}$ is left adjoint to $(-)^a$,Cf.[Almost Ring Theory P22].

Prop. (4.7.1.8). $(-)_{!!}$ preserves faithfully flatness.

Proof: Cf.[Almost Ring theory P52]**?** □

Def. (4.7.1.9). For an almost commutative algebra A, a **left module** is an almost module $M \subset \mathrm{Mod}_R^a$ that has a left action $A \otimes M \to M$ that has natural commutative diagrams as one expects. And for any R-algebra A, there are natural maps $\mathrm{Mod}_A \to \mathrm{Mod}_{A^a}^a$.

Almost Homological Algebra

2 Almost Commutative Algebra

Def. (4.7.2.1) [Almost Notations]. Given a R-module M, an element $f \in M$ is called **almost zero** if $I \cdot f = 0$, and M is called **almost zero** if all $f \in M$ is almost zero.

Denote
$$M^a = j^*M \in \mathrm{Mod}_R^a, \quad M_* = j_*M^a = \mathrm{Hom}(I, M), \quad M_! = j_!M^a = I \otimes M.$$

Then there are morphisms $M_! \to M \to M_*$, which becomes isomorphisms after almostification.

Prop. (4.7.2.2). If $I=(f^{\frac{1}{p^\infty}})$, then $M_*=\{x\in M[f^{-1}]|f^{\frac{1}{p^n}}x\in A\}$ for all n.

Prop. (4.7.2.3). If $M\to N$ is almost surjective maps of K^0-algebras that $M/I\to N/I$ is surjective, then $M\to N$ is surjective.

Proof: As I is flat over K^0, if $M\to N\to Q\to 0$ is the cokernel, tensoring A/I, as $M/I\to N/I$ is surjective, $Q/IQ=0$, but Q is almost zero thus $IQ=0$, so $Q=0$. □

Def. (4.7.2.4) [Almost Properties]. Something is called **almost XXX** if it is XXX when passed to the category of almost R-modules. For example,

- elements of M_* are called **almost elements** of M.
- M is called **almost flat** iff $M^a\otimes -$ is exact on Mod_R^a, which is equivalent to $Tor_{>0}^R(M,N)$ is almost zero for all N.
- M is called **almost projective** iff $\mathrm{alHom}(M,-)$ is exact on Mod_R^a, which is equivalent to $\mathrm{Ext}_R^{>0}(M,N)$ is almost zero for all N.
  Notice this is not equivalent to projective in Mod_R^a, because R is almost projective, but $\mathrm{Hom}_{R^a}(R^a,M^a)=\mathrm{Hom}(I,M)$ is not exact as I is not projective: $\mathrm{Ext}^1_{R^a}(R^a,R^a)=\mathrm{Ext}^1_R(I,R)=\mathrm{Ext}^2(k,R)$, which is not 0 if R is the valuation ring of a non-spherically complete perfectoid field K, like $\widehat{\overline{\mathbb{Q}_p}}$**?**.
- M is called **almost finitely generated/almost finitely presented** if for any $\varepsilon\in I$, there is a f.g./f.p. $M_\varepsilon\to M$ with N_ε generators that the kernel and cokernel are killed by ε. It is called **uniformly almost finitely generated** iff N_ε is independent of ε.
  Notice this definition doesn't depends on M chosen**?**
- If S is of char$p$, it is called **almost perfect** iff S_* is perfect.

Prop. (4.7.2.5) [Enough Almost Injectives]. The category mod_R^a has enough injectives. In fact j^*,j_* both preserves injectives, because they has exact left adjoints, so I is injective R-module iff I^a is injective R^a-module, and J is injective R^a-module iff J_* is injective R-module. So to construct an injective resolution in R^a, pass to R-modules using either $(-)_*$ or $(-)_!$ and find an injective resolution, then almostificate it.

Prop. (4.7.2.6) [Derived Functors of $(-)_*$]. Notice that $\mathrm{Hom}_{R^a}(M^a,N^a)=\mathrm{Hom}_R(I\otimes M,N)$ by adjointness, so using(4.7.2.5),

$$\mathrm{Ext}^k_{R^a}(M^a,N^a)=\mathrm{Ext}^k_R(M_*,N)=\mathrm{Ext}^k_R(M,R\,\mathrm{Hom}(I,N)),$$

then as $M_*=\mathrm{Hom}(I,M)$, the derived functor of $(-)_*$ is just $\mathrm{Ext}^k_R(I,M)=\mathrm{Ext}^k_{R^a}(R^a,M^a)$.

Notice that $\mathrm{Ext}^k_{R^a}(M,N)$ are all almost zero, as $j^aj_*=\mathrm{id}$, and use trivial Grothendieck spectral sequence.

Prop. (4.7.2.7) [(Example) A Quadratic Extension of a Perfectoid Field]. If $K=\widehat{Q_p[p^{\frac{1}{p^\infty}}]}$ and $L=K(\sqrt{p})$ with $p\neq 2$, then L^0 is a uniformly almost f.p. projective K^0-module.

Proof: It suffices to find for each n a K^0-module R_n of rank 2 that $R_n\to L^0$ is injective with cokernel annihilated by $p^{\frac{1}{p^n}}$. For this, consider $R_n=K^0\oplus K^0p^{\frac{1}{2p^n}}$, then $L^0=\widehat{\mathrm{colim}_n}R_n$.

Notice that the cokernel of $R_n\to R_{n+1}$ is killed by $p^{\frac{1}{p^n}}$, because

$$p^{\frac{1}{p^n}}\cdot p^{\frac{1}{2p^{n+1}}}=p^{\frac{(p+1)/2}{p^{n+1}}}\cdot p^{\frac{1}{2p^n}}\subset R_n.$$

So by killing one by one, the cokernel of $R_n \to \mathrm{colim}_n R_n$ is killed by any p-power with power larger than $\sum \frac{1}{p^n}$, in particular by $p^{\frac{1}{p^n-1}}$. So $\mathrm{colim}_n R_n$ is an extension of R_0 by a cokernel killed by p, so it is also p-adically complete, and $L^0 = \mathrm{colim}_n R_n$. Now Consider $0 \to R_n \to \mathrm{colim}_n R_n \to \mathrm{Coker}$, then $\mathrm{Ext}^n(\mathrm{colim}_n R_n, N) = \mathrm{Ext}^n(\mathrm{Coker}, N)$ is killed by $p^{\frac{1}{p^n-1}}$ for all n, so it is killed by I, thus $\mathrm{colim}_n R_n$ is almost projective. □

Completions and Closures

Prop. (4.7.2.8) [prc and Completion]. If A is a ring with a nonzero-divisor f that $A \subset A[f^{-1}]$ is p-root closed(prc), then:

- $\widehat{A} \subset \widehat{A}[f^{-1}]$ is p-root closed.
- If f admits a compatible p-power roots, then $A_* \subset A_*[f^{-1}]$ is p-root closed(where almost mathematics is performed w.r.t $(f^{\frac{1}{p^\infty}})$.

Proof: We first replace A with its maximal separated quotient $A/(\cap_n f^n A = I)$: f is still non-zero-divisor, because if $fg \in I$, then $fg \in f^n A$ for all n, so $g \in f^{n-1}A$ as f is non-zero-divisor. And it is p-root closed, because if $a^p \in A/I[f^{-1}]$, then $a^p = b + f^{-c}d$ for c integer and $d \in I$. Notice $I = fI = f^c I$ by(4.2.2.16), so $f^{-c}d \in I$ as well, so $a \in A$.

Now A is f-separated, in particular, $A \hookrightarrow \widehat{A}$.

1: If $g \in \widehat{A}[f^{-1}]$ and $g^p \in \widehat{A}$, then $f^N g \in \widehat{A}$ for some N and choose a $m \geq N(p-1)$, then by the density, $g = g_0 + f^m g_1$ for some $g_0 \in A[f^{-1}]$, $g_1 \in \widehat{A}$. Notice $f^N g_0 \in \widehat{A}$, now

$$g^p = g_0^p + p g_0^{p-1} f^m g_1 + \ldots + (f^m g_1)^p,$$

By definition of m, all terms except g_0^p are in $\widehat{A}$, so $g_0^p \in A$, so $g_0 \in A$, and $g \in \widehat{A}$.

2: Use the convention(4.7.2.2), if $g \in A_*[f^{-1}]$ that $g^p \in A_*$, then $f^{\frac{1}{p^n}} g^p \in A$ for all n, so $(f^{\frac{1}{p^{n+1}}} g)^p \in A$, thus $f^{\frac{1}{p^{n+1}}} g \in A$, hence $g \in A_*$. □

Prop. (4.7.2.9) [ic and Completion]. Let A be a ring with a non-zero-divisor f, if $A \subset A[f^{-1}]$ is integrally closed, then:

- $\widehat{A} \subset \widehat{A}[f^{-1}]$ is integrally closed.
- If f admits a compatible p-power roots, then $A_* \subset A_*[f^{-1}]$ is integrally closed(where almost mathematics is performed w.r.t $(f^{\frac{1}{p^\infty}})$.

Proof: We first replace A with its maximal separated quotient $A/(\cap_n f^n A = I)$: f is still non-zero-divisor and I is f-divisible as in the proof of(4.7.2.8). And it is integrally closed, because if g satisfies a monic polynomial $h(X) \in A/I[f^{-1}][X]$, then choose a lifting, $h(g) \in I[f^{-1}] = I \subset A$, so g is integral over A thus $g \in A$, and $g \in A/I$. Now A is f-separated and $A \hookrightarrow \widehat{A}$.

1: If $g \in \widehat{A}[f^{-1}]$ satisfies a polynomial $H \in \widehat{A}[X]$, then $g = f^{-c}h$ for $h \in \widehat{A}$, and then h satisfies a polynomial $H(f^c x)$, and choose an approximation of coefficients of $H(x)$ and h_0 of h mod f^{cn}, then it is clear that $H(f^c h_0) \in f^{cn}\widehat{A} \cap A = f^{cn}A$, so when dividing back, $g_0 = f^{-c}h_0$ is integral over A thus $g_0 \in A$, thus $h_0 \in f^c A$, and $h \equiv h_0 \mod f^{cn}$, thus $h \in f^c \widehat{A}$, and $g \in A$.

2: Use the convention(4.7.2.2), if $g \in A_*[f^{-1}]$ is integral over A_*, then there are polynomial H that $H(g) = 0$, now if $\varepsilon = f^{\frac{1}{p^k}}$ consider another polynomial $H(x/\varepsilon)$, then its coefficients are all in A, thus εg is integral over A thus $\varepsilon g \in A$, and then $g \in A_*$. □

Prop. (4.7.2.10) [tic and Completion]. Let A be a ring with a non-zero-divisor f that admits a compatible system of p-power roots $f^{\frac{1}{p^n}}$ for all $n > 0$, and A is totally integrally closed(tic) in $A[f^{-1}]$, then $\widehat{A}$ is totally integrally closed in $\widehat{A}[f^{-1}]$ and $A = A^*$.

Proof: 1: Notice totally integrally closed is p-root closed, so $\widehat{A} \subset \widehat{A}[f^{-1}]$ is p-root closed. Now if $f^k g^{\mathbb{N}} \subset \widehat{A}$ for some k, then by prc, $f^{\frac{k}{p^n}} g \in \widehat{A}$ for all n, thus g in an almost zero element in $\widehat{A}[f^{-1}]/\widehat{A} \cong A[f^{-1}]/A$, and then g is totally integrally closed over A, because for any n, let $n < p^k$, then $f^{\frac{1}{p^k}} g \in A$, thus $f^{\frac{n}{p^k}} g \in A$, and $fg^n \in A$.

2: Because $f^{\frac{1}{p^k}} A_* \subset A$ by convention(4.7.2.2), clearly A_* is totally integrally closed in A, thus $A_* \subset A$. □

Almost Étale Map

Def. (4.7.2.11). A map $A \to B$ of R^a-algebras is called **almost étale** iff:

- B is almost f.p. projective over A.
- (Unramifiedness(4.4.6.10))There exists a diagonal idempotent $e \in (B \otimes_A B)_*$. i.e. $e^2 = e$ and $\mu_*(e) = 1$, and $\ker(\mu)_* \cdot e = 0$, where $\mu : B \otimes_A B \to B$ is the multiplication map.

Prop. (4.7.2.12) [Example of Almost Étale Maps]. Let $K = \widehat{Q_p[p^{\frac{1}{p^\infty}}]}$ and $L = K(\sqrt{p})$ with $p \neq 2$, then L^0/K^0 is uniformly almost f.p projective K^0-module, by(4.7.2.7). We show it is finite étale: flatness is clear, as L^0/K^0 is torsion-free and K^0 is a valuation ring and use(4.7.3.3).

For unramifiedness, notice that

$$L \otimes_K L \cong L \times L : (a, b) \mapsto (ab, a\sigma(b)).$$

by(2.2.7.6), the diagonal idempotent e is given by

$$e = \frac{1}{2p^{\frac{1}{2p^n}} \otimes 1}(1 \otimes p^{\frac{1}{2p^n}} + p^{\frac{1}{2p^n}} \otimes 1)$$

for any $n \geq 0$, then we see $p^{\frac{1}{p^n}} e \in L^0 \otimes_{K^0} KL^0$ for all n, thus $e \in (L^0 \otimes_{K^0} L^0)_*$.

Lemma (4.7.2.13) [Lemma for Almost Purity in Characteristic p]. If $\eta : R \to S$ is an integral map of perfect rings. If $\eta[t^{-1}]$ is finite étale for some $t \in R$, then η is almost finite étale w.r.t the ideal $I = (t^{\frac{1}{p^\infty}})$.

Proof: Firstly, we may assume R, S are both t-torsion-free, because the t-torsion part $R[t^\infty]$ and $S[t^\infty]$ is almost zero: if $t^c\alpha = 0$, then $t^c\alpha^{p^n} = 0$, so $t^{\frac{c}{p^n}}\alpha = 0$. So we reduce to $R/R[t^\infty] \to S/S[t^\infty]$, which doesn't change anything.

Now we reduce to the case that R, S are integrally closed in $R[t^{-1}]$ and $S[t^{-1}]$: it suffices to show that $R_{int} \subset R_*$, thus they are almost isomorphic. For this, an element $f \in R_{int}$ satisfies $f^{\mathbb{N}} t^k \in R$ for some k, so by perfectness, $ft^{\frac{k}{p^n}} \in R$ for all n, so $f \in R_*$.

Now check unramifiedness: let $e \in (S \otimes_R S)[t^{-1}]$ be a diagonal idempotent, then $t^c e \in S \otimes_R S$ for some c, now $e^2 = e$, so easily $e \in (S \otimes_R S)_*$.

Now check almost finite projective: for $m > 0$, represent $t^{\frac{1}{p^m}} e = \sum a_i \otimes b_i \in S \otimes_R S$, then use the map $S \xrightarrow{\alpha} R^n \xrightarrow{\beta} S$ as in(4.4.7.14), then $\beta\alpha = t^{\frac{1}{p^m}}$ on S, as S is t-torsion free, $R^n \to S$ is injective with $t^{\frac{1}{p^m}}$-torsion cokernel, for any m. So S is almost finite projective. □

Prop. (4.7.2.14) [Almost Purity in Characteristic p]. If R is a perfect ring of char$p$, then using the almost mathematics w.r.t. $I = (t^{\frac{1}{p^\infty}})$, $S \to S_*[t^{-1}]$ gives an isomorphism of categories: $R_{af\acute{e}t} \cong R[t^{-1}]_{f\acute{e}t}$.

Proof: As in the proof of(4.7.2.13), we may assume R is t-torsion-free. Notice that any integral extension of $R[t^{-1}]$ comes from an integral extension of R(choose the integral closure), so the lemma above(4.7.2.13) tells us the functor is essentially surjective.

Now we construct an inverse functor, $S_*[t^{-1}]$ maps to T^a, where T is the integral closure of R in $S_*[t^{-1}]$. By lemma(4.7.2.15) below, S is almost perfect. So S_* is t-torsion-free, as if $t^c f = 0$, then $t^{\frac{c}{p^n}} f = 0$ for all n, so $f = 0 \in (S_*)_* = S_*$. So now $S_* \subset S_*[t^{-1}]$. Clearly T is also perfect and t-torsion-free. So $R \to T$ is an integral extension that is identified with $R[t^{-1}] \to S_*[t^{-1}]$ after inversion of t.

To show that $T^a = S$, it suffices to show $T_* = S_*$. for $f \in T$, $f^{\mathbb{N}}$ spans a finite module of $T[t^{-1}] = S_*[t^{-1}]$, so $t^c f^{\mathbb{N}} \subset S_*$, then by perfectness, $f \in (S_*)_* = S_*$, so $T_* \in S_*$. Conversely, if $g \in S_*$, then $tg^{\mathbb{N}}$ lies in a f.g. R-module of $S_*[t^{-1}]$, by almost f.g.. So $t^c g^{\mathbb{N}} \subset T$, and then by perfectness $g \in T_*$. □

Lemma (4.7.2.15). Almost finite étale map of rings of char$p$ is almost relatively perfect.

Proof: Cf.[Bhatt notes on Perfectoid Spaces P28]. □

3 Almost Mathematics on Perfectoid Fields

Prop. (4.7.3.1) [Almost Elements]. If K is a perfectoid field, $R = K^0$ and $I = K^{00}$, M is an R-module, then

- If M is torsion-free, then $M_* = \{m \in M \otimes_{K^0} K | Im \in M\} = \{m \in M \otimes_{K^0} K | t^{\frac{1}{p^n}} m \in M\}$,by(10.3.8.12) and(4.7.2.2).
- $I_* = R_* = R$. More generally, for an ideal $J \subset R$, let $c = \sup\{|x| | x \in J\}$, then $J_* = \{a \in K, |a| \leq c\}$.

Prop. (4.7.3.2). Let K be a perfectoid field with a pseudo-uniformizer π. If $\alpha : M \to N$ is an almost surjective map of K^0-algebras that M is π-adically separated and N is π-torsion-free that $\alpha \mod \pi$ is an almost isomorphism, then α is an almost isomorphism.

Proof: We may replace N with the image of α as to assume α is surjective. Now if $L = \ker \alpha$, then the π-torsion-freeness of N shows L/π is the kernel of $(\alpha \mod \pi)$, and L/π is almost zero, thus L is almost π-divisible, but it is also π-separated, thus it is almost zero(using $t^{\sum_i \frac{1}{p^{a_i}}} m \in \cap_n t^n L$). □

Prop. (4.7.3.3) [Almostification and Completeness]. Let K be a perfectoid field with a pseudo uniformizer t and $R = K^0, I = K^{00}$, let $M \in \mathrm{Mod}_R^a$, then:

- M is almost flat iff M_* is R-flat iff $M_!$ is R-flat.
- Assume M is almost flat, then M is t-adically complete iff M_* does.
- Assume M is almost flat, then for each $f \in K^0$, $fM_* \cong (fM)_*$, and $M_*/fM_* \subset (M/fM)_*$. And for any $\varepsilon \in I$, the image of $(M/f\varepsilon M)_*$ and M_*/fM_* in $(M/fM)_*$ are identical.

Proof: 1: R is a valuation ring, so M_* is R-flat iff $M_*[t]$ is flat by(4.4.1.12), as t is a pseudo uniformizer. As $(-)_*$ is left exact, $M_*[t] = (M[t])_*$, so if M is almost flat, then $M[t] = 0$ as t is nonzero-divisor, so M_* is R-flat. The converse is true as $M = (M_*)^a$, and the tensor is compatible.

For $(-)_!$, this follows from the observation that $(-)_!$ and $(-)^a$ are both exact and commute with tensor products, and notice $M_! \otimes N = (M \otimes N^a)_!$.

2: As $(-)^a$ commutes with all limits and colimits, if M_* is t-adically complete then so does $M = (M_*)^a$. Conversely, if M is R-flat and t-adically complete, then $M_!, M_*$ are also R-flat, and consider the commutative diagram:

$$\begin{array}{ccc} M_! & \xrightarrow{a} & \lim(M/t^n M)_! = \lim M_!/t^n M_! = \widehat{M_!} \\ \downarrow d & & \downarrow b \\ M_* & \xrightarrow{c} & \lim(M/t^n M)_* \end{array}$$

then d is almost isomorphism by(4.7.1.2) and so does b because $(-)^a$ commutes with all limits, and c is an isomorphism as $(-)_*$ commutes with limits and M is t-adically complete. So a is also almost isomorphism.

Now notice $M_!$ is flat hence t-torsion-free, so the kernel of a, d must be 0, with almost zero cokernels. Now(4.2.3.9) shows first $M_!$ is complete and next M_* is complete.

3: Notice $(fM_*)^a = fM$ as $(-)^a$ is exact, so

$$(fM)_* = \mathrm{Hom}(I, fM_*) = \{y \in M_*[t^{-1}] | Iy \subset fM_*\} = f\{y \in M_*[t^{-1}] | Iy \subset M_*\} = fM_*$$

and $M_*/fM_* \subset (M/fM)_*$ follows from the left exactness of $(-)_*$.

For the last assertion, consider the commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & M & \xrightarrow{f} & M & \longrightarrow & M/fM & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \| & & \\ 0 & \longrightarrow & M/\varepsilon M & \xrightarrow{f} & M/f\varepsilon M & \longrightarrow & M/fM & \longrightarrow & 0 \end{array}$$

and apply $(-)_* = \mathrm{Hom}_{R^a}(R^a, -)$ and use(4.7.2.6), then

$$\begin{array}{ccccccccc} 0 & \longrightarrow & M_*/fM_* & \xrightarrow{a} & (M/fM)_* & \longrightarrow & \mathrm{Ext}^1_{R^a}(R^a, M)[f] & \longrightarrow & 0 \\ & & \downarrow & & \| & & \downarrow c & & \\ 0 & \longrightarrow & (M/f\varepsilon M)_* & \xrightarrow{b} & (M/fM)_* & \longrightarrow & \mathrm{Ext}^1_{R^a}(R^a, M/\varepsilon M) & & \end{array}$$

To show a, b has the same image, it suffices to show that c is injective. For this, it suffices to show $\mathrm{Ext}^1_{R^a}(R^a, M) \to \mathrm{Ext}^1_{R^a}(R^a, M/\varepsilon M)$ is injective. Consider the exact sequence $0 \to M \xrightarrow{\varepsilon} M \to M/\varepsilon M \to 0$, it suffices to show that $\varepsilon \, \mathrm{Ext}^1_{R^a}(R^a, M) = 0$, and this is obvious as $\varepsilon \in I$(4.7.2.6). □

Prop. (4.7.3.4) [General Completeness and Almostification]. More generally, if $J = (f_1, \ldots, f_r) \subset R$ is a f.g. ideal, then an R^a-module M is J-adically complete iff M_* does.

Proof: Cf.[Perfectoid Spaces Bhatt P32]. □

Banach Space

Prop. (4.7.3.5) [Uniform Banach K-Algebra]. If K is a non-Archimedean perfectoid(perfect) field with a pseudo uniformizer t, then the following categories are equivalent:

- The category of uniform Banach K-algebras.

- The category $\mathcal{D}_{tic}$ of t-adically complete and t-torsionfree K^0-algebras A with A totally integrally closed in $A[t^{-1}]$(4.2.1.1).
- The category $\mathcal{D}_{ic}$ of t-adically complete and t-torsionfree K^0-algebras that A is integrally closed in $A[t^{-1}]$ and $A = A_*$.
- The category $\mathcal{D}_{prc}$ of t-adically complete and t-torsionfree K^0-algebras that A is p-root closed in $A[t^{-1}]$ and $A = A_*$.

Proof: The last three are equivalent, because if $A \in \mathcal{D}_{tic}$, then $A = A_*$ by(4.7.2.10), as K is perfect by(10.3.8.4). So $\mathcal{D}_{tic} \subset \mathcal{D}_{ic} \subset \mathcal{D}_{prc}$, so it suffices to show that $\mathcal{D}_{prc} \subset \mathcal{D}_{tic}$. Now for any f that $f^{\mathbb{N}} \subset t^{-k}A$, then $t^k f^{p^n} \subset A$, and A is p-root closed, so $t^{\frac{k}{p^n}} f \subset A$ for all n, so $f \in A_*$(4.7.2.3), but $A_* = A$.

The equivalence of $1, 2$ is general, by(12.2.4.8). □

Prop. (4.7.3.6). If K is a perfectoid field, then the category of uniform Banach spaces has all colimits and limits.

Proof: Cf.[Bhatt P38]. □

4.8 Simplicial Commutative Algebras

Main references are [Model Categories and Simplicial Methods, Paul Goerss and Kristen Schemmerhorn], [Simplicial Commutative Rings, Mathew].

1 Simplicial Groups

Prop. (4.8.1.1). A morphism of simplicial groups, when regarded as simplicial set, is a Kan fibration iff

$$X \to \pi_0 X \otimes_{\pi_0(Y)} Y$$

is surjective. In particular, any simplicial group is a Kan complex.

Proof: Cf.[Simplicial Homology Theory Jardine P12] □

Def. (4.8.1.2) [Simplicial Modules]. A **simplicial module** over a simplicial ring $R_\bullet$ is a map of simplicial map $R_\bullet \times M_\bullet \to M_\bullet$ that is a ring action.

2 Simplicial R-Modules and Resolutions

Def. (4.8.2.1) [Moore Complex]. Giving a simplicial object in an Abelian category, we can have a **Moore chain complex** with Čech-like differentials. $\partial_n = \sum_1^n (-1)^i d_i$. And we have $\partial^2 = 0$.

Proof: Should use $d_i d_j = d_{j-1} d_i$ for $i < j$. □

Def. (4.8.2.2)[Normalized Moore complex of a simplicial R-Module]. The **normlized Moore complex** of a simplicial R-module M is the chain complex

$$NM : \cdots \to NM_n \xrightarrow{(-1)^n d_n} NM_{n-1} \to \cdots$$

where $NM_n = \bigcap_{i=0}^{n-1} \ker(d_i) \in M_n$. This is a chain complex because $d_{n-1}d_n = d_{n-1}d_{n-1}$ is 0 on NM_n. In fact NM is preserved by all injections.

The **homotopy groups** $\pi_*(M)$ of M is defined to be the homology of the normalization of M. And it can be shown that as a set $\pi_n(M)$ is just the n-th homotopy group of the geometrization of the

The **degenerate complex** of a Moore complex DM is the chain complex that $D_n = \sum_{i=0}^{n-1} s_i M_{n-1}$ is a sub chain complex of M by the relation of d_i, s_j.

Def. (4.8.2.3). A morphism of simplicial Abelian groups is called a **weak equivalence** is it induces an isomorphism on the homotopy groups.

Prop. (4.8.2.4)[Differential Graded Structures]. For any simplicial commutative R-algebra A, the homotopy groups $\pi_*(A)$ form a graded commutative R-ring.

Proof: The group structure on $\pi_*(A)$ is given by smash products. Cf.[Simplicial Commutative Algebras, Mathew, P2]. □

Cor. (4.8.2.5) [π_0 is an Algebra]. If Y is a simplicial commutative R-algebra, then $\pi_0(Y) = Y_0/(\mathrm{Im}(d_0 - d_1))$, which is an algebra.

Proof: It suffices to show $\mathrm{Im}(d_0 - d_1)$ is an ideal of Y_0: If $a \in Y_0$, then

$$(d_0 - d_1)(s_0(a)y) = d_0 s_0(a) d_0(y) - d_1 s_0(a) d_1(y) = a(d_0 - d_1)(y).$$

□

Prop. (4.8.2.6). if $R_\bullet$ is a simplicial ring and $M_\bullet$ is a simplicial $R_\bullet$-ring, then $\pi_*(M)$ is a graded $\pi_*(R)$-module.

Prop. (4.8.2.7). The simplicial homology of the Moore complex of the bar resolution BG of group homology with coeeficient in R is just the group homology $H_n(G,R)$ for the trivial module R. And it has the same homology with the geometrization $|BG|$.

Lemma (4.8.2.8). $A_* \cong NA_* \oplus DA_*$ as a complex, $NA_*, A_*, (A/DA_*)$ are all homotopically equivalent.

Proof: We define similarly $N_k A_*$ and $D_k A_*$ and induct on k, our conclusion is the case $k = n-1$. When $k = 0$, $\mathrm{Im}\, d_0 \oplus \ker s_0 A_n = A_n$ because $d_0 s_0 = id_{n-1}$ thus $A_{n-1} \xrightarrow{s_0} A_n$ is a split injection.

There are two split exact rows by simplicial relations:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & N_{k-1}A_{n-1} & \xrightarrow{s_k} & N_{k-1}A_n & \xrightarrow{1-s_k d_k} & N_k A_n & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & A_{n-1}/D_{k-1}A_{n-1} & \xrightarrow{s_k} & A_n/D_{k-1}A_n & \longrightarrow & A_n/D_k A_n & \longrightarrow & 0 \end{array}$$

The first one split because it has a right section, the second one split because it has a left section. So by induction, $N_k A_n \to A_n/D_k A_n$ is an isomorphism, thus $N_k A_n \oplus D_k A_n = A_n$ because it splits.

For the homotopy equivalence, Cf.[Jardine P150]. □

Prop. (4.8.2.9)[Dold-Kan Correspondence]. For $R \in \mathcal{R}\mathrm{ing}$, the normalized Moore complex(4.8.2.2) functor N gives an equivalence of categories:

$$N_* : s\,\mathcal{M}\mathrm{od}_R \cong Ch_{\geq 0}(\mathcal{A}).$$

and the inverse is given by

$$(\sigma C_\bullet)_n = \bigoplus_{[n]\twoheadrightarrow[k]} C_k$$

and a morphism $\sigma_n \to \sigma_m$ for a morphism $[m] \to [n]$ is defined as follows: For $[n] \twoheadrightarrow [k]$, write $[m] \to [n] \to [k]$ as $[m] \twoheadrightarrow [r] \xrightarrow{\psi} [k]$ where φ is injective, thus maps $a \in C_k$ in σC_n to $\psi^*(a) \in C_r$ in σC_m, where ψ^* is zero unless $\psi = d^n : \Delta[n-1] \to \Delta[n]$. And homotopy groups and homology groups correspond via this equivalence, so does weak equivalences.

Proof: $\sigma(\mathcal{C}_\bullet)$ defines a simplicial Abelian group because of the uniqueness of the the canonical decomposition. There is a natural map from $\sigma(N\mathcal{A})$ to $\mathcal{A}$.

Now the task is to show that $\sigma(NA) \cong A$ and $N(\sigma C) \cong C$. We has $N(\sigma C)_n = C_n$ because $d^i C_n$ is 0 for $i \neq n$ and the other components are all degeneracies thus are not in $N(\sigma C)_n = C_n$ by(4.8.2.8).

Then we prove $\sigma(NA) \cong A$. It is a surjection by(4.8.2.8) and induction. For the injectivity, if $(a_\varphi) \neq 0$ is mapped to 0, a_{id_n} is 0 by(4.8.2.8). And we choose an ordering on the $\varphi : [n] \to [k]$ by dominating, and suppose ψ is a minimal one. Now choose a section ξ of ψ that ξ is the maximal section, thus $\varphi\xi$ cannot by id_k for any other φ. Now by induction we have $a_\psi = 0$, contradiction. □

Cor. (4.8.2.10) [Trivial Simplicial Algebra]. There is a functor form an R-algebra S to a trivial simplicial R-algebra $s(S)$, it is a fully faithful embedding and π_0 is left adjoint to it.

Proof: This is the adjointness of(3.9.1.12) under the equivalent σ(4.8.2.9). □

Cor. (4.8.2.11) [Model Structure on $s\,\mathcal{M}\mathrm{od}_R$]. By(3.4.4.2) applied to the equivalence with $Ch_{\geq 0}R$, $s\,\mathcal{M}\mathrm{od}_R$ has the structure of a model category where a morphism $X \to Y$ is

- an equivalence if it is a weak equivalence,
- a fibration if $NX_n \twoheadrightarrow NY_n$ for any $n \geq 1$.
- a cofibration if the the maps of the degenerate diagrams is of the form

$$X_n \to Y_n = X_n \oplus \bigoplus_{\varphi:[n]\twoheadrightarrow[k]} \varphi^* P_k$$

compatible with the differential, and P_k are all projectives.

Prop. (4.8.2.12) [Fibrations]. A fibration of simplicial R-modules is a fibration iff it is a fibration of simplicial sets. Moreover, by(4.8.1.1), this is equivalent to $X \to \pi_0 X \otimes_{\pi_0(Y)} Y$ is surjective.

Proof: □

Prop. (4.8.2.13) [Simplicial Model Structure]. $s\,\mathcal{M}\mathrm{od}_R$ admits a simplicial model category structure.

Proof: Firstly $s\,\mathcal{M}\mathrm{od}_R$ is a simplicial category tensored and cotensored over $\mathcal{S}et_\Delta$(3.1.7.7) by(3.5.1.6), then it suffices to show(3.4.5.3)?. □

Prop. (4.8.2.14) [Model Structure on $s\,\mathcal{CR}\mathrm{ing}_R$]. By(3.4.4.2) applied to the forgetful functor to $\mathcal{S}et_\Delta$, Let R be a commutative algebra, then the category of simplicial commutative algebras $sCAlg_R$ has a simplicial model category structure where a morphism is

- a weak equivalence if it is a weak equivalence of simplicial sets.
- a fibration if it is fibration of simplicial sets.

Proof: □

Cor. (4.8.2.15). For a ring map $R \to S$, the tensor product $S \otimes_R -$ and forgetful functor form a Quillen adjunction between $s\,\mathcal{CR}\mathrm{ing}_R$ and $s\,\mathcal{CR}\mathrm{ing}_S$.

Def. (4.8.2.16) [Free Morphisms]. A morphism of simplicial R-algebras is called **free** if it is s-free(3.5.1.5) on the a set of objects P_k where P_k are projective R-modules.

Prop. (4.8.2.17) [Cofibrations in $sAlg_R$]. A morphism in $sAlg_R$ is a cofibration iff it is a retraction of a free morphism(4.8.2.16). In particular, a cofibrant simplicial R-algebra is the symmetrization of a chain of projective R-modules.

Proof: This follows from(3.4.4.2)(3.1.7.10) and notice the free morphisms just corresponds free commutative algebra applied to the attaching cell morphism in the category of sets. □

Simplicial Resolutions

Def. (4.8.2.18) [Simplicial Resolutions].

- Let $M \in \mathrm{Mod}_R$, a **simplicial resolution** of M is a cofibrant replacement of M, or equivalently, it is an augmented simplicial R-module $X \to M$ that $NX \to M$ is a projective resolution.
- Let $M \in \mathcal{CR}\mathrm{ing}_R$, a **free resolution** of M is free cofibrant replacement of M, or equivalently, it is an augmented simplicial commutative R-algebras $X \to M$ that $NX \to M$ is a resolution of R-modules, and P_n are all projective(3.1.1.21) in Alg_R. Notice we can always choose a free resolution only only cofibrant resolution by(3.4.8.3) and Dold-Kan complex.

Def. (4.8.2.19) [Bar Resolution]. Let $\mathcal{C}$ be a category and $T : \mathcal{C} \to \mathcal{C}$ a monad, and X is an algebra over T(3.2.1.2), then we can form a simplicial T-algebras where $B(T, X)_n = T^{n+1}X$ where the simplicial operators come from the action of T on itself and the action of T on X.

Then there is a simplicial morphism $B(T, X) \to X$, which is a simplicial homotopy.

Remark (4.8.2.20). If $\mathcal{C}$ is the category of sets, R is an algebra and T is a functor that sends a set S to $R[S]$, then a T-algebra is just an R-algebra, and the bar resolution is just the canonical resolution, and it is a cofibrant replacement, by(4.8.2.17).

Prop. (4.8.2.21). If $f, g : A^\bullet \to B^\bullet$ are two homotopic maps of cosimplicial Abelian groups, then f, g induces an isomorphism between their totalizations.

Proof: Cf.[[Sta]019S]. □

3 Properties

Def. (4.8.3.1). If A is a ring and $f_1, \ldots, f_n \in A$, the Koszul complex is defined to be

$$Kos(A, f_1, \ldots, f_n) = A \otimes^L_{\mathbb{Z}[X_1,\ldots,X_n]} \mathbb{Z}.$$

We want to extend this definition to the case of simplicial commutative rings.

Now if A is a simplicial ring and $f_1, \ldots, f_n \in \pi_0(A)$, let $g_1, \ldots, g_n$ in A_0 lifting f_i, then we define

$$Kos(A, f_1, \ldots, f_n) = A \otimes^L_{\mathbb{Z}[X_1,\ldots,X_n]} \mathbb{Z}.$$

Then we need to check that this is independent of the lifting: if there is another set of lifting h_i, because we have identities

$$A \otimes^L_{\mathbb{Z}[X_1,\ldots,X_n]} \mathbb{Z} \cong (A \otimes^L_{\mathbb{Z}[X_1,\ldots,X_n]} \mathbb{Z}[X_1]) \otimes^L_{\mathbb{Z}[X]} \mathbb{Z}$$

it suffices to prove for $n = 1$. Then there is a $\gamma \in A_1$ that $d_0(\gamma) = g, d_1(\gamma) = h$. Then we consider the evaluating maps

$$e_0, e_1 : \underline{\mathrm{Hom}}(\Delta_1, A) \to A$$

are weak equivalences**?**, and then the maps

$$e_0 : \underline{\mathrm{Hom}}(\Delta_1, A) \otimes^L_{\gamma,\mathbb{Z}[X]} \mathbb{Z} \to A \otimes^L_{g,\mathbb{Z}[X]} \mathbb{Z}$$

$$e_1 : \underline{\mathrm{Hom}}(\Delta_1, A) \otimes^L_{\gamma,\mathbb{Z}[X]} \mathbb{Z} \to A \otimes^L_{h,\mathbb{Z}[X]} \mathbb{Z}$$

are also weak equivalences, so we are done.

And if M is a simplicial A-module, then we define

$$Kos(M, f_1, \ldots, f_n) = M \otimes^L_A Kos(A, f_1, \ldots, f_n)$$

Def. (4.8.3.2) [Flatness]. A map $A \to B$ of simplicial rings is called **(faithfully)flat** if $\pi_0(B)$ is (faithfully)flat over $\pi_0(A)$ and $\pi_i(A) \otimes_{\pi_0(A)} \pi_0(B) \to \pi_i(B)$ is an isomorphism for any i.

Prop. (4.8.3.3). Flatness is stable under base change.

Proof: Cf.[Emerton note, completely flatness, P12]. □

Prop. (4.8.3.4). If $\pi_0(A) \otimes^L_A M$ is (faithfully)flat over $\pi_0(A)$, then M is (faithfully)flat over A.

Proof: Cf.[Emerton note, completely flatness, P12]. □

Def. (4.8.3.5). If A is a simplicial ring and M is a simplicial A-module, if $I = (f_1, \ldots, f_n)$ is an ideal of $\pi_0(A)$, then M is called ***I*-completely flat** over A if $Kos(M, f_1, \ldots, f_n)$ is flat over $Kos(A, f_1, \ldots, f_n)$.

Clearly if M is A-flat, then it is I-completely flat.

Prop. (4.8.3.6) [Flatness and Derived Completion]. If A is a simplicial ring, M is a flat simplicial A-module, and $I = (f_1, \ldots, f_n)$ is an ideal of $\pi_0(A)$, then its derived I-completion $\widehat{M} = ho\lim_n Kos(M, f_1^N, \ldots, f_n^N)$ is I-completely flat. The proof is similar to that of(4.9.7.4).

Prop. (4.8.3.7) [Relative Regular Sequence]. If $A \to B$ is a map of simplicial rings, then $x_1, x_2, \ldots, x_n \in \pi_0(B)$ is called **regular with respect to $A_\bullet$** if

$$A \to Kos(B, x_1, \ldots, x_n)$$

is flat. And if $I = (f_1, \ldots, f_m) \in \pi_0(A)$, then it is called ***I*-completely regular** if

$$Kos(A, f_1, \ldots, f_m) \to Kos(A, f_1, \ldots, f_m) \otimes^L_A Kos(B, x_1, \ldots, x_n) = Kos(B, f_1, \ldots, f_m, x_1, \ldots, x_n)$$

is flat. In particular, regular relative to $A_\bullet$ implies I-completely regular relative to $A_\bullet$.

Prop. (4.8.3.8). If $(f_1, \ldots, f_{r-1}, f)$ is regular w.r.t. A and $(f_1, \ldots, f_{r-1}, g)$ is regular w.r.t A, then $(f_1, \ldots, f_{r-1}, fg)$ is also regular w.r.t A. In particular, for any $n_i > 0$, $f_1^{n_1}, \ldots, f_r^{n_r}$ is also regular w.r.t. A.

Proof: Similarly as in(4.4.4.6), we have a distinguished triangle

$$Kos(M, f_1, \ldots, f_{r-1}, f) \to Kos(M, f_1, \ldots, f_{r-1}, fg) \to Kos(M, f_1, \ldots, g).$$

Then we can use induction. □

Prop. (4.8.3.9) [Regular and Derived Completion]. If $x_1, \ldots, x_n \in \pi_0(B)$ is regular w.r.t A, then they are I-completely regular w.r.t. A in the derived I-completion $\widehat{B}$. The proof is similar to that of(4.8.3.6).

4 Non-Abelian Derived Functors

Def. (4.8.4.1) [∞-Category of Chain Complexes]. Let $\mathcal{A}$ be an additive category, then $\mathrm{Ch}(\mathcal{A})$ is enriched over $\mathrm{Ch}(\mathcal{A}\mathrm{b})$, and the Dold-Kan correspondence can be made into a right-lax monoidal functor by**?**[S. Schwede and B. Shipley. Equivalences of monoidal model categories.], so $N_*(\mathrm{Ch}(\mathcal{A}))$ is enriched over $s\mathcal{A}\mathrm{b}$, which consists of Kan complexes(4.8.1.1). Thus $N_*(\mathrm{Ch}(\mathcal{A}))$ is Bergner-fibrant, and we can define the **∞-category of chain complexes**

$$\mathrm{Ch}_\infty(\mathcal{A}) = N_\Delta(N_*(\mathrm{Ch}(\mathcal{A}))),$$

which is an ∞-category by(3.5.4.9).

Prop. (4.8.4.2) [Left Derived Functor]. Let $F : \mathcal{P}\mathrm{oly}_A \to \mathcal{C}$ be a functor where $\mathcal{C}$ is any ∞-category admitting all colimits (e.g. $D_\infty(\mathcal{A}\mathrm{b})$), then there exists a left Kan extension LF of F along $\mathcal{P}\mathrm{oly}_A \subset \mathcal{CR}\mathrm{ing}_A$ that

- LF commutes with filtered colimit.
- LF commutes with geometric realization of simplicial resolutions: given $B \in \mathcal{CR}\mathrm{ing}_A$ and a simplicial resolution $P_\bullet \to B$ by A-algebras, the geometric realization $|LF(P_\bullet)|$ is equivalent to $LF(B)$.

which is called the **left derived functor** of F.

Proof: Cf.[Bhatt, Prism, 7.1.2]. □

4.9 Derived Commutative Algebras

Main references are [Sta].

[Sta]Chap15 contains many beautiful results working on the derived category of rings, and is used heavily in Scholze's Thesis.

The basic construction of Rtensor and RHom should be redone at the level of ringed sites, Cf.[Sta]Chap21.

This section is obsolete and should be redone in the language of ∞-categories.

1 Basics

Prop. (4.9.1.1) [Product in $D(R)$]. Let R be a ring and $K_n \in D(R)$, then the product in $D(R)$ of K_n is given by $\prod I_n$, where I_n are K-injective resolutions of K_n.

Proof: This is immediate from(3.9.2.7). □

Def. (4.9.1.2) [Homotopy Fiber Square]. A square of Abelian groups is called a **homotopy fiber square** if it is a homotopy fiber square in the derived category, or equivalently, the kernel of the two rows(or the two columns) are isomorphic.

This notion is identical to the notion of pullback square when the rows or the columns are surjective.?

Prop. (4.9.1.3) [Bockstein Differential]. Let I be an invertible ideal of A, for any $M^\bullet \in D(A)$, we use the Breuil-Kisin Twist notation(7.7.5.1) and consider the exact triangle

$$M^\bullet \otimes_A^L A/I\{i+1\} \to M^\bullet \otimes_A^L I^i/I^{i+2} \to M^\bullet \otimes_A^L A/I\{i\}$$

obtained from the exact triangle

$$I^{n+1}/I^{n+2} \to I^n/I^{n+2} \to I^n/I^{n+1}$$

tensoring $\mathcal{O}_\Delta$. Then we get a Bockstein differential

$$\beta^n : H^n(M^\bullet \otimes_A^L A/I\{n\}) \to H^{n+1}(M^\bullet \otimes_A^L A/I\{n+1\})$$

Then these maps satisfy $\beta^{n+1} \circ \beta^n = 0$.

Proof: Consider the morphism of distinguished triangles:

$$\begin{array}{ccccc} I^{n+1}/I^{n+3} & \longrightarrow & I^n/I^{n+3} & \longrightarrow & I^{n+1}/I^{n+1} \\ \downarrow & & \downarrow & & \downarrow \\ I^{n+1}/I^{n+2} & \longrightarrow & I^n/I^{n+2} & \longrightarrow & I^{n+1}/I^{n+2} \end{array}$$

then we see for any $M^\bullet \in D(A)$, β^n factors as

$$H^n(M^\bullet \otimes_A^L I^n/I^{n+1}) \to H^{n+1}(M^\bullet \otimes_A^L I^{n+1}/I^{n+3}) \to H^{n+1}(M^\bullet \otimes_A^L I^{n+1}/I^{n+2})$$

and also we consider the distinguished triangle

$$I^{n+2}/I^{n+3} \to I^{n+1}/I^{n+3} \to I^{n+1}/I^{n+2}$$

to see that the composition

$$H^{n+1}(M^\bullet \otimes_A^L I^{n+1}/I^{n+3}) \to H^{n+1}(M^\bullet \otimes_A^L I^{n+1}/I^{n+2}) \xrightarrow{\beta^{n+1}} H^{n+2}(M^\bullet \otimes_A^L I^{n+2}/I^{n+3})$$

is 0, and this two observation gives the result. □

Injective Amplitude

Prop. (4.9.1.4) [Injective Amplitude]. For $K \in D(A)$, the following are equivalent:

- K has finite amplitude in $[a, b]$.
- $\mathrm{Ext}^i(N, K) = 0$ for any $N \in D^0(A)$ and $i \notin [a, b]$.
- $\mathrm{Ext}^i(A/I, K) = 0$ for any ideal I of A.

Proof: $1 \to 2 \to 3$ is clear. For $3 \to 1$: Notice $\mathrm{Ext}^n(A, K) = H^n(K)$, $H^i(K) = 0$ for any $i \notin [a, b]$. Then K is represented by a complex

$$0 \to I^a \to I^a \to I^{a+1} \to \ldots \to I^b \to \ldots.$$

Let $J = \ker(I^b \to I^{b+1})$, then K is also represented by

$$0 \to I^a \to I^a \to I^{a+1} \to \ldots \to I^b \to J \to 0.$$

Let $K' = (I^a \to \ldots \to I^b) \in D(A)$, then there is an distinguished triangle

$$J[-b] \to K \to K' \to J[1-b],$$

which induces an exact sequence $\mathrm{Ext}^b(R/I, K') \to \mathrm{Ext}^1(R/I, J) \to \mathrm{Ext}^{b+1}(R/I, K)$ for any ideal $I \subset A$. Then by $1 \to 2$, $\mathrm{Ext}^1(R/I, J) = 0$, implying J is injective. □

Prop. (4.9.1.5) [Dedekind Domain]. Let R be a Dedekind domain, then every ideal I is finite torsion-free thus projective over R, so every R-module has injective dimension≤ 1. In particular, $\mathrm{Ext}^i(M, N) = 0$ for any $i \geq 2$ and $M, N \in \mathcal{M}\mathrm{od}_R$. In particular, by(3.9.3.26). any $K \in D^+(R)$ is isomorphic to a direct sum of their cohomology groups.

Prop. (4.9.1.6). Let $(R, \mathfrak{m}, k)$ be a Noetherian local ring and $K \in D^+(R)$ have finite cohomology modules, then K has finite injective dimension iff $\mathrm{Ext}^i_R(k, K) = 0$ for i large.

Proof: Cf.[Sta]0AVJ. □

2 Derived Tensor and Tor

Prop. (4.9.2.1)[Differential Graded Structure]. If K is a commutative A-algebra object in $D(A)$ in the monoidal structure defined in(5.3.3.8), then $\oplus_{n \geq 0} H^n(K^\bullet)$ carries a natural graded commutative A-algebra structure.

Proof: Compare with(4.8.2.4).

We may replace K by a K-flat resolutions L^1(5.3.3.3) that the algebra structure map for K is represented by a morphism $L_1^\bullet \otimes_A L_1^\bullet \to L^2$ of complexes where L^2 is a complex quasi-isomorphic to K, hence the graded A-algebra structure is clear by(3.7.8.2), and it is commutative by(3.7.8.1). (How to check the structure is uniquely determined**?**). □

Tor

Def. (4.9.2.2) [Tor]. Let M, N be A-module, then the torsion group $\mathrm{Tor}_n^A(M, N)$ is defined to be $H^n(M \otimes_{\mathcal{O}}^L N)$, compatible with the definition in(5.3.3.11).

Def. (4.9.2.3) [Torsion Group]. Let A be a commutative ring, B an A-algebra and I be an ideal, then the **I-torsion** of B is defined to be $\mathrm{Tor}_1^A(A/I, B)$, denoted by $B[I]$. In case $I = (f)$, it can be checked that $B[f]$ is the set of elements of B that killed by f.

Also we denote $B[I^\infty] = \mathrm{colim}_{n\to\infty} B[I^n]$. And B is said to have **bounded f-torsion** iff $B[f^\infty] = B[f^n]$ for some n.

Prop. (4.9.2.4). If A is a commutative ring with bounded I-torsions and B is a flat A-module, then B also has bounded I-torsions. (Because tensoring B is exact).

Prop. (4.9.2.5) [Balancing Tor]. In the category of rings, $\mathrm{Tor}_n(A, B) = \mathrm{Tor}_n(B, A)$. This can be seen using spectral sequence of the double complex of flat resolutions of A and B. Similarly, we have two definitions of $\mathrm{Ext}^i(M, N)$ are compatible.

Proof: □

Prop. (4.9.2.6) [Base Change]. For a ring extension $R \to S$, using projective resolution and spectral sequence, there is a first quadrant homology spectral sequence:

$$E^2_{pq} = \mathrm{Tor}_p^S(\mathrm{Tor}_q^R(A, S), B) \Rightarrow \mathrm{Tor}_{p+q}^R(A, B).$$

Similarly, for Ext,

$$E_2^{pq} = \mathrm{Ext}_S^p(A, \mathrm{Ext}_R^q(S, B)) \Rightarrow \mathrm{Ext}_R^{p+q}(A, B).$$

Prop. (4.9.2.7) [Universal Coefficient Theorem]. Let P be a free R-module so $d(P_n)$ are all flat, then $Z(P_n)$ are also flat and

$$0 \to d(P_{n+1}) \to Z_n \to H_n \to 0$$

is a free resolution. we have an exact sequence:

$$0 \to H_n(P) \otimes_R M \to H_n(P \otimes_R M) \to \mathrm{Tor}_1^R(H_{n-1}(P), M).$$

$$0 \to \mathrm{Ext}_R^1(H_{n-1}(P), M) \to H^n(\mathrm{Hom}_R(P, M)) \to \mathrm{Hom}(H_n(P), M) \to 0$$

and these exact sequences non-canonically split because Z_n is a direct summand of P_n, thus $Z_n \otimes M$ is a direct summand of $P_n \otimes M$ and a fortiori $Z_n(P_n \otimes M)$. so $H_n(P) \otimes M$ is a direct summand of $H_n(P \otimes_R M)$.

Internal Hom and Derived Tensor

Prop. (4.9.2.8). If R is a ring and $K, L, M \in D(R)$, then

$$R\,\mathrm{Hom}_R(K, R\,\mathrm{Hom}(L, M)) = R\,\mathrm{Hom}_R(K \otimes_R^L L, M).$$

Proof: This is a special case of(5.3.3.29). □

Cor. (4.9.2.9).

$$\mathrm{Hom}_{D(R)}(K, R\,\mathrm{Hom}(L, M)) = \mathrm{Hom}_{D(R)}(K \otimes_R^L L, M),$$

i.e., derived tensor is left adjoint to internal Hom.

Proof: This follows from taking H^0, by(3.9.3.18). □

Prop. (4.9.2.10) [Derived Base Change Adjunction]. For a ring map $R \to S$ and any $L \subset D(R), M \subset D(S)$, there is an isomorphism

$$\mathrm{Hom}_R(L, M) \cong \mathrm{Hom}_S(L \otimes_R^L S, M)$$

Proof: This follows from(5.3.3.16). □

3 Rlim

Def. (4.9.3.1) [Rlim]. Rlim is the derived limit(3.9.6.1) in $D(\mathcal{A}b)$ restricted to the inverse systems consisting of discrete complexes.

Lemma (4.9.3.2). The set of Mittag-Leffler Complexes in $\mathcal{A}b(\mathbb{N})$ is adapted for $R\lim$.

Proof: Firstly, for any complex (A_n), we can associate to it the complex (B_n) where $B_n = A_n \oplus A_{n-1} \oplus \ldots \oplus A_1$, then (B_n) is a Mittag-Leffler complex and $(A_n) \hookrightarrow (B_n)$. So ML complexes are sufficiently large.

Now for any exact sequence of complexes $0 \to (A_n) \to (B_n) \to (C_n) \to 0$, if A_n is ML, then $\lim B_i \to \lim C_i$ is surjective: for an element $(c_i) \in \lim C_i$, let $E_i = \pi_i^{-1}(c_i) \in B_i$, then (E_i) is an inverse system of nonempty sets, and it suffices to show (E_i) is ML, because then(3.1.1.45) will show there is a element $(e_i) \in \lim E_i \subset \lim B_i$ that maps to (c_i).

For this, Cf.[Sta]0598. □

Prop. (4.9.3.3) [Rlim].

- If (A_n) is Mittag-Leffler, then $R^1\lim((A_n)) = 0$.
- $R\lim((A_n))$ is represented by the complex in degree $0, 1$:

$$\prod_n A_n \to \prod_n A_n : (x_n) \mapsto (x_n - f_{n+1}(x_{n+1}))$$

.

- for any $(A_n) \in Ab(\mathbb{N})$ we have $R^p\lim((A_n)) = 0$ for $p > 1$.

Proof: 1 follows from(4.9.3.2) and(3.9.3.2).

$2, 3$: We use(3.9.3.2) again. Notice the complex (B_n) where $B_n = A_n \oplus A_{n-1} \oplus \ldots \oplus A_1$ and the complex (C_n) where $C_n = A_{n-1} \oplus A_{n-2} \oplus \ldots \oplus A_1$ form an exact sequence of complexes

$$0 \to (A_n) \to (B_n) \to (C_n) \to 0$$

where $B_n \to C_n : (x_i) \mapsto (x_i - f_{i+1}(x_{i+1}))$, and $(B_n), (C_n)$ are both ML, so we are done. □

4 Lifting Complexes

Prop. (4.9.4.1) [Lifting Projective Complex Along Thickening]. Let R be a ring and I be a nilpotent ideal, and $K \in D(R)$. Now if $K \otimes_R^L R/I$ is represented by a bounded above complex of projective R/I-modules, then there is a complex P of bounded above complex of projective R-modules that $P \cong K \in D(R)$, and $P \otimes_R R/I \cong E$.

Proof: Cf.[[Sta]09AR]. □

5 Pseudo-Coherent and Perfect Modules

Def. (4.9.5.1) [Pseudo-Coherent Modules]. Let R be a ring, $m \in \mathbb{Z}$, then $K \in D(R)$ is called an m**-pseudo-coherent module** iff there exists a complex $E^\bullet \in K^b(R)$ and a morphism $\alpha : E^\bullet \to K^\bullet$ where $K^\bullet$ represents K, s.t. $H^i(\alpha)$ is an isomorphism for $i > m$, and surjective for $i = m$.

$K \in D(R)$ is called a **pseudo-coherent module** if it is represented by a bounded above complex of finite free R-modules.

Prop. (4.9.5.2). If A is Noetherian and $C^\bullet$ is a complex of A-modules bounded above that every cohomology group H^i is a finite A-module, then there is a complex $L^\bullet$ of finite free A-modules, that $g: L^\bullet \to C^\bullet$ is a quasi-isomorphism.

Moreover, if C^i are all flat A-modules, then $L^\bullet \otimes_A M \to C^\bullet \otimes_A M$ is quasi-isomorphism for every M.

Proof: $C^\bullet$ is bounded above so we choose $L^n = 0$, and use induction to construct L^n that $H^i(L) \to H^i(C)$ is isomorphism for $i > n+1$ and surjection for $i = n+1$. For this, choose a generator $x_1, \ldots, x_r$ of $H^n(C)$ in $Z^n(C)$, and let $y_{r+1}, \ldots, y_s$ be a generator of $g^{-1}(B^{n+1}(C))$(Noetherian used), and let $g(y_i) = dx_i$ for $x_i \in C^n$.

Now let L^n be freely generated by $e_1, \ldots, e_s$ and $de_i = 0$ for $i \le r$ and $de_i = y_i$ for $i > r$, and let $g: L^n \to C^n$ be $ge_i = x_i$. Then it can be verified to be a quasi-isomorphism.

If C^i are all flat, we check isomorphism for all f.g. modules M, because $\otimes$ and cohomology all commutes with direct limits. Use induction, for n large, both are 0, and if we write $0 \to R \to F \to M \to 0$, for F finite free, then there is a commutative diagram of long exact sequences, and for F, H^i are obviously isomorphism, so I can use five lemma. □

Def. (4.9.5.3)[Perfect Complexes of Modules]. Let R be a ring, then $K \in D(R)$ is called a **perfect module** if K is quasi-isomorphic to a bounded complex of finite projective R-modules. An R-module M is called perfect iff $M[0]$ is perfect.

Prop. (4.9.5.4) [Perfectness and Pseudo-Coherence]. An object $K \in D(R)$ is perfect iff it is pseudo-coherent and has finite Tor amplitude.

Proof: Cf.[Sta]0658. □

Prop. (4.9.5.5). If R is a regular ring of finite dimension, then an object $K \in D(R)$ is perfect iff $K \in D^b(R)$ and each $H^i(K)$ is a finite R-module.

Proof: Cf.[Sta]066Z. □

Prop. (4.9.5.6) [Duality of Perfect Complexes]. Let K be a perfect complex of $D(A)$, then the **dual complex** $K^\vee = R\operatorname{Hom}(K, A)$ is also a perfect complex and $(K^\vee)^\vee \cong K$. Also, there is a functorial isomorphism

$$L \otimes_A^L K^\vee = R\operatorname{Hom}_A(K, L)$$

Proof: Cf.[Sta]07VI. □

Prop. (4.9.5.7). If A is a ring and K_n is a system of perfect objects in $D(A)$, then for any $E \in D(A)$, there is an isomorphism

$$R\operatorname{Hom}_A(ho\operatorname{colim} K_n, E) \cong R\lim E \otimes_A^L K_n^\vee$$

Proof: By(4.9.5.6), $R\lim E \otimes_A^L K_n^\vee = R\lim R\operatorname{Hom}(K_n, E)$ which fits into a distinguished triangle

$$R\lim R\operatorname{Hom}(K_n, E) \to \prod \operatorname{Hom}(K_n, E) \to \prod \operatorname{Hom}(K_n, E)$$

. So it suffices to show that

$$\prod \operatorname{Hom}(K_n, E) \cong R\operatorname{Hom}_A(\oplus K_n, E).$$

This follows from Yoneda lemma and(5.3.3.28)(5.3.3.29). □

Prop. (4.9.5.8) [Perfectness and Thickening]. If R is a ring, $I \subset R$ is a nilpotent ideal, and $K \in D(R)$. If $K \otimes_R^L R/I$ is perfect in $D(R/I)$, then K is perfect in R. Moreover, if $K \otimes_R^L R/I = 0$, then $K = 0$.

Proof: Let $\overline{P}^\bullet \cong K \otimes_R^L R/I$ where P is a complex of finite projective R/I-modules, then by(4.9.4.1) there is a complex of projective R-modules P that $P/IP \cong \overline{P}$. Then it follows from Nakayama that P is bounded. □

Pseudo-Coherent Modules

Def. (4.9.5.9) [Pseudo-Coherent Complexes of Modules]. Let $R \in \mathcal{CA}\mathrm{lg}$, $K \in D(R)$ is called an m**-pseudo-coherent module** if there exists a perfect object $E \in D(R)$ and a morphism $E \to K$ that induces isomorphisms on H^i for $i > m$ and surjection on H^m.

$K \in D(R)$ is called a **pseudo-coherent module** if it is represented by a bounded above complex of finite free R-modules.

6 Derived Completeness

Cf.[Sta]Chap15.90.

Def. (4.9.6.1). For a ring $A, f \in A$ and a complex $K \in D(A)$, we denote by $T(K, f)$ a derived limit of the system

$$\ldots \to K \xrightarrow{f} K \xrightarrow{f} K$$

Prop. (4.9.6.2) [Properties of $T(K, f)$]. For a ring $A, f \in A$ and $K \in D(A)$, the following are equivalent:

1. $T(K, f) = 0$.
2. $R\operatorname{Hom}_A(A_f, K) = 0$.
3. $\operatorname{Ext}_A^n(A_f, K) = 0$ for all n.
4. $\operatorname{Hom}_{D(A)}(E, K) = 0$ for all $E \in D(A_f)$.
5. For any $p \in \mathbb{Z}$, $\operatorname{Hom}_A(A_f, H^p(K)) = 0$ and $\operatorname{Ext}_A^1(A_f, H^p(K)) = 0$.
6. For any $p \in \mathbb{Z}$, $T(H^p(K), f) = 0$.

Proof: 2, 3 is clearly equivalent.

$4 \to 3$ is clear, and for $3 \to 4$: Let $I^\bullet$ be a complex representing K, then 3 says $\operatorname{Hom}_A(A_f, I^\bullet)$ is acyclic, and $\operatorname{Hom}_{D(A)}(E, K) = \operatorname{Hom}_{K(A)}(E, I^\bullet) = \operatorname{Hom}_{K(A_f)}(E, \operatorname{Hom}_A(A_f, I^\bullet))$. As $\operatorname{Hom}_A(A_f, I^\bullet)$ is both acyclic and K-injective(3.7.8.6), we get it is homotopic to 0 by(3.9.2.1), thus we get 4.

$1 \iff 3$: There is a free resolution of A_f given by

$$0 \to \oplus_n A \to \oplus_n A \to A_f \to 0$$

where the first map is $(a_n) \mapsto (a_n - f a_{n-1})$, and the second map is $(a_n) \mapsto \sum a_i/f^i$. Applying $\operatorname{Hom}_A(-, I^\bullet)$, we get a distinguished triangle

$$R\operatorname{Hom}_A(A_f, K) \to \prod K \to \prod K.$$

So this shows $R\operatorname{Hom}_A(A_f, K)$ is just $T(K, f)$, so we get $1 \iff 3$.

1 $\iff$ 5 $\iff$ 6: There is a spectral sequence convergence(choose a finite free resolution of A_f then rotate and use(3.9.7.10)):

$$E_2^{p,q} = \mathrm{Ext}^q_A(A_f, H^p(K)) \Rightarrow: \mathrm{Ext}^{p+q}(A_f, K)$$

This spectral sequence degenerates at E_2 because A_f has a length 1 resolution by free A-modules hence the E_2 page has only 2 rows. So there is an exact sequence

$$0 \to \mathrm{Ext}^1_A(A_f, H^{p-1}(K)) \to \mathrm{Ext}^1_A(A_f, K) \to \mathrm{Hom}_A(A_f, H^p(K)) \to 0.$$

Then we are done. □

Lemma (4.9.6.3). Let A be a ring, $K \in D(A)$, then the set I of f that $T(K, f) = 0$ is a radical ideal of A.

Proof: If $T(K, f) = 0$ and $g \in A$, then A_{gf} is a A_f-module, then

$$\mathrm{Ext}^n_A(A_{gf}, K) = \mathrm{Hom}_{D(A)}(A_{gf}[-n], K)(5.3.3.32) = 0$$

by(4.9.6.2) item4. Then $T(K, gf) = 0$ by(4.9.6.2) again. And if $f, g \in I$, there is an exact sequence

$$0 \to A_{f+g} \to A_{f(f+g)} \oplus A_{g(f+g)} \to A_{fg(f+g)} \to 0$$

by(4.4.2.3) and a easy check that the last term is surjective. Then from the long exact sequence of Ext, we get $\mathrm{Ext}^n(A_{f+g}, K) = 0$ for any n. Finally if $f^n \in I$, then $f \in I$, because $A_f = A_{f^n}$. □

Def. (4.9.6.4) [Derived Completeness]. Let A be a ring, $K \in D(A)$, I is an ideal of A, then K is said to be **derived complete** w.r.t I if $T(K, f) = 0$ for any $f \in A$. Let $D_{comp}(A, I)$ denote the subcategory consisting of derived I-complete objects in $D(A)$.

Let M be an A-module, then M is called **derived complete** w.r.t I if $M[0] \in D(A)$ is derived complete w.r.t I.

Prop. (4.9.6.5). A $\aleph_0$-filtered colimit of derived I-complete rings is also derived I-complete.

Proof: Cf.[Bhatt, Prism, 5.4.3]. □

Prop. (4.9.6.6) [Complete and Derived Complete]. Let A be a ring and I be an ideal, M an A-module, then

- If M is I-adically complete, then $T(M, f) = 0$ for any $f \in I$.
- If $T(M, f) = 0$ for all $f \in I$ and I is f.g., then $M \to \lim M/I^n M$ is surjective.

In particular, if I is f.g., M is I-adically complete iff M is derived I-adically complete and $\cap I^n M = 0$.

In particularly, when M is f.g. over A Noetherian and $I \subset \mathrm{rad}(A)$, derived I-complete is equivalent to I-complete(4.2.2.14).

Proof: If M is I-adically complete, by(4.9.6.2), it suffices to show that $\mathrm{Hom}(A_f, M) = 0$ and $\mathrm{Ext}^1(A_f, M) = 0$. But $M = \varprojlim_n M/I^n M$, and $\mathrm{Hom}(A_f, M/I^n M) = 0$, because $f \in I$. For Ext, use(3.9.3.24), for any extension

$$0 \to M \to E \to A_f \to 0,$$

chose arbitrary e_n that maps to $1/f^n$. Then $\delta_n = f e_{n+1} - e_n \in M$. We consider

$$e'_n = e_n + \delta_n + f\delta_{n+1} + f^2\delta_{n+2} + \dots,$$

which exist because M is I-adically complete. Then $fe'_{n+1} = e'_n$, so this gives a splitting of the extension.

Conversely, if $I = (f_1, \ldots, f_r)$ and $T(M, f_i) = 0$ for any i, then by(4.2.3.16), we can assume $I = (f)$. Then consider the extension

$$0 \to M \to E \to A_f \to 0$$

where $E = (M \oplus \bigoplus Ae_n)/(x_n - fe_{n+1} + e_n) \to A_f$ that maps M to 0 and e_n to $1/f^n$. This extension splits by(4.9.6.2) and(3.9.3.24), thus there is an element $x + e_0$ that generate a copy of A_f in E.

But then $x + e_0 = x - x_0 + fe_1 = x - x_0 - fx_1 + f^2 e_2 \ldots$, which implies $x - x_0 - fx_1 - f^2 x_2 - \ldots - f^{n-1}x_{n-1} \in f^n E + A_f$ for any n. Then $x - x_0 - fx_1 - f^2 x_2 - \ldots - f^{n-1}x_{n-1} \in f^n M$, because $E = M \oplus A_f$. Then we are done. □

Prop. (4.9.6.7). If $M \in D(A/I) \subset D(A)$, then M is derived-I-complete. (This follows from the definition of $T(M, f)$).

Prop. (4.9.6.8)[Category of Derived Complete Modules]. Let I be an ideal of A, then the derived I-complete A-modules form a weak Serre subcategory of Mod_A. In particular, $D_{comp}(A, I)$ is also a weak Serre subcategory.

Proof: If $f : M \to N$ is a map of derived I-complete A-modules, then we consider the complex $K = (M \to N)$, then there is an exact sequence $0 \to M[1] \to K \to N \to 0$, so we have $\mathrm{Ext}^n(A_f, K) = 0$ for any $f \in I, n \in \mathbb{Z}$ because M, N does(4.9.6.2), so K is derived I-complete by(4.9.6.2) again. Then we have $\ker(f), \mathrm{Coker}(f)$ are derived I-complete, by(4.9.6.2) again. Extension is also clear. □

Lemma (4.9.6.9). If R is ring, I is an ideal, and $K \in D(R)$ that $K \otimes^L_R R/I = 0$, then $K \otimes^L_R M$ for any $M \in D^b(R)$ with all the cohomology groups I-power torsions.

Proof: We use the truncation(3.7.4.6), then it suffices to prove for M discrete. Now $M = \cup M[I^n]$, and we have $K \otimes^L_R M = ho\operatorname{colim} K \otimes^L_R M[I^n]$, so we may assume $I^n M = 0$ for some n. Consider the R-algebra $R' = R/I^n \oplus M$, where $M^2 = 0$, then it suffices to show $K' = K \otimes^L_R R' = 0$. Now $0 = K \otimes^L_R R/I = K' \otimes^L_{R'} R/I$, so by(4.9.5.8) $K' = 0$. □

Prop. (4.9.6.10) [Derived Nakayama]. the derived tensor product $- \otimes^L_A A/I$ reflects isomorphism on $D_{comp}(A, I)$, i.e. if $M \otimes^L_A A/I = 0$, then $M = 0$.

Proof: Let $I = (f_1, \ldots, f_r)$, by(4.9.6.9), $M \otimes^L_A K_n = 0$ for any $K_n = Kos(A, f_1^n, \ldots, f_r^n)$, so $K = R\lim K \otimes^L_A K_n = 0$. □

Cor. (4.9.6.11). If I is f.g. and M is a derived I-complete A-module that $M/IM = 0$, then $M = 0$.

Proof: ?This should be an immediate corollary.

Let $I = (f_1, \ldots, f_r)$, if $M \neq 0$, let i be the largest integer that $M/(f_1, \ldots, f_i)M \neq 0$, then N is also derived I-complete by(4.9.6.8). But $f_{i+1} : N \to N$ is surjective, so $T(N, f_{i+1}) \neq 0$, contradiction. □

Prop. (4.9.6.12). If A is derived I-complete, then (A, I) is a Henselian pair.

Proof: Cf.[[Sta]0G3H]?. □

Prop. (4.9.6.13) [Derived I-Completion]. If $I=(f_1,\ldots,f_n)$ is f.g. in A, the inclusion of categories $D_{comp}(A,I)\subset D(A)$ has a left adjoint, which maps K to

$$\widehat{K}=R\operatorname{Hom}((A\to\prod_{i_0}A_{f_{i_0}}\to\prod_{i_0<i_1}A_{f_{i_0}f_{i_1}}\to\ldots\to A_{f_1,\ldots f_r}),K).$$

called the **derived I-completion** of K.

Moreover, this construction is identical to $K\mapsto K^\bullet=R\lim(K\otimes_A^L K_n^\bullet)$, by(4.9.5.7) and(4.4.4.7).

Proof: There is a map $(A\to\prod_{i_0}A_{f_{i_0}}\to\prod_{i_0<i_1}A_{f_{i_0}f_{i_1}}\to\ldots\to A_{f_1,\ldots f_r})\to A$, which induces a morphism $K\to\widehat{K}$. Now by(5.3.3.28), $R\operatorname{Hom}(A_f,\widehat{K})$ is isomorphic to

$$R\operatorname{Hom}((A_f\to\prod_{i_0}A_{ff_{i_0}}\to\prod_{i_0<i_1}A_{ff_{i_0}f_{i_1}}\to\ldots\to A_{ff_1,\ldots f_r}),K)$$

as A_f is A-flat. Now this one is 0 for any $f\in I$, by(4.4.4.7), so $\widehat{K}$ is derived I-complete.

Conversely, if $\widehat{K}$ is derived I-complete, then $R\operatorname{Hom}(A_f,K)=0$ for any $f\in I$, thus $K\to\widehat{K}$ is an isomorphism is we inductively use the stupid truncation(3.7.4.6). □

Cor. (4.9.6.14). If M is an A-module, then $H^0(\widehat{M})$ is the derived-I-completion in the category of modules, by(3.9.1.12).

Cor. (4.9.6.15). (4.9.6.2) show the notion of derived I-complete and derived I-completion only depends on $\operatorname{rad} I$.

Principal Ideal Case

Prop. (4.9.6.16) [Bounded Torsion and Derived Completion]. Let A be a commutative ring and $f\in A$. If M is an A-module that has bounded f^∞-torsion, then the derived f-completion of M as a complex is a module and coincides with the classical f-adic completion.

Proof: The derived f-completion is defined to be

$$\widehat{M}=R\lim_n(M\otimes^L_{\mathbb{Z}[X]}\mathbb{Z}[X]/(x^n))=R\lim_n(M\xrightarrow{f^n}M).$$

So by(3.9.6.5), there are exact sequences

$$R^1\lim_n M/f^nM\cong H^1(\widehat{M})$$

$$0\to R^1\lim M[f^n]\to H^0(\widehat{M})\to\lim_n M/f^n\to 0$$

$$H^{-1}(\widehat{M})\cong\lim_n M[f^n]$$

Now the hypothesis implies that $(M[f^n])$ is Mittag-Leffler and $\lim_n M[f^n]=0$, so we have the desired result. □

Cor. (4.9.6.17). Let R be a perfect $\mathbb{F}_p$-algebra, then the derived p-completion and p-adic completion of R coincide.

7 Derived Completely Properties

Def. (4.9.7.1)[Derived Completely Properties]. Let A be a commutative ring and I is a f.g. ideal, then $M \subset D(A)$ is called ***I*-completely (faithfully)flat/smooth/étale/...** iff $M \otimes_A^L A/I$ is discrete and is a (faithfully)flat A/I-module.

M is said to have **finite *I*-completely Tor amplitude** if $M \otimes_A^L A/I$ is is a bounded complex in $D(A/I)$.

Clearly, any flat/smooth/étale A-module M is I-completely flat/smooth/étale/... for any I. And M has finite I-completely amplitude if M has a finite resolution of flat A-modules.

Prop. (4.9.7.2)[*I*-Completely F.F. Descent]. If $A \to B \to B'$ are ring maps and I is an ideal of A,

1. If C is a B-algebra and B is I-completely f.f. over A, then C is I-completely (f.)f. over A iff C is I-completely (f.)f. over B.
2. If $B \to B'$ is I-completely flat, M is a B-module, then M is I-completely flat over A iff $M \otimes_B^L B'$ is I-completely flat over A.

Proof: 1: One direction is easy, for the other, if C is I-completely (f.)f. over A, then

$$C \otimes_A^L A/I = C \otimes_B^L B \otimes_A^L A/I = (C \otimes_B^L B/I) \otimes_{B/I} (B \otimes_A^L A/I)$$

is a discrete and (f.)f. C/I-module iff $(C \otimes_B^L B/I)$ does, as $(B \otimes_A^L A/I)$ is f.f. over B/I.

2: This is because $(B' \otimes_B^L M) \otimes_A^L A/I \cong B' \otimes_B^L (M \otimes_A^L A/I)$. □

Prop. (4.9.7.3). If I is generated by a Koszul-regular sequence, then any A-module M has finite I-completely Tor amplitude.

Proof: This is because $A/i \cong A \otimes^L_{\mathbb{Z}[X_1,\ldots,X_r]} \mathbb{Z}$ in this case, so $M \otimes^L A/I \cong M \otimes^L_{\mathbb{Z}[X_1,\ldots,X_r]} \mathbb{Z}$, which has f.m. homology groups because $\mathbb{Z}$ has a finite free $\mathbb{Z}[X_1, \ldots, X_n]$-resolution(4.4.4.1). □

Prop. (4.9.7.4)[*I*-Completely Flatness and Derived Completion]. Let A be a commutative ring and I be f.g., then the derived I-completion of a I-completely (faithfully)flat/étale M is I-completely (faithfully)flat/étale, both the complex and the module. In fact, $H^0(\widehat{M}) \otimes_A^L A/I \cong \widehat{M} \otimes_A^L A/I \cong M \otimes_A^L A/I$.

Proof: Because objects in the image of $D(A/I) \to D(A)$ are all derived I-complete, by(4.9.6.7), so there is an isomorphism $M \otimes_A^L A/I \cong \widehat{M} \otimes_A^L A/I$ for any M, because they are both left adjoint to $\mathcal{M}od_{A/I} \subset D(A)$, by the definition of derived I-completion and(4.9.2.10). So $\widehat{M} \otimes_A^L A/I \cong M \otimes_A^L A/I = M \otimes_A A/I$, which is a flat A/I-module. □

Prop. (4.9.7.5) [Flatness and Completed Derived Tensor]. The completed derived tensor of a I-completely flat/étale module is discrete and I-completely flat/étale.

Proof: If M is an I-completely flat A-module, then $M \widehat{\otimes}_A^L B$ is I-complete and I-completely flat by(4.9.7.4), and $(M \widehat{\otimes}_A^L B) \otimes_B^L B/I = H^0(M \widehat{\otimes}_A^L B) \otimes_B^L B/I = M \otimes_A^L B/I$, because they are both left adjoint of the forgetful functor $\mathcal{M}od_{B/I} \subset D(A)$. Then we have $M \widehat{\otimes}_A^L B \cong H^0(M \widehat{\otimes}_A^L B)$ is discrete, as they are both I-complete, by(4.9.6.2) and derived Nakayama. □

Prop. (4.9.7.6). A is derived I-completely flat iff A is I^n-completely flat for any $n > 0$. Moreover, in this case, A is derived J-completely flat for any ideal J that $I \subset \operatorname{rad} J$.

Proof: The exact sequence
$$0 \to I/I^2 \to A/I^2 \to A/I \to 0$$
induces distinguished triangles
$$(M \otimes_A^L A/I) \otimes_{A/I}^L I/I^2 \to M \otimes_A^L I/I^2 \to M \otimes_A^L A/I^2 \to M \otimes_A^L A/I$$
which shows $M \otimes_A^L I/I^2$ is discrete, $= N$. Then N is an A/I^2-module that $N \otimes_{A/I^2}^L A/I = M/IM$ is A/I-flat. Then N is A/I^2 flat: for any A/I^2-module L, let $L' = IL$ and $L'' = L/IL$ which are both A/I-modules, then there is a distinguished triangle
$$N \otimes_{A/I^2}^L L' \to N \otimes_{A/I^2}^L L \to N \otimes_{A/I^2} L''$$
and
$$N \otimes_{A/I^2}^L L' = (N \otimes_{A/I^2}^L A/I) \otimes_{A/I}^L L' = (M/IM) \otimes_{A/I} L'$$
$$N \otimes_{A/I^2}^L L'' = (N \otimes_{A/I^2}^L A/I) \otimes_{A/I}^L L'' = (M/IM) \otimes_{A/I} L''$$
are both discrete, hence so does $N \otimes_{A/I^2}^L L$, implying it is A/I^2-flat.

In a similar fashion, we can show M is I/I^n-flat for any n. And if $I \subset \operatorname{rad} J$, then $I^n \subset J$, so $M \otimes_A^L A/J = (M \otimes_A^L A/I^n) \otimes_{A/I^n}^L A/J$ is discrete and A/J-flat. □

Prop. (4.9.7.7). Let A be a ring and I be an invertible ideal, then any derived (p, I)-complete and (p, I)-completely flat A-complex $M \in D(A)$ is discrete and (p, I)-complete. Moreover, for any $n \geq 0$, we have $M[I^n] = 0$ and $M/I^n M$ has bounded p^∞-torsion.

Proof: M is (I^n, p)-completely flat by(4.9.7.6), so we fine $M \otimes_A^L A/I^n$ is p-completely flat in $D(A/I^n)$. Notice that A/I^n has bounded p^∞-torsion by induction(I invertible used), (4.9.7.11) says $M \otimes_A^L A/I^n$ is discrete in $D(A/I^n)$ and has bounded p^∞-torsion, and is p-adically complete. In particular,
$$M \otimes_A^L A/I^n = (M \otimes_A^L A/I^{n+1}) \otimes_{A/I^{n+1}}^L A/I^n$$
So if we denote $M \otimes_A^L A/I^n = M_n$, then $M_n = M_{n+1}/I^n M_{n+1}$, as M is derived I-complete, we have $M = R\lim(M \otimes^L A/I^n)$, so clearly M is discrete. And then we have $M \otimes^L AA/I^n = M/I^n M$, which means $M[I^n] = 0$, and $M/I^n M$ has bounded p^∞-torsion. Now because M is derived (p, I)-complete,
$$M = R\varprojlim_{m,n}((M \otimes_A I^n \to M) \otimes_{A/I^n} (A/I^n \xrightarrow{p^m} A/I^n)) = R\varprojlim_{m,n}(M/I^n \xrightarrow{p^m} M/I^n) = R\varprojlim_{m,n}(M/(I^n, p^n))$$
is (p, I)-complete. □

Lemma (4.9.7.8). Let C be a commutative ring with a f.g. ideal J, and D a C-algebra that has finite J-complete Tor amplitude, then the J-completed base change operator $-\widehat{\otimes}_C^L D$ commutes with totalization in $D^{\geq 0}(C)$ and $D^{\geq 0}(D)$, i.e. if $M^\bullet$ is a cosimplicial object with in $D^{\geq 0}(C)$ with totalization M, then
$$\operatorname{Tot}(M^\bullet)\widehat{\otimes}_C^L D \cong \operatorname{Tot}(M^\bullet \widehat{\otimes}_C^L D)$$
via the natural map.

Proof: Cf.[Scholze, Prism, 4.22].**?** □

Prop. (4.9.7.9)[Elkik's Algebrization Theorem]. Let A be a commutative ring and I is a f.g. ideal, then an A-algebras is derived I-completely étale/smooth iff it is the derived I-completion of some étale/smooth A-algebra.

Proof: if it is the derived I-completion of some étale/smooth algebra, then it is derived I-completely étale/smooth by(4.9.7.4). Converse, Cf.[A. Arabia, "Relèvements des algèbres lisses et de leurs morphismes", Commentarii Mathematici Helvetici 76 (2001), 607–639.]. □

Lemma (4.9.7.10). Let A be a ring, if M is an A-module with bounded f^∞-torsion, i.e. $M[f^\infty] = M[f^c]$ for some $c > 0$, then there are maps

$$(M \xrightarrow{f^n} M) \to M/f^n M, \quad M/f^{n+c} \to (M \xrightarrow{f^n} M)$$

in $D(A)$ inducing an equivalence between two pro-objects $\{M \xrightarrow{f^n} M\}$ and $\{M/f^n\}$.

Proof: The first map is obvious, for the second map, use the following commutative diagram:

$$\begin{array}{ccc} M/M[f^c] & \xrightarrow{f^{n+c}} & M \\ \downarrow f^c & & \downarrow \\ M & \xrightarrow{f^n} & M \end{array}$$

the upper row is injective thus isomorphic to $M/f^{n+c}M$, then this gives the map. It can be checked that this is an equivalence of pro-objects**?**. □

Prop. (4.9.7.11). Let A be a commutative ring that has bounded f^∞-torsion, then for a $M \in D(A)$, the following is equivalent:

- M is derived f-complete and f-completely flat.
- M is discrete and is represented by a f-adically complete module that $M/f^n M$ is A/f^n-flat for any $n > 1$ and M has bounded f^∞-torsion.

Furthermore, in this case, $M \otimes_A A[f^\infty] = M[f^\infty]$.

Proof: By(4.9.7.10), $\{A/f^n A\}$ and $\{Kos(A, f^n)\}$ are two equivalence pro-objects in $D(A)$. So if 1 or 2 holds, then M is derived f-complete, so

$$M = R\lim(M \otimes_A^L Kos(A, f^n)) = R\lim(M \otimes_A^L A/f^n A).$$

Now if 1 holds, then $M_n = M \otimes_A^L A/f^n A$ is discrete by(4.9.7.6), and $M_n = M_{n+1}/f^n M_{n+1}$ is surjective:

$$M \otimes^L AA/f^n A = (M \otimes_A^L A/f^{n+1} A) \otimes_{A/f^{n+1}}^L A/f^n.$$

So $M = R\lim(M \otimes_A^L A/f^n A)$ is discrete. Then $M \otimes_A A/f^n = M \otimes_A^L A/f^n$ is flat over A/f^n.

Next we prove $M \otimes_A A[f^\infty] = M[f^\infty]$: There is an exact sequence

$$0 \to (A[f^n])[1] \to Kos(A, f^n) \to A/f^n \to 0$$

Then tensoring $M \otimes_A^L$ gives a distinguished triangle

$$(M \otimes_A^L A[f^n])[1] \to Kos(M, f^n) \to M \otimes_A^L A/f^n.$$

Notice that

$$M \otimes^L_A A[f^n] = (M \otimes^L_A A/f^n) \otimes^L_{A/f^n} A[f^n] = (M \otimes_A A/f^n) \otimes^L_{A/f^n} A[f^n] = M \otimes_A A[f^n]$$

by flatness, so the distinguished triangle shows $M \otimes_A A[f^n] \cong H^{-1}(Kos(M, f^n)) = M[f^n]$.

Conversely, if 2 holds, then there are equivalences of pro-objects

$$\{M \otimes^L_A A/f^n\} \cong \{M \otimes^L_A Kos(A, f^n)\} = \{Kos(M, f^n)\} \cong \{M/f^n M\}$$

by(4.9.7.10) as M has bounded f^∞-torsion. So

$$\widehat{M} = R\lim\{M \otimes^L_A Kos(A, f^n)\} = R\lim\{M/f^n M\} = M[0]$$

so M is derived p-complete. And the constant system

$$\{M \otimes^L_A A/f\} = \{M \otimes^L_{A/f^n} A/f^n \otimes^L_{A/f^n} A/f\} \cong \{M/f^n M \otimes^L_{A/f^n} A/f\} = \{M/fM\}$$

where we used $M/f^n M$ is A/f^n-flat. So $M \otimes^L_A A/f \cong M/fM$ is flat over A/f. □

8 Duality

Def. (4.9.8.1) [Dualizing Complexes]. Let A be a Noetherian ring, then a **dualizing complex** for A is a complex $\omega_A \in D(A)$ s.t.

- ω_A has finite injective dimension.
- $H^i(\omega_A)$ are all finite A-modules.
- $A[0] \to R\,\mathrm{Hom}(\omega_A, \omega_A)$ is a quasi-isomorphism.

Prop. (4.9.8.2) [Dualizing Complex is Local]. Let A be a Noetherian ring,

- If $B = S^{-1}A$ and $\omega_A \in D(A)$ is a dualizing complex for A, then $\omega_A \otimes^L_A B$ is a dualizing complex for B.
- If $(f_1, \ldots, f_n) = (1) \in A$, and $\omega_A \in D(A)$ satisfies $(\omega_A)_{f_i}$ are dualizing complexes for A_{f_i} for any i, then ω_A is a dualizing complex for A.

Proof: Cf.[Sta]0A7G, 0A7H. □

Def. (4.9.8.3) [Dualizing Modules]. Let $(A, \mathfrak{m}, k)$ be a Noetherian local ring and ω_A a normalized dualizing complex for A, then $[\omega_A] = H^{-\dim A}(\omega_A)$ is called a **dualizing module** for A.

Def. (4.9.8.4) [Relative Dualizing Complex]. Cf.[Sta]0E9M.

Quasi-Finite Case

Cf.[Sta]Chap49.4.

Prop. (4.9.8.5).

5 Algebraic Geometry I: Scheme Theory

5.1 Sites, Sheaves, Topoi and Stacks

References are [Sta], [Ols16], [Vis08] and [Fibered Category to Algebraic Stacks Lamb].

1 Sites

Def. (5.1.1.1) [Sites]. A **site** is given by a category $\mathcal{C}$ and a set $\mathrm{Cov}(\mathcal{C})$ of families of morphisms with fixed target, called the **coverings** of $\mathcal{C}$ that:

- An isomorphism is a covering.
- Coverings of covering is a covering.
- Base change of a covering is a covering.

Sometimes A site is wrongly called a **topology**, the difference is that the morphism of site is looks like a reverse of a morphism of topology(5.1.1.5). We never talk about the category of sites, but we use $\mathcal{C} \in \mathcal{S}\mathrm{ite}$ to mean that $\mathcal{C}$ is a site.

Def. (5.1.1.2) [Discrete Topology]. A **discrete topology** or chaotic topology is a site that the only coverings are identies. In this way, we can regard any category as a site.

Def. (5.1.1.3) [Noetherian Topology]. An object U in a site $\mathcal{C}$ is called **quasi-compact** if for each covering of U, f.m. of them still forms a covering of U. The site $\mathcal{C}$ is called **Noetherian** if each object of $\mathcal{C}$ is quasi-compact.

Given a site $\mathcal{C}$, we can define a new site $\mathcal{C}^f$ whose coverings are coverings of $\mathcal{C}$ that are finite. Then this is truly a site and it is Noetherian.

Def. (5.1.1.4) [Comma Topology]. For a site $\mathcal{C}$ and an object S, we have the comma category $\mathcal{C}/S$(3.1.1.17), and we can define a topology on it where the coverings are coverings of $\mathcal{C}$ that is compatible over S.

Def. (5.1.1.5) [Continuous Functor]. A **continuous functor** between sites $\mathcal{C} \to \mathcal{D}$ is a functor that preserves covering and any base change by morphisms in a covering.

A **morphism of sites** $\mathcal{C} \to \mathcal{D}$ is given by a continuous functor $u : \mathcal{D} \to \mathcal{C}$ that u_s(5.1.2.11) is exact.

This exact condition is easy to be satisfied, by(5.1.2.14).

Def. (5.1.1.6) [Cocontinuous functors]. A **cocontinuous functor** between sites $u : \mathcal{C} \to \mathcal{D}$ is a functor that for any $U \in \mathcal{C}$ and any covering $\{V_i \to u(U)\}$ in $\mathcal{D}$, there is a covering $\{U_i \to U\} \in \mathcal{C}$ that refines $\{V_i \to u(U)\}$ after the functor u.

Topologies and Sieves

Def. (5.1.1.7) [Sieves]. For a covering $\mathcal{U} = \{U_i \to U\}$ in a category $\mathcal{C}$, define a subfunctor $h_{\mathcal{U}} \subset h_U$, where for each X $h_{\mathcal{U}}(X)$ consists of elements in $\mathrm{Hom}(X, U)$ that factor through some $U_i \to U$.

A **sieve** $\mathcal{S}$ on U is a subfunctor of h_U. Notice that any sieve must by of the form $h_{\mathcal{U}}$, by choosing $\mathcal{U}$ to consist of all arrows in $\{S(T)\}_{T\in\mathcal{C}}$.

Def. (5.1.1.8). If $\mathcal{T}$ is a Grothendieck topology on a category $\mathcal{C}$, then a sieve $S \subset h_U$ over U is said to **belong to** $\mathcal{T}$ or just a sieve of the site $\mathcal{C}$ if there exists a covering $\mathcal{U}$ of U that $h_{\mathcal{U}} \subset S$.

G-Spaces

Def. (5.1.1.9) [G-Spaces]. A **G-space** is a set X with a family of subsets of X that they form a site w.r.t inclusions and that covering are all set-theoretic coverings(but not necessarily conversely). These subsets are called **admissible opens** of X and covers are called **admissible covers**. (In other words, a G-topological space is a "topological space without unions"). Morphisms of G-spaces is simultaneously a continuous map and a morphism of sites.

Def. (5.1.1.10) [Completeness]. The completeness of a G-topological space X:

- G0: $\varnothing$ and X are admissible open.
- G1: Let $\{U_i \to U\}$ be an admissible cover, then a subset $V \subset U$ is admissible if $V \cap U_i$ are all admissible.
- G2: Let $\{U_i \to U\}$ be a cover of admissible opens for U admissible, then the cover is admissible if it has an admissible cover as a refinement.

Lemma (5.1.1.11) [Admissible is Local]. If G_2 is satisfied for a G-topological space X, then for an admissible covering $\{X_i \to X\}$ and another covering $\{U_i \to X\}$ between admissible opens, it is admissible iff $U_i \cap X_j$ is an admissible covering for X_j for each j. (By composition, $\{U_i \cap X_i \to X\}$ is admissible, and it refines $\{U_i \to X\}$).

Prop. (5.1.1.12) [Glue of Complete G-topological spaces]. For sets $\cup X_i = X$, if there are Grothendieck category $\mathcal{I}_i$ on X_i making X_i into a G-topological space, and they all satisfies the completeness conditions G_0, G_1, G_2 of(5.1.1.10). Assume that $X_i \cap X_j$ is $\mathcal{I}_i$-open in X_i and $\mathcal{I}_i, \mathcal{I}_j$ restrict to the same topology on $X_i \cap X_j$, then there is a unique Grothendieck category $\mathcal{I}$ on X making X a G-topological space that:

- X_i is $\mathcal{I}$-open and $\mathcal{I}$ restricts to $\mathcal{I}_i$ on X_i,
- $\mathcal{I}$ satisfies the completeness conditions G_0, G_1, G_2.
- X_i is a $\mathcal{I}$-covering of X.

Proof: By(5.1.1.10) and(5.1.1.11), the uniqueness is straightforward, for the existence,

- check Grothendieck first: Composition, base change.
- check condition 1: by hypothesis, and(5.1.1.10) applied to $X_i \cap X_j \to X_i$(this is admissible because id_{X_i} refined it).
- check condition 2: G_0 obvious, G_1 by if $V \cap U_i \cap X_i$ admissible, then $V \cap X_i$ admissible by admissibility of $U_i \to U$, then V is admissible, G_2: obvious
- check condition 3: because $X_i \cap X_j \to X_i$ is admissible.

□

Def. (5.1.1.13). A G-topological space is called **connected** iff there isn't two nonempty admissible open subset X_1, X_2 that $X_1 \cap X_2 = \varnothing$ and $\{X_1, X_2 \to X\}$ is an admissible cover.

$\mathcal{G}$-torsor

Def. (5.1.1.14) [Torsors]. Let $\mathcal{C}$ be a site and $\mathcal{G} \in \mathcal{S}\mathrm{h}^{\mathcal{G}\mathrm{rp}}(\mathcal{C})$, then a **pseudo $\mathcal{G}$-torsor** is a sheaf of sets $\mathcal{F}$ over $\mathcal{C}$ endowed with an action $\mathcal{G} \times \mathcal{F} \to \mathcal{F}$ that $\mathcal{G} \times \mathcal{F} \to \mathcal{F} \times \mathcal{F} : (g, f) \mapsto (gf, f)$ is an isomorphism.

A pseudo $\mathcal{G}$-torsor is called a **$\mathcal{G}$-torsor** if for any $U \in \mathcal{C}$, there is a covering $\{U_i \to U\}$ that $\mathcal{F}(U_i)$ is non-empty for each i.

Prop. (5.1.1.15). A $\mathcal{G}$-torsor on a site is trivial iff $\Gamma(\mathcal{C}, \mathcal{F}) \neq 0$(5.3.1.1).

Proof: This is because the transitive action of $\mathcal{G}$ on the global section induces an isomorphism $\mathcal{G} \to \mathcal{F}$. □

Prop. (5.1.1.16). If $\mathcal{C}$ is a subcanonical site, and $\mathcal{G}$ a sheaf of groups over $\mathcal{C}$, then a sheaf of sets $\mathcal{F}$ together with an action $\alpha : \mathcal{G} \times \mathcal{F} \to \mathcal{F}$ is a G-torsor iff for any $U \in \mathcal{C}$, there is a covering $\{U_i \to U\}$ that the restrictions to U_i are trivial torsors, i.e. $\alpha|_{\mathcal{C}/U_i} = \pi_2 : \mathcal{G}|_{U_i} \times \mathcal{F}|_{U_i} \to \mathcal{F}|_{U_i}$.

Proof: If $\mathcal{F}$ is a $\mathcal{G}$-torsor, then the restrictions of the torsor on U_i are trivial because they have global sections in $\Gamma(\mathcal{C}/U_i, \mathcal{F}) = \mathcal{F}(U_i)$, by(5.1.1.15). Conversely, if there is a covering $\{U_i \to U\}$ that the restrictions to U_i are trivial torsors, then the map $\mathcal{G} \times \mathcal{F} \to \mathcal{F} \times \mathcal{F} : (g, f) \mapsto (gf, f)$ are isomorphisms when restricted to U_i, which means $\mathcal{G}(U) \times \mathcal{F}(U) \to \mathcal{F}(U) \times \mathcal{F}(U)$ is an isomorphism for any U, because they are sheaves, so it is an isomorphism, and $\mathcal{F}$ is a $\mathcal{G}$-torsor. □

Cor. (5.1.1.17) [Representable G-Torsor]. If $\mathcal{C}$ is a site and G is a group object in $\mathcal{C}$, then

- $X \to Y$ is a G-torsor in the category $\mathcal{C}/Y$ iff $X \to Y$ is a G-equivariant map(where the action of G on Y is trivial), $G \times X \to X \times_Y X : (g, x) \mapsto (gx, x)$ is an isomorphism, and $\{X \to Y\}$ is refined by a covering of Y.
- If $\mathcal{C}$ is a subcanonical site, then $X \to Y$ is a G-torsor in the category $\mathcal{C}/Y$ iff $X \to Y$ is a G-equivariant map(where the action of G on Y is trivial), and there exists a covering $\{Y_i \to Y\}$ that each $Y_i \times_Y X \to Y_i$ is a trivial torsor, i.e. G-equivariantly isomorphic to $G \times Y_i \to Y_i$.

Cor. (5.1.1.18). If $\mathcal{C}$ is a site and G is a group object in $\mathcal{C}$, $X \to Y$ is a G-torsor in the category $\mathcal{C}/Y$, then the map $G \times G \times X \to X \times_Y X \times_Y X : (g, h, x) \mapsto (ghx, hx, x)$ is an isomorphism.

Presheaves

Def. (5.1.1.19) [Presheaves]. Let $\mathcal{C}, \mathcal{D} \in \mathcal{C}\mathrm{at}$, then a **presheaf** of objects in $\mathcal{D}$ on $\mathcal{C}$ is a functor $\mathcal{C}^{op} \to \mathcal{D}$. The category of presheaves of objects in $\mathcal{D}$ on $\mathcal{C}$ is denoted by $\mathcal{PS}\mathrm{h}(\mathcal{C}; \mathcal{D})$. For any $U \in \mathcal{C}$, $\Gamma(U, -)$ is the functor $\mathcal{PS}\mathrm{h}(\mathcal{C}; \mathcal{D}) \to \mathcal{D} : F \mapsto F(U)$.

Prop. (5.1.1.20). If $\mathcal{D}$ is complete or cocomplete, and the same is true for $\mathcal{PS}\mathrm{h}(\mathcal{C}; \mathcal{D})$.

Def. (5.1.1.21) [Coherent Sheaves]. For $\mathcal{C} \in \mathcal{C}\mathrm{at}$, denote $\mathcal{PS}\mathrm{h}_\infty(\mathcal{C}) = \mathcal{PS}\mathrm{h}(\mathcal{C}; \mathcal{G}\mathrm{rpd}_\infty)$(3.6.2.5), called the category of **coherent sheaves** on $\mathcal{C}$. It is complete and cocomplete.

Def. (5.1.1.22) [Points]. A **point of a site** is a Cf.[Sta]00Y3.

2 Sheaves and Topoi

Def. (5.1.2.1) [Sheaves]. Let $\mathcal{C}$ be a site and $\mathcal{D} \in \mathcal{C}at_\infty$, then $\mathcal{F} \in \mathcal{PS}h(\mathcal{C}; \mathcal{D})$ is called a **sheaf** of objects in $\mathcal{D}$ on $\mathcal{C}$ iff for any sieve $\mathcal{S}$ on U belong to $\mathcal{C}$, the natural map

$$\mathrm{Map}(h_U, \mathcal{F}) \to \mathrm{Map}(h_{\mathcal{U}}, \mathcal{F})$$

is an equivalence?.

Def. (5.1.2.2) [Separate Presheaves]. Let $\mathcal{C}$ be a site, then $\mathcal{F} \in \mathcal{PS}h^{\mathcal{S}et}(\mathcal{C})$ is called a **separated presheaf** if $F(U) \hookrightarrow \prod_i F(U_i)$ is injective for any covering $\mathcal{U} = \{U_i \to U\} \in \mathrm{Cov}(\mathcal{C})$.

Def. (5.1.2.3)[Effective Epimorphisms]. An epimorphism $\{U_i \to V\}$ in a category is called a **family of effective epimorphisms** if

$$\mathrm{Hom}(V, Z) \to \prod \mathrm{Hom}(U_i, Z) \rightrightarrows \prod \mathrm{Hom}(U_i \times_V U_j, Z)$$

is exact for each Z. Similarly for a **family of universal effective epimorphisms**.

Prop. (5.1.2.4) [Subcanonical Site]. The class of all families of universal effective epimorphisms in a category forms a Grothendieck topology, called the **canonical topology**. It is the finest topology that all representable presheaves are sheaves.

Topologies that are coarser than the canonical topology are called **subcanonical topology**. Equivalently, a subcanonical topology is a topology that every representable presheaf is a sheaf.

Proof: We only need to verify that family of universal effective epimorphisms is closed under composition. For this, first prove epimorphism, then use epimorphism to prove effectiveness. Universal follows routinely. Cf.[Tamme]. □

Prop. (5.1.2.5). For a subcanonical topology on a site $\mathcal{C}$, its restriction on a localizing category $\mathcal{C}/S$ is subcanonical.

Proof: The only nontrivial part is that the glued morphism is a morphism over S. For this, consider its composition that maps to S, then the uniqueness of the exact sequence(5.1.2.3) will show that it is truly a S-morphism. □

Prop. (5.1.2.6). Let $\mathcal{C}$ be a subcanonical site, and $f : X \to Y$ is an arrow in $\mathcal{C}/S$, suppose there is a covering $\{S_i \to S\}$ that the pullback of f to $\mathcal{C}/S_i$ are all isomorphisms, then f is an isomorphism.

Proof: This follows from(5.1.3.6) and(5.1.3.8). □

Prop. (5.1.2.7) [Sheafification]. Let $\mathcal{C}$ be a site, consider the functor

$$(\cdot)^+ : \mathcal{PS}h^*(\mathcal{C}) \to \mathcal{S}h^*(\mathcal{C}) : F^+(U) = \varinjlim \ker(\prod_i F(U_i) \rightrightarrows \prod_{i,j} F(U_i \times_U U_j)) = \check{H}^0(U, F).$$

Then

- For $F \in \mathcal{PS}h^*(\mathcal{C})$, F^+ is separated.
- If $F \in \mathcal{PS}h^*(\mathcal{C})$ is separated, $F \to F^+$ is injective and $F^+ \in \mathcal{S}h^*(\mathcal{C})$. (The problem of separated is that the cover may not be identical in $U_i \times_U U_j$ but only on a cover of it).
- $(\cdot)^+$ is left exact.

- **sheafification functor** $(\cdot)^\# : \mathcal{PSh}^* \to \mathcal{Sh}^* : F \mapsto F^\# = F^{++}$ is exact and it is left adjoint to the forgetful functor.

So the forgetful functor is left exact and it preserves injectives. Thus the sheaf cokernel is the shifification of the presheaf kernel, the sheaf kernel is the presheaf kernel.

Proof: The separatedness is simple. For sheaf condition, an element of $F^+(U_i)$ is represented by a covering $\{V_{ij} \to U_i\}$, and there restriction to $U_i \times_U U_j$ coincide by separatedness hence the covering $\{V_{ij} \to U\}$ is an element of $F^+(U)$.

Sh is left exact because $(-)^+$ is left exact from $\mathcal{PSh}^*$ to $\mathcal{PSh}^*$ by(5.3.2.4) checked on every element U. It is right exact trivially, hence it is exact. □

Def. (5.1.2.8) [Constant Sheaves]. The **constant sheaf** $\underline{S}$ for a set S is the sheafification of the constant presheaf $U \mapsto S$.

Transfer of Sheaves under Morphisms of Sites

Def. (5.1.2.9) [Functoriality of Presheaves]. Given a functor of sites $u : \mathcal{C} \to \mathcal{C}'$, which should be regarded as an inverse map, there are maps

$$u^p F'(U) = F'(u(U)) : \mathcal{PSh}(\mathcal{C}') \to \mathcal{PSh}(\mathcal{C}), \quad u_p(F)(U') = \varinjlim_{U_i | U' \to u(U_i)} F(U_i) : \mathcal{PSh}(\mathcal{C}) \to \mathcal{PSh}(\mathcal{C}')$$

Then u_p is left adjoint to u^p.

We can also define a functor

$$_pu : {_pu}(F)(U') = \varprojlim_{\{U_i | u(U_i) \to U'\}^{op}} F(U_i) : \mathcal{PSh}(\mathcal{C}) \to \mathcal{PSh}(\mathcal{C}').$$

Then this functor is right adjoint to u^p, by duality.

Proof: A map $f \in \mathrm{Mor}(u_p(F), G)$ is represented by compatible maps

$$\varinjlim_{U_i : U' \to u(U_i)} F(U_i) \to G(U'),$$

and this is represented by compatible maps $F(U_i) \to G(U')$ which is indexed over $\prod_{U' \in \mathcal{C}'} \mathcal{I}_{U'}$, where $\mathcal{I}_{U'} = \{U_i : U' \to u(U_i)\}$. Now this is equivalent to compatible maps $F(U_i) \to G(u(U_i))$, which is a map $g \in \mathrm{Mor}(F, u^p(G))$. □

Cor. (5.1.2.10). u^p is exact.

Def. (5.1.2.11) [Functoriality of Sheaves].

- Given a continuous functor $u : \mathcal{C} \to \mathcal{C}'$ between sites, there are maps

$$u_s = \sharp \circ u_p \circ \iota : \mathcal{S} \to \mathcal{S}', \quad u^s = u^p \circ \iota : \mathcal{S}' \to \mathcal{S}.$$

  u_s is left adjoint to u^s, by adjointness of u_p, u^p and $\sharp, \iota$.

- Given a cocontinuous functor $u : \mathcal{C} \to \mathcal{C}'$ between sites, there are maps

$$u^s = \sharp \circ u^p \circ \iota : \mathcal{S}' \to \mathcal{S}, \quad {_su} = {_pu} \circ \iota : \mathcal{S} \to \mathcal{S}'.$$

  u^s is left adjoint to $_su$, by adjointness of $u^p, {_pu}$ and $\sharp, \iota$. Moreover, u^s is exact.

Proof: 1: Notice if $\mathcal{F}$ is a sheaf, then $u^s\mathcal{F}$ is also a sheaf, by continuity(5.1.1.5).

2: ${}_pu\mathcal{F}$ is a sheaf by [Sta]00XK**?**. u^p is clearly right exact, and it is left exact because $\iota, \sharp$ do, and u^p is exact by(5.1.2.10). ☐

Cor. (5.1.2.12). When u is continuous, $(u_p(G))^\sharp \cong (u_p(G^\sharp))^\sharp$ for any presheaf G on T.
When u is cocontinuous, $(u^pG)^\sharp \cong (u^p(G^\sharp))^\sharp$ for any presheaf G on T.

Proof: Use Yoneda lemma. ☐

Prop. (5.1.2.13). For $Z \in T$, $u_p h_Z = h_{u(Z)}$.

Proof: Use the adjointness of u_p, u^p(5.1.2.9), then for any presheaf F,

$$\mathrm{Hom}(u_p h_Z, F) = \mathrm{Hom}(h_Z, u^p F) = f^p(F)(Z) = F(f(Z)),$$

thus we are done by Yoneda lemma. ☐

Prop. (5.1.2.14) [When is u_s Exact]. If $f : \mathcal{C} \to \mathcal{C}'$ is a continuous functor between sites that $\mathcal{I}_{U'}$ is cofiltered for any $U' \in \mathcal{C}'$, where $\mathcal{I}_{U'}$ is the category of all pairs (U, φ) where $U \in \mathcal{C}$ and $\varphi : U' \to u(U)$, then u_s is exact.

In particular, this is the case when $\mathcal{C}, \mathcal{C}'$ both have weakly final objects and finite fiber products and u preserves them. Notice the condition of weakly final objects can be released if we can show $\mathcal{I}_{U'}$ is nonempty for any U'.

Proof: It suffices to show the left exactness of u_p. By definition, $u_p(U') = \varinjlim_{\mathcal{I}_{U'}^{op}} F_{U'}$ where $F_{U'}$ is the covariant functor $(U, \varphi) \to F(U)$. Because $\mathcal{I}_{U'}^{op}$ is filtered, this colimit process is exact form $\mathrm{Hom}(\mathcal{I}_{U'}^{op}, \mathcal{A}b)$ to $\mathcal{A}b$ and u_p is exact. Now shifification is also exact(5.1.2.7), so we conclude.

The last assertion is clear.(Notice the weakly-final object are used to assure $\mathcal{I}_{U'}$ is nonempty.) ☐

Prop. (5.1.2.15) [Localization Site]. For a site T and $Z \in T$, there is a site T/Z as objects over T, and $i : T/Z \to T$ is continuous. Then i^s is exact.

Proof: $R^q i^s(F) = (i^p(\mathcal{H}^q(F)))^\sharp$(5.3.1.7), and $(\mathcal{H}^q(F))^\sharp = 0$(5.3.2.14), so it suffices to show i^p and $\sharp$ commutes. But i^s and $^+$ commutes obviously. ☐

Prop. (5.1.2.16) [Sheaf Condition is Local]. To check sheaf condition for presheaf w.r.t. a topology, it suffice to show that for any covering, there is a refinement covering of it that sheaf condition hold, because by the definition of sheafification functor, $F^+ = F$, so F is a sheaf.

Cor. (5.1.2.17). For two topology on a same category that $\mathcal{I}'$ is finer than $\mathcal{I}$, then any $\mathcal{I}'$-sheaf is a $\mathcal{I}$-sheaf. And if any covering in $\mathcal{I}'$ can be refined by a covering in $\mathcal{I}$, then $\mathcal{S} \to \mathcal{S}'$ is an equivalence of categories. In particular, if T is Noetherian, $\mathcal{S}(T)$ and $\mathcal{S}(T^f)$(5.1.1.3) are equivalent.

Topoi

Def. (5.1.2.18) [Topoi]. A **topos** is an Abelian category that is equivalent to the category of sheaves $\mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C})$ on a site $\mathcal{C}$. A **morphism of topoi** $f : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \to \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{D})$ is an adjunction

$$f^{-1} : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{D}) \rightleftarrows \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) : f_*$$

s.t. f^{-1} is exact. Compositions of morphisms of topoi are defined routinely. A **2-morphism of topoi** between two morphisms of topoi $f, g : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \to \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{D})$ is a natural transformation $t : f_* \to g_*$.

Prop. (5.1.2.19) [Presheaves and Topoi]. $\mathcal{C} \in \mathcal{C}\mathrm{at}$ is a Grothendieck category iff it is a left exact, reflective accessible localization**??** of $\mathcal{P}\mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{A})$ for some $\mathcal{A} \in \mathcal{C}\mathrm{at}$.

Sites and Topoi

Prop. (5.1.2.20) [Continuous Maps and Topoi]. A morphism of sites $f : \mathcal{D} \to \mathcal{C}$ consists of a continuous functor $u : \mathcal{C} \to \mathcal{D}$ that u_s is exact, so it induces a functor of topoi $f : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \to \mathcal{S}\mathrm{h}(\mathcal{D})$, if we define $f^{-1} = u_s$, $f_* = u^s$, by(5.1.2.11).

Prop. (5.1.2.21) [Cocontinuous Maps and Topoi]. Let $u : \mathcal{C} \to \mathcal{D}$ be a cocontinuous functor between sites, then this defines a morphism of topoi $g : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \to \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{D})$, if we define $g^{-1} = u^s$ and $g_* = {}_s u$, by(5.1.2.11).

Prop. (5.1.2.22) [Cocontinuous Map with a Right Adjoint]. Let $u : \mathcal{C} \to \mathcal{D}$ be a cocontinuous functor between sites with a right adjoint $v : \mathcal{D} \to \mathcal{C}$, then the morphism of topoi $g : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \to \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{D})$ is pretty simple,

$$g^{-1}\mathcal{G}(U) = \mathcal{G}(u(U)), \quad g_*\mathcal{F}(V) = \mathcal{F}(v(V)).$$

This holds in particular for localization of sites.

Proof: It follows from adjunction that $u^p h_V = h_{v(V)}$, so $g^{-1}(h_V^\sharp) = (u^p h_V^\sharp)^\sharp = (u^p h_V)^\sharp = h_{v(V)}^\sharp$, and

$$(g_*\mathcal{F})(V) = \mathrm{Hom}(h_V^\sharp, g_*\mathcal{F}) = \mathrm{Hom}(g^{-1}h_V^\sharp, \mathcal{F}) = \mathrm{Hom}(h_{v(V)}^\sharp, \mathcal{F}) = \mathcal{F}(v(V)).$$

The other identity is clear. □

Prop. (5.1.2.23) [Continuous and Cocontinuous Maps and Topoi]. Let $u : \mathcal{C} \to \mathcal{D}$ be a functor between sites that satisfies

- u is continuous and cocontinuous,
- u is fully faithful,
- $\mathcal{C}$ has final objects and fiber products and u preserves them.

then there are two maps of topoi: $f = (u_s, u^s) : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{D}) \to \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}), g = (u^s, {}_s u) : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \to \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{D})$ induced by u(5.1.2.20)(5.1.2.14)(5.1.2.21). They satisfy $f \circ g = \mathrm{id}_{\mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C})}$, and $f^{-1} = u_s$ is fully faithful.

In particular, if we define $g_! = u_s$, then there are two adjunctions

$$(g_!, g^{-1}) : \mathcal{S}\mathrm{h}(\mathcal{C}) \rightleftharpoons \mathcal{S}\mathrm{h}(\mathcal{D}), \quad (g^{-1}, g_*) : \mathcal{S}\mathrm{h}(\mathcal{D}) \rightleftharpoons \mathcal{S}\mathrm{h}(\mathcal{C}).$$

Proof: We need to show that for any $\mathcal{F} \in \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C})$, $\mathcal{F} \cong g^{-1}g_!\mathcal{F}$ and $g^{-1}g_*\mathcal{F} \cong \mathcal{F}$. For this, Cf.[Sta]00XT.?

Then $f^!$ is fully faithful follows from the equality $\mathcal{F} \cong g^{-1}g_!\mathcal{F}$. □

Prop. (5.1.2.24) [Special Cocontinuous Maps and Topoi]. A functor $u : \mathcal{C} \to \mathcal{D}$ between sites is called a **special cocontinuous functor** if:

- u is continuous and cocontinuous,
- Given any $a, b : U' \to U \in \mathcal{C}$ s.t. $u(a) = u(b) : u(U') \to u(U)$, there is a covering $\{f_i : U_i' \to U'\}$ that $af_i = bf_i$.
- Given any $U', U \in \mathcal{C}$ and a morphism $c : u(U') \to u(U) \in \mathcal{D}$, there exists a covering $\{f_i : U_i' \to U'\} \in \mathcal{C}$ and morphisms $c_i : U_i' \to U$ that $u(c_i) = c \circ u(f_i)$.
- Given any $V \in \mathcal{D}$, there is a covering of the form $\{u(U_i) \to V\}$ in $\mathcal{D}$.

Then the induced morphism of topoi $g : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \cong \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{D})$(5.1.2.21) is an equivalence of topoi.

Proof: Cf.[Sta]03A0.? □

Cor. (5.1.2.25) [Comparing Topologies]. Let $\mathcal{C}'$ be a fully subcategory of $\mathcal{C}$, and

- $i : \mathcal{C}' \to \mathcal{C}$ is continuous, i.e. $\mathrm{Cov}(\mathcal{C}') \to \mathrm{Cov}(\mathcal{C})$.
- $i : \mathcal{C}' \to \mathcal{C}$ is cocontinuous, i.e. any covering $\{U_i \to U'\} \in \mathrm{Cov}(\mathcal{C})$ s.t. $U' \in \mathcal{C}'$ has a refinement $\{U_j' \to U'\} \in \mathrm{Cov}(\mathcal{C}')$.
- Each $U \in \mathcal{C}$ has a covering $\{U_i \to U\} \in \mathrm{Cov}(\mathcal{C})$ with $U_i \in T'$.

then $i : \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}') \to \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C})$ is an equivalence of topoi. i^{-1} is just the restriction functor, and i_* is called the **extension functor of sheaves**.

In particular, this applies to the case $i : \mathcal{C}' = \mathcal{C}/Z \to \mathcal{C}$, the localization category, in with case for $Z' \in \mathcal{C}/Z$, $i^{-1}F(Z') = F(Z')$ is called the **restriction sheaf**.

Prop. (5.1.2.26) [Localizing at Sheaves]. Let $\mathcal{C}$ be a site and $\mathcal{F}_i$ be a set of topos on $\mathcal{C}$, then there is an equivalence $\mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}) \cong \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{C}')$ induced by a special cocontinuous functor $\mathcal{C} \to \mathcal{C}'$(5.1.2.24) s.t.

- $\mathcal{C}'$ has the subcanonical topology,
- A family of morphisms $\{V_i \to V\}$ are a covering of $\mathcal{C}'$ iff $\coprod h_{V_I} \to h_V$ is surjective.
- $\mathcal{C}'$ has fiber products and a final object.
- Every subsheaf of a representable sheaf is representable,
- Each $g_*\mathcal{F}_i$ is a representable sheaf.

Proof: Cf.[Sta]03CI. □

3 Stacks

Def. (5.1.3.1) [Stacks]. Let $\mathcal{F} \to \mathcal{C}$ be a fibered category on a site $\mathcal{C}$. Then $\mathcal{F}$ is called a **prestack** over $\mathcal{C}$ if for each covering $\{U_i \to U\}$ in $\mathcal{C}$, the functor $\mathrm{Hom}(h_U, \mathcal{F}) \to \mathrm{Hom}(h_{\mathcal{U}}, \mathcal{F})$(5.1.1.7) is fully faithful. It is called a **stack** over $\mathcal{C}$ if it is moreover an equivalence of categories.

Def. (5.1.3.2) [Category of Descent Datum]. Let $\mathcal{F} \to \mathcal{C}$ be a fibered category on a site $\mathcal{C}$, $U \in \mathcal{C}$ and $\mathcal{U}$ is a covering of U. Given a choice of fibered products U_{ij}, U_{ijk} in $\mathcal{C}$, we can define the **category of descent datum** $\mathcal{F}_{desc}(\mathcal{U})$ to be the category of tuples $(\xi_i, \xi_{ij}, \xi_{ijk})$ where $\xi_\alpha \in \mathcal{F}(U_\alpha)$ with Cartesian morphisms between them that are commutative. A morphism in $\mathcal{F}_{desc}(\mathcal{U})$ is a family of morphisms $(\varphi_i, \varphi_{ij}, \varphi_{ijk})$ commuting with the Cartesian morphisms.

Then there is an equivalence of categories $\mathrm{Hom}(h_{\mathcal{U}}, \mathcal{F}) \cong \mathcal{F}_{desc}(\mathcal{U})$.

Proof: For any $F : h_{\mathcal{U}} \to \mathcal{F}$, $U_i \to U \in h_{\mathcal{U}}(U_i)$, applying F to the arrows $\mathrm{id}_{U_i}, U_{ij} \to U_i, U_{ijk} \to U_{ij} \in h_{\mathcal{U}}$, we get an element in $\mathcal{F}_{desc}(\mathcal{U})$. Also a natural transformation $F \to G$ maps to a morphism in $\mathcal{F}_{desc}(\mathcal{U})$, so we get a functor $T : \mathrm{Hom}(h_{\mathcal{U}}, \mathcal{F}) \to \mathcal{F}_{desc}(\mathcal{U})$.

Conversely, choose an arbitrary choice of pullbacks(that coincide with $\xi_{ij} \to \xi_i$), for any arrow $f : T \to U \in h_{\mathcal{U}}(T)$, we choose a U_i that $T \to U$ factors as $T \to U_i \to U$(also for $f = \mathrm{id}_{U_i}$, choose U_i), then define $F(f)$ as the pullback of ξ_i along $T \to U_i$. For any morphisms $T' \to T \to U \in h_{\mathcal{U}}$ and their choice of U_i, U_j that $T' \to U$ factors through $U_j \to U$ and $T \to U$ factors as $U_i \to U$, then $T' \to U_j$ factors through U_{ij}, i.e. we have a commutative diagram

$$\begin{array}{ccccc} T' & \longrightarrow & U_{ij} & \longrightarrow & U_j \\ \downarrow & & \downarrow & & \downarrow \\ T & \longrightarrow & U_i & \longrightarrow & U \end{array}.$$

Then by Cartesian properties, we get a unique map $F(T') \to F(T)$, which is Cartesian by(3.1.8.8). It can be shown these maps make F a functor, using Cartesian property and the existence of ξ_{ijk}. And also for any map of descent datum, we get a natural transformation in $\mathrm{Hom}(h_{\mathcal{U}}, \mathcal{F})$. Thus we get a functor $S : \mathcal{F}_{desc}(\mathcal{U}) \to \mathrm{Hom}(h_{\mathcal{U}}, \mathcal{F})$.

The construction of S shows T is essentially surjective and full, and also faithful, so (S, T) is an equivalence of categories. □

Def. (5.1.3.3) [Everyday Descent Datums]. Let $\mathcal{F}/\mathcal{C}$ be a fibered category on a site $\mathcal{C}$, $U \in \mathcal{C}$ and $\mathcal{U}$ is a covering of U. Given a choice of fibered products U_{ij}, U_{ijk} in $\mathcal{C}$ and a cleavage of $\mathcal{F}/\mathcal{C}$, let $\mathcal{F}(\mathcal{U})$ be the category of tuples (ξ_i, φ_{ij}) where $\xi_i \in \mathcal{F}(U_i)$ and φ_{ij} are isomorphisms $\varphi_{ij} : \mathrm{pr}_1^* \xi_i \cong \mathrm{pr}_2^* \xi_j \in \mathcal{F}(U_{ij})$ s.t.

$$\mathrm{pr}_{13}^* \varphi_{ik} = \mathrm{pr}_{23}^* \varphi_{jk} \circ \mathrm{pr}_{12}^* \varphi_{ij} : \mathrm{pr}_1^* \xi_i \cong \mathrm{pr}_3^* \xi_k.$$

WARNING: Notice this doesn't make sense unless we insect three isomorphisms such as $\mathrm{pr}_{12}^* \mathrm{pr}_1^* \xi_i \cong \mathrm{pr}_{13}^* \mathrm{pr}_1^* \xi_i$.

Then there is a (non-canonical!)equivalence of categories $\mathcal{F}_{desc}(\mathcal{U}) \to \mathcal{F}(\mathcal{U})$.

Proof: For $(\xi_i, \xi_{ij}, \xi_{ijk}) \in \mathcal{F}_{desc}(\mathcal{U})$, there are isomorphisms $\xi_{ij} \cong \mathrm{pr}_1^* \xi_i$ and $\xi_{ij} \cong \mathrm{pr}_2^* \xi_j$, which gives an isomorphism $\varphi_{ij} : \mathrm{pr}_1^* \xi_i \to \mathrm{pr}_2^* \xi_j$. This gives an element of $\mathcal{F}(\mathcal{U})$, by comparison with ξ_{ijk}.

Conversely, given $(\xi_i, \varphi_{ij}) \in \mathcal{F}(\mathcal{U})$, choose an ordering on I, for $i < j$, let $\xi_{ij} = \mathrm{pr}_1^* \varphi_i$, and $\mathrm{pr}_2^* \circ \varphi_{ij} : \xi_{ij} \to \xi_j$ is Cartesian. And for $i < j < k$, let $\xi_{ijk} = \mathrm{pr}_1^* \xi_i$, then there are Cartesian morphisms $\xi_{ijk} \to \xi_{ij}, \xi_{ijk} \to \xi_{ik}, \xi_{ijk} \to \xi_{jk}$ by Cartesian properties, and it can be verified that the cocycle condition guarantees the diagram can be completed. □

Cor. (5.1.3.4) [Cocycle Conditions]. If $\mathcal{F}/\mathcal{C}$ is a rigid fibered category, then there is no need to check the cocycle condition, because every automorphism over id_U is trivial.

Cor. (5.1.3.5) [Stacks and Sheaves]. A rigid (pre)stack over a site $\mathcal{C}$ is equivalent to a (pre)sheaf on $\mathcal{C}$, by(3.1.8.28).

Cor. (5.1.3.6). A site is subcanonical iff any representable fibered category $h_U \to C$ is a stack.

Prop. (5.1.3.7) [Equivalence Categories and Stacks]. Let $\mathcal{F} \to \mathcal{G}$ be an equivalence of fibered categories over a site $\mathcal{C}$, then $\mathcal{F}$ is a prestack/stack(in groupoid) iff $\mathcal{G}$ is.

Proof: There is a strict commutative diagram of categories

$$\begin{array}{ccc} \mathrm{Hom}(h_U, \mathcal{F}) & \longrightarrow & \mathrm{Hom}(h_{\mathcal{U}}, \mathcal{F}) \\ \downarrow & & \downarrow \\ \mathrm{Hom}(h_U, \mathcal{G}) & \longrightarrow & \mathrm{Hom}(h_{\mathcal{U}}, \mathcal{G}) \end{array}$$

that the vertical arrows are equivalences of categories, then we are done. □

Prop. (5.1.3.8) [Prestack and Hom Functor]. Let $\mathcal{F}$ be a fibered category over a site $\mathcal{C}$, then $\mathcal{F}$ is a prestack iff for any object S of $\mathcal{C}$ and two objects $\xi, \eta \in \mathcal{F}(S)$, the presheaf $\underline{\mathrm{Hom}}_S(\xi, \eta) : (\mathcal{C}/S)^{op} \to \mathcal{S}et$(3.1.8.19) is a sheaf in the comma site $\mathcal{C}/S$(5.1.1.4).

Proof: By(5.1.3.7), it suffices to show $\mathcal{H}om_S(\xi, \eta)$ is a stack in the comma topology $\mathcal{C}/S$. Then it can be shown that $\mathrm{Hom}(h_U, \underline{\mathrm{Hom}}_S(\xi, \eta)) \to \mathrm{Hom}(h_{\mathcal{U}}, \underline{\mathrm{Hom}}_S(\xi, \eta))$ is an equivalence of categories iff $\mathrm{Hom}(h_U, \mathcal{F}) \to \mathrm{Hom}(h_{\mathcal{U}}, \mathcal{F})$ is fully faithful. □

Lemma (5.1.3.9). Let $\mathcal{F}$ be a prestack over a site $\mathcal{C}$, S, S' be sieves belonging to the topology of $\mathcal{C}$ that $S' \subset S$, then the restriction functor
$$\mathrm{Hom}_{\mathcal{C}}(S,\mathcal{F}) \to \mathrm{Hom}_{\mathcal{C}}(S',\mathcal{F})$$
is faithful.

Proof: it suffices to show for $S' = h_{\mathcal{U}}$ for some covering $\mathcal{U}$. Let $F, G \in \mathrm{Hom}_{\mathcal{C}}(S',\mathcal{F})$ and φ, ψ be two natural transformations from F to G that induce the same natural transformation from the restriction of F to $h_{\mathcal{U}}$ to the restriction of G to $h_{\mathcal{U}}$, then $\varphi = \psi$. For this, just notice there are commutative diagrams
$$\begin{array}{ccc} F(T\times_U U_i/U) & \xrightarrow{\varphi_{T\times_U U_i/U}} & G(T\times_U U_i/U) \\ \downarrow & & \downarrow \\ F(T/U) & \xrightarrow{\varphi_{T/U}} & G(T/U) \end{array},$$
where the vertical arrows are Cartesian, and the hypothesis implies $\varphi_{T\times_U U_i/U} = \psi_{T\times_U U_i/U}$. Then we deduce $\varphi_{T/U} = \psi_{T/U}$ as $\underline{\mathrm{Hom}}_T(F(T/U), G(T/U))$ is a sheaf, as $\mathcal{F}$ is a presheaf(5.1.3.8). □

Prop. (5.1.3.10) [Stack and Sieves]. A prestack $\mathcal{F} \to \mathcal{C}$ is stack iff for any $U \in \mathcal{C}$ and any sieve $\mathcal{S}$ on U belonging to $\mathcal{T}$,
$$\mathrm{Hom}(h_U,\mathcal{F}) \to \mathrm{Hom}(\mathcal{S},\mathcal{F})$$
is an equivalence of categories.

Proof: Let $\mathcal{S}$ be a sieve on U belong to $\mathcal{C}$, choose a covering $\mathcal{U}$ of U that $h_{\mathcal{U}} \subset \mathcal{S} \subset h_U$, then there is a factorization
$$\mathrm{Hom}(h_{\mathcal{U}},\mathcal{F}) \to \mathrm{Hom}(\mathcal{S},\mathcal{F}) \to \mathrm{Hom}(h_U,\mathcal{F}).$$
Then we are done by(5.1.3.9). □

Cor. (5.1.3.11). let $\mathcal{T}, \mathcal{T}'$ be two topologies on a category $\mathcal{C}$ that T' is subordinate to $\mathcal{T}$ and $\mathcal{F} \to C$ is a fibered category, then if $\mathcal{F}$ is a prestack/stack relative to $\mathcal{T}$, it is also true for $\mathcal{T}'$.

Prop. (5.1.3.12)[2-Fiber Products of Stacks]. There is a natural 2-category of stacks over $\mathcal{C}$ defined as a sub-2-category of the 2-category of fibered-categories over $\mathcal{C}$, and the $(2,1)$-category of stacks over $\mathcal{C}$ has 2-fibered products, which coincides with that of(3.1.8.15).

Proof: Let $\mathcal{X} \to \mathcal{S}, \mathcal{Y} \to \mathcal{S}$ be morphisms of stacks over $\mathcal{C}$, then the category $\mathcal{X} \times_{\mathcal{S}} \mathcal{Y}$ is a fibered category over $\mathcal{C}$, by(3.1.8.15). It remains to show that the morphism presheaves sheaves and descent datum are effective.

For this, Cf.[Sta]026G. □

Prop. (5.1.3.13) [Associated Stack in Groupoids]. Let $\mathcal{C}$ be a site and $\mathcal{F}$ be a prestack, and $\mathcal{F}_{cart}$ is the associated category fibered in groupoids(3.1.8.24), then $\mathcal{F}_{cart}$ is also a prestack. And in this case, $\mathcal{F}$ is a stack iff $\mathcal{F}_{cart}$ is a stack.

Proof: The categories $\mathcal{F}(\mathcal{U})$ and $\mathcal{F}_{cart}(\mathcal{U})$ have the same isomorphism classes of objects, as isomorphisms are Cartesian, so it suffices to show $\mathcal{F}$ is a prestack iff $\mathcal{F}_{cart}$ is a prestack. For this, use(5.1.3.8) and consider $\xi, \eta \in \mathcal{F}(U)$ and a covering $\{U_i \to U\}$, if there are arrows $\alpha_i : \xi_i \to \eta_i$ that are compatible, then there is a unique arrow $\alpha : \xi \to \eta$ restricting to α_i, thus it suffices to show α is Cartesian. But since $\mathcal{F}_{cart}$ is a category fibered in groupoids, each α_i is invertible, and their inverses glue together to a morphism $\beta : \eta \to \xi$ which is the inverse of α, so α is also an isomorphism thus Cartesian. □

Prop. (5.1.3.14)[2-Fibered Products of Stacks Fibered in Groupoids]. Let $\mathcal{C}$ be a category, the 2-category of stacks fibered in groupoids over $\mathcal{C}$(automatically a $(2,1)$-category) has 2-fiber products, and coincide with that of(5.1.3.12).

Proof: This is clear from(5.1.3.12) and(3.1.8.26). □

Prop. (5.1.3.15)[Equivalence of Stacks]. Let $F : \mathcal{S}_1 \to \mathcal{S}_2$ be a morphism of stacks over a site $\mathcal{C}$. If F is fully faithful, then F is an equivalence iff for any $x \in \mathcal{S}_{2,U}$, there exists a covering $\{f_i : U_i \to U\}$ s.t. $f_i^* x$ is in the essential image of the functor $F : \mathcal{S}_{1,U} \to \mathcal{S}_{2,U}$.

Proof: Easy. □

Prop. (5.1.3.16)[Subcanonical Site Prestack]. If $\mathcal{C}$ is a subcanonical site(5.1.2.4) and $\mathcal{P}$ is a class of arrows in $\mathcal{C}$ stable under base change, then the corresponding fibered category $\mathcal{P} \to \mathcal{C}$ is a prestack.

Proof: By(5.1.3.8), we need to prove for any covering $\{U_i \to U\}$ and arrows $X \to U, Y \to U$, $X_i = U_i \times_U X$, and $X_{ij} = U_{ij} \times_U X$ and analogous for Y, if there are arrows $f_i : X_i \to Y_i$ over U_i that the arrows $X_{ij} \to Y_{ij}$ induced by f_i and f_j coincide, then there is a unique arrow $f : X \to Y$ over U that induces f_i.

Notice that the composite $X_i \xrightarrow{f_i} Y_i \to Y$ give sectiosn $g_i \in h_Y(X_i)$, and the pullback of g_i, g_j to X_{ij} coincide by hypothesis. Now h_Y is a sheaf by hypothesis, so there is an arrow $f : X \to Y$ that pulls back to f_i on X_i. Finally f is compatible over U because $(Y \to U) \circ f$ and $(X \to U)$ coincide when composed with $X_i \to X$, and h_U is a sheaf. □

Prop. (5.1.3.17) [Category of Sheaves is a Stack]. Let $\mathcal{C}$ be a site, we denote $(\mathcal{S}\mathrm{h}/\mathcal{C})(X) = \mathcal{S}\mathrm{h}(\mathcal{C}/X)$, then $\mathcal{S}\mathrm{h}/\mathcal{C}$ is a stack over $\mathcal{C}$.

Proof: To show $Sh/\mathcal{C}$ is a prestack, by(5.1.3.8), it suffices to show for any $F, G \in \mathcal{S}\mathrm{h}(\mathcal{C}/X)$, $\underline{\mathrm{Hom}}_X(F, G)$ is a sheaf. For this, let $\{U_i \to U\}$ be a covering, and $\varphi_i : F_{U_i} \to G_{U_i}$ be morphisms of sheaves that their restrictions to $F_{U_{ij}} \to \mathcal{G}_{U_{ij}}$ are compatible, then for any $T \to U$, there are commutative diagrams

$$\begin{array}{ccccc} F(T) & \longrightarrow & \prod_i F_i(T_i) & \longrightarrow & \prod_{i,j} F_{ij}(T_{ij}) \\ \downarrow & & \downarrow & & \downarrow \\ G(T) & \longrightarrow & \prod_i G_i(T_i) & \longrightarrow & \prod_{i,j} G_{ij}(T_{ij}) \end{array}$$

where $\varphi_T : F(T) \to G(T)$ is the unique function of sets that makes the diagram commutative. And it can be shown that these φ_T defines a natural transformation $F_U \to G_U$.

Now for any covering $\{U_i \to U\}$ and a descent datum (F_i, F_{ij}), we need to show it is effective. We define a function F on $\mathcal{C}/U$: $F(T) = \mathrm{equal}(\prod_i F(T_i) \rightrightarrows \prod_{ij} F(T_{ij}))$, then it can be shown that this is a sheaf by spectral seqence.

Then it suffices to check $F_{U_k} = F_k$. For any $T \to U_k$, T_i maps to U_{ik}, so $F_i(T_i) = F_k(T_i)$, thus for any $s \in F_k(T)$, we can produce an element $(s_{T_i}) \in \prod_i F_i(T_i)$ that satisfies compatibility conditions, which gives us an element of $F(T)$. It can be shown this is a natural transformation $F_k \to F_{U_k}$, and it is an isomorphism of sheaves. □

Prop. (5.1.3.18)[Descent Along Torsors]. Let $\mathcal{C}$ be a site, G a group object and $X \to Y$ a G-torsor, $\mathcal{F} \to \mathcal{C}$ a stack. Then there exists a canonical equivalence of categories between $\mathcal{F}(Y)$ and the category of G-equivariant objects $\mathcal{F}^G(X)$(3.1.8.17).

Proof: By(5.1.1.17) $X \to Y$ is refined by a covering, thus by(5.1.3.10), $\mathcal{F}(Y)$ is equivalent to $\mathcal{F}(X \to Y)$. And we check $\mathcal{F}(X \to Y) \cong \mathcal{F}^G(X)$. Then by(5.1.1.18), $\mathcal{F}(X \to Y)$ consists of elements $\xi \in \mathcal{F}(X), \eta \in \mathcal{F}(G \times X)$ and Cartesian arrows φ_1, φ_2 over α, π_2. Cf.[Vis08]P106.? □

Stackifications

Prop. (5.1.3.19) [Stackification]. Let $\mathcal{C}$ be a site and $p:\mathcal{F}\to\mathcal{C}$ a fibered category over $\mathcal{C}$, then there exists a stack $p':\mathcal{F}'\to\mathcal{C}$ and a morphism $G:\mathcal{F}\to\mathcal{F}'$ of fibered categories over $\mathcal{C}$ s.t. for any stack $\mathcal{X}\to\mathcal{C}$, a morphism $F:\mathcal{F}\to\mathcal{X}$ of fibered categories over $\mathcal{C}$ factors through G 2-commutatively and uniquely up to 2-isomorphisms. In other words, there is a canonical equivalence of categories:

$$\mathrm{Mor}_{Fib/\mathcal{C}}(\mathcal{F},\mathcal{X})\cong\mathrm{Mor}_{\mathcal{S}\mathrm{ta}/\mathcal{C}}(F',\mathcal{X}).$$

In particular, such a stack $\mathcal{F}'$ is determined up to unique 2-isomorphisms, and is called the **stackification** of $\mathcal{F}$.

Proof: By(3.1.8.20), we may assume $\mathcal{F}$ is split, thus $\mathcal{F}$ corresponds to the functor $\mathcal{C}^{op}\to Cat: U\mapsto\mathrm{Hom}(h_U,\mathcal{F})$. Then we define a functor

$$\mathcal{F}':\mathcal{C}^{op}\to\mathcal{C}\mathrm{at}:U\mapsto\varinjlim_{\mathcal{U}\in\mathrm{Cov}(U)}\mathrm{Hom}(h_{\mathcal{U}},\mathcal{F}).$$

then there is a natural map of fibered categories $\mathcal{F}\to\mathcal{F}'$. For any stack $\mathcal{X}\to C$, because $\mathrm{Hom}(h_U,\mathcal{X})\to\mathrm{Hom}(h_{\mathcal{U}},\mathcal{X})$ is an isomorphism for any covering $\mathcal{U}$ of U, we get the desired equivalence of categories. □

Cor. (5.1.3.20). Let $G:\mathcal{S}\to\mathcal{S}'$ be the stackification of a fibered category over $\mathcal{C}$, then

- For any $U\in\mathcal{C}$ and $x,y\in\mathcal{S}_U$, the map
$$\mathcal{H}om(x,y)\to\mathcal{H}om(G(x),G(y))$$
identifies the RHS as the shifification of the LHS.
- For any $U\in\mathcal{C}$ and $x\in\mathcal{S}'_U$, there exists a covering $\{U_i\to U\}$ that for any i, $x|_{U_i}$ is in the essential image of $G_U:\mathcal{S}_U\to\mathcal{S}'_U$.

Proof: Cf.[Sta]0435. □

Prop. (5.1.3.21) [Stackifications Commute with 2-Fibered Products]. Stackifications commute with 2-fibered products.

Proof: Cf.[Sta]04Y1. □

Prop. (5.1.3.22). If $\mathcal{F},\mathcal{G}$ are prestacks over a topological space X, if there is a morphism $\eta:\mathcal{F}\to\mathcal{G}$ that satisfies:

- $\mathcal{F}$ is a stack and $\mathcal{G}$ is a prestack.
- η induces isomorphisms on stalks.
- $\eta(U):\mathcal{F}(U)\to G(U)$ is fully faithful.

Then η is an equivalence of prestacks. In particular, $\mathcal{G}$ is also a stack.

Proof: Let $\mathcal{H}$ be the stackification of $\mathcal{G}$, then $\mathcal{F}\to\mathcal{G}\to\mathcal{H}$ is a morphism of stacks that is isomorphism on the stalk, so it is an isomorphism**?**. But G is separated, so for any open U, $\mathcal{F}(U)\to\mathcal{G}(U)$, $\mathcal{G}(U)\to\mathcal{H}(U)$ is fully faithful, and their composition is an equivalence, thus both of them are equivalences. □

Gerbes

Def. (5.1.3.23) [Gerbe]. Let $\mathcal{C}$ be a site, a **gerbe** over $\mathcal{C}$ is a stack in groupoids over $\mathcal{C}$ s.t.

- For any $U \in \mathcal{C}$, there is a covering $\{U_i \to U\}$ that S_{U_i} is nonempty for any i.
- For any $U \in \mathcal{C}$ and $x, y \in \mathcal{S}_U$, there exists a covering $\{U_i \to U\}$ that $x|_{U_i} = y|_{U_i}$ for any i.

Prop. (5.1.3.24). Let $p : \mathcal{S} \to \mathcal{C}$ be a gerbe over a site $\mathcal{C}$, assume that for all $U \in \mathcal{C}$ and $x \in \mathcal{S}_U$, the sheaf of groups $\mathrm{Aut}(x)$ on $\mathcal{C}/U$ is Abelian, then there exists a sheaf of Abelian groups over $\mathcal{C}$ and for any $x \in \mathcal{S}_U$ an isomorphism $\mathcal{G}|_U \to \mathrm{Aut}(x)$ that for any morphism $\varphi : x \to y \in \mathcal{S}_U$, the diagram

$$\begin{array}{ccc} \mathcal{G}|_U & = & \mathcal{G}|_U \\ \downarrow & & \downarrow \\ \mathrm{Aut}(x) & \xrightarrow{\alpha \mapsto \varphi \circ \alpha \circ \varphi^{-1}} & \mathrm{Aut}(y) \end{array}$$

is commutative.

Proof: It can be checked by using the fact $\mathrm{Aut}(x)$ is Abelian that there are canonical morphisms $\mathrm{Aut}(x) \to \mathrm{Aut}(y)$ induced by any morphism $\varphi : x \to y$.

If there is no morphism from x to y, then we can use the condition of gerbe to obtain morphisms $\mathrm{Aut}(x)|_{U_i} \to \mathrm{Aut}(y)|_{U_i}$ locally, and then glue together. Similarly, if $\mathcal{S}_U$ is empty, then we can restrict to a covering and then glue.

Finally, notice this gives an Abelian sheaf $\mathcal{G} = \mathrm{Aut}$ on $\mathcal{C}$. □

Bands

4 Sites over Schemes

Prop. (5.1.4.1). Fiber products exist in the category of schemes, by(5.2.7.15).

Zariski Topology

Def. (5.1.4.2) [Zariski Topology]. The **Zariski topology** has the the covering of a scheme T as classes of open immersions $\{T_i \to T\}$ that their images cover T.

The **Zariski site** $\mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/S$ has the objects as all schemes over S.

The **small Zariski site** S_{Zar} has the objects as all open subschemes over S.

The **restricted Zariski site** $S_{\mathrm{Zar}\,fp}$ has the objects as all schemes that are qcqs open subschemes of S.

The **big affine Zariski site** $\mathcal{A}\mathrm{ff}_{\mathrm{Zar}}/S$ has the objects as all schemes affine over S.

These are all topologies because open immersions satisfies base change trick(5.4.4.60).

In particular when the cover has only one element and is affine, the descent datum is equivalent to compatible isomorphisms

$$\varphi_{13} : N \otimes_A B \otimes_A B \xrightarrow{\varphi_{12}} B \otimes_A M \otimes_B \xrightarrow{\varphi_{23}} B \otimes_A B \otimes_A M.$$

Def. (5.1.4.3) [Zariski Stacks]. The category of sheaves on $\mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/S$ is denoted by $\mathcal{S}\mathrm{h}_{\mathrm{Zar}}/S$. The category of stacks on $\mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/S$ is denoted by $\mathcal{S}\mathrm{ta}_{\mathrm{Zar}}/S$.

Prop. (5.1.4.4) [Affine and Full Sites]. The inclusion functor $\mathcal{A}\mathrm{ff}_{\mathrm{Zar}}/S \to \mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/S$ is a special cocontinuous functor, so by(5.1.2.24), it induces an equivalence of topoi $\mathcal{S}\mathrm{h}(\mathcal{A}\mathrm{ff}_{\mathrm{Zar}}/S) \cong \mathcal{S}\mathrm{h}_{\mathrm{Zar}}/S$.

Def. (5.1.4.5) [Restriction to Small Sites]. The inclusion functor $S_{\mathrm{Zar}} \to \mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/S$ satisfies the hypothesis of(5.1.2.23), thus induces morphisms of topoi

$$\pi_S : \mathcal{S}\mathrm{h}_{\mathrm{Zar}}/S \to \mathcal{S}\mathrm{h}(S_{\mathrm{Zar}}), \quad i_S : \mathcal{S}\mathrm{h}(S_{\mathrm{Zar}}) \to \mathcal{S}\mathrm{h}_{\mathrm{Zar}}/S$$

that satisfies $\pi_S \circ i_S = \mathrm{id}_{S_{\mathrm{Zar}}}$. In particular, $i_S^{-1}\mathcal{F}$ is called the **restriction to small sites** of $\mathcal{F}$.

Prop. (5.1.4.6). A sheaf w.r.t the small Zariski topology is equivalent to a sheaf on S, trivially, so the sheaf cohomology on $\mathcal{A}\mathrm{ff}_{\mathrm{Zar}}/S$ is equivalent to usual sheaf cohomology on S.

Prop. (5.1.4.7) [Transfer of Big Sites]. Let $f : T \to S \in \mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/S$, then $\mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/T \to \mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/S$ is a localization, so by(5.1.2.22) it induces a morphism of topoi

$$f : \mathcal{S}\mathrm{h}_{\mathrm{Zar}}/T \to \mathcal{S}\mathrm{h}_{\mathrm{Zar}}/S : f^{-1}\mathcal{G}(U/T) = \mathcal{G}(U/S), \quad f_*\mathcal{F}(U/S) = \mathcal{F}(U \times_S T/T).$$

Prop. (5.1.4.8) [Transfer of Small Sites]. Let $f : T \to S \in \mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/S$, then the base change functor $S_{\mathrm{Zar}} \to T_{\mathrm{Zar}}$ is continuous, and by(5.1.2.14) induces a morphism of topoi

$$f : \mathcal{S}\mathrm{h}_{\mathrm{Zar}}/T \to \mathcal{S}\mathrm{h}_{\mathrm{Zar}}/S.$$

Prop. (5.1.4.9). By**??**, if X is qs, then $\mathcal{S}\mathrm{h}(X_{\mathrm{Zar}}) \to \mathcal{S}\mathrm{h}(X_{\mathrm{Zar}\,fp})$ is an equivalence by i_s and i^s.

Étale Topology

Def. (5.1.4.10) [Étale Topology]. The **étale topology** has the covering of a scheme T as classes of étalemorphisms that their images cover T.

The **étale site** $\mathcal{S}\mathrm{ch}_{\text{ét}}/S$ has the objects as all schemes over S.
The **small étale site** $S_{\text{ét}}$ has the objects as all schemes that are étale over S.
The **restricted étale site** $S_{\text{ét}\,fp}$ has the objects as all schemes that are étale and qcqs over S.
The **big affine étale site** $\mathcal{A}\mathrm{ff}_{\text{ét}}/S$ has the objects as all schemes affine over S.
These are truly topologies because étale is stable under base change and composition.

Prop. (5.1.4.11). Zariski covering is étale , because open immersions are étale.

Prop. (5.1.4.12). For a family of maps in $S_{\text{ét}}$ to be a covering, it suffices to check their image is adjointly surjective, by(5.6.6.4).

Prop. (5.1.4.13) [Affine and Full Sites]. The inclusion functor $\mathcal{A}\mathrm{ff}_{\text{ét}}/S \to \mathcal{S}\mathrm{ch}_{\text{ét}}/S$ is a special cocontinuous functor, so by(5.1.2.24), it induces an equivalence of topoi $\mathcal{S}\mathrm{h}(\mathcal{A}\mathrm{ff}_{\text{ét}}/S) \cong \mathcal{S}\mathrm{h}_{\text{ét}}/S$.

Def. (5.1.4.14) [Restriction to Small Sites]. The inclusion functor $S_{\text{ét}} \to \mathcal{S}\mathrm{ch}_{\text{ét}}/S$ satisfies the hypothesis of(5.1.2.23), thus induces morphisms of topoi

$$\pi_S : \mathcal{S}\mathrm{h}_{\text{ét}}/S \to \mathcal{S}\mathrm{h}(S_{\text{ét}}), i_S : \mathcal{S}\mathrm{h}(S_{\text{ét}}) \to \mathcal{S}\mathrm{h}_{\text{ét}}/S$$

that satisfies $\pi_S \circ i_S = \mathrm{id}_{S_{\text{ét}}}$. In particular, $i_S^{-1}\mathcal{F}$ is called the **restriction to small sites** of $\mathcal{F}$.

Prop. (5.1.4.15). Any étale covering of a qc scheme can be refined a finite covering by affine étale schemes, this is because étale map are open(5.6.6.3).

Def. (5.1.4.16) [Étale Stacks]. The category of sheaves on $\mathcal{S}\mathrm{ch}_{\text{ét}}/S$ is denoted by $\mathcal{S}\mathrm{h}_{\text{ét}}/S$. The category of stacks on $\mathcal{S}\mathrm{ch}_{\text{ét}}/S$ is denoted by $\mathcal{S}\mathrm{ta}_{\text{ét}}/S$.

Prop. (5.1.4.17). For a qc scheme X, $X_{\text{ét}\,fp}$ is a Noetherian topology, because étale map is open, and any object in $X_{\text{ét}\,fp}$ is qc.

Prop. (5.1.4.18) [Transfer of Big Sites]. Let $f: T \to S \in \mathcal{S}\mathrm{ch}_{\text{ét}}/S$, then the functor $u: \mathcal{S}\mathrm{ch}_{\text{ét}}/T \to \mathcal{S}\mathrm{ch}_{\text{ét}}/S$ is cocontinuous, and has base change as a right adjoint, so by(5.1.2.22) it induces a morphism of topoi

$$f: \mathcal{S}\mathrm{h}_{\text{ét}}/T \to \mathcal{S}\mathrm{h}_{\text{ét}}/S: f^{-1}\mathcal{G}(U/T) = \mathcal{G}(U/S), \quad f_*\mathcal{F}(U/S) = \mathcal{F}(U \times_S T/T).$$

Prop. (5.1.4.19) [Transfer of Small Sites]. Let $f: T \to S \in \mathcal{S}\mathrm{ch}_{\text{ét}}/S$, then the base change functor $S_{\text{ét}} \to T_{\text{ét}}$ is continuous, and by(5.1.2.14) induces a morphism of topoi

$$f: \mathcal{S}\mathrm{h}(T_{\text{ét}}) \to \mathcal{S}\mathrm{h}(S_{\text{ét}})$$

Prop. (5.1.4.20). If X is qs, then $\mathcal{S}\mathrm{h}(X_{\text{ét}}) \to \mathcal{S}\mathrm{h}(X_{\text{ét}\,fp})$ is an equivalence by i_s and i^s.

Proof: Want to use(5.1.2.25), one condition is satisfied by(5.1.4.15), so it suffice to check any $X' \in X_{\text{ét}}$ has an étale covering by schemes étale and qcqs over X. For any point $p \in X'$, there is an affine nbhd U' that maps to an affine nbhd U' of X, so $U' \to U$ is étaleand qcqs, and $U \to X$ is open immersion and qs, it is qc because X is qs and U is qc(5.4.4.27). So these affine nbhds U' cover X'. □

Prop. (5.1.4.21) [Cohomology Big and Small Sites]. The inclusion of small sites to the big sites has no infection on the sheaf cohomology, by(5.3.1.4). This is applicable to all topologies τ considered here.

Prop. (5.1.4.22) [Topological Invariance of Étale Sites]. If $f: S' \to S$ is universally homeomorphism, then $f: S'_{\text{ét}} \to S_{\text{ét}}$ is an equivalence of sites.

In particular this applies to $S' = S_{\text{red}}$.

Proof: Cf.[Étale Cohomology Conrad P18]. □

Smooth Topology

This topology will be shown to be identical to the étale topology, so it is not so important.

Def. (5.1.4.23)[Smooth Topology]. The **smooth topology** has the covering of a scheme T as classes of smooth morphisms that their images cover T.

The **big smooth site** $\mathcal{S}\mathrm{ch}_{\mathrm{sm}}/S$ has the objects as all schemes over S.

The **small smooth site** S_{sm} has the objects as all schemes that are smooth over S.

The **restricted smooth site** $S_{\text{ét}\,fp}$ has the objects as all schemes that are smooth and qcqs over S.

The **big affine smooth site** $\mathcal{A}\mathrm{ff}_{\text{ét}}/S$ has the objects as all schemes affine over S.

These are truly topologies because smoothness is stable under base change and composition.

Syntomic Topology

Def. (5.1.4.24) [Syntomic Topology]. The **syntomic topology** has the covering of a scheme T as classes of syntomic morphisms that their images cover T.

fppf Topology

Def. (5.1.4.25)[Fppf Topology]. The **fppf topology** has the covering of a scheme T as classes of flat locally of finite presentation morphisms that their images cover T. (f.f.+locally of f.p.).

The **big Zariski site** $\mathcal{S}\mathrm{ch}_{\mathrm{fppf}}/S$ has the objects as all schemes over S.

The **big affine Zariski site** $\mathcal{A}\mathrm{ff}_{\mathrm{fppf}}/S$ has the objects as all schemes affine over S.

They are all topologies because flatness and finite presentedness satisfy base change trick by(5.6.2.1) and(5.6.1.1).

Prop. (5.1.4.26)[Syntomic Covering is Fppf]. A syntomic covering is fppf by definition(4.4.4.18).

Prop. (5.1.4.27). A fppf covering of an affine scheme can be refined a finite affine fppf covering, because fppf map are open(5.6.2.10).

Def. (5.1.4.28) [Fppf Stacks]. The category of sheaves on $\mathcal{S}\mathrm{ch}_{\mathrm{fppf}}/S$ is denoted by $\mathcal{S}\mathrm{h}_{\mathrm{fppf}}/S$. The category of stacks on $\mathcal{S}\mathrm{ch}_{\mathrm{fppf}}/S$ is denoted by $\mathcal{S}\mathrm{ta}_{\mathrm{fppf}}/S$.

fpqc Topology

Def. (5.1.4.29) [Fpqc Topology]. The **fpqc topology** has the covering of a scheme T as classes of flat morphisms s.t. their images cover T and for any affine open $U \subset T$, the restriction on T can be refined by a finite affine cover of open affine subschemes of the covering(f.f.+qc). It is a topology by(5.6.2.1) and(5.4.4.25).

When the covering consists of affine schemes, it is called a **standard fpqc covering**.

Def. (5.1.4.30) [Fpqc Stacks]. Defining fpqc sites has inescapable set-theoretic difficulties, thus we don't consider fpqc sites and fpqc cohomologies. Cf.[Sta]0BBK.

Nevertheless, we will denote the category of presheaves on $\mathcal{S}\mathrm{ch}/S$ satisfying the sheaf condition w.r.t. the fpqc topology by $\mathcal{S}\mathrm{h}_{\mathrm{fpqc}}/S$, and denote the category of fibered categories over $\mathcal{S}\mathrm{ch}/S$ satisfying the sheaf condition w.r.t. the fpqc topology by $\mathcal{S}\mathrm{ta}_{\mathrm{fpqc}}/S$.

Prop. (5.1.4.31) [fppf is fpqc]. Fppf coverings are fpqc.

Proof: Use(5.6.2.10), we see that fppf covering consists of open morphisms, thus it is qc because affine scheme is quasi-compact. □

Prop. (5.1.4.32). A covering consisting of flat morphisms refined by a fpqc covering is a fpqc covering.

Hence being fpqc is local on the target, because a Zariski cover is a fpqc covering.

If U is a covering consisting of flat morphisms that there is a fpqc covering V that $U \times V \to V$ is a fpqc covering, then U is fpqc, because $U \times V$ does and it refines U.

Lemma (5.1.4.33) [Checking Sheaf Condition]. Let $S \in \mathcal{S}\mathrm{ch}$, $F \in \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}((\mathcal{S}\mathrm{ch}_S)_{\mathrm{fpqc}})$ is a sheaf iff it is a sheaf w.r.t the Zariski topology and satisfies sheaf property w.r.t the single covering $V \to U$ f.f. between affine schemes.

Proof: This follows from(5.1.3.5)(5.1.3.6) and(5.1.5.7). □

Prop. (5.1.4.34) [fpqc Site is Subcanonical]. The coverings in $(\mathcal{S}\mathrm{ch}_S)_{\mathrm{fpqc}}$ are families of universal effective epimorphisms. In other words, $(\mathcal{S}\mathrm{ch}_X)_{\mathrm{fpqc}}$ is subcanonical.

In particular, for any covering $\mathcal{U} = \{U_i \to X\} \in \mathrm{Cov}((\mathcal{S}\mathrm{ch}_S)_{\mathrm{fpqc}})$ and $\{V_{ijk} \to U_i \times_X U_j\} \in \mathrm{Cov}((\mathcal{S}\mathrm{ch}_S)_{\mathrm{fpqc}})$,

$$X = \mathrm{Coeq}(\coprod_{i,j,k} V_{ijk} \rightrightarrows \coprod_i U_i) \in \mathcal{S}\mathrm{ch}_S\,.$$

Proof: By(5.1.4.33), it suffices to show that any representable presheaf is a sheaf w.r.t Zariski topology and f.f. affine morphisms. The Zariski case follows from(5.1.5.3), for the second, $\operatorname{Spec} B \to \operatorname{Spec} Z$, for any scheme X, the morphism corresponds to $0 \to \operatorname{Hom}(R, A) \to \operatorname{Hom}(R, B) \to \operatorname{Hom}(R, B \otimes_A B)$, but this follows immediately from(4.4.2.2), with $M = A$. □

Cor. (5.1.4.35). For $f : Y \to X$ a morphism of schemes, if $Z \in X_\tau$ for the above topologies τ, then $f^*(\operatorname{Hom}_X(-, Z)) \cong \operatorname{Hom}(-, Z \otimes_X Y)$, in other words, the inverse sheaf of a representable sheaf is representable.

Proof: By definition, $f^*(\operatorname{Hom}_X(-, Z))$ is the sheaf associated to the presheaf $f_p(\operatorname{Hom}_X(-, Z))$, which by(5.1.2.13) is just the presheaf represented by $Z \otimes_X Y$, but by the proposition, it is already a sheaf. □

Prop. (5.1.4.36) [Coherent Sheaves on $\mathcal{S}\mathrm{ch}_{\mathrm{fpqc}}/X$]. Let $\mathcal{F} \in \mathfrak{QCoh}(X)$, then the functor $X' \to \Gamma(X', \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{O}_{X'})$ satisfies the the axiom for Abelian sheaves on $\mathcal{S}\mathrm{ch}_{\mathrm{fpqc}}/X$, by(5.1.5.13).

Prop. (5.1.4.37) [Qco Sheaves on Sites]. For $X \in \mathcal{S}\mathrm{ch}, \tau \in$\{fppf, étale, smooth, syntomic, Zariski\}, restriction defines an equivalence of categories

$$\mathfrak{QCoh}(X) \cong \mathfrak{QCoh}(\mathcal{S}\mathrm{ch}_\tau/X).$$

And if $\tau \in$\{Zariski, étale\}, restriction defines an equivalence of categories

$$\mathfrak{QCoh}(X) \cong \mathfrak{QCoh}(X_\tau).$$

Proof: Cf.[Sta]03DX. □

PH-Covering

Def. (5.1.4.38) [Standard PH-Covering].

Def. (5.1.4.39) [PH-Topology].

Prop. (5.1.4.40) [Zariski Covering is PH-Covering]. A Zariski covering is a PH-covering.

Proof: Cf.[[Sta]0DBH]. □

Prop. (5.1.4.41). A proper surjective morphism is a ph-covering.

Proof: Cf.[[Sta]0DES]. □

V-Topology

Def. (5.1.4.42) [Standard V-Covering]. A finite family of morphisms morphism $T_i \to X$ of affine schemes is a covering in the **standard v-topology** if for any morphism $\operatorname{Spec} V \to X$ where V is a valuation ring, there is an extension of valuation rings(10.3.2.11) $V \to W$ and a morphism $\operatorname{Spec} W \to \operatorname{Spec} V \times_X T_i$ for some i.

Def. (5.1.4.43) [V-Topology]. A family of morphisms $\{T_i \to T\}$ is called a **v-covering** in the **v-topology** if for any open affine subscheme U of T, the base change is refined by a standard v-covering of U.

The v-coverings form a topology, by[[Sta]0ETJ].

Lemma (5.1.4.44). A standard fpqc covering is a standard v-covering.

Proof: Cf.[[Sta]022E]. □

Prop. (5.1.4.45) [fpqc Covering is v-Covering]. A fpqc covering is a v-covering.

Proof: This follows immediately from(5.1.4.44). □

Prop. (5.1.4.46). A standard ph-covering is a standard v-covering.

Proof: Cf.[[Sta]0ETD] □

Prop. (5.1.4.47) [ph-Covering is V-Covering]. A ph-covering is a v-covering.

Proof: This follows immediately from(5.1.4.46). □

Cor. (5.1.4.48). A proper and surjective map is a v-covering, by(5.1.4.47) and(5.1.4.41).

Arc-Topology

Def. (5.1.4.49) [Arc-Topology]. A finite family of morphisms $\{T_i \to X\}$ of schemes is a covering in the **arc-topology** if for any morphism $\operatorname{Spec} V \to X$ where V is a rank1-valuation ring, there is a rank1-valuation ring W and a morphism $\operatorname{Spec} W \to \operatorname{Spec} V \times_X T_i$ for some i that $V \to W$ is f.f..

Prop. (5.1.4.50). V-coverings are arc coverings.

Proof: This is by the definition and(10.3.2.11). □

5 Descent for Algebraic Spaces

Main references are [Sta]Chap34, 10.158.

General Principal

Prop. (5.1.5.1). A property of schemes is called **local** in a topology if for any covering $\{U_i \to S\}$, S has P iff U_i has P. A property of morphisms is called **local** in a topology if for any covering $\{U_i \to S\}$, $X \to S$ has P iff $X \times_S U_i \to U_i$ has P.

Prop. (5.1.5.2) [Twists and Čech Cohomology]. Let ξ be an object of a stack $\mathcal{F}$ over a site $\mathcal{C}$ lying over an object U of $\mathcal{C}$, we call an object $\xi' \in \mathcal{F}(U)$ a **twist** of ξ if there is some covering $\{U_i \to U\}$ that the pullback of ξ and ξ' to $U_i \to U$ are isomorphic.

Then there is a natural bijection between $\mathcal{F}(U)$-isomorphism classes of twists of ξ with $\check{H}^1(U, \underline{\operatorname{Aut}}(\xi))$.

Proof: Cf.[Appendix of Lamb]. □

Zariski Descent

Lemma (5.1.5.3) [Zariski Descent of Qco Sheaves]. The fibered category $X \mapsto (\mathcal{QC}\mathrm{oh}/X)$ is a stack over $\mathcal{S}\mathrm{ch}_{\mathrm{Zar}}/S$.

Proof: This is a consequence of(5.1.3.17) and the fact quasi-coherentness is a Zariski local property. □

Prop. (5.1.5.4) [Zariski Descent of Schemes]. The fibered category $X \mapsto \mathcal{S}\mathrm{ch}/X$ is in $\mathcal{S}\mathrm{ta}_{\mathrm{Zar}}/S$.

Proof: Firstly it is a prestack by(5.1.3.16) and(5.1.4.34).

To show any descent datum of effective, let $\{U_i \to U\}$ be a Zariski covering, and $X_i \to U_i$ be schemes with descent datum $\varphi_{ij} : X_i \times_{U_i} U_{ij} \cong X_j \times_{U_j} U_{ij}$, then we define $X = \coprod X_i/\sim$, where $x_i \sim x_j$ if $x_i \in Uij, x_j \in U_{ji}$ and $\varphi_{ij}(x_i) = \varphi_{ji}(x_j)$. It can be shown this is an equivalence relation. Denote $\varphi_i : X_i \to X$ the natural map, and $U_i = \varphi_i(X_i)$. Define the topology on X as the quotient topology. In particular, φ_i is a homeomorphism onto the image. Then we can use(5.1.3.17) to glue the sheaves of rings $(\varphi_i)_*(\mathcal{O}_{X_i})$ to a sheaf of rings $\mathcal{O}_X$ on X that $\varphi_i^*\mathcal{O}_X = \mathcal{O}_{X_i}$. Also we have a map $f : X \to U$ by set-theoretical and topological consideration. For the structure map $f^{-1}(\mathcal{O}_U) \to \mathcal{O}_X$, use(5.1.3.17). □

Cor. (5.1.5.5). If $\mathcal{P}$ is a subclass of arrows of schemes that is stable under base change and local on the target, then $\mathcal{P}/S$ is a stack over $(\mathcal{S}\mathrm{ch}/S)_{Zar}$.

Cor. (5.1.5.6) [Zariski Descent of Schemes with a Qco Sheaf]. The fibered category $X \mapsto$ {Schemes over X with a Qco sheaf $\mathcal{F}$} is a stack in the Zariski topology $\mathcal{S}\mathrm{ch}_{Zar}/S$.

Proof: This is a combination of(5.1.5.4) and(5.1.5.3). □

Fpqc Descent

Prop. (5.1.5.7) [Reduction to Affine Case]. Let S be a scheme and $\mathcal{F}$ be a fibered category over $\mathcal{S}\mathrm{ch}/S$. Suppose that

- $\mathcal{F}$ is a stack w.r.t. the Zariski topology.
- When $V \to U$ is a f.f. morphism of affine S-schemes, $\mathcal{F}(U) \to \mathcal{F}(V \to U)$ is an equivalence of categories.

then $\mathcal{F}$ is a stack w.r.t the fpqc topology.

Proof: Firstly, to show $\mathcal{F}$ is a prestack, using(5.1.3.8), it suffices to show for an S-scheme $T \to S$ and objects $\xi, \eta \in \mathcal{F}(T)$, the functor

$$\underline{\mathrm{Hom}}_T(\xi, \eta) : (\mathcal{S}\mathrm{ch}/T)^{op} \to \mathcal{S}\mathrm{et}$$

is a sheaf. But then we can use(5.1.4.33) to achieve this.

Next, according to(3.1.8.20) and(5.1.3.7), we may assume $\mathcal{F}$ is splitting.

Notice that $\mathcal{F}(\varnothing)$ is equivalent to the category pt. This is because $\mathcal{F}(\varnothing)$ is equivalent to $\mathcal{F}(\mathcal{U})$, where $\mathcal{U}$ is the null Zariski covering of $\varnothing$(with no mapping or obejcts at all!). Then for any disjoint union of open subschemes $U = \coprod U_i$, there is a natural isomorphism of categories $\mathcal{F}(U) \cong \prod_i \mathcal{F}(U_i)$.

Thus for any covering $\mathcal{U} = \{U_i \to X\}$, to show $\mathcal{F}(X) \to \mathcal{F}(\mathcal{U})$ is an equivalence of categories, it suffices to show that $\mathcal{F}(X) \to \mathcal{F}(\coprod U_i \to X)$ is an equivalence of categories: this is because $\coprod U_i \times_X \coprod U_i \cong \coprod U_i \times_X U_j$, so $\mathcal{F}(\coprod U_i \to X) \to \mathcal{F}(\mathcal{U})$ is an equivalence of categories.

If $\mathcal{U} = \{V \to U\}$ is a covering of F with a single morphism that is qc and U is affine, then by the proof of(5.1.3.10), we can choose a finite affine cover of V reduce to the case of covering of f.m. affine maps, then we finish by the case above.

If $\mathcal{U} = \{V \to U\}$ is a covering of F with a single morphism and U is affine, then we can find a Zariski covering $\{V_i \to V\}$ that each V_i is qc. and surjects onto U. Then there are maps of categories $\mathcal{F}(U) \to \mathcal{F}(\{V \to U\}) \to \mathcal{F}(\{V_i \to V\})$, where $\mathcal{F}(U) \to \mathcal{F}(\{V_i \to V\})$ is an equivalence and $\mathcal{F}(U) \to \mathcal{F}(\{V \to U\})$ is fully faithful. Thus to show $\mathcal{F}(U) \to \mathcal{F}(\{V \to U\})$ is an equivalence, it suffices to show $\mathcal{F}(\{V \to U\}) \to \mathcal{F}(\{V_i \to V\})$ is faithful, which is true by(5.1.3.9).

For general case, Cf.[Vis08]P88. □

Prop. (5.1.5.8). Mor $/S : X \mapsto \mathcal{S}\mathrm{ch}/X$ is a prestack over $\mathcal{S}\mathrm{ch}_{\mathrm{fpqc}}/S$, by(5.1.4.34) and(5.1.3.16).

Def. (5.1.5.9) [Affine Fpqc Descent Datum]. For $A \to B \in \mathcal{CA}\mathrm{lg}$, define a category $\mathcal{M}\mathrm{od}_{A\to B}$ as follows: its objects are pairs (N, ψ), where $N \in \mathcal{M}\mathrm{od}_B$ and $\psi : N \otimes_A B \to B \otimes_A N$ is an isomorphism of $B \otimes_A B$-modules s.t. that

$$\psi_{12} \circ \psi_{01} = \psi_{02} : N \otimes_A B \otimes_A B \to B \otimes_A B \otimes_A N$$

where ψ_{ij} is permuting the i, j-parts using ψ. The morphisms in $\mathcal{M}\mathrm{od}_{A\to B}$ are maps in $\mathcal{M}\mathrm{od}_B$ that is compatible with ψ.

There is a natural functor $\mathcal{M}\mathrm{od}_{A\to B} \to \mathcal{M}\mathrm{od}_B$.

Lemma (5.1.5.10) [Affine Fpqc Descent]. For $A \to B \in \mathcal{CA}\mathrm{lg}$, there is a functor $F : \mathcal{M}\mathrm{od}_A \to \mathcal{M}\mathrm{od}_{A\to B}$, where M is mapped to $(B \otimes_A M, \psi_M)$ with

$$\psi_M : (B \otimes_A M) \otimes_A B \to B \otimes_A (B \otimes_A M) : b \otimes m \otimes b' \mapsto b \otimes b \otimes m.$$

Then when $A \to B$ is f.f., this is an equivalence of categories.

Proof: We construct an inverse T that maps (N, ψ) to $\{n | \psi(n \otimes 1) = 1 \otimes n\}$. Then $TF \cong \mathrm{id}$ because of the first exactness of(4.4.2.2).

And for $FT \cong \mathrm{id}$, let $T((N, \psi)) = M$. Notice if $\psi(n \otimes 1) = \sum_i b_i \otimes n_i$, then by cocycle condition,

$$\sum_i b_i \otimes 1 \otimes n_i = \sum_i b_i \otimes \psi(n_i \otimes 1).$$

so $\psi(N \otimes 1) \subset \ker(\mathrm{id}_B \otimes (n \mapsto \psi(n \otimes 1) - 1 \otimes n)) = B \otimes M$ because B/A is flat.

So we defined a map $N \xrightarrow{\Psi} B \otimes_A M \in \mathcal{M}\mathrm{od}_B$, and the composition $B \otimes_A M \xrightarrow{\text{mul.}} N \xrightarrow{\Psi} B \otimes_A M$ is identity, because

$$\psi(bm \otimes 1) = (b \otimes 1)\psi(m \otimes 1) = (b \otimes 1)(1 \otimes m) = b \otimes m.$$

This shows Ψ is surjective. And Ψ is injective because $n \mapsto n \otimes 1$ is injective as B/A is f.f., and ψ is an isomorphism. So Ψ is an isomorphism of $N \cong FT(N)$.

Finally, to show $\psi = \psi_M$, as now $B \otimes_A M \xrightarrow{\text{mul.}} N$ is an isomorphism, we check

$$\psi((bm) \otimes b') = (b \otimes b')\psi(m \otimes 1) = (b \otimes b')(1 \otimes m) = b \otimes (b'm).$$

□

Remark (5.1.5.11). In fact, a descent datum is always effective iff $A \to B$ is universally injective. Cf.[Sta]. And f.f. extension is u.i.(4.4.1.28).

Prop. (5.1.5.12)[fpqc Descent for Qco Sheaves]. Let S be a scheme, then $\mathcal{QC}oh\,/\,\mathcal{S}ch \in \mathcal{S}ta_{\text{fpqc}}\,/S$.

Proof: We use(5.1.5.7), the first condition is satisfied by(5.1.5.3), and for the second condition, let $\operatorname{Spec} B \to \operatorname{Spec} A$ be a f.f. morphism of affine schemes, then $\mathcal{QC}oh(\operatorname{Spec} B \to \operatorname{Spec} A)$ is equivalent to $\operatorname{Mod}_{A\to B}$, and $\mathcal{QC}oh(\operatorname{Spec} A)$ is equivalent to Mod_A, so the conclusion follows from(5.1.5.10). □

Cor. (5.1.5.13). For any $\mathcal{F} \in \mathcal{QC}oh(S)$, the functor $(\mathcal{S}ch\,/S)^{op} \to \mathcal{A}b : T \to \Gamma(T, f^*\mathcal{F}) \in \mathcal{S}ta_{\text{fpqc}}\,/S$, hence are also sheaves w.r.t. the fppf, étale, Zariski topologies.

Proof: Because this functor is just $\underline{\operatorname{Hom}}_S(\mathcal{O}_S, \mathcal{F})$, and it is a sheaf(5.1.3.8). □

Cor. (5.1.5.14). If $\mathscr{P}$ is a property of Qco sheaves that is stable under base change and fpqc local, then $\mathcal{QC}oh_{\mathcal{P}}\,/S \in \mathcal{S}ta_{\text{fpqc}}\,/S$.

Prop. (5.1.5.15) [Descending Affine Morphisms]. For a scheme S, let $\mathscr{P}$ be the class of affine arrows in $\mathcal{S}ch\,/S$ that denote by $\operatorname{Mor}_S^{\mathcal{A}ff}$ the resulting fibered category, then $\operatorname{Mor}_S^{\mathcal{A}ff} \in \mathcal{S}ta_{\text{fpqc}}\,/S$.

Proof: Firstly $\operatorname{Mor}^{\mathcal{A}ff}\,/S \in \mathcal{S}ta_{\text{Zar}}\,/S$, and it satisfies the affine fpqc descent condition of(5.1.5.7)(Notice the $\{n|\psi(n\otimes 1) = 1\otimes n\}$ is now a ring, because ψ is a ring homomorphism), so we are done by(5.1.5.7). □

Cor. (5.1.5.16). If $\mathscr{P}$ is a subclass of affine arrows stable under base change and fpqc local on the target, then $\operatorname{Mor}^{\mathscr{P}}\,/S \in \mathcal{S}ta_{\text{fpqc}}\,/S$.

Prop. (5.1.5.17) [Descent via Ample Invertible Sheaves]. Let S be a scheme and $\mathscr{P}$ be a class of flat proper morphisms of f.p. in $\mathcal{S}ch\,/S$ that is local in the fpqc topology. Assume that for each object $\xi : X \to U \in \mathscr{P}$, we have an invertible sheaf $\mathcal{L}_\xi$ on X that is ample relative to $X \to U$, and for an arrow $f : (X \xrightarrow{\xi} U) \to (Y \to \eta V)$, we have an isomorphism $\rho_f : f^*\mathcal{L}_\eta \cong \mathcal{L}_\xi$ that satisfies $\rho_{gf} = \rho_f \circ f^*\rho_g$, then $\operatorname{Mor}^{\mathscr{P}}\,/S \in \mathcal{S}ta_{\text{fpqc}}\,/S$.

Proof: Cf.[Vistoli, P96].**?** □

Étale Descent

Prop. (5.1.5.18) [Galois Descent]. Let L/K be a finite separable field extension with Galois group G, then $\operatorname{Spec} L \to \operatorname{Spec} K$ is a G-torsor in the étale topology. so Galois descent is a special case of étale descent along torsors(5.1.3.18).

Notice this is also true for arbitrary finite separable field extensions with continuity condition added, because we can take direct limits of categories over its finite normal subextensions.

Proof: Consider the locally constant group scheme $\underline{G} = \operatorname{Spec}(\prod_{g\in G} K)$, let $X = \operatorname{Spec} L, Y = \operatorname{Spec} K$, then $\{X \to Y\}$ is an étale cover, and the action $\underline{G} \times X \to X$ is given by

$$L \to \prod_{g\in G} L : x \mapsto \prod_{g\in G} (g(x)).$$

Thus $X \to Y$ is a G-equivariant map, and there is an isomorphism $G\times X \cong X \times_Y X : (g, x) \mapsto (gx, x)$ that corresponds to the isomorphism

$$L \otimes_K L \cong \prod_{g\in G} L : (a, b) \mapsto \prod_{g\in G} (g(a)b)$$

□

Cor. (5.1.5.19) [Galois Descent of Closed Immersions]. Let X be a scheme over a field k, and K/k be a Galois field extension with Galois group Γ, $X' = X \otimes_k K$. Then the category of closed subschemes of X is equivalent to the category of closed subschemes that is base change from some $X_{k'}$ where k'/k is finite, and is stable under the action of Γ. This weird finiteness condition can be removed when X is locally algebraic over k.

Proof: This is because the class of closed immersions is a stack(5.1.5.16). □

Remark (5.1.5.20). When Y is a subvariety of X and $K = k^s$, to check Y is stable under action of Γ, it suffices to check that the geometric points is closed under action of Γ. This is because the geometric points are dense in Y'(5.10.1.10).

Cor. (5.1.5.21) [Galois Descent for Ideals of Algebras]. Let $A \in \mathcal{CA}\mathrm{lg}_k$, and K/k be a Galois field extension with Galois group Γ, then the category of ideals of A is equivalent to the category of ideals of A_K that is base change from some $A_{k'}$ where k'/k is finite, and is stable under the action of Γ. This weird finiteness condition can be removed when A is f.g. over k.

Cor. (5.1.5.22) [Galois Descent of Morphisms]. Let X, Y be locally algebraic schemes over k and K/k a Galois field extension with Galois group Γ, $X' = X \otimes_k K, Y' = Y \otimes_k K$. If Y is separated, then a morphism $\varphi' : X' \to Y'$ arises from a morphism $X \to Y$ iff its graph $\Gamma_{\varphi'} \subset X' \times_{k'} Y'$ is stable under action of Γ. In this case φ is unique.

And when X, Y are varieties and $K = k^s$, then it suffices to check the map

$$\varphi'(k^s) : X'(k^s) \to Y'(k^s)$$

commutes with action of Γ.

Cor. (5.1.5.23) [Galois Descent for Qco Sheaves]. Let K/k be a Galois extension with Galois group Γ and X be a scheme over k with $X' = X \otimes_k K$, then $\mathfrak{QCoh}/X \to (\mathfrak{QCoh}/X')^\Gamma$ is an equivalence of categories.

Proof: This is because $\mathfrak{QCoh}/\mathcal{S}\mathrm{ch}$ is a fpqc stack(5.1.5.12). □

Cor. (5.1.5.24) [Galois Descent for Vector Spaces]. Let L/K be a Galois extension, then the functor $V \mapsto L \otimes_K V$ induces an equivalence $\mathcal{V}\mathrm{ect}_K \cong \mathrm{Rep}_L(\mathrm{Gal}(L/K))$.

Prop. (5.1.5.25) [Failure of Étale Descent for proper smooth morphisms]. Cf.[Vis08]P107.

Descending Properties

Prop. (5.1.5.26) [Properties of Morphisms Local in Fpqc Topology]. The following properties of morphisms are local on the target w.r.t. the fpqc topology.

1. quai-compact.
2. (quasi-)separated.
3. Universally closed.
4. universally open.
5. universally submersive.
6. surjective.

7. universally injective.
8. universally homeomorphism.

□

Prop. (5.1.5.27) [Properties of Schemes Local in the Fppf Topology]. •

Proof: Cf.[Sta]Chap34.13. □

Prop. (5.1.5.28) [Descending Properties that is not Fpqc Local].

- If $X \to Y$ is a faithfully flat morphism of schemes and X is (geo.)reduced, then Y is also (geo.)reduced.
- If $X \to Y$ is a faithfully flat morphism of f.p. between schemes and X is (geo.)regular, then Y is also (geo.)regular.

Proof: Looking stalkwise, these follows from(4.4.2.1). □

Prop. (5.1.5.29) [Torsors]. Let G be a group object in $(\mathcal{S}\mathrm{ch}_S)_\tau$ and $X \to S$ a G-torsor. Then if τ is a subcanonical site and $\mathscr{P}$ is a property that is local on $(\mathcal{S}\mathrm{ch}_S)_\tau$ and $G \to S$ has $\mathscr{P}$, then $X \to S$ has P.

Proof: By(5.1.1.17), there is a covering $\{Y_i \to S\}$ s.t. each $X \times_S Y_i \to Y_i \cong G \times_S Y_i$ is trivial, thus each $X \times_S Y_i \to Y_i$ has P, and then $X \to S$ has P. □

Weil Restrictions

Def. (5.1.5.30) [Weil Restrictions]. Let L/k be a finite extension of fields, $X \in \mathcal{S}\mathrm{ch}/L$, then the **Weil restriction** $\mathrm{res}_{L/k}(X)$ is the scheme over k representing the functor

$$\mathcal{S}\mathrm{ch}/k \to \mathcal{S}\mathrm{et} : S \mapsto X(S \times_k L).$$

Prop. (5.1.5.31). Let L/k be a finite extension of fields, and $X \in \mathcal{S}\mathrm{ch}/L$. If every finite subset of X is contained in some affine open subset of X, then $\mathrm{res}_{L/K}(X)$ exists. In particular, this applies to the case that X is quasi-projective.

Proof: Cf.[BLR90, Chap7.6. Thm4]. □

6 Étale Torsors

Prop. (5.1.6.1). For $X \in \mathcal{S}\mathrm{ch}$, $\check{H}^1(X, \mathrm{GL}(n)) \cong \mathcal{V}\mathrm{ect}^n(X)$ as pointed sets, by(5.1.5.2).

5.2 Ringed Topoi, Ringed Sites, Ringed G-Spaces and Schemes

1 Ringed Topoi, Ringed Sites

Def. (5.2.1.1)[Ringed Topoi]. A **ringed topos** is a pair $(\mathcal{Sh}(\mathcal{C}), \mathcal{O})$ where $\mathcal{C}$ is a site and $\mathcal{O}$ is a unital object in $\mathcal{Sh}(\mathcal{C})$, called the **structure sheaf**. A morphism of of ringed topoi $(f, f^\sharp) : (\mathcal{C}, \mathcal{O}) \to (\mathcal{C}', \mathcal{O}')$ consists of a morphism of topoi(5.1.2.18) $f : \mathcal{Sh}(\mathcal{C}) \to \mathcal{Sh}(\mathcal{C}')$ and a map of sheaves of rings $f^\sharp : f^{-1}\mathcal{O}' \to \mathcal{O}$. A composition of morphism of topoi is defined to be $(g, g^\sharp)\circ(f, f^\sharp) = (g\circ f, f^\sharp \circ f^{-1}(g^\sharp))$.

Def. (5.2.1.2)[Ringed Sites]. A **ringed site** is pair $(\mathcal{C}, \mathcal{O})$ where $\mathcal{C}$ is a site and $\mathcal{O}$ is a sheaf of rings on $\mathcal{C}$, called the **structure sheaf**. A ringed site induces a ringed topos. A morphism of ringed sites is a morphism of sites that the induced morphism of topoi(5.1.2.20) is a morphism of ringed topoi(5.2.1.1).

A site is naturally a ringed site where $\mathcal{O} = \underline{\mathbb{Z}}$ the constant sheaf(5.1.2.8). So we only consider ringed sites afterwards, then a morphism of ringed sites is naturally a morphism of ringed sites. So whenever we say $\mathcal{C}$ is a site, it is understood as a ringed site $(\mathcal{C}, \underline{\mathbb{Z}})$.

Prop. (5.2.1.3) [Ringed Topoi and Ringed Sites]. Let $(f, f^\sharp) : (\mathcal{Sh}(\mathcal{C}), \mathcal{O}_C) \to \mathcal{Sh}(\mathcal{D}, \mathcal{O}_D)$ be a morphism of ringed topoi, then we can find ringed sites $(\mathcal{C}', \mathcal{O}_{\mathcal{C}'})$ and $(\mathcal{D}', \mathcal{O}_{\mathcal{D}'})$ and a diagram

$$\begin{array}{ccc} (\mathcal{Sh}(\mathcal{C}), \mathcal{O}_{\mathcal{C}}) & \xrightarrow{(f,f^\sharp)} & (\mathcal{Sh}(\mathcal{D}), \mathcal{O}_{\mathcal{D}}) \\ \downarrow{\scriptstyle (g,g^\sharp)} & & \downarrow{\scriptstyle (e,e^\sharp)} \\ (\mathcal{Sh}(\mathcal{C}'), \mathcal{O}_{\mathcal{C}'}) & \xrightarrow{(h,h^\sharp)} & (\mathcal{Sh}(\mathcal{D}'), \mathcal{O}_{\mathcal{D}'}) \end{array}$$

where

- $(g, g^\sharp)$ and $(e, e^\sharp)$ are equivalence of ringed topoi.
- $\mathcal{C}', \mathcal{D}'$ have final objects and finite products.
- $(h, h^\sharp)$ is induced by a continuous functor $\mathcal{D}' \to \mathcal{C}'$ that the preserves the final object and finite products,(thus induces a morphism of sites by(5.1.2.14)).

Moreover, given a set of sheaves $\mathcal{F}_i$ on $\mathcal{C}$ and a set of sheaves $\mathcal{G}_i$ on $\mathcal{D}$, we may choose C' and $\mathcal{D}'$ that these sheaves are representable by objects in $\mathcal{C}'$ or $\mathcal{D}'$.

Proof: [Sta]03CR. □

Prop. (5.2.1.4) [Multiplicative Structure Sheaf]. Given a ringed topoi $(\mathcal{Sh}(\mathcal{C}), \mathcal{O})$, the presheaf $U \mapsto \mathcal{O}^*(U)$ is a sheaf of groups, called the **multiplicative structure sheaf** $\mathcal{O}^*$.

Proof: This comes from the sheaf property of $\mathcal{O}$ and the fact the inverse of an element is unique. □

Def. (5.2.1.5)[Local Ringed Site]. A ringed site $(\mathcal{C}, \mathcal{O})$ is called a **local ringed site** if

$$\varnothing^\sharp \to \mathrm{Equalizer}(0, 1 : \mathrm{pt} \to \mathcal{O})$$

is an isomorphism of sheaves, and for any $U \in \mathcal{C}$ and $f \in \mathcal{O}(U)$, there exists a covering $\{U_i \to U\}$ s.t. for any j, either $f|_{U_i}$ is invertible or $(1 - f)|_{U_i}$ is invertible.

Prop. (5.2.1.6)[Characterizing Local Ringed Sites]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site, the following are equivalent:

- $(\mathcal{C}, \mathcal{O})$ is a local ringed site.
- (Partition of Unity) For any $U \in \mathcal{C}$, $f_1, \ldots, f_n \in \mathcal{O}(U)$ that $(f_1, \ldots, f_n) = (1)$, there is a covering $\{U_i \to U\}$ that for each j, there exists an i that f_i is invertible on U_j.
- The map of sheaves of sets:
$$(\mathcal{O} \otimes \mathcal{O}) \coprod (\mathcal{O} \times \mathcal{O}) \to \mathcal{O} \times \mathcal{O}$$
which maps (f, a) in the first component to (f, af) and (f, b) in the second component to $(f, b(1-f))$ is surjective.

Proof: Cf.[Sta]04ES. □

Def. (5.2.1.7) [Local Ringed Topoi]. If $f : \mathcal{S}\mathrm{h}(\mathcal{C}') \to \mathcal{S}\mathrm{h}(\mathcal{C})$ is a morphism of topoi and $(\mathcal{C}, \mathcal{O})$ is a local ringed site, then $(\mathcal{S}\mathrm{h}(\mathcal{C}'), f^{-1}\mathcal{O})$ is also a local ringed site. In particular, being a local ringed site is an intrinsic property, so we can define **local ringed topoi** to be ringed topoi that the underlying ringed sites are local ringed.

Proof: Because f^{-1} is exact(5.1.2.18) and commutes with products and equalizers, it maps the isomorphism
$$\varnothing^\sharp \to \mathrm{Equalizer}(0, 1 : \mathrm{pt} \to \mathcal{O})$$
to the corresponding isomorphism of $\mathcal{C}'$, and also the sejection of
$$(\mathcal{O} \otimes \mathcal{O}) \coprod (\mathcal{O} \times \mathcal{O}) \to \mathcal{O} \times \mathcal{O}$$
in(5.2.1.6) to that of $\mathcal{C}'$, thus $(\mathcal{S}\mathrm{h}(\mathcal{C}'), f^{-1}\mathcal{O})$ is also a local ringed site. □

Def. (5.2.1.8) [Morphisms of Local Ringed Topoi]. A **morphism of local ringed topoi** is a morphism of ringed topoi $(f, f^\sharp) : (\mathcal{S}\mathrm{h}(\mathcal{C}), \mathcal{O}_C) \to (\mathcal{S}\mathrm{h}(\mathcal{D}), \mathcal{O}_D)$ that the diagram of sheaves
$$\begin{array}{ccc} f^{-1}(\mathcal{O}_{\mathcal{D}}^*) & \xrightarrow{f^\sharp} & \mathcal{O}_{\mathcal{C}}^* \\ \downarrow & & \downarrow \\ f^{-1}(\mathcal{O}_{\mathcal{D}}) & \xrightarrow{f^\sharp} & \mathcal{O}_{\mathcal{C}} \end{array}$$
is Cartesian, where $\mathcal{O}_C^*$ is the multiplicative structure sheaf(5.2.1.4). Morphisms of local ringed topoi are stable under compositions.

Ringed Spaces

Def. (5.2.1.9) [Ringed Spaces]. A **ringed space** is a pair $(X, \mathcal{O}_X)$ consisting of a topological space X and a sheaf of rings $\mathcal{O}_X$ on X. A morphism of ringed spaces $(X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)$ consists of a pair $(f, f^\sharp)$ where f is a continuous map $X \to Y$ and $f^\sharp$, which induces a map of sites (f^{-1}, f_*) : $X_{\mathrm{Zar}} \to Y_{\mathrm{Zar}}$(5.2.6.7), and $f\sharp$ is a map $f^\sharp : f^{-1}(\mathcal{O}_Y) \to \mathcal{O}_X$(5.2.6.2), such that $(f, f^\sharp)$ is a map of ringed topoi(5.2.1.1).

Def. (5.2.1.10) [Local Ringed Space]. A **local ringed space** is a topological space X with a sheaf of rings $\mathcal{O}_X$ that $(X, \mathcal{O}_X)$ forms a local ringed site(5.2.1.5). A morphism of local ringed space is a morphism of ringed spaces that the corresponding morphism of ringed topoi $(\mathcal{S}\mathrm{h}(\mathcal{C}), \mathcal{O}_{\mathcal{C}}) \to (\mathcal{S}\mathrm{h}(\mathcal{D}), \mathcal{O}_{\mathcal{D}})$ is a morphism of local ringed topoi(5.2.1.8).

Prop. (5.2.1.11). A ringed space $(X, \mathcal{O}_X)$ is a locally ringed space iff any stalks $\mathcal{O}_{X,x}$ is either 0 or a local rings.

Proof: Cf.[Sta]04ET. □

2 Modules on Ringed Topoi

Main References are [Sta]Chap 18.

Def. (5.2.2.1) [Modules on Ringed Topoi]. Let $(\mathcal{S}h(\mathcal{C}),\mathcal{O})$ be a ringed topos, then a sheaf of $\mathcal{O}$-modules is a presheaf of $\mathcal{O}$-modules that the underlying presheaf of Abelian groups is a sheaf.

Def. (5.2.2.2) [Support]. Let $(X,\mathcal{O}_X)$ be a ringed space, $\mathcal{F}$ a $\mathcal{O}_X$-module, then the **support** of $\mathcal{F}$ is the set of points x that $\mathcal{F}_x\neq 0$. It is denoted by $\mathrm{Supp}(\mathcal{F})$. For a section $s\in\Gamma(X,\mathcal{F})$, $\mathrm{Supp}(s)$ is defined to be the set of points x that $s_x\neq 0\in\mathcal{F}_x$.

Prop. (5.2.2.3). Glueing sheaves is available for ringed spaces, similar to(5.1.5.3).

Proof: □

Prop. (5.2.2.4). Glueing ringed spaces is available.

Proof: □

Def. (5.2.2.5) [Local Properties of Modules]. On a ringed site $(\mathcal{C},\mathcal{O})$, an $\mathcal{O}$-module $\mathcal{F}$ is called locally has property P if for any object $U\in\mathcal{C}$, there is a covering $\{U_i\to U\}$ that $\mathcal{F}|_{U_i}$ has property P.

Def. (5.2.2.6) [Intrinsic Properties of Modules]. An **intrinsic property** of sheaves of modules in a ringed topos $(\mathcal{S}h(\mathcal{C}),\mathcal{O})$ that is invariant under equivalence of topoi.

Def. (5.2.2.7) [Tensor Products Sheaf]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site and $\mathcal{F},\mathcal{G}$ be $\mathcal{O}$-modules, then the **tensor product** $\mathcal{F}\otimes_{\mathcal{O}}\mathcal{G}$ is defined to be the shifification of the presheaf $U\mapsto\mathcal{F}(U)\otimes_{\mathcal{O}(U)}\mathcal{G}(U)$.

The tensor product is easily seen to be an intrinsic notion(5.2.2.6), so it can be defined on any ringed topoi.

Prop. (5.2.2.8) [Base Change]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site and $\mathcal{O}_2$ be a sheaf $\mathcal{O}_1$-algebras, $\mathcal{G}$ be a sheaf of $\mathcal{O}_1$-module and $\mathcal{F}$ a sheaf of $\mathcal{O}_2$-module, then

$$\mathrm{Hom}_{\mathcal{O}_1}(\mathcal{G},\mathcal{F}_{\mathcal{O}_1})=\mathrm{Hom}_{\mathcal{O}_2}(\mathcal{G}\otimes_{\mathcal{O}_1}\mathcal{O}_2,\mathcal{F}).$$

Proof: This can be seen from the definition of tensor product and the fact shifification doesn't bother because $\mathcal{F}$ is a sheaf. □

Def. (5.2.2.9) [Transfer of Modules on Ringed Sites]. Let $(f,f^\sharp)$ be a morphism of ringed topoi $(\mathcal{S}h(\mathcal{C}),\mathcal{O})\to(\mathcal{S}h(\mathcal{C}'),\mathcal{O}')$, then there are functor:

- the **pushforward**: $f_*:\mathcal{M}od(\mathcal{O})\to\mathcal{M}od(\mathcal{O}'):f_*\mathcal{F}=f_*\mathcal{F}$ as a $\mathcal{O}'$-module via $\mathcal{O}'\to f_*\mathcal{O}$.
- the **pullback** $f^*:\mathcal{M}od(\mathcal{O}')\to\mathcal{M}od(\mathcal{O}):f^*\mathcal{G}=\mathcal{O}\otimes_{f^{-1}\mathcal{O}'}f^{-1}\mathcal{G}$ via $f^\sharp:f^{-1}\mathcal{O}'\to\mathcal{O}$. f^* is left adjoint to f_*, by the adjointness of f^{-1} and f_*(5.1.2.18).

If $(f,f^\sharp)$ is a morphism of ringed sites $(\mathcal{C},\mathcal{O})\to(\mathcal{C}',\mathcal{O}')$, then there is an **extension by zero** functor:

- (Extension by zero): For the localization of sites $j_U:(\mathcal{C}/U,\mathcal{O}_U)\to(\mathcal{C},\mathcal{O})$ the localization map of site, $j_U^*=j_U^{-1}$ has a left adjoint $j_{U!}$ defined by shifification of the presheaf

$$\mathcal{G}\mapsto j_{U!}(\mathcal{G}):j_{U!}(\mathcal{G})(V)=\bigoplus_{\varphi:V\to U}\mathcal{G}(V\xrightarrow{\varphi}U\in\mathcal{C}/U).$$

Proof: To show $j_{U!}$ is left adjoint to j_U^*, Cf.[Sta]03DI. □

Remark (5.2.2.10). The f^* may not be exact. f^{-1} is exact, but we tensored with $\mathcal{O}_X$, it is exact when f is flat(5.2.2.15).

Prop. (5.2.2.11) [Extension by Zero is Exact]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $U \in \mathcal{C}$, then the extension by zero functor $j_{U!} : \mathcal{M}od(\mathcal{O}_U) \to \mathcal{M}od(\mathcal{O})$ is exact and reflects exactness.

Proof: It is right exact because is a left adjoint, and it is left exact by direct inspection.
For refection of exactness, Cf.[Sta]0E8G.? □

Prop. (5.2.2.12) [Tensor Products and Pullbacks]. Tensor products commute with pullbacks, in particular with taking stalks. So tensoring with a locally free sheaf is exact.

Proof: By(5.2.3.3) and(5.2.3.5), for any $\mathcal{O}$-module $\mathcal{H}$,

$$\mathrm{Hom}(f^*\mathcal{F} \otimes f^*\mathcal{G}, \mathcal{H}) = \mathrm{Hom}(\mathcal{F}, f_*\mathcal{H}om(f^*\mathcal{G}, \mathcal{H})) = \mathrm{Hom}(\mathcal{F}, \mathcal{H}om(\mathcal{G}, f_*\mathcal{H})) = \mathrm{Hom}(f^*(\mathcal{F} \otimes \mathcal{G}), \mathcal{H}).$$

□

Prop. (5.2.2.13) [$j_{U!}$ Commutes with Restriction]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $U \in \mathcal{C}, \mathcal{G} \in \mathcal{M}od(\mathcal{O}_U), \mathcal{F} \in \mathcal{M}od(\mathcal{O})$, then there is a natural isomorphism $j_{U!}\mathcal{G} \otimes_{\mathcal{O}} \mathcal{F} \cong j_{U!}(\mathcal{G} \otimes_{\mathcal{O}_U} \mathcal{F}|_U)$

Proof: By(5.2.3.3) and(5.2.3.5), for any $\mathcal{H} \in \mathcal{M}od(\mathcal{O})$,

$$\begin{aligned}\mathrm{Hom}_{\mathcal{O}}(j_{U!}(\mathcal{G} \otimes_{\mathcal{O}_U} \mathcal{F}|_U), \mathcal{H}) &= \mathrm{Hom}_{\mathcal{O}_U}(\mathcal{G} \otimes_{\mathcal{O}_U} \mathcal{F}|_U, \mathcal{H}|_U) = \mathrm{Hom}_{\mathcal{O}_U}(\mathcal{G}, \mathcal{H}om_{\mathcal{O}}(\mathcal{F}|_U, \mathcal{H}|_U)) \\ &= \mathrm{Hom}_{\mathcal{O}_U}(\mathcal{G}, \mathcal{H}om_{\mathcal{O}_U}(\mathcal{F}, \mathcal{H})|_U) = \mathrm{Hom}_{\mathcal{O}}(j_{U!}\mathcal{G}, \mathcal{H}om_{\mathcal{O}}(\mathcal{F}, \mathcal{H})) \\ &= \mathrm{Hom}_{\mathcal{O}}(j_{U!}\mathcal{G} \otimes_{\mathcal{O}} \mathcal{F}, \mathcal{H})\end{aligned}$$

then use Yoneda lemma. □

Prop. (5.2.2.14) [Properties of Tensor Products]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $\mathcal{F}, \mathcal{G}$ be sheaves of $\mathcal{O}$-modules, then

1. If $\mathcal{F}, \mathcal{G}$ are locally free, then so does $\mathcal{F} \otimes \mathcal{G}$.
2. If $\mathcal{F}, \mathcal{G}$ are locally finite free, then so does $\mathcal{F} \otimes \mathcal{G}$.
3. If $\mathcal{F}, \mathcal{G}$ are locally generated by sections, then so does $\mathcal{F} \otimes \mathcal{G}$.
4. If $\mathcal{F}, \mathcal{G}$ are of f.t., then so does $\mathcal{F} \otimes \mathcal{G}$.
5. If $\mathcal{F}, \mathcal{G}$ are quasi-coherent., then so does $\mathcal{F} \otimes \mathcal{G}$.
6. If $\mathcal{F}, \mathcal{G}$ are of f.p., then so does $\mathcal{F} \otimes \mathcal{G}$.
7. If $\mathcal{F}$ is of f.p. and $\mathcal{G}$ is coherent, then $\mathcal{F} \otimes \mathcal{G}$ is coherent. In particular, if $\mathcal{F}, \mathcal{G}$ are coherent, then so does $\mathcal{F} \otimes \mathcal{G}$(5.2.2.27).

Proof: Cf.[Sta]03L6. □

Flat Modules

Def. (5.2.2.15) [Flat Modules and Flat Morphisms]. Let $\mathcal{C}$ be a site and $\mathcal{O}$ a presheaf of rings, then a presheaf $\mathcal{F}$ of $\mathcal{O}$-modules is called **flat** if the functor $P\mathcal{M}od(\mathcal{O}) \to P\mathcal{M}od(\mathcal{O}) : \mathcal{G} \mapsto \mathcal{G} \otimes_{\mathcal{O}} \mathcal{F}$ is exact.

Let $\mathcal{C}$ be a ringed site, and $\mathcal{F}$ is a sheaf of $\mathcal{O}$-modules, then it is called **flat** if the functor $\mathcal{M}od(\mathcal{O}) \to \mathcal{M}od(\mathcal{O}) : \mathcal{G} \mapsto \mathcal{G} \otimes_{\mathcal{O}} \mathcal{F}$ is exact.

A morphism $(f, f^\sharp)$ is called a **flat morphism** if the ring map $f^\sharp : f^{-1}\mathcal{O}' \to \mathcal{O}$ is flat, or equivalently, the pullback functor(5.2.2.9) f^* is exact.

If $(f, f^\sharp)$ is a morphism of ringed topoi $(\mathcal{S}\mathrm{h}(\mathcal{C}), \mathcal{O}) \to (\mathcal{S}\mathrm{h}(\mathcal{C}'), \mathcal{O}')$, and $\mathcal{F}$ is a sheaf of $\mathcal{O}$-modules, then $\mathcal{F}$ is **flat** over $(\mathcal{S}\mathrm{h}(\mathcal{C}'), \mathcal{O}')$ if $\mathcal{F}$ is flat over $f^{-1}\mathcal{O}'$.

Prop. (5.2.2.16). Let $\mathcal{C}$ be a site and $\mathcal{O}$ a presheaf of rings with shifification $\mathcal{O}^\sharp$.

- If $\mathcal{F}$ is a presheaf of $\mathcal{O}$-modules that each $\mathcal{F}(U)$ is flat $\mathcal{O}(U)$-modules, then $\mathcal{F}$ is flat.
- If $\mathcal{F}$ is a flat presheaf of $\mathcal{O}$-modules, then $\mathcal{F}^\sharp$ is a flat $\mathcal{O}^\sharp$-modules.
- A filtered colimits of flat presheaves of modules is flat. A direct sum of flat presheaves of modules is flat.
- A filtered colimits of flat sheaves of modules is flat. A direct sum of flat sheaves of modules is flat.

Prop. (5.2.2.17) [Flatness is Stalkwise]. Let $(X, \mathcal{O}_X)$ be a ringed space, then an $\mathcal{O}_X$-module $\mathcal{F}$ is flat iff the stalks $\mathcal{F}_x$ are all flat $\mathcal{O}_{X,x}$-modules.

Proof: Cf.[Sta]05NE. □

Prop. (5.2.2.18) [Flat Morphism and Support]. Let $f : (X, \mathcal{O}_X) \to (X', \mathcal{O}_{X'})$ be a flat morphism of local ringed spaces, $\mathcal{F}$ an $\mathcal{O}_{X'}$-module, then $\mathrm{Supp}(f^*(\mathcal{F})) = f^{-1}(\mathrm{Supp}(\mathcal{F}))$.

Proof: Use the fact flat ring map of local rings is faithfully flat. □

Modules of Finite Type & Finite Presentation

Def. (5.2.2.19) [Finite Type]. An $\mathcal{O}$-module is called if **finite type** iff locally a quotient of a finite free sheaf.

Prop. (5.2.2.20) [Extension of F.T. Sheaves]. if $0 \to \mathcal{F}_1 \to \mathcal{F}_2 \to \mathcal{F}_3 \to 0$ is an exact sequence of $\mathcal{O}$-modules and $\mathcal{F}_1, \mathcal{F}_3$ are of f.t., then $\mathcal{F}_2$ is of f.t..

Proof: For any $U \in \mathcal{C}$, choose a covering $\{U_i \to U\}$ that $\mathcal{F}_3(U_i)$ is generated by f.m. sections, then by passing to a covering, we may assume these sections come from $\mathcal{F}_2$. Pass to another covering that $\mathcal{F}_1$ is generated by f.m. sections, then on this covering, $\mathcal{F}_2$ is generated by f.m. sections. □

Def. (5.2.2.21) [Finite Presentation]. A sheaf of modules $\mathcal{F}$ is called **of finite presentation** iff locally it is a cokernel of two finite free modules. The pullback of a f.p. sheaf is f.p, by the left adjointness of f^*.

Prop. (5.2.2.22) [FP-FT-FT]. If $f : \mathcal{G} \to \mathcal{F}$ is a surjection of $\mathcal{O}$-modules, $\mathcal{F}$ is of f.p. and $\mathcal{G}$ is of f.t., then the kernel is of finite type.

Proof: We first show for $\mathcal{G} = \mathcal{O}^n$: By pass to covering, we can construct a diagram

$$\begin{array}{ccccccccc} & & \mathcal{O}^m_{U_{ij}} & \longrightarrow & \mathcal{O}^n_{U_{ij}} & \longrightarrow & \mathcal{F}|_{U_{ij}} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle\alpha} & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \ker(f)|_{U_{ij}} & \longrightarrow & \mathcal{G}|_{U_{ij}} & \longrightarrow & \mathcal{F}|_{U_{ij}} & \longrightarrow & 0 \end{array}$$

and then use snake lemma. The image and cokernel of α are all of f.t., then $\ker(f)|_{U_{ij}}$ is of f.t. by(5.2.2.20).

For general $\mathcal{G}$, locally choose a surjection $\varphi : \mathcal{O}^n_{U_i} \to \mathcal{G}|_{U_i}$, then $\ker(f|_{U_i}) = \varphi(\ker(\varphi \circ f|_{U_i}))$, which is of f.t.. □

Prop. (5.2.2.23). Pullbacks of a module of finite type is of finite type. Pullback of a module of finite presentation is of finite presentation.

Finite type and finite presentation are local on the target.

Proof: This is because pullback is a left adjoint thus right exact. They are local on the target because they are defined locally. □

Prop. (5.2.2.24) [Support is Zariski Closed]. If $(X, \mathcal{O}_X)$ is a ringed space and $f : \mathcal{G} \to \mathcal{F}$ is surjective at a point x and $\mathcal{F}$ is of f.t., then it is surjective on a Zariski nbhd of x. Thus the support of a f.t. sheaf is closed (look at $0 \to \mathcal{F}$).

Proof: Choose a nbhd of x that $\mathcal{F}(U)$ is generated by $s_1, \ldots, s_n \in \mathcal{F}(U)$, because f is surjective at the stalk of x, after shrinking U, we may assume $s_i = f(t_i)$ for $t_i \in \mathcal{G}(U)$, so f is surjective on U. □

(Quasi-)Coherent Sheaves

Def. (5.2.2.25) [Quasi-Coherent Sheaf]. An $\mathcal{O}$-module $\mathcal{F}$ on a ringed site is called **quasi-coherent** iff locally it is a cokernel of two free modules. A locally f.p. sheaf of modules is Qco.

Prop. (5.2.2.26) [Associated Qco Sheaves]. And for a ringed space $(X, \mathcal{O}_X)$ and a $R = \Gamma(X, \mathcal{O}_X)$-module M, we have a coherent sheaf $\mathcal{F}_M$ on X, defined as $\pi^*(M)$, where M is seen as a qco sheaf on (pt, R). It is the sheaf associated to the presheaf $U \mapsto \mathcal{O}_X(U) \otimes M$.

This construction is a functor from the category of R-module to the category of Qco $\mathcal{O}_X$-modules, and it commutes with colimits because π^* does. And it is left adjoint to Γ by(5.2.2.9):

$$\mathrm{Hom}_A(M, \Gamma(X, \mathcal{G})) \cong \mathrm{Hom}_{\mathcal{O}_X}(\mathcal{F}_M, \mathcal{G})$$

Def. (5.2.2.27) [Coherent Sheaves]. A **coherent sheaf** is a $\mathcal{O}$-module $\mathcal{F}$ that is of f.t. and for any object U and for any set of elements of $\Gamma(U, \mathcal{F})$, the kernel of $\oplus \mathcal{O}_U \to \mathcal{F}|_U$ is of f.t..

A coherent sheaf is of f.p., by base change to a smaller covering, and it is Qco.

Prop. (5.2.2.28) [Properties of Coherent Sheaves]. Any f.t. subsheaf of a coherent sheaf is coherent, by definition. Any kernel of a morphism from a f.t. sheaf to a coherent sheaf is of f.t..

$\mathcal{C}oh(X)$ is a weak Serre subcategory of $\mathcal{M}od_{\mathcal{O}_X}$. In particular, if $\mathcal{O}_X$ is coherent, then a sheaf is coherent iff it is f.p.

Proof: Let $\mathcal{G}$ be a sheaf of f.t. and $\mathcal{F}$ be a coherent sheaf. For any map $f : \mathcal{G} \to F$ and $U \in \mathcal{C}$, let $\{U_i \to U\}$ be a covering that there are surjections $\varphi_i : \mathcal{O}_{U_i}^{n_i} \to G|_{U_i}$. Then $\ker(f \circ \varphi_i)$ is a $\mathcal{O}_U$-module of f.t.. Now $\varphi_i : \ker(f \circ \varphi_i) \to \ker(f)|_{U_i}$ is a surjection, so $\ker(f)|_{U_i}$ is of f.t., and $\ker(f)$ is of f.t..

The kernel of a map between coherent sheaves is of f.t. by the result above, thus it is coherent.

Let $\varphi : \mathcal{F}_1 \to \mathcal{F}$ be a map between coherent sheaves, then $\mathrm{Im}(\varphi)$ and $\mathrm{Coker}(\varphi)$ are of f.t.. For any $U \in \mathcal{C}$ and sections $\overline{s}_i$ of $\mathrm{Coker}(\varphi)(U)$ inducting a map $\overline{\Phi} : \mathcal{O}_U^n \to \mathrm{Coker}(\varphi)|_U$, we can choose a covering $\{U_i \to U\}$ that $\overline{s}_i$ comes from $s_i \in \mathcal{F}(U_i)$ for any i. Now we can choose coverings $\{U_{ij} \to U_i\}$ that there are surjections $\mathcal{O}_{U_{ij}}^{n_{ij}} \to \mathrm{Im}(\varphi)(U_{ij})$. Consider the commutative diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathcal{O}|_{U_{ij}}^{n_{ij}} & \longrightarrow & \mathcal{O}|_{U_{ij}}^{n_{ij}} \oplus \mathcal{O}_{U_{ij}}^n & \longrightarrow & \mathcal{O}_{U_{ij}}^n & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow{\scriptstyle \Phi} & & \downarrow & & \\
0 & \longrightarrow & \mathrm{Im}(\varphi)|_{U_{ij}} & \longrightarrow & \mathcal{F}|_{U_{ij}} & \longrightarrow & \mathrm{Coker}(\varphi)|_{U_{ij}} & \longrightarrow & 0
\end{array},$$

then snake lemma gives a surjection $\ker\Phi \to \ker(\overline{\Phi}) \to 0$. Because $\ker\Phi$ is of f.t., so does $\ker(\overline{\Phi})$, and $\mathrm{Coker}(\varphi)$ is coherent.

Let $0 \to \mathcal{F}_1 \to \mathcal{F}_2 \to \mathcal{F}_3 \to 0$ be an exact sequence that $\mathcal{F}_1, \mathcal{F}_3$ is coherent, then by(5.2.2.20), $\mathcal{F}_2$ is of f.t.. For any object $U \in \mathcal{C}$, consider the commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & 0 & \longrightarrow & \mathcal{O}_U^n & \longrightarrow & \mathcal{O}_U^n & \longrightarrow & 0 \\ & & \downarrow & & \downarrow{\scriptstyle\varphi_1} & & \downarrow{\scriptstyle\varphi_2} & & \\ 0 & \longrightarrow & \mathcal{F}_1|_U & \longrightarrow & \mathcal{F}_2|_U & \longrightarrow & \mathcal{F}_3|_U & \longrightarrow & 0 \end{array},$$

the snake lemma gives an exact sequence $0 \to \ker(\varphi_1) \to \ker(\varphi_2) \to \mathcal{F}_1|_U$. So $\ker(\varphi_1)$ is of f.t., so $\mathcal{F}_2$ is coherent. □

Prop. (5.2.2.29). The pullback of a (quasi-)coherent module is a (quasi-)coherent, because f^* is a left adjoint.

Prop. (5.2.2.30). (Quasi-)Coherence is local on the target.

Proof: This is because they are defined locally. □

Prop. (5.2.2.31). Let $(X, \mathcal{O}_X)$ be a ringed space and $x \in X$.

- Let $f : \mathcal{G} \to \mathcal{F}$ be a map of $\mathcal{O}_X$-modules. If $\mathcal{G}$ is of f.t. and $\mathcal{F}$ is coherent, and f is injective at the stalk of x, then there exists a nbhd U of x that $f|_U$ is injective.
- Let $f : \mathcal{G} \to \mathcal{F}$ be a map of coherent $\mathcal{O}_X$-modules that is surjective at the stalk of x, then there exists a nbhd U of x that $f|_U$ is surjective.
- Let $f : \mathcal{G} \to \mathcal{F}$ be a map of coherent $\mathcal{O}_X$-modules that is isomorphism at the stalk of x, then there exists a nbhd U of x that $f|_U$ is an isomorphism.

Proof: 1: Consider the kernel of f, then it is of f.t. by definition(5.2.2.27). Then $\ker(f)_x = 0$, so there is a nbhd U of x that $\ker(f)|_U = 0$, by(5.2.2.24), which means $f|_U$ is injective.

2: this is immediate from(5.2.2.24).

3 follows from 1 and 2. □

3 Construction of Sheaves

Internal Hom

Def. (5.2.3.1) [Internal Hom]. Let $\mathcal{C}$ is a category and $\mathcal{O}$ is a presheaf of rings, $\mathcal{F}, G$ be presheaves of $\mathcal{O}$-modules, then $U \mapsto \mathrm{Hom}_{\mathcal{O}|_U}(\mathcal{F}|_U, \mathcal{G}|_U)$ defines a presheaf $\mathcal{H}om(\mathcal{F}, \mathcal{G})$ of $\mathcal{O}$-modules, and there is a natural evaluation map

$$\mathcal{F} \otimes_{\mathcal{O}} \mathcal{H}om(\mathcal{F}, \mathcal{G}) \to \mathcal{G}.$$

Now if $\mathcal{C}$ is a site and $\mathcal{O}$ is a sheaf of rings, $\mathcal{F}, G$ be sheaves of $\mathcal{O}$-modules, then $\mathcal{H}om_{\mathcal{O}}(\mathcal{F}, \mathcal{G})$ is a sheaf of $\mathcal{O}$-modules by(5.1.3.17), called the **internal Hom sheaf**. Denote $\mathcal{H}om(\mathcal{F}, \mathcal{O})$ by $\mathcal{F}^\vee$.

Prop. (5.2.3.2). Internal Hom sheaf commutes with localization: $\mathcal{H}om_{\mathcal{O}_U}(\mathcal{F}|_U, \mathcal{G}|_U) = \mathcal{H}om_{\mathcal{O}}(\mathcal{F}, \mathcal{G})|_U$. This follows from thedefinition.

Prop. (5.2.3.3) [Tensoring and Inner Hom]. If $\mathcal{C}$ is a site, $\mathcal{O}$ is a sheaf of rings and $\mathcal{F}, \mathcal{G}, \mathcal{H}$ are sheaves of $\mathcal{O}$-modules, then there is a canonical isomorphism of sheaves:

$$\mathcal{H}om_{\mathcal{O}}(\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}, \mathcal{G}) \cong \mathcal{H}om_{\mathcal{O}}(\mathcal{F}, \mathcal{H}om_{\mathcal{O}}(\mathcal{H}, \mathcal{G})).$$

In particular, taking limit over $\mathcal{C}$, we see $- \otimes_{\mathcal{O}} \mathcal{H}$ is left adjoint to $\mathcal{H}om_{\mathcal{O}}(\mathcal{F}, -)$:

$$\mathrm{Hom}_{\mathcal{O}}(\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}, \mathcal{G}) \cong \mathrm{Hom}_{\mathcal{O}}(\mathcal{F}, \mathcal{H}om_{\mathcal{O}}(\mathcal{H}, \mathcal{G})).$$

In particular, the monoidal category of $\mathcal{O}_X$-modules is closed(5.2.2.15).

Proof: Omitted(Recall the definition of tensor product sheaf(5.2.2.7)). □

Prop. (5.2.3.4).

$$\mathcal{H}om(\varinjlim A_i, B) \cong \varprojlim \mathcal{H}om(A_i, B) \quad \mathcal{H}om(A, \varprojlim B_i) \cong \varprojlim \mathcal{H}om(A, B_i)$$

Proof: This is immediate from(3.1.5.10). □

Prop. (5.2.3.5). f^* is left adjoint to f_* by(5.2.2.9): $\mathrm{Hom}_{\mathcal{O}_X}(f^*\mathcal{G}, \mathcal{F}) \cong \mathrm{Hom}_{\mathcal{O}_Y}(\mathcal{G}, f_*\mathcal{F})$. In fact

$$f_*(\mathcal{H}om_{\mathcal{O}}(f^*\mathcal{G}, \mathcal{F})) \cong \mathcal{H}om_{\mathcal{O}'}(\mathcal{G}, f_*\mathcal{F}).$$

by checking on every open subset $U \subset Y$.

Prop. (5.2.3.6). Let $\mathcal{C}$ be a site and $\mathcal{O} \to O'$ is a map of sheaves of rings, then for any $\mathcal{G} \in \mathcal{M}\mathrm{od}(\mathcal{O}')$ and $\mathcal{F} \in \mathcal{M}\mathrm{od}(\mathcal{O})$, there is a natural isomorphism

$$\mathrm{Hom}_{\mathcal{O}}(\mathcal{G}, \mathcal{F}) = \mathrm{Hom}_{\mathcal{O}'}(\mathcal{G}, \mathcal{H}om_{\mathcal{O}}(\mathcal{O}', \mathcal{F})).$$

by checking on every open subset $U \subset Y$.

Prop. (5.2.3.7). Let $f_* : (X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)$ be a morphism of ringed spaces, and $\mathcal{F}, \mathcal{G}$ are $\mathcal{O}_Y$-modules. If $\mathcal{F}$ is f.p. and f is flat, then the canonical map

$$f^*\mathcal{H}om_{\mathcal{O}_Y}(\mathcal{F}, \mathcal{G}) \to \mathcal{H}om_{\mathcal{O}_X}(f^*\mathcal{F}, f^*\mathcal{G})$$

is an isomorphism.

Proof: ? □

Prop. (5.2.3.8). Let $(X, \mathcal{O}_X)$ be a ringed space and $\mathcal{F}, \mathcal{G}$ be $\mathcal{O}_X$-modules. If $\mathcal{F}$ is f.p. or locally free, then the canonical map

$$\mathcal{H}om(\mathcal{F}, \mathcal{G})_x \to \mathrm{Hom}_{\mathcal{O}_{X,x}}(\mathcal{F}_x, \mathcal{G}_x)$$

is an isomorphism.

Proof: Choose a presentation of $\mathcal{F}$. This follows from the exactness of taking stalks and(5.2.3.4). □

Prop. (5.2.3.9). Let $(X, \mathcal{O}_X)$ be a ringed site and $\mathcal{F}, \mathcal{G}$ be $\mathcal{O}_X$-modules. If $\mathcal{F}$ is f.p. and $\mathcal{G}$ is coherent, then $\mathcal{H}om(\mathcal{F}, \mathcal{G})$ is also coherent. In particular, this applies to $\mathcal{F}, \mathcal{G}$ both coherent.

Proof: This follows from(5.2.3.4) and(5.2.2.28). □

Tensor Sheaves

Def. (5.2.3.10) [Tensor Sheaves]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site and $\mathcal{F}$ an $\mathcal{O}$-module, then we define

- $T(\mathcal{F})$ to be the sheafification of the presheaf $U\mapsto T_{\mathcal{O}_X(U)}(\mathcal{F}(U))$(4.1.1.20).
- $\wedge\mathcal{F}$ to be the sheafification of the presheaf $U\mapsto \wedge_{\mathcal{O}_X(U)}(\mathcal{F}(U))$(4.1.1.20).
- $\mathrm{Sym}(\mathcal{F})$ to be the sheafification of the presheaf $U\mapsto \mathrm{Sym}_{\mathcal{O}_X(U)}(\mathcal{F}(U))$(4.1.1.20).

Cor. (5.2.3.11). Over a ringed space $(X,\mathcal{O}_X)$, the construction of $T(\mathcal{F}),\wedge(\mathcal{F})$ and $Sym(\mathcal{F})$ commutes with taking stalks, because the construction of tensor algebras and shifification are both left adjoints(4.1.1.21). Also they commutes with pullbacks, because they satisfy the same universal properties.

Prop. (5.2.3.12). let $\mathcal{F}$ be an $(\mathcal{C},\mathcal{O})$-module, then the following properties are preserved under the construction of $T(\mathcal{F}),\wedge(\mathcal{F})$ and $\mathrm{Sym}(\mathcal{F})$:

- Locally generated by sections.
- Finite Type.
- Finite Presented.
- Coherent.
- Quasi-coherent.
- Locally free.

Proof: Cf.[Sta]01CL. □

4 Sheaf of Differentials

Prop. (5.2.4.1). If $\mathcal{C}$ is a site and $\mathcal{O}_1\to\mathcal{O}_2$ is a homomorphism of sheaves of rings and $\mathcal{F}$ is a sheaf of $\mathcal{O}_2$-modules, then an $\mathcal{O}_1$**-derivation** from $\mathcal{O}_2$ to $\mathcal{F}$ is a map that for any $U\in\mathcal{C}$, the map $\mathcal{O}_2(U)\to\mathcal{F}(U)$ is a $\mathcal{O}_1(U)$-derivation(4.4.3.1).

Prop. (5.2.4.2) [Sheaf of Differentials]. Let $\mathcal{C}$ be a site and $\mathcal{O}_1\to\mathcal{O}_2$ is a homomorphism of sheaves of rings and $\mathcal{F}$ is a sheaf of $\mathcal{O}_2$-modules, then the functor $\mathcal{M}od(\mathcal{O}_2)\to Ab:\mathcal{F}\to Der_{\mathcal{O}_1}(\mathcal{O}_2,\mathcal{F})$ is representable by a sheaf of modules $\Omega_{\mathcal{O}_2/\mathcal{O}_1}$, called the **sheaf of differentials**. and the map $d:\mathcal{O}_2\to\Omega_{\mathcal{O}_2/\mathcal{O}_1}$ is called the universal derivation.

Proof: The construction is similar to that of(4.4.3.4): if for any sheaf $\mathcal{F}$ we denote $\mathcal{O}_2[\mathcal{F}]$ generated by shifification of the presheaf $U\mapsto\mathcal{O}_2(U)[\mathcal{F}(U)]$, then $\Omega_{\mathcal{O}_2/\mathcal{O}_1}$ is the cokernel of

$$\mathcal{O}_2[\mathcal{O}_2\times\mathcal{O}_2]\oplus\mathcal{O}_2[\mathcal{O}_2\times\mathcal{O}_2]\oplus\mathcal{O}_2[\mathcal{O}_1]\to\mathcal{O}_2[\mathcal{O}_2]$$

□

Prop. (5.2.4.3) [Localness of Sheaf of Differentials]. If $\mathcal{O}_1\to\mathcal{O}_2$ is a homomorphism of presheaves of rings, then $\Omega_{\mathcal{O}_2^\sharp/\mathcal{O}_1^\sharp}$ is the sheafification of the presheaf $U\mapsto\Omega_{\mathcal{O}_2(U)/\mathcal{O}_1(U)}$.

Proof: This is because the construction of $\Omega_{\mathcal{O}_2^\sharp/\mathcal{O}_1^\sharp}$(4.4.3.4) for all U gives an exact sequence of presheaves, and the shifification of which is just the construction in(5.2.4.2), so we are done because shifification is exact(5.1.2.7). □

Prop. (5.2.4.4) [Change of Sites]. Let $f:\mathcal{Sh}(\mathcal{D})\to\mathcal{Sh}(\mathcal{C})$ be a morphism of topoi and $\varphi:\mathcal{O}_1\to\mathcal{O}_2$ a homomorphism of rings on $\mathcal{C}$, then there is a canonical isomorphism $f^{-1}\Omega_{\mathcal{O}_2/\mathcal{O}_1}\cong\Omega_{f^{-1}\mathcal{O}_2/f^{-1}\mathcal{O}_1}$ compatible with the universal derivations.

Proof: This follows from the construction(5.2.4.2) and the fact f^{-1} is exact(5.2.4.2). □

Prop. (5.2.4.5) [Functoriality of Ω]. Let $\varphi:(\mathcal{O}_1\to\mathcal{O}_2)\to(\mathcal{O}_1'\to\mathcal{O}_2')$ be a commutative diagram of sheaves of rings over a site $\mathcal{C}$, then the map $\mathcal{O}_1'\to\mathcal{O}_2'$ composed with the derivative $\mathcal{O}_2'\to\Omega_{\mathcal{O}_2'/\mathcal{O}_1'}$ is a $\mathcal{O}_1'$-derivative, thus we obtain a map of $\mathcal{O}_2$-modules $\Omega_{\mathcal{O}_2/\mathcal{O}_1}\to\Omega_{\mathcal{O}_2'/\mathcal{O}_1'}$, or equivalently a map of $\mathcal{O}_2'$-modules $\Omega_{\mathcal{O}_2/\mathcal{O}_1}\otimes_{\mathcal{O}_2}\mathcal{O}_2'\to\Omega_{\mathcal{O}_2'/\mathcal{O}_1'}$. Thus $\Omega_{-/-}$ is a functor of arrows.

Moreover, if $\mathcal{O}_2'=\mathcal{O}_2\otimes_{\mathcal{O}_1}\mathcal{O}_1'$, then this map is an isomorphism, by(5.2.4.3) and(4.4.3.6).

Prop. (5.2.4.6). Let $\mathcal{O}_1\to\mathcal{O}_2\to\mathcal{O}_2'$ be a map of sheaves of rings that $\mathcal{O}_2\to\mathcal{O}_2'$ is surjective with kernel $\mathcal{I}\subset\mathcal{O}_2$, then there is a canonical exact sequence of $\mathcal{O}_2'$-modules

$$\mathcal{I}/\mathcal{I}^2\to\Omega_{\mathcal{O}_2/\mathcal{O}_1}\otimes_{\mathcal{O}_2}\mathcal{O}_2'\to\Omega_{\mathcal{O}_2'/\mathcal{O}_1}\to 0,$$

where the first map is characterized by mapping local sections f of $\mathcal{I}$ to $df\otimes 1$.

Proof: The first map is well-defined if $d(\mathcal{I}^2)=0$. To show the exactness, let $\mathcal{O}_2''\subset\mathcal{O}_2'$ to be the presheaf of $\mathcal{O}_1$-algebras that $\mathcal{O}_2''(U)$ the image of $\mathcal{O}_2(U)\to\mathcal{O}_2'(U)$. Then there is an exact sequence

$$\mathcal{I}(U)/\mathcal{I}(U)^2\to\Omega_{\mathcal{O}_2(U)/\mathcal{O}_1(U)}\otimes_{\mathcal{O}_2(U)}\mathcal{O}_2''(U)\to\Omega_{\mathcal{O}_2''(U)/\mathcal{O}_1(U)}\to 0$$

by(4.4.3.8). Now shifification of these presheaves gives use the desired result by(5.2.4.3). □

Def. (5.2.4.7) [Sheaf of Differentials]. Let $(X,\mathcal{O}_X)\to(S,\mathcal{O}_S)$ be a morphism of ringed sites,

- Let $\mathcal{F}$ be an $\mathcal{O}_X$-module, an S-derivation from $\mathcal{O}_X$ to $\mathcal{F}$ is a derivation over $f^{-1}\mathcal{O}_S$. The set of S-derivations is denoted by $\mathrm{Der}_S(\mathcal{O}_X,\mathcal{F})$.
- the **sheaf of differentials** $\Omega_{X/S}$ is defined to be a sheaf of modules $\Omega_{\mathcal{O}_X/f^{-1}\mathcal{O}_S}$(5.2.4.2), with a universal derivation $d_{X/S}:\mathcal{O}_X\to\Omega_{X/S}$.

5 Locally Free sheaves

Prop. (5.2.5.1). Pullbacks of (finite)locally free sheaves are (finite)locally free. Sub-$\mathcal{O}_X$-modules of a (finite)locally free sheaf is (finite)locally free, by(2.2.4.21).

Prop. (5.2.5.2) [Finite Locally Free Sheaves and $\mathcal{H}om$]. For any finite locally free sheaf $\mathcal{E}$ on a ringed site $(\mathcal{C},\mathcal{O})$:

- $\mathcal{E}^{\vee\vee}\cong\mathcal{E}$.
- $\mathcal{H}om_{\mathcal{O}}(\mathcal{E},\mathcal{F})\cong\mathcal{E}^\vee\otimes_{\mathcal{O}}\mathcal{F}$.
- $\mathcal{H}om_{\mathcal{O}}(\mathcal{F},\mathcal{G})\otimes\mathcal{H}\cong\mathcal{H}om_{\mathcal{O}}(\mathcal{F},\mathcal{G}\otimes_{\mathcal{O}}\mathcal{H})$ if $\mathcal{F}$ or $\mathcal{H}$ is finite locally free.
- $\mathcal{H}om_{\mathcal{O}}(\mathcal{E}\otimes\mathcal{F},\mathcal{G})\cong\mathcal{H}om_{\mathcal{O}}(\mathcal{F},\mathcal{E}^\vee\otimes\mathcal{G})$, by the first and(5.2.3.3).

Proof: We define the map, and verify locally, which is by1. □

Prop. (5.2.5.3). $\mathcal{H}om(\mathcal{H},-)$ is exact for any locally free sheaf $\mathcal{H}$.

Invertible Sheaves

Def. (5.2.5.4)[Invertible Sheaf]. An **invertible sheaf** $\mathcal{L}$ on a ringed topoi $(\mathcal{S}h(\mathcal{C}),\mathcal{O})$ is an invertible object in the symmetric monoidal category $\mathcal{M}od_{\mathcal{O}}$(3.1.5.21).

Prop. (5.2.5.5). Let $(\mathcal{C},\mathcal{O})$ be a ringed site and $\mathcal{L}$ an $\mathcal{O}$-module, the following are equivalent:

- $\mathcal{L}$ is an invertible sheaf.
- there exists some $\mathcal{O}$-module $\mathcal{N}$ that $\mathcal{L}\otimes_{\mathcal{O}}\mathcal{N}\cong\mathcal{O}$.

And in this case, $\mathcal{L}$ is flat and of finite presentation, and $\mathcal{N}\cong\mathcal{H}om_{\mathcal{O}}(\mathcal{L},\mathcal{O})$.

Proof: $\mathcal{L}$ is flat because tensoring $\mathcal{L}$ is an equivalence thus exact. Let $\psi:\mathcal{L}\otimes_{\mathcal{O}}\mathcal{N}\cong\mathcal{O}$ the isomorphism, U an element of $\mathcal{C}$, then by construction of $\otimes$, after localization, we may assume there exists sections $x_i\in\mathcal{L}(U), y_i\in\mathcal{N}(U)$ that $\psi(x_i\otimes y_i)=1$. Then there is an automorphism of $\mathcal{L}|_U: x\mapsto\sum\psi(x\otimes y_i)x_i$. This automorphism factors through

$$\mathcal{L}|_U\to\mathcal{O}_U^{\oplus n}\to\mathcal{L}|_U,$$

thus $\mathcal{L}|_U$ is a direct summand of a finite free $\mathcal{O}_U$-module, thus $\mathcal{L}$ is of finite presentation.

Assume $\mathcal{L}$ is invertible, consider the evaluation map

$$\mathcal{L}\otimes_{\mathcal{O}}\mathcal{H}om(\mathcal{L},\mathcal{O})\to\mathcal{O},$$

and by(5.2.3.3),

$$\mathrm{Hom}(\mathcal{O},\mathcal{O})=\mathrm{Hom}_{\mathcal{O}}(\mathcal{L}\otimes\mathcal{N},\mathcal{O})\to\mathrm{Hom}_{\mathcal{O}}(\mathcal{N},\mathcal{H}om_{\mathcal{O}}(\mathcal{L},\mathcal{O})).$$

The image of 1 gives a morphism $\mathcal{N}\to\mathcal{H}om_{\mathcal{O}}(\mathcal{L},\mathcal{O})$. Tensoring $\mathcal{L}$ gives the inverse of the evaluation map. □

Cor. (5.2.5.6). The pullback of an invertible sheaf is an invertible sheaf, because tensoring commutes with pullbacks(5.2.2.12).

Def. (5.2.5.7) [Picard Groups]. For any ringed site $(\mathcal{C},\mathcal{O})$, there is a set of invertible modules over $\mathcal{C}$ that any invertible module is isomorphic to exactly one of them. Then this set forms an Abelian group, called the **Picard group** $\mathrm{Pic}(\mathcal{O})$.

Prop. (5.2.5.8)[Invertible Sheaves and Locally Free Sheaves of Rank 1]. If $(X,\mathcal{O}_X)$ is a ringed space, then any locally free $\mathcal{O}_X$-module of rank 1 is invertible. And when $(X,\mathcal{O}_X)$ is a local ringed space, the converse holds as well.

Proof: Assume $\mathcal{L}$ is locally free of rank 1 and consider the evaluation map(5.2.3.1)

$$\mathcal{L}\otimes_{\mathcal{O}}\mathcal{H}om(\mathcal{L},\mathcal{O})\to\mathcal{O}.$$

This map is an isomorphism when restricting to any trivializing covering of $\mathcal{L}$, so it is an isomorphism. Thus $\mathcal{L}$ is invertible by(5.2.5.5).

Assume $(\mathcal{S}h(\mathcal{C}),\mathcal{O})$ is a local ringed topoi and $\mathcal{L}$ is invertible, the proof of(5.2.5.5) shows there exists a covering $\{U_i\to U\}$ that $\mathcal{L}|_{U_i}$ is a direct summand of a finite free $\mathcal{O}_{U_i}$-module. Replacing U_i by U, let π be the projection of $\mathcal{O}_U^r$ onto $\mathcal{L}|_U$ which corresponds to a matrix with entries in $\mathcal{O}(U)$. The image of π acting on $\mathcal{O}(U)^r$ is a finite free $\mathcal{O}(U)$-module M, thus there are $f_1,\ldots,f_t$ generating unit ideal of $\mathcal{O}(U)$ such that M_{f_i} is finite free. Now by definition of local ringed topoi(5.2.1.6), after replacing U by a covering, we may assume M is finite free, which means $\mathcal{L}|_U$ is free summand of $\mathcal{O}_U^r$. But $\mathcal{L}$ is invertible, thus rank of $\mathcal{L}$ is 1. □

Prop. (5.2.5.9). Let X be a locally ringed space and $\mathcal{L} \in \mathrm{Pic}(X)$ that is generated by global sections $s_0, \ldots, s_n$. If $\mathcal{F}$ is the kernel of the map $\mathcal{O}_X^{\oplus n+1} \to \mathcal{L}$, then $\mathcal{F} \otimes \mathcal{L}$ is globally generated.

Proof: $\mathcal{F}$ is finite locally free of rank n by(5.2.5.1). The elements

$$s_{ij} = (0, \ldots, 0, s_j, 0, \ldots, 0, s_i, , \ldots, 0) \in \Gamma(X, \mathcal{L}^{\oplus n+1})$$

is in $\Gamma(X, \mathcal{F} \otimes \mathcal{L})$, and it can be verified locally s.t. they generate $\mathcal{F} \otimes \mathcal{L}$. □

6 Sheaves on Spaces

Sheaves on Topological Spaces

Remark (5.2.6.1). A topological space can be regarded as a ringed space by assigning the locally constant sheaf $\underline{\mathbb{Z}}$ as the structure sheaf.

Def. (5.2.6.2)[Grothendieck's Six Operators]. Let $f : X \to Y$ be a continuous map of topological spaces, then the inverse image defines a continuous map between sites $Y_{Zar} \to X_{Zar}$, so by(5.1.2.9) and(5.1.2.11) we can define

- the **pushforward** $f^p F$, $f^p F(U) = F(f^{-1}(U))$ sends presheaf to presheaf.
- the **direct image** $f_* \mathcal{F}$, $f_* \mathcal{F}(U) = \mathcal{F}(f^{-1}(U))$ sends sheaf to sheaf.
- the **inverse image** $f_p \mathcal{G}$, $f_p \mathcal{G}(U) = \varinjlim_{f(U) \subset V} \mathcal{G}(V)$ that sends presheaf to presheaf.
- the **inverse image** $f^{-1}\mathcal{G} = f_s(\mathcal{G})$ that sends sheaf to sheaf.
- For a morphism of locally compact spaces, we can define a **proper direct image**:

  $$f_!(\mathcal{F})(U) = \{s \in \Gamma(f^{-1}(U), \mathcal{F}) | \, \mathrm{Supp}(s) \to U \text{ proper}\}$$

  This is a subsheaf of $f_*\mathcal{F}$ and it is left exact. we denote $\Gamma_c(X, \mathcal{F})$ as the group $f_!(\mathcal{F})$ where $f : X \to \mathrm{pt}$. And the stalk $f_!(\mathcal{F})_y = \Gamma_c(f^{-1}(y), \mathcal{F}|_{f^{-1}(y)})$ Cf.[Gelfand P224 P225].
- the **proper inverse image** (special case) $i^!$ for a closed immersion $Z \subset X$ defined by

  $$i^!(\mathcal{F})(U = V \cap Z) = \{s \in \Gamma(V, \mathcal{F}) | \, \mathrm{Supp}(s) \in Z\}.$$

  sends Abelian sheaves to Abelian sheaves.
- the internal tensor product.
- the internal Hom.

Proof: Check that $f_!$ is a sheaf: it is separated clearly, it suffices to show that for a covering $\cup U_i = W$ and $\xi_i \in F(f^{-1}(U_i))$, the section $\xi \in F(f^{-1}(W))$ they generated by sheaf property of F is in $f_! F(W)$. For a compact subset K, there is a finite cover $\cup_i U_i$ of it, thus $K - \cup_{i \neq j} U_j$ is compact in U_j, thus its inverse image is compact in $\mathrm{Supp}(\xi)$. there are f.m. U_j, thus the inverse image of K is compact in $\mathrm{Supp}(\xi)$. □

Def. (5.2.6.3)[Stalks]. The convenience of rings spaces compared to the case of sites is the it has stalk functors: For any presheaf $\mathcal{F}$ on X and a point $i : x \to X$, define the **stalk** $\mathcal{F}_x = i_p(\mathcal{F})$(5.2.6.2).

Prop. (5.2.6.4)[Stalks Commutes with Shifification]. Taking stalks commutes with shifification.

Proof: Cf.[Sta]007Z. □

Prop. (5.2.6.5). If a sheaf on a ringed space has only one non-vanishing stalk, then it is a skyscraper sheaf. (Because the restriction map to that point for every open set is an isomorphism).

Prop. (5.2.6.6)[Stalks]. Taking stalks is a left adjoint to the skyscraper sheaf from Presheaves to Sets, thus it preserves cokernel. Moreover, for a map of sheaves $\mathcal{F} \to \mathcal{G}$ on X,

- φ is a monomorphism iff φ_x is injective for all $x \in X$.
- φ is an epimorphism iff φ_x is surjective for all $x \in X$.
- φ is an isomorphism iff φ_x is surjective for all $x \in X$.

Proof: 1: If φ is a monomorphism, then φ_x is clearly. Conversely, if φ_x are all injective, if $s \in \mathcal{F}(U)$ mapsto $0 \in (U)$, then s_x mapsto $0 \in \mathcal{G}_x$ for all x, thus $s_x = 0$ for all x, thus $s = 0$.

2: If φ is an epimorphism, then φ_x is surjective by definition. The converse is also true.

3: If φ_x is isomorphism for all x, then φ is monomorphism by 1, and for any $t \in \mathcal{G}(U)$, t is locally coming from some section of s, and these sections are compatible on their intersections because of monomorphism, so they glue together to a section $s \in \mathcal{F}(U)$ that $\varphi(U)(s) = t$. □

Prop. (5.2.6.7)[Topological Spaces and Sites]. Let $f : X \to Y$ be a continuous map of topological spaces, then f induces a map of sites $X \to Y$ because f^{-1} is exact(5.1.2.14), thus induces a map of topoi $f : \mathcal{S}\mathrm{h}(X) \to \mathcal{S}\mathrm{h}(Y)$(5.1.2.20).

Cor. (5.2.6.8). Let $f : X \to Y$ be a continuous map of topological spaces,

- Let $\mathcal{G}$ be a presheaf on Y, then there is a canonical bijection of stalks $(f_p(\mathcal{G}))_x = \mathcal{G}_{f(x)}$. If $\mathcal{G}$ is a sheaf on Y, then there is a canonical bijection of stalks $(f^{-1}(\mathcal{G}))_x = \mathcal{G}_{f(x)}$.
- f^{-1} is left adjoint to f_*.
- $f_!$ is left exact when X, Y are locally compact. And $j_!$ is left adjoint to the functor j^{-1} for an inclusion of open subset $j : U \subset X$.
- $i^!$ is right adjoint to i_* for a closed immersion $i : Z \to X$, in particular i_* is exact when i is a closed immersion.

Proof: 1: This is because $(-)_p$ commutes with composition(5.2.6.3), and also shification commutes with $(-)_p$(5.2.6.4).

2: This is immediate.

3:

4: The adjointness follows form the fact that any section under a homomorphism $i_*\mathcal{G} \to \mathcal{F}$ has support contained in Z. □

Prop. (5.2.6.9). Let $i : Z \to X$ be a closed immersion, then the functor $i_* : \mathcal{A}\mathrm{b}(Z) \to \mathcal{A}\mathrm{b}(X)$ is exact, fully faithful, with the essential image those sheaves with support in Z.

Prop. (5.2.6.10) [Canonical Exact Sequences]. We have a canonical exact sequences of sheaves of modules:

$$0 \to j_!(\mathcal{F}|_U) \to \mathcal{F} \to i_*(\mathcal{F}|_Z) \to 0$$

$$0 \to i_* i^!_Y \mathcal{F} \to \mathcal{F} \to j_*(\mathcal{F}|_U) \to 0$$

(check on stalks), which is important to use reduction to calculate sheaf cohomology. The latter induces long exact sequences:

$$0 \to H^0_Y(X, \mathcal{F}) \to H^0(X, \mathcal{F}) \to H^0(U, \mathcal{F}|_U) \to H^1_Y(X, \mathcal{F}) \to \cdots$$

Proof: Cf.[Sta]02UT. □

Prop. (5.2.6.11). On a topological space X, for a qc open subset U, $(\oplus\mathcal{F}_i)(U) = \oplus\mathcal{F}_i(U)$. This uses the compactness of U.

Morphisms of Local Ringed Spaces

Def. (5.2.6.12)[Open Immersion of Ringed Spaces]. A morphism $f : (X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)$ of ringed spaces is called an **open immersion** if f is a homeomorphism of X onto an open subset of Y, and the map $f^\sharp : f^{-1}(\mathcal{O}_Y) \to \mathcal{O}_X$ is an isomorphism.

Prop. (5.2.6.13). Let $(X, \mathcal{O}_X)$ be a ringed space, $U \subset X$ an open subset, and $\mathcal{O}_U = \mathcal{O}_X|_U$ is a sheaf of rings on U, then $(U, \mathcal{O}_U) \to (X, \mathcal{O}_X)$ is an open immersion, and $(U, \mathcal{O}_U)$ is called the **open subspace** associated to U.

Prop. (5.2.6.14) [Universal Property of Open Immersions]. Let $f : (X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)$ be an open immersion of ringed spaces, then it has the universal property that any morphism of ringed spaces $(T, \mathcal{O}_T) \to (Y, \mathcal{O}_Y)$ that factors set-theoretically through $f(X)$ factors uniquely through $(X, \mathcal{O}_X)$.

Def. (5.2.6.15) [Closed Immersion]. Let $i : Z \to X$ be a morphism of local ringed spaces, then i is called a **closed immersion** if:

- i is a homeomorphism of Z onto a closed subspace of X.
- the map $\mathcal{O}_X \to i_*\mathcal{O}_Z$ corresponding to $f^\sharp$ is surjective with kernel $\mathcal{I}$.
- the $\mathcal{O}_X$-module $\mathcal{I}$ is locally generated by sections.

And for a closed immersion, $\mathcal{I}$ is called the **ideal sheaf** of i.

Def. (5.2.6.16) [Closed Immersion Defined by Ideals]. Let $(X, \mathcal{O}_X)$ be a local ringed space, and $\mathcal{I} \subset \mathcal{O}_X$ a sheaf of ideals on X locally generated by sections , Let Z be the support of the sheaf of rings $\mathcal{O}_X/\mathcal{I}$. Z is closed in X because it is the support of 1. by(5.2.6.9), there is a unique sheaf of rings $\mathcal{O}_Z$ on Z that $i_*\mathcal{O}_Z = \mathcal{O}_X/\mathcal{I}$. For any $z \in Z$, the stalk $\mathcal{O}_z = \mathcal{O}_{X,z}/\mathcal{I}_z$ is a quotient of a local ring and is non-zero, thus a local ring. Then $(Z, \mathcal{O}_Z)$ is a local ringed space and $i : (Z, \mathcal{O}_Z) \to (X, \mathcal{O}_X)$ is a closed immersion, called the **closed immersion defined** $\mathcal{I}$.

Prop. (5.2.6.17) [Closed Immersions are Equivalent to Ideals]. Let $f : X \to Y$ be a closed immersion of local ringed spaces with ideal sheaf $\mathcal{I}$. Let $i : Z \to X$ be the closed immersion defined by $\mathcal{I}$(5.2.6.16), then f is isomorphic to i.

Proof: Because $f_*\mathcal{O}_Z \cong \mathcal{O}_X/\mathcal{I}$ on X. □

Prop. (5.2.6.18). For a closed immersion of ringed spaces f, f_* on $\mathcal{O}_X$-mod is fully faithful, with image those modules annihilated by $\mathcal{I}$, where $\mathcal{I}$ is the structural kernel.

Proof: Cf.[Sta]08KS. □

7 Spec and Schemes

Def. (5.2.7.1)[Spectrum]. Given a commutative ring A, the **spectrum** of A Spec A is a locally ringed space whose underlying space is the set of primes of A, and the topology is generated by the standard open subsets $D(f) = \{\mathfrak{p} | f \notin \mathfrak{p}\}$.

To define the structure sheaf $\mathcal{O}_X$, we first define a sheaf on the site of standard open subsets, which takes value R_f on $D(f)$. This is truly a sheaf by(4.4.2.3), and then we can use(5.1.2.25) to extend this sheaf to a sheaf on $\operatorname{Spec} A$, called the structure sheaf $\mathcal{O}_X$.

A locally ringed space of the form $\operatorname{Spec} A$ is called an **affine scheme**. The category of affine schemes is denoted by $\mathcal{A}\mathrm{ff}$.

Def. (5.2.7.2) [Schemes]. The category $\mathcal{S}\mathrm{ch}$ of **schemes** is the full subcategory of the category of local ringed spaces(5.2.1.10) consisting of local ringed spaces that are locally isomorphic to $\operatorname{Spec} A$.

Lemma (5.2.7.3). If X is a local ringed space, $x \in X$, and $Y = \operatorname{Spec} A$ an affine scheme, $f : X \to Y$ is a morphism, consider the ring map $\Gamma(X, \mathcal{O}_X) \xrightarrow{f^\sharp} \Gamma(Y, \mathcal{O}_Y) \to \mathcal{O}_{X,x}$, and consider the inverse image $\mathfrak{p}$ of $\mathfrak{m}_x$, which corresponds to $y \in Y$, then $f(x) = y$.

Proof: There are commutative diagrams

$$\begin{array}{ccc} \Gamma(Y, \mathcal{O}_Y) & \longrightarrow & \mathcal{O}_{Y,f(x)} \\ \downarrow & & \downarrow \\ \Gamma(X, \mathcal{O}_X) & \longrightarrow & \mathcal{O}_{X,x} \end{array}$$

and the map of local rings is a local ring map. So the inverse image of $\mathfrak{m}_x$ is just $\mathfrak{m}_{f(x)}$, so $\mathfrak{m}_{f(x)} = \mathfrak{m}_y$. □

Prop. (5.2.7.4). Let X be a local ringed spaces and $Y = \operatorname{Spec} A$ an affine scheme, then the map $\operatorname{Hom}(X, \operatorname{Spec} A) \to \operatorname{Hom}(A, \Gamma(X, \mathcal{O}_X))$ is an isomorphism.

Proof: The inverse map is constructed as follows: for any $\varphi : A \to \Gamma(X, \mathcal{O}_X)$ and $x \in X$, define $\Phi(x)$ to be the point corresponding to the inverse image of $\mathfrak{m}_x$ in $A \to \Gamma(X, \mathcal{O}_X) \to \mathcal{O}_{X,x}$. In this way, $\Phi^{-1}(D(f))$ is just $D(\varphi(f)) \subset X$ which is open, thus Φ is continuous. Now we want to construct a sheaf homomorphism $f^{-1}(\mathcal{O}_Y) \to \mathcal{O}_X$, and it suffices to construct compatible maps on the affine open basis $D(f)$, by(5.1.3.17). Now $\Gamma(D(f), \mathcal{O}_Y) = A_f$, and because f is invertible on $D(\varphi(f))$, there is by universal property a unique map $A_f \to D(\varphi(f))$ extending φ. Then by universal property these maps are compatible. Notice the construction here also shows the homomorphism is determined by the map set-theoretically.

Finally, we need to show this induces a local ring map on the stalks, and this is quite obvious from the definition.

Then we show these two maps are inverse to each other: It suffices to show any ring map $A \to \Gamma(X, \mathcal{O}_X)$ comes uniquely from a map $X \to Y$: the uniqueness is proven by(5.2.7.3), and the sheaf homomorphism is determined by the set-theoretical map by the above argument. □

Cor. (5.2.7.5) [Adjointness of Spec and Γ]. The Spec operator $\operatorname{Spec} : \mathcal{C}\mathcal{A}\mathrm{lg}^{op} \to \mathcal{S}\mathrm{ch}$ is right adjoint to $X \to \Gamma(X, \mathcal{O}_X)$:

$$\operatorname{Hom}_{\mathcal{S}\mathrm{ch}}(X, \operatorname{Spec}(A)) \cong \operatorname{Hom}_{\mathcal{C}\mathcal{A}\mathrm{lg}}(A, \Gamma(X, \mathcal{O}_X)).$$

Notice the category of schemes is a full subcategory of the category of locally ringed spaces.

Cor. (5.2.7.6). $\mathcal{A}\mathrm{ff}$ is equivalent to $\mathcal{C}\mathcal{A}\mathrm{lg}^{op}$.

Prop. (5.2.7.7) [Points of Schemes]. Let X be a scheme and R a local ring, then there is a natural bijection between morphisms $\operatorname{Spec} R \to X$ and pairs (p, φ) where $p \in X$ is a point and $\varphi : \mathcal{O}_{X,x} \to R$ is a local ring map.

Proof: Consider where the closed point of $\operatorname{Spec} R$ is mapped to and choose an affine open nbhd of that point, then we reduce to the affine case, which is by(5.2.7.5). □

Cor. (5.2.7.8). if $f : Y \to X$ is a morphism of schemes that $f(y) = x$, then we have a commutative diagram

$$\begin{array}{ccc} \mathcal{O}_{Y,y} & \longrightarrow & Y \\ \downarrow & & \downarrow \\ \mathcal{O}_{X,x} & \longrightarrow & X \end{array}$$

Cor. (5.2.7.9). The points of X are in bijection with equivalent classes of morphisms from the spectra of fields to X, and each equivalent class contains a minimal element $\operatorname{Spec} k(x) \to X$.

Proof: This is because a local ring map from $\mathcal{O}_{X,x}$ to a field factors through $k(x)$. □

Prop. (5.2.7.10). The closure of a subset T of $\operatorname{Spec}(A)$ is $V(\cap p, p \in T)$.

Prop. (5.2.7.11) [Scheme is Sober]. The underlying space of a scheme is sober.

Proof: Firstly this is true for affine schemes, by(3.11.4.13). Then notice for any affine open subscheme U, the generic point for $Z \cap U$ is the generic point for Z. □

Construction of Schemes

Prop. (5.2.7.12) [Global Spec]. There is an S-scheme $f : \mathbf{Spec}_S \mathcal{A} \to S$ for every Qco sheaf of $\mathcal{O}_S$-algebras $\mathcal{A}$ on S that for any affine open subscheme $U \subset X$, $f^{-1}(U) \cong \operatorname{Spec} \mathcal{A}(U)$ over U. This construction is right adjoint to the direct image map:

$$\operatorname{Hom}_{\mathcal{CAlg}_{\mathcal{O}_S}}(\mathcal{A}, \pi_*\mathcal{O}_X) \cong \operatorname{Hom}_{\mathcal{Sch}/S}(X, \mathbf{Spec}_S \mathcal{A}).$$

and defines an equivalence of affine morphisms over S and Qco $\mathcal{O}_S$-algebras. Moreover, this defines an equivalence of the category of $\mathcal{A}$-modules and the category of $\mathcal{O}_{\mathbf{Spec}\,\mathcal{A}}$-modules.

Proof: Choose an affine open covering $\{U_i \to X\}$ of X, and consider the schemes $\operatorname{Spec} \mathcal{A}(U_i) \to U_i$ over U_i, then their restrictions to U_{ij} are compatible, because this is true after further restriction to an affine open covering of U_{ij}, we can use(5.1.5.4). Then we can use(5.1.5.4) to get an S-scheme $f : \mathbf{Spec}_S \mathcal{A} \to S$ that $f^{-1}(U_i) \cong \operatorname{Spec} \mathcal{A}(U_i)$.

Now we check that for any affine open subset $U \subset X$, $f^{-1}(U) \cong \operatorname{Spec} \mathcal{A}(U)$ over U. But this is true after base change to $U_i \cap U$ for any i, so it is true, by(5.1.5.4).

To show the adjointness condition, by(5.1.5.4), it suffices to show canonical(thus compatible) isomorphism for S affine. In this case, this reduces to(5.2.7.5). □

Cor. (5.2.7.13). Let S be a scheme and $\mathcal{A}$ is a Qco sheaf of $\mathcal{O}_S$-algebras, then

- For any morphism $g : S' \to S$, $S' \times_S \mathbf{Spec}_S(\mathcal{A}) \cong \mathbf{Spec}_{S'}(g^*\mathcal{A})$.
- The natural map $\mathcal{A} \to \pi_*\mathcal{O}_{\mathbf{Spec}_S(\mathcal{A})}$ is an isomorphism of $\mathcal{O}_S$-algebras.

Proof: 1: It can be checked that $S' \times_S \mathbf{Spec}_S(\mathcal{A})$ and $\mathbf{Spec}_{S'}(g^*\mathcal{A})$ satisfy the same universal property.

2: It suffices to check on affine opens, then it is trivial. □

Lemma (5.2.7.14) [Affine Case]. Fiber product of affine schemes is also affine that corresponds to the tensor product of their corresponding rings, by(5.2.7.5).

Prop. (5.2.7.15) [Finite Limits of Schemes]. Fiber products exist in the category of schemes, and there is a final object $\operatorname{Spec}\mathbb{Z}$, so arbitrary limits exist in the category of schemes(3.1.1.47).

In fact, finite limits exists in the category of ringed spaces, and finite limits of schemes coincide with finite limits as ringed spaces.

Proof: Let $f: X \to S, g: Y \to S$, and U_i is an affine open covering of S, V_ij is an affine open covering of $f^{-1}(U_i)$ and W_{ik} is an affine open covering of $g^{-1}(U_i)$, then we can check $h_{V_{ij}} \times_{h_{U_i}} h_{W_{ik}}$ is a covering of $h_X \times_{h_S} h_Y$ by representable open subfunctors(8.7.1.13), by(5.2.7.14), thus it is representable. □

Cor. (5.2.7.16) [Open Subschemes]. Let $X \to S, Y \to S$, and $V \subset X, W \subset Y$ be open subschemes mapping into open subscheme $U \subset S$, then there is a natural open immersion $V \times_U W \to X \times_S Y$ with image $\pi_1^{-1}V \cap \pi_2^{-1}(W)$.

Proof: There is a natural map $V \times_U W \to X \times_S Y$ by Yoneda lemma, and this map has the universal property that any map $f: (T, \mathcal{O}_T) \to X \times_S Y$ that $\pi_1 \circ f$ has image in V and $\pi_2 \circ f$ has image in W factors uniquely through $V \times_U W$. But so does the open immersion $\pi_1^{-1}V \cap \pi_2^{-1}(W) \to X \times_S Y$(5.2.6.14), so they are equal. □

Cor. (5.2.7.17). Let $f: X \to S, g: Y \to S$, and U_i is an affine open covering of S, V_ij is an affine open covering of $f^{-1}(U_i)$ and W_{ik} is an affine open covering of $g^{-1}(U_i)$, then

$$X \times_S Y = \cup_i \cup_{j,k} V_{ij} \times_{U_i} W_{ik}$$

is an affine open covering of $X \times_S Y$.

Also, the structure sheaf of $X \otimes_S Y$ is given by $\mathcal{O}_{X\times_S Y} = \pi_1^{-1}\mathcal{O}_X \otimes_{\pi^{-1}\mathcal{O}_S} \pi_2^{-1}\mathcal{O}_Y$.

Cor. (5.2.7.18). The equalizer of two morphisms from X to Y exists, it is a locally closed subscheme of X, and it is a closed subscheme of X if Y is separated.

Proof: because it is the base change of $\Delta: Y \to Y \times Y$(3.1.1.47), then use(5.4.4.76). □

Remark (5.2.7.19) [Infinite Product of Schemes Doesn't Exists]. WARNING: infinite products of schemes may not exists, Cf.[Sta]0CNH. Intuitively, if you want to glue affine products together, you will notice you can identify only those products that is equal a.e..

Remark (5.2.7.20). Let X be a scheme over S and $S' \to S$ is a morphism of schemes, then we sometimes denote $X \times_S S'$ by $X_{S'}$, if no confusion is caused.

Def. (5.2.7.21) [Generic Fibers and Special Fibers]. If X is a scheme over an integral ring A, then the **generic fiber** of X/A is the stalk X_η, where $\eta = (0) \in \operatorname{Spec} A$.

If X is a scheme over a ring R, a **special fiber** is the stalk of X over a maximal ring $\mathfrak{m}$.

8 Rational Maps

Def. (5.2.8.1) [Rational Maps]. Let $X, Y \in \mathcal{S}\mathrm{ch}/S$ and Y/S separated, a **rational map** over S $f: X \to Y$ is an equivalence class of maps $U \to Y$ over S where U is an open dense subset of X. A **rational function** on X is a rational map $X \to \mathbb{A}^1$. It has a ring structure. The ring of rational functions is denoted by $R(X)$.

Because two rational maps are equivalent iff they are compatible on the intersection of their domain as Y/S is separated, a rational map $\varphi: X \to Y$ has a maximal domain of definition, denoted by $\operatorname{dom}(\varphi)$.

Prop. (5.2.8.2). If X is a scheme with f.m. generic points η_i, then

$$R(X) = \prod \mathcal{O}_{X,\eta_i}.$$

Proof: Cf.[Sta]01RV. □

Def. (5.2.8.3) [Birational Maps]. $X, Y \in \mathcal{S}\mathrm{ch}/S$ are called **birational** over S if they are isomorphic in the category of S-schemes with dominant rational maps.

Prop. (5.2.8.4). Two schemes X, Y over S are birational over S iff there are nonempty open subschemes $U \subset X, V \subset Y$ that are isomorphic over S.

Proof: □

Def. (5.2.8.5) [S-Dense Subsets]. Let $X \in \mathcal{S}\mathrm{ch}/S$, a subscheme $U \subset X$ is called **S-dense** if U_s is dense in X_s for any $s \in S$.

Prop. (5.2.8.6). Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{pf}}/S$ and $V \subset X$ is a qc open subscheme, then the set of points $s \in S$ s.t. $V_s \subset X_s$ is not dense is locally constructible in S. And if V is S-dense in X, then it is also schematically dense in X.

Proof: Cf.[**?**]P56. □

Prop. (5.2.8.7). If $X \in \mathcal{S}\mathrm{ch}_{qc}/S$ and $U \subset X$ is an S-dense open subscheme, then U contains an S-dense open subscheme of S that is qc.

Proof: Cf.[**?**]P56. □

Def. (5.2.8.8) [S-Rational Maps]. Let $X, Y \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,loc.pf}}/S$ an **S-rational map** $f : X \to Y$ is an equivalence class of maps $U \to Y$ over S where U is an open subset of X that is S-dense.

Because two rational maps are equivalent iff they are compatible on the intersection of their domain as Y/S is separated, a rational map $X \to Y$ has a maximal domain of definition.

Def. (5.2.8.9) [S-Birational Maps]. Let $X, Y \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,loc.pf}}/S$ are called **S-birational** if they are isomorphic in the category of S-schemes with dominant S-rational maps.

Prop. (5.2.8.10). The notion of S-rational and S-birational maps are stable under base change, because a base change of fields is flat locally of f.p. thus open.

Prop. (5.2.8.11) [Faithfully Flat Descent]. Let $X', X, Y \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,loc.pf}}/S$ and $\varphi : Y \to S$ an S-rational map,

- If $f : X' \to X$ flat, then $\varphi \circ f$ is an S-rational map $X' \to Y$, and $\mathrm{dom}(\varphi \circ f) = f^{-1}(\mathrm{dom}(\varphi))$. In particular, if f is f.f. and $\varphi \circ f$ is a morphism, then φ is also a morphism.
- If $T \to S$ is flat, then the base change $\varphi_T : X_T \to Y_T$ satisfies $\mathrm{dom}(\varphi_T) = \mathrm{dom}(\varphi) \times_S T$.

Proof: Cf.[BLR90]P58. □

9 Associated Points

Main References are [Sta]Chap30.

Def. (5.2.9.1). For a scheme X and a Qco sheaf $\mathcal{F}$ on X, a point is called **associated to** $\mathcal{F}$ iff $\mathfrak{m}_x$ is associated to $\mathcal{F}_x$, which is equivalent to $\mathfrak{m}_x$ are all zero-divisors in M by(4.2.5.18). When $\mathcal{F} = \mathcal{O}_X$, x is called an **associated point of** X.

Prop. (5.2.9.2). If X is locally Noetherian, then an associated prime is equivalent to it is an associated prime of $\Gamma(X, \mathcal{O}_X)$ of $\Gamma(U, \mathcal{F})$ for a nbhd U of x.

Proof: Cf.[[Sta]02OK]. □

Prop. (5.2.9.3). Same results of associated points are parallel to the discussion of associated primes:

- relations of $Ass(\mathcal{F})$ w.r.t exact sequences(4.2.5.14).
- $Ass(\mathcal{F}) \subset \mathrm{Supp}(\mathcal{F})$(4.2.5.16).
- When X is locally Noetherian and $\mathcal{F}$ is coherent, for a quasi-compact open set U of X, the number of associated points in U is finite(4.2.5.16).
- When X is locally Noetherian, $\mathcal{F} = 0$ iff $Ass(\mathcal{F})$ is empty(4.2.5.16).
- When X is locally Noetherian, If $Ass(\mathcal{F}) \subset$ an open subset U, then $\Gamma(X, \mathcal{F}) \to \Gamma(U, \mathcal{F})$ is injective(4.2.5.22).
- If X is locally Noetherian, then the minimal elements(under specialization) of $\mathrm{Supp}(\mathcal{F})$ are associated points of $\mathcal{F}$. in particular, any generic point of an irreducible component of X is an associated points of X.
- If X is locally Noetherian, then if a map $\varphi : \mathcal{F} \to \mathcal{G}$ that is injective at all the stalks of $Ass(\mathcal{F})$, then φ is injective.

10 Others

Frobenius

Def. (5.2.10.1) [Frobenius]. Let $p \in \mathbf{P}, r \in \mathbb{Z}, q = p^r, k \in \texttt{Field}, \#k = q, X_0 \in \mathcal{S}\mathrm{ch}/k, X = X_0 \otimes_k \overline{k}$,

- The **absolute Frobenius** for X or X_0 is the automorphism $\varphi_{r,X} : X \to X$ that is the p^r-th power on $\mathcal{O}_X$.
- $F_X = \mathrm{id}_{X_0} \times_k \varphi^{-1}_{\overline{k}/k}$, called the **arithmetic Frobenius**, which is not k-linear!
- $\mathrm{Fr}_X = \varphi_{X_0} \times_k \mathrm{id}_{\overline{k}} : X \to X$, which is $\overline{k}$-linear, called the **geometric Frobenius**.
- Let U be a X_0-scheme, then the **relative Frobenius** $F_{U/X_0,r} : U \to \varphi^*_{r,X_0}(U)$ is defined by the universal property of the base change of U by $\varphi^r_{X_0}$. $F_{U/X_0,1}$ is denoted by F_{U/X_0}.

Prop. (5.2.10.2). $\mathrm{Fr}_X = \varphi_{r,X} \circ F_X : X \to X$.

Proof: Easy. □

Prop. (5.2.10.3). F_{U/X_0} is a universal homeomorphism. In particular, if $U \to X_0$ is étale, then it is an isomorphism.

Proof: Because $U \to X, X \times_{\varphi_X, X} U \to X$ are both étale, F_U/X_0 is étale. And from the fact both both φ_{X_0} and φ_{U_0} are universally bijective, we see F_{U_0/X_0} is universally bijective. So it must be an isomorphism**?**. □

Prop. (5.2.10.4). If X is a scheme over a field k of char p, then $X^{(p)}$ is reduced iff X is geometrically reduced. This follows from(5.4.3.2).

5.3 Cohomology on Ringed Sites

Main references are [Sta], [Har77] and [Sheaf Cohomology, Anonymous]. Should be refreshed with the language of ∞-categories?

- We use notations defined in Sites, Sheaves, Topoi and Stacks.

1 Derived Cohomology

$D(\mathcal{M}\text{od}(\mathcal{O}))$

Def. (5.3.1.1) [Setups]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site, write $K(\mathcal{O}) = K(\mathcal{M}\text{od}(\mathcal{O})), D(\mathcal{O}) = D(\mathcal{M}\text{od}(\mathcal{O}))$. The Abelian category $\mathcal{M}\text{od}(\mathcal{O})$ contains enough injectives by(3.7.3.29) and(3.7.3.23), so we can consider right derived functor for any left exact functor.

1. (Hom) Let K be a presheaf of sets on $\mathcal{C}$, then $\mathcal{F} \mapsto \text{Hom}_{\mathcal{PS}\text{h}(\mathcal{C})}(K,\mathcal{F})$ is a left exact functor $\mathcal{M}\text{od}(\mathcal{O})$ to $\mathcal{A}\text{b}$, thus we denote its derived functors as $H^i(K,\mathcal{F})$.
2. (Section) The **section functor** $\Gamma(U,\mathcal{F})$ is the left exact functor $\mathcal{M}\text{od}(\mathcal{O}) \to \mathcal{M}\text{od}(\mathcal{O}(U))$ and call the derived functors $H^i(U,\mathcal{F}) = H^i(R\Gamma(U,\mathcal{F}))$ as the ***i*-th cohomology** of $\mathcal{F}$ at U. In fact, this functor is just $\text{Mor}_{\mathcal{PS}\text{h}(\mathcal{C})}(h_U,\mathcal{F})$ defined in(5.3.1.1).
3. (Global Section) Let e be the final object in $\mathcal{PS}\text{h}(\mathcal{C})$, then we define the **global section** functor $\Gamma(\mathcal{C},-)$ to be the left exact functor $\mathcal{M}\text{od}(\mathcal{O}) \to \mathcal{A}b : \mathcal{F} \to \text{Mor}_{\mathcal{PS}\text{h}(\mathcal{C})}(e,\mathcal{F}) = \varprojlim_{X\in\mathcal{C}^{op}}\Gamma(X,\mathcal{F})$, then we define its derived functor $R(\mathcal{C},\mathcal{F})$, and call the derived functors $H^i(\mathcal{C},\mathcal{F}) = H^i(R\Gamma(\mathcal{C},\mathcal{F}))$ the ***i*-th cohomology groupg** of $\mathcal{F}$ on $\mathcal{C}$.
4. (Pushforward) Let $(\mathcal{S}\text{h}(\mathcal{C}),\mathcal{O}) \to (\mathcal{S}\text{h}(\mathcal{D}),\mathcal{O}')$ be a morphism of topoi, then f_* is a left exact functor from $\mathcal{M}\text{od}(\mathcal{O})$ to $\mathcal{M}\text{od}(\mathcal{O}')$(5.1.2.18), and we call its derived functors R^if_* the ***i*-th higher direct images**.
5. (Shifification) Let shifification functor $\iota : \mathcal{PS}\text{h}(\mathcal{C}) \to \mathcal{S}\text{h}(\mathcal{C})$ is left exact, and we call the derived functors $\mathcal{H}^p(F)$ the **sheaf-cohomology presheaves** of F.

Def. (5.3.1.2) [$\mathbb{G}_a, \mathbb{G}_m$]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site, denote $\mathbb{G}_{a,\mathcal{C}} = \mathcal{O}, \mathbb{G}_{m,\mathcal{C}} = \mathcal{O}^*$.

Prop. (5.3.1.3) [Global Section as Pushforward]. For a ringed site $(\mathcal{C},\mathcal{O})$, if we endow $\mathcal{C}$ with the discrete topology, then there is a functor $\mathcal{C} \to \text{pt}$ which is cocontinuous, thus induce a morphism of ringed topoi $\pi : (\mathcal{S}\text{h}(\mathcal{C}),\mathcal{O}) \to (\mathcal{S}\text{h}(\text{pt}) \cong \mathcal{A}\text{b}, \Gamma(\mathcal{C},\mathcal{O}))$(5.1.2.21). Then π_* is exactly $\mathcal{F} \mapsto \Gamma(\mathcal{C},\mathcal{F})$, so $R\pi_*\mathcal{F} = H^i(\mathcal{C},\mathcal{F})$.

Prop. (5.3.1.4) [Change of Topologies]. Let $\mathcal{C},\mathcal{C}'$ be sites and $i : \mathcal{C}'$ be a fully subcategory of $\mathcal{C}$, $i : \mathcal{C}' \to \mathcal{C}$ is continuous and cocontinuous satisfying the hypothesis of(5.1.2.23), then for $\mathcal{F} \in \mathcal{S}\text{h}(\mathcal{C}'), \mathcal{G} \in \mathcal{S}\text{h}(\mathcal{C})$, there are functorial isomorphisms

$$H^p(\mathcal{C}', U, i^{-1}\mathcal{G}) \cong H^p(\mathcal{C}, U, \mathcal{G}).$$

And if i satisfies the hypothesis of(5.1.2.25), then moreover there are functorial isomorphisms

$$H^p(\mathcal{C}', U, F') \cong H^p(\mathcal{C}; U, i_*F') = H^p(\mathcal{C}; i(U), i_!F')$$

Proof: For the first assertion, notice g^{-1} preserves injectives because it is right adjoint to $g_! = f^{-1}$ is exact(5.1.2.23).

The second assertion follows immediate from(5.1.2.25). □

Calculations

Prop. (5.3.1.5) [Locality of Cohomologies]. Let $(\mathcal{C},\mathcal{O})$ be a ring site and $U\in\mathcal{C}$, then for $\mathcal{F}\in\mathcal{M}\mathrm{od}(\mathcal{O}_X)$, $H^n(U,\mathcal{F})=H^n(\mathcal{C}/U,\mathcal{F}|_U)$, by(5.3.4.2) and the composition of derived functors applied to the pullback $j^*:\mathcal{C}/U\to\mathcal{C}$.

Prop. (5.3.1.6) [Sheaf-Cohomological Presheaves]. The forgetful functor is right adjoint to the exact shifification functor, the composition of derived functors applied to the functor $\Gamma(U,-)\circ\iota$ from $\mathcal{PS}\mathrm{h}(\mathcal{C})$ to $\mathcal{A}\mathrm{b}$ shows its right derived functor is

$$\mathcal{H}^p(F)=R^p\iota(F):U\to H^p(U,F).$$

Prop. (5.3.1.7) [Higher Direct Image]. For $f:(\mathcal{C}',\mathcal{O}')\to(\mathcal{C},\mathcal{O})$ a morphism of ringed topoi and $\mathcal{F}\in\mathcal{S}\mathrm{h}(\mathcal{C})$, the composition of derived functors applied to the functor $(\sharp\circ(f_*)^{\mathcal{PS}\mathrm{h}})\circ\iota$(because $\sharp,(f_*)^{\mathcal{PS}\mathrm{h}}$ are exact(5.1.2.10)) shows that $R^pf_*\mathcal{F}=(f_*\mathcal{H}^p(\mathcal{F}))^\sharp$. So flask sheave thus flabby sheave are right acyclic for f_*.

In particular, $R^pf_*\mathcal{F}$ can be calculated locally on the base.

Prop. (5.3.1.8) [Relative Leray Spectral Sequence]. Let

$$(f,f^\sharp):(\mathcal{S}\mathrm{h}(\mathcal{C}),\mathcal{O})\to(\mathcal{S}\mathrm{h}(\mathcal{C}'),\mathcal{O}'),\quad (g,g^\sharp):(\mathcal{S}\mathrm{h}(\mathcal{C}'),\mathcal{O}')\to(\mathcal{S}\mathrm{h}(\mathcal{D}),\mathcal{O}_{\mathcal{D}})$$

be morphisms of ringed topoi, then the natural transformation $R(g\circ f)\to Rg_*\circ Rf_*$ is an isomorphisms, and for any $\mathcal{F}^\bullet\in K^+(\mathcal{O})$, there is a spectral sequence convergence

$$E_2^{p,q}=R^pg_*R^qf_*(\mathcal{F}^\bullet)\Longrightarrow E^n=R^n(g\circ f)_*\mathcal{F}^\bullet.$$

Proof: This is just the Grothendieck spectral sequence(3.9.7.11), where the condition is satisfied by(5.3.1.7) and(5.3.4.12). □

Cor. (5.3.1.9) [Leray Spectral Sequence]. Let $(f,f^\sharp):(\mathcal{S}\mathrm{h}(\mathcal{C}),\mathcal{O})\to(\mathcal{S}\mathrm{h}(\mathcal{C}'),\mathcal{O}')$ be a morphism of ringed topoi, then for any $\mathcal{F}^\bullet\in K^+(\mathcal{O})$, then $R\Gamma(\mathcal{C},-)\to R\Gamma(\mathcal{C}',-)\circ Rf_*$ is an isomorphism, and there is a spectral sequence convergence

$$E_2^{p,q}=H^p(\mathcal{C}',R^qf_*(\mathcal{F}^\bullet))\Rightarrow E^n=H^n(\mathcal{C},\mathcal{F}^\bullet).$$

Prop. (5.3.1.10) [Relative Mayer-Vietoris Sequence]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site and $\mathcal{U}:\{U\to X,V\to X\}$ is a covering s.t. $U\to X$ is a monomorphism, then for any $\mathcal{F}\in\mathcal{S}\mathrm{h}(\mathcal{O})$ and any morphism of ringed sites $f:(\mathcal{C},\mathcal{O})\to(\mathcal{C}',\mathcal{O}')$, there is a long exact sequence of sheaves in $\mathcal{S}\mathrm{h}(\mathcal{O}')$:

$$0\to(f|_X)_*(\mathcal{F}|_X)\to(f|_U)_*(\mathcal{F}|_U)\oplus(f|_V)_*(\mathcal{F}|_V)\to(f|_{U\cap V})_*(\mathcal{F}|_{U\cap V})\to R^1(f|_X)_*(\mathcal{F}|_X)\to\ldots$$

that is functorial in $\mathcal{F}$.

Proof: Choose a functorial injection resolution $\mathcal{F}\to\mathcal{I}^\bullet$(3.9.2.9), then there is an exact sequence of complexes

$$0\to(f|_X)_*(\mathcal{I}^\bullet|_X)\to(f|_U)_*(\mathcal{I}^\bullet|_U)\oplus(f|_V)_*(\mathcal{I}^\bullet|_V)\to(f|_{U\cap V})_*(\mathcal{I}^\bullet|_{U\cap V})\to 0$$

because injective sheaves are flabby(5.3.4.9) and $(U\times_X V)\times_X f^{-1}W\to V\times_X f^{-1}W$ is a monomorphism for any $W\in\mathcal{C}'$. Then we take the long exact sequence of cohomology. □

Cor. (5.3.1.11) [Mayer-Vietoris Sequence]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $\mathcal{U} : \{U \to X, V \to X\}$ is a covering s.t. $U \to X$ is a monomorphism, then for any $\mathcal{F} \in \mathcal{S}h(\mathcal{O})$, there is a long exact sequence

$$0 \to H^0(X, \mathcal{F}) \to H^0(U, \mathcal{F}) \oplus H^0(V, \mathcal{F}) \to H^0(U \times_X V, \mathcal{F}) \to H^1(X, \mathcal{F}) \to \ldots$$

that is functorial in $\mathcal{F}$.

Prop. (5.3.1.12) [Compatibility with Algebraic Structures]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $\mathcal{F} \in \mathcal{S}h(\mathcal{C})$, $K \in \mathcal{PS}h(\mathcal{C})$, then $H^*(K, \mathcal{F})$ is the same calculated as $\mathcal{O}$-modules or Abelian sheaves.

Proof: Denote $(C, \underline{\mathbb{Z}})$ the trivial ringed site and $ab : (C, \mathcal{O}) \to (C, \underline{\mathbb{Z}})$ the forgetful functor, then ab is exact and $\mathrm{Hom}(K, \mathcal{F}_{ab}) = \mathrm{Hom}(K, \mathcal{F})$, thus we can use the Leray spectral sequence(5.3.1.9). □

Prop. (5.3.1.13)[Direct Products]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $\mathcal{F}_i$ be a family of sites indexed over a set I, then for any presheaf of sets K on $\mathcal{C}$, there is a Leray spectral sequence convergence(5.3.1.8)

$$H^p(K, R^q(\prod_i)\mathcal{F}_i) \to R^n(\prod_i \mathrm{Hom}(K, \cdot))(\mathcal{F}_i) \cong \prod_i H^n(K, \mathcal{F}_i).$$

In particular, $H^1(K, \prod_i \mathcal{F}_i) \to \prod_i H^1(K, \mathcal{F}_i)$ is injective.

Prop. (5.3.1.14) [Filtered Colimits]. $H^n(U, -)$ commutes with filtered colimits if T is a Noetherian topology.

Proof: $n = 0$ case follows from the fact the colimit presheaf is already a sheaf, because for any finite cover, the Čech complex of the limit sheaf is the filtered colimit of Čech complexes, and filtered colimit is exact.

And a filtered colimits of injective sheaves is flask, because flask need only be checked for finite coverings at this case(because of the fact T and T^f have equivalent category of sheaves(5.1.1.3) and definition of flask(5.3.4.8)), and a filtered colimit of exact Čech complexes is exact. So we can choose a functorial injective resolution(3.9.2.9) and use the colimit resolution to calculate the cohomology. □

Lemma (5.3.1.15). ?? If X is a qs ringed space, then $\mathcal{S}h(X) \to \mathcal{S}h(X_{fp})$ is an equivalence by i_s and i^s, where fp is the subtopology of X generated by qcqs open subsets.

Proof: The proof is the same proof as that of(5.1.4.20). □

Prop. (5.3.1.16) [Filtered Colimits]. $H^i(U, -)$ commutes with direct limits if X is a qs ringed space and $U \subset X$ is qc.

Proof: This follows from**??** the same way(7.4.1.8) follows from(5.1.4.20). □

Low Dimensions

Cf.[Sta]Chap21.5-7.

Prop. (5.3.1.17) [H^1 and Picard Group]. Let $(\mathcal{C}, \mathcal{O})$ be a local ringed site, then there is a canonical isomorphism of Abelian groups

$$H^1(\mathcal{C}, \mathcal{O}^*) = \mathrm{Pic}(\mathcal{O}).$$

Proof: Let $\mathcal{L}$ be an invertible sheaf, them there exists a subsheaf

$$\mathcal{L}^* : U \mapsto \{s \in \mathcal{L}(U) | s\cdot : \mathcal{O}(U) \to \mathcal{L}(U) \text{ is an isomorphism}\}.$$

Notice if $f \in \mathcal{O}^*(U)$ and $s \in \mathcal{L}^*(U)$, then $fs \in \mathcal{L}^*(U)$, and any two $s, s' \in \mathcal{L}^*(U)$ differ by an element of $\mathcal{O}^*(U)$, so $\mathcal{L}^*$ is a pseudo-$\mathcal{O}^*$-torsor. Moreover, as $\mathcal{L}$ is locally free of rank 1 by(5.2.5.8), so $\mathcal{L}^*(U)$ has sections locally, so it is an $\mathcal{O}^*$-torsor.

In this way, we get a map

$$\mathrm{Pic}(\mathcal{O}) \to \mathrm{Tor}(\mathcal{O}_X^*) \cong H^1(X, \mathcal{O}_X^*)(5.3.2.18).$$

This map is injective: if $\mathcal{L}$ corresponds to a trivial torsor, then $\mathcal{L}^*$ has a global section, and then $\mathcal{L}$ is also trivial. This map is also surjective, because if $\mathcal{F}$ is an $\mathcal{O}_X^*$-torsor, then we can define

$$\mathcal{L}_1 : U \mapsto [\mathcal{F}(U) \otimes \mathcal{O}(U)]/\mathcal{O}(U)^*,$$

where the action is given by $f \cdot (s, g) = (fs, f^{-1}g)$, and $\mathcal{L}_1$ is an $\mathcal{O}$-module given the addition $(s, g) + (s', g') = (s, g + \frac{s'}{s}g)$, where $\frac{s'}{s} \in \mathcal{O}(U)$ satisfies $\frac{s'}{s} \cdot s = s'$. Then the shifification $\mathcal{L}$ of $\mathcal{L}$ is a locally trivial bundle that maps $\mathcal{F}$. □

Prop. (5.3.1.18) [H^2 **and Objects of Gerbes**]. Let $\mathcal{C}$ be a site and $\mathcal{S} \to \mathcal{C}$ be a gerbe whose automorphism sheaves are Abelian. Let $\mathcal{G}$ be the sheaf defined in(5.1.3.24). If U is an object of $\mathcal{C}$ that

- there exists a cofinal system of coverings $\{U_i \to U\}$ that for any such covering, $H^1(U_i, \mathcal{G}) = 0, H^1(U_i \times_U U_j, \mathcal{G}) = 0$,
- $H^2(U, \mathcal{G}) = 0$.

Then $\mathcal{S}_U$ is non-empty.

Proof: By hypothesis, there is a covering $\{U_i \to U\}$ and x_i in $\mathcal{S}$ lying over U_i. By item1, after refining the covering, we may assume $H^1(U_i, \mathcal{G}) = 0$ and $H^1(U_{ij}, \mathcal{G}) = 0$. Consider the sheaf

$$\mathcal{F}_{ij} = \mathrm{Isom}(x_i|_{U_{ij}}, x_j|_{U_{ij}})$$

on $\mathcal{C}_{/U_{ij}}$, then there is an action $\mathcal{G}_{U_{ij}} \times \mathcal{F}_{ij} \to \mathcal{F}_{ij}$. Then $\mathcal{F}_{ij}$ is a pseudo $\mathcal{G}|_{U_{ij}}$-torsor and clearly a torsor because any two objects of a gerbe is locally isomorphic.

By(5.3.2.18), these torsors are trivial, thus having a global section. In other words, there are isomorphisms $\varphi_{ij} : x_i|_{U_{ij}} \to x_j|_{U_{ij}}$. To get an object x over U, it suffices to manage the choices of φ_{ij} to get a descent datum. For this, use the fact $H^2(U, \mathcal{G}) = 0$ and $\check{H}^2(\mathcal{U}, \mathcal{G}) \to H^2(U, \mathcal{G})$ is injective by Cech to Derived spectral sequence(5.3.2.13). □

Others

Prop. (5.3.1.19). Let $K' \to K$ be a map of presheaves of sets on $\mathcal{C}$ whose shifification is surjective. Set $K'_p = K' \times_K \times \ldots \times_K K'$, then for any $\mathcal{F} \in \mathcal{S}h(\mathcal{C})$, there is a spectral sequence convergence

$$E_1^{p,q} = H^q(K'_p, \mathcal{F}) \Rightarrow H^{p+q}(K, \mathcal{F}).$$

Proof: Since shifification is exact, $(K'_p)^\sharp = (K')^\sharp_p$. Then we use(5.1.2.26) to change to a larger site $\mathcal{C}'$ where the topoi are equivalent and K', K are objects in $\mathcal{C}'$ and $K' \to K$ is a covering, then we use the E_1 page of the Čech to derived spectral sequence(5.3.2.13). Notice this need modification, the modification goes back to the proof of the Grothendieck spectral sequence, where we choose the natural Čech complex resolution in place of the CE resolution, because we have(5.3.2.3). □

Cor. (5.3.1.20)[Čech-Alexander Resolution]. If $\mathcal{C}$ is a site with the indiscrete topology, X a weakly final object(3.1.1.8) of $\mathcal{C}$, then for any Abelian sheaf $\mathcal{F}$ on $\mathcal{C}$, the total cohomology $R\Gamma(\mathcal{C},\mathcal{F})$ is represented by the Čech complex

$$\mathcal{F}(X)\to\mathcal{F}(X\times X)\to\mathcal{F}(X\times X\times X)\to\ldots.$$

Proof: By(5.3.4.10), $H^q(X^p,\mathcal{F})=0$ for $q>0$. The assumption says $h_X\to *$ is surjective, thus the conclusion is a special case of(5.3.1.19). □

2 Čech Cohomology

Def. (5.3.2.1)[Čech Complex and Čech Cohomology]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site and $\mathcal{U}:\{U_i\to U\}$ be a covering, we have a canonical complex of presheaves $\mathbb{Z}_{\mathcal{U},\bullet}$ defined to be

$$\cdots\to\bigoplus_{i_0,i_1,i_2}j_!\mathbb{Z}_{U_{i_0i_1i_2}}\to\bigoplus_{i_0,i_1}j_!\mathbb{Z}_{U_{i_0i_1}}\to\bigoplus_{i_0}j_!\mathbb{Z}_{U_{i_0}}\to 0.$$

And for any presheaf of $\mathcal{O}_X$-module $\mathcal{F}$, the complex

$$\mathrm{Hom}^\bullet_{Psh(\mathcal{O})}(\mathbb{Z}_{\mathcal{U},\bullet}\otimes\mathcal{O},\mathcal{F})\cong\mathrm{Hom}^\bullet_{P\mathcal{A}\mathrm{b}}(\mathbb{Z}_{\mathcal{U},\bullet},\mathcal{F})$$

is called the **Čech complex** $\check{\mathcal{C}}^\bullet(\mathcal{U},\mathcal{F})$ of $\mathcal{F}$. The cohomology $\check{H}^*(\mathcal{U},\mathcal{F})$ of $\check{\mathcal{C}}^\bullet(\mathcal{U},\mathcal{F})$ is called the **Čech cohomology** of $\mathcal{F}$ w.r.t $\mathcal{U}$.

$\mathbb{Z}_{\mathcal{U},\bullet}$ is exact except in degree 0, where the homology is $j_!\mathbb{Z}_U$. This is because we have a homotopy: choose a fixed i_0, for a $s\in\Gamma(U_{i_1\ldots i_n},\mathcal{F})$, we map it to $(hs)_{ii_1\ldots i_n}=\delta_{i,i_0}s$**?**. In particular, an injective sheaf is Čech acyclic.

Lemma (5.3.2.2). The Čech complexes $\check{\mathcal{C}}^\bullet(\mathcal{U},-)$ induces a functor from $\mathcal{PS}\mathrm{h}(\mathcal{C})$ to $K^+(\mathcal{A}\mathrm{b})$, which is an exact functor.

Proof: Because in each degree this functor is a sum of functors of the form $\mathcal{F}\mapsto\mathcal{F}(U)$, which are exact functors on $\mathcal{PS}\mathrm{h}(\mathcal{C})$. □

Prop. (5.3.2.3) [Čech Complex as Derived Functors]. Let $\mathcal{C}$ be a site and $\mathcal{U}:\{U_i\to U\}$ be a covering, then $\check{H}^0(\mathcal{U},-)$ is left exact, and for $\mathcal{F}\in\mathcal{S}\mathrm{h}(\mathcal{C})$, there are functorial quasi-isomorphisms

$$\check{\mathcal{C}}^\bullet(\mathcal{U},\mathcal{F})\to R\check{H}^0(\mathcal{U},\mathcal{F})$$

which is functorial in $\mathcal{F}$.

Proof: Choose a functorial injective resolution of presheaves $\mathcal{I}^\bullet$ of $\mathcal{F}$, and consider the double complex $\check{\mathcal{C}}(\mathcal{U},\mathcal{I}^\bullet)$. There are maps of complexes

$$\check{\mathcal{C}}(\mathcal{U},\mathcal{F})\to\mathrm{Tot}(\check{\mathcal{C}}(\mathcal{U},\mathcal{I}^\bullet)),\quad\check{H}^0(\mathcal{U},\mathcal{I}^\bullet)\to\mathrm{Tot}(\check{\mathcal{C}}(\mathcal{U},\mathcal{I}^\bullet))$$

which are both quasi-isomorphism by an application of spectral sequence and the fact the columns and rows are exact in positive degrees: The columns are exact because of(5.3.2.2) and the rows are exact because $\mathbb{Z}_{\mathcal{U},\bullet}$ is exact in positive degrees(5.3.2.1) and $\mathcal{I}^p$ are injective. Then we have the desired quasi-isomorphism, and it is functorial in $\mathcal{F}$. □

Cor. (5.3.2.4) [Čech Cohomologies]. If we take filtered colimit for coverings, $\mathcal{F} \to \check{H}^0(U, \mathcal{F}) = H^0(U, \mathcal{F})$ is a left exact functor from presheaves to sets, the derived complex is just $\varinjlim_{\mathcal{U}} \check{\mathcal{C}}^\bullet(\mathcal{U}, \mathcal{F})$, and the derived functors are just $\varinjlim_{\mathcal{U}} \check{H}^q(\mathcal{U}, \mathcal{F})$.

Proof: This is because we can take colimit of the conclusion of(5.3.2.3), because the colimit is filtered by(5.3.2.5) so exact, so the Čech complex also represents the derived complex. □

Lemma (5.3.2.5). The refinement morphism of Čech cohomologies of two coverings doesn't depends on the refinement map chosen.

Proof: For two refinement map, there is a commutative diagram

$$\begin{array}{ccc} \prod F(U_i) & \xrightarrow{d^0} & \prod F(U_i \times_U U_j) \\ \big\downarrow f-g & \swarrow \Delta^1 & \\ \prod F(U'_j) & & \end{array}$$

so it induce the same map on the kernel. □

Def. (5.3.2.6) [Alternating Čech Complexes]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $\mathcal{U} : \{U_i \to U\} \in \mathrm{Cov}(\mathcal{C})$, $\mathcal{F} \in \mathcal{S}\mathrm{h}(\mathcal{O})$, then the **alternating Čech complex** of $\mathcal{F}$ is defined to be the subcomplex

$$\check{C}^\bullet_{\mathrm{alt}}(\mathcal{U}, \mathcal{F}) = \{s \in \check{C}^\bullet(\mathcal{U}, \mathcal{F}) | s_{i_0, \ldots, i_p} = 0 \text{ if } i_m = i_n, m \neq n, s_{i_{\sigma(0)}, \ldots, i_{\sigma(p)}} = \mathrm{sgn}(\sigma) s_{i_0, \ldots, i_p}\} \subset \check{C}^\bullet(\mathcal{U}, \mathcal{F}).$$

It is truly a subcomplex.

Prop. (5.3.2.7) [Alternating and Usual Complexes]. Let $(\mathcal{X}, \mathcal{O}_X)$ be a ringed space, $\mathcal{U} : \{U_i \to U\} \in \mathrm{Cov}(\mathcal{C})$, $\mathcal{F} \in \mathcal{S}\mathrm{h}(\mathcal{O}_X)$, then the inclusion

$$\check{C}^\bullet_{\mathrm{alt}}(\mathcal{U}, \mathcal{F}) \to \check{C}^\bullet(\mathcal{U}, \mathcal{F})$$

is a homotopy equivalence.

Proof: Cf.[Sta]01FM. The proof is rather complicated.? □

Remark (5.3.2.8). WARNING: This is not right for ringed sites, e.g. the étale sites, for example, cf.(7.4.1.23).

Comparison Theorems

Prop. (5.3.2.9). If two coverings are refinements of each other, then their Čech cohomology is isomorphic.

Proof: Because the refinement morphism doesn't depends on the refinement map(5.3.2.5). □

Prop. (5.3.2.10) [Comparison Theorem for Čech Acyclicity]. If there are two coverings $\mathfrak{U}, \mathfrak{V}$ and a presheaf $\mathcal{F}$, then we can construct a double Čech complex with the (p, q)-term being $\mathcal{F}(U_{i_1, \ldots i_p} \cap V_{j_1, \ldots j_q})$. Then the vertical and horizontal arrays calculate the Čech cohomology $\prod_j H^*(\mathfrak{U}|_{V_{j_1 \ldots, j_q}}, \mathcal{F})$, $\prod_i H^*(\mathfrak{V}|_{U_{i_1 \ldots, i_q}}, \mathcal{F})$ respectively.

So by Spectral sequence(3.9.7.8), if both higher Čech cohomology group $H^k(\mathfrak{U}|_{V_{j_1 \ldots, j_q}}, \mathcal{F})$, $H^k(\mathfrak{V}|_{U_{i_1 \ldots, i_q}}, \mathcal{F})$ vanish, i.e., they are both $\mathcal{F}$-acyclic, then $H^*(\mathfrak{U}, \mathcal{F}) \cong H^*(\mathfrak{V}, \mathcal{F})$.

Cor. (5.3.2.11). If $\mathfrak{V}$ is a refinement of $\mathfrak{U}$, and $\mathfrak{V}|_{U_{i_1,\ldots,i_p}}$ are all $\mathcal{F}$ acyclic, then $H^*(\mathfrak{U},\mathcal{F})\cong H^*(\mathfrak{V},\mathcal{F})$.

Proof: It suffices to prove $\mathfrak{U}|_{V_{i_1,\ldots,i_q}}$ is $\mathcal{F}$-acyclic. But $\mathfrak{U}|_{V_{i_1,\ldots,i_q}}$ and $\mathrm{id}_{V_{i_1,\ldots,i_q}}$ are refinements of each other, so(5.3.2.9) settles the proof. □

Cor. (5.3.2.12). If $\mathfrak{V}|_{U_{i_1,\ldots,i_p}}$ is $\mathcal{F}$-acyclic, then the covering $H^*(\mathfrak{U}\times\mathfrak{V},\mathcal{F}) = H^*(\{U_i\cap V_j\},\mathcal{F})\cong H^*(\mathfrak{U},\mathcal{F})$.

Proof: Because $\mathfrak{V}|_{U_{i_1,\ldots,i_p}}$ and $\mathfrak{U}\times\mathfrak{V}|_{U_{i_1,\ldots,i_p}}$ are refinement of each other, so $\mathfrak{U}\times\mathfrak{V}|_{U_{i_1,\ldots,i_p}}$ are $\mathcal{F}$-acyclic by(5.3.2.9), and $\mathfrak{U}\times\mathfrak{V}$ refines $\mathfrak{U}$, so(5.3.2.11) can be applied. □

Prop. (5.3.2.13)[Čech to Derived]. For any $\mathcal{F}\in\mathcal{S}\mathrm{h}(\mathcal{C})$, the Grothendieck spectral sequence applied to $\Gamma(U,-)=H^0(\{U_i\to U\},-)\circ\iota=\check{H}^0(U,-)\circ\iota$ gives us:

$$H^p(\{U_i\to U\},\mathcal{H}^q(\mathcal{F}))\Longrightarrow H^{p+q}(U,\mathcal{F}).$$

$$\check{H}^p(U,\mathcal{H}^q(F))\Longrightarrow H^{p+q}(U,\mathcal{F}).$$

Cor. (5.3.2.14)[$\check{H}^0$ of Sheaf-Cohomology Presheaves]. For any $\mathcal{F}\in\mathcal{S}\mathrm{h}(\mathcal{C})$, $\mathcal{H}^p(\mathcal{F})^{++}=\mathcal{H}^p(F)^\sharp=0$ for $p>0$, so

$$\mathcal{H}^p(\mathcal{F})^+(U)=\check{H}^0(U,\mathcal{H}^p(F))=0\quad p>0.$$

because $\mathcal{H}^p(\mathcal{F})^+$ is separated by(5.1.2.7). In particular, for any $s\in H^p(U,\mathcal{F}),p>0$, there exists a covering $\mathcal{U}$ of U s.t. $s|_{U_i}=0$ for any i.

Thus the low degree of Čech to sheaf says(3.9.7.12):

$$0\to\underline{\check{H}^1(U,\mathcal{F})\to H^1(U,\mathcal{F})}\to 0\to\check{H}^2(U,\mathcal{F})\to H^2(U,\mathcal{F})\to\check{H}^1(U,\mathcal{H}^1(\mathcal{F}))\to\check{H}^3(U,\mathcal{F})\to H^3(U,\mathcal{F}).$$

Proof: By Grothendieck spectral sequence applied to forgetful functor and exact $\sharp$ functor, where the condition are satisfied by(5.3.4.3). □

Cor. (5.3.2.15) [Acyclic Covering Calculates Derived Cohomologies]. If we have $H^q(U_{i_0i_1\ldots i_r},\mathcal{F})=0,q>0$, then $H^p(\{U_i\to U\},\mathcal{F})=H^p(U,\mathcal{F})$ as $\mathcal{O}_X(U)$-modules.

Proof: Because $H^p(\{U_i\to U\},\mathcal{H}^q(F))$ vanish for $q>0$. □

Prop. (5.3.2.16)[Čech Acyclic Čech Comparison]. If $\mathcal{C}$ be a ringed site, $\mathfrak{G}\subset\mathcal{C}$, $\mathrm{Cov}\subset\mathrm{Cov}(\mathcal{C})$ and $\mathcal{F}\in\mathcal{S}\mathrm{h}(\mathcal{C})$ that

- For any $\{U_i\to U\}\in\mathrm{Cov}$, $U_i,U\in\mathfrak{G}$, and $U_{i_0,\ldots,i_p}\in\mathfrak{G}$.
- $\mathrm{Cov}|_U$ is cofinal in $\mathrm{Cov}(\mathcal{C}/U)$ for any $U\in\mathfrak{G}$.
- $\check{H}^q(U,\mathcal{F})=0$ for any $U\in\mathfrak{G}$ and $q>0$.

Then $H^p(X,\mathcal{F})=\check{H}^p(X,\mathcal{F})=H^p(\{U_i\to X\},\mathcal{F})$ for any $\{U_i\to X\}\in\mathrm{Cov}$.

Proof: By(5.3.2.15), we only have to show that $H^q(U,\mathcal{F})=0$ for $U\in\mathfrak{G}$ and $q>0$. Use induction on q, use Čech to sheaf2: $\check{H}^p(U,\mathcal{H}^q(\mathcal{F}))\Rightarrow H^{p+q}(U,\mathcal{F})$. The case $q\neq 0$ is by condition2, 3, and induction hypothesis. For $p=0$, use (5.3.2.14). □

Non-Abelian Čech Cohomologies

Def. (5.3.2.17) [Non-Abelian Cohomology]. Let $\mathcal{C}$ be a site and $\mathcal{G} \in \mathcal{S}\mathrm{h}^{\mathcal{G}\mathrm{rp}}(\mathcal{C})$, for any covering $\mathcal{U} = \{U_i \to U\} \in \mathrm{Cov}(\mathcal{C})$, we can define a **non-Abelian Čech cohomology** $\check{H}^1(\mathcal{U}, \mathcal{G})$ as follows: Define $Z^1(\mathcal{U}, \mathcal{G})$=sets of families

$$\{(c_i)|c_i \in \Gamma(U_{ij}, \mathcal{G}) : c_{jk}c_{ik}^{-1}c_{ij} = 1\}.$$

If $\mathsf{c} \in Z^1(G, M)$, then for any $g \in \Gamma(U, \mathcal{G})$,

$$\mathsf{c}_g = (c'_{ij} = g|_{U_i}^{-1} c_{ij} g|_{U_j})$$

is also in $Z^1(\mathcal{U}, \mathcal{G})$. This defines an equivalence relation on $Z^1(\mathcal{U}, \mathcal{G})$, the equivalence classes are called $\check{H}^1(G, M)$. This is compatible with the commutative case.

Taking filtered colimit over all coverings of U, we can also define $\check{H}^1(U, \mathcal{G})$.

Prop. (5.3.2.18) [H^1 and Torsors]. Let $\mathcal{C}$ be a site and $\mathcal{H} \in \mathcal{S}\mathrm{h}(\mathcal{C})$, then there is a canonical isomorphism of $\mathcal{H}$-torsors(5.1.1.14) and $H^1(\mathcal{C}, \mathcal{H})$.

Proof: Cf.[Sta]03AJ. Should have a non-commutative version. □

Prop. (5.3.2.19) [Long Exact Sequence of Non-Abelian Čech Cohomologies]. Let $\mathcal{C}$ be a site and $1 \to \mathcal{A} \to \mathcal{B} \to \mathcal{C} \to 1$ is an exact sequence in $\mathcal{S}\mathrm{h}^{\mathcal{G}\mathrm{rp}}(\mathcal{C})$, then for any $U \in \mathcal{C}$, there is a long exact sequence of pointed sets

$$1 \to \Gamma(U, \mathcal{A}) \to \Gamma(U, \mathcal{B}) \to \Gamma(U, \mathcal{C}) \xrightarrow{\delta} \check{H}^1(U, \mathcal{A}) \to \check{H}^1(U, \mathcal{B}) \to \check{H}^1(U, \mathcal{C}) \xrightarrow{\Delta} \check{H}^2(U, \mathcal{A})$$

the last term is defined only when $\mathcal{A}$ is in the center of $\mathcal{B}$ and U satisfies: For any covering $\mathcal{U}$ and a refinement $\mathcal{W} \to \mathcal{U} \times \mathcal{U}$, there exists a refinement $\mathcal{U}' \to \mathcal{U}$ s.t. $\mathcal{U}' \times \mathcal{U}'$ is a refinement of $\mathcal{W}$.

δ is defined as follows: for $c \in \Gamma(\mathcal{C}, \mathcal{C})$, by taking a covering $\{U_i \to U\}$, we may assume that $c|_{U_i} = b_i \in \Gamma(U_i, \mathcal{B})$, then $a_{ij} = b_i^{-1} b_j$ is a cocycle, and a different choice differ by a cocyle, so this is well-defined.

Δ is defines as: for any covering $\mathcal{U}$ of U and $\mathsf{c} = (c_{ij})$ a cocycle in $\check{H}^1(\mathcal{U}, \mathcal{C})$, by passing to a refinement, we may assume that $c_{ij} \in \Gamma(U_{ij}, \mathcal{B})$, then $\delta(\mathsf{c})$ is represented by the 2-cocycle $a_{ijk} = c_{jk}c_{ik}^{-1}c_{ij} \in \Gamma(U, \mathcal{A})$.

Proof: **??**The verification of well-definedness of Δ is checked at [Serre Local Fields P124].**?**

For the exactness at C^G, the definition of δ shows that $\delta(c) = 1$ iff there is an inverse image b that $b^{-1}\sigma(b) = 1$ for all σ.

For the exactness at $H^1(G, A)$, $a_\sigma = b^{-1}\sigma(b)$ if a_σ is in the image of δ. Conversely, the image of b in C is in C^G, so it is in the image of δ.

For the exactness at $H^1(G, B)$, one way is clear, and for the other, if $\pi(b_\sigma) = c^{-1}\sigma(c)$, then if t is an inverse image of c, then $tb_\sigma\sigma(t)^{-1}$ is a cocycle in A cohomologous to b_σ.

For the exactness at $H^1(G, C)$, one way is clear, and if b_s is an inverse image of b_s and $a_{\sigma,\tau} = b_\sigma\sigma(b_\tau)b_{\sigma\tau}^{-1}$ is a coboundary, then it is $a_\sigma\sigma(a_\tau)a_{\sigma\tau}^{-1}$, so we change b to $a_\sigma^{-1}b_\sigma$, as A is in the center of B, this lifts c to a cocycle in B. □

Prop. (5.3.2.20) [Hilbert's Theorem 90]. For L/K a Galois extension, $H^1(\mathrm{Gal}(L/K), \mathrm{GL}_n(L)) = 1$, where L is equipped with the discrete topology.

Proof: We prove any cocycle is a coboundary, for this, notice any cocycle factor through a finite quotient, and the images of it is contained in a finite extension of K, hence it reduce to the case of L/K finite.

By definition, this is equivalent to any B-semi-linear representation of G free of finite rank is trivial, which is by(15.1.1.14). □

Cor. (5.3.2.21) [semi-linear representations]. The proposition implies that any semi-linear L-representation of $G_{L/K}$ is trivial.

Cor. (5.3.2.22). $H^1(G(L/K), SL_n(L)) = 1$. This is seen from the exact sequence $1 \to \mathrm{SL}(n, L) \to \mathrm{GL}(n, L) \to L^\times \to 1$.

3 Derived Homology

K-Flat Complexes

Def. (5.3.3.1) [K-flat Complexes]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site, a complex $\mathcal{K}^\bullet$ of $\mathcal{O}$-modules is called ***K*-flat** if for any acyclic complex $\mathcal{F}^\bullet$ of $\mathcal{O}$-modules, the total complex $\mathrm{Tot}^\oplus(\mathcal{F}^\bullet \otimes_{\mathcal{O}} \mathcal{K}^\bullet)$ is acyclic, or equivalently, tensoring with $\mathcal{K}^\bullet$ maps quasi-iso to quasi-iso, by the long exact sequence and the fact tensoring is an exact functor of triangulated categories(3.7.8.4).

Prop. (5.3.3.2). If K, K' are K-flat complexes of $\mathcal{O}$-modules,

- $\mathrm{Tot}^\oplus(K \otimes_{\mathcal{O}} K')$ is K-flat.
- If (K_1, K_2, K_3) is a distinguished triangle in $K(\mathcal{O})$, if two of them is K-flat, then the third is also K-flat.
- Any bounded above complex of flat $\mathcal{O}$-modules is K-flat.
- Any filtered colimits of K-flat complexes are K-flat.

Proof: 1: This follows from(3.7.8.2).

3: use(3.7.8.4), and the long exact sequence.

4: Cf.[Sta]06YQ.

5: because we are taking termwise-colimit, and Tot and tensor all commute with filtered colimits. □

Prop. (5.3.3.3) [K-Flat Resolutions]. Any complex $P^\bullet$ of $\mathcal{O}$-modules has a K-flat resolution $K^\bullet \to P^\bullet$, moreover, each term of $K^\bullet$ is a flat $\mathcal{O}$-module and $K^\bullet \to P^\bullet$ is termwise surjective.

Proof: Cf.[Sta]06Y4. □

Lemma (5.3.3.4). Let $P \to Q$ be a quasi-iso of K-flat complexes of $\mathcal{O}$-modules, then for any complex L of $\mathcal{O}$-modules, $\mathrm{Tot}(L \otimes P) \to \mathrm{Tot}(L \otimes Q)$ is a quasi-isomorphism.

Proof: Choose a K-flat resolution(5.3.3.3) K of L, then notice

$$\mathrm{Tot}(L \otimes P) \cong \mathrm{Tot}(K \otimes P) \cong \mathrm{Tot}(K \otimes Q) \cong \mathrm{Tot}(L \otimes Q)$$

by definition of K-flatness(5.3.3.1). □

Prop. (5.3.3.5) [Pullback of K-Flat is K-Flat]. Let $f : (\mathcal{S}\mathrm{h}(\mathcal{C}'), \mathcal{O}_{\mathcal{C}'}) \to (\mathcal{S}\mathrm{h}(\mathcal{C}), \mathcal{O}_{\mathcal{C}})$ be a morphism of ringed topoi, then f^* maps K-flat complexes to K-flat complexes.

Proof: Cf.[Sta]0G7E. □

Derived Tensor Product and Tor

Def. (5.3.3.6) [Derived Tensor Product]. Let $\mathcal{A}\to\mathcal{B}$ be a homomorphism of sheaves of rings over a site $\mathcal{C}$, then the functor $\mathrm{Tot}^{\oplus}(-\otimes_{\mathcal{O}}-)$ is a bi-exact bifunctor of triangulated categories $K(\mathcal{A})\times K(\mathcal{B})\to D(\mathcal{B})$ by(3.7.8.4)(3.7.7.8), and the class of K-flat complexes in $K(\mathcal{A})$ and K-flat complexes in $K(\mathcal{B})$ satisfies the condition of (the dual of)**??** by(5.3.3.1) and(5.3.3.3), so we get a left derived functor

$$-\otimes^L_{\mathcal{A}}-: D(\mathcal{A})\times D(\mathcal{B})\to D(\mathcal{B}),$$

called the **derived tensor product**. And if any of $M^\bullet,N^\bullet\in K(\mathcal{A})$ is K-flat, the natural map $M^\bullet\otimes^L_{\mathcal{A}}N^\bullet\to\mathrm{Tot}^{\oplus}(M^\bullet\otimes_{\mathcal{A}}N^\bullet)$ is an isomorphism in $D(\mathcal{B})$

Prop. (5.3.3.7). Let $\mathcal{A}\to\mathcal{B}$ be a homomorphism of sheaves of rings over a site $\mathcal{C}$. Let $N^\bullet$ be a $\mathcal{B}$-module, then for $M^\bullet\in D(\mathcal{A})$, there are a functorial isomorphisms

$$M^\bullet\otimes^L_{\mathcal{A}}N^\bullet\cong(M^\bullet\otimes^L_{\mathcal{A}}\mathcal{B})\otimes^L_{\mathcal{B}}N^\bullet$$

Proof: Consider both sides as right derived functors of the multi-exact multifunctor. As this is true for $\mathrm{Tot}^{\oplus}$, these follow from the universal property and(3.9.3.14), the conditions are satisfied by(5.3.3.3)(5.3.3.4)(5.3.3.5). □

Cor. (5.3.3.8) [Commutative Monoidal Structure]. If $\mathcal{A}=\mathcal{B}=\mathcal{C}=\mathcal{O}$ and $K,L,M\in K(\mathcal{O})$, there are natural isomorphisms

$$K\otimes^L L\cong L\otimes^L K,\quad (K\otimes^L L)\otimes^L M\cong K\otimes^L(L\otimes^L M).$$

Thus $D^*(\mathcal{O})$ has a commutative monoidal structure.

Remark (5.3.3.9) [WARNING]. If M,N are two A-modules, then we can define $M_R\otimes^L_R N$ and $M\otimes^L_R N_R$, but there are no reason for them to be isomorphic.

Prop. (5.3.3.10). Let $\mathcal{A}\to\mathcal{B}\to\mathcal{C}$ be homomorphism of sheave of rings on a site $\mathcal{C}$, then for $M^\bullet\in K(\mathcal{A})$, $N^\bullet\in K(\mathcal{B})$ and $K^\bullet\in K(\mathcal{C})$, there are functorial isomorphisms

$$(M\otimes^L_A N)\otimes^L_B K=M\otimes^L_A(N\otimes^L_B K)=(M\otimes^L_A C)\otimes^L_C(N\otimes^L_B K)$$

and

$$(M\otimes^L_A N)\otimes^L_B K\cong(M\otimes^L_A K)\otimes^L_C(N\otimes^L_B C)$$

Proof: Consider both sides as right derived functors of the multi-exact multifunctor. As these are true for $\mathrm{Tot}^{\oplus}$, these follow from the universal property and(3.9.3.14), the conditions are satisfied by(5.3.3.3)(5.3.3.4)(5.3.3.5). □

Def. (5.3.3.11) [Tor Modules]. Let $\mathcal{F},\mathcal{G}$ be $\mathcal{O}$-modules, then the **Tor modules** $\mathrm{Tor}^{\mathcal{O}}_p(\mathcal{F},\mathcal{G})$ is defined to be $H^{-p}(\mathcal{F}\otimes^L_{\mathcal{O}}\mathcal{G})$.

Prop. (5.3.3.12) [Flatness and Tor]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site, and $\mathcal{F}$ is an $\mathcal{O}$-module. Then $\mathcal{F}$ is a flat $\mathcal{O}$-modules iff $\mathrm{Tor}^{\mathcal{O}}_1(\mathcal{F},\mathcal{G})=0$ for any $\mathcal{O}$-module $\mathcal{G}$.

Proof: If $\mathcal{F}$ is flat, then clearly $\mathrm{Tor}^{\mathcal{O}}_1(\mathcal{F},\mathcal{G})=0$ for any $\mathcal{O}$-module $\mathcal{G}$. Conversely, use the long exact sequence associated to $\mathcal{F}\otimes^L_{\mathcal{O}}\cdot$(3.7.8.4). □

Def. (5.3.3.13)[Relative Cup Product]. Let $f:(\mathcal{S}\mathrm{h}(\mathcal{C}),\mathcal{O}_\mathcal{C})\to(\mathcal{S}\mathrm{h}(\mathcal{D}),\mathcal{O}_\mathcal{D})$ be a morphism of ringed topoi, then for any $K,L\in D(\mathcal{O}_\mathcal{C})$, there is a canonical functorial **relative cup product**

$$Rf_*K\otimes^L_{\mathcal{O}_\mathcal{D}}Rf_*L\to Rf_*(K\otimes^L_{\mathcal{O}_\mathcal{C}}L)$$

in $D(\mathcal{O}_\mathcal{D})$ that is the adjunction map of the map

$$Lf^*(Rf_*K\otimes^L_{\mathcal{O}_\mathcal{D}}Rf_*L)\to Lf^*Rf_*K\otimes^L_{\mathcal{O}_\mathcal{C}}Lf^*Rf_*L\to K\otimes^L_{\mathcal{O}_\mathcal{C}}L$$

by(5.3.3.15). This map is symmetric and associative.

In particular, if $(\mathcal{S}\mathrm{h}(\mathcal{D}),\mathcal{O}_\mathcal{D})=(\mathcal{S}\mathrm{h}(\mathrm{pt}),\Gamma(\mathcal{C},\mathcal{O}_\mathcal{C})=A)$(5.3.1.3), we get a map

$$R\Gamma(\mathcal{C},K)\otimes^L_A R\Gamma(\mathcal{C},L)\to\Gamma(\mathcal{C},K\otimes^L_{\mathcal{O}_\mathcal{C}}L).$$

Derived Pullback

Def. (5.3.3.14) [Derived Pullback]. Let $f:(\mathcal{S}\mathrm{h}(\mathcal{C}'),\mathcal{O}')\to(\mathcal{S}\mathrm{h}(\mathcal{C}),\mathcal{O})$ be a morphism of ringed site, define the **derived pullback**

$$Lf^*:D(\mathcal{O})\to D(\mathcal{O}'):\mathcal{F}^\bullet\mapsto f^{-1}\mathcal{F}^\bullet\otimes^L_{f^{-1}\mathcal{O}}\mathcal{O}'(5.3.3.6).$$

In particular, if $\mathcal{F}^\bullet$ is K-flat, then there are natural isomorphisms $Lf^*\mathcal{F}^\bullet\cong f^*\mathcal{F}^\bullet$.

Moreover, Lf^* is also naturally isomorphic to the left derived functor of the pullback morphism f^*, by composition of derived functors applied to the $f^*=\mathrm{Tot}(\cdot\otimes_{f^{-1}\mathcal{O}}\mathcal{O}')\circ f^{-1}$ where f^{-1} is exact. In particular, Lf^* only depends on the underlying map f^* of ringed topoi.

Prop. (5.3.3.15). Let $f:(\mathcal{S}\mathrm{h}(\mathcal{C}),\mathcal{O}_\mathcal{C})\to(\mathcal{S}\mathrm{h}(\mathcal{D}),\mathcal{O}_\mathcal{D})$, $g:(\mathcal{S}\mathrm{h}(\mathcal{D}),\mathcal{O}_\mathcal{D})\to(\mathcal{S}\mathrm{h}(\mathcal{E}),\mathcal{O}_\mathcal{E})$ be a morphism of ringed topoi, then

- There is a natural isomorphism $L(g\circ f)^*\cong Lf^*\circ Lg^*$. In particular, as localizing map j^* is exact, Lf^* can be calculated locally on the base.
- For $\mathcal{F}^\bullet,\mathcal{G}^\bullet\in\mathcal{M}\mathrm{od}_{\mathcal{O}_\mathcal{D}}$, there are natural functorial isomorphisms

$$Lf^*(\mathcal{F}^\bullet\otimes^L_{\mathcal{O}_\mathcal{D}}\mathcal{G}^\bullet)\cong Lf^*\mathcal{F}^\bullet\otimes^L_{\mathcal{O}_\mathcal{C}}Lf^*\mathcal{G}^\bullet.$$

  In particular, as localizing map j^* is exact, the derived tensor product can be calculated locally on the base.
- For $\mathcal{F}^\bullet\in\mathcal{M}\mathrm{od}_{\mathcal{O}_\mathcal{C}},\mathcal{G}^\bullet\in\mathcal{M}\mathrm{od}_{\mathcal{O}_\mathcal{D}}$, there are natural functorial isomorphisms

$$\mathcal{F}^\bullet\otimes^L_{\mathcal{O}_\mathcal{C}}Lf^*\mathcal{G}^\bullet\cong\mathcal{F}^\bullet\otimes^L_{f^{-1}\mathcal{O}_\mathcal{D}}f^{-1}\mathcal{G}'$$

- For $\mathcal{F}^\bullet,\mathcal{G}^\bullet\in\mathcal{M}\mathrm{od}_{\mathcal{O}_\mathcal{D}}$, the natural isomorphisms satisfy a commutative diagram

$$\begin{array}{ccc}
Lf^*(\mathcal{F}^\bullet\otimes^L_{\mathcal{O}_\mathcal{D}}\mathcal{G}^\bullet) & \longrightarrow & Lf^*\,\mathrm{Tot}^\oplus(\mathcal{F}^\bullet\otimes_{\mathcal{O}_\mathcal{D}}\mathcal{G}^\bullet)\\
\downarrow & & \downarrow\\
Lf^*\mathcal{F}^\bullet\otimes^L_{\mathcal{O}_\mathcal{C}}Lf^*\mathcal{G}^\bullet & & f^*\,\mathrm{Tot}^\oplus(\mathcal{F}^\bullet\otimes_{\mathcal{O}_\mathcal{D}}\mathcal{G}^\bullet)\\
\downarrow & & \downarrow\\
f^*\mathcal{F}^\bullet\otimes^L_{\mathcal{O}_\mathcal{C}}f^*\mathcal{G}^\bullet & \longrightarrow & \mathrm{Tot}^\oplus(f^*\mathcal{F}^\bullet\otimes_{\mathcal{O}_\mathcal{C}}f^*\mathcal{G}^\bullet)
\end{array}$$

Proof: 1, 2, 3: These follow from(5.3.3.10).

4: By a universal argument, $(\mathcal{F}^\bullet,\mathcal{G}^\bullet)\mapsto Lf^*(\mathcal{F}^\bullet\otimes^L_{\mathcal{O}_\mathcal{D}}\mathcal{G}^\bullet)$ is the derived functor of the bi-exact bifunctor

$$F:K(\mathcal{O}_\mathcal{D})\times K(\mathcal{O}_\mathcal{D})\to D(\mathcal{O}_\mathcal{C}):(\mathcal{F}^\bullet,\mathcal{G}^\bullet)\mapsto f^*\,\mathrm{Tot}^\oplus(\mathcal{F}^\bullet\otimes_{\mathcal{O}_\mathcal{D}}\mathcal{G}^\bullet).$$

Then by the universal property, both natural transformations corresponds to a natural transformation $\theta_i:LF\to LF$. So it suffices to show that they are isomorphic. But K-flat morphisms are essentially surjective in $D(\mathcal{O}_\mathcal{D})$, thus it suffices to prove the diagram is commutative for $\mathcal{F},\mathcal{G}$ K-flat. But in this case, there are commutative diagrams

$$\begin{array}{ccc} LF(\mathcal{F}^\bullet,\mathcal{G}^\bullet) & \xrightarrow{\eta_{(\mathcal{F},\mathcal{G})}} & F(\mathcal{F}^\bullet,\mathcal{G}^\bullet)\\ \downarrow{\scriptstyle \theta_i\star(Q_{\mathcal{O}_\mathcal{D}}\times Q_{\mathcal{O}_\mathcal{D}})} & & \downarrow{\scriptstyle \mathrm{id}}\\ LF(\mathcal{F}^\bullet,\mathcal{G}^\bullet) & \xrightarrow{\eta_{(\mathcal{F},\mathcal{G})}} & F(\mathcal{F}^\bullet,\mathcal{G}^\bullet)\end{array}$$

and $\eta_{(\mathcal{F},\mathcal{G})}$ is an isomorphism, so $\theta_1=\theta_2$. □

Prop. (5.3.3.16) [Adjunction]. Lf^* is left adjoint to Rf_*, by(3.9.3.15) and(5.2.2.9).

Prop. (5.3.3.17) [Base Change Map]. Let

$$\begin{array}{ccc} (\mathcal{S}\mathrm{h}(\mathcal{C}'),\mathcal{O}_{\mathcal{C}'}) & \xrightarrow{g'} & (\mathcal{S}\mathrm{h}(\mathcal{C}),\mathcal{O}_\mathcal{C})\\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f}\\ (\mathcal{S}\mathrm{h}(D'),\mathcal{O}_{D'}) & \xrightarrow{g} & (\mathcal{S}\mathrm{h}(\mathcal{D}),\mathcal{O}_\mathcal{D})\end{array}$$

be a commutative diagram of ringed topoi, then for any $K\in D(\mathcal{O}_\mathcal{C})$, there is a canonical base change map

$$Lg^*Rf_*K\to R(f')_*L(g')^*K$$

functorial in K, and this map is compatible with composition of diagrams.

Proof: By adjunction(5.3.3.16), this follows from the canonical map

$$Rf_*K\to Rg_*R(f')_*L(g')^*K=Rf_*R(g')_*L(g')^*K,$$

which comes from the adjunction map $K\to R(g')_*L(g')^*K$. □

Cor. (5.3.3.18) [Flat Base Change Morphism]. Let

$$\begin{array}{ccc} (\mathcal{S}\mathrm{h}(\mathcal{C}'),\mathcal{O}_{\mathcal{C}'}) & \xrightarrow{g'} & (\mathcal{S}\mathrm{h}(\mathcal{C}),\mathcal{O}_\mathcal{C})\\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f}\\ (\mathcal{S}\mathrm{h}(\mathcal{D}'),\mathcal{O}_{\mathcal{D}'}) & \xrightarrow{g} & (\mathcal{S}\mathrm{h}(\mathcal{D}),\mathcal{O}_\mathcal{D})\end{array}$$

be a commutative diagram of ringed sites. Assume both g,g' are flat, then for any $\mathcal{F}^\bullet\in K^+(\mathcal{O}_\mathcal{C})$, there is a canonical base change map

$$g^*Rf_*\mathcal{F}^\bullet\to Rf'_*(g')^*\mathcal{F}^\bullet.$$

and when $(\mathcal{S}\mathrm{h}(\mathcal{D}'),\mathcal{O}_\mathcal{D})=(\mathcal{S}\mathrm{h}(\mathcal{C}/U),\mathcal{O}_U)$ is the localizing site, then this map is an isomorphism

$$(Rf_*\mathcal{F}^\bullet)_U\cong Rf'_*\mathcal{F}^\bullet_U.$$

Proof: The last assertion follows from the fact the restriction of a K-injective is also a K-injective(5.3.4.2). □

Def. (5.3.3.19) [Projection Map]. Let $f : (\mathcal{Sh}(\mathcal{C}), \mathcal{O}_{\mathcal{C}}) \to (\mathcal{Sh}(\mathcal{D}), \mathcal{O}_{\mathcal{D}})$ be a morphism of ringed topoi, then for any $E \in D(\mathcal{O}_{\mathcal{C}})$ and $K \in D(\mathcal{O}_{\mathcal{D}})$, there is a canonical functorial **projection map**

$$Rf_*E \otimes^L_{\mathcal{O}_{\mathcal{D}}} K \to Rf_*(E \otimes^L_{\mathcal{O}_{\mathcal{C}}} Lf^*K)$$

which is the adjunction of the map

$$Lf^*(Rf_*E \otimes^L_{\mathcal{O}_{\mathcal{D}}} K) \cong Lf^*Rf_*E \otimes^L_{\mathcal{O}_{\mathcal{C}}} Lf^*K \to E \otimes^L_{\mathcal{O}_{\mathcal{C}}} Lf^*K$$

by(5.3.3.15).

Prop. (5.3.3.20) [Projection Formula]. In situation(5.3.3.19), if K is perfect(5.3.4.17), then the projection map is an isomorphism.

Proof: To check it is an isomorphism, it suffice to find a covering $\{U_i \to V\}$ for each $V \in \mathcal{C}$ that this map is an isomorphism on U_i.(To see this, look at H^i, and notice $U \mapsto \mathcal{Mod}(\mathcal{O}_U)$ is a stack). Then we may assume K is a finite complex of $\mathcal{O}_U$-modules consisting of finite free $\mathcal{O}_U$-modules. And then we use truncation to reduce to the case K is discrete, in which case it is trivial. □

Inner Hom

Def. (5.3.3.21) [Sheaf Hom Complexes]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $P^\bullet, Q^\bullet \in K(\mathcal{O})$, we define the **Sheaf Hom complex** $\mathcal{H}om^\bullet(P^\bullet, Q^\bullet)$ to be

$$\mathcal{H}om^n(P^\bullet, Q^\bullet) = \prod_i \mathcal{H}om_{\mathcal{O}}(P^i, Q^{n+i})(5.2.3.1),$$

with the differential giving by $d(\{f_k\})_i = \{df_i - (-1)^i f_{i+1}d\}$ and suitable signatures.

It is clear that

$$\Gamma(U, \mathcal{H}om^\bullet_{\mathcal{O}}(P^\bullet, Q^\bullet)) = \mathrm{Hom}^\bullet_{\mathcal{O}_U}(P^\bullet|_U, Q^\bullet|_U), \quad \Gamma(\mathcal{C}, \mathcal{H}om^\bullet_{\mathcal{O}}(P^\bullet, Q^\bullet)) = \mathrm{Hom}^\bullet_{\mathcal{O}}(P^\bullet|_U, Q^\bullet|_U)$$

and

$$H^n(\Gamma(U, \mathcal{H}om^\bullet(P^\bullet, Q^\bullet))) = \mathrm{Hom}_{K(\mathcal{O}_U)}(P^\bullet|_U, Q^\bullet|_U[n]), \quad H^n(\Gamma(\mathcal{C}, \mathcal{H}om^\bullet(P^\bullet, Q^\bullet))) = \mathrm{Hom}_{K(\mathcal{O})}(P^\bullet, Q^\bullet[n]).$$

Prop. (5.3.3.22) [Adjunction]. For $\mathcal{K}^\bullet, \mathcal{M}^\bullet, \mathcal{L}^\bullet \in K(\mathcal{O})$, there is a canonical functorial isomorphism:

$$\mathcal{H}om^\bullet(K, \mathcal{H}om^\bullet(L, M)) = \mathcal{H}om^\bullet(\mathrm{Tot}(K \otimes_R L), M).$$

Proof: Cf.[Sta]0A5Y. □

Prop. (5.3.3.23). For $\mathcal{K}^\bullet, \mathcal{M}^\bullet, \mathcal{L}^\bullet \in K(\mathcal{O})$, there are canonical functorial morphisms:

- $\mathrm{Tot}(\mathcal{H}om(\mathcal{K}^\bullet, \mathcal{L}^\bullet) \otimes_{\mathcal{O}} \mathcal{K}^\bullet) \to \mathcal{L}^\bullet$,
- $\mathrm{Tot}(\mathcal{H}om^\bullet(L, M) \otimes_{\mathcal{O}} \mathcal{H}om^\bullet(K, L)) \to \mathcal{H}om^\bullet(K, M)$,
- $\mathrm{Tot}(\mathcal{H}om^\bullet(L, M) \otimes_{\mathcal{O}} K) \to \mathcal{H}om^\bullet(\mathcal{H}om^\bullet(K, L), M)$,
- $\mathrm{Tot}(K \otimes_{\mathcal{O}} \mathcal{H}om^\bullet(M, L)) \to \mathcal{H}om^\bullet(M, \mathrm{Tot}(K \otimes_{\mathcal{O}} L))$,

- $K\to\mathcal{H}om^\bullet(L,\mathrm{Tot}(K\otimes_{\mathcal{O}}L))$.

Proof: All these are consequences of(5.3.3.22). □

Lemma (5.3.3.24). Let $(\mathcal{C},\mathcal{O})$ be a site and $(\mathcal{I}^\bullet)'\to\mathcal{I}^\bullet$ be a quasi-isomorphism of K-injective $\mathcal{O}$-modules and $(\mathcal{L}^\bullet)'\to\mathcal{L}^\bullet$ be a quasi-isomorphism of $\mathcal{O}$-modules, then the natural map

$$\mathcal{H}om^\bullet(\mathcal{L}^\bullet,(\mathcal{I}^\bullet)')\to\mathcal{H}om^\bullet((\mathcal{L}^\bullet)',\mathcal{I}^\bullet)$$

is a quasi-isomorphism.

Proof: $H^n(\mathcal{H}om^\bullet(\mathcal{L}^\bullet,(\mathcal{I}^\bullet)'))$ is the the sheaf $U\mapsto\mathrm{Hom}_{K(\mathcal{O}_U)}(\mathcal{L}^\bullet_U,(\mathcal{I}^\bullet)'_U[n])$, and $(\mathcal{I}^\bullet)'_U[n]$ is K-injective by(5.3.4.2). □

Def. (5.3.3.25) [Internal Hom]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site, $K(\mathcal{O})$ has enough K-injectives, thus by(3.9.3.13), we can define the **internal Hom**

$$R\mathcal{H}om:D(\mathcal{O})^{op}\times D(\mathcal{O})\to D(\mathcal{O})$$

as the right derived functor of the bi-exact bifunctor $\mathcal{H}om^\bullet:K(\mathcal{O})^{op}\times K(\mathcal{O})\to D(\mathcal{O})$, where the conditions are satisfied by(5.3.3.24).

Prop. (5.3.3.26)[Internal Hom and Localization]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site, for any $\mathcal{G},\mathcal{F}\in K(\mathcal{O})$ and $U\in\mathcal{C}$, the natural transformation

$$R\mathcal{H}om(\mathcal{F},\mathcal{G})|_U\to R\mathcal{H}om(\mathcal{F}|_U,\mathcal{G}|_U)$$

is an isomorphism. In particular, we can calculate $\mathcal{E}xt$ locally.

Proof: This follows from(5.3.3.21)(5.3.4.2) and trivial Grothendieck duality applied to restrictions. □

Prop. (5.3.3.27) [Derived Hom and Internal Hom]. For a ringed site $(\mathcal{C},\mathcal{O})$ and $\mathcal{F},\mathcal{G}\in D(\mathcal{O})$, $U\in\mathcal{C}$,

$$R\Gamma(\mathcal{C},R\mathcal{H}om(\mathcal{F},\mathcal{G}))=R\,\mathrm{Hom}(\mathcal{F},\mathcal{G}),\quad R\Gamma(U,R\mathcal{H}om(\mathcal{F},\mathcal{G}))=R\,\mathrm{Hom}_{\mathcal{O}_U}(\mathcal{F}|_U,\mathcal{G}|_U).$$

In particular,

$$\Gamma(U,R\mathcal{H}om(\mathcal{F},\mathcal{G}))=\mathrm{Hom}_{D(\mathcal{O}_U)}(\mathcal{F}|_U,\mathcal{G}|_U),$$

and

$$H^0(\mathcal{C},R\mathcal{H}om(\mathcal{F},\mathcal{G}))=\mathrm{Hom}_{D(\mathcal{O})}(\mathcal{F},\mathcal{G}),\quad H^p(\mathcal{C},R\mathcal{H}om(\mathcal{F},\mathcal{G}))=\mathrm{Ext}^p_{\mathcal{O}}(\mathcal{F},\mathcal{G})$$

by(5.3.3.21)(5.3.4.2)(5.3.4.13) and the composition of derived functors.

Prop. (5.3.3.28). If $\mathcal{K},\mathcal{L},\mathcal{M}\in D(\mathcal{O})$, then there is a natural isomorphism

$$R\mathcal{H}om_{\mathcal{O}}(\mathcal{K},R\mathcal{H}om(\mathcal{L},\mathcal{M}))\cong R\mathcal{H}om_{\mathcal{O}}(\mathcal{K}\otimes^L_{\mathcal{O}}\mathcal{L},\mathcal{M}).$$

Proof: Consider both sides as the derived functor of the triple-exact triple-functor

$$K(\mathcal{O})^{op}\times K(\mathcal{O})^{op}\times K(\mathcal{O})\to D(\mathcal{O}):(\mathcal{K}^\bullet,\mathcal{L}^\bullet,\mathcal{M}^\bullet)\mapsto\mathrm{Tot}^{\oplus}(\mathcal{K}^\bullet\otimes_{\mathcal{O}}\mathrm{Tot}^{\oplus}(\mathcal{L}^\bullet\otimes_{\mathcal{O}}\mathcal{M}^\bullet)),$$

the conditions are satisfied by(5.3.4.13)(5.3.3.3). As this is true for Tot by(5.3.3.22), this follows from the universal properties and(3.9.3.14). □

Cor. (5.3.3.29) [Adjunction]. By(5.3.3.28), taking $H^0(R\Gamma(\mathcal{C},-))$, we get:

$$\mathrm{Hom}_{D(\mathcal{O})}(\mathcal{K}, R\mathcal{H}om(\mathcal{L},\mathcal{M})) = \mathrm{Hom}_{D(\mathcal{O})}(\mathcal{K}\otimes^L \mathcal{L},\mathcal{M}).$$

that is, derived tensor is left adjoint to internal hom.

Prop. (5.3.3.30). Given complexes $\mathcal{K},\mathcal{L},\mathcal{M}\in D(\mathcal{O})$, there are canonical functorial morphisms:

- $\mathcal{H}om(K,L)\otimes^L_{\mathcal{O}} K\to L$,
- $R\mathcal{H}om(L,M)\otimes^L_{\mathcal{O}} R\mathcal{H}om(K,L)\to R\mathcal{H}om(K,M)$,
- $R\mathcal{H}om(L,M)\otimes^L_{\mathcal{O}} K\to R\mathcal{H}om(R\mathcal{H}om(K,L),M)$,
- $K\otimes^L_{\mathcal{O}} R\mathcal{H}om(M,L)\to R\mathcal{H}om(M,K\otimes^L_{\mathcal{O}} L)$,
- $K\to R\mathcal{H}om(L,K\otimes^L_{\mathcal{O}} L)$.

Proof: These are direct consequences of(5.3.3.29). □

Prop. (5.3.3.31). Let $(\mathcal{S}\mathrm{h}(\mathcal{C}),\mathcal{O})\to(\mathcal{S}\mathrm{h}(\mathcal{C}'),\mathcal{O}')$ be a morphism of ringed site and $\mathcal{K},\mathcal{L}\in D(\mathcal{O})$, there is a natural morphism

$$Rf_*R\mathcal{H}om_{\mathcal{O}}(L,K)\to R\mathcal{H}om_{\mathcal{O}'}(Rf_*L,Rf_*K).$$

Proof: This follows from the adjunction(5.3.3.28)(5.3.3.30) and the relative cup product(5.3.3.13). □

Def. (5.3.3.32) [Internal Ext Groups]. For any $\mathcal{G},\mathcal{F}\in K(\mathcal{O})$, we define the **internal Ext groups**

$$\mathcal{E}xt^n_{\mathcal{O}}(\mathcal{G},\mathcal{F}) = H^i(R\mathcal{H}om(\mathcal{G},\mathcal{F}))\in \mathcal{M}\mathrm{od}(\mathcal{O}).$$

Prop. (5.3.3.33). For $\mathcal{E},\mathcal{F},\mathcal{L}\in\mathcal{M}\mathrm{od}(\mathcal{O}_X)$ and $\mathcal{L}$ finite locally free,

$$\mathcal{E}xt^i(\mathcal{F}\otimes\mathcal{L},\mathcal{G})\cong\mathcal{E}xt^i(\mathcal{F},\mathcal{L}^\vee\otimes\mathcal{G})\cong\mathcal{E}xt^i(\mathcal{F},\mathcal{G})\otimes\mathcal{L}^\vee$$

because there are maps between them(5.2.5.2), and $\mathcal{E}xt$ is local, so check locally. In particular,

$$\mathrm{Ext}^i(\mathcal{F}\otimes\mathcal{L},\mathcal{G}) = \mathrm{Ext}^i(\mathcal{F},\mathcal{L}^\vee\otimes\mathcal{G}).$$

Prop. (5.3.3.34) [Spectral Sequences for Internal Ext]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site and $\mathcal{K}^\bullet\in K^-(\mathcal{O}),\mathcal{F}^\bullet\in K^+(\mathcal{O})$, then there are spectral sequence convergence

$$E_2^{i,j}=\mathcal{E}xt^i_{\mathcal{O}}(H^{-j}(\mathcal{K}^\bullet),\mathcal{F}^\bullet)\Longrightarrow \mathcal{E}xt^{i+j}_{\mathcal{O}}(\mathcal{K}^\bullet,\mathcal{F}^\bullet).$$

$$E_1^{i,j}=\mathcal{E}xt^j_{\mathcal{O}}(\mathcal{K}^{-i},\mathcal{F}^\bullet)\Longrightarrow \mathcal{E}xt^{i+j}_{\mathcal{O}}(\mathcal{K}^\bullet,\mathcal{F}^\bullet)$$

$$E_2^{i,j}=H^i(\mathcal{C},\mathcal{E}xt^j_{\mathcal{O}}(\mathcal{K}^\bullet,\mathcal{F}^\bullet))\Longrightarrow \mathrm{Ext}^{i+j}_{\mathcal{O}}(\mathcal{K}^\bullet,\mathcal{F}^\bullet)$$

Proof: 1, 2: Choose a (bounded below) injective resolution $\mathcal{I}^\bullet$ of $\mathcal{F}^\bullet$, and these are the two spectral sequences associated to the double complex $\mathcal{H}om^\bullet_{\mathcal{O}}(\mathcal{K}^\bullet,\mathcal{I}^\bullet)$.

3: Use Grothendieck spectral sequence on(5.3.3.27). □

4 Acyclic Sheaves

Prop. (5.3.4.1) [Pushforward of Injectives]. Let $f : (\mathcal{S}\mathrm{h}(\mathcal{C}), \mathcal{O}_C) \to (\mathcal{S}\mathrm{h}(\mathcal{D}), \mathcal{O}_D)$ be a flat map of ringed topoi, then f preserves injectives, as f^* is exact.

Prop. (5.3.4.2) [Restriction of (K-)Injectives]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site, $U \in \mathcal{C}$, then

- If $\mathcal{K}^\bullet$ be a K-injective complex $\mathcal{O}$-modules, then $(\mathcal{K}^\bullet)|_U$ is a K-injective complex of $\mathcal{O}_U$-modules.
- If $\mathcal{I}$ is an injective $\mathcal{O}$-module, then $\mathcal{I}|_U$ is an injective $\mathcal{O}$-module.

Proof: Use(3.9.2.6) and the fact j_U^* is right adjoint to the exact functor $j_{U!}$(5.2.2.9)(5.2.2.9). □

Prop. (5.3.4.3). If $\mathcal{I} \in \mathcal{S}\mathrm{h}(\mathcal{C})$ is injective, then $\mathcal{I}$ is also injective in $\mathcal{PS}\mathrm{h}(\mathcal{C})$.

Proof: Because restriction is right adjoint to the exact shifification functor. □

Prop. (5.3.4.4). For an injective sheaf $\mathcal{F}$ on a site $(\mathcal{C}, \mathcal{O})$, $F(U)$ is injective Abelian group for every $U \in \mathcal{C}$.

Proof: This is because for the morphism $i : \mathrm{pt} \to \mathcal{C} : \mathrm{pt} \mapsto U$, i_p is exact($i_p A(V) = \oplus_{\mathrm{Hom}(V,U)} A$), hence i^p preserves injectives. □

Flask Sheaves

Def. (5.3.4.5) [Totally Acyclic Sheaves]. A **totally acyclic sheaf** on a ringed site $(\mathcal{C}, \mathcal{O})$ is an object in $\mathcal{S}\mathrm{h}(\mathcal{C})$ that is acyclic for any functor $\mathrm{Hom}_{\mathcal{PS}\mathrm{h}(\mathcal{C})}(K, -)$.

Prop. (5.3.4.6) [Characterization of Totally Acyclic Sheaves]. Let $\mathcal{C}$ be a site and $\mathcal{F} \in \mathcal{S}\mathrm{h}(\mathcal{C})$, then $\mathcal{F}$ is totally acyclic iff

- $\mathcal{F}$ is acyclic for $\Gamma(U, -)$ for any $U \in \mathcal{C}$.
- For every surjection $K' \to K$ of sheaves of sets the extended Čech complex

$$0 \to H^0(K, \mathcal{F}) \to H^0(K', \mathcal{F}) \to H^0(K' \times_K K', \mathcal{F}) \to \dots$$

  is exact.

Proof: Cf.[Sta]07A1. □

Prop. (5.3.4.7). A totally acyclic sheaf is acyclic for any map of ringed topoi $f : (\mathcal{S}\mathrm{h}(\mathcal{C}), \mathcal{O}_C) \to (\mathcal{S}\mathrm{h}(\mathcal{D}), \mathcal{O}_D)$.

Proof: This follows from the description of $R^i f_*$ in(5.3.1.7). □

Def. (5.3.4.8)[Flask Sheaves]. A **flask sheaf** on a ringed site $(\mathcal{C}, \mathcal{O})$ is an object of $\mathcal{S}\mathrm{h}(\mathcal{C})$ that satisfies the following equivalent conditions:

- it is acyclic for ι.
- It is acyclic for any $\check{H}^0(\{U_i \to U\}, -)$
- It is acyclic for all $\Gamma(U, -)$.

In particular a totally acyclic sheaf is flask.

A **flabby sheaf** is an object of $\mathcal{S}\mathrm{h}(\mathcal{C})$ that for any monomorphism $U \to V$, $\mathcal{F}(V) \to \mathcal{F}(U)$ is surjective;

Proof: 1 $\iff$ 3 is by(5.3.1.6),

3 $\to$ 2: use Čech to sheaf1(5.3.2.13), notice the $q>0$ terms vanish, thus $\check{H}^p(\{U_i\to U\},\mathcal{F}) = H^p(U,\mathcal{F})=0$.

2 $\to$ 3 follows from(5.3.2.16). ☐

Prop. (5.3.4.9). Injective sheaves are flabby, Flabby sheaves on a ringed space are flask.

Proof: For the first assertion, use(5.2.2.9) and the fact $j_!\mathcal{O}_U\to j_!\mathcal{O}_V$ is a monomorphism for $V\to U$ a monomorphism by definition(5.2.2.9).

For the last assertion, use(3.9.3.29): Injectives are flabby, so it is sufficiently large. For an exact sequence $0\to\mathcal{F}\to\mathcal{G}\to\mathcal{H}\to 0$ of sheaves, if $\mathcal{F}$ is flabby, then H is just the presheaf cokernel. (It reduces to $\check{H}^1(\{U_i\to U\},F)=0$, and this is done by Zorn's lemma). Thus if $\mathcal{F}$ is flabby, $\mathcal{G}$ is flabby iff $\mathcal{H}$ is flabby(by five lemma). ☐

Prop. (5.3.4.10). On a discrete site, all sheaves is flask, because ι is the identity functor.

Prop. (5.3.4.11). Filtered colimits of flabby sheaves is flabby. (This is because filtered colimits are exact).

Filtered colimits of injective sheaves over a Noetherian topological space is injective. (Use Baer criterion, then notice every sub-object of $\mathbb{Z}_U$ is finitely generated because it has only f.m. connected component(3.11.3.4) so it maps to some F_α).

Prop. (5.3.4.12) [Pushforward of Totally Acyclic/Flask Sheaves]. Let $f:(\mathcal{S}h(\mathcal{C}),\mathcal{O}_C)\to(\mathcal{S}h(\mathcal{D}),\mathcal{O}_D)$ be a map of ringed topoi(reps. ringed site), then f_* maps totally acyclic(resp. flask) sheaves to totally acyclic(resp. flask) sheaves(5.3.4.5)(5.3.4.8). in particular, it maps injectives to totally acyclic sheaves.

Proof: By(5.2.1.3) we may assume f is a map of ringed sites, and $K=h_U$ for some $U\in\mathcal{C}$. Then we notice $H^*(\{U_i\to U\},f_*\mathcal{F}) = H^*(\{f^{-1}(U_i)\to f^{-1}(U)\},\mathcal{F})$, then we can use(5.3.2.16) to show $f_*\mathcal{F}$ is totally acyclic. ☐

Prop. (5.3.4.13) [Technical Lemma]. If $\mathcal{K}^\bullet$ is K-flat $\mathcal{O}$-modules and $\mathcal{I}^\bullet$ is K-injective $\mathcal{O}$-modules, then $\mathcal{H}om^\bullet(\mathcal{K}^\bullet,\mathcal{I}^\bullet)$ is K-injective.

Proof: Use definitions(5.3.3.1)(3.9.2.1) and(5.3.3.22). ☐

Prop. (5.3.4.14). If $\mathcal{I}$ is an injective $\mathcal{O}_X$-module, then for a coherent locally free sheaf $\mathcal{L}$, $\mathcal{L}\otimes\mathcal{I}$ is also injective, because tensoring with $\mathcal{L}$ is adjoint to tensoring with $\mathcal{L}^\vee$(5.2.5.2), which is exact.

<u>Pseudo-Coherent Sheaves</u>

Def. (5.3.4.15) [Strictly Perfect Complexes of Modules]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site, a **strictly perfect complex of $\mathcal{O}$-modules** of $\mathcal{O}$-modules is a finite complex of $\mathcal{O}$-modules that each term is a direct summand of a finite free $\mathcal{O}$-module.

Def. (5.3.4.16) [Pseudo-Coherent Complexes of Modules]. Let $(\mathcal{C},\mathcal{O})$ be a ringed site, then $\mathcal{K}\in D(\mathcal{O}_X)$ is called an m**-pseudo-coherent $\mathcal{O}_X$-module** if for any $U\in\mathcal{C}$, there exists a covering $\{U_i\to U\}$ s.t. for any i, there are strictly perfect object $E_i\in D(\mathcal{O}_{U_i})$ and a morphism $E_i\to K|_{U_i}$ that induces isomorphisms on H^i for $i>m$ and surjection on H^m.

$K\in D(R)$ is called a **pseudo-coherent $\mathcal{O}_X$-module** if it is m-pseudo-coherent for any m.

Perfect Sheaves

Def. (5.3.4.17) [Perfect Complexes of Modules]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site, a **perfect complex of $\mathcal{O}$-modules** of $\mathcal{O}$-modules is an object E in $\mathcal{D}(\mathcal{O})$ that for any $U \in \mathcal{C}$ there is a covering $\{U_i \to U\}$ that $E|_{U_i}$ is can be represented by a strictly perfect complexes(5.3.4.15).

Prop. (5.3.4.18). Every mapping from a strictly perfect complex to an acyclic complex has a cover of open sets that on each open set the map is nullhomotopic.

Proof: This is true for a single direct summand of a finite free sheaf, and we can use induction to prove, Cf.[Sta]08C7. □

Cor. (5.3.4.19). The strictly perfect complexes are fake "K-projective" objects in $K(\mathcal{O}_X)$. Note it is note technically K-projective, but it has all the properties of K-projective when proven, noticing the fact it is irrelevant when taken shifification.

Def. (5.3.4.20) [Perfect Sheaves]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site, an object $K^\bullet$ in $K(\mathcal{O})$ **perfect** if there is a covering $\mathcal{U}$ that on each U_i there is a quasi-iso $K_i^\bullet \to K^\bullet|_{U_i}$ with $K_i^\bullet$ strictly perfect.

This is equivalent to $K^\bullet$ is locally represented by perfect objects in $D(\mathcal{O})$ by the fact that perfect object is fake K-projective.

Prop. (5.3.4.21). When X is local ringed space, perfectness is equivalent to the fact that it is locally a finite free $\mathcal{O}_{U_i}$-module.

Proof: This is because direct summand of a finite free module is free, Cf.[Sta]0BCI. □

Prop. (5.3.4.22) [Strictly Perfect Modules are "Acyclic" for Hom$^\bullet$]. If $(\mathcal{C}, \mathcal{O})$ is a ringed site and $\mathcal{E}^\bullet, \mathcal{F}^\bullet \in K(\mathcal{O})$, then $R\mathcal{H}om(\mathcal{E}^\bullet, \mathcal{F}^\bullet)$ can be calculated directly by $\mathcal{H}om^\bullet(\mathcal{E}, \mathcal{F})$ in the following cases:

- $\mathcal{E}^\bullet$ is strictly perfect.
- $\mathcal{E}^\bullet \in D^-(\mathcal{O}_X), \mathcal{F}^\bullet \in D^+(\mathcal{O}_X)$, and each term $\mathcal{E}^n$ is a direct summand of a finite free $\mathcal{O}_X$-module.

Proof: Cf.[Sta]08I5, 08DM. □

Prop. (5.3.4.23) [Duals]. Let K be a perfect object in $D(\mathcal{O})$, then

- $K^\vee = R\mathcal{H}om(K, \mathcal{O})$ is also a perfect object, and $(K^\vee)^\vee \cong K$.
- For any $M \in D(\mathcal{O})$, there are functorial isomorphisms

$$M \otimes^L K^\vee \cong R\mathcal{H}om(K, M), \quad H^0(\mathcal{C}, M \otimes^L K^\vee) \cong \mathrm{Hom}_{D(\mathcal{O})}(K, M).$$

Proof: Cf.[Sta]08JJ. □

Def. (5.3.4.24) [Relative Perfect Modules]. Let $(X, \mathcal{O}_X) \to (S, \mathcal{O}_S)$ be a morphism of ringed sites that is flat and locally of f.p., then $E \in D(\mathcal{O}_X)$ is called a **perfect object relative to S** if E is pseudo-coherent and E locally has finite tor dimension as an object in $D(f^{-1}\mathcal{O}_S)$. Cf.[Sta]08CG.

5 Topological Sheaves

References are [Sheaf Cohomology, Anonymous].

A topological space can be seen as a ringed site, so the theory of ringed sites applies to topological spaces.

Acyclic sheaves

Def. (5.3.5.1). An Abelian sheaf on a paracompact Hausdorff topological space X is called
soft iff is and $\forall$ closed $V, \mathcal{F}(X) \to \mathcal{F}(V)$ is surjective. A flabby sheaf is soft.
fine iff the sheaf of rings $\mathrm{Hom}(\mathcal{F}, \mathcal{F})$ is soft.
Fine and soft are local properties (Use Zorn's lemma to construct one-by-one).

Prop. (5.3.5.2). For a sheaf of *unital rings* over a paracompact Hausdorff space X, the following are equivalent,

1. it is a soft sheaf.
2. for any disjoint closed sets V, W, there is a section of X that is 0 on V, and 1 on W.
3. it possesses a partition of unity.
4. it is a fine sheaf.

Note any soft sheaf possesses a partition of unity.

Proof: $1 \iff 2$ is easy and $1 \to 3$ is the to choose a closed locally finite subcover and use Zorn's lemma to construct one-by-one. For $3 \to 1$, notice a closed section can extend to a slightly larger nbhd.

Because for a sheaf of rings $\mathcal{F}$, a partition of unity is equivalent to a partition of unity $\mathrm{Hom}(\mathcal{F}, \mathcal{F})$, so 34 are equivalent because 13 are equivalent. □

Cor. (5.3.5.3).

- Note that a fine sheaf possesses a decomposition of section because the previous proposition applies to $\mathrm{Hom}(\mathcal{F}, \mathcal{F})$, and a partition of unity in $\mathrm{Hom}(\mathcal{F}, \mathcal{F})$ yields a decomposition of section in $\mathcal{F}$. Thus a fine sheaf is soft. (extend to a small nbhd and use partition of unity).
- The sheaf of modules over a soft sheaf of rings is soft, by partition of unity.
- The continuous function sheaf on a paracompact Hausdorff space or the smooth function sheaf on a smooth manifold is fine, thus any smooth module is fine (Use bump function).

Prop. (5.3.5.4). Soft sheaf, e.g. fine sheaf is adapted to $\Gamma(X, -)$. (Similar as in(5.3.4.9), notice flabby is soft and the others are the same as before).

Prop. (5.3.5.5). Let X be a locally compact space of finite compact dimension, when S is a soft sheaf, and one of S and $\mathcal{F}$ is flat, then $S \otimes_k \mathcal{F}$ is soft. Cf.[Cohomology of Sheaves Iversen P319].

Prop. (5.3.5.6). Over a locally compact space of finite dimension, any flat sheaf $\mathcal{F}$ on X has a resolution of soft flat sheaves.

Proof: Cf.[Gelfand P232]. □

Lemma (5.3.5.7). A constant sheaf on an irreducible topological space is flabby, thus flask.

Basics

Prop. (5.3.5.8). If $i : Z \to X \in \mathcal{T}\mathrm{op}$ is a closed immersion, then for any $\mathcal{F} \in \mathcal{S}\mathrm{h}(Z)$, $H^*(Z, \mathcal{F}) = H^*(Z, i_*\mathcal{F})$.

Proof: This is because i_* is exact(5.2.6.7), so we can apply the Leray spectral sequence(5.3.1.9). □

Comparison Theorems

Prop. (5.3.5.9) [Singular]. For any locally contractible topological space X and $G \in \mathcal{A}b$, there are canonical isomorphisms

$$H^*_{\text{sing}}(X, G) \cong H^*(X, \underline{G}).$$

Proof: Shifification of the singular cochain complex is a flabby presheaf resolution of $\underline{G}$ because it is locally contractible, check on stalks. Then we only have to prove $C^\bullet(X) \to (C/V)^\bullet(X)$ is quasi-isomorphism, where V is the presheaf of locally vanishing cochain. It suffice to prove $V^\bullet(X)$ is exact.

For any i-cocycle φ, for any $i-1$-complex σ, use barycentric subdivision, we can construct a c_σ whose boundary is σ and other simplexes on which ϕ vanishes, so we have the coboundary of $\eta : \sigma \to \varphi(c_\sigma)$ is φ. □

Lemma (5.3.5.10) [Poincaré]. For a smooth manifold X of dimension n, there is an exact sequence

$$0 \to \underline{\mathbb{R}}_X \xrightarrow{\mathrm{d}} \Omega^0 \xrightarrow{\mathrm{d}} \Omega^1 \xrightarrow{\mathrm{d}} \ldots \xrightarrow{\mathrm{d}} \Omega^n \to 0$$

Proof: □

Prop. (5.3.5.11) [DeRham]. For any smooth manifold X,

$$H^*_{\text{dR}}(X, \underline{\mathbb{R}}_X) \cong H^*(X, \underline{\mathbb{R}})$$

Where the right is constant sheaf cohomology.

Proof: Use the fact that smooth sheaf is fine so adapted to sheaf cohomology(5.3.5.4), and Poincaré lemma(5.3.5.10). □

Prop. (5.3.5.12) [Period Maps]. For a smooth manifold X, by a similar method as(5.3.5.9), we can define a **differentiable singular cohomology** $H^*_{\text{sing},\infty}(X)$, and prove a canonical isomorphism

$$H^*_{\text{sing},\infty}(X, \mathbb{R}) \cong H^*(X, \overline{\mathbb{R}}).$$

Then combining with(5.3.5.11), we get a canonical isomorphism

$$H^*_{\text{dR}}(X, \underline{\mathbb{R}}_X) \cong H^*_{\text{sing},\infty}(X, \mathbb{R})$$

which can be described as follows: there is a map of sheaves

$$\Omega^k \to C^\bullet_{\text{sing},\infty}(X)$$

that is locally defined to be $\omega \mapsto \sigma \mapsto \int_\sigma \omega$, then this map gives a map of complexes

$$\Omega^\bullet \to C^\bullet_{\text{sing},\infty}(X)$$

that induces the isomorphism.

Proof: ? Cf.[Warner, P206]. □

Prop. (5.3.5.13) [Čech and Sheaf Cohomology]. For a paracompact Hausdorff space X, there are isomorphisms

$$\check{H}^i(X, \mathbb{Z}) \cong H^i(X, \mathbb{Z}).$$

Proof: Cf.[Godement, Prop5.10.1].? □

Cohomology with Proper Support

References are [Cohomology of Sheaves Iversen].

Prop. (5.3.5.14). Soft sheaf is adapted to $f_!$ when X, Y are locally compact. Cf.[Gelfand P226]. So we can use soft resolution to define $R^i f_!$, in particular, when $Y = \mathrm{pt}$, we denote it by $H^i_c(X, \mathcal{F})$. Using(5.2.6.2), we get the stalk of $R^i f_!(\mathcal{F})$ at y is just $H^i_c(f^{-1}(y), \mathcal{F}|_{f^{-1}(y)})$.

Def. (5.3.5.15). The **compact dimension** of a locally compact topological space is the smallest n that $H^i_c(X, \mathcal{F}) = 0$ for $i > n$. It is also the maximal length of minimal soft resolution.

$\dim_c \mathbb{R}^n = n$, and when Y is an open or closed subset of X, $\dim_c Y \le \dim_c X$. $\dim_c$ is local in the sense if every point has a nbhd of dimension$\le n$, then $\dim_c X \le n$. Cf.[Iversen].

Prop. (5.3.5.16) [Proper Pushforward Commutes with Pullback]. For a pullback diagram

$$\begin{array}{ccc} X \times_Y Z & \xrightarrow{\tau'} & X \\ \downarrow{\scriptstyle \pi'} & & \downarrow{\scriptstyle \pi} \\ Z & \xrightarrow{\tau} & Y \end{array}$$

we have $\tau^{-1}(\pi_! \mathcal{F}) = \pi'_!(\tau')^{-1}\mathcal{F}$.

Proof: □

Cohomology on Noetherian Spaces

There are three basic objects, the derived functor for f_* as an Abelian sheaf, f_* as a $\mathcal{O}_X$-module, $\Gamma(U, -)$ as an Abelian sheaf. Notice that an Abelian group is just a $\mathbb{Z}$-module.

Prop. (5.3.5.17) [Grothendieck Vanishing]. The sheaf cohomology of an Abelian sheaf over a Noetherian topological space of dimension n vanish for $k > n$.

Proof: Use(5.2.6.10) and(5.3.5.8) and long exact sequence, we can reduce to the case of X irreducible. Then we induct on dimension. Notice first any sheaf is a filtered colimits of sheaf generated by f.m sections, thus we can use(5.3.1.14) to reduce to f.m sections case. And notice $\mathcal{F}_{\alpha'} \to \mathcal{F}_\alpha \to \mathcal{G}$, then G Is generated by at most $|\alpha| - |\alpha'|$ elements, so reduce to the one section case.

Now it is a quotient sheaf of $\mathbb{Z}$, look at the kernel R. If the kernel is $d\mathbb{Z}$ at the generic pt, then $R|_V \cong \mathbb{Z}$ on some nbhd, and $R|_V/\mathbb{Z}$ supports on a lower dimension set, then we only need to consider the pushout of constant sheaf $\mathbb{Z}_U$.

Now there is an exact sequence $0 \to \mathbb{Z}_U \to \mathbb{Z} \to \mathbb{Z}_Y \to 0$(5.2.6.10), $\mathbb{Z}$ is flabby(5.3.5.7) so flask, and the conclusion follows by induction.

Cf.[Sta]02UU.? □

Prop. (5.3.5.18). For $f : X \to Y$, if $\mathcal{I}$ is an injective module on X, then $\check{H}^p(\{U_i \to U\}, f_*\mathcal{I}) = 0$ for every open cover for an open subset U(5.3.4.8). This is because Čech cohomology is a derived functor. (Notice $f_*\mathcal{I}$ may not be injective when f is not flat).

Cor. (5.3.5.19) [Mayer-Vietoris]. For $X = U \cup V$, there is a long exact sequence

$$0 \to H^0(X, \mathcal{F}) \to H^0(U, \mathcal{F}) \otimes H^0(V, \mathcal{F}) \to H^0(U \cap V, \mathcal{F}) \to H^1(X, \mathcal{F}) \to \cdots$$

derived from the Čech to sheaf1 because it has only two column, just wrap out the definition.

5.4 Properties of Schemes

Main References are [Har77], [Sta], [?]nd [Tin20].

1 Basic Scheme Properties

Affine Local Properties of Schemes

Lemma (5.4.1.1) [Nike's Trick]. In a scheme X and $x \subset \operatorname{Spec} A \cap \operatorname{Spec} B$, x has an open nbhd in $\operatorname{Spec} A \cap \operatorname{Spec} B$ that are distinguished in both $\operatorname{Spec} A$ and $\operatorname{Spec} B$.

Proof: Choose a nbhd of x that is distinguished in $\operatorname{Spec} A$ that is contained in $\operatorname{Spec} \cap \operatorname{Spec} B$, then because distinguished of distinguished is distinguished, we may assume $i : \operatorname{Spec} A \subset \operatorname{Spec} B$. Now let $f \in B$ be an element that $D(f) \subset \operatorname{Spec} A$, then I claim $D(i^\sharp(f)) = D(f)$, this will finish the proof, but this is equivalent to $i^{-1}(\operatorname{Spec} B_f) = \operatorname{Spec} A_{i^\sharp(f)}$, which is true for ideal-theoretical reason. □

Prop. (5.4.1.2) [Affine Communication Theorem]. A property P of affine open subsets is called **affine local** if: $\operatorname{Spec}(A)$ has $P \Rightarrow$ all $\operatorname{Spec}(A_f)$ has P, and any cover of $\operatorname{Spec}(A_{f_i})$ has $P \Rightarrow \operatorname{Spec}(A)$ has P. Notice a stalk-wise property is obviously affine-local.

Now if we call X has $\widetilde{P}$ if $X = \bigcup_i \operatorname{Spec} A_i$ that A_i has P. Then the following is equivalent:

- any open affine subscheme of X has P.
- any open subscheme of X has $\widetilde{P}$.
- X has a cover of open subschemes that has $\widetilde{P}$.
- X has $\widetilde{P}$.

Proof: $1 \to 2 \to 3 \to 4$ is obvious. It suffices to prove $4 \to 1$: if $X = \cup \operatorname{Spec} A$, for any open affine subscheme of X, by(5.4.1.1), it can be covered by distinguished opens that are also distinguished in some $\operatorname{Spec} A_i$, so by hypothesis it has P. □

Remark (5.4.1.3). When proving locality of morphism properties using affine communication theorem, one usually resort to Local Properties.

Prop. (5.4.1.4) [List of Stalkwise Properties]. All properties defined by a stalkwise ring-theoretic property that is stalkwise.(4.1.4.2)

Prop. (5.4.1.5) [List of properties affine local on the target]. (All the property besides the H-projectiveness is local on the target).

1. Because affineness is local on the target(5.1.5.26), all properties defined by a ring-theoretic property local on the target is local on the target(4.1.4.4).
2. All properties that is stalkwise.
3. All properties that satisfies faithfully flat descent.(5.1.5.26)
4. Locally projective morphism.

Prop. (5.4.1.6) [List of properties affine local on the source]. (not complete)

1. All properties defined to be local ring map property local on the source.(4.1.4.4)
2. Openness.

Proof:

1. Trivial.
2. Trivial.

□

Irreducible

Def. (5.4.1.7) [Irreducible Schemes]. A scheme is called **irreducible** iff its underlying topological space is irreducible.

Prop. (5.4.1.8) [Nearly Affine Local]. For a scheme, the following are equivalent:

1. It is irreducible.
2. There is an affine cover U_i of X that U_i are all irreducible and $U_i \cap U_j \neq \varnothing$.
3. Every affine open subset of X is irreducible.

Proof: A scheme is sober(5.2.7.11), if X is irreducible, then X has a unique generic pt η that $\overline{\{\eta\}} = X$, then $2, 3$ all holds. If 2 holds, then for a decomposition $X = Z_1 \cup Z_2$, any U_i belongs to Z_1 or Z_2, so it is easy to see $Z_1 = X$ or $Z_2 = X$. If 3 holds, then choose an affine cover U_i of X, then $U_i \cap U_j \neq 0$, otherwise $U_i \coprod U_j$ is affine and not irreducible, contradiction, so 2 holds. □

Cor. (5.4.1.9). The fiber product of irreducible schemes is irreducible, because .

Reducedness

Def. (5.4.1.10) [Reduced Schemes]. A scheme is called **reduced** if $\mathcal{O}_X(U)$ is reduced for every open set U. Reduced is a stalk-wise property(5.4.1.5), it suffices to check reducedness at closed pts.

Prop. (5.4.1.11). For a reduced scheme X, $\Gamma(X, \mathcal{O}_X) \to \prod_{x\in X} k(x)$ is injective.

Prop. (5.4.1.12). If X is locally Noetherian, the set of points with reduced stalk is open in X.

Proof: This set is just the set of points x that $\mathcal{N}_x = 0$, where $\mathcal{N}$ is the sheaf of nilradicals, which is coherent, so it has closed supports(5.5.1.38). □

Prop. (5.4.1.13) [Reduction]. There is a $X_{\text{red}} \to X$ associated tot every scheme, it is $\mathbf{Spec}(\mathcal{O}_X/\mathcal{N})$ where $\mathcal{N}$ is the sheaf of nilpotent elements. This construction is right adjoint to the forgetful functor by the adjoint property of **Spec**(5.2.7.12). $X_{\text{red}} \to X$ is an closed immersion.

It's useful to change to X_{red} when the proposition only involve topology because X_{red} has the same topology as X. A map can induce a map on their reduced structure.

Prop. (5.4.1.14) [Induced Reduced Scheme Structure]. Let Z be a locally closed subset of a scheme X, There is a unique reduced subscheme Z_{red} of X with underlying topological space Z, called the **induced reduced scheme structure** of Z. It has the universal property that any morphism from a reduced scheme Y to X that has image in Z factors through this subscheme(By virtue of reducedness).

In particular, there is a closed subscheme structure X_{red} of X, called the **underlying reduced subscheme** of X.

Proof: The uniqueness is clear by the universal property. The existence is clear when X is affine and Z is closed in X. Then we can use the uniqueness to glue them to a global subscheme structure.
□

Integral

Def. (5.4.1.15) [Integral Schemes]. A scheme X is called **integral** if $\mathcal{O}_X(U)$ are all integral. This is equivalent to reduced and irreducible. So a scheme is integral iff there is an integral open affine cover that are pairwise-intersect(5.4.1.7).

The category of integral schemes is denoted by $\mathcal{S}\mathrm{ch}^{\mathrm{int}}$.

Proof: If X is irreducible and reduced, then so does any affine subscheme $\operatorname{Spec} R$, so R is integral as (0) is the generic prime, because it has only one minimal prime consisting of nilpotent elements. Conversely, if X is reduced, then any affine subscheme $\operatorname{Spec} R$ is integral so reduced, and is irreducible by the presence of prime (0). □

Cor. (5.4.1.16). The projective space over an integral scheme is integral. (Check the affine covers are dense). The projective space $P^n_{\mathbb{Z}}$ is integral.

Prop. (5.4.1.17)[Integral is Almost Stalkwise]. Let X be a non-empty and connected scheme, then X is integral iff all the

Def. (5.4.1.18)[Function Field]. Let X be an integral scheme with generic point η, then $R(X) \cong \mathcal{O}_{X,\eta}$ is a field(5.2.8.2), called the **function field of** X, denoted by $K(A)$. Then any rational function on X is defined on an open dense subset of X.

Prop. (5.4.1.19). If X is an integral scheme and Z_1, Z_2 are closed subschemes of X with generic points η_1, η_2, then $\mathcal{O}_{X,\eta_1} \not\subseteq \mathcal{O}_{X,\eta_2}$. In particular, if $Z = \{x\}$ consists of a closed point, then there is a rational function defined near x that is not in $\mathcal{O}_{X,\eta_2}$.

Proof: [Sta]02NF. □

Noetherian

Def. (5.4.1.20) [Noetherian Scheme]. A scheme is called **locally Noetherian** if it can be covered by open affine schemes of noetherian rings. It is called **Noetherian** if moreover it is quasi-compact.

(Locally)Noetherian is affine local(5.4.1.5).

Prop. (5.4.1.21)[Noetherian Scheme is Noetherian]. The underlying space of a Noetherian scheme is a Noetherian space.

Proof: By(3.11.3.3), we are reduced to the affine case. Now it is clear from the definition. □

Prop. (5.4.1.22). Any locally closed subscheme of a (locally)Noetherian scheme is (locally)Noetherian. In particular, an subset of a Noetherian scheme is quasi-compact.

Proof: This is because any localization and quotients of a Noetherian ring is Noetherian(4.1.1.40), and any subset of a Noetherian space is quasi-compact(3.11.3.2)(5.4.1.21). □

Prop. (5.4.1.23) [Finitely Many Irreducible Components]. For a closed subscheme in a locally Noetherian space, the collection of its irreducible components is locally finite in X, because a Noetherian space has f.m. irreducible components(3.11.3.4).

In particular, a locally Noetherian space is locally connected.

Prop. (5.4.1.24). Let k'/k be a f.g. field extension, then a scheme X over k is locally Noetherian iff $X_{k'}$ is locally Noetherian.

Proof: Locally Noetherian is affine local, so the problem is totally ring-theoretic. If $X_{k'}$ is Noetherian, then so does X by ff descent(4.4.2.1). If X is Noetherian, then so does $X_{k'}$ by(4.1.1.44). □

Jacobson

Def. (5.4.1.25). An scheme is called **Jacobson** iff its underlying topological space is Jacobson(3.11.3.21). In particular, an affine scheme $\operatorname{Spec} R$ is Jacobson iff R is Jacobson(4.2.6.5).

So by(3.11.3.22), being Jacobson is a local property.

Prop. (5.4.1.26) [Locally Algebraic Scheme is Jacobson]. For a scheme locally algebraic over a field k, the set of closed points X_0 is dense in every closed subset of X, Because it is a Jacobson space by(3.11.3.22) and(4.2.6.10). Equivalently, every locally closed subset of X contains a closed point.

Moreover, the residue field of a closed point is finite over k by(4.2.6.10), and the converse is also true. In particular, by(5.2.7.9), the closed points of X are just the geometric points.

Proof: For the converse, because $k \subset A/\mathfrak{p}_x \subset k(x)$ are finite hence integral extensions, by(4.2.1.3) $A/\mathfrak{p}_x$ is a field, thus x is a closed point. □

Cor. (5.4.1.27) [Algebraic Scheme Preserves Closed Points]. A morphism between algebraic schemes over a field k maps closed points to closed points.

Remark (5.4.1.28). When X is geo.reduced, a stronger statement shows the set of separable closed points of X is dense in X, Cf.(5.4.3.3).

Cor. (5.4.1.29) [Check Surjectiveness on Closed Points]. If a morphism of locally algebraic schemes over a field k is surjective on closed points, then it is surjective.

Proof: By Chevalley theorem(5.6.1.5), the image is a locally constructible set, thus the supplement set is also locally constructible. Now if it is not surjective, then there is an open closed subset $U \cap Z$ not in the image. But this set contains a closed point by(5.4.1.26), which is a contradiction . □

Cohen-Macaulay

Def. (5.4.1.30) [Cohen-Macaulay Schemes]. A **Cohen-Macaulay scheme** of a C.M. scheme is a scheme $X \in \mathcal{S}\mathrm{ch}$ s.t. all its stalks is C.M. local. Thus being C.M. is a stalkwise property.

Catenary Schemes

Def. (5.4.1.31) [Catenary Schemes]. A **catenary scheme** is a scheme that its underlying space is catenary. A scheme S is called **universally catenary** iff S is locally Noetherian and every scheme locally of f.t. over S is catenary.

(Universally) catenary is a stalkwise property, by(4.1.4.2).

Prop. (5.4.1.32) [Catenary and Dimension Functions]. Let $X \in \mathcal{S}\mathrm{ch}$ be locally Noetherian, then X is catenary iff locally around every point there is a dimension function, by(3.11.3.39).

Example (5.4.1.33) [Universally Catenary Schemes]. The following are some examples of universally catenary schemes, by(4.2.4.7).

- A scheme locally of f.t. over a universally catenary scheme.
- A C.M. scheme.
- Spectrum of a 1-dimensional Noetherian domains,
- Spectrum of a fields.

Japanese & Nagata Schemes

Def. (5.4.1.34) [Japanese & Nagata Schemes]. A (universally) **Japanese scheme** is a scheme that can be covered by open affine spectrum of (universally) Japanese rings(4.3.8.1). A **Nagata scheme** is a scheme that can be covered by open affine spectrum of Nagata rings(4.3.8.1).

Prop. (5.4.1.35). Being (universally) Japanese or Nagata is a local property, and are stable under taking open subschemes, by(4.3.8.1).

Prop. (5.4.1.36). Let X be a locally Noetherian scheme, then X is Nagata iff every integral closed subscheme Z of X is Japanese.

Proof: One direction is clear. If every integral closed subscheme Z of X is Japanese, let $U = \operatorname{Spec} A \subset X$ be an affine open subscheme and $Z = V(\mathfrak{p}) \subset U$, we need to show $A/\mathfrak{p}$ is Japanese. Consider $\overline{Z}$ with the reduced induced structure is an integral closed subscheme of X and Z is an open subscheme of $\overline{Z}$, thus $\overline{Z}$ is Japanese and so is Z by(5.4.1.34). □

2 Normal & Regular

Def. (5.4.2.1) [Normal & Regular Schemes]. A scheme is called **normal** if all its stalks are normal domains(4.3.5.1), or equivalently all its affine sections are normal rings. In particular, a normal scheme is reduced.

A locally Noetherian scheme is called **regular** iff all its stalk are regular local rings(4.3.5.17), i.e. all affine opens are regular rings. Regular only have to be checked at close pt by(4.3.5.17).

Def. (5.4.2.2). Let X be a locally Noetherian scheme, the points x that $\mathcal{O}_{X,x}$ is a regular local ring is called the **regular locus** of X, and the complement of the regular locus is called the **singular locus** of X.

Prop. (5.4.2.3) [Noetherian and Integral]. Let X be a locally Noetherian scheme, then X is normal iff it is a disjoint union of integral normal schemes.

Proof: It suffices to show that a connected locally Noetherian scheme is integral. Thus it suffices to show it is irreducible. Suppose there are several irreducible components, and let p be a intersection point, then we may assume X is affine, then this follows from(4.3.5.4). □

Cor. (5.4.2.4). A normal scheme is integral iff it is connected.

Prop. (5.4.2.5). If X is an integral normal scheme, then $\Gamma(X, \mathcal{O}_X)$ is a normal ring.

Proof: If X is integral, then $R = \Gamma(X, \mathcal{O}_X)$ is integral. If $f = a/b \in K(R)$ that is integral over R, then for any affine open $U \subset X$, $b|_U$ is non-zero as X is integral, thus $f|_U$ is integral over $\mathcal{O}_X(U)$ thus $f|_U \in \mathcal{O}_X(U)$, thus $f \in R$. □

Prop. (5.4.2.6) [Normalization]. For an integral scheme X, there is a $X_{nom} \to X$ which is $\mathbf{Spec}(\mathcal{O}_{X,nom})$, any dominant morphism f from a normal integral scheme to X will factor through X_{nom}. (Use the adjointness for **Spec** and notice f maps generic to generic).

Proof:

□

Prop. (5.4.2.7) [Normalizations are Birational]. The normalization of an integral scheme X is a finite birational map.

Proof: ? □

Prop. (5.4.2.8) [Normalization is not flat]. Non-trivial normalization is never flat.

Proof: Use(5.6.2.6).? □

Prop. (5.4.2.9) [Regular and Normal]. Regular scheme is C.M and locally factorial, hence normal, by(4.3.5.21) and(4.3.5.19). A Normal scheme is regular in codimension 1, by(4.3.5.32).

Cor. (5.4.2.10). A regular connected scheme X is irreducible, by(5.4.2.4).

Prop. (5.4.2.11). For a locally Noetherian scheme of dimension≤ 1, normal is equivalent to regular, by(10.3.3.4).

Factorial Schemes

Def. (5.4.2.12) [Factorial Schemes]. A **factorial scheme** is a scheme that all the local rings are UFD.

Prop. (5.4.2.13). If A is a UFD, then $\operatorname{Spec} A$ is factorial.

Dedekind Scheme

Def. (5.4.2.14) [Dedekind Scheme]. A **Dedekind scheme** is an integral Noetherian normal scheme of dimension 1.

Prop. (5.4.2.15). Let X be a Dedekind scheme and $x \in X$ is a closed pt, let $\widehat{X} = \operatorname{Spec}(\widehat{\mathcal{O}}_{X,x}) \to X$ be the completion of X at x, then there is a pullback of categories:

$$\begin{array}{ccc} \mathrm{Bun}_X & \longrightarrow & \mathrm{Bun}_{X\setminus\{x\}} \\ \downarrow & & \downarrow \\ \mathrm{Bun}_{\widehat{X}} & \longrightarrow & \mathrm{Bun}_{\widehat{X}\setminus\{x\}} \end{array}$$

Proof: We may study locally near x, then we can assume that X is affine. Now shrink X even more, we can assume that x is defined by a single $f \in A$(localized at the maximal ideal defined by x), then we finish by(4.4.2.12). □

3 Geometrical properties

Def. (5.4.3.1) [Geometric Properties over Fields].

- A scheme X is called **geometrically integral/reduced/separated/irreducible**... over a field k iff for any field extension k'/k, $X_{k'}$ is integral/reduced/separated/....
- A locally Noetherian scheme is called **geometrically regular** iff for any f.g. field extension K/k, X_K is regular. It is stalkwise by(5.4.3.18).

Geo.reducedness

Prop. (5.4.3.2) [Geo.Reduced]. For a scheme X over a field k, the following are equivalent:

1. X is geometrically reduced.
2. For every reduced k-scheme Y, the product $X \otimes_k Y$ is reduced.
3. All stalks are geometrically reduced ring.
4. X is reduced and for every maximal point η of X, the residue field $k(\eta)$ is separable over k.
5. $X_{k^{per}}$ is reduced.
6. X_K is reduced for every finite purely inseparable field extension K/k.
7. $X_{k^{1/p}}$ is reduced.

In particular, if k has characteristic 0, then geo.reduced $\iff$ reduced.

Proof: As reduced is local, these all follows from(4.3.6.2). □

Prop. (5.4.3.3) [Geo.Reduced and Arithmetic Points]. Let X be a locally algebraic geo.reduced scheme over a field k, then the set of closed points with finite separable field extensions $k(x)/k$ is dense in X.

Proof: Combine(5.6.4.19) and(5.6.4.21). □

Def. (5.4.3.4) [Density of Points]. Let X be an algebraic scheme over a field k and k'/k be a field extension, then a subset $S \subset X(k')$ is said to be **schematically dense** in X if the only closed subscheme $Z \subset X$ over k that $S \subset Z(k')$ is X itself.

? Should merge with the definition of scheme-theoretical image.

Prop. (5.4.3.5) [Schematically Dense Subset]. Let X be an algebraic scheme over a field k, $S \subset X(k)$ be a subset. Then the following are equivalent:

1. S is schematically dense in X.
2. X is reduced and S is dense in $|X|$.
3. The family of homomorphisms $\mathcal{O}_X \to k : f \mapsto f(s)$ is jointly injective.

Proof: $1 \to 2$: Let $\overline{S}$ be the induced reduced structure of the closure S in X(5.4.1.14), then $\overline{S} = X$, so X is reduced with $X = \overline{S}$.

$2 \to 3$: ? Cf.[Milne Algebraic Groups, P10]. □

Cor. (5.4.3.6). A schematically dense subset remains schematically dense after field base changes.

Cor. (5.4.3.7). The schematic closure of a subset commutes with base change.

Proof: Use the third definition in(5.4.3.5), notice that the valuation maps are also jointly injective because k'/k is flat. □

Cor. (5.4.3.8). If X admits a schematically dense subset S, then X is geo.reduced.

Prop. (5.4.3.9). If $X(k')$ is dense in X, then X is reduced. Conversely, if $X(k')$ is dense in $|X_{k'}|$ and X is geo.reduced, then $X(k')$ is dense in X.

Proof: X is reduced because $X_{\mathrm{red}}(k') = X(k')$. Conversely if $Z \subset X$ is a closed subscheme that $Z(k') = X(k')$, then $|Z_{k'}| = |X_{k'}|$ by condition, and then $Z_{k'} = X_{k'}$ as $X_{k'}$ is reduced. Thus $Z = X$ by flatness. □

Cor. (5.4.3.10)[Geometric Points Schematically Dense]. If X is locally algebraic and geo.reduced, then $X(k')$ is schematically dense in X for any separably closed field k' containing k.

Proof: $X(k')$ is dense in $|X_{k'}|$ by(5.4.3.3), thus it is schematically dense in X by the proposition. □

Cor. (5.4.3.11). If Z, Z' are closed subvarieties of a locally algebraic algebraic scheme X over k that $Z(k') = Z'(k') \subset X(k')$ for some separably closed field k' containing k, then $Z = Z'$. In other words, a closed subvariety of X is determined by the subset $Z(k^s) \subset X(k^s)$.

Proof: The closed subscheme $Z \cap Z'$ satisfies $Z \cap Z'(k') = Z(k')$, so $Z \cap Z' = Z$ by(5.4.3.10). Similarly $Z \cap Z' = Z'$. □

Geo.Connected and Geo.Irreducible

Prop. (5.4.3.12) [Geo.Connectedness]. For a scheme X over a field k, the following are equivalent:

- For every connected k-scheme Y, the product $X \otimes_k Y$ is connected.
- X is geometrically connected.
- X_{K^s} is connected.
- X_K is connected for any finite separable extension K/k.

Proof: Cf. [Sta]0385, 0389.? □

Prop. (5.4.3.13) [Invariance of Base Change]. Let X be a scheme over a field k and k'/k a field extension, then X is geo.connected iff $X_{k'}$ is geo.connected.

Proof: Cf.[Sta]054N. □

Prop. (5.4.3.14). Let $T \to X$ be a map of schemes over a field k, if T is geo.connected and X is connected, then X is geo.connected.

Proof: Cf.[Sta]056R. □

Cor. (5.4.3.15) [Connected with a Rational Point]. Let X be a scheme over a field k. Assume X is connected and has a point x that k is alg.closed in $k(x)$, then X is geo.connected. In particular, if X is connected and has a rational point, then X is geo.connected.

Proof: Cf.[Sta]04KV. □

Prop. (5.4.3.16) [Geometrically Irreducible]. For a scheme X over a field k, the following are equivalent:

- For every irreducible k-scheme Y, the product $X \otimes_k Y$ is irreducible.
- X is geometrically irreducible.
- X_{k^s} is irreducible.
- X is irreducible and if η is the generic pt of X, then k is separably closed in $k(\eta)$.
- X_K is irreducible for any finite separable extension K/k.

Proof: Cf.[Gortz P136].? □

Geo.Integral

Cor. (5.4.3.17) [geometrically Integral]. For a scheme X over a field k, the following are equivalent:

- For every integral k-scheme Y, the product $X \otimes_k Y$ is integral.
- X is geometrically integral.
- X_K is irreducible for any finite extension K/k.
- $X_{\overline{k}}$ is integral.
- X is integral and if η is the generic pt of X, then k is alg.closed in $k(\eta)$ and $k(\eta)/k$ is separable.

Proof: $1 \to 2 \to 3 \to 4$ is easy, Cf.[Gortz P136].**?** □

Geometrically Regular

Prop. (5.4.3.18). Let X be a locally Noetherian scheme over a field k, then X is geometrically regular iff the local ring $\mathcal{O}_{X,x}$ is geometrically regular over k. Thus it suffice to check for finite purely inseparable field extensions k'/k, by(4.3.6.6).

Proof: For a finite purely inseparable field extension, $\mathcal{O}_{X,x} \otimes_k k'$ is also a local ring because their spectra are the same(4.1.7.26), so $\mathcal{O}_{X,x}$ is geometrically regular by(4.3.6.6).

Conversely, if $\mathcal{O}_{X,x}$ is geo.regular, then for any field extension k'/k, stalks of $X_{k'}$ are localization of $\mathcal{O}_{X,x} \otimes_k k'$, so it is regular by(4.3.5.17). □

Cor. (5.4.3.19). A geometrically regular ring is geometrically reduced, by(4.3.5.19) and(5.4.3.2).

Prop. (5.4.3.20) [Partially Invariance Under Base Change]. If k'/k is a f.g. field extension, then $X_{k'}$ is geo.regular over k' iff X_k is geo.regular over k.

In fact, this is true for any field extension k'/k if X is locally algebraic over k, because in this case geo.regular is equivalent to smoothness.

Proof: One direction is trivial, for the other, Cf.[Sta]038W**?**. □

4 Basic Morphism Properties

Main references are [Sta]02WE.

Base Change Trick

Prop. (5.4.4.1) [Base Change Trick]. If a property P of morphisms satisfy:

- Closed immersion has P.
- Stable under base change and composition.

Then

- it is stable under product.
- $g \circ f : X \to Y \to Z$ has P and g separated implies f has P.
- it is stable under f_{red}. (Notice $X_{\text{red}} \to X$ is closed immersion).

Proof: For the product, we may assume one of them is identity and use composition, but then the product is just base change, so it has P.

For the second, factorize $f : X \to X \times_Z Y \to Y$, the first is base change of $\Delta : Y \to Y \times_Z Y$, so it satisfies P because g is separable, and the second map is a base change of $X \to Z$, so it satisfies P, so f satisfies P.

$X_{\text{red}} \to X \to Y = X_{\text{red}} \to Y_{\text{red}} \to Y$ has P because $X_{\text{red}} \to X$ is closed immersion, and $Y_{\text{red}} \to Y$ is separable because closed immersion is separable(checked directly), so by what has been proved, $X_{\text{red}} \to Y_{\text{red}}$ has P. □

Prop. (5.4.4.2). Lists of properties satisfying the base change trick(5.4.4.1)(not complete):

1. Universal closed/universal injective morphisms.
2. Affineness.
3. Morphisms (locally)of finite type.
4. Finite Morphisms.
5. Integral Morphisms.
6. Morphisms (locally)of finite presentation.
7. Quasi-affine morphisms.
8. Closed Immersions.
9. Quasi-compactness.
10. (Quasi-)Separatedness.
11. Proper.
12. Unramified.
13. Monomorphisms.
14. (Locally) Quasi-finiteness.
15. H-projectiveness.

Proof:

1. Trivial.
2. Because affineness is local on the target(5.4.1.5), this follows from(5.2.7.17) and(5.2.7.14).
3. Trivial.
4. Trivial.
5.
6. By(4.3.7.9).
7. Affine morphism is quasi-compact: because quasi-compactness is local on the target, we can reduced to the affine case, thus it is quasi-compact, by(5.4.4.26). To show a base change of quasi-compact morphism is quasi-compact, because quasi-compactness is local on the target(5.4.1.5), then we can choose a cover by affine opens that the image is contained in an affine open, thus it reduces to show a map between affine schemes is quasi-compact, which is(5.4.4.26).
8. For closed immersions, use(5.2.7.16) and check locally, for open immersions, use(5.2.7.16).

9. It suffices to show an affine map is quasi-compact.
10. Closed immersion is separated is checked directly. Composition: For $X \to Y \to Z$, the diagonal map decomposes as $X \to X \times_Y X \to X \times_Z X$, the second one is closed immersion(or quasi-compact) by(5.4.4.78), so this follows from that of closed immersion and qc. Base change: The diagonal commutes with base change(3.1.1.48), so this follows from that of closed immersion and qc.
11. Because universally closed, f.t. and separatedness both do(5.4.4.2).
12.
13.
14.

□

Injectivity and Monomorphisms

Def. (5.4.4.3) [Injectivity and Monomorphisms]. A morphism of schemes is called **injective** if it is injective topologically. A morphism of schemes is called a monomorphism if it is a monomorphism in the category of schemes.

Prop. (5.4.4.4) [Universally Injective]. For a morphism of schemes $X \to S$, the following are equivalent:

- It is universally injective.
- It is injective and the residue field extension are all purely inseparable.
- The diagonal map is surjective.
- For any field K, $\mathrm{Hom}(\mathrm{Spec}\, K, X) \to \mathrm{Hom}(\mathrm{Spec}\, K, S)$ is injective.

In particular, any monomorphism is universally injective.

Proof: $1 \to 4$: For $s \in \mathrm{Hom}(\mathrm{Spec}\, K, S)$, a $x \in \mathrm{Hom}(\mathrm{Spec}\, K, X)$ mapping to s is a section of the injective map $X \times_S \mathrm{Spec}\, K \to \mathrm{Spec}\, K$, which is unique if it exists.

$4 \to 1$: If $S' \to S$ is a morphism, $X' = X \times_S S'$, and $x, x' \in X'$ map to the same point $s' \in S'$, then we can choose a common field extension $K/k(s')$ of $k(x)/k(s)$ and $k(x')/k(s)$. Then we get two elements in $\mathrm{Hom}(\mathrm{Spec}\, K, X')$, and the hypothesis says they map to the same element in $\mathrm{Hom}(\mathrm{Spec}\, K, X)$. Thus they are the same, as X' is the fiber product.

$1 \to 2$: It the residue field extension is not purely inseparable, then tensoring with this field extension, we get two points mapping to the same, contradiction.

$2 \to 4$: It the residue field extension is purely inseparable, then $k(x) \to K$ is determined by the composition, $k(s) \to k(x) \to K$, which means 4 is true.

$1 \to 3$: If $X \to S$ is universally injective, then $X \times_S X \to X$ is injective, and $\Delta_{X/S}$ is a section of this map, thus it must be surjective.

$3 \to 1$: If $\Delta_{X/S}$ is surjective, then for any base change $S' \to S$, $\Delta_{X'/S'}$ is surjective, thus $X' \to S'$ is injective, thus 1 holds. □

Prop. (5.4.4.5)[Monomorphism and Injectivity]. A morphism of schemes $j : X \to Y$ is a monomorphism if j is an injective map and for any $x \in X$, $\mathcal{O}_{Y,f(x)} \to \mathcal{O}_{X,x}$ is surjective.

Proof: First check topologically, then check the local ring map. □

Cor. (5.4.4.6). For any scheme X and a point x, $\mathrm{Spec}\, \mathcal{O}_{X,x} \to X$ is a monomorphism.

Closed Map

Prop. (5.4.4.7) [Universal Closed]. Universal closedness is local on the basis and satisfies the base change trick(5.4.4.2).

Prop. (5.4.4.8). If g is surjective, then $f \circ g$ is universally closed iff f is universally closed (because surjective is S.u.B).

Prop. (5.4.4.9)[Closed Map and Specialization]. The image of a quasi-compact morphism is closed iff it is stable under specialization. And it is a closed map iff specializations lift along f.

Proof: For the first, the question is local, so reduce to Y affine, and then X is qc$= \cup U_i$, then we can replace X by an affine $\coprod U_i$, then reduce to the affine case(4.1.7.14).

For the second, for any closed subset of X with its induced reduced structure, the restriction to it is still qc and specialization lifts, so we prove the image is closed. Now the image is stable under specialization, so the result follows from the first assertion. □

Affine Map

Prop. (5.4.4.10). X is affine if there is a finite set of elements $f_i \in \Gamma(X, \mathcal{O}_X)$ that generate the unit ideal and X_{f_i} is affine.

Proof: First prove that $X_{f_i} \cap X_{f_j} = X_{f_i f_j}$ is affine because affine intersect X_{f_i} is affine. Second, prove $\Gamma(X_f, \mathcal{O}_X) = \Gamma(X, \mathcal{O}_X)_f$, finally glue them to get a map $X \to \mathrm{Spec}(A)$ and use the fact isomorphism is local on the target(5.4.1.5). X is affine scheme if $X \to \mathrm{Spec}(\Gamma(X))$ is affine. □

Cor. (5.4.4.11). Affineness is affine local on the target, and it satisfies the base change trick(5.4.4.2).

Lemma (5.4.4.12) [Serre Criterion of Affineness].

- A qc scheme X is isomorphic to an affine scheme iff $H^1(X, \mathcal{I}) = 0$ for every Qco sheaf of ideals $\mathcal{I}$.
- If X is qcqs, then it suffices to show $H^1(X, \mathcal{I}) = 0$ for every Qco sheaf of ideals $\mathcal{I}$ of f.t..
- If $f : X \to Y$ is a quasi-compact morphism between quasi-separated schemes, then f is affine iff for any Qco sheaf of ideals $\mathcal{I}$ on X, $R^1 f_* \mathcal{I} = 0$.

Proof: **?** Cf.[Sta]01XF.

The case of affine scheme is proven by(5.7.1.1) and(5.7.1.2). The converse: For every point p, choose an open affine nbhd U, let $Y = X - U$, by the exact sequence

$$0 \to \mathcal{I}_{Y \cup \{p\}} \to \mathcal{I}_Y \to k(P) \to 0,$$

we have a surjective map $\Gamma(X, \mathcal{I}_Y) \to \Gamma(X, k(P))$ thus there is a $f \in A = \Gamma(X, \mathcal{O}_X)$ that $P \in X_f \subset U$ is affine. So using(5.4.4.10), we only have to show that for f.m f_i, they generate $\Gamma(X, \mathcal{O}_X)$. This is by considering the kernel F of $\mathcal{O}_X^r \to \mathcal{O}_X : (a_1, \ldots, a_r) \to \sum f_i a_i$, and there is a filtration on F, the quotient of which are all coherent sheaves because kernel and cokernel are Qco, and there by induction and hypothesis, $H^1(X, F) = 0$, thus the result.

2: In the qcqs case, by(5.7.1.6), we can use filtered colimit to show that $H^1(X, \mathcal{I}) = 0$ for any Qco sheaf of ideals.

3: For any affine open U of Y, the inclusion $U \to Y$ is qc, thus $f^{-1}(U) \to X$ is also qc. Now any Qco sheaf of ideals $\mathcal{I}$ on U extends to a Qco sheaf of ideals on X by(5.5.1.8), then we can use Leray spectral sequence to conclude that $H^1(f^{-1}(U), \mathcal{I}) = 0$, so $f^{-1}(U)$ is affine. □

Cor. (5.4.4.13). For a Noetherian scheme X, X is affine iff X_{red} is affine.

Proof: The canonical exact sequence(5.2.6.10) reads: $0 \to \mathcal{N}\mathcal{F} \to \mathcal{F} \to i_* i^* \mathcal{F} \to 0$, so iff X_{red} is affine, then we have $H^i(\mathcal{F}) \cong H^i(\mathcal{N}\mathcal{F})$, and notice $\mathcal{N}^k = 0$ for some k. □

Cor. (5.4.4.14). For a Noetherian reduced scheme X, X is affine iff each irreducible component is affine. (The same as the above, notice that $\prod p_i = 0$, for the minimal primes of A). (The reducedness can be dropped by the last proposition).

Lemma (5.4.4.15). If a morphism $X \to Y$ is a homeomorphism onto a closed subset of Y, then f is affine.

Proof: Cf.[[Sta]04DE]. □

Quasi-affine

Def. (5.4.4.16) [Quasi-Affine Morphism]. A scheme is called **quasi-affine** iff it is isomorphic to a qc open subscheme of an affine scheme. A morphism is called **quasi-affine** iff the inverse of any affine scheme is quasi-affine.

Prop. (5.4.4.17). Quasi-affine is local on the target and satisfies the base change trick.

Proof: Cf.[Sta]01SN. □

Prop. (5.4.4.18). Any qc immersion i of a quasi-affine scheme is quasi-affine.

Proof: As i is qc, i factors through a map $Z \to U \to X$, where U is a quasi-compact open subset of X. Thus it suffices to consider the closed immersion case, which is clear. □

Prop. (5.4.4.19). A morphism $f : X \to S$ is quasi-affine iff $\mathcal{O}_X$ is f-ample. In particular, A scheme is quasi-affine iff $\mathcal{O}_X$ is ample.

Proof: Cf.[Sta]01QE. □

Cor. (5.4.4.20). Let X be a quasi-affine scheme and $H^p(X, \mathcal{O}_X) = 0$ for $p > 0$, then X is affine.

Proof: By(5.4.4.19) $\mathcal{O}_X$ is ample, then by(5.5.4.18), X is affine. □

Prop. (5.4.4.21) [Descent]. Let X be a scheme over a field k and K/k be a field extension, then X is quasi-affine iff X_K is quasi-affine.

Proof: Cf.[Sta]0BDD. □

Dominant

Prop. (5.4.4.22). Let $f : X \to S$ be a map of schemes.

- If every generic point of irreducible components of S is in the image of f, then f is dominant.
- If f is quasi-compact, then the converse is also true. More precisely, if a generic point η is not in the image, then it is not in the closure of the image.
- If X has only f.m. irreducible component, then the converse is also true.

Proof: Cf.[Sta]Chap28.8. □

Prop. (5.4.4.23) [Dominant Map between Integral Schemes]. If $f : X \to S$ is a map between integral schemes, then the following are equivalent:

- f is dominant.
- $f(\eta_X) = \eta_Y$.
- for some(all) affine open subset $U \subset X, V \subset Y$ with $f(U) \subset V$, the ring map $\mathcal{O}_Y(V) \to \mathcal{O}_X(U)$ is injective.
- for some(all) $x \in X$, the local ring map $\mathcal{O}_{Y,f(x)} \to \mathcal{O}_{X,x}$ is injective.

Proof: Cf.[Sta]0CC1. □

Def. (5.4.4.24) [Dominant Rational Maps]. A rational map between irreducible schemes is called a **dominant map** if it maps the generic point to the generic point.

Quasi-Compact

Prop. (5.4.4.25) [Quasi-Compact Morphism]. A morphism $f : X \to S$ of schemes is quasi-compact iff the inverse image of any quasi-compact open subsets is quasi-compact, because affine opens form a basis of X.

Quasi-compactness is local on the target and satisfies the base change trick(5.4.4.2).

Prop. (5.4.4.26). A map between affine schemes is quasi-compact.

Proof: Because quasi-compactness is local on the target(5.4.1.5), it suffices to show the inverse image of a distinguished open subset is quasi-compact, and this is true. □

Prop. (5.4.4.27). Let $f : X \to Y$, $g : Y \to Z$. If $g \circ f$ is quasi-compact and g is qs, then f is qc.

Proof: Factor it through $X \to X \times_Z Y \to Y$. The second map is a base change of $X \to Z$ hence qc, the first map is a section of $X \times_Z Y \to X$, which is a base change of $Y \to Z$, hence qs, so by(14.5.3.19), the first map is also qc. □

Prop. (5.4.4.28). Any map between Noetherian schemes is quasi-compact, by(5.4.1.22).

Finite Type

Def. (5.4.4.29) [Morphisms of Finite Type]. A morphism $f : X \to S$ is called of **locally of finite type** if for there exists an affine open cover $\{\mathrm{Spec}(B_i)\}$ of S that $f^{-1}(U_i)$ has an affine open cover of spec of finite generated B_i-algebras. It is called **finite type** if moreover it is quasi-compact.

Let $k \in \mathtt{Field}$, then $S \in \mathcal{S}\mathrm{ch}/k$ is called **(locally)algebraic** iff S is (locally)of finite type over $\mathrm{Spec}\, k$.

For $S \in \mathcal{S}\mathrm{ch}$, denote $\mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S(\mathcal{S}\mathrm{ch}^{\mathrm{ft}}/S)$ the full subcategory of $\mathcal{S}\mathrm{ch}/S$ consisting of (locally) of finite type schemes over S.

(Locally)Finite type is affine local on the target and on the source, and satisfies the base change trick(5.4.4.2).

Prop. (5.4.4.30) [Closed Subschemes Descending Chain Stablizes]. The closed subschemes of an algebraic scheme X over a field k satisfy the descending chain condition.

Proof: As X is Noetherian, the topological chain $|Z_1| \supset |Z_2| \supset \ldots$ stablizes, so we may assume $|X| = |Z_1| = |Z_2| = \ldots$. Now choose a finite affine cover $\mathrm{Spec}\, A_i$ of X, then Z_i corresponds to ideals I_i of A_i, so they stablizes, as A_i are Noetherian. □

Cor. (5.4.4.31). Arbitrary intersection of closed subschemes of an algebraic scheme X is well-defined.

Prop. (5.4.4.32) [Algebraic Schemes of Dimension 0]. Let X be a locally algebraic variety over a field k of dimension 0, then X is a disjoint union of f.d. local Artinian k-algebras.

Proof: Cf.[Sta]06LH.**?** □

Prop. (5.4.4.33) [Dimensions for Locally Algebraic k-Schemes]. Let k be a field and X is a locally algebraic k-scheme.

if X is irreducible, then $\dim X = \dim U$ for any nonempty open $U \subset X$.

Proof: It suffices to show any two affine open subsets U, U' of X have the same dimension, then use(3.11.3.26). Now $U \cap U' \neq \varnothing$ as X is irreducible, and then it contains a maximal pt x by Hilbert's Nullstellensatz, and then $\dim U = \dim(\mathcal{O}_{X,x}) = \dim U'$ because f.g. algebras over a field is catenary.
□

Integral & Finite Map

Def. (5.4.4.34) [Finite and Integral Map]. A morphism $f : X \to S$ is called **integral** if it is affine and there is a affine open covering $U_i = \operatorname{Spec} A_i$ of S that $f^{-1}(U_i) = \operatorname{Spec} B_i$ and $A_i \to B_i$ is integral.

Integral is affine local on the target and satisfies the base change trick(5.4.4.2).

A morphism $f : X \to S$ is called **finite** if it is affine and there is a affine open covering $U_i = \operatorname{Spec} A_i$ of S that $f^{-1}(U_i) = \operatorname{Spec} B_i$ and B_i are finite modules over A_i.

Finiteness is affine local on the target and satisfies the base change trick(5.4.4.2).

A morphism $f : X \to S$ is called **(locally) quasi-finite** if it is (locally)of f.t. and the inverse of a point is a discrete set.

Prop. (5.4.4.35) [Integral Morphism is Closed]. Specialization lifts along an integral morphism. In particular, an integral morphism is closed, by(5.4.4.9).

Proof: If $f(x) = y, y \to y'$, then we can choose an open affine U containing y', which also contains y. So we can choose an open affine containing x mapping into U, then it reduces to the affine case(4.1.7.13). □

Prop. (5.4.4.36) [Chevalley]. If $f : Y \to X$ is integral surjective, Y is affine, then X is affine.

Proof: Cf.[Sta]05YU. □

Lemma (5.4.4.37). If $f : Y \to X$ is finite surjective, Y is affine, then X is affine.

Proof:

□

Prop. (5.4.4.38) [Finite and Integral]. A morphism is finite iff it is integral of f.t..

Prop. (5.4.4.39) [Integral and Affine u.c.]. Integral map is equivalent to u.c. and affine.

Proof: Integral is stable under base change. And if it is integral, then it is closed by(4.2.1.5).

Conversely, we need to prove if $\operatorname{Spec} B \to \operatorname{Spec} A$ is u.c., then $A \to B$ is integral. For any $a \in B$, let J be the kernel of $A[X] \to B[X]/(aX-1)$, then if $f \in J$, then $f(X) = (aX-1)q(X)$, and $X^{deg(f)} f(\frac{1}{X}) = (a - X) X^{\deg(q)} q(\frac{1}{X})$ vanishes at a, so it suffices to find a $f \in J$ with constant term 1. It suffices to show that $\operatorname{Spec}(A[X]/J + (x))$ is empty:

As f is universally closed, $\operatorname{Spec} B[X] \to \operatorname{Spec} A[X]$ is closed, thus the image of $\operatorname{Spec}(B[X]/(aX-1))$ is closed in $\operatorname{Spec} A$, which is the underlying set of $\operatorname{Spec} A/J$, by(5.4.4.64). Now notice $T = \operatorname{Spec}(A[X]/J+(x)) \times_{\operatorname{Spec}(A[X]/J)} \operatorname{Spec}(B[X]/(aX-1))$ is empty, because $(A[X]/J+(x)) \otimes_{A[X]/J} (B[X]/(aX-1)) = \operatorname{Spec} A \otimes_{\operatorname{Spec} A[X]} \operatorname{Spec}(B[X]/(aX-1)) = 0$, as X is invertible in $B[X]/(aX-1)$ but vanish in A. But $T \to \operatorname{Spec}(A[X]/J+(x))$ is surjective, as a base change of $\operatorname{Spec}(B[X]/(aX-1)) \to \operatorname{Spec} A/J$, thus we are done. □

Def. (5.4.4.40)[Degree of Finite Morphisms at a Point]. Suppose $\pi : X \to Y$ is a finite morphism, then $\pi_* \mathcal{O}_X$ is a $\mathcal{O}_Y$-module of f.t.. Let $p \in Y$, then the **degree of** π **at** p is the rank of this sheaf on Y(5.5.1.11), which is an upper-semicontinuous function(5.5.1.41).

Prop. (5.4.4.41). The degree of a finite morphism $\pi : X \to Y$ at p is the dimension over $k(p)$ of the fiber of π at p. In particular, the degree is zero iff $\pi^{-1}(p) = 0$.

Proof: Look affine locally. □

Lemma (5.4.4.42). For $f : Y \to X$ finite surjective and X locally Noetherian, for every integral subscheme Z of X with generic point ξ, there is a coherent sheaf $\mathcal{F}$ on Y that the support of $f_*\mathcal{F}$ is Z and $(f_*Z)_\xi$ is annihilated by $\mathfrak{m}_\xi$.

Proof: W consider an inverse image of $\xi = \xi'$, and let $Z' = \overline{\{\xi'\}}$ with the induced reduced structure, then let $\mathcal{F} = i_* \mathcal{O}_{Z'}$ on Y, $\mathcal{F}$ is coherent, then we need to show that $(f_*\mathcal{F})_\xi$ is annihilated by m_ξ. This is because it factors through Z.**?** Cf.[Sta]01YO. □

Quasi-Finiteness

Def. (5.4.4.43) [Quasi-Finite Morphisms]. **?**

(Locally)Quasi-finite morphisms are local on the target and satisfies base change trick.

Prop. (5.4.4.44) [Characterization of Quasi-Finiteness]. Let $f : X \to S$ be a morphism, then the following are equivalent:

- f is quasi-finite.
- f is locally quasi-finite and quasi-compact.
- f is locally of f.t., quasi-finite and has finite fibres.

Proof: Cf.[Sta]01TJ, 02NH. □

Prop. (5.4.4.45). Immersions are locally quasi-finite.

Prop. (5.4.4.46). Let $f : X \to S$ be a morphism of schemes and $s \in S$. Assume that f is locally of f.t. and $f^{-1}(s)$ is a finite set, then X_s is a finite discrete topological space, and f is quasi-finite at every point of $f^{-1}(s)$.

Proof: Cf.[Sta]02NG. □

Prop. (5.4.4.47) [Zariski's Main Theorem]. Let $f : Y \to X$ be an affine morphism of f.t.. Let $Y \xrightarrow{f'} X' \xrightarrow{\nu} X$ where X' is the normalization of X in Y, then there exists an open subscheme $U' \subset X'$ that $(f')^{-1}(U) \to U$ is an isomorphism and $(f')^{-1}(U)$ is the set of points at which f is quasi-finite.

Proof: Cf.[Sta]03GT. □

Prop. (5.4.4.48) [Quasi-Finite Locus is Open]. Let $f : X \to S$ be a morphism of schemes, then the set of points of X that f is quasi-finite is an open subset $U \subset X$, and $U \to S$ is locally quasi-finite.

Proof: Cf.[Sta]01T1. □

Prop. (5.4.4.49) [Zariski's Main Theorem]. For a morphism $X \to S$ that is quasi-finite and separated, if S is qcqs, Then there is a factorization $X \to T \to S$ that $X \to T$ is a qc open immersion and $T \to S$ is finite.

Proof: Cf.[Sta]05K0. □

Prop. (5.4.4.50). If $f : Y \to X$ is a quasi-finite morphism of schemes, and $T \subset Y$ is nowhere dense, then $f(T) \subset X$ is also nowhere dense.

Proof: Cf.[Sta]03J2. □

Generically Finiteness

Def. (5.4.4.51) [Generically Finite Morphisms]. A **generically finite morphism** is a morphism $f : X \to Y$ locally of f.t. and there exists a dense open subset $U \subset X$ s.t. $U \to Y$ is locally quasi-finite.

Lemma (5.4.4.52). Let $R \to S$ be a ring map of f.t., if $\mathfrak{p} \subset R$ is a minimal prime that there are f.m. primes in S lying over $\mathfrak{p}$, then there is a $g \in R$, $g \notin \mathfrak{p}$ that $R_g \to S_g$ is finite.

Proof: The condition means $S_\mathfrak{p}/\mathfrak{p}S_\mathfrak{p}$ has only f.m. primes and $\mathfrak{p}S_\mathfrak{p}$ is locally nilpotent. Then $\kappa(\mathfrak{p}) \to S_\mathfrak{p}/\mathfrak{p}S_\mathfrak{p}$ if finite. Let x_i generate S over R, then there are polynomials $P_i \in R[X]$ that $P_i(x_i) = 0 \in S_\mathfrak{p}/\mathfrak{p}S_\mathfrak{p}$, and thus $P_i^{e_i}(x_i) = 0 \in S_\mathfrak{p}$. Now choose $g \notin \mathfrak{p}$ that g divides the common divisors of the coefficients of P_i and $P_i(x_i) = 0 \in S_g$, then $R_g \to S_g$ is finite. □

Prop. (5.4.4.53) [Generically Finiteness]. Let $f : X \to Y$ be a morphism of finite type. If $\eta \in Y$ is a generic point, then:

- $f^{-1}(\eta)$ is a finite set iff there are affine opens $U_i \subset X, i = 1, \ldots, n$ and $V \subset Y$ that $f(U_i) \subset V, \eta \in V$ and $f^{-1}(\eta) \subset \cup U_i$ and $U_i \to V$ are finite.
- If f is qs, then we can further restrict to $n = 1$.
- If f is qcqs, then we can further restrict to $U_1 = f^{-1}(V)$.

Proof: These are local on Y, so we can change Y to an affine open subscheme containing η.

1: If these affine opens exist, then $\#f^{-1}(\eta) < \infty$ because finite maps are quasi-finite(5.4.5.5).

If $f^{-1}(\eta) = \{\xi_1, \ldots, \xi_n\}$, choose affine opens U_i around each ξ_i, then we reduce to the affine case(5.4.4.52).

2: Cf.[Sta]02NW.

3: □

Prop. (5.4.4.54) [Extension of Fraction Fields]. Let $f : X \to Y$ be a dominant morphism locally of f.t. between integral schemes, then the following are equivalent:

- tr.deg $K(X)/K(Y) = 0$.
- $K(X)/K(Y)$ is finite.

- there exists non-empty affine opens $U \subset X, V \subset Y$ s.t. $f(U) \subset V$ and $U \to V$ is finite.
- the generic point of X is the only point mapping to the generic point of Y.
- If f is qc or qs, we can assume $U = f^{-1}(V)$.

Proof: Cf.[Sta]02NX. □

Def. (5.4.4.55) [Degree Generically Finite Morphisms]. Let $f : X \to Y$ be a dominant morphism of f.t. between integral schemes, then by(5.4.4.23), f induces an injective map of function fields $K(Y) \to K(X)$, the degree of $[K(X) : K(Y)]$ is called the **degree of** f, denoted by $\deg(f)$. It is a positive integer or ∞.

When $\deg(f)$ is finite(i.e. the conditions of(5.4.4.54) hold), it is called a **separable/purely inseparable morphism** if the field extension $K(X)/K(Y)$ is separable/purely inseparable. And also we can define the separable, inseparable degree of f.

Immersions

Def. (5.4.4.56) [Immersions]. A **closed immersion** of schemes is a closed immersion of local ringed spaces(5.2.6.15). A **closed subscheme** of a scheme X is a closed sub-ringed space(5.2.6.15) that is also a scheme.

An **open immersion** of schemes is an open immersion of local ringed spaces(5.2.6.15). An **open subscheme** of a scheme X is an open subspace(5.2.6.15) that is also a scheme.

Open and closed immersions are affine local on the target(5.4.1.5).

An **immersion** is a morphism that is a closed immersion of an open immersion.

Lemma (5.4.4.57) [Closed Immersion for Schemes]. Let $f : Y \to X$ be a morphism of schemes that induces a homeomorphism of Y onto a closed subset of X, and $f^\sharp : \mathcal{O}_X \to f_*\mathcal{O}_Y$ is surjective, then it is a closed immersion(5.2.6.15).

Proof: It suffices to show that the kernel of $f^\sharp$ is Qco. For this, notice that f is quasi-compact, and it is a monomorphism by(5.4.4.5), in particular separated by(5.4.4.86). Then(5.5.1.6) shows $f_*\mathcal{O}_Y$ is Qco. Then the kernel is Qco by(5.5.1.3). □

Prop. (5.4.4.58) [Closed Subschemes of Affine Schemes]. The closed sub-ringed spaces of $X = \operatorname{Spec} A$ are all closed subschemes, and they corresponds to ideals $I \subset A$:

- If $I \subset A$ is an ideal, then the morphism $Z = \operatorname{Spec} A/I \to \operatorname{Spec} A$ is a homeomorphism of Z onto a closed subspace $V(I)$ of X, and also the stalk map at a point $\mathfrak{p} \subset Z$ is $R_\mathfrak{p} \to (R/I)_{\mathfrak{p}/I} = R_\mathfrak{p}/IR_\mathfrak{p}$, which is surjective. So this is a closed immersion by(5.4.4.57).
- By(5.2.6.17), for any closed subscheme Z of X with sheaf of ideals $\mathcal{I}$, Z is isomorphic to the closed subscheme of X defined by $\mathcal{I}$. Now $\mathcal{I}$ is locally generated by sections, so the quotient sheaf $\mathcal{O}_X/\mathcal{I}$ is a Qco sheaf, so it is of the form $\widetilde{S}$ for some A-module S, by(5.5.1.2). Then $\mathcal{I}$, as the kernel of $\mathcal{O}_X \to \widetilde{S}$, is also Qco(5.5.1.3), so it equals $\widetilde{I}$ for some ideal $I \subset A$. Thus $S = R/I$, and we are done.

Prop. (5.4.4.59) [Closed Subscheme of Schemes]. The closed sub-ringed spaces of a scheme X are all closed subschemes, and they corresponds to Qco $\mathcal{O}_X$-sheaves of ideals via the ideal sheaf(5.2.6.15):

Proof: Let $i : Y \to X$ be a closed immersion, for any $x \in X$, choose an open affine nbhd U of $x \in X$, then $i : i^{-1}(U) \to U$ is also a closed immersion, so it corresponds to $\operatorname{Spec} A/I \to \operatorname{Spec} A$ for some ideal I by(5.4.4.58). So Z is a scheme, and the ideal sheaf $\mathcal{I}$ is Qco. □

Prop. (5.4.4.60). Closed immersion satisfies the base change trick(5.4.4.2). Open immersion are stable under base change and composition. Immersions are stable under base change and composition.

Proof: For immersion, shrink the open subset. □

Remark (5.4.4.61). A open immersion followed by a closed immersion can be written as a closed immersion followed by an open immersion, but not reversely. The reverse happens if the immersion is quasi-compact or the source is reduced (use the reduced induced structure).

Def. (5.4.4.62) [Scheme-Theoretical Image]. For a morphism $f : X \to Y$, there is a closed scheme called **scheme-theoretic image** that is the smallest closed subscheme of Y that f factors through Z.

For an immersion of schemes, the scheme-theoretic image of the immersion is called the **scheme-theoretic closure**.

Proof: Consider the kernel of the structural map, and the kernel contains a maximal Qco sheaf of ideals $\mathcal{I}$ by(5.5.1.12). □

Prop. (5.4.4.63). If $\begin{array}{ccc} X_1 & \xrightarrow{f_1} & Y_1 \\ \downarrow & & \downarrow \\ X_2 & \xrightarrow{f_2} & Y_2 \end{array}$ be a commutative diagram of schemes and $Z_i \subset Y_i$ be the scheme-theoretic image of f_i, then it induces a commutative diagram $\begin{array}{ccccc} X_1 & \longrightarrow & Z_1 & \longrightarrow & Y_1 \\ \downarrow & & \downarrow & & \downarrow \\ X_2 & \longrightarrow & Z_2 & \longrightarrow & Y_2 \end{array}$.

Proof: It suffices to show Z_1 factors through the closed subscheme $Z_2 \times_{Y_2} Y_1$ of Y_1, which follows from the universal property of Z_1. □

Prop. (5.4.4.64). Let $f : X \to Y$ be a qc morphism of schemes and Z be the scheme-theoretical image, then

- the kernel $\mathcal{I} = \ker(\mathcal{O}_Y \to f_*\mathcal{O}_X)$ is Qco, thus Z is the closed subscheme determined by $\mathcal{I}$.
- For any open subscheme $U \subset Y$, the scheme-theoretical image of $f|_{f^{-1}(U)}$ is equal to $Z \cap U$.
- $f(X)$ is dense in Z.

Proof: 1: As being Qco is local, it suffices to show for Y affine. Then $X = \cup U_i$ is a finite union of affine schemes. Now take $X' = \coprod U_i$, then there are maps $X' \xrightarrow{f'} X \to Y$. Then $\mathcal{O}_X$ is a subsheaf of $f'_*\mathcal{O}_X$. So $\mathcal{I} = \ker(\mathcal{O}_Y \to f_*f'_*\mathcal{O}_{X'})$. Now $f \circ f'$ is qcqs, thus by(5.5.1.6), $f_*f'_*\mathcal{O}_{X'}$ is Qco, thus also $\mathcal{I}$ is Qco.

2 follows from 1 as the formation of $\mathcal{I}$ commutes with restriction to open subschemes.

3 follows from 2 as the scheme-theoretical image of empty set is empty. □

Prop. (5.4.4.65). If $f : X \to Y$ is a morphism and X is reduced, then the scheme-theoretical image of f is the induced-reduced structure(5.4.1.14) of $\overline{f(X)} \subset Y$.

Proof: This is clear. □

Def. (5.4.4.66) [Scheme-Theoretically Dense]. An open subscheme $U \subset X$ is called **scheme-theoretically dense** if for any open subscheme V of X, the scheme-theoretical closure of $U \cap V$ in V is equal to V.

Prop. (5.4.4.67). If the inclusion $U \to X$ is qc, then U is scheme-theoretically dense in X iff the scheme-theoretical closure of U is X, by(5.4.4.64).

Prop. (5.4.4.68). Let $j : U \to X$ be an open immersion of schemes, then U is scheme-theoretically dense in X iff $\mathcal{O}_X \to j_*\mathcal{O}_U$ is injective.

Proof: If it is not injective, then we can find an open subscheme V of X that the kernel is non-zero, thus it contains a non-zero Qco ideal sheaf, which means the scheme-theoretical closure of $U \cap V$ is not V. □

Cor. (5.4.4.69). If U, V are open subschemes of X scheme-theoretically dense in X, then $U \cap V$ is also scheme-theoretically dense in X.

Proof: $\mathcal{O}_X \to \mathcal{O}_X(U) \to \mathcal{O}_X(U \cap V)$ is injective. □

Prop. (5.4.4.70) [Scheme-Theoretical Image of Immersions]. Let $f : Z \to X$ be an immersion and either f is qc or Z is reduced. Let $\overline{Z}$ be the scheme-theoretically image of f, then the morphism $Z \to \overline{Z}$ is an open immersion that identifies Z with a scheme-theoretical dense open subscheme of $\overline{Z}$, and also Z is dense in $\overline{Z}$.

Proof: Cf.[Sta]01RG. □

Prop. (5.4.4.71) [Immersion to be Closed]. An immersion f is a closed immersion iff the image is closed.

Proof: Let $i : Y \to U$ be a closed immersion where $j : U \subset X$ is an open subscheme, then i is associated to an ideal sheaf $\mathcal{I}$ of $\mathcal{O}_U$. Now because $\mathcal{I}|_{U \setminus f(Y)} = \mathcal{O}_{U \setminus f(Y)}$, we can glue $\mathcal{I}$ and $\mathcal{O}|_{X \setminus f(Y)}$ to a sheaf of ideals $\mathcal{J} \subset \mathcal{O}_X$. Now $j^* O_X/\mathcal{J} = \mathcal{O}_U/\mathcal{I} \cong i_*\mathcal{O}_Y$, thus $\mathcal{O}_X \to f_*\mathcal{O}_Y = j_*(\mathcal{O}_U/\mathcal{I}) = j_*j^*(\mathcal{O}_X/\mathcal{J})$ is surjective, because $\mathcal{O}_U/\mathcal{I}$ is supported on a closed subset of U. Thus f is a closed immersion by(5.4.4.57). □

Prop. (5.4.4.72) [Immersions are Monomorphisms]. An immersion is a monomorphism.

Proof: It is easy to check(5.4.4.5) for both open and closed immersions. □

Prop. (5.4.4.73) [Equivalent Definitions of Closed Immersion]. The following are equivalent for a morphism f:

- f is a closed immersion.
- f is a proper monomorphism.
- f is proper, unramified and u.i..
- f is a u.c., unramified monomorphism.
- f is u.c., unramified and u.i..
- f is u.c., locally of f.t. and a monomorphism.
- f is u.c., u.i., locally of f.t. and formally unramified.

Proof: $4 - 7$ are equivalent by(5.6.5.13). For the rest, Cf. [Sta], 04XV. □

Universal Homeomorphism

Prop. (5.4.4.74). A morphism is a universally homeomorphism iff it is integral, surjective and universally injective.

Proof: A universally homeomorphism is affine by(5.4.4.15). It is clearly u.c, so it is integral by(5.4.4.39). Conversely, it is integral hence u.c, and universally bijective, so it is universally homeomorphism. □

Cor. (5.4.4.75). The reduction $X_{\mathrm{red}} \to X$ is a universal homeomorphism, as closed immersion is u.c..

Separatedness

Def. (5.4.4.76) [Separatedness]. A map $f : X \to Y$ is called **separated** if the diagonal $\Delta : X \to X \times_Y X$ is a closed immersion. It is called **quasi-separated** if the diagonal is quasi-compact.

In fact Δ is always an immersion because maps between affine scheme is separated so $\Delta(X)$ is closed in $\cup U_{ij} \otimes_{V_i} U_{ij}$ where U, V are affine open, hence it suffice to check the image is closed.

Prop. (5.4.4.77). (Quasi-)Separateness is local on the target because closed immersion and quasi-compact is local on the target(5.4.1.5).

(Quasi-)Separatedness satisfies base change trick by(5.4.4.2).

Prop. (5.4.4.78) [Graph]. By(3.1.1.50), for $X \to S$ and $Y \to S$, the map $X = X \times_Y Y \to X \times_S Y$ is an immersion. It is closed immersion if $Y \to S$ is separated, and it is qc if $Y \to S$ is quasi-separated.

Cor. (5.4.4.79). for $X \to Y$ is a morphism of schemes over S, the map $X = X \times_Y Y \to X \times_S Y$ is an immersion. It is closed immersion if $Y \to S$ is separated, and it is qc if $Y \to S$ is quasi-separated.

Cor. (5.4.4.80). If $s : S \to X$ is a section of $f : X \to S$, the above proposition applies to this case, because $S = S \times_X X \to S \times_S X = X$.

Prop. (5.4.4.81) [Characterization of Separatedness]. A morphism is quasi-separated iff for any two affine open that mapped into an affine open, their intersection is quasi-compact. This is because quasi-compact is local on the target.

A morphism is separated iff for any two affine open that mapped into an affine open, their intersection is affine and $\mathcal{O}(U) \otimes_{\mathcal{O}(W)} \mathcal{O}(V) \to \mathcal{O}(U \cap V)$ is surjective. This is because closed immersion is local on the target(5.4.1.5).

Cor. (5.4.4.82). A locally Noetherian scheme is quasi-separated.

Cor. (5.4.4.83). If $g \circ f$ is (quasi-)separated, then so is f.

Cor. (5.4.4.84). If X is (quasi-)separated, then $X \to Y$ is (quasi-)separated.

Prop. (5.4.4.85) [Injective Maps are Separated]. Injective maps of schemes are separated.

Proof: Let $f : X \to Y$ be an injective map. Firstly $X \times_Y X$ is a union of affine subschemes of the form $U \times_V U$ where U, V are affine and $f(U) \subset V$: let $z \in X \times_Y X$, then $\pi_1(z) = \pi_2(z)$, because they map to the same point in Y, thus we can choose affine nbhds U, V of $\pi_1(z)$ and $f(\pi_1(z))$. Now for each of these $U \times_V U$, $\Delta : U \to U \times_V U$ is closed immersion, thus Δ_X is also closed immersion(5.4.1.5). □

Cor. (5.4.4.86). monomorphisms are separated because they are universal injective(5.4.4.4), and immersions are separated.

Prop. (5.4.4.87). (Quasi-)Affine morphism is separated (Check closed immersion directly).

Prop. (5.4.4.88). if $f : X \to S$ is affine, $h : Y \to S$ is separated, and $g : X \to Y$ is a morphism over S, then g is affine.

Proof: Decompose g as $X \to X \times_S Y \to Y$, where the first map is base change of Δ_Y and the second map is base change of f, so they are both affine. □

Prop. (5.4.4.89) [Scheme-Theoretic Equalizer]. If X, Y are schemes over S and $a, b : X \to S$ are morphisms, then there is a largest locally closed subscheme Z of X that $a|_Z = b|_Z$. And if Y/S is separated, Z is a closed subscheme of X.

Proof: By definition, Z should be the fibered product:

$$\begin{array}{ccc} Z & \longrightarrow & X \\ \downarrow & & \downarrow{\scriptstyle (a,b)} \\ Y & \xrightarrow{\Delta_Y} & Y \times_S Y \end{array}$$

then the theorem follows from the definition and base change trick of locally closed morphisms. □

Prop. (5.4.4.90) [Qsqc Lemma]. Let X be a qcqs scheme and $s \in \Gamma(X, \mathcal{O}_X)$, then there is a natural isomorphism $\Gamma(X, \mathcal{O}_X)_s \cong \Gamma(X_s, \mathcal{O}_X)$.

Proof: Firstly this is true for X affine by definition(5.2.7.1). In general, let U_i be an affine open cover of X that $U_i \cap U_j = \cup_{k=0}^{c_{ij}} U_{ijk}$ be a finite cover by affine opens, then there is an exact sequence

$$\Gamma(X, \mathcal{O}_X) \to \prod_i \Gamma(U_i, \mathcal{O}_X) \to \prod_{ijk} \Gamma(U_{ijk}, \mathcal{O}_X).$$

Then we can take localization by s to get an exact sequence

$$\Gamma(X, \mathcal{O}_X)_s \to \prod_i \Gamma(D(s, U_i), \mathcal{O}_X)_s \to \prod_{ijk} \Gamma(D(s, U_{ijk}), \mathcal{O}_X)_s.$$

but $D(s, U_i)$ is an open cover of X_s with $D(s, U_i) \cap D(s, U_j) = \cup_k D(s, U_{ijk})$, thus we get a natural isomorphism $\Gamma(X, \mathcal{O}_X)_s \cong \Gamma(X_s, \mathcal{O}_X)$. □

5 Proper & Projective

Prop. (5.4.5.1) [Proper]. A morphism that is separated, of finite type and universally closed is called **proper**.

Properness is local on the target, because all these three properties do(5.4.1.5). Properness satisfies the base change trick(5.4.4.2).

Prop. (5.4.5.2). The class of proper morphisms satisfies the base change trick(5.4.4.1), by valuation criterion(5.4.5.13) and fibered products tricks.

Proof: Closed immersion is proper because it is f.t. and is affine so separated(5.4.4.76), and it is universally closed because immersions are stable under base change(5.4.4.60). □

Prop. (5.4.5.3) [Image of Proper Map]. If $f : X \to Y$ is morphism between separated schemes f.t over S, then if X is proper, then f is proper(by base change trick) thus the image is closed, and is proper over S in its scheme-theoretic structure.

Proof: Notice proper is qc, so by(5.4.4.62), the scheme-theoretic closure has the same underlying space as the image. Then use(5.4.4.8) to show it is u.c.. □

Cor. (5.4.5.4) [Connected Proper to Affine Constant]. A morphism from a connected proper scheme to an Noetherian affine scheme $\operatorname{Spec} A$ is constant.

Proof: Because the image is proper, by(5.7.4.12), the global section of its image is a finite module over k thus Artinian(4.1.3.4) so has finitely many points and is discrete. But X is connected, thus it is constant. □

Prop. (5.4.5.5) [Chevalley]. Let $f: X \to Y$ be a morphism of schemes, the following are equivalent:

- f is finite.
- f is proper and affine.
- f is proper with finite fibers.
- f is proper and locally quasi-finite.
- f is separated, u.c., locally of f.t. and has finite fibres.

Proof: The fiber of $f: X \to S$ is $\operatorname{Spec}(k(y) \otimes_A B)$, which is Artinian(4.1.3.4), so it has finitely many primes and they are all closed. Finite morphism is proper because it is integral(5.4.4.39).

The converse follows from Zariski's main theorem(5.4.4.49).

Cf.[Sta]02LS. □

Cor. (5.4.5.6) [Quasi-Affine+Proper imply Affine]. Let $f: X \to \operatorname{Spec} A$ be a quasi-affine and proper map, then f is affine.

Proof: This follows from(5.7.2.8)(5.4.4.20) and the fact $H^p(X, \mathcal{O}_X) = 0$ for $p > 0$. □

Prop. (5.4.5.7) [Quasi-Finite+Proper Imply Finite]. Let $f: X \to S$ be a proper morphism of schemes and $s \in S$ that $f^{-1}(s)$ is a finite set, then there exists a nbhd V of $s \in S$ that $f^{-1}(V) \to V$ is finite.

Proof: By(5.4.4.46), f is quasi-finite at the points of $f^{-1}(s)$. By(5.4.4.48) the set U of points that f is quasi-finite is open. Denote $Z = X \backslash U$, then $f(Z)$ is closed in S and doesn't contain s. Then $V = S \backslash f(Z)$ satisfies the requirement by(5.4.5.5). □

Prop. (5.4.5.8) [Generically Finite+Proper Imply Finite]. Let $f: X \to S$ be a proper morphism of locally Noetherian schemes and $y \in Y$ satisfies $\dim \mathcal{O}_{Y,y} \leq 1$, and if one of the following holds:

- For every generic point η of X s.t. $f(\eta)$ generalizes y, $k(\eta)/k(f(\eta))$ is algebraic.
- f is quasi-finite at every generic point of x.
- f is quasi-finite on a dense subset of X.

then there exists an open nbhd V of $y \in Y$ s.t. $f^{-1}(V) \to V$ is finite.

Proof: Cf.[Sta]0AB7. □

Prop. (5.4.5.9). If X is a separated scheme over a field k of dimension> 0 and $x \in X$ is a closed point, then $X \backslash \{x\}$ is not proper over k.

Proof: Cf.[Sta]0A24. □

Def. (5.4.5.10)[Modification and Alteration]. A **modification** of $X \in \mathcal{S}ch$ is a scheme X' together with a proper birational map $X' \to X$.

A **alteration** of X is a scheme X' together with a proper dominant morphism $f : X' \to X$ that for some non-empty open U of X, $f^{-1}(U) \to U$ is finite.

Prop. (5.4.5.11) [Modifications and Alterations]. Any modification is an alteration. And if $Y \to X \in \mathcal{S}ch$ be an alteration, then it can be decomposed into $Y \to W \to X$ where $Y \to X$ is a modification and $W \to X$ is finite surjective.

Proof: ?Use Stein factorization. □

Valuation Criteria

Lemma (5.4.5.12) [Valuation Criteria Lemma]. If X is a scheme and $x \to y$ is a specialization of pts, then for any field extension $K/k(x)$, there is a valuation ring $A \subset K$ and a morphisms $\operatorname{Spec} A \to X$ that maps the generic pt η to x and the unique closed pt to y.

Moreover, if X is locally Noetherian, then A can be chosen to be a DVR.

Proof: There is a morphism $\mathcal{O}_{X,y} \to k(x) \to K$, so there is a valuation ring A with field of fractions K that dominate the image of $\mathcal{O}_{X,y}$ by(10.3.2.1), which is also a local ring(4.1.1.9). Then this is what we desire.

For the locally Noetherian case, add(10.3.3.7). □

Prop. (5.4.5.13) [Valuation Criteria]. The valuation criterion for $\operatorname{Spec} K \to \operatorname{Spec} R$ where R is a valuation ring with field of fractions K: Given a morphism $f : X \to S$,

1. If it is qc, then it is universally closed iff there is at least one lifting.
2. it is separated iff it is quasi-separated and there is at most one lifting.
3. it is proper iff it is finite type, quasi-separated and lifting exists uniquely.

Moreover, if S is locally Noetherian and f is locally of f.t., then it suffices to check for discrete valuation rings. *Proof:*

1. Firstly, in this case, by(5.4.4.9), it suffices to prove that: specializations lift along any base change of f iff it has has least one lifting. If specializations lift along any base change of f, change S to $\operatorname{Spec} A$ and X to $X \times_S \operatorname{Spec} A$. Let x' be the image of $\operatorname{Spec} K \to X$, then by hypothesis there is a specialization $x' \to x$ where x mapsto the closed pt of $\operatorname{Spec} A$. Then we get a map $A \to \mathcal{O}_{X,x} \to k(x') \to K$, which is exactly the quotient map $A \to K$. So the image of $\mathcal{O}_{X,x}$ in K dominates A, which means it is just A. Thus we get a map $\mathcal{O}_{X,x} \to A$, which gives a map $\operatorname{Spec} A \to X$ that commutes $\operatorname{Spec} K$.
   Converly, if f has at least one lifting, then any base change of f also has at least one lifting by categorial reason. Thus it suffices to show specializations lift along f. Let $s' \to s$ be a specialization in S and $x' \in X$ maps to s', we can apply(5.4.5.12) to $k(s') \subset k(x') = K$, then we get a lifting diagram, and the image of the closed pt of $\operatorname{Spec} A$ under the lifting is a point mapping to s.
2. If it is separated, then if there are two lifting, then consider their equalizer, it is a closed subscheme of $\operatorname{Spec} A$ by(5.2.7.18), and it contains the generic pt, so it equals $\operatorname{Spec} A$, as desired. Conversely, if there are at most one lifting, then we want to prove the diagonal is closed. But by (5.4.4.76) and(5.4.4.71) and the valuation criterion for u.c., it suffices to prove the existence

of a lifting for the diagonal map(5.4.5.13). But in fact, a valuation digram for the diagonal correspond to two lifting of a valuation criterion for $X \to S$, then they are the same, and $\operatorname{Spec} A \to X \times_S X$ lifts along the diagonal.

3. follows from the above two.

□

Prop. (5.4.5.14)[Extension of Rational Maps]. Let X, Y be schemes over S, X is locally Noetherian and Y/S is proper. If there is a morphism from an open subset U of X to Y, and there is a point x in the closure of U with the stalk being a valuation ring, then the morphism can be extended to an open set containing x.

Proof: We can replace X by an affine open nbhd of X. By(5.4.6.1), we assume X is affine and $\Gamma(X, \mathcal{O}_X) \subset \mathcal{O}_{X,x}$. In particular X is integral with generic pt ξ with residue field K. Then U contains ξ. By the valuation criterion(5.4.5.13), the morphism $\operatorname{Spec} K \xrightarrow{\xi} U \to Y$ can be lifted to a morphism $\operatorname{Spec} \mathcal{O}_{X,x} \to Y$, thus lemma(5.4.6.2) shows there is a morphism on a nbhd V of X spreading this morphisms.

Now because Y/S is separated, the equalizer of this morphism and f on their intersection is a closed subscheme by(5.4.4.89), but it contains ξ, so they coincide on the intersection, so we are done. □

Prop. (5.4.5.15) [Singularity in Codimension1]. Let $\varphi : X \to X'$ be a rational map of a locally Noetherian scheme X/K regular in codimension1 to a proper scheme X'/K with maximal domain U, then

$$\operatorname{codim}(X \backslash U, X) \geq 2.$$

In particular, if X is non-singular curve, then φ is a morphism.

Proof: Use(5.4.5.14), noticing that the stalk at a point of codimention1 is a DVR(4.3.5.20). □

Projective Morphism

Def. (5.4.5.16) [Projective Morphism]. A **projective** morphism $X \to Y$ is a closed immersion $X \to \operatorname{Proj}(\mathcal{E})$ for some Qco f.t. module $\mathcal{E}$ over Y.

An **H-projective** morphism $X \to Y$ is a closed immersion $X \to \mathbb{P}^n_Y$.

An **H-quasi-projective** morphism is a H-projective morphism composed with a quasi-compact open immersion.

A **locally projective** morphism $f : X \to Y$ is a morphism f that there exists a covering U_i of Y that $f^{-1}(U_i) \to U_i$ is projective.

Some proposition about projective is written before the language of Hartshorne so I may not have changed them to the more general notion of projectiveness yet.

Prop. (5.4.5.17). For a morphism $f : X \to S$, he following are equivalent:

- f is locally projective.
- There is a covering U_i of S that $f^{-1}(U_i) \to U_i$ is H-projective.

Proof: Clearly 2 implies 1, and for the converse, it suffices to show that projective morphism is locally H-projective. Locally on each affine open nbhd $U = \operatorname{Spec} R$, X_U is isomorphic to a closed subscheme of $P(\mathcal{E})$ for some f.t. Qco sheaf of $\mathcal{O}_U$-modules $\mathcal{E}$. Write $\mathcal{E} = \widetilde{M}$ for some f.t. R-module

M, and choose a set of generators $x_1,\dots,x_n$ for M, which induces a surjection of graded R-algebra $R[X_0,\dots,X_n]\to \mathrm{Sym}_R(M)$, then the corresponding morphism $P(\mathcal{E})\to\mathbb{P}^n$ is a closed immersion, so $f^{-1}(U)$ is a H-projective scheme over U. □

Prop. (5.4.5.18). H-(quasi-)projectiveness is stable under base change and composition. (because Segre embedding is closed). Disjoint union of f.m. projective morphisms is projective (embed into the Segre embedding).

Proof: [Sta]01WE. □

Cor. (5.4.5.19) [Projective Maps are Proper]. Projective morphisms are locally projective and locally projective morphisms are proper. Thus a quasi-projective morphism is locally of f.t. and separated(5.4.4.86).

Proof: Because locally projective and proper are both local on the base(5.4.4.2), it suffices to show that H-projective morphism is proper by(5.4.5.17).

Because properness satisfies base change trick(5.4.4.2), it suffices to show $\mathbb{P}^n_S\to S$ is proper. Also this is base change of $\mathbb{P}^n_{\mathbb{Z}}\to\mathbb{Z}$, it suffices to check this one. $\mathbb{P}^n_{\mathbb{Z}}$ is clearly separated by(14.5.3.20)(looking at the natural affine covering), and qc. Finally we show it is u.c. using valuation criterion(5.4.5.13):

Let $\begin{array}{ccc}\mathrm{Spec}\,K & \longrightarrow & X\\ \downarrow & \nearrow & \downarrow\\ \mathrm{Spec}\,R & \longrightarrow & \mathrm{Spec}\,\mathbb{Z}\end{array}$ be a diagram, by induction on n, we may assume the image ξ_1 of $\mathrm{Spec}\,K$ is not contained in any of the hypersurface $V(x_i)$, then x_i are all invertible in $\mathcal{O}_{\xi_1}$, and there is a morphism $\varphi: k(\xi_1)\to K$. Let f_{ij} be the image of x_i/x_j under φ, and choose k which f_{k0} has the minimal valuation, then $f_{ik}\in R$ for any i, which means the there is a map

$$\mathbb{Z}[x_0/x_k,\dots,x_n/x_k]\to R$$

compatible with φ, or equivalently a map $\mathrm{Spec}\,R\to D(x_k)\subset X$ commuting the diagram. □

Prop. (5.4.5.20)[Descent for Projectiveness]. Let X be a scheme over a field k, and K/k is a field extension, then X_k is (quasi-)projective iff X_K is (quasi-)projective.

Proof: This follows from(5.5.4.19) and f.f. descent. □

Prop. (5.4.5.21). H-Projective scheme over $\mathrm{Spec}\,A$ is of the form $\mathrm{Proj}\,S$ where $S_0=A$ and S is f.g over S_0 by S_1(5.5.2.11).

Proof: □

Prop. (5.4.5.22) [Projective Morphisms and Closed Embeddings]. Let k be an alg.closed field and $\pi: X\to Y$ is a projective morphism of algebraic schemes over k that is injective on closed points and injective on tangent vectors at closed points, then π is a closed embedding.

Proof: Cf.[Vak17]P506. □

Prop. (5.4.5.23) [Chow's Lemma]. Let $X\to S$ be separated of f.t over a qcqs S, then there is a birational, H-projective map $\pi: X'\to X$ over S that X' is quasi-projective over S.

If X is proper, then X' is projective over S. And if X is integral/irreducible/reduced over S, X' can also be chosen to be so.

Proof: We only prove for S Noetherian, for the general case, Cf.[Sta]0203.

In this case all schemes here are Noetherian. Suppose $X_i, i \le r$ are irreducible components of X with generic points η_i, by(5.4.6.5) and the fact X is qc we can find a finite affine cover $X = \cup U_i$ that each U_i contains all the generic points of X, thus $U = U_1 \cap \ldots \cap U_n$ is dense in X. Let X^* be the schematic-closure of U in X, and $U_i^* = U_i \cap X^*$, then we may replace X by X^* and assume that U is schematically dense in X by(5.4.4.67) as X is qs. By(5.5.4.22) and(5.4.4.19), there are immersions $U_i \to \mathbb{P}_S^{n_i}$ together with a closed subscheme $Z_i \subset \mathbb{P}_S^{n_i}$ that $U_i \to Z$ is a scheme-theoretically dense open immersion(5.4.4.70).

Consider the map $(j_1, \ldots, j_m) : U \to \mathbb{P}_S^{n_i} \times \ldots \times \mathbb{P}_S^{n_m}$ with scheme-theoretic image Z, and the commutative diagrams

$$\begin{array}{ccc} U & \xrightarrow{(j_1,\ldots,j_m)} & \mathbb{P}_S^{n_i} \times \ldots \times \mathbb{P}_S^{n_m} \\ \downarrow & & \downarrow \pi_i \\ U_i & \xrightarrow{j_i} & \mathbb{P}_S^{n_i} \end{array},$$

which induces a map $p_i : Z \to Z_i$(5.4.4.63) which is proper.

Consider $p_i^{-1}(j_i(U_i)) = V_i$ and $X' = \cup_i V_i$ which is an open subscheme of $Z \subset \mathbb{P}_S^{n_i} \times \ldots \times \mathbb{P}_S^{n_m}$ thus quasi-projective over S.

Finally, we prove that the morphism $p_i : V_i \to U_i$ glue together to a proper birational morphism $\pi : X' \to X$: this is because they are compatible on U, which is scheme-theoretically dense in V_i for each i thus also also scheme-theoretically dense in $V_i \cap V_j$, thus p_i and p_j are compatible on $V_i \cap V_j$ as the target X is separated over S.

To show π is proper, firstly notice $\pi^{-1}(U_i) = V_i$: there are decompositions $V_i \to \pi^{-1}(U_i) \to U_i$, where $V_i \to U_i$ is proper, thus $V_i \to \pi^{-1}(U_i)$ is also proper and V_i is schematically dense in $\pi^{-1}(U_i)$ because it contains U, so it is and isomorphism.

For the same reason $U \to \pi^{-1}(U)$ is an isomorphism. Finally π is projective because it factors through some map $X' \to X \times_S \mathbb{P}_S^n = \mathbb{P}_X^n$ and it is proper.

If X is reduced, then X' is reduced by(5.4.4.65), and if X is irreducible, then $X' = Z$ is the closure of $j(X)$ by(5.4.4.70), which is irreducible. □

6 Technical Lemmas

Lemma (5.4.6.1). Let X be a scheme and x a point, then there exists an open affine nbhd U of x that $\mathcal{O}_X(U) \to \mathcal{O}_{X,x}$ is injective, if any of the follows holds:

- X is integral.
- X is locally Noetherian.
- X is reduced with f.m. irreducible components.

Proof: This problem is clearly local hence follows from the algebra case(4.1.1.34). □

Lemma (5.4.6.2) [Spread Out Stalk Morphism]. Let X, Y be schemes over S, $s \in S$ and x, y be pts over S, then:

- Let $f, g : X \to Y$ be morphisms over S that $f(x) = g(x) = y$ and $f_x^\sharp = g_x^\sharp$, then $f = g$ on a nbhd U of x if any of the following holds:
  (a) Y/S is locally of f.t..

  (b) X is integral.

(c) X is locally Noetherian.

(d) X is reduced with f.m. irreducible components.

- Let $\varphi : \mathcal{O}_{Y,y} \to \mathcal{O}_{X,x}$ be a local ring map over $\mathcal{O}_{S,s}$, then there is a morphism f from a nbhd U of x mapping to Y that $f(x) = y$, and $f_x^\sharp = \varphi$, if any of the following holds:
  (a) Y/S is locally of f.p..

  (b) Y/S is locally of f.t. and X is integral.

  (c) Y/S is locally of f.t. and X is locally Noetherian.

  (d) Y/S is local of f.t. and X is reduced with f.m. irreducible components.

Proof: Cf.[[Sta]0BX6]. □

Prop. (5.4.6.3) [Base Change of Fields is Quotient Map]. For any scheme X over a field k and algebraic extensions K/k, $X_K \to X$ is a quotient map, as it is surjective(5.6.2.1), continuous and closed(5.4.4.39).

Lemma (5.4.6.4). Let X be a qs scheme and Z_i be a finite set of irreducible components of X. Let η_i be the generic point of Z_i, then there are open affine subsets $\eta_i \in U_i$ that $U_1, \ldots, U_n$ are pairwise disjoint.

Proof: □

Lemma (5.4.6.5). Let X be a qs scheme and Z_i be a finite set of irreducible components of X. Let η_i be the generic point of Z_i and $x \in X$, then there is an affine open subset of X containing x and η_i.

Proof: Let $x \in Z_1, \ldots, Z_r$ but $x \notin Z_{r+1}, \ldots, Z_n$, then we can find an arbitrary affine open nbhd W of x that contains $\eta_1, \ldots, \eta_r$ but not $\eta_{i+1}, \ldots, \eta_n$. By(5.4.6.4), we may choose pairwise disjoint affine open nbhds $\eta_{r+1} \in U_{r+1}, \ldots, \eta_m \in U_n$. Now $U_i \cap W$ is quasi-compact and doesn't contain η_i, so we can shrink U_i s.t. $W \cap U_i = \varnothing$ by(4.1.7.24). Then $U = W \coprod (\coprod U_i)$ satisfies the desired condition. □

Main references are [Sta]and [Vak17].

5.5 Quasi-Coherent Sheaves on Schemes

1 (Quasi-)Coherent Sheaves

Lemma (5.5.1.1) [Associated Qco Sheaves on Affine Scheme]. On an affine scheme $\operatorname{Spec} A$, there is a sheaf $\widetilde{M}$, that is M_f on $\operatorname{Spec} A_f$. To check it is a sheaf, we only need to check to affine coverings, and this follows from(4.4.2.2).

Prop. (5.5.1.2) [Qco Sheaves on Affine Schemes]. $M \mapsto \widetilde{M}$ is an equivalence to the category of quasi-coherent sheaves over $\operatorname{Spec} A$. In particular,

$$\operatorname{Hom}_A(M, \Gamma(X, \mathcal{G})) \cong \operatorname{Hom}_{\mathcal{O}_X}(\widetilde{M}, \mathcal{G}),$$

so $M \mapsto \widetilde{M}$ commutes with colimits and is exact, and commutes with pullbacks.

When A is Noetherian, this also induces an equivalence between finite A-modules and coherent sheaves over $\operatorname{Spec} A$, because finiteness for modules is local(5.4.1.5).

Proof: For any A-module M, there is a sheaf of modules $\mathcal{F}_M$ on $X = \operatorname{Spec} A$ by(5.2.2.26). This is left adjoint to Γ and defines a functor from the category of A-modules to the category of $\mathcal{O}_{\operatorname{Spec} A}$-modules.

By universal property of $\mathcal{F}_M$(5.2.2.26), there is a natural map $\mathcal{F}_M \to \widetilde{M}$ corresponding to the ring map $M \mapsto \Gamma(\operatorname{Spec} A, \widetilde{M}) = M$. The induced maps on the stalk at a point x is $M \otimes_A \mathcal{O}_{X,x} \to M_{\mathfrak{p}}$, which is isomorphism, so $\mathcal{F}_M \cong \widetilde{M}$.

From the universal property of $\widetilde{M} = \mathcal{F}_M$, $\operatorname{Hom}(\widetilde{M}, \widetilde{N}) = \operatorname{Hom}(M, N)$, thus $\sim$ is fully faithful, to show it is an equivalence, it suffices to show for any Qco sheaf $\mathcal{F}$ on $\operatorname{Spec} A$, the natural map $\widetilde{\Gamma(X, \mathcal{F})} \to \mathcal{F}$ is an isomorphism:? Cf.[Sta]01IA.

If $0 \to M_1 \to M \to M_2 \to 0$ is exact, then $0 \to \widetilde{M_1} \to \widetilde{M} \to \widetilde{M_2} \to 0$ is exact, because localization is exact. □

Prop. (5.5.1.3) [properties of (Quasi-)Coherent Sheaves on Schemes].

- $\mathfrak{QCoh}(X)$ and $\mathfrak{Coh}(X)$ are weak Serre subcategories of $\mathfrak{Mod}_{\mathcal{O}_X}$, and $\mathfrak{Coh}(X)$ is a Serre subcategory of $\mathfrak{QCoh}(X)$.
- Colimits in $\mathfrak{Mod}(\mathcal{O}_X)$ preserves $\mathfrak{QCoh}(X)$, because localization is exact.
- Tensor product of two (Q)co sheaf is (Q)co, and locally free if they are locally free. More explicitly, $\widetilde{M \otimes_A N} \cong \widetilde{M} \otimes_{\mathcal{O}_X} \widetilde{N}$ as tensor product commutes with π^*.
- If $\mathcal{F}$ is Qco, then so does $T(\mathcal{F}), \operatorname{Sym}(\mathcal{F})$ and $\wedge(\mathcal{F})$, by(5.2.3.12).
- Given $\mathcal{F}, \mathcal{G} \in \mathfrak{QCoh}(\mathcal{F})$ that $\mathcal{F}$ is f.p., $\mathcal{H}om(\mathcal{F}, \mathcal{G}) \in \mathfrak{QCoh}(X)$, by(5.2.3.2) and(5.5.1.2). More explicitly, affine locally $\mathcal{H}om_X(\widetilde{M}, \widetilde{N}) = \widetilde{\operatorname{Hom}_A(M, N)}$.
- pullback preserves $\mathfrak{QCoh}(X)$ and $\mathfrak{Coh}(X)$, by(5.2.2.29). More explicitly, if $\operatorname{Spec} B \subset Y$ is mapped into $\operatorname{Spec} A \subset X$, then $f^*(\mathcal{F})(\operatorname{Spec} B) = \mathcal{F}(\operatorname{Spec} A) \otimes_A B$, using the fact $\widetilde{M} = \mathcal{F}_M = \pi^* M$.

Proof: 1: $\mathfrak{Coh}(X)$ follows from(5.2.2.28). For $\mathfrak{QCoh}(X)$, it follows from(5.5.1.2) that the kernel and cokernel of $\varphi : \widetilde{M} \to \widetilde{N}$ is just $\widetilde{\ker \varphi}$ and $\widetilde{\operatorname{Coker} \varphi}$ which is Qco, for the extension of Qco, use(5.7.1.3) that the global section is exact, so there is a morphism of exact sequences $\widetilde{\Gamma(X, \mathcal{F}_i)}(U) \to \mathcal{F}_i(U)$, and five lemma gives the result. □

Prop. (5.5.1.4) [Qco Sheaves of F.T./F.P]. Let $X = \operatorname{Spec} A$ and $\mathcal{F} = \widetilde{M}$ a Qco sheaf on X, then $\mathcal{F}$ is of f.t./f.p. if M is of f.t/f.p. over A.

Proof: These follows from the fact finiteness/f.p. are local properties for modules over a ring(4.1.4.4). □

Def. (5.5.1.5) [Locally Projective Qco Sheaves]. Let X be a scheme, then a **locally projective Qco sheaf** is a Qco sheaf $\mathcal{F}$ on X that is affine locally a locally projective module sheaf.

Being locally projective for Qco sheaves satisfies fpqc descent, by(4.4.2.1).

Prop. (5.5.1.6) [Qcqs Pushforward]. If f is qcqs, then the pushforward of of a Qco sheaf is Qco. (Used in**??**).

Proof: The question is local so we let Y be affine, and then X is qcqs, so we cover it with affine opens U_i and their intersections are U_{ijk}. Then we see by sheaf property

$$0 \to f_*\mathcal{F} \to \oplus_i f_*(\mathcal{F}|_{U_i}) \to \oplus_{ijk} f_*(\mathcal{F}|_{U_{ijk}})$$

The last two are Qco because two are maps between affine schemes, so the first is Qco. □

Prop. (5.5.1.7) [Qco Sheaves on Qcqs Schemes]. For a qcqs scheme X and $s \in \Gamma(X, \mathcal{O}_X)$, and a Qco module $\mathcal{F}$, $(\Gamma(X, \mathcal{F}))_s \cong \Gamma(X_s, \mathcal{F})$.

Proof: The canonical map $f : X \to \operatorname{Spec} \Gamma(X, \mathcal{O}_X)$(5.2.7.5) is qcqs, so $f_*\mathcal{F}$ is Qco on $\operatorname{Spec} \Gamma(X, \mathcal{O}_X)$ by(5.5.1.6). Then the result follows from the fact $f^{-1}(\operatorname{Spec}(\Gamma(X, \mathcal{O}_X)_s)) = X_s$ and the definition of f_*. □

Lemma (5.5.1.8) [Extending Qco Sheaves]. Let $i : U \to X$ be a quasi-compact open immersion of schemes, $\mathcal{F}$ a Qco $\mathcal{O}_X$-module and $\mathcal{G} \subset \mathcal{F}|_U$ a Qco $\mathcal{O}_U$-submodule, then there exists a Qco $\mathcal{O}_X$-submodule $\mathcal{G}' \subset \mathcal{F}$ that $\mathcal{G}'|_U = \mathcal{G}$

Proof: immersion is separated(5.4.4.86), so $i_*\mathcal{G}$ is a Qco $\mathcal{O}_X$-sheaf by(5.5.1.6), and it is a submodule of $i_*i^*\mathcal{F}$, so the kernel

$$\mathcal{H} = \ker(\mathcal{F} \oplus i_*\mathcal{G} \to i_*i^*\mathcal{F})$$

is also Qco by(5.5.1.3), and $\mathcal{H} \subset \mathcal{F}$, $\mathcal{H}|_U = \mathcal{G}$. □

Prop. (5.5.1.9) [Extending Qco Sheaves of F.T.]. Let X be a qcqs scheme, and $U \subset X$ a qc open subset, $\mathcal{F}$ a Qco $\mathcal{O}_X$-module and $\mathcal{G} \subset \mathcal{F}|_U$ a Qco $\mathcal{O}_U$-submodule of f.t., then there exists a Qco $\mathcal{O}_X$-submodule $\mathcal{G}' \subset \mathcal{F}$ of finite type that $\mathcal{G}'|_U = \mathcal{G}$.

Proof: Let n be the minimal number of affine open subsets U_i that $X = U \bigcup \cup U_i$, by induction on n, it suffices to prove for $n = 1$. Thus we may assume $X = U \cup V$ where U, V are affine opens. Now $U \cap V$ is qc because X is qs. Then we can change (X, U) to $(V, U \cap V)$, because we can glue the resulting sheaf. Then we reduce to the case X is affine.

Let $X = \operatorname{Spec} R$ and $\mathcal{F} = \widetilde{M}$, then by(5.5.1.8), there exists a Qco sheaf $\widetilde{N}$ that $\widetilde{N}|_U = \mathcal{G}$. By hypothesis we can cover U by f.m. open affine $D(f_i)$ that N_{f_i} is f.g., by element $x_{ij}/f_j^{n_i}$. Let N' be the submodule of N generated by these elements x_{ij}, then $\widetilde{N'}$ meets our requirement. □

Cor. (5.5.1.10) [Qco Sheaf is a Direct Union of Qco Sheaves of F.T.]. Let X be a qcqs scheme, then any Qco sheaf $\mathcal{F}$ on X is a direct colimit of its Qco subsheaves of f.t..

Proof: It is a direct colimit because the sum of two Qco sheaves of f.t. is also Qco of f.t.. Now for any affine open $U \subset X$ and $s \in \mathcal{O}_X(U)$, s generates a Qco $\mathcal{O}_U$-submodule of f.t. of $\mathcal{F}|_U$, and by(5.5.1.9) this extends to a Qco $\mathcal{O}_X$-submodule of $\mathcal{F}$. Then we see that the direct colimit of Qco subsheaves of f.t. of $\mathcal{F}$ contains elements of $\mathcal{F}(U)$ for any affine open subset U, thus it is just $\mathcal{F}$. □

Def. (5.5.1.11) [Rank of Sheaves]. Let X be a scheme and $\mathcal{F}$ a Qco sheaf on X, $p \in X$, then the **rank of $\mathcal{F}$ at p** is $\mathrm{rank}_p(\mathcal{F}) = \dim_{k(p)} \mathcal{F}_p/\mathfrak{m}_p\mathcal{F}_p$.

Prop. (5.5.1.12) [Maximal Qco Submodule]. For X a scheme and any $\mathcal{O}_X$-module $\mathcal{F}$, there is a Qco submodule of $\mathcal{F}$ maximal among all Qco submodules of $\mathcal{F}$. This is because a direct colimit of Qco sheaves is Qco(5.5.1.3).

Prop. (5.5.1.13) [Integral and Finite Modules]. Let X be a qcqs scheme and $\mathcal{A}$ an integral Qco $\mathcal{O}_X$-submodule, then

- $\mathcal{A}$ is the directed colimits of its finite Qco $\mathcal{O}_X$-modules.
- $\mathcal{A}$ is a direct colimit of finite and finitely presented Qco $\mathcal{O}_X$-modules.

Proof: Cf.[Sta]0817. □

Def. (5.5.1.14). ?

- for a closed immersion $Y \to X$, there is $i^! : \mathfrak{QCoh}(X) \to Qco(Y)$ that is right adjoint to i_*: $i^!\mathcal{G} = i^*((\mathcal{H}_Z(\mathcal{G}))')$, where $\mathcal{H}_Z(\mathcal{G})$ is the sheaf of sections annihilated by $\mathcal{I}$ and $\mathcal{F}'$ is the maximal Qco sheaf of $\mathcal{F}$.
- For f proper between locally Noetherian scheme, there is a inverse sheaf $f^!\mathcal{G} = \mathcal{H}om_Y(f_*\mathcal{O}_X, \mathcal{G})$, which maps $Qco(Y)$ to $\mathfrak{QCoh}(X)$ by(5.5.1.33) and**??**. When f is affine, in particular when it is finite, then $f^!$ is right adjoint to f_* on Qco(5.8.6.13).

Associated Points

Def. (5.5.1.15) [Weakly Associated Points]. Let $X \in \mathfrak{Sch}$ and $\mathcal{F} \in \mathfrak{QCoh}(X)$, then a **weakly associated point of $\mathcal{F}$** is the set of points $x \in X$ that $\mathfrak{m}_x \subset \mathcal{O}_{X,x}$ is weakly associated to the module $\mathcal{F}_x$. The set of w.ass points are denoted by $\mathrm{WeakAsso}(\mathcal{F})$. The **weakly associated points of X** is the weakly associated points of $\mathcal{O}_X$.

Similarly we can stalkwise define the set of **associated points** of X.

Def. (5.5.1.16) [Embedded Points]. Let X be a scheme and $\mathcal{F}$ a Qco sheaf on X, then an **embedded point** of $\mathcal{F}$ is an associated point that is a specialization of another associated point.

Prop. (5.5.1.17) [Properties of Associated Points]. Let X be a scheme and $\mathcal{F}_i$ be Qco sheaves on X, then

1. $Ass(\mathcal{F}) \subset \mathrm{WeakAsso}(\mathcal{F}) \subset \mathrm{Supp}(\mathcal{F})$.
2. If $0 \to \mathcal{F}_1 \to \mathcal{F}_2 \to \mathcal{F}_3 \to 0$ is an exact sequence, then $WeakAss(\mathcal{F}_1) \subset WeakAss(\mathcal{F}_2)$, and $WeakAss(\mathcal{F}_2) \subset \mathrm{WeakAsso}(\mathcal{F}_1) \cup \mathrm{WeakAsso}(\mathcal{F}_3)$.
3. $WeakAss(\mathcal{F}) = \varnothing$ iff $\mathcal{F} = 0$.
4. The generic points of $\mathrm{Supp}(\mathcal{F})$ are in $\mathrm{WeakAsso}(\mathcal{F})$. In particular, generic points of X are in $WeakAss(X)$.

5. If X is locally Noetherian, then $Ass(\mathcal{F}) = \mathrm{WeakAsso}(\mathcal{F})$.
6. If X is reduced, then $\mathrm{WeakAsso}(X)$ is just the generic points of X. In particular, X has no embedded points.
7. If X is locally Noetherian, then an associated point is an embedded point iff it is not a generic point of $\mathrm{Supp}(\mathcal{F})$.
8. If X is locally Noetherian and $\mathcal{F}$ is coherent, then $\mathcal{F}$ has no embedded points iff it satisfies (S_1).
9. If X is locally Noetherian of dimension≤ 1, then X is C.M. iff it has no embedded points.

Proof: By(4.2.5.21), these reduces to the affine case, so they follows from

- (4.2.5.13)(4.2.5.16).
- (4.2.5.14).
- (4.2.5.16).
- (4.2.5.16).
- (4.2.5.21).
- (4.2.5.24).
- (4.2.5.23).
- [Sta]031Q.
- [Sta]0BXG.

□

Prop. (5.5.1.18). Let X be a scheme and $\mathcal{F} \in \mathfrak{QCoh}(X)$. If U is an open subset of X that contains $\mathrm{WeakAsso}(\mathcal{F})$, then $\Gamma(X, \mathcal{F}) \to \Gamma(U, \mathcal{F})$ is injective.

Proof: If $s \subset \Gamma(X, \mathcal{F})$ be a section that restricts to 0 on U, let $\mathcal{F}'$ be the subsheaf generated by s, then $WeakAss(\mathcal{F}') \subset \mathrm{WeakAsso}(\mathcal{F})$, but $\mathrm{Supp}(\mathcal{F}') \subset X \backslash U$, thus $WeakAss(\mathcal{F}') = 0$, so $\mathcal{F}' = 0$ by(5.5.1.17). □

Prop. (5.5.1.19) [Schematically Dense and Associated Points]. Let X be a locally Noetherian scheme and $U \subset X$ an open subset, then the following are equivalent:

- U is schematically dense in X.
- U is dense in X and contains all the embedded points of X.
- U contains $Ass(X)$.

Proof: The problem is local, so we assume $X = \mathrm{Spec}\, A$, then $2, 3$ are clearly equivalent.

Let $U = \cup_i D(f_i)$, then by(5.4.4.64), U is schematically dense in A iff $A \to \prod A_{f_i}$ is injective. If $\mathfrak{p} = Ann(x)$ for some $x \in A$, then x maps to some non-zero element of A_{f_i}, then $f_i \notin \mathfrak{p}$, so $\mathfrak{p} \subset D(f_i) \subset U$. Conversely, if $Ass(X) \subset U$, then every map $A \to A_\mathfrak{p}$ factors through $A \to A_{f_i}$ for some i, so injectivity of $A \to \prod_{\mathfrak{p} \in Ass(X)} A_\mathfrak{p}$ implies injectivity of $A \to \prod_i A_{f_i}$. □

Prop. (5.5.1.20). Let X be a scheme and $\varphi : \mathcal{F} \to \mathcal{G} \in \mathfrak{QCoh}(X)$ that $\mathcal{F}_x \to \mathcal{G}_x$ is injective for any $x \in WeakAss(\mathcal{F})$, then φ is injective.

Proof: The hypothesis says $WeakAss(\ker(\varphi)) = 0$, so $\ker(\varphi) = 0$ by(5.5.1.17). □

Fitting Ideals

Def. (5.5.1.21) [Fitting Ideals]. Let $X \in \mathcal{S}\mathrm{ch}$ and $\mathcal{F} \in \mathcal{QC}\mathrm{oh}^{\mathrm{ft}}(X)$, the **fitting ideal** of $\mathcal{F}$ is defined to be**?** Cf.[Sta]0C3C.

Locally Free Sheaves

Prop. (5.5.1.22) [Locally Free is Stalkwise]. $\mathcal{F} \in \mathcal{QC}\mathrm{oh}^{\mathrm{pf}}(X)$ is locally free iff its stalks are all free, by(4.3.1.7).

Def. (5.5.1.23). Let $X \in \mathcal{S}\mathrm{ch}$ and $\delta : X \to \mathbb{N}$ a locally constant function, then the category of locally free sheaves of rank δ is denoted by $\mathcal{C}\mathrm{oh}^{\mathrm{free},\delta}(X)$. The category of locally free sheaves is denoted by $\mathcal{C}\mathrm{oh}^{\mathrm{free}}(X)$

Prop. (5.5.1.24) [Locally Free Sheaves]. Suppose $0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0$ is an exact sequence of sheaves on a scheme X, then

- If $\mathcal{F}', \mathcal{F}''$ are both locally free, then so is $\mathcal{F}$.
- If $\mathcal{F}, \mathcal{F}'$ are both locally free of finite rank, then so is $\mathcal{F}'$.

Proof: Firstly of all in each case all sheaves are Qco by(5.5.1.3).

1: on an affine open $U = \operatorname{Spec} A \subset X$, the exact sequence is induced by $0 \to A^I \to \Gamma(U, \mathcal{F}) \to A^J \to 0$, so it splits and $\Gamma(U, \mathcal{F}) \cong A^{I+J}$ is free.

2: on an affine open $U = \operatorname{Spec} A \subset X$, the exact sequence is induced by $0 \to \Gamma(U, \mathcal{F}') \to A^m \to A^n \to 0$, where the map $A^m \to A^n$ is represented by a $n \times m$ matrix M. Then U is covered by open subsets U_i that some $n \times n$ minor of M is invertible. Then after a change of coordinates on each subset, $\mathcal{F}(U_i) \cong A^{m-n}$. □

Prop. (5.5.1.25). For a exact sequence $0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0$ in $\mathcal{QC}\mathrm{oh}^{\mathrm{free}}(X)$, there is a filtration of $\operatorname{Sym}^r \mathcal{F}$:

$$0 = \mathcal{G}^{r+1} \subset \mathcal{G}^r \subset \ldots \subset \mathcal{G}^0 = \operatorname{Sym}^r \mathcal{F}$$

that

$$\mathcal{G}^p / \mathcal{G}^{p+1} \cong \operatorname{Sym}^p \mathcal{F}' \otimes \operatorname{Sym}^{r-p} \mathcal{F}''.$$

Proof: On any affine open subset, choose a splitting of the exact sequence, then use coordinates. □

Prop. (5.5.1.26). For a exact sequence $0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0$ in $\mathcal{C}\mathrm{oh}^{\mathrm{free}}(X)$, there is a filtration of $\wedge^r \mathcal{F}$:

$$0 = \mathcal{G}^{r+1} \subset \mathcal{G}^r \subset \ldots \subset \mathcal{G}^0 = \wedge^r \mathcal{F}$$

that

$$\mathcal{G}^p / \mathcal{G}^{p+1} \cong \wedge^p \mathcal{F}' \otimes \wedge^{r-p} \mathcal{F}''.$$

In particular,

$$\wedge \mathcal{F}' \otimes \wedge \mathcal{F}'' \cong \wedge \mathcal{F}.$$

and when $\mathcal{F}'' \cong \mathcal{L}$ is a line bundle, there is an exact sequence

$$0 \to \wedge^r(\mathcal{F}') \to \wedge^r(\mathcal{F}) \to \wedge^{r-1}(\mathcal{F}') \otimes \mathcal{L} \to 0$$

Proof: On any affine open subset, choose a splitting of the exact sequence, then use coordinates. □

Prop. (5.5.1.27) [Perfect Pairing Wedge Product Sheaf]. Let $\mathcal{F}$ be a locally free sheaf of rank n, then there is a perfect pairing $\wedge^r\mathcal{F}\otimes\wedge^{n-r}\mathcal{F}\to\wedge\mathcal{F}$ which is a perfect pairing, i.e. it induces an isomorphism $\wedge^r\mathcal{F}\cong(\wedge^{n-r}\mathcal{F})^\vee\otimes\wedge\mathcal{F}$.

Proof: The map is natural, and the isomorphism can be seen at the level of stalls, by(5.2.3.11). □

Prop. (5.5.1.28). Let $0\to\mathcal{F}\to\mathcal{G}\to\mathcal{H}\to 0$ is an exact sequence in $\mathfrak{QCoh}(X)$ where $\mathcal{H}$ is a locally free sheaf, then for any Qco sheaf $\mathcal{E}$ of X, then for any Qco sheaf $\mathcal{E}$ on X, there is an exact sequence of sheaves

$$0\to\mathcal{H}om(\mathcal{H},\mathcal{E})\to\mathcal{H}om(\mathcal{G},\mathcal{E})\to\mathcal{H}om(\mathcal{F},\mathcal{E})\to 0.$$

In particular, $0\to\mathcal{H}^\vee\to\mathcal{G}^\vee\to\mathcal{F}^\vee\to 0$ is exact.

Proof: As $\mathcal{H}om(-,\mathcal{E})$ is left exact, it suffices to show the last one is surjective. This is local, so we may assume $0\to\mathcal{F}\to\mathcal{G}\to\mathcal{H}\to 0$ is $0\to M\to N\to A^n\to 0$, so this sequence splits, and the then $\mathcal{H}om(\mathcal{G},\mathcal{E})\to\mathcal{H}om(\mathcal{F},\mathcal{E})$ is surjective, by(5.5.1.3). □

Prop. (5.5.1.29) [Grothendieck]. Every object in $\mathfrak{Coh}^{\text{free},r}(\mathbb{P}^1_k)$ is isomorphic to $\bigoplus_{i=1}^r\mathcal{O}(a_i)$ for a unique non-decreasing sequence of integers $a_1,\ldots,a_r$.

Proof: Use induction on r. The $r=1$ case follows from(5.5.3.16). For a general r, let $\mathcal{E}\in\mathfrak{Coh}^{\text{free},r}(\mathbb{P}^1_k)$, then $\mathcal{E}(m)$ is generated by global sections for m large as $\mathcal{O}_{\mathbb{P}^1}$ is ample, and $H^0(\mathcal{E}(-m))=H^1(\mathcal{E}^\vee(m))=0$ by Serre duality and(5.7.2.5), so there is a maximal m s.t. there is a non-zero map $\mathcal{O}(m)\to\mathcal{E}$. The image of this map is also locally free and has degree$\geq m$ by(5.11.2.8), so it must has degree m and $\mathcal{O}_X(m)\to\mathcal{E}$ is injective by(5.11.2.8). Now the cokernel $\mathcal{F}$ is also locally free, because otherwise let $\mathcal{F}_{\text{tor}}$ be the torsion part of $\mathcal{F}$(5.11.2.16), and let $\mathcal{N}$ be the inverse image of $\mathcal{F}_{\text{tor}}$ in $\mathcal{E}$, then it is locally free thus invertible, and $\mathcal{O}(m)\hookrightarrow\mathcal{N}$, so $N=\mathcal{O}(m)$ by(5.11.2.8), and $\mathcal{F}_{\text{tor}}=0$.

There is an exact sequence

$$0\to\mathcal{O}(-1)\to\mathcal{E}(-m-1)\to\mathcal{F}(-m-1)\to 0$$

which induces $H^0(\mathcal{E}(-m-1))=H^0(\mathcal{F}(-m-1))=0$ as $H^1(\mathbb{P}^1_k,\mathcal{O}(-1))=0$, so by induction hypothesis $\mathcal{F}=\oplus_{i=1}^{r-1}\mathcal{O}(a_i)$ and $a_i\leq m$. To show this sequence splits, notice $\mathrm{Ext}^1(\mathcal{F}(-m-1),\mathcal{O}(-1))=\oplus_{i=1}^{r-1}H^1(\mathcal{O}(m-a_i))=0$. □

Prop. (5.5.1.30) [Splitting Principal]. Let X be an integral scheme and $\mathcal{E}\in\mathfrak{Coh}^{\text{free}}(X)$, then there exists a modification $X'\to X$ s.t. $f^*\mathcal{E}$ has a filtration by invertible sheaves.

Proof: Use induction on $\mathrm{rank}(\mathcal{E})$. If $\mathrm{rank}(\mathcal{E})\leq 1$, this is trivial, otherwise let $\mathrm{rank}(\mathcal{E})=r$, $P=\mathbf{P}(\mathcal{E})$, then $\pi:P\to X$ is proper and there is a canonical surjection $\pi^*\mathcal{E}\to\mathcal{O}_P(1)$, with kernel in $\mathfrak{Coh}^{\text{free},r-1}(P)$. Let U be an open subset of X s.t. E is trivial, then $\pi^{-1}(U)\cong\mathbb{P}^{r-1}_U$. Let $s:U\to\mathbb{P}^{r-1}(U)$ be a section, and let X' be the scheme-theoretic closure of U, which is integral. Then $X'\to X$ is proper and thus a modification. Now $f^*\mathcal{E}$ has an invertible quotient, and we are done by induction hypothesis. □

Coherent Sheaves

Prop. (5.5.1.31) [$\mathfrak{Coh}(X)$]. The category of coherent sheaves on a scheme X is denoted by $\mathfrak{Coh}(X)$. When $\mathcal{O}_X \in \mathfrak{Coh}(X)$, $\mathfrak{Coh}(X) = \mathfrak{QCoh}^{\mathrm{pf}}(X)$(5.2.2.28).

In particular when X is locally Noetherian, $\mathfrak{Coh}(X) = \mathfrak{QCoh}^{\mathrm{ft}}(X)$. And the notion of coherence are used usually only when X is locally Noetherian.

(Quasi-)coherence is an affine local property by(5.2.2.30). $\mathfrak{QCoh}(X)$ is an Abelian category, by(5.2.2.28).

Lemma (5.5.1.32). If f is finite, then f_* maps coherent sheaves to coherent sheaves.

Proof: This is trivial. □

Prop. (5.5.1.33) [Proper Pushforward]. If f is a proper morphism between locally Noetherian schemes, then f_* maps coherent sheaves to coherent sheaves.

Proof: Immediate from Grothendieck's coherence theorem(5.7.4.11). □

Prop. (5.5.1.34) [Artin-Rees]. Let X be a Noetherian scheme, $\mathcal{F}$ a coherent $\mathcal{O}_X$-module, $\mathcal{G}$ a Qco subsheaf of $\mathcal{F}$, $\mathcal{I} \subset \mathcal{O}_X$ a Qco sheaf of ideals, then there exists some $c > 0$ that for all $n \geq c$

$$\mathcal{I}^{n-c}(\mathcal{I}^c\mathcal{F} \cap \mathcal{G}) = \mathcal{I}^n\mathcal{F} \cap \mathcal{G}.$$

Proof: Cover X by f.m. affine open subsets, then this follows from the affine case(4.2.2.13). □

Cor. (5.5.1.35) [Vanish Analytically]. Let X be a Noetherian scheme, $\mathcal{F}$ a coherent $\mathcal{O}_X$-module, for any element $f \in \bigcap_n \mathfrak{m}_x^n\mathcal{F}$, f vanishes at a nbhd of x.

Proof: This follows from the intersection theorem(4.2.2.14). □

Prop. (5.5.1.36) [Deligne]. On a Noetherian scheme X, let $\mathcal{F}$ be a Qco sheaf, $\mathcal{G}$ be a coherent sheaf and $\mathcal{I}$ be a Qco sheaf of ideals correspongding to Z, $U = X - Z$, then we have

$$\varinjlim \mathrm{Hom}_{\mathcal{O}_X}(\mathcal{I}^n\mathcal{G}, \mathcal{F}) \cong \mathrm{Hom}_{\mathcal{O}_U}(\mathcal{G}|_U, \mathcal{F}|_U).$$

In particular,

$$\varinjlim \mathrm{Hom}_{\mathcal{O}_X}(\mathcal{I}^n, \mathcal{F}) \cong \Gamma(U, \mathcal{F}).$$

Proof: Cf.[Sta]01YB. □

Prop. (5.5.1.37) [Kleinmann]. If X is a Noetherian integral separated locally factorial scheme, then every coherent sheaf on X is a quotient of a finite locally free sheaf.

Proof: Cf.[Hartshorne P238].**?** □

Prop. (5.5.1.38) [Support of Modules]. For $X \in \mathcal{S}ch$ and $\mathcal{F} \in \mathfrak{QCoh}^{\mathrm{ft}}(X)$, the support(5.2.2.2) $\mathrm{Supp}(\mathcal{F})$ is closed by(5.2.2.24).

For a flat morphism f, $\mathrm{Supp}(f^*(\mathcal{F})) = f^{-1}(\mathrm{Supp}\,\mathcal{F})$, by(5.2.2.18).

Proof: because affine locally, for a set of generators x_i of M, $\mathrm{Ann}(\mathcal{F}) = \cup\,\mathrm{Ann}(x_i)$, and $Ann(x_i)$ is closed. □

Cor. (5.5.1.39). Any coherent sheaf on an integral scheme is locally free over a dense open subset.

Cor. (5.5.1.40)[Geometric Nakayama]. If $\mathcal{F} \in \mathfrak{QCoh}^{\mathrm{ft}}(X)$ and for some $p \in U \subset X$ and $a_1, \ldots, a_n \in \mathcal{F}(U)$ generate $\mathcal{F}_p \otimes k(p)$, then there is an affine nbhd $V \subset U$ that $a_1, \ldots, a_n$ generate $\mathcal{F}(V)$.

Cor. (5.5.1.41) [Upper-Semicontinuity of Ranks]. For a Qco sheaf $\mathcal{F}$ of f.t. over X, the rank function $p \mapsto \mathrm{rank}_p(\mathcal{F})$ is an upper semicontinuous function on X.

Proof: By Nakayama, $\varphi(y)$ is equal to the minimal number of generators of the $\mathcal{O}_y$-module $\mathcal{F}_y$. But these generators extends to a nbhd of y, so $\varphi \leq n$ on this nbhd. □

Def. (5.5.1.42)[Schematic Support]. Let X be a scheme and $\mathcal{F}$ a Qco sheaf of f.t. over X, then the **annihilating ideal** is the ideal $\mathcal{I} \subset \mathcal{O}_X$ that is affine-locally defined by $\mathrm{Ann}(\mathcal{F}(U)) \subset \mathcal{O}_X(U)$, and the **schematic support** $\mathrm{Supp}(\mathcal{F})$ of $\mathcal{F}$ is the closed subscheme of X corresponding to $\mathrm{Ann}(\mathcal{F})$.

Prop. (5.5.1.43). Let $\mathcal{F}$ be a Qco sheaf of f.t. over a reduced scheme that the rank function $\mathrm{rank}_p(\mathcal{F})$ is locally constant, then it is locally free.

Proof: Let $\mathrm{rank}_p(\mathcal{F}) = n$, by(5.5.1.38), for any $x \in X$, there exists an affine nbhd $U = \mathrm{Spec}\, A$ of x and a surjection $f : \mathcal{O}_U^n \to \mathcal{F}_U$. Consider the kernel of f. If $(r_1, \ldots, r_n)$ is in the kernel and $r_1 \neq 0$, then $r_1 \notin \mathfrak{p}$ for some prime $\mathfrak{p}$ of A, as A is reduced. Then $\mathrm{rank}_{x_\mathfrak{p}}(\mathcal{F}) < n$, contradiction. □

Torsion-Free Sheaves

Def. (5.5.1.44)[Torsion Sheaves]. Let X be an integral scheme, then a **torsion sheaf** is a Qco sheaf that its stalk at the generic point of X vanishes. Equivalently, for any affine open $U \subset X$, $\mathcal{F}(U)$ is a torsion $O_X(U)$-module.

Prop. (5.5.1.45). Any

Prop. (5.5.1.46). A torsion $\mathcal{O}_X$-module of f.t. on an integral scheme vanish on a dense open subset.

Prop. (5.5.1.47). For X integral, any $\mathcal{F} \in \mathfrak{QCoh}(X)$ factors as $0 \to \mathcal{F}_{\mathrm{tor}} \to \mathcal{F} \to \mathcal{F}_{tf} \to 0$, where $\mathcal{F}$ is a torsion sheaf(5.5.1.44) and $\mathcal{F}_{tf}$ is Qco and torsion-free.

Cor. (5.5.1.48). The subpresheaf $U \mapsto \{s \in \mathcal{F}(U) | s_\eta = 0\}$ is a sheaf, and it is also Qco as on an affine open $U \subset X$, it is just $\mathcal{F}(U)_{\mathrm{tor}}$. So the quotient is clearly Qco and torsion-free.

Devissage of Coherent Sheaves

Lemma (5.5.1.49). Let X be a Noetherian scheme and $\mathcal{F} \in \mathfrak{Coh}(X)$, let $\mathcal{I}$ be a sheaf of ideals that correspond to Z, then $\mathrm{Supp}(\mathcal{F}) \subset Z$ iff $\mathcal{I}^n \mathcal{F} = 0$ for some n. (This follows easily from Noetherian and(4.2.5.8)).

Lemma (5.5.1.50). Let X be a Noetherian scheme and $\mathcal{F} \in \mathfrak{Coh}(X)$ s.t. $\mathrm{Supp}(\mathcal{F}) = Z_1 \cup Z_2$ where Z_1, Z_2 are closed, then there is an exact sequence of coherent sheaves $0 \to \mathcal{G}_1 \to \mathcal{F} \to \mathcal{G}_2 \to 0$ that $\mathrm{Supp}(\mathcal{G}_i) \subset Z_i$.

Proof: Let $\mathcal{I}$ be the ideal defining the induced reduced structure of Z_2, we use the exact sequence $0 \to \mathcal{I}^n \mathcal{F} \to \mathcal{F} \to \mathrm{Coker} \to 0$ and use (5.5.1.49) on $X \backslash Z_2$ to find n large that $\mathrm{Supp}(\mathcal{I}^n \mathcal{F}) \subset Z_1$, and notice Coker has support in Z_2. □

Lemma (5.5.1.51). Let X be an integral scheme and $Z \subset X$ an integral closed subscheme with generic point Z. If $\mathcal{F} \in \mathfrak{Coh}(X)$ satisfies $\mathcal{F}_\xi$ is annihilated by $\mathfrak{m}_\xi$, then there exists some $r \geq 0$ and sheaf of ideals $\mathcal{I}$ on Z and an injection $i_*(\mathcal{I}^{\oplus r}) \hookrightarrow \mathcal{F}$ that is an isomorphism at ξ.

Proof: Cf.[Sta]01YE. □

Prop. (5.5.1.52). Let X be a Noetherian scheme and $\mathcal{F} \in \mathfrak{Coh}(X)$, then there is a filtration of coherent sheaves that the quotients are pushforward of ideal sheaves on integral subschemes of X. This is analogous to the filtration in the module case.

Proof: We consider the set of these counterexamples and their Supp, then use Noetherian induction. The minimal one Z is irreducible, otherwise from(5.5.1.50) we find a filtration for it. Let the ideal of sheaf of the induced reduced structure of Z be $\mathcal{I}$, then $\mathcal{I}^n\mathcal{F} = 0$ for some n by(5.5.1.49), then we may assume $\mathcal{I}\mathcal{F} = 0$. Then we use(5.5.1.51) to finish the proof. □

Cor. (5.5.1.53) [Basic Devissage]. Let X be a Noetherian scheme and P be a property of coherent sheaves on X s.t.

(1) for an exact sequence of sheaves:$0 \to \mathcal{F}_1 \to \mathcal{F} \to \mathcal{F}_2 \to 0$, if $\mathcal{F}_i$ has P, then $\mathcal{F}$ has P.

(2) for any integral closed subscheme $i : Z \subset X$ and any Qco sheaf of ideals $\mathcal{I}$ on Z, P holds for $i_*\mathcal{I}$.

then P holds for any coherent sheaf of X.

Lemma (5.5.1.54). Cf.[Sta]01YH.

Prop. (5.5.1.55) [Devissage of Coherent Sheaves I]. Let X be a Noetherian scheme and P be a property of coherent sheaves on X s.t.

(1) for an exact sequence $0 \to \mathcal{F}_1 \to \mathcal{F} \to \mathcal{F}_2 \to 0 \in \mathfrak{Coh}(X)$, if two of them have P, then the third also has P.

(2) For every integral closed subscheme Z of X with generic point ξ, there is a $\mathcal{G} \in \mathfrak{Coh}(X)$ that

(a) $\operatorname{Supp} \mathcal{G} = Z$.

(b) $\mathcal{G}_\xi \cong \mathcal{O}_X/\mathfrak{m}_x$.

(c) P holds for $\mathcal{G}$.

Then P holds for every coherent sheaf on X.

Proof: Suppose otherwise, let Z be the minimal couterexample of item2 of(5.5.1.55). Then it is easily seen that P holds for any $\mathcal{F}$ with support strictly contained in $\mathbb{Z}$. Then take $\mathcal{G}$ as in item2, and let $0 \to i_*(\mathcal{I}^{\oplus r}) \hookrightarrow \mathcal{G} \to \text{Coker} \to 0$, then Supp(Coker) is strictly contained in Z, and $r = 1$ by hypothesis, so $i_*(\mathcal{I})$. Then for any other sheaf of ideals $\mathcal{I}'$ on Z, if $\mathcal{I}'$ is supported on a smaller subscheme, then it has P, otherwise there are two exact sequences

$$0 \to i_*\mathcal{I} \to i_*(\mathcal{I} + \mathcal{I}') \to \mathcal{Q} \to 0,$$

$$0 \to i_*\mathcal{I}' \to i_*(\mathcal{I} + \mathcal{I}') \to \mathcal{Q} \to 0,$$

where $\mathcal{I}, \mathcal{Q}$ are supported on smaller subschemes, so P also holds for $\mathcal{I}'$. □

Prop. (5.5.1.56) [Devissage of Coherent Sheaves II]. Let X be a Noetherian scheme and P be a property of coherent sheaves on X s.t.

(1) for an exact sequence of sheaves:$0 \to \mathcal{F}_1 \to \mathcal{F} \to \mathcal{F}_2 \to 0$, if $\mathcal{F}_i$ has P, then $\mathcal{F}$ has P.

(2) If $\mathcal{F}^{\oplus r}$ has P, then $\mathcal{F}$ has P.

(3) For every integral closed subscheme Z of X with generic point ξ, there is a $\mathcal{G} \in \mathfrak{Coh}(X)$ that

(a) $\mathrm{Supp}\,\mathcal{G} = Z$.
(b) $\mathcal{G}_\xi$ is annihilated by $\mathfrak{m}_\xi$.
(c) For every sheaf of ideals $\mathcal{I}$ on X that $\mathcal{I}_\xi = \mathcal{O}_{X,\xi}$, there is a Qco subsheaf $\mathcal{G}' \subset \mathcal{I}\mathcal{G}$ that $\mathcal{G}'_\xi = \mathcal{G}_\xi$ and P holds for $\mathcal{G}'$.

Then P holds for every coherent sheaf on X.

Proof: Cf.[Sta]01YM. □

2 Projective Spaces

Prop. (5.5.2.1). For any graded ideal $I \subset S$, $V_+(I) = \varnothing$ iff $S_+ \subset \sqrt{I}$.

Proof: □

Def. (5.5.2.2) [Projective Schemes]. For a graded ring S, we have a scheme $\mathrm{Proj}(S)$ that consists of homogenous primes of S minus S_+ and the affine cover is $D(f) = \{p|f \not\subseteq p\}$, and $\mathcal{O}(D(f)) = \mathrm{Spec}\,S_{(f)}$, where $S_{(T)}$ is the degree zero part of $T^{-1}S$. It has $\mathcal{O}_p = S_{(p)}$.

Proof: Cf.[Sta]01M5**?** □

Cor. (5.5.2.3). For any graded ring S, $\mathrm{Proj}(S)$ is a separated scheme.

Proof: Check that for standard affine opens $D_+(f)$ and $D_+(g)$, $D_+(f) \cap D_+(g) = D_+(fg)$ is affine open, and $S_{(f)} \otimes_{\mathbb{Z}} S_{(g)} \to S_{(fg)}$ is surjective, which are both clear. □

Prop. (5.5.2.4)[Representing Functor of Projective Schemes]. Let S be a graded ring generated by S_1 over S_0, then $\mathrm{Proj}(S)$ represents the functor that maps a scheme Y to the set of pairs $(\mathcal{L}, \psi)$, where $\mathcal{L}$ is an invertible sheaf on Y, and $\psi : S \to \Gamma_*(Y, \mathcal{L})$ is a graded ring homomorphism that $\mathcal{L}$ is generated by the global sections $\psi(S_1)$, up to strict equivalences.

Proof: Cf.[Sta]01NA. □

Prop. (5.5.2.5)[Associated Qco Sheaves]. Let M be a graded S-module, then

- there is a unique Qco sheaf $\widetilde{M} \in \mathfrak{QCoh}(\mathrm{Proj}(S))$ s.t. $\Gamma(D_+(f), \widetilde{M}) = M_f$ and the restrictions are compatible with base changes..
- For a point $x \in \mathrm{Proj}(S)$ corresponding to a homogenous prime not containing S_+, $\widetilde{M}_x = M_{(p)}$.
- $M \mapsto \widetilde{M}$ is an exact functor from the category of graded S-modules to $\mathfrak{QCoh}(\mathrm{Proj}(S))$.
- There is a canonical ring map $S_0 \to \Gamma(\mathrm{Proj}(S), \mathcal{O}_{\mathrm{Proj}_S})$ and canonical S_0-module map $M_0 \to \Gamma(\mathrm{Proj}(S), \widetilde{M})$.

Proof: **?**
4: This follows from the fact short exact sequences can be checked on stalks, and item2. □

Cor. (5.5.2.6). There is a canonical morphism of schemes $\mathrm{Proj}(S) \to \mathrm{Spec}\,S_0$.

Prop. (5.5.2.7). If $X \subset \mathbb{P}^n_k$ is a closed subvariety disjoint from a d-dimensional subspace $L \subset \mathbb{P}^n_k$, then the projection $\pi : X \to \mathbb{P}^{n-d-1}$ with center L induces a finite map $X \to \pi(X)$.

Proof: Cf.[Shafarovich 1, P63]. □

Cor. (5.5.2.8). If $F_0, \ldots, F_s$ are forms of degree $m > 0$ on $\mathbb{P}^n_k$ having no common zero on a closed subvariety $X \subset \mathbb{P}^n$, then $\varphi(x) = [F_0(x), \ldots, F_s(x)]$ defines a finite map $\varphi : X \to \varphi(X)$.

Proof: Let $v_m : \mathbb{P}^n \to \mathbb{P}^N$ be the Veronese embedding of degree m, then $X \to v_m(X)$ is an isomorphism, and φ is a composition of v_m and a projection $\mathbb{P}^N_k \to \mathbb{P}^n_s$, thus it is a finite map, by(5.5.2.7). □

Prop. (5.5.2.9) [Tensor and Proj]. For two graded ring with the same $S_0 = A$, $\mathrm{Proj}(S \times_A T) \cong X \times_A Y$, where $(S \times_A T)_n = S_n \times_A T_n$

Proof: □

Def. (5.5.2.10) [Relative Proj]. The **relative Proj** $\mathcal{S}$ over locally Noetherian Y of a Qco graded $\mathcal{O}_Y$-algebra $\mathcal{S}$ f.g. over $\mathcal{S}_0$ by coherent $\mathcal{S}_1$ is the glueing of locally $\mathrm{Proj}\, S$. $\mathrm{Proj}\, \mathcal{S} \to Y$ is locally projective thus proper. It is equipped with invertible sheaf $\mathcal{O}(1)$ by glueing.

Prop. (5.5.2.11) [Closed Subscheme of Projective Scheme]. The closed scheme of $X = \mathbb{P}^n_A$ corresponds to the saturated homogenous ideal $\mathcal{I}_Y$, (i.e. for any s, if there is an n that for any i, $x_i^n s \in \mathcal{I}_Y$, then $s \in I_Y$).

So projective scheme over $\mathrm{Spec}\, S_0$ corresponds to $\mathrm{Proj}\, S$, where S are f.g. over S_0 by S_1 saturated in the sense above.

Proof: A closed immersion is proper, thus the kernel $\mathcal{I}_Y$ of the structural map is a Qco(5.5.1.3), so it must be an ideal on every affine open, because Qco is affine local. Then we should use(5.5.3.6), $\Gamma_*(\mathcal{I}_Y)$ will suffice. Cf.[Hartshorne Ex2.5.10]. □

Prop. (5.5.2.12). The global section of a projective space $\mathrm{Proj}\, S \to \mathrm{Spec}\, S_0$ is just S_0, this is by(5.5.3.6).

Prop. (5.5.2.13). A quasi-projective scheme X over a field k of dimension r can be covered by $r+1$ open affine subsets. This is because there are r hyperplane that intersect X non-empty. This can happen by choosing a hyperplane non-intersecting the generic point of X, otherwise we choose many hyperplane, then their intersection is empty.

Sheaves on Proj

Def. (5.5.2.14) [Serre Twisting Sheaves]. Let S be a graded ring and $X = \mathrm{Proj}(S)$, there are Qco **Serre twisting sheaves** $\mathcal{O}_X(n) = \widetilde{S(n)}$. For $\mathcal{F} \in \mathfrak{QCoh}(\mathrm{Proj}(S))$, the **Serre twisting sheaf** of $\mathcal{F}$ is the sheaf $\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{O}_X(n)$.

Prop. (5.5.2.15). Let S be a graded ring and $X = \mathrm{Proj}(S)$,

1. there are canonical maps
$$\mathcal{O}_X(m) \otimes_{\mathcal{O}_X} \mathcal{O}_X(n) \to \mathcal{O}_X(m+n),$$
inducing a map of graded rings $S \to \Gamma_*(X, \mathcal{O}_X) = \oplus_{n \geq 0} \Gamma(X, \mathcal{O}_X(n))$.
2. For any $\mathcal{F} \in \mathcal{S}\mathrm{h}(\mathcal{O}_X)$, there are canonical maps
$$\mathcal{O}_X(n) \otimes_{\mathcal{O}_X} \mathcal{F} \to \mathcal{F}(n).$$
inducing a map of graded module structure of $\Gamma_*(X, \mathcal{O}_X)$ on $\Gamma_*(X, \mathcal{F}) = \oplus_{n \geq 0} \Gamma(X, \mathcal{F}(n))$.

3. There is a canonical map $\widetilde{\Gamma_*(X,\mathcal{F})} \to \mathcal{F}$ that is identity on global sections.
4. For any graded S-module M, let $M(n) = M \otimes_S S(n)$, there are maps $\widetilde{M}(n) \to \widetilde{M(n)}$. (Use property of Qco sheaves).
5. For graded rings M, N over S, there are canonical maps $\widetilde{M} \otimes_{\mathcal{O}_X} \widetilde{N} \to \widetilde{M \otimes_S N}$.

Proof: □

Prop. (5.5.2.16). Let S be a graded ring s.t. S is generated by S_1 over S_0, then

1. $(M \otimes_S N)_{(f)} \cong M_{(f)} \otimes_{S_{(f)}} N_{(f)}$ for $f \in S_1$.
2. There canonical maps in item1, 4, 5 of(5.5.2.15) are isomorphisms.
3. For a graded ring map $S \to T$, we have the corresponding Proj map $f : U \to T$ that $f^*(\widetilde{M}) \cong \widetilde{(M \otimes_S T)}|_U$ and $f_*(\widetilde{N}|_U) \cong \widetilde{N_S}$. That's to say, $f^*(\widetilde{M}(n)) = f^*(\widetilde{M})(n)$ and $f_*(\widetilde{M}(n)) = f_*(\widetilde{M})(n)$.

Proof: 1:

2: By1 and check locally that tensoring f^n is an isomorphism on $D_+(f)$. □

Cor. (5.5.2.17). $\mathcal{O}_X(n) \otimes \mathcal{O}_X(m) \cong \mathcal{O}_X(n+m)$ for any scheme X projective over Y.

Prop. (5.5.2.18) [Twisting of Proj]. With notation as in (5.5.2.10), Let $S' = S * \mathcal{L} : S'_d = S_d \otimes \mathcal{L}^d$, then $\varphi : \operatorname{Proj} S' \to \operatorname{Proj} S$ is an isomorphism that induces

$$\mathcal{O}'(1) \cong \varphi^*\mathcal{O}(1) \otimes \pi'^*\mathcal{L}.$$

Prop. (5.5.2.19). If Y is Noetherian and admits an ample invertible sheaf, then by definition, we have $S_1 \otimes \mathcal{L}^n$ is base point free for some n, thus we have a morphism $\operatorname{Proj}(S * \mathcal{L}^n) \to \mathbb{P}^N_Y$, so $P = \operatorname{Proj} S$ is H-quasi-projective with $\mathcal{O}(1) = \mathcal{O}_P(1) \otimes \pi^*\mathcal{L}^n$.

Relative Projective Spaces

Def. (5.5.2.20) [Relative Projective Spaces].

Def. (5.5.2.21) [Projective Bundles]. Let S be a scheme, $\pi : V \to S$ is called an **Qco vector bundle** if it is affine, and $\pi_*\mathcal{O}_V$ endowed with the structure of a graded $\mathcal{O}_S$-algebra structure $\pi_*\mathcal{O}_V = \oplus\mathcal{E}_n$, where $\mathcal{E}_0 = \mathcal{O}_S$, and $\operatorname{Sym}^n \mathcal{E}_1 \to \mathcal{E}_n$ is an isomorphism for any n. The category of Qco vector bundles on S is denoted by $\mathcal{V}\mathrm{ect}^{\mathfrak{QCoh}}(S)$.

A morphism of affine bundles is a map $E' \to E$ over S that the associated map $f_* : \pi_*\mathcal{O}_V \to \pi'_*\mathcal{O}_{V'}$ is compatible with grading.

For $\mathcal{E} \in \mathfrak{QCoh}(X)$, we can define the **associated vector bundle** $V(\mathcal{E})$ as $\mathbf{Spec}_S \operatorname{Sym}(\mathcal{E})$(5.2.3.10)(5.2.7.12). In this way, the category of Qco vector bundles over S is anti-equivalent to the category of Qco $\mathcal{O}_S$-algebras.

For $\mathcal{E} \in \mathfrak{QCoh}(X)$, we can define the **associated projective bundle** $\mathbf{P}(\mathcal{E})$ as $\mathbf{Proj}_S \operatorname{Sym}(\mathcal{E})$(5.2.3.10)(5.2.7.12). It is equipped with a Serre twisting sheaf $\mathcal{O}(1)$, which is the glue of locally the Serre sheaf in projective space. There is a surjective morphism $\pi^*(\mathcal{E}) \to \mathcal{O}(1)$ (local check).

Prop. (5.5.2.22). Let $g : Y \to X$ by a scheme over X, a morphism $Y \to \mathbf{P}(\mathcal{E})$ over X is equivalent to an invertible sheaf $\mathcal{L}$ on Y and a surjective map $g^*\mathcal{E} \to \mathcal{L}$.

In particular, giving a morphism $X \to \mathbf{P}^n_A$ is equivalent to a base point free invertible sheaf with n generators on X.

Proof: If there is a morphism, it will pullback $\pi^*(\mathcal{E}) \to \mathcal{O}(1)$ into $g^*\mathcal{E} \to \mathcal{L}$. For the coverse, construct locally and glue, we have the natural morphisms $A[x_1/x_i, \ldots, x_n/x_i] \to \mathcal{O}_{X_{s_i}} : x_j/x_i \to s_j/s_i$ in a homogenous sense. It is natural hence glue together. For the module, maps $x_i \to s_i$. □

Cor. (5.5.2.23). All automorphisms of $\mathbb{P}^n_k$ is linear.

Proof: The Picard group of $\mathbb{P}^n_k$ is $\mathbb{Z}$ and is generated by $\mathcal{O}(1)$(5.5.3.16), so the automorphism will map $\mathcal{O}(1)$ to $\mathcal{O}(\pm 1)$ and $\mathcal{O}(-1)$ has no global section(5.5.3.5). And the globals section is n-dimensional and determines the morphism by the prop. □

Def. (5.5.2.24) [Projective Space]. Let A be a ring, the **projective space** $\mathbb{P}^n_A$ is defined to be

$$\mathbf{P}^n_A = \mathrm{Proj}(A[T_0, \ldots, T_n])$$

with $\deg(T_i) = 1$. It represents the functor that maps a scheme T to the equivalence classes of pairs $(\mathcal{L}, (s_0, \ldots, s_n))$, where $\mathcal{L}$ is an invertible sheaf on T, and $s_0, \ldots, s_n \in \Gamma(T, \mathcal{L})$ that generate $\mathcal{L}$ by(5.5.2.22). For any scheme S, $\mathbf{P}^n \times_{\mathbb{Z}} S$ is called the projective space over S.

Prop. (5.5.2.25). Let R be a ring and $X = \mathbb{P}^n_R$, $\mathcal{F} \in \mathfrak{QCoh}(X)$, then the canonical map $\widetilde{\Gamma_*(X, \mathcal{F})} \to \mathcal{F}$(5.5.2.15) is an isomorphism.

Proof: Cf.[Sta]03GM.**?** This is a corollary. □

Prop. (5.5.2.26) [Closed Subschemes of $\mathbb{P}^n_R$]. Let Z be a closed subscheme of $\mathbb{P}^n_R$, then it is of the form

$$Z = \mathrm{Proj}(R[X_0, \ldots, X_n]/I) \subset \mathrm{Proj}(R[X_0, \ldots, X_n])$$

where $I = \oplus I_n$ and $I_n = \ker(R[X_0, \ldots, X_n]_d \to \Gamma(Z, \mathcal{O}_Z(d)))$.

Proof: Cf.[Sta]03GI.**?** □

Prop. (5.5.2.27) [Segre Embedding]. Let S be a scheme, there is a natural closed immersion

$$\mathbf{P}^m_S \times_S \mathbf{P}^n_S \to \mathbf{P}^{mn+m+n}_S$$

called the **Segre embedding**.

Proof: It suffices to a prove for $S = \mathbb{Z}$, and in this case, it suffices to write down an invertible sheaf on $\mathbf{P}^m_S \times_S \mathbf{P}^n_S$ with $(n+1)(m+1)$ global sections that generate it. Then we take the invertible sheaf $\mathcal{L} = \pi_1^*\mathcal{O}_{\mathbf{P}^m}(1) \otimes \pi_2^*\mathcal{O}_{\mathbf{P}^n}(1)$. and the sections X_iY_j, where $(X_0, \ldots, X_m)$ generate $\mathcal{O}_{\mathbf{P}^m}(1)$ and $(Y_0, \ldots, Y_n)$ generate $\mathcal{O}_{\mathbf{P}^n}(1)$.

It is a closed immersion by[Sta]01WD.**?** □

Prop. (5.5.2.28) [Venerose Embedding].

3 Invertible Sheaves

General invertible sheaves on a ringed site is treated in5.

Prop. (5.5.3.1) [Faithfully Flat Descent]. To show a quasi-coherent sheaf is a line bundle, it suffices to show fpqc-locally, by(4.4.2.1).

Def. (5.5.3.2) [Basepoint-Freene Line Bundles]. Let $\mathcal{L}$ be a line bundle over a scheme X over a field k, then it is called **basepoint free** if the intersections $\{\mathrm{div}(s)|s \in H^0(V)\}$ is empty.

Prop. (5.5.3.3). If X is qcqs over a field k and K/k is a field extension, then $\mathcal{L}$ is basepoint free iff $\mathcal{L}_K$ is basepoint free over X_K.

Proof: By flat base change(5.7.5.1), $H^0(X_K, \mathcal{L}_K) = H^0(X, \mathcal{L}) \otimes_k K$. □

Prop. (5.5.3.4) [Relative Triviality]. Let $f : X \to Y$ be a finite morphism of schemes and $\mathcal{L} \in \mathrm{Pic}(X)$, then for any $y \in Y$, there exists a nbhd U of $y \in Y$ s.t. $\mathcal{L}|_{f^{-1}(U)}$ is trivial.

Proof: Cf.[Sta]0BUT. □

Prop. (5.5.3.5)[Global Sections]. Let $\mathcal{L}$ be an invertible sheaf over qcqs scheme X, for $\mathcal{F} \in \mathfrak{QCoh}(X)$, let the **global section functor** $\Gamma_*(\mathcal{F}) = \oplus\Gamma(X, \mathcal{F} \otimes \mathcal{L}^n)$, then

$$\Gamma_*(\mathcal{F})_{(f)} \cong \mathcal{F}(X_f).$$

where $s \in \Gamma(X, \mathcal{L})$. In particular that if there is a section f of $\mathcal{F}$ on X_s, then for some n, $f \otimes s^n$ is a global section of $\mathcal{F} \otimes \mathcal{L}^n$.

Proof: This is nearly the same as the proof that $(\mathrm{Spec}\, A)_f = \mathrm{Spec}\, A_f$, Cf.[Sta]01PW.**?** □

Cor. (5.5.3.6). When $X = \mathrm{Proj}\, S$ projective over $\mathrm{Spec}\, S_0$ and $\mathcal{F} \in \mathfrak{QCoh}(X)$, $\widetilde{\Gamma_*(\mathcal{F})} \cong \mathcal{F}$, where $\Gamma_*(\mathcal{F}) = \oplus_{n\in\mathbb{Z}}\Gamma(X, \mathcal{F}(n))$, which is a graded S-module. In particular, Γ_* for projective space $\mathbb{P}^n_A$ equals $A[x_1, \ldots, x_n]$.

Def. (5.5.3.7) [Regular Sections].

Prop. (5.5.3.8) [Complete Series]. Let $H^0(X, \mathcal{L})$ be the sections that corresponds to injective maps $\mathcal{L}^{-1} \to \mathcal{O}_X$, then there is a canonical isomorphism

$$H^0(X, \mathcal{L})_{reg}/H^*(X, \mathcal{O}_X^*) \cong |\mathcal{L}|.$$

Notice when X is not integral, $H^0(X, \mathcal{L})_{reg}$ may not equal $H^0(X, \mathcal{L})$.

Proof: Cf.[Kle05]P22. □

Prop. (5.5.3.9)[Meromorphic Sections]. Let X be a locally Noetherian scheme having no embedded points, then every invertible sheaf $\mathcal{L} \in \mathrm{Pic}(X)$ has a meromorphic section. In particular, this applies for X integral, by(5.5.1.17).

Proof: Cf.[Sta]0EMI. □

Picard Groups

Remark (5.5.3.10) [Picard Groups]. The Picard group $\mathrm{Pic}(X)$ of a local ringed space $(X, \mathcal{O}_X)$ is defined in(5.2.5.7), and it is isomorphic to $H^1(X, \mathcal{O}_X^*)$ by(5.3.1.17).

Prop. (5.5.3.11) [Class Group]. If $X = \mathrm{Spec}\, \mathcal{O}$ where $\mathcal{O}$ is a Dedekind domain, then by(4.2.7.8), the isomorphism class of invertible sheaves on X is equivalent to the isomorphism class of fractional ideals modulo principle ideals. Thus $\mathrm{Pic}(\mathcal{O})$ equals the class group of $\mathcal{O}$(4.2.7.9). In particular, if R is a UFD, then $\mathrm{Pic}(\mathrm{Spec}\, R) = 0$.

Def. (5.5.3.12) [Invertible Sheaf Associated to Cartier Divisors]. For a Cartier divisor on a scheme X, we can define $\mathcal{O}(D)$ the **Line bundle associated to** D as the sub $\mathcal{O}_X$-module of $\mathcal{K}$ locally generated by (f_i^{-1}), where $D = (f_i)$ locally. Equivalently, it is the line bundle $\mathcal{I}_D^{-1}$.

Def. (5.5.3.13) [Linear Series]. Let $\mathcal{L} \in \mathrm{Pic}(X)$, then denote $|\mathcal{L}|$ the **complete linear series** of effective Cartier divisors D s.t. $\mathcal{L}(D) \cong \mathcal{L}$.

Def. (5.5.3.14) [Weil divisor of an invertible Sheaf]. For X a locally Noetherian integral scheme and $\mathcal{L}$ an invertible sheaf in $\mathcal{K}$, if $s \in \Gamma(X, \mathcal{K} \otimes \mathcal{L})$ is a meromorphic section of $\mathcal{L}$(which exists by(5.5.3.9)), for any prime Weil divisor Z with generic pt η, define $\mathrm{ord}_Z(s) = \mathrm{ord}_{\mathcal{O}_{X,\eta}}(s/s_\eta)$(4.1.2.10), for any s_η a generator of $\mathcal{L}_\eta$ over $\mathcal{O}_{X,\eta}$. This is independent of s_η chosen.

The prime Weil divisors that $\mathrm{ord}_Z(s) \neq 0$ is locally finite, the same as in(7.1.2.18). And any two different sections s_i defines Weil divisors up to a difference of $\mathrm{div}(f)$(7.1.2.18). So we can define the **Weil divisor class associated to** $\mathcal{L}$ as $\sum \mathrm{ord}_Z(s)[Z]$ for any meromorphic section s of $\mathcal{L}$.

It is easy to verify that this induces a homomorphism from $\mathrm{Pic}(X)$ to $\mathrm{Cl}(X)$.

Prop. (5.5.3.15) [Cl-Pic]. For a normal integral locally Noetherian scheme, the above map $\mathrm{Pic}(X) \to \mathrm{Cl}(X)$(5.5.3.14) is an injection. It is an isomorphism iff all local rings of X are UFD.

Explicitly, the inverse image of a prime Weil divisor D is the sheaf $\mathcal{O}_X(D) = \mathcal{H}om(\mathcal{I}_D, \mathcal{O}_X) = \mathcal{I}_D^{-1}$, and there is an exact sequence of sheaves on X:

$$0 \to \mathcal{O}_X(-D) = \mathcal{I}_D \to \mathcal{O}_X \to i_*\mathcal{O}_D \to 0$$

In particular, this applies to non-singular prevarieties over a field k, by(5.4.2.9).

Proof: If it is not injective, then some meromorphic section on $\mathcal{L}$ has no associated Weil divisors, then it suffices to show $\mathcal{L}$ is trivialized by s. Consider on an affine subscheme $\mathrm{Spec}\, A$, then $\mathrm{ord}_{A_\mathfrak{p}}(s) = 0$ for each minimal prime $\mathfrak{p}$ of A, but $A_\mathfrak{p}$ is DVR by(4.3.5.20), so $s \in A_\mathfrak{p}^*$ for each minimal prime $\mathfrak{p}$, so $s \in A^*$ by(4.3.5.11). This shows s trivialize $\mathcal{L}$.

To show it is surjective, it suffices to show any Weil divisor D is in the image: notice D is an effective Cartier divisor by(5.8.1.4), and by definition(5.8.1.5) the vanishing of the canonical section $1_D \in \mathcal{O}_X(D)$ is exactly D. □

Prop. (5.5.3.16) [Examples of Picard Groups].

- If X is a locally Noetherian normal integral separated scheme, then so are $X \times \mathrm{Spec}\,\mathbb{Z}[T]$ and $\mathbb{P}^n_X$, and $\mathrm{Cl}(X \times \mathrm{Spec}\,\mathbb{Z}[T]) = \mathrm{Cl}(X)$ and $\mathrm{Cl}(\mathbb{P}^n_X) = \mathbb{Z} \oplus \mathrm{Cl}(X)$.
- For a UFD R, $\mathrm{Pic}(\mathbb{A}^n_R) \cong \mathrm{Cl}(\mathbb{A}^n_R) = 0$.
- For a UFD R, $\mathrm{Pic}(\mathbb{P}^n_R) \cong \mathrm{Cl}(\mathbb{P}^n_R) \overset{\deg}{\cong} \mathbb{Z}$, and it is generated by $\mathcal{O}_{\mathbb{P}^n_R}(1)$.
- For any UFD R, $\mathrm{Pic}(\mathbb{P}^1_R \times \mathbb{P}^1_R) \cong \mathrm{Cl}(\mathbb{P}^1_R \times \mathbb{P}^1_R) \cong \mathbb{Z} \oplus \mathbb{Z}$.
- If k is a field and $Y \subset \mathbb{P}^n_k$ is a hypersurface of degree d, then $\mathrm{Pic}(\mathbb{P}^n_k \backslash Y) \cong \mathrm{Cl}(\mathbb{P}^n_k \backslash Y) \cong \mathbb{Z}/d\mathbb{Z}$.

Proof: By(5.5.3.15) and(7.1.5.7)(7.1.7.10)(7.1.5.8)(7.1.5.9). □

Prop. (5.5.3.17). Let X be a complete prevariety over a field k of characteristic $p > 0$, then for any n prime to p and any purely inseparable field extension k'/k, the natural map

$$\mathrm{Pic}(X)[n] \to \mathrm{Pic}(X_{\overline{k}})[n]$$

is an isomorphism.

Proof: Cf.[Sta]0CD5. □

4 Ample Invertible Sheaves

Prop. (5.5.4.1). Let $X \in \mathcal{S}\mathrm{ch}$ and $\mathcal{L} \in \mathrm{Pic}(X)$. Then for any affine open $U \subset X$ and a section s of $\mathcal{L}$, $X_s \cap U$ is affine.

Proof: It suffices to show: If R is a ring, N is an invertible R-module and $s \in N$, then $U = \{\mathfrak{p} | s \notin \mathfrak{p}N\}$ is an affine open subset of $\mathrm{Spec}\, R$. For this, let $R' = \varinjlim_{-\otimes s} N^{\otimes n}$, then in fact $U = \mathrm{Spec}\, R'$. Because locally, R' is just R_s via an isomorphism $N_f \cong R_f$. □

Def. (5.5.4.2) [Ample Invertible Sheaves]. On a quasi-compact scheme X, an **ample invertible sheaf** is a line bundle $\mathcal{L} \in \mathrm{Pic}(X)$ s.t. there is some $n \in \mathbb{Z}_+$ and sections $s_i \in \Gamma(X, \mathcal{L}^n)$ that X_{s_i} is an affine cover of X. In particular, an ample invertible sheaf is globally generated.

For a qc morphism $f : X \to Y$, an invertible sheaf on X is called **f-ample** iff it is ample restricted to every open subscheme $f^{-1}(V)$, where V is an affine open in Y. In particular, an invertible sheaf $\mathcal{L}$ on a quasi-compact scheme X is ample iff it is f-ample where $f : X \to \mathrm{Spec}\, Z$.

Prop. (5.5.4.3). An invertible sheaf $\mathcal{L}$ is (f-)ample iff $\mathcal{L}^m$ is (f-)ample.

Prop. (5.5.4.4) [Ample Implies Separatedness]. When there is a f-ample invertible sheaf for $f : X \to Y$ qc, then f is separated. In particular, if there is an ample line bundle over a qc scheme X, then X is separated.

Proof: [Sta]09MP.? □

Prop. (5.5.4.5) [Characterizing Ampleness]. Let X be a qc scheme and $\mathcal{L}$ be an invertible sheaf on X, $S = \Gamma_*(X, \mathcal{L})$, then the following are equivalent:

1. $\mathcal{L}$ is ample.
2. The open subsets X_s, where $s \in \Gamma_*(X, \mathcal{L})$ homogeneous, cover X, and the associated morphism $X \to \mathrm{Proj}\, S$ is an open immersion.
3. The open subsets X_s where $s \in \Gamma_*(X, \mathcal{L})$ homogeneous, form a topological basis for X.
4. The open subsets X_s that is affine and where $s \in \Gamma_*(X, \mathcal{L})$ homogeneous, form a topological basis for X.
5. For any Qco sheaf $\mathcal{F}$ on X, the sum of images of the canonical maps $\Gamma(X, \mathcal{F} \otimes \mathcal{L}^n) \otimes \mathcal{L}^{\otimes -n} \to \mathcal{F}$ is surjective.
6. X is quasi-separated, and for any Qco sheaf $\mathcal{F}$ on X of f.t., $\mathcal{F} \otimes \mathcal{L}^{\otimes n}$ is generated by global sections for n sufficiently large.
7. X is quasi-separated, and for any Qco sheaf $\mathcal{F}$ on X of f.t., there exists an integer n that $\mathcal{F}$ is a quotient of a direct sum of f.m. copies of $\mathcal{L}^{\otimes -n}$.

Proof: Cf.[Sta]01Q3.? □

Cor. (5.5.4.6). The pullback of an ample invertible sheaf along a qc immersion is an ample invertible sheaf.

Cor. (5.5.4.7). Let S be a quasi-separated scheme and X, Y be schemes over S. If $\mathcal{L}$ is an ample invertible sheaf over X and $\mathcal{N}$ an ample invertible sheaf over Y, then $\mathcal{M} = \mathrm{pr}_1^* \mathcal{L} \otimes_{\mathcal{O}_{X \times_S Y}} \mathrm{pr}_2^* \mathcal{N}$ is ample over $X \times_S Y$.

Proof: Because $X \times_S Y \to X \times Y$ is a qc immersion, by(5.5.4.6), it suffices to show for $S = \mathrm{Spec}\, Z$. Then if X_s is an affine nbhd of x and Y_t is an affine nbhd of Y, then $(X \times Y)_{\pi_1^* s \otimes \pi_2^* t}$ is an affine nbhd of $x \times y$. □

Cor. (5.5.4.8)[Tensor Product of Ample Invertible Sheaves is Ample]. If M an invertible sheaf generated by global sections and $\mathcal{L}$ is an ample invertible sheaf, then $\mathcal{L} \otimes \mathcal{M}$ is ample. In particular if $\mathcal{L}, \mathcal{M}$ are ample invertible sheaves, then $\mathcal{L} \otimes \mathcal{M}$ is ample.

Proof: For any $x \in X$ and U a nbhd of x, choose $s \in \Gamma(X, \mathcal{L}^n)$ that $x \in X_s \subset U$, and choose $t \in \Gamma(X, \mathcal{M})$ that $t_x \neq 0$, then $x \in X_{s \otimes t^n} \subset U$, thus X_r form a basis for X where $r \in \Gamma(X, (\mathcal{L} \otimes \mathcal{M})^n)$, so $\mathcal{L} \otimes \mathcal{M}$ is ample. □

Cor. (5.5.4.9). If $\mathcal{L}$ is ample and $\mathcal{M}$ is an invertible sheaf, then $\mathcal{M} \otimes \mathcal{L}^{\otimes n}$ is ample for n sufficiently large.

Proof: This is because $\mathcal{L} \otimes \mathcal{M}^n$ is generated by global sections for n sufficiently large, thus $\mathcal{L} \otimes \mathcal{M}^{n+1}$ is ample, by(5.5.4.8). □

Prop. (5.5.4.10)[Gluing Ample Invertible Sheaves]. Let X be a qc scheme s.t. there is an affine open covering of the form X_{s_i} where s_i are sections of $\mathcal{L}_i$ and $\mathcal{L}_i$ are globally generated line bundles in $\mathrm{Pic}(X)$, then X has an ample line bundle.

Proof: Let X_{s_i} be an affine open covering of X where s_i are sections of globally generated invertible sheaves $\mathcal{L}_i$, $i = 1, \ldots, r$. As $\mathcal{L}_i$ are globally generated, let $X = \cup_j X_{t_{ij}}$ for $j = 0, 1, \ldots, m_i$ where $t_{i0} = s_i$. Then for the line bundle $\otimes_i \mathcal{L}_i$, the sections $t_{1,j_1} \otimes \ldots \otimes t_{r,j_r}$ where at least one of j_i equals 0, covers X, and they are all affine by(5.5.4.1). So $\otimes_i \mathcal{L}_i$ is ample. □

Prop. (5.5.4.11). $f : X \to Y$, let $\mathcal{L}$ be f-ample on X and $\mathcal{M}$ ample on Y, then $\mathcal{L} \otimes f^* \mathcal{M}^n$ is ample for n large.

Proof: Cf.[Sta]0892? □

Cor. (5.5.4.12). If $f : X \to Y$ is quasi-affine, then the pullback of an ample invertible sheaf is ample, by(5.4.4.19) and(5.5.4.3).

Prop. (5.5.4.13)[Pullback of Ampleness]. If $f : Y \to X$ is finite and surjective morphism between schemes **proper over a Noetherian affine scheme**, then for any invertible sheaf $\mathcal{L}$ on X, $\mathcal{L}$ is ample iff $f^* \mathcal{L}$ is ample.

Proof: Cf.[Sta]0B5V.?

One direction follows from(5.5.4.12), For the other we use Serre criterion(5.7.2.8) and devissage(5.5.1.56). We only verify 3: By(5.4.4.42), there exists such coherent sheaf $f_* \mathcal{F}$ for any integral subscheme, and for a any Qco sheaf of ideals $\mathcal{I}$, $\mathcal{I} f_* \mathcal{F} = f_*(f^{-1} \mathcal{I} \mathcal{F})$ because f is affine, thus

$$H^p(X, \mathcal{I} f_* \mathcal{F}) = H^p(X, f_*(f^{-1} \mathcal{I} \mathcal{F} \otimes \mathcal{L}^n)) = H^p(Y, f^{-1} \mathcal{I} \mathcal{F} \otimes \mathcal{L}^n)$$

by projection formula, and f is affine. This vanish for n large. □

Cor. (5.5.4.14) [Ampleness and Irreducible Components]. Let X be a scheme proper over a Noetherian affine scheme, then an invertible sheaf $\mathcal{L}$ on X is ample iff it is ample on the induced reduced structure of irreducible components of X.

Proof: This is(5.5.4.13) applied to the case $\coprod_i X_i \to X$. □

Prop. (5.5.4.15) [Ampleness Restricted to Reduced Case]. If $i : Z \to X$ is a closed immersion of schemes that induce homeomorphism on the underlying topology, then $\mathcal{L}$ is ample iff $i^*\mathcal{L}$ is ample.

In particular, this applies to $X_{\mathrm{red}} \to X$.

Proof: Cf.[Sta]09MW.? □

Prop. (5.5.4.16). Let $f : X \to Y$ be a proper morphism of schemes and $\mathcal{L}$ an invertible sheaf on X. If $y \in Y$ satisfies $\mathcal{L}_y$ is ample on X_y, then there is a nbhd U of $y \in Y$ that $\mathcal{L}|_{f^{-1}(U)}$ is f-ample.

Proof: Cf.[Sta]0D2S. □

Prop. (5.5.4.17) [Finite Map and Ample]. Let $\mathcal{L}$ be a basepoint-free line bundle on a proper scheme X, then the associated map $X \to P\Gamma(X, \mathcal{L})$ is finite iff $\mathcal{L}$ is ample.

Proof: Cf.[Positivity in Algebraic Geometry, P28]. □

Prop. (5.5.4.18). Let X be a scheme. Let $\mathcal{L}$ be an ample invertible $\mathcal{O}_X$-module. Let n_0 be an integer. If $H^p(X, \mathcal{L}^{-n}) = 0$ for $n \geq n_0$ and $p > 0$, then X is affine.

Proof: Cf.[Sta]0EBD. □

Prop. (5.5.4.19) [Descent of Ample Line Bundles]. Let K/k be a field extension, X a scheme over k s.t. there exists an ample line bundle on X_K, then X also has an ample line bundle.

Proof: Cf.[Sta]0BDC. □

Very Ample Invertible Sheaves

Def. (5.5.4.20) [Very Ampleness]. Let $f : X \to S$ be a morphism, a **f-very ample** invertible sheaf on X is the pullback of $\mathcal{O}(1)$ along some immersion $X \to \mathrm{Proj}(\mathcal{E})$ for some Qco module $\mathcal{E}$ over Y, Cf.(5.5.2.14). It is called **H-very ample** iff $\mathcal{E}$ is trivial. Notice when X is proper, this immersion must be closed by(5.4.5.3).

When S is affine and $f : X \to S$ is of f.t., f-very ample is equivalent to H-very ample.

Proof: Cf.[Sta]02NP. □

Prop. (5.5.4.21) [Tensor Product of Very Ample Line Bundles]. Let $f : X \to \mathrm{Spec}\, A$ be a morphism. If $\mathcal{L}$ is H-very ample and $\mathcal{M}$ is generated by global sections, then $\mathcal{L} \otimes \mathcal{M}$ is H-very ample. In particular, the tensor product of two H-very ample invertible sheaves is H-very ample.

Proof: The hypothesis means $\mathcal{L} = \varphi^*\mathcal{O}(1)$, where $\varphi : X \to \mathbb{P}^n_A$ is an immersion, and $\mathcal{M} = \psi^*\mathcal{O}(1)$, where $\psi : X \to \mathbb{P}^m_k$ is a morphism. Then the product $T : X \to \mathbb{P}^n_k \times \mathbb{P}^m_k$ is also an immersion, by base change trick(5.4.4.2), as $\mathbb{P}^n_k \times \mathbb{P}^m_k \to \mathbb{P}^n_k$ is separated. Then $S \circ T : X \to \mathbb{P}^{mn+m+n}$, where $S : \mathbb{P}^n_k \times \mathbb{P}^m_k \to \mathbb{P}^{mn+m+n}$ is the Segre embedding, is also an immersion, and $(ST)^*\mathcal{O}(1) \cong \mathcal{L} \otimes \mathcal{M}$, thus it is H-very ample. □

Prop. (5.5.4.22) [Ample and H-Very Ample]. If $f : X \to S$ is locally of f.t. and $\mathcal{L}$ is an ample invertible sheaf on X, then $\mathcal{L}^{\otimes m}$ is H-very ample for m sufficiently large.

Proof: Choose an affine open cover $\{V_i\}$ of S. By(5.5.4.5), there are f.m. affine opens X_{s_i} that cover X refining a inverse image of $\{V_i\}$. Now $\mathcal{O}_X(X_{s_i})$ is f.g. over $\mathcal{O}_S(V_i)$, so we can find f.m. $f_{ij} \in \mathcal{O}_X(X_{s_i})$ that generates it over $\mathcal{O}_S(V_i)$. By(5.5.3.5), we can write each $f_{ij} = s_{ij}/s_i^{e_{ij}}$ for some a_{ij} homogenous. We can multiply by a factor to make all the $s_i^{e_{ij}}$ the same degree N, and $f_{ij} = s_{ij}s_i^{N/\deg(s_i)-e_{ij}}$, then all the elements s_i, s_{ij} generates the invertible sheaf $\mathcal{L}$, thus inducing a map $j : X \to \mathbb{P}^m_k$. This map is an immersion, because $j^{-1}(D(T_i)) = X_{s_i}$ and the function T_{ij}/T_i on $D(T_i)$ pulls back to s_{ij}/s_j. Thus j is locally a closed immersion, thus an immersion.

Now $\mathcal{L}^{\otimes d_1}$ is H-very ample for some d_1, in particular it is separated, and by(5.5.4.5) there is some d_2 that $\mathcal{L}^{\otimes d}$ is generated by global sections for all $d \geq d_2$, then by(5.5.4.21), $\mathcal{L}^{\otimes d}$ is H-very ample for $d \geq d_1 + d_2$. □

Prop. (5.5.4.23) [f-Very Ample Implies f-Ample]. If $f : X \to S$ is qc, then f-very ample implies f-ample.

Proof: Cf.[Sta]01VN.**?** □

Cor. (5.5.4.24) [Serre]. If $f : X \to S$ is of f.t. and S is affine, $\mathcal{L}$ is an invertible sheaf on X, then the following are equivalent:

- $\mathcal{L}$ is ample .
- $\mathcal{L}$ is f-ample.
- $\mathcal{L}^{\otimes n}$ is (H-)f-very ample for some (all large)n.

Proof: This follows from(5.5.4.20)(5.5.4.22) and(5.5.4.23). □

Cor. (5.5.4.25). If $f : X \to S$ is of f.t. and S is qausi-compact, $\mathcal{L}$ is an invertible sheaf on X, then the following are equivalent:

- $\mathcal{L}$ is f-ample.
- $\mathcal{L}^{\otimes n}$ is (H-)f-very ample for some (all large)n.

Proof: Cf.[Sta]01VU. □

5 Sheaf of Differentials

Prop. (5.5.5.1) [Differentials on Schemes]. Consider a morphism of schemes $X \to Y$, we define the sheaf of differentials $\Omega_{X/Y}$ together with an S-derivative $\mathcal{O}_X \to \Omega_{X/S}$ as for ringed sites(5.2.4.7). Then it is a Qco sheaf by(5.2.4.5). In fact, If $U = \operatorname{Spec} A$ is mapped into $\operatorname{Spec} B \subset S$, then $\Omega_{X/S}(U) \cong \widetilde{\Omega_{A/B}}$.

In particular, the stalk of $\Omega_{X/S}$ at a point $x \in X$ is $\Omega_{\mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)}}$.

Thus when $X \to Y$ is locally of f.t.(or locally of f.p.), then $\Omega_{X/S}$ is an $\mathcal{O}_X$-module of f.t.(or of f.p.).

Prop. (5.5.5.2) [Base change and Differentials]. Let $\begin{array}{ccc} X' & \xrightarrow{f} & X \\ \downarrow{\scriptstyle g'} & & \downarrow{\scriptstyle g} \\ S' & \longrightarrow & S \end{array}$ be a commutative diagram of schemes, then there is a canonical map

$$f^*\Omega_{X/S} \to \Omega_{X'/S'}$$

which is an isomorphism if the diagram is a fiber product square.

Proof: Such a diagram gives a diagram $(f^{-1}g^{-1}\mathcal{O}_S \to f^{-1}\mathcal{O}_X) \to ((g')^{-1}(\mathcal{O}_{S'}) \to \mathcal{O}_{X'})$ of sheaves of rings on X'_{Zar}, thus the conclusion follows from(5.2.4.5) and(5.2.7.17). □

Prop. (5.5.5.3). Let X, Y be schemes over another scheme S, then

$$\pi_1^*\Omega_{X/S} \oplus \pi_2^*\Omega_{Y/S} \cong \Omega_{X\times_S Y/S},$$

where the maps are given by(5.5.5.2).

Proof: It suffices to check on affine subschemes, so we may assume X, Y, S are affine, thus the map is given by

$$\Omega_{A/S} \oplus_S B \oplus_{A\otimes_S B} \Omega_{B/S} \otimes_S A \to \Omega_{A\otimes_S B/S}$$

which is an isomorphism by(4.4.3.6). □

Prop. (5.5.5.4). Let X, Y be schemes over another scheme S, then $\Omega_{X\times_S Y/S} \cong \pi_1^*\Omega_{X/S} \otimes \pi_2^*\Omega_{Y/S}$.

Prop. (5.5.5.5) [Jacobi-Zariski Sequence]. Let $f : X \to Y$ and $g : Y \to Z$, then there is an exact sequence of sheaves on X:

$$f^*\Omega_{Y/Z} \to \Omega_{X/Z} \to \Omega_{X/Y} \to 0.$$

Where the maps come from(5.5.5.2).

Proof: Immediate from(4.4.3.8). □

Prop. (5.5.5.6). The stalk of the differential sheaf $\Omega_{X/k}$ at a rational point x of a scheme over a field k is just the Zariski cotangent space $\mathfrak{m}_x/\mathfrak{m}_x^2$(5.6.4.22).

Proof: Using the Jacobi exact sequence(4.4.3.8) on an affine nbhd $\operatorname{Spec} A$ of x for A and $\mathfrak{m}_x$. Then we verified that there is a right inverse of $A/\mathfrak{m}^2 \to k(x) = x$, then it follows that $\mathfrak{m}_x/\mathfrak{m}_x^2 \cong \Omega_{A/k} \otimes_A k(x) = \Omega_{A_{\mathfrak{m}_x}/k}$ which is the stalk of $\Omega_{X/k}$ by(5.5.5.1). □

Prop. (5.5.5.7) [Euler Exact Sequence]. If $X = \mathbb{P}^n_A = \operatorname{Proj}(A[x_0, \ldots, x_n])$ over $Y = \operatorname{Spec} A$, then there is an exact sequence

$$0 \to \Omega_{X/A} \to (\mathcal{O}_X(-1))^{n+1} \to \mathcal{O}_X \to 0.$$

$\Omega_{X/A}$ is locally free by(5.10.1.16), so by taking dual and exterior powers,

$$0 \to \mathcal{O}_X \to \mathcal{O}_X(1)^{n+1} \to \mathcal{T}_X \to 0, \quad \mathcal{K}_X \cong \mathcal{O}_X(-n-1).$$

Proof: Let $S = A[x_0, \ldots, x_n], E = S(-1)^{\oplus n+1}$ with a basis $e_0, \ldots, e_n$, then there is a map of S-graded modules $E \to S$ with kernel M. $E \to S$ is surjective in all dimension≥ 1, so we have an exact sequence

$$0 \to \widetilde{M} \to \widetilde{E} \to \mathcal{O}_X \to 0.$$

Notice $E_{(x_i)} \to S_{(x_i)}$ is given by $e_j \mapsto x_j/x_i$, so $\widetilde{M}|_{D(x_i)}$ is a free sheaf generated by sections $(1/x_i)e_j - (x_j/x_i^2)e_i, j \neq i$. So we can define $\varphi_i : \Omega_{X/A}|_{D(x_i)} \to \widetilde{M}|_{D(x_i)} : d(x_j/x_i) \mapsto (1/x_i)e_j - (x_j/x_i^2)e_i, j \neq i$ mapping isomorphically onto the kernel. It suffices to show this map glue to a map $\Omega_{X/A} \to \widetilde{E}$: On $D(x_ix_j)$, $x_k/x_i = (x_k/x_j) \cdot (x_j/x_i)$, so

$$d(\frac{x_k}{x_i}) - \frac{x_k}{x_j}d(\frac{x_j}{x_i}) = \frac{x_j}{x_i}d(\frac{x_k}{x_j}).$$

Applying φ_i to the LHS and φ_j to the RHS gives the same element $(1/x_i)e_k - (x_k/x_ix_j)e_j$, which shows compatibility. □

Conormal Sheaves

Def. (5.5.5.8) [Conormal Sheaf of an Immersion]. Let $i : Z \to X$ be a closed immersion with corresponding sheaf of ideals $\mathcal{I}$. Consider the Qco sheaf $\mathcal{I}/\mathcal{I}^2$, which is annihilated by $\mathcal{I}$, thus corresponds to a sheaf on Z by(5.2.6.18), called the **conormal sheaf** $\mathcal{C}_{Z/X}$ of Z.

More generally, if i is any immersion, we can define the conormal sheaf as the conormal sheaf of the closed immersion $i : Z \to X \backslash \partial Z$. And also the **normal sheaf** $\mathcal{N}_{Z/X}$ is defined to be $\mathcal{N}_{Z/X} = \mathrm{Hom}_{\mathcal{O}_Z}(\mathcal{I}/\mathcal{I}^2, \mathcal{O}_Z)$.

Prop. (5.5.5.9) [Pullback of Conormal Sheaf]. Let $\begin{array}{ccc} Z' & \xrightarrow{i} & X \\ \downarrow f & & \downarrow g \\ Z' & \xrightarrow{i'} & X' \end{array}$ be a fiber product square where i, i' are immersions, then the canonical map

$$f^*\mathcal{C}_{Z'/X'} \to C_{Z/X}$$

is surjective, and if g is flat, it is an isomorphism.

Proof: Change X' to $X' \backslash \partial Z'$ and X to $X \backslash (g^{-1}\partial Z' \cup \partial Z)$, we may assume i is a closed immersion. Then we may localize to the case X' and X is affine. Then we notice if $R' \to R$ is a ring map and $I' \subset R'$ is an ideal, with $I = I'R$, then $(I'/(I')^2) \otimes_{R'} R \to I/I^2$ is surjective, and if R/R' is flat, then $I \cong I' \otimes_{R'} R$, and the map is an isomorphism. □

Prop. (5.5.5.10). Let $Z \xrightarrow{i} Y \to X$ be immersions of schemes, then there is a canonical exact sequence

$$i^*\mathcal{C}_{Y/X} \to \mathcal{C}_{Z/X} \to \mathcal{C}_{Z/Y} \to 0$$

Proof: By changing Y to $Y \backslash \partial Z$ and X to $X \backslash (\partial(Y \backslash Z))$, we can assume the immersions are closed immersion. Now by restricting to affine subsets, it suffices to show that for surjective ring maps $C \to B \to A$, if $I = \ker(B \to A), J = \ker(C \to A), K = \ker(C \to B)$, then there is an exact sequence

$$K/K^2 \otimes_B A \to J/J^2 \to I/I^2 \to 0.$$

But this follows from the observation $K = \ker(J \to I)$. □

Prop. (5.5.5.11) [Conormal Sheaf of the Diagonal]. Let $f : X \to S$ be a morphism, then there is a canonical isomorphism between $\Omega_{X/S}$ and the conormal sheaf of the diagonal $\Delta : X \to X \otimes_S X$.

Proof: Cf.[Sta]08S2.? □

Cor. (5.5.5.12). If $f : X \to S$ is a monomorphism, e.g. an immersion, then $\Omega_{X/S} = 0$.

Prop. (5.5.5.13). If $f : Z \to X$ is an immersion of schemes over S, then there is an exact sequence of sheaves on Z:

$$\mathcal{C}_{Z/X} \to i^*\Omega_{X/S} \to \Omega_{Z/S} \to 0.$$

Proof: Replace X be $X \backslash \partial Z$, we can assume f is a closed immersion. This follows immediate from(5.2.4.6). □

Prop. (5.5.5.14). If $i : Z \to X$ is an immersion over S that locally has a left inverse, then the canonical sequence

$$0 \to \mathcal{C}_{Z/X} \to i^*\Omega_{X/S} \to \Omega_{Z/S} \to 0.$$

is locally split exact. In particular, if $s : S \to X$ is a section of the structure morphism $X \to S$, then the map $\mathcal{C}_{S/X} \to s^*\Omega_{X/S}$ is an isomorphism.

Proof: Cf.[Sta]0474.**?** □

Prop. (5.5.5.15). Let $\begin{array}{ccc} Z & \xrightarrow{i} & X \\ & \searrow^{j} & \downarrow \\ & & Y \end{array}$ be a commutative diagram where i, j are immersions, then there is a canonical exact sequence

$$\mathcal{C}_{Z/Y} \to \mathcal{C}_{Z/X} \to i^*\Omega_{X/Y} \to 0,$$

where the first arrows comes from(5.5.5.9) and the second map comes from(5.5.5.13).

Proof: By replacing Y by $Y \backslash \partial Z$ and X by $X \backslash (\partial i(Z) \cup \partial j(Z))$, then we may assume i, j are closed immersion. Then we check locally, the exactness follows from(6.1.1.5). □

5.6 More Properties of Schemes

Main references are [Sta].

Notation (5.6.0.1).

- Use notations defined in Properties of Schemes.

1 Finitely Presentedness

Def. (5.6.1.1) [Locally of Finite Presentation]. A morphism between schemes $f : Y \to X$ is called **of locally finite presentation** iff for any point $x \in X$, there is an open affine mapped into an open affine that the ring map is of finite presentation. It is called **of finite presentation** iff moreover it is qcqs.

locally of finite presentation is local on the source and target and it is stable under composition and base change but it doesn't satisfies the base change trick by(5.4.1.6)(5.4.1.5) and(4.3.7.9).

Prop. (5.6.1.2). Open immersion is locally of finite presentation.

Prop. (5.6.1.3). When the target is locally Noetherian, (locally)finite type and (locally)finite presentation is equivalent.

Prop. (5.6.1.4). For $f : X \to Y$ over S, if X/S is locally of f.p. and Y/S is locally of f.t., then f is locally of f.p.. If moreover X is of f.t. and Y is qs, then f is of f.t..

Proof: The first follows from(4.3.7.11), the second needs to check qcqs. Qc follows from(5.4.4.27). □

Prop. (5.6.1.5) [Chevalley]. A qc morphism locally of f.p. maps locally constructible subset to locally constructible subset.

Proof: We prove $f(E) \cap U_i$ is constructible for every U_i affine open in X. The inverse image of U_i is qc, hence a locally constructible set is constructible (3.11.3.10). So we reduce to the affine case(4.1.7.3). □

Cor. (5.6.1.6). As in the proposition, if Y is qc, and the image is dense in Y, then it contains an open dense subset of Y, by(3.11.3.17).

2 Flatness

Def. (5.6.2.1) [Flatness for Schemes]. Flat modules and flat morphisms over schemes are defined in the same way as that of ringed spaces(5.2.2.15).

Prop. (5.6.2.2). Flatness is stalkwise by(5.2.2.17), it is stable under base change and compositions. $\mathcal{F} \in \mathfrak{Coh}(X)$ is flat over X iff it is locally free, by(4.4.1.10)

Thus for $\mathcal{F} \in \mathfrak{QCoh}(X)$, flatness is equivalent to: For any affine open subsets $\operatorname{Spec} A \subset X$, $\Gamma(\operatorname{Spec} A, \mathcal{F})$ is flat over A, because flatness is also stalkwise for modules(4.1.4.2). Similarly, a morphism of schemes $f : X \to Y$ is flat iff for any affine opens $\operatorname{Spec} B \subset X, \operatorname{Spec} A \subset Y$ that $f(\operatorname{Spec} B) \subset \operatorname{Spec} A$, B is flat over A.

Prop. (5.6.2.3). For a flat morphism of ringed space, f^* is exact.

Proof: Because it is f^{-1} followed by tensoring with $\mathcal{O}_X$, check on stalks. □

Prop. (5.6.2.4) [Faithfully Flat Descent for Flat Modules]. Let $f : X \to Y$ be a morphism of schemes over S and $\mathcal{G} \in \mathfrak{QCoh}(Y)$, then $\mathcal{G}$ is flat over S iff $f^*\mathcal{G}$ is flat over S. In particular, Y is flat over S iff X is flat over S.

Proof: This follows from(4.4.1.6). □

Prop. (5.6.2.5). For a Qco sheaf $\mathcal{F}$ on a scheme X, the following are equivalent, by(4.3.1.7).

1. $\mathcal{F}$ is finite projective.
2. $\mathcal{F}$ is f.p. and flat.
3. $\mathcal{F}$ is f.p. and all its localizations at (maximal)primes are free.
4. $\mathcal{F}$ is finite locally free.
5. $\mathcal{F}$ is finite and locally free.
6. $\mathcal{F}$ is finite and all its localizations at primes are free and the function $p \to \dim_{k(p)} \mathcal{F} \otimes_R k(p)$ is a locally constant function on $\operatorname{Spec} R$.

Cor. (5.6.2.6). Let $f : X \to Y$ be a finite morphism of locally Noetherian schemes and Y is reduced, the following are equivalent:

- f is flat.
- $f_*\mathcal{O}_X$ is locally free.
- $\dim_{k(x)}(\pi_*\mathcal{O}_X)_x \otimes k(x)$ is a locally constant function for $x \in Y$.

Proof: 3 follows from(5.5.1.43). □

Prop. (5.6.2.7) [Going-Down]. Generalizations lift along a flat morphism.

Proof: We can find an affine nbhd, then choose a nbhd of the inverse image, then a generalization in an affine open is a true generalization, so it reduce to the affine case. The rest follows from going-down(4.4.1.19). □

Cor. (5.6.2.8) [Flat Map and Irreducible Components]. A flat morphism maps generic points to generic points.

Prop. (5.6.2.9) [Flat Map and Associated Points]. Let $f : X \to S$ be a morphism of schemes that S is locally Noetherian, and $\mathcal{F}$ a Qco sheaf on X. If $\mathcal{F}$ is flat over S, then f maps $WeakAss(\mathcal{F})$ to $Ass(S)$. In particular, if X is flat over S, then f maps $WeakAss(X)$ to $Ass(S)$.

Proof: Let $x \in X, f(x) = s$ that $s \in Ass(S)$, then we get a map $(\mathcal{O}_{S,s}, \mathfrak{m}_s) \to (\mathcal{O}_{X,x}, \mathfrak{m}_x)$. If $\mathfrak{m}_s$ is not associated point, then by prime avoidance(4.1.1.4), there is some $m \in \mathfrak{m}_s$ that is not a non-zero divisor, by(4.2.5.17), so $f^\sharp(m)$ is also a non-zero divisor on $\mathcal{F}_x$, so $\mathfrak{m}_x$ is not a weakly associated point of $\mathcal{F}$. □

Prop. (5.6.2.10) [Flat Map is Open]. A flat morphism locally of f.p. is (universally)open, hence it is qc.

And a qc f.f. morphism of schemes is a quotient map.

Proof: It suffices to consider the affine case. Then the assertion follows from(4.4.1.32).

For the second, by(5.6.2.7), a subset whose inverse image is closed is stable under specialization(surjectiveness used), then it is closed by(5.4.4.9) □

Prop. (5.6.2.11) [Cartier Divisor and Flat Base Change].

- The flat base change of Cartier divisor is also a Cartier divisor.
- The flat base change of a regular embedding is also a regular embedding.
- The flat base change commutes with blow up, by universal property.

Prop. (5.6.2.12) [Flat Pullback of Closed Subschemes]. Let $Z \subset X$ be a closed subscheme corresponding to a Qco sheaf of ideals $\mathcal{I}$, and $f : X' \to X$ be a flat morphism, then the pullback $Z' \subset X'$ is a closed subscheme that corresponds to the ideal sheaf $f^*\mathcal{I}$.

Proof: This is because f^* is exact. □

Prop. (5.6.2.13) [Pullback of Flat Closed Subschemes]. Let X be a scheme over S, $S' \to S$ be a morphism of schemes, and $Z \subset X$ be a closed subscheme corresponding to a Qco sheaf of ideals $\mathcal{I}$ flat over $\mathcal{S}$, then the pullback $Z' \subset X'$ is a closed subscheme that corresponds to the ideal sheaf $f^*\mathcal{I}$.

Prop. (5.6.2.14) [Flat Loci is Open]. For a morphism $f : X \to S$ locally of f.p., and $\mathcal{F} \in \mathfrak{QCoh}^{\mathrm{pf}}(X)$, then the set of points of X that $\mathcal{F}$ is flat over S is open. In particular, if f is a closed map, then the set of points of Y that $\mathcal{F}$ is flat is open.

Proof: Cf.[Sta]00RC.**?**
The last assertion follows from the first one. □

Prop. (5.6.2.15) [Generic Flatness]. For a morphism $f : X \to S$ of f.t., if S is reduced and $\mathcal{F}$ is a Qco f.t. $\mathcal{O}_X$-module, then there exists an open dense subset U of S that $X_U \to U$ is flat, of f.p., and $\mathcal{F}_{X_U}$ is flat over U and of f.p. over $\mathcal{O}_U$.

Proof: As flat and f.p. is local on the base, it suffices to show for S affine. Then this almost immediately reduces to the affine case**??**y choosing an affine cover of X, except that we need X_U to be qs over U. To achieve this, it suffices to do it second time and let $X = \cup_{i\leq n} \operatorname{Spec} B_i = \cup X_i$, and $X_i \cap X_j = D(I_{ij})$, $M_{ij} = B_i/I_{ij}$, then choose f large enough that over S_f, all M_{ij} are f.p. over B_i, then by(4.2.5.9), $X_{i,f} \cap X_{j,f}$ is qc, thus X_f is f.p. over S_f. □

Prop. (5.6.2.16) [Fibral Criterion of flatness]. Let $S \in \mathfrak{Sch}$ and $f : X \to Y$ in $\mathfrak{Sch}/S$, $\mathcal{F} \in \mathfrak{QCoh}^{\mathrm{pf}}(X)$. Let $x \in X, y = f(x)$ and x maps to $s \in S$. Suppose X, Y are both locally Noetherian or X is locally of f.p. over S and Y is locally of f.t. over S, then the following are equivalent:

- $\mathcal{F}$ is flat over S at x and $\mathcal{F}_s$ is flat over Y_s at x.
- Y is flat over S at y and $\mathcal{F}$ is flat over Y at x.

Proof: Cf.[Sta]039B, 039C. □

Prop. (5.6.2.17) [Hilbert Polynomial Constant in Flat Family]. For X/T projective, where T is an integral Noetherian scheme and $X \subset \mathbb{P}^n_T$. Then for each point T, X_t is a closed subscheme of $\mathbb{P}^n_{k(t)}$, so we can consider its Hilbert Polynomial P_t. Then X/T is flat iff P_t is independent of T.

?Needs huge improvement.

Proof: $P_t(m) = \dim_{k(t)} H^0(X_t, \mathcal{O}_{X_t}(m))$ for m large by(5.7.3.10). And we may let $X = \mathbb{P}^n_T$ and prove for any coherent sheaf $\mathcal{F}$. Moreover, we may let T be a affine local Noetherian, because flatness is local and we only need to compare Hilbert polynomial with the generic point. Now we prove a stronger assertion: The following are equivalent:

- $\mathcal{F}$ is flat over T.
- $H^0(X, \mathcal{F}(m))$ is a free A-module of finite rank, for m large.
- The Hilbert polynomial P_t of $\mathcal{F}_t$ on $X_t = \mathbb{P}^n_{k(t)}$ is independent of t.

$1 \to 2$: Use the canonical cover and Čech cohomology, then we notice when m is large, $H^0(X, \mathcal{F}(m))$ is a kernel of the Čech resolution, so it is flat. And it is also finite by(5.7.4.12). Then it is free because it is flat by(4.4.1.10).

$2 \to 1$: Let $M = \oplus_{m \geq m_0} H^0(X, \mathcal{F}(m))$, then $\widetilde{M} = \mathcal{F}$(5.5.3.6), notice that the truncation doesn't affect.

$2 \to 3$: It suffice to prove that for any $t \in T$, when m is large,

$$H^0(X_t, \mathcal{F}_t(m)) \cong H^0(X, \mathcal{F}(m)) \otimes_A k(t).$$

For this, we may use(5.7.5.1) to pass to the localization and assume t is the closed pt of T. Then $A \to k(t)$ is surjective and we may let $A^q \to A \to k \to 0$, then by(5.7.4.8), we have $H^0(X_t, \mathcal{F}_t(m))$ is the cokernel of $H^0(X, \mathcal{F}(m))^q \to H^0(X, \mathcal{F}(m))$, but this cokernel is $H^0(X, \mathcal{F}(m)) \otimes_k$ because tensoring is right-adjoint, so we are done.

$3 \to 2$: We have the rank of $H^0(X, \mathcal{F}(m))$ at the generic and closed point of T are the same(still use $H^0(X_t, \mathcal{F}_t(m)) \cong H^0(X, \mathcal{F}(m)) \otimes_A k(t)$.) Now(4.4.8.1) gives $H^0(X, \mathcal{F}(m))$ is free. It is f.g. automatically. □

Cor. (5.6.2.18). For a flat morphism to a connected scheme T, the dimension, degree, and arithmetic genus of the fibers are independent of t.

Proof: By(5.7.3.6)and (5.7.3.12). □

Def. (5.6.2.19). For a surjective map of varieties $f : X \to T$ over an alg.closed field k, its fiberes over closed points with induced reduced structure $X_{(t)}$ is called a **algebraic family of varieties parametrized by** T if

1. $f^{-1}(t)$ is irreducible of dimension $\dim X - \dim T$ for every closed point t.
2. If ζ is the generic point of $f^{-1}(t)$, then $F^\sharp \mathfrak{m}_t$ generates the maximal ideal $\mathfrak{m}_\zeta \subset \mathcal{O}_{\zeta, X}$.

Prop. (5.6.2.20). if $X_{(t)}$ is an algebraic family of normal varieties over an alg.closed field k parametrized by a nonsingular curve T, then it is a flat family of schemes.

Proof: By(5.11.1.20), $X \to T$ is flat. So what we need to do is to prove X_t is reduced so $X_t = X_{(t)}$. Let $A = \mathcal{O}_{x,X}$, let u_t be a uniformizer of $\mathcal{O}_{t,T}$, then A/tA is the local ring of x on X_t. By hypothesis X_t is irreducible so tA has a unique minimal prime p in A, and t generate the maximal ideal of A_p by hypothesis. The local ring of $X_{(t)}$ is A/p, so A/p is normal by hypothesis. Then the result follows from(4.3.5.13). □

Cor. (5.6.2.21) [Igusa]. Let $X_{(t)}$ be an algebraic family of normal varieties in $\mathbb{P}^n_k$ for k alg.closed parametrized a variety T, then the Hilbert polynomials of $X_{(t)}$ are independent of t.

Proof: **?** Why is X/T projective? Cf.[Hartshorne P265]. □

Degenerating Techniques

Finite Locally Free Morphism

Def. (5.6.2.22) [Finite Locally Free]. A morphism $f : X \to Y$ is called **finite locally free of rank** d iff it is affine, and $f_*\mathcal{O}_X$ is a finite locally free $\mathcal{O}_Y$-module of rank d.

Cor. (5.6.2.23). If f is finite locally free of rank n, then for any locally free sheaf E of rank k on X, f_*E is locally free of rank nk.

Prop. (5.6.2.24). f is finite locally free iff it is finite, flat and of f.p.. In particular, when Y is locally Noetherian, this is equivalent to f is finite flat.

Proof: Both notions are local on the target, so we reduce to the ring case, which is(4.3.1.7). □

Cor. (5.6.2.25). Finite locally freeness is stable under composition and base change, and it is local on the target.

Prop. (5.6.2.26) [Trace and Norm]. Let $f : Y \to X$ be a finite locally free map of constant rank, then there are trace and norm maps $\mathrm{tr} : f_*\mathcal{O}_Y \to \mathcal{O}_X, \mathrm{Nm} : f_*\mathcal{O}_Y \to \mathcal{O}_X$ compatible with arbitrary base change.

Proof: The proof is the same as that of(4.3.1.11). □

Prop. (5.6.2.27). Let $f : Y \to X$ be a finite locally free map of constant rank, and $b \in \Gamma(Y, \mathcal{O}_Y)$, then $f(Z(b)) = Z(\mathrm{Nm}(b))$.

Proof: We can assume X is affine, then we need to show that for a prime $\mathfrak{p}$ with inverse images $\mathfrak{p}_i$, $b \in \cup\mathfrak{p}_i$ iff $Nm(b) \in \mathfrak{p}$. We localize at $\mathfrak{p}$, then $\mathrm{Nm}(b) \in \mathfrak{p}$ iff $\mathrm{Nm}(b)$ is non-invertible iff multiplication by b is non-invertible iff b is non-invertible iff $b \notin \cup\mathfrak{p}_i$, because $\mathfrak{p}_i$ are all the maximal ideals of $B_{\mathfrak{p}}$. □

3 Dimensions

Main references are [Mat80] and [Vak17]Chap11.

Prop. (5.6.3.1) [Locally Algebraic Scheme is Catenary]. If X is a locally algebraic scheme over a field k purely of dimension n, and Y an irreducible subscheme of X, then $\dim Y + \mathrm{codim}(Y, X) = \dim X$.

Proof: Choose an affine open of the generic point of Y, then we are reduced to the affine case(4.2.4.3)(4.2.4.7). □

Prop. (5.6.3.2). For any scheme, $\dim \mathcal{O}_x = \mathrm{codim}(\overline{\{x\}}, X)$.

Prop. (5.6.3.3). For an integral scheme algebraic over a field k,

$$\dim X = \dim \mathcal{O}_{p,X} = \dim U = \mathrm{tr.deg}\ K(X)/k$$

for any closed point p and any open subscheme U.

Proof: Use closed point are dense(5.4.1.26) and <u>k is universal catenary</u> to prove it is true for some U and all the closed point in it, so other U's because X is irreducible. The last equation follows from(4.2.4.23). □

Prop. (5.6.3.4) [Finite Surjection Preserves Dimension]. Let $X\to Y$ be a surjective finite morphism of algebraic integral schemes over a field k, then $\dim X=\dim Y$.

Proof: The hypothesis implies that for any affine open $\operatorname{Spec} A\subset Y$, the inverse image is $\operatorname{Spec} B$ that $A\to B$ is an injective integral ring extension, so we can use(5.6.3.3) and(4.2.4.14). □

Prop. (5.6.3.5). Let X be a locally Noetherian scheme, if $U\subset X$ is an open subscheme that $U\to X$ is affine, then every irreducible complements of $X-U$ has codimension≤ 1. And if U is dense, then equality must hold.

Proof: Cf.[Sta]0BCU. □

Prop. (5.6.3.6) [Local Dimensions]. Let Let X be a locally algebraic scheme over a field k and $x\in X$, then the local dimension $\dim_x(X)$ equals the maximal dimension of irreducible components of X passing through x, by(4.2.4.27).

Prop. (5.6.3.7). If $f:X\to Y\in \mathcal{S}\mathrm{ch}^{\text{loc.ft}}/S$, $x\in X$ and $s=f(x)$, then

$$\dim_x(X_s)=\dim \mathcal{O}_{X_s,x}+\operatorname{tr.deg}_{k(s)}k(x).$$

Proof: This reduces to the case $Y=\operatorname{Spec} k(s)$, and it follows from(4.2.4.28). □

Prop. (5.6.3.8) [Semicontinuity of Dimension]. Let $f:X\to S$ be a morphism of schemes locally of f.t., then the function $x\mapsto \dim_x(X_{f(x)})$ is upper-semicontinuous on X.

Moreover, if f is of f.p., then the open subsets $\{x|\dim_x(X_{f(x)})\leq n\}$ is retrocompact.

Proof: This follows directly from(4.2.4.32). □

Prop. (5.6.3.9) [Local Dimension and Base Change]. Let

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X\\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f}\\ S' & \xrightarrow{g} & S \end{array}$$

be a fiber product diagram of schemes, and f is locally of f.t.. Suppose $x'\in X', x=g'(x'), s=g(s')$. Then

- $\dim_x(X_s)=\dim_{x'}(X_{s'})$.
- $$\dim \mathcal{O}_{F,x'}=\dim \mathcal{O}_{X'_{s'},x'}-\dim \mathcal{O}_{X_s,x}=\operatorname{tr.deg}_{k(s)}(k(x))-\operatorname{tr.deg}_{k(s')}(k(x'))$$
  where F is the fiber of the morphism $X'_{s'}\to X_s$ over x. In particular, $\dim \mathcal{O}_{X'_{s'},x'}\geq \dim \mathcal{O}_{X_s,x}$ and $\operatorname{tr.deg}_{k(s')}(k(x'))\leq \operatorname{tr.deg}_{k(s)}(k(x))$.
- Given s',s,x that $f(x)=g(s')$, there exists an $x'\in X'$ that $\dim \mathcal{O}_{X'_{s'},x'}=\dim \mathcal{O}_{X_s,x}$ and $\operatorname{tr.deg}_{k(s')}(k(x'))=\operatorname{tr.deg}_{k(s)}(k(x))$.

Proof: It can be reduced to the case that $S=\operatorname{Spec} k(s), S'=\operatorname{Spec} k(s')$ and X,X' affine. Then 1 follows from(4.2.4.31), and $2,3$ follows from(4.2.4.26). □

Cor. (5.6.3.10) [Dimension and Field Extension]. Let K/k be a field extension, X a locally algebraic scheme over k purely of dimension n, then X_K is a scheme purely of dimension n.

Remark (5.6.3.11). This proposition shows in particular local dimension behaves better than the dimension of the stalk.

Def. (5.6.3.12) [Relative Dimensions]. A morphism of schemes which locally of f.t. is called of **relative dimension** n iff all fibers X_s are equidimensional of dimension n.

Prop. (5.6.3.13). Being a morphism of relative dimension n is stable under field extension, by(5.6.3.10).

Dimension and Flatness

Prop. (5.6.3.14) [Faithfully Flat Morphism]. If $f: Y \to X$ is a faithfully flat morphism, then $\dim Y \geq \dim X$.

Proof: This is easy from(5.6.2.7). □

Prop. (5.6.3.15) [Integral Flat Morphisms]. If $f: X' \to X$ is an integral flat morphism of schemes, and X is pure of dimension n, then so does X'. The converse holds if f is faithfully flat.

Proof: By(5.6.2.8) and(5.4.4.35), f maps an irreducible component of X' onto an irreducible component of X, Then by(3.11.3.26), the proposition reduces to the affine case(4.2.4.15). If f is faithfully flat, then every irreducible component of X is in the image. □

Cor. (5.6.3.16) [Dimension and Field Extension]. If K/k is an algebraic extension, X a scheme over k purely of dimension n, then X_K is a scheme purely of dimension n. Compare with(5.6.3.10).

Prop. (5.6.3.17) [Dimension Extension and Flatness]. Let $f: X \to Y, g: Y \to S$ be locally of f.t., $x \in X, y = f(x), s = g(y)$, then

$$\dim_x(X_s) \leq \dim_x(X_y) + \dim_y(Y_s).$$

Moreover, equality holds if $\mathcal{O}_{X,x}/\mathcal{O}_{Y,y}$ is flat.

In particular, if $S = \operatorname{Spec} k$ and X, Y are irreducible and X is flat over Y, then $\dim X_y = \dim X - \dim Y$ for any $y \in Y$.

Proof: By(5.6.3.7) and the fact transcendental degree is additive, this reduces to

$$\dim \mathcal{O}_{X_s,x} \leq \dim \mathcal{O}_{X_y,x} + \dim \mathcal{O}_{Y_s,y}.$$

We can assume X, Y is affine and $S = \operatorname{Spec} k(s)$, so the rest follows from(4.2.4.13). □

Cor. (5.6.3.18). If $f: X \to Y, g: Y \to Z$ are of relative dimension m and n(5.6.3.12), and f is flat, then $g \circ f$ is of relative dimension $m + n$.

Cor. (5.6.3.19) [Generic Dimension Equation]. If $f: X \to Y$ is a dominant morphism of irreducible algebraic schemes over K that X is reduced, then there is a dense open subset U of Y that for any $y \in Y$,

$$\dim(X_y) = \dim X - \dim Y.$$

Proof: This is a combination of the above proposition and generic flatness(5.6.2.15). □

Prop. (5.6.3.20) [Relative Dimension and Base Change]. By(5.6.3.9), the base change of a morphism of locally algebraic schemes over a field k of relative dimension n is still of relative dimension n. In particular, for a variety over K a field, the dimension is invariant under base change of fields.

Cor. (5.6.3.21). Let Y, Z be irreducible locally algebraic schemes over k, then $Y \times_k Z$ is pure of dimensional $\dim(Y) + \dim(Z)$.

Proof: Combine(5.6.3.20) and(5.6.3.17). □

Prop. (5.6.3.22). For a morphism $f : X \to Y$ between locally Noetherian schemes which is flat and locally of f.t and of relative dimension n, then if $y = f(x)$, we have $\dim_x(X_y) = \dim_x(X) - \dim_y(Y)$.

Proof: Shrinking the nbhd, we may assume $\dim_x(X) = \dim X$ and $\dim_y(Y) = \dim Y$ and X, Y are affine. Now f is locally of f.p. and flat, so it is open(5.6.2.10). So we may assume f is surjective. Then $\dim \mathcal{O}_{X,a} = \dim \mathcal{O}_{Y,b} + \dim \mathcal{O}_{X_b,a} = \mathcal{O}_{Y,b} + n$ by(4.2.4.13), then taking supremum**??**, the result follows. □

Cor. (5.6.3.23). For a morphism of schemes that is flat and of f.t., if Y is irreducible, then X is equidimensional of dimension $\dim Y + n$ iff X_y is equidimensional of dimension n for every $y \in Y$.

Proof: The proof highly relies on(5.6.3.3).

If X is equidimensional of dimension $\dim Y + n$, for $Z \subset X_y$ an irreducible component, choose a closed pt x of Z not contained in any other irreducible component, then

$$\dim_x Z = \dim_x X - \dim_y Y = \dim X - \dim \overline{\{x\}} - \dim Y + \dim \overline{\{y\}}.$$

The two closures are of the same dimension because by(4.2.6.10), their quotient field extension is finite, and use(4.2.4.14).

Conversely, for an irreducible component of X, choose a closed pt x of Z not contained in any other irreducible component, then the image is also closed, by(5.4.1.27), so the result is immediate. □

Prop. (5.6.3.24). If $f : X \to Y$ is a proper flat morphism of schemes of f.p., then the dimension of fibers of f is a locally constant function.

Proof: Cf.[Sta]04DJ.**?** □

4 Smoothness

Def. (5.6.4.1) [Smooth Morphisms]. A **smooth morphism** $f : X \to Y$ between schemes is a morphism that there is an open affine cover $\{U_i\}$ of S and an open affine cover V_{ij} of $f^{-1}(\{U_i\})$ that the ring map is smooth(4.4.5.12). In particular, it is locally of f.p.. A **standard smooth morphism** is the Spec map of a standard smooth ring map.

Smoothness is local on the source and target(4.4.5.13). Smoothness is stable under base change and composition(4.4.5.13).

Prop. (5.6.4.2). For a smooth morphism $X \to S$, the morphism of differential $\Omega_{X/S}$ is locally free and $\dim_x \Omega_{X/S} = \dim_x(X_{f(x)})$(local dimension(3.11.3.25)).

Proof: We can assume that $X \to S$ is standard smooth, so by the proof in(4.4.5.12), $\Omega_{X/S}$ is free of dimension $n - c$, and also standard smooth is relative global complete intersection(4.4.5.11), so $U_{f(x)}$ is equidimensional of dimension $n - c$, thus the result. □

Cor. (5.6.4.3) [Differential Criterion of Smoothness]. If $X \to S$ is a flat of relative dimension n, then X is smooth over S iff it is locally of f.p. and $\Omega_{X/S}$ is locally free of dimension n, by(4.4.5.23).

Prop. (5.6.4.4) [Smooth Morphism is Open]. Smooth morphism is syntomic hence flat. Smooth morphism is locally of f.p. Hence smooth morphism is universally open(5.6.2.10).

Smooth morphism is locally standard smooth(4.4.5.12).

Prop. (5.6.4.5) [Fiberwise and Stalkwise]. For a morphism $X \to S$ locally of f.p., the following are equivalent:

- It is smooth at a point $x \in X$ over $s \in S$.
- $\mathcal{O}_{X,x}/\mathcal{O}_{X,f(x)}$ is flat and $X_{f(x)}/k(f(x))$ is smooth at x, by(4.4.5.20).
- $\mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)}$ is flat and $\Omega_{X/S,x}$ can be generated by $\dim_x(X_{f(x)})$ elements, by(5.6.4.2) and(4.4.5.23).
- $\mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)}$ is flat and $\Omega_{X_s/s,x} \otimes_{\mathcal{O}_{X_s,x}} k(x) = \Omega_{X/S,x} \otimes_{\mathcal{O}_{X,x}} k(x)$ can be generated by $\dim_x(X_{f(x)})$ elements, by Nakayama, because $\Omega_{X/S,x}$ is of f.p. by(4.4.3.9).

In particular, A smooth morphism can be seen as a family of smooth schemes.

Proof: □

Cor. (5.6.4.6) [Smoothness over DVR]. Let R be a DVR with fraction field K and residue field k, then an integral R-scheme X of f.t. is smooth over R iff $X_K \neq \varnothing$ and both X_K/K and X_k/k are smooth.

Proof: Notice that it is flat iff $X_K \neq \varnothing$. □

Prop. (5.6.4.7). If $X \to Y$ is a smooth map of schemes over S, then by(5.5.5.5)(4.4.5.5), there is an exact sequence of sheaves:

$$0 \to f^*\Omega_{Y/S} \xrightarrow{df^*} \Omega_{X/S} \to \Omega_{X/Y} \to 0$$

Prop. (5.6.4.8). If $Z \to X \to S$, Z/S is smooth and $Z \to X$ is an immersion, then there is an exact sequence of sheaves(5.5.5.13)(4.4.5.6):

$$0 \to \mathcal{C}_{Z/X} \to i^*\Omega_{X/S} \to \Omega_{Z/S} \to 0$$

Prop. (5.6.4.9). If $X \to Y \to S$, and $X \to Y$ are faithfully flat and locally of f.p., X/S is smooth, then Y/S is smooth.

Proof: Cf.[Sta]05B5. □

Prop. (5.6.4.10). If $f : X \to S$ is faithfully flat and locally of f.p., then the set of points of S s.t. f is smooth is table under base change.

Proof: □

Prop. (5.6.4.11). By(5.6.4.5)(5.6.4.2), A morphism is smooth of relative dimension n is equivalent to fppf+fibers equidimensional of dimension n and $\Omega_{X/S}$ is locally free of dimension n.

Prop. (5.6.4.12) [Jacobian Criterion for Projective Schemes]. Let X be a closed subscheme of $\mathbb{P}^n_R$ defined by r polynomials $F_1(X_0, \ldots, X_n), \ldots, F_r(X_1, \ldots, X_n)$, then for $x \in X$, X is smooth at x iff the Jacobian has rank$\geq n - \dim_{\mathfrak{r}} X$ at x iff the Jacobian has rank$= n - \dim_x X$ at x.

Proof: Assume that x is in the standard open $X_0 \neq 0$, then we can use Euler's identity $\sum X_i \frac{\partial F}{\partial X_i} = \dim(F)F$ to eliminate the first row, then divide by $X_0^{\dim F}$ to get the Jacobian on the affine open $\operatorname{Spec} R[\frac{X_1}{X_0}, \ldots, \frac{X_n}{X_0}]$, so we finish by(4.4.5.24). □

Prop. (5.6.4.13) [Generic Smoothness on the Source]. Let $\pi : X \to Y$ be a dominant map of integral schemes of f.t. that $K(Y) \to K(X)$ is separable, then thee is a non-empty open subscheme $U \subset X$ that $\pi|_U$ is smooth of relative dimension $\dim X - \dim Y$.

Proof: This reduces to the affine case, and follows from(4.4.5.29) and(5.6.3.17). □

Prop. (5.6.4.14)[Generic Smoothness on the Target]. Let $\pi : X \to Y$ be a morphism of k-varieties where $\operatorname{char} k = 0$, and X is smooth over k, then there is a dense open subset $U \subset Y$ that $\pi^{-1}(U) \to U$ is smooth.

Proof: Cf.[Vak17]P681. □

Smooth over Fields

Prop. (5.6.4.15)[Differential Criterion of Smoothness]. Let X be a scheme algebraic over a field k.

- If X is equidimensional of dimension n, then X is smooth over k iff $\Omega_{X/S}$ is locally free of dimension n.
- If $\Omega_{X/k}$ is locally free, and k is of char 0 or k is perfect and X is reduced, then X is smooth over k.

Proof: 1: This follows from(5.6.4.3).
2: If k is of characteristic 0, then this follows from(4.4.5.28).
perfect case: [Sta]04QP.? □

Prop. (5.6.4.16)[Smooth over Field and Geo.Regular]. For a scheme locally algebraic over a field k, X is geometrically regular iff it is smooth over k. In particular, if k is perfect, then smoothness is equivalent to regularity, by(5.4.3.18).

Proof: The question is local around x, so may assume X is affine. Then this follows from(4.4.5.27). □

Cor. (5.6.4.17) [Hartshorne Definition]. By(5.6.4.5) and(5.6.4.16), a morphism between schemes algebraic over a field k is smooth of relative dimension n iff f is flat and every fiber of f is geometrically regular of dimension n.

Cor. (5.6.4.18). A smooth scheme over a field k is regular hence normal.

Prop. (5.6.4.19) [Smoothness and Separable Closed Points]. Let X be smooth over a field k, then the set of closed points of X with finite separable residue field $k(x)/k$ is dense in X.

Proof: It suffices to show there exists one such points. By(5.6.6.7), we can assume $X \xrightarrow{\pi} \mathbb{A}^d_k \to k$, where π is étale. Thus X is open in A^d_k by(5.6.6.3). Then we can choose a closed point of $\pi(X)$ s.t. the residue field is finite separable, as k^{sep} is infinite. Then choose an inverse image, then the residue if finite étaleover k, by(5.6.6.8). This point is clearly closed. □

Prop. (5.6.4.20)[Smoothness at Rational Points]. Let X be a locally algebraic scheme over a field k. Let $x \in X$ that $k(x)/k$ is finite separable, then X is smooth at x iff it is x is a regular point, by(4.4.5.26).

Prop. (5.6.4.21) [Geo.Reduced Scheme Generic Smooth]. Let X be a locally algebraic scheme over a field k that is geometrically reduced, then it contains an open dense subset that is smooth over k.

Proof: The problem is local, so we may assume X is affine, consider its irreducible components, all their intersections can be removed, because they are nowhere dense, so we may assume X is irreducible. So X is integral, let η be the generic pt, then $k(\eta)/k$ is separable, by(5.4.3.2). Then choose an affine subscheme $\operatorname{Spec} A \subset X$, then A is smooth at (0) over k, by(4.4.5.29), then by definition, it is smooth on some dense open subscheme of X. □

Tangent Spaces

Def. (5.6.4.22) [Relative Tangent Spaces]. Let X be a scheme over S and $x \in X$, define $T^*_{X/S,x} = \Omega_{X/S,x} \otimes_{\mathcal{O}_{X,x}} k(x)$, and $T_{X/S,x} = \operatorname{Hom}_{k(x)}(T^*_{X/S,x}, k(x)) = \operatorname{Hom}_{\mathcal{O}_{X,x}}(\Omega_{X/S,x}, k(x))$, called the **relative tangent space** of X over S at x.

When $x \in X$ mapping to $s \in S$, $T_{X/S,x} = \operatorname{Hom}_{k(x)}(\mathfrak{m}_x/\mathfrak{m}_x^2, k(x))$, where $\mathfrak{m}_x$ is the maximal ideal of the stalk of $x \in X_s$.

Then it can be verified that for a k-scheme and a rational point $x \in X$, $T_{X,x}$ is in bijection with $\operatorname{Mor}_k(\operatorname{Spec} k[\varepsilon], X)$ that maps the closed point to x.

Prop. (5.6.4.23) [Tangent Map]. Let $f : X \to Y$ be a morphism of schemes over S, $x \in X$, $f(x) = y$. Assume $k(x) = k(y)$, then f defines a natural linear map

$$df : T_{X/S,x} \to T_{Y/S,y} : \operatorname{Hom}_{\mathcal{O}_{X,x}}((\Omega_{X/S})_x, k(x)) \to \operatorname{Hom}_{\mathcal{O}_{X,x}}((f^*\Omega_{Y/S})_x, k(x)) \text{(5.5.5.5)} = \operatorname{Hom}_{\mathcal{O}_{X,x}}(\Omega_{Y/S,y} \otimes_{\mathcal{O}_{Y,y}} \mathcal{O}_{X,x}, k(y)) = \operatorname{Hom}_{\mathcal{O}_{Y,y}}(\Omega_{Y/S,y}, k(y))$$

Cor. (5.6.4.24). Via similar argument, if $k(x) = k(s) = k(y)$, there is an isomorphism

$$T_{X/S,x} \oplus T_{Y/S,y} \cong T_{X \times_S Y,(x,y)}.$$

Prop. (5.6.4.25). Let X be a scheme over a field k and $x \in X$ with residue field $k(x)$, then the tangent space is canonical isomorphic to $\operatorname{Mor}(k(x)[\varepsilon], X)$ that maps the closed point to x. And the vector bundle structure is given by the cogroup structure on $\operatorname{Spec} k[\varepsilon] : \mu : k[\varepsilon] \otimes k[\varepsilon] \to k[\varepsilon]$.

Prop. (5.6.4.26) [Krull's Principal Tangent Theorem]. Let $Z \subset X$ be a closed subscheme with ideal of definition $\mathcal{I}$, $x \in Z$, then $T_{Z,x}$ is the subspace of $T_{X,x}$ cut out by $(\mathcal{I} \mod \mathfrak{m}_x^2)$.

In particular, $\mathcal{T}_{Y \cap Z,p} = T_{Y,p} \cap T_{Z,p} \subset T_{X,p}$.

Prop. (5.6.4.27) [Tangent Criterion of Smoothness]. By(5.6.4.16)(5.6.4.20) and the definition of regular local ring, if X is a locally algebraic scheme over a field k, then X is smooth at a point x with residue field $k(x)/k$ separable iff $\dim_{k(x)} T_{X,x}$ equals($\leq$) the dimension of $\mathcal{O}_{X,x}$.

Bertini's Theorem

Prop. (5.6.4.28) [Bertini]. Let k be a field. For any quasi-projective scheme $X \subset \mathbb{P}^n_k$ smooth away from f.m. points, there is an open dense subset U of the dual projective space $\mathbb{P}^{n\vee}_k$ s.t. for any closed point $[H] \subset U$, H doesn't contain any component of X, and the scheme $H \cap X$ is smooth over k.

Moreover, if X is a variety and $\dim X \geq 2$, the smooth cut is even a smooth variety by(5.8.6.25)and(5.4.2.10).

Proof: Let $\mathbb{P}^n = \operatorname{Proj} k[x_0,\ldots,x_n], (\mathbb{P}^n)^\vee = \operatorname{Proj} k[a_0,\ldots,a_n]$, Let $\overline{X}$ be cut out by equations $f_1,\ldots,f_r$, we define a projective scheme $Z\subset \mathbb{P}^n\times(\mathbb{P}^n)^\vee$ be cut by the equations

- f_r.
- $f_{r+1}=\sum a_i x_i$.
- determinants of $(r+1)\times(r+1)$-minors of $(\frac{\partial f_i}{\partial x_j})_{(r+1)\times n}$.

Now for any $(x,[H])\in Z$, $x\in X, x\in H$ that $[H]$ is closed in $(\mathbb{P}^n)^\vee$, the last equation means $X\cap H$ is non-smooth at p or contains the irreducible component passing p, by Jacobian criterion(5.6.4.12). Now consider the projection $Z\to X$, for each closed point $p\in X$ that $\dim_p X=d$, the codimension of the fiber of Z over x is of dimension $r-1=n-\dim_x X-1$(To see this, one way is use regularity and tangent space, another way is to use the fact (x_i) is orthogonal to $(\frac{\partial f_i}{\partial x_j})_j$ for all i by Euler identity, so the $r+1$ restrictions of (a_i) are linearly independent), then by(5.6.3.17), $\dim Z=\dim \pi_1^{-1}(Z)\leq n-1$, Thus the image of Z in $\mathbb{P}^{n\vee}_k$ is also a closed subscheme of dimension$\leq n-1$.

If X has f.m. singular points, we also need to cut out the surfaces $N_{k(x)/k}(\sum x_i^k a_i)$, where (x_i^j) are the f.m. closed singular points of x. They are also of dimension $n-1$. □

Cor. (5.6.4.29) [Bertini's Theorem for Surfaces]. Similarly, for any $d\geq 0$, a generic dimension d surface intersect X at a smooth subscheme, by using Veronese embedding.

Cor. (5.6.4.30). When $X\subset\mathbb{P}^n_k$ is a projective k-variety where k has characteristic 0, the scheme Z in $\mathbb{P}^{n\vee}_k$ is called the **dual variety** of X. When X is irreducible and smooth, it is of dimension $n-1$.

Proof: □

Prop. (5.6.4.31). The dual variety of the dual variety is X itself.

Proof: Cf.[Joe Harris, Algebraic Geometry, 15.24]. □

Prop. (5.6.4.32) [Kleinman-Bertini]. Let X be a k-variety that is homogenous space for a k-variety G over a field k, suppose $\alpha: Y\to X,\beta: Z\to X$ are morphisms of varieties, then

- There is a non-zero open subset $V\subset G$ that for any closed point $\sigma\in V$, $\dim \sigma(Y)\times_X Z=\dim Y+\dim Z-\dim X$.
- If Y,Z are smooth over k of characteristic 0, then there is a non-empty open subset $V\subset G$ that $(G\times_k Y)\times_X Z\to G$ is smooth. In particular, for any closed point $\sigma\in V$, $\sigma(Y)\times_X Z$ is smooth over $k(\sigma)$ of dimension $\dim Y+\dim Z-\dim X$.

Proof: Let $\Gamma=(G\times_k Y)\times_X Z$, then there is a map $\Gamma\to Y\times_k Z$. $Y\times_k Z$ has dimension $\dim Y+\dim Z$ by(5.6.3.21), and there is a base change diagram

$$\begin{array}{ccc}(G\times_k Y)\times_X Z & \longrightarrow & Y\times_k Z\\ \downarrow & & \downarrow\\ G\times_k X & \longrightarrow & X\times_k X\end{array},$$

and $G\times X\to X\times X$ is flat as it is equivariant under $G\times G$-action, by(5.6.2.15), thus $\Gamma\to Y\times_k Z$ is flat of relative dimension $\dim G-\dim X$, thus it has dimension $\dim Y+\dim Z+\dim G-\dim X$.

1: This follows from(5.6.3.19) applied to the map $G\times_k Y\times_X Z\to G$.

2: As $G\times X\to X\times X$ is flat, and its fiber are isomorphic to G_x, which is the fiber of the map $o_x: G\to X$, and this map is smooth by(5.6.4.14), thus $G\times X\to X\times X$ is smooth, and then the assertion follows from(5.6.4.14). □

Cor. (5.6.4.33). Let Z be a smooth k-variety where $\mathrm{char} k = 0$. Let V be a f.d. basepoint-free line series on Z, then the section of a general element of V is smooth.

Proof: Apply Kleinman-Bertini to $\varphi_V : Z \to \mathbb{P}V^\vee$, $Y = V(\sum a_i x_i) \in PV \times PV^\vee \to PV^\vee$, $X = PV^\vee$. □

5 Unramified

More advanced materials to learn at [Sta]Chap40.

Def. (5.6.5.1) [Unramified Morphism]. A morphism is called **(G-)unramified** iff there is an open affine cover U_i and an open affine cover of $f^{-1}(U_i)$ that the induced ring map is (G-)unramified(4.4.6.4). Equivalently, $\Omega_{X/S} = 0$ and it is locally of f.t.(f.p.).

(G-)unramifiedness is local on the source and target(5.4.1.5)(5.4.1.6). (G-)unramifiedness is stable under base change and composition(4.4.6.4). Moreover, unramifiedness satisfies the base change trick.

Prop. (5.6.5.2). An unramified map is locally quasi-finite.

Proof: Cf.[Sta]02V5. □

Prop. (5.6.5.3) [Fiberwise]. A morphism is (G-)unramified iff it is locally of f.t.(f.p.) and all the fibers X_s are disjoint unions of spectra of finite separable extensions of $k(p)$.

Proof: By(4.4.6.7), Notice $pS_q = qS_q$ is equivalent to every q is minimal in X_p, which is equivalent to X_p is discrete. □

Cor. (5.6.5.4) [Unramified over Fields]. A scheme over a field k is unramified iff it is a disjoint union of spectra of finite separable extensions of k, because locally of f.p. is trivially satisfied.

Prop. (5.6.5.5) [Diagonal is Open]. A morphism $X \to S$ is (G-)unramified iff it is of f.t.(f.p.) and the diagonal is a clopen immersion of X, thus all of X.

Proof: If it is unramified, then the diagonal is an open immersion by(4.4.6.10). Conversely, $\Omega_{X/S}$ is just the conormal sheaf of the diagonal map, so it is zero. □

Cor. (5.6.5.6) [Sections of Unramified Morphism]. Any section of an unramified morphism is an open immersion. In particular, a section of a separable unramified morphism is a clopen immersion.

Proof: This follows from the proposition and the fact $S \to X$ is a base change of $\Delta_{X/S}$. □

Cor. (5.6.5.7). Let X, Y be schemes over S, if f, g are two maps from X to Y, then if Y/S is unramified and f, g are equal on a pt x of X(both on image and residue field), then there is a nbhd of x that f, g are equal.

Proof: This follows as $\Delta_{Y/S}$ is open immersion, so the set that f, g are equal is open in X. □

Prop. (5.6.5.8) [Fiberwise]. For a morphism $f : X \to S$ locally of f.t.(f.p.), let $x \in X, s = f(x)$, then the following are equivalent:

- It is (G-)unramified at x,
- The fiber X_s is unramified over $k(s)$ at x, by(5.6.5.3).
- $\Omega_{X_s,x} = 0$.

- $\Omega_{X_s/s,x} \otimes_{\mathcal{O}_{X_s,x}} k(x) = \Omega_{X/S,x} \otimes_{\mathcal{O}_{X,x}} k(x) = 0$ by(4.4.6.6).
- $\mathfrak{m}_s \mathcal{O}_{X,x} = \mathfrak{m}_x$ and $k(x)/k(f(x))$ is separable.

Proof: $1 \to 2 \to 3 \to 4$ is clear. $4 \to 1$: Nakayama implies $\Omega_{X/S,x} = 0$, thus $\Omega_{X/S}$ vanishes on a nbhd of x as it is Qco of f.t..

$4 \iff 5$ follows from(4.4.6.7). □

Cor. (5.6.5.9) [Generic Unramifiedness]. Let $f : X \to Y$ be a finite separable dominant morphism of integral schemes, then there exists an open dense nbhd U of Y s.t. $f : f^{-1}(U) \to U$ is unramified.

Prop. (5.6.5.10). If $X \to Y \to S$ is unramified, then X/Y is also unramified. And if X/S is G-unramified and Y/S is of f.t., then X/Y is G-unramified.

Proof: By(5.6.1.4)and(5.5.5.5). □

Prop. (5.6.5.11) [Unramified Points Base Change]. If f is of f.t.(f.p.), then the set of points of S that f is unramified is stable under base change.

Proof: □

Prop. (5.6.5.12)[Tangent Criterion of unramifiedness]. Let $f : X \to Y$ be a morphism of schemes locally of f.t. over S, $x \in X, y = f(x)$, then the following are equivalent:

- $df : T_{X/S,x} \to T_{Y/S,y}$ is an injection(5.6.4.23).
- f is unramified at x.

Proof: It follows from(5.6.4.23) that df is an isomorphism iff $(f^*\Omega_{Y/S})_x \otimes_{\mathcal{O}_{X,x}} k(x) \to \Omega_{X/S,x} \otimes_{\mathcal{O}_{X,x}} k(x)$ is surjective, which by Jacobi-Zariski(5.5.5.5) is equivalent to $\Omega_{X/Y,x} \otimes_{\mathcal{O}_{X,x}} k(x) = 0$, and this is equivalent to f is unramified at x by(5.6.5.8). □

Prop. (5.6.5.13) [Unramified U.i. Morphisms]. For a morphism f of schemes, the following are equivalent:

- f is unramified and a monomorphism.
- f is unramified and universal injective.
- f is locally of f.t., formally unramified and universal injective.
- f is locally of f.t. and a monomorphism.
- f is locally of f.t. and X_y is either empty or $X_y \to y$ is an isomorphism for all $y \in Y$.

Proof: Cf.[Sta], 05VH. □

Prop. (5.6.5.14) [Unramified and Smoothness]. Let $f : X \to Y$ be a morphism of schemes over S s.t. X/S is smooth(of relative dimension n) and Y/S is unramified, then f is also smooth(of relative dimension n).

Proof: This follows from differential criterion(5.6.4.3) and(5.6.1.4). Notice to show it is flat, use the fact $\Delta_{Y/S}$ and $X \times Y \to Y$ are both flat(5.6.5.5). □

Noetherian Case

Prop. (5.6.5.15). Let S be a Noetherian scheme, $X \to S$ a qc unramified morphism and $Y \to S$ a morphism with Y Noetherian, then $\mathrm{Mor}_S(Y, X)$ is a finite set.

Proof: Cf.[Sta], 0AKI. □

Prop. (5.6.5.16) [Unramified Morphisms and DVR]. Let R_v be a DVR with fraction field K and $\varphi : X \to X'$ be a morphisms of schemes of f.t. over R_v. Let $Q \in X'(K)$ and $P \in X(\overline{K})$ with $\varphi(P) = Q$. Let $w|v$ be a valuation of $K(P)$ extending v. If P extends to an R_w-valued point $\overline{P}$ of X, then using the fact $R_w \cap K = R_v$, we see Q also extends to a R_v-valued point of X'.

Denote the image of the maximal ideal of R_w under $\overline{P}$ by $P(w)$, then if φ is unramified at $P(w)$, then $K(P)/K$ is unramified in w.

Proof: Since the unramified point is open, φ is also unramified at P, thus $K(P)/K$ is separable(5.6.5.8). For the rest, Cf.[Diophantine Geometry, P598]**?**. □

6 Étale

More advanced materials to learn at [Sta]Chap40.

Def. (5.6.6.1) [Étale Morphisms]. An **étale morphism** $f : X \to Y$ of schemes is a morphism s.t there is an open affine cover $\{U_i\}$ of S and an open affine cover V_{ij} of $f^{-1}(\{U_i\})$ that the ring map is étale. A **standard étale morphism** is the Spec map of a standard étale ring map.

étale is local on the source and target(4.4.7.5). Étale is stable under base change and composition(4.4.7.5).

Prop. (5.6.6.2) [Properties of Étale Morphisms].

- Étale at a point x is equivalent to smooth and unramified at a x(4.4.7.4).
- Étale at a point x is equivalent to flat and G-unramified at that point, by(4.4.7.11). So étaleover field is equivalent to G-unramified, because over a field it is obviously flat.
- Étale at a point x is equivalent to locally standard étale at that point(4.4.7.17).
- A morphism is étale iff it is smooth of relative dimension 0, by definition(5.6.4.11).
- Étale is equivalent to flat, locally of f.p. and formally unramified, by(4.4.7.11).

Cor. (5.6.6.3). Étale map is smooth, hence syntomic, flat.

Étale map is universally open because it is flat and locally of f.p.(5.6.2.10).

Prop. (5.6.6.4). If X, Y are étaleover S, then any map $X \to Y$ is étale, by(4.4.7.13).

Prop. (5.6.6.5) [Fiberwise]. A morphism of schemes is étale iff it is flat, locally of f.p., and every fiber X_s is a disjoint union of spectra of finite separable field extensions of $k(s)$.

Proof: Follows from(5.6.6.2)(5.6.5.3) and(4.4.7.10). □

Cor. (5.6.6.6) [Étale Over Fields]. A scheme is étale over a field k iff it is a disjoint union of spectra of finite separable field extensions. In particular, étaleover fields is equivalent to unramified over fields.

Prop. (5.6.6.7) [Smoothness and Étale]. If $f : X \to Y$ is smooth at x, then there exist a nbhd U of $x \in X$ and nbhd V of $f(x) \in Y$ that it factors through $U \xrightarrow{\pi} \mathbb{A}^d \to V$, where π is étale.

Proof: Any standard smooth morphism can be factorized as an étalemap over a polynomial algebra, as easily seen. □

Prop. (5.6.6.8) [Stalkwise and Fiberwise]. For a morphism locally of f.p., by(5.6.5.8) and(5.6.4.5), the following are equivalent:

- It is étale at a point x.
- $\mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)}$ if flat and $X_{f(x)}/k(x)$ is smooth at x.
- $\mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)}$ if flat and $X_{f(x)}/k(x)$ is unramified at x.
- $\mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)}$ is flat and $\Omega_{X_{f(x)},x} = 0$.
- $\mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)}$ is flat and $\Omega_{X_s/s,x} \otimes_{\mathcal{O}_{X_s,x}} k(x) = \Omega_{X/S,x} \otimes_{\mathcal{O}_{X,x}} k(x) = 0$.
- $\mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)}$ is flat and $\mathfrak{m}_{f(x)}\mathcal{O}_{X,x} = \mathfrak{m}_x$ and $k(x)/k(s)$ separable.

In particular, an étalemorphism can be seen as a family of smooth schemes.

Prop. (5.6.6.9) [Étale Schemes over Field]. Let k be a field and k^s its separable closure. Let $\Gamma = \mathrm{Gal}(k^s/k)$, then the functor $X \mapsto X(k^s)$ is an equivalence between étale schemes over k to the category of discrete Γ-sets.

Proof: Cf.[Sta]03QR.**?** □

Prop. (5.6.6.10). If $X \to Y \to S$, and $X \to Y$ are faithfully flat and locally of f.p., $X \to S$ is étale, then $Y \to S$ is also étale.

Proof: Cf.[Sta]05B5. □

Cor. (5.6.6.11). If $f : X \to S$ is faithfully flat and locally of f.p., then the set of points of S s.t. f is étale is table under base change.

Proof: This follows from(5.6.5.11) and(5.6.4.10). □

Def. (5.6.6.12) [Étale Neighborhood]. For a point $s : \mathrm{Spec}\, k \to X$, an étale nbhd of s in X is defined to be an étale map $U \to X$ that s factors through U.

Prop. (5.6.6.13). For a morphism $f : Y \to X$ of schemes étale over field k, then f is surjective iff $Y(k_s) \to X(k_s)$ is surjective.

Proof: If $Y \to X$ is surjective, then**?** □

Étale Connected Components

Def. (5.6.6.14) [Étale Connected Components]. Let X be a scheme over a field k, let $\pi_0(X) = \mathrm{Spec}(\pi(X))$, where $\pi(X)$ is the largest étale subalgebra of $\Gamma(X)$(4.4.7.23).

Prop. (5.6.6.15). Let X be an algebraic scheme over a field k, then

- for any field extension k'/k, $\pi_0(X_{k'}) = \pi_0(X)_{k'}$.
- Let Y be a schemes over a field k, then $\pi_0(X \times Y) = \pi_0(X) \times \pi_0(Y)$.

Proof: 1: Cf.[Mil17b]P15.

2: There is a map $\pi(X) \times_k \pi(Y) \to \pi(X \times Y)$. Because π commutes with base change, we can base change to separable closure. In this case, it suffices to show if X, Y is connected then $X \times Y$ is connected, but this follows from(5.4.3.12). □

Prop. (5.6.6.16). Let X be an algebraic scheme over a field k, then

- The mapping $\varphi : X \to \pi_0(X)$ induces a 1 to 1 correspondence of points of $\pi_0(X)$ and connected components of X.
- For all $x \in \pi_0(X)$, the fiber $\varphi^{-1}(x)$ is geo.connected over $k(x)$.

Proof: $\pi_0(X)$ is discrete, so the inverse image of each point is a sum of connected components of X. But this must be connected, because $\pi_0(X_{k(x)}) = \pi_0(X)_{k(x)} = k(x)$. Also, this implies for the alg.closure $\overline{k}$ of $k(x)$, $\pi_0(X_{\overline{k}}) = \pi_0(X_{k(x)})_{\overline{k}} = \overline{k}$, thus $X_{\overline{k}(x)}$ is geo.connected. □

<u>**Noetherian Case**</u>

7 Zariski's Main Theorem

References are [Sta]Chap36.38.

Prop. (5.6.7.1)[Zariski's Main Theorem]. For a morphism $X \to S$ that is quasi-finite and separated, if S is qcqs, Then there is a factorization $X \to T \to S$ that $X \to T$ is a qc open immersion and $T \to S$ is finite.

Proof: Cf.[[Sta]05K0]. □

8 Complete Intersection

Should be refreshed with intrinsic definition of locally complete intersection, Cf.[Sta].

Def. (5.6.8.1) [Regular Embedding]. A **regular embedding** of codimension r is a locally closed embedding $X \to Y$ that for $p \in X$, the ideal of X in the local ring $\mathcal{O}_{Y,p}$ is generated by a regular sequence of length r.

Def. (5.6.8.2)[Complete Intersection]. A **complete intersection** of codimension r in Y is a closed subscheme X that is the intersection of r effective Cartier divisors D_i that at each point $p \in X$, the equations defining D_i form a regular sequence.

Def. (5.6.8.3) [Locally Complete Intersection]. A closed subscheme Y of a nonsingular variety X over a field k is called **locally complete intersection** iff Y is locally generated by $r = \mathrm{codim}(Y, X)$ elements. By(4.3.4.17) Y is C.M.. In particular, by(5.10.1.16), a regular variety is always a locally complete intersection.

Def. (5.6.8.4) [Syntomic Morphisms]. A **standard syntomic morphism** is the Spec map of a global complete intersection ring map(4.4.4.11). A **syntomic morphism** is a morphism that is locally a standard syntomic morphism.

Prop. (5.6.8.5). Syntomic is local on the source and target, stable under base change and composition, by(4.4.4.12).

Prop. (5.6.8.6). Syntomic is equivalent to flat, locally of f.p.+fibers being local complete intersections.

Proof: This follows from(4.4.4.18). □

Cor. (5.6.8.7). Syntomic morphisms are universally open.

Prop. (5.6.8.8). An open immersion is syntomic, because localizations are global complete intersections(4.4.4.12).

Prop. (5.6.8.9). If $f : X \to S$ is a syntomic map, then the function $x \mapsto \dim_x(X_{f(x)})$ is locally constant on X. If it is standard syntomic, then it is constant.

Proof: It suffices to prove for syntomic maps, Cf.[Sta]02K0. □

Prop. (5.6.8.10). A local complete intersection has its ideal sheaf $\mathcal{I}$, then $\mathcal{I}/\mathcal{I}^2$ locally free by(4.3.4.16).

Prop. (5.6.8.11). If Y is a complete intersection in $\mathbb{P}^n_k$ of hypersurfaces of degree $d_1, \ldots, d_r$, then $\omega_Y = \mathcal{O}_Y(\sum d_i - n - 1)$.

Proof: Use the exact sequence $0 \to \mathcal{O}_Z(n-d) \to \mathcal{O}_Z \to i_*\mathcal{O}_Y \to 0$ and(5.10.1.17). □

Prop. (5.6.8.12). For a complete intersection of dimension q, $H^i(Y, \mathcal{O}_Y(n)) = 0$ for $0 < i < q$. And the natural map $\Gamma(P, \mathcal{O}_P(n)) \to H^0(Y, \mathcal{O}_Y(n))$ is a surjection for every n. In particular, Y is connected, and the arithmetic genus $p_a(Y) = \dim H^q(Y, \mathcal{O}_Y)$.

Proof: We use induction, the case $Y = P$ follows from(5.7.2.1), let $Y = Z \cap H$, where H has degree d, then

$$0 \to \mathcal{O}_Z(n-d) \to \mathcal{O}_Z \to i_*\mathcal{O}_Y \to 0$$

thus use long exact sequence. The rest is easy. □

5.7 Cohomology of Schemes

Main references are [Sta]Chap29.

Notation (5.7.0.1).
- Use notations defined in Cohomology on Ringed Sites.

1 Zariski Cohomology

Qco Sheaves

Lemma (5.7.1.1) [Zariski-Poincare]. A Qco sheaf on an affine scheme X is Čech-acyclic.

Proof: Because the principal affine covers are cofinal in the ordering of covers, we only need to consider principal affine covers. Let $R \to A = \prod R_{f_i}$, then it is f.f., so we can use(4.4.2.2), just notice the higher term is $\prod_{i_0,\ldots,i_n} R_{f_{i_0}\cdots f_{i_n}}$. □

Prop. (5.7.1.2)[Čech Cohomology on Separated Schemes]. If X is separated and $\mathcal{F} \in \mathfrak{QCoh}(X)$, $H^p(X,\mathcal{F}) = \check{H}^p(X,\mathcal{F}) = H^p_{\text{alt}}(\{U_i \to X\}, F)$ for any open affine covering $\{U_i \to X\}$.

Proof: Use(5.3.2.16) and(5.3.2.6), the family of affine open subsets of X satisfies the requirement because X is separated and(5.7.1.1), thus the result It can be calculated by alternating complexes by(5.3.2.7). □

Cor. (5.7.1.3) [Affine Cohomological Vanishing]. If X is affine and $\mathcal{F} \in \mathfrak{QCoh}(X)$, $H^i(X,\mathcal{F}) = 0$ for $i > 0$.

For a qcqs scheme X, choose a finite affine cover $U_1, \ldots, U_t$ of X, then for any $\mathcal{F} \in \mathfrak{QCoh}(X)$, $H^n(X,\mathcal{F}) = 0$ for $n \geq d$, where

$$d = \max_{I \subset \{1,\ldots,t\}} (|I| + t(U_I))$$

and $t(Y)$ is the minimal cardinality of an affine open cover of Y.

Proof: The last assertion follows form Čech to sheaf2(5.3.2.13) and(5.7.1.2), as U_I is separated for any $I \neq \varnothing$. □

Remark (5.7.1.4). Compare with(6.2.0.4)**?**.

Prop. (5.7.1.5) [$\mathfrak{QCoh}(X)$ vs. $\mathfrak{Mod}(\mathcal{O}_X)$]. If X is a Noetherian scheme, then injective objects in $\mathfrak{QCoh}(X)$ are all flabby(5.3.4.8), thus nearly calculating all cohomologies are legitimate in the category $\mathfrak{QCoh}(X)$.

However, in general, this is not true, as there are examples of injective A-module $\mathcal{I}$ s.t. $\widetilde{I}$ is not flask on Spec A, by [Sta]0274.

Proof: We use the Deligne formula(5.5.1.36) and the definition of injective, by considering the sheaf of ideals of the corresponding induced reduced structure. □

Prop. (5.7.1.6)[Filtered Colimits]. By(5.3.1.16), if X is qcqs, then sheaf cohomology on X commutes with filtered colimits.

Prop. (5.7.1.7)[$\mathcal{E}xt$ For Coherent Sheaves]. On a locally Noetherian scheme, for $\mathcal{F} \in \mathfrak{QCoh}(X)$ and $\mathcal{G} \in \mathfrak{Coh}(X)$, $\mathcal{E}xt^i(\mathcal{F},\mathcal{G}) \in \mathfrak{QCoh}(X)$, and affine locally are given by $\text{Ext}^i(\mathcal{F}(U),\mathcal{G}(U))$.

Moreover $\mathcal{G} \in \mathfrak{Coh}(X)$, then $\mathcal{E}xt^i(\mathcal{F},\mathcal{G}) \in \mathfrak{Coh}(X)$.

Proof: This follows from(5.8.5.13) and(5.8.5.10). □

Prop. (5.7.1.8). When X is locally Noetherian and $\mathcal{F} \in \mathfrak{Coh}(X)$,

$$\mathcal{E}xt^i(\mathcal{F}, \mathcal{G})_x \cong \mathrm{Ext}^i_{\mathcal{O}_x}(\mathcal{F}_x, \mathcal{G}_x).$$

Proof: Taking stalk is exact.**?** □

Cor. (5.7.1.9). If X is locally Noetherian, suppose that every coherent sheaf is a quotient of a locally free sheaf, we can define the **homological dimension** $hd(\mathcal{F})$ of a coherent sheaf $\mathcal{F}$ as the minimal length of a flat resolution of $\mathcal{F}$. Then $hd(\mathcal{F}) \leq n \iff \mathcal{E}xt^i(\mathcal{F}, \mathcal{G}) = 0$ for every $\mathcal{G}$ and every $i > n$. And $hd(\mathcal{F}) = \sup pd_{\mathcal{O}_{X,x}} \mathcal{F}_x$, by(5.7.1.8).

Prop. (5.7.1.10) [Künneth Formula]. If X, Y are qcqs over a field k and $\mathcal{F}, \mathcal{G}$ be Qco $\mathcal{O}_X, \mathcal{O}_Y$-modules, then there is a canonical isomorphism:

$$H^n(X \times_{\mathrm{Spec}\, k} Y, \mathrm{pr}_1^* \mathcal{F} \otimes_{\mathcal{O}_{X \otimes_{\mathrm{Spec}\, k} Y}} \mathrm{pr}_2^* \mathcal{G}) \cong \oplus_{p+q=n} H^p(X, \mathcal{F}) \otimes_k H^q(Y, \mathcal{G}).$$

Proof: Cf.[Sta]0BEF.**?** □

Prop. (5.7.1.11). On a locally Noetherian scheme X, any Qco sheaf $\mathcal{F}$ admits a resolution of Qco sheaves that are flabby.

Proof: Because $\mathfrak{QCoh}(X)$ is Serre subcategory,**?** □

Lemma (5.7.1.12) [Gabber]. Let X be a scheme, then there exists a cardinal κ that every Qco sheaf is a colimit of its κ-generated Qco subsheaves.

Proof: Cf.[Sta]077N. □

Prop. (5.7.1.13) [Qco Cohomology Comparison]. For $X \in \mathfrak{Sch}, \mathcal{F} \in \mathfrak{QCoh}(X), \tau \in$\{fppf, étale, smooth, syntomic, Zariski\}, there are canonical isomorphisms

$$H^p(X, \mathcal{F}) \cong H^p(\mathfrak{Sch}_\tau / X, \mathcal{F}) \cong H^p(X_{\mathrm{Zar}}, \mathcal{F}) \cong H^p(X_{\text{ét}}, \mathcal{F}).$$

Proof: Let $\mathcal{C} = \mathfrak{Sch}_\tau / X$ or $X_{\text{ét}}, X_{\mathrm{Zar}}$. We use(5.3.2.16) with $\mathfrak{G}$ the set of affine schemes and Cov the subset of $\mathrm{Cov}(\mathcal{C})$ consisting of morphisms between affine schemes. Then Čech vanishing is clear in the affine case by(4.4.2.2). Thus(5.3.2.16) says $H^p(\mathcal{C}, \mathcal{F}_\mathcal{C}) = 0$ for $p > 0$.

Next, if $U \subset X$ is an affine open s.t. $U \to X$ is separated. Let $\mathcal{U}$ be an affine open covering of U, then all $U_{i_0, \ldots, i_p}$ are affine, thus

$$H^p(\mathcal{C}, \mathcal{F}_\mathcal{C}) = \check{H}(\mathcal{U}, \mathcal{F}_\mathcal{C}) = H^p(U, \mathcal{F}|_U)$$

by(5.3.2.15).

Finally, for X, take an injective resolution $\mathcal{F} \to \mathcal{I}^\bullet$, and an injective resolution $\mathcal{F}_\mathcal{C} \to \mathcal{J}^\bullet$. Then the latter restricts to a chain complex $\mathcal{F} \to \mathcal{J}^\bullet|_X$, which is exact because it is exact on any affine open $U \subset X$ as $H^p(\mathcal{C}, \mathcal{F}_\mathcal{C}) = 0$ for $p > 0$. Thus by(3.9.2.5), there is a map $\mathcal{J}^\bullet|_X \to \mathcal{I}^\bullet$, inducing a map $H^p(\mathcal{C}, \mathcal{F}_\mathcal{C}) = H^p(X, \mathcal{J}^\bullet) \to H^p(X, \mathcal{I}^\bullet) \cong H^p(X, \mathcal{F})$.

To show these map are isomorphisms, take an affine open covering $\mathcal{U}$ of X, then there are Čech-to-derived spectral sequences

$${}^\tau E_2^{p,q} = \check{H}^p(\mathcal{U}, \mathcal{H}^q(\mathcal{F}^a)) \Rightarrow H^{p+q}(\mathcal{C}, \mathcal{F}_\mathcal{C}), \quad E_2^{p,q} = \check{H}^p(\mathcal{U}, \mathcal{H}^q(\mathcal{F}^a)) \Rightarrow H^{p+q}(\mathcal{C}, \mathcal{F}).$$

The map $\mathcal{J}^\bullet|_X \to \mathcal{I}^\bullet$ induces a map $\check{C}^\bullet(\mathcal{U}, \mathcal{J}) \to \check{C}^\bullet(\mathcal{U}, \mathcal{I})$ which induces a map of the spectral sequences. But as each affine open of X is separated over X, the E^2-page is an isomorphism by what we have proved. Thus $\mathcal{H}^q(\mathcal{F}^a)) \to H^{p+q}(\mathcal{C}, \mathcal{F})$ is an isomorphism. □

Prop. (5.7.1.14). For $X \in \mathcal{S}\mathrm{ch}, \tau \in$ {fppf, étale, smooth, syntomic, Zariski},

$$H^1_\tau(X, \mathbb{G}_m) \cong \mathrm{Pic}(X)(5.5.3.10).$$

Proof: As these X_τ are all locally ringed sites, by(5.3.1.17), $H^1_\tau(X, \mathbb{G}_m) \cong \mathrm{Pic}(X_\tau)$. Thus it suffices to prove that

$$\mathrm{Pic}(X_{\mathrm{Zar}}) \to \mathrm{Pic}(X_{\text{ét}}) \to \ldots \to \mathrm{Pic}(X_{\mathrm{fppf}})$$

are isomorphisms. Then this is because any invertible sheaf is quasi-coherent by(5.2.5.8), so $\mathrm{Pic}(X_\tau)$ are in fact the group of invertible objects in $\mathfrak{QCoh}(X_\tau)$. But $\mathfrak{QCoh}(X_\tau)$ are all equivalent categories, by fpqc descent for Qco sheaves(5.1.5.12). □

2 Proper Schemes

Prop. (5.7.2.1) [Cohomology of Projective Space]. Let $X = \mathbb{P}^r_A$ we have:

(1)

$$H^q(X, \mathcal{O}_X(d)) = \begin{cases} (A[T_0, \ldots, T_r])_d & q = 0 \\ 0 & q \neq 0, r \\ (\frac{1}{T_0 \ldots T_r} A[\frac{1}{T_0}, \ldots, \frac{1}{T_r}])_d & q = r \end{cases}$$

(2) The cup product defines a perfect pairing

$$H^0(X, \mathcal{O}_X(n)) \times H^r(X, \mathcal{O}_X(-n-r-1)) \to H^r(X, \mathcal{O}_X(-r-1)) \cong A.$$

Proof: X is separated, we use Cech cohomology. Let $\mathcal{F} = \oplus_{d \in \mathbb{Z}} \mathcal{O}_X(d)$, then $\mathcal{F}$ is a Qco graded ring. Let $U_{i_0, \ldots i_k}$ be the affine open subset $U(x_{i_0}) \cap \ldots U(x_{i_k})$ of X, then $\mathcal{F}(U_{i_0, \ldots, i_k}) = A[T_0, \ldots, T_r, T_{i_0}^{-1}, \ldots, T_{i_k}^{-1}]$ as graded rings, and the cohomology $H^\bullet(\mathcal{F})$ is calculated by the Čech complex(5.3.2.1)

$$\check{C}^\bullet = \prod_i A[T_0, \ldots, T_r, T_i^{-1}] \to \prod_{i,j} A[T_0, \ldots, T_r, T_i^{-1}, T_j^{-1}] \to \ldots \to A[T_0, \ldots, T_r, T_1^{-1}, \ldots, T_r^{-1}].$$

This complex has a natural $\mathbb{Z}^r$-grading, and the differential is natural inclusion thus preserves the grading, i.e.

$$\check{C}^\bullet = \bigoplus_{v \in \mathbb{Z}^r} \check{C}^\bullet(v)$$

where if we set $NEG(v) = \{i \in \{0, \ldots, r\} | v_i < 0\}$, then

$$\check{C}^\bullet(v) = \prod_{NEG(v) \subset \{i\}} AT_0^{v_0} \ldots T_r^{v_r} \to \prod_{NEG(v) \subset \{i,j\}} AT_0^{v_0} \ldots T_r^{v_r} \to \ldots \to AT_0^{v_0} \ldots T_r^{v_r}$$

is the subcomplex of $\check{C}^\bullet$. So it suffices to calculate the cohomology of $\check{C}^\bullet(v)$ for each v.

If $NEG(v) = \{0, 1, \ldots, n\}$, then there is only one term, so

$$H^\bullet(\check{C}^\bullet(v)) = \begin{cases} AT_0^{v_0} \ldots T_r^{v_r} & q = r \\ 0 & \text{otherwise} \end{cases}.$$

The sum of all such v clearly contribute to $\frac{1}{T_0 \ldots T_r} A[\frac{1}{T_0}, \ldots, \frac{1}{T_r}]$ in degree r.

If $NEG(v) = 0$, then the complex is isomorphic to the Čech complex calculating cohomology of $\mathrm{Spec}\, A$ using the trivial cover $\{V_i \to \mathrm{Spec}\, A\}, V_i \cong \mathrm{Spec}\, A$ times $T_0^{v_0} \ldots T_r^{v_r}$. As Spec is separated, it is just to the sheaf cohomology of $\operatorname{Spec} A$, which is A is degree 0 and 0 otherwise by(5.7.1.1). The sum of all such v clearly contribute to $A[T_0,\dots,T_r]$ in degree 0.

Finally, for other v, choose a $j\in\{0,1,\dots,n\}\backslash NEG(v)$, then the maps

$$h:\check{C}^{p+1}(v)\to\check{C}^p(v):h(s)_{i_0\dots i_p}=s_{ji_0i_p}$$

(where we are using the alternating Čech complex) induces a homotopy between 0 and id, so $\check{C}^{p+1}(v)$ have trivial cohomologies.

The pairing given by cup product makes $T_0^{v_0}\dots T_r^{v_r}$ dual to $T_0^{-1-v_0}\dots T_r^{-1-v_r}$, thus it is a perfect pairing. □

Cor. (5.7.2.2). when $n>0$, $H^r(X,\mathcal{O}_X(n-r-1))=0$. Notice this an instance of the Kodaira vanishing theorem when k has characteristic 0(11.9.7.3).

Prop. (5.7.2.3). Let $X=\mathbb{P}^n_k$ and $0\le p,q\le n$, then $H^q(X,\Omega^p_X)=0$ for $p\neq q$ and when $p=q$, $H^q(X,\Omega^p_X)=k$.

Proof: By(5.5.1.26) and(5.5.5.7), there is an exact sequence $0\to\Omega^q\to\wedge^q\mathcal{O}(-1)\to\Omega^{q-1}\to 0$, and the middle has vanishing q-th cohomology by(5.7.2.1), thus we can induct and (5.7.2.1) gives the result. □

Prop. (5.7.2.4) [Cohomology of Complete Intersections]. Let X be a closed subscheme of $\mathbb{P}^n_k$ defined by a single homogenous equation $f(x_0,x_1,x_2)$ of degree d, then show that $\dim H^0(X,\mathcal{O}_X)=1$, and if $n\ge 2$, $\dim H^1(X,\mathcal{O}_X)=(d-1)(d-2)/2$.

Proof: By(5.5.3.15), there is an exact sequence of sheaves on $\mathbb{P}^n_k$:

$$0\to\mathcal{O}_{\mathbb{P}^n_k}(-d)\cong\mathcal{O}_{\mathbb{P}^n_k}(-X)\to\mathcal{O}_{\mathbb{P}^n_k}\to i_*\mathcal{O}_X\to 0$$

which induces a long exact sequence(5.7.4.2):

$$\begin{aligned}H^0(\mathbb{P}^n_k,\mathcal{O}_{\mathbb{P}^n_k}(-d))\to H^0(\mathbb{P}^n_k,\mathcal{O}_{\mathbb{P}^n_k})\to H^0(X,\mathcal{O}_X)\to H^1(\mathbb{P}^n_k,\mathcal{O}_{\mathbb{P}^n_k}(-d))\\ \to H^1(\mathbb{P}^n_k,\mathcal{O}_{\mathbb{P}^n_k})\to H^1(X,\mathcal{O}_X)\to H^2(\mathbb{P}^n_k,\mathcal{O}_{\mathbb{P}^n_k}(-d))\to H^2(\mathbb{P}^n_k,\mathcal{O}_{\mathbb{P}^n_k})\end{aligned}$$

By(5.7.2.1), this reads:

$$0\to k\to H^0(X,\mathcal{O}_X)\to 0\to 0\to H^1(X,\mathcal{O}_X)\to H^2(\mathbb{P}^n_k,\mathcal{O}_{\mathbb{P}^n_k}(-d))\to 0,$$

and if $n=2$, $\dim H^2(\mathbb{P}^2_k,\mathcal{O}_{\mathbb{P}^n_k}(-d))=(d-1)(d-2)/2$.

? It is faster using Hilbert Polynomial. □

Lemma (5.7.2.5) [Cohomology of Projective Space]. Let R be a Noetherian ring and $n\ge 0$, then for any coherent sheaf $\mathcal{F}$ on $\mathbb{P}^n_R$,

- $H^i(\mathbb{P}^n_R,\mathcal{F}(n))=0$ for $i>0$ and n large enough.
- For any i, $H^i(\mathbb{P}^n_R,\mathcal{F})$ is a finite R-module.
- For any $k\in\mathbb{Z}$, $\bigoplus_{d\ge k}H^0(\mathbb{P}^n_R,\mathcal{F}(d))$ is a finite $R[T_0,\dots,T_n]$-module.

Proof: 1: The assertions are true for $\mathcal{O}_X(n)$ by(5.7.2.1), and for general $\mathcal{F}$, we use descending induction on i. This is true for $i > n$ by Čech cohomology(5.7.1.2). For general $i > 0$, choose a surjection $\bigoplus \mathcal{O}_X(n_i) \to \mathcal{F}$ with coherent kernel $\mathcal{R}$(5.5.4.5), then there is an exact sequence

$$H^i(X, \oplus \mathcal{O}_X(n_i + n)) \to H^i(X, \mathcal{F}(n)) \to H^{i+1}(X, \mathcal{R}(n)),$$

and the left term vanish for n large(5.7.2.1), and the right term vanish by induction hypothesis.

2: Notation as above, we use descending induction on i. This is true for $i > n$ by Čech cohomology(5.7.1.2). For general $i > 0$, $H^i(X, \oplus \mathcal{O}_X(n_i))$ is finite by(5.7.2.1), and $H^{i+1}(X, \mathcal{R})$ is finite by induction hypothesis, thus $H^i(X, \mathcal{F}(n))$ is also finite.

3: Notation as above, for n large, $H^i(X, \oplus \mathcal{O}_X(n_i + n)) \to H^i(X, \mathcal{F}(n))$ is surjective. Thus $M_k = \bigoplus_{d \geq k} H^0(\mathbb{P}^n_R, \mathcal{F}(d))$ is a quotient of $N_k = \bigoplus_{d \geq k} H^0(\mathbb{P}^n_R, \mathcal{O}_X(d))$ for k large. Notice for k small enough, $N_k \cong \oplus_i R[T_0, \ldots, T_n][i]$ is a finite graded $R[T_0, \ldots, T_n]$-module, thus N_k is finite for any k as $R[T_0, \ldots, T_n]$ is Noetherian. Then M_k is finite for k large, and each $H^0(\mathbb{P}^n_R, \mathcal{F}(d))$ is itself finite by item 2, thus M_k is a finite $R[T_0, \ldots, T_n]$-module for any k. □

Prop. (5.7.2.6) [Cohomology of Proper Schemes]. Let X be a proper scheme over a Noetherian ring A, $\mathcal{L}$ an ample invertible sheaf on X and $\mathcal{F} \in \mathfrak{Coh}(X)$, then

- $H^i(X, \mathcal{F} \otimes \mathcal{L}^{\otimes d}) = 0$ for $i > 0$ and d large enough.
- The graded ring $A = \bigoplus_{n \geq 0} H^0(X, \mathcal{L}^{\otimes n})$ is a f.g. R-algebra.
- For any $k \in \mathbb{Z}$, $\bigoplus_{d \geq k} H^0(X, \mathcal{F} \otimes \mathcal{L}^{\otimes d})$ is a finite A-module.

Proof: By(5.5.4.24), there exists a $d > 0$ and some immersion $i : X \to \mathbb{P}^n_A$ that $i^* \mathcal{O}_{\mathbb{P}^n_A}(1) \cong \mathcal{L}^{\otimes d}$, and i is a closed immersion because X is proper. Let $S = R[T_0, \ldots, T_n]$.

1: By projection formula(5.7.4.6),

$$i_*(\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}^{\otimes nd+q}) = i_*(\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}^{\otimes q})(n).$$

Then by(5.7.4.2) and(5.7.2.5), for n large enough, $H^p(X, \mathcal{F} \otimes \mathcal{L}^{\otimes q}) = 0$ for any $0 \leq q \leq d-1$, $p > 0$.

2: By proof of item1 and(5.7.2.5), we see $\oplus_{n \geq 0} A_{nd+q}$ is a finite graded S-module for any q, thus $A = \oplus_{q=0}^{d-1} \bigoplus_{n \geq 0} A_{nd+q}$ is a f.g. R-module.

3: Similarly, we see $\bigoplus_{d \geq k} H^0(X, \mathcal{F} \otimes \mathcal{L}^{\otimes d})$ is a finite graded S-module, and the S-module structure factors through $S \to A$, thus it is a finite A-module. □

Lemma (5.7.2.7). For an invertible sheaf $\mathcal{L}$ on a qc scheme X, if for each Qco sheaf of ideals $\mathcal{I} \in \mathcal{O}_X$, there exists an n that $H^1(X, \mathcal{I} \otimes \mathcal{L}^n) = 0$, then $\mathcal{L}$ is ample.

Proof: For any closed pt P, choose an open affine nbhd U that $\mathcal{L}$ is trivial, let $Y = X - U$, by the exact sequence $0 \to \mathcal{I}_{Y \cup \{p\}} \to \mathcal{I}_Y \to k(P) \to 0$, for each n,

$$0 \to \mathcal{I}_{Y \cup \{p\}} \otimes \mathcal{L}^n \to \mathcal{I}_Y \otimes \mathcal{L}^n \to k(P) \otimes \mathcal{L}^n \to 0.$$

Thus by assumption for some n the map $\Gamma(X, \mathcal{I}_Y \otimes \mathcal{L}^n) \to \Gamma(X, k(P) \otimes \mathcal{L}^n)$ is surjective. Now $k(P) \otimes \mathcal{L}^n \cong A/\mathfrak{m}_P$, so we let $s \in \Gamma(X, \mathcal{I}_Y \otimes \mathcal{L}^n)$ maps to a section in $\Gamma(X, k(P) \otimes \mathcal{L}^n)$ that corresponds to $1 \in A/\mathfrak{m}_P$, then $P \in \mathrm{Supp}(s) \subset U$, and $\mathrm{Supp}(s)$ is affine. So we find an affine nbhd X_s for every closed pt of X.

Finally these X_s cover X, because the complement of $\cup X_s$ is closed in X thus qc, then it contains a closed point by(3.3.6.1). □

Prop. (5.7.2.8)[Serre's Cohomological Criterion of Ampleness]. If X is proper over a Noetherian affine scheme, $\mathcal{L}$ is an invertible sheaf, then the following is equivalent.

- $\mathcal{L}$ is ample
- For any $\mathcal{F} \in \mathfrak{Coh}(X)$, for n large enough, $H^p(X, \mathcal{F} \otimes \mathcal{L}^n) = 0$ for $p > 0$.
- For any Qco sheaf of ideals $\mathcal{I} \in \mathcal{O}_X$, there exists an $n \geq 1$ that $H^1(X, \mathcal{I} \otimes \mathcal{L}^{\otimes n}) = 0$

(Notice in this case H-ample $\iff$ ample).

Proof: $1 \to 2$: This follows from(5.7.2.6). $2 \to 3$ is trivial. $3 \to 1$: (5.7.2.7). □

Lichtenbaum's theorem

Lemma (5.7.2.9). Let X is a variety and $\mathcal{F} \in \mathfrak{Coh}(\mathcal{O}_X)$. If $H^d(X, \mathcal{F}) \neq 0$, then $\dim X \geq d$, and if equality holds, X is proper.

Proof: Cf.[Sta]0G5E. □

Prop. (5.7.2.10) [Lichtenbaum]. Let X be a non-empty separated scheme of f.t. over a field k of dimension d, then the following are equivalent:

- $H^d(X, \mathcal{F}) = 0$ for all $\mathcal{F} \in \mathfrak{Coh}(X)$.
- $H^d(X, \mathcal{F}) = 0$ for all $\mathcal{F} \in \mathfrak{QCoh}(X)$.
- No irreducible component of X of dimension d is proper over k.

Proof: Cf.[Sta]0G5F. □

3 Euler Characteristics

Def. (5.7.3.1) [Euler Characteristic]. Let X be proper over a field k and $\mathcal{F} \in \mathfrak{Coh}(X)$, then the **Euler characteristic** of $\mathcal{F}$ is defined to be:

$$\chi(\mathcal{F}) = \sum (-1)^i \dim_k H^i(X, \mathcal{F}).$$

It is definable by Grothendieck vanishing(5.3.5.17) and Grothendieck coherence theorem(5.7.4.12), and It is clearly an additive functor on $\mathfrak{Coh}(X)$.

Prop. (5.7.3.2). For a proper scheme X over a field k and $\mathcal{L}_i$ be invertible sheaves on X. Then for any $\mathcal{F} \in \mathfrak{Coh}(X)$,

$$\chi(X, \mathcal{F} \otimes \mathcal{L}_1^{n_1} \otimes \cdots \otimes \mathcal{L}_r^{n_r})$$

is a polynomial in $(n_1, \ldots, n_r)$ of total degree at most $\dim \operatorname{Supp} \mathcal{F}$.

Proof: Cf.[Sta]0BEM. □

Prop. (5.7.3.3). Let $f : Y \to X$ be morphism between schemes proper over field k and $\mathcal{F} \in \mathfrak{Coh}(X)$,

$$\chi(Y, \mathcal{F}) = \sum (-1)^i \chi(X, R^i f_* \mathcal{F}).$$

In particular, if f is affine(finite), then $\chi(Y, \mathcal{F}) = \chi(X, f_* \mathcal{F})$.

Prop. (5.7.3.4). This formula makes sense by(5.7.4.4) and(5.7.4.12), and it is true by Leray spectral sequence(5.3.1.9).

Prop. (5.7.3.5). If X is a proper scheme and $\mathcal{F} \in \mathcal{C}\mathrm{oh}(X)$ with $\dim \mathrm{Supp}(\mathcal{F}) = 0$, then $\mathcal{F}$ is generated by global sections, $H^i(X, \mathcal{F}) = 0$ for $i > 0$, and

$$\chi(X, \mathcal{F} \otimes \mathcal{E}) = n\chi(X, \mathcal{F})$$

for any $\mathcal{E} \in \mathcal{V}\mathrm{ect}^n(X)$.

Proof: The first two are clear as $\mathcal{F} = i_*\mathcal{G}$ where $i : \mathrm{Supp}(\mathcal{F}) \to X$. The last assertion follows from the projection formula(5.7.4.6) $i_*(\mathcal{G} \otimes i^*\mathcal{E}) \cong \mathcal{F} \otimes \mathcal{E}$. □

Def. (5.7.3.6) [Arithmetic Genus]. The **arithmetic genus** of a proper scheme of dimension r over a field is defined to be $p_a(X) = (-1)^r(\chi(\mathcal{O}_X) - 1)$(5.7.3.1). In particular, when X is a complete curve over a field k, then $p_a(X) = \dim_k H^1(X, \mathcal{O}_X)$(5.10.1.12).

The arithmetic genus is stable under base change of fields, by flat base change theorem.

Prop. (5.7.3.7) [Arithmetic Genus of Product]. By Künneth formula, if X, Y are proper schemes of dimension r, s over a field k, then

$$H^n(X \otimes_k Y, \mathcal{O}_{X\otimes_k Y}) \cong \bigoplus_{0\le k\le n} H^k(X, \mathcal{O}_X) \otimes H^{n-k}(Y, \mathcal{O}_Y).$$

Thus $\chi(X \times_k Y) = \chi(X)\chi(Y)$. In particular, we have

$$p_a(X \times Y) = p_a(X)p_a(Y) + (-1)^s p_a(X) + (-1)^r p_a(Y).$$

Prop. (5.7.3.8) [Arithmetic Genus of Complete Intersections]. Let C be a smooth complete intersection of a degree m surface S_1 and a degree n surface S_2 in $\mathbb{P}^3_k$, then $p_a(C) = \frac{1}{2}(mn(m + n - 4) + 2)$.

Proof: There are exact sequences $0 \to \mathcal{O}_{\mathbb{P}^3_k}(-S_i) \to \mathcal{O}_{\mathbb{P}^3_k} \to \mathcal{O}_{S_i} \to 0$, which gives

$$0 \to \mathcal{O}_{\mathbb{P}^3_k}(-S_2)|_{S_1} \to \mathcal{O}_{S_1} \to \mathcal{O}_{S_1\cap S_2} \to 0.$$

So by adjunction formula,

$$\mathcal{K}_C = \mathcal{K}_{S_1}(S_1 \cap S_2)|_C = \mathcal{K}_{\mathbb{P}^3_k}(S_1)(S_2)|_C = \mathcal{O}_C(m + n - 4).$$

So $2g - 2 = mn(m + n - 4)$. □

Prop. (5.7.3.9) [Asymptotic Riemann-Roch]. If X is a proper scheme over a field k of dimension d and $\mathcal{L}$ is an ample invertible sheaf, then $\dim \Gamma(X, \mathcal{L}^n) \sim cn^d$.

Proof: Cf.[Sta]0BJ8. □

Hilbert Polynomials

References are [Hartshorne I.7] and [Vak17].

Prop. (5.7.3.10) [Hilbert Polynomial]. For a projective scheme over a field k and a coherent sheaf $\mathcal{F}$, there is a polynomial **Hilbert polynomial** $P \in \mathbb{Q}[\lambda]$ that $\chi(\mathcal{F}(n)) = P(n)$, and $\deg P \le \dim \mathrm{Supp}(\mathcal{F})$.

This Hilbert polynomial is compatible with the definition in(5.7.3.12), because by(5.7.4.7), the higher cohomology group vanishes for n large, so $\chi(\mathcal{F}(n)) = \Gamma(\mathcal{F}(n)) = \Gamma_*(\mathcal{F})_n$.

Proof: □

Prop. (5.7.3.11). Let $X \hookrightarrow Y \hookrightarrow \mathbb{P}^n_k$ be a sequence of closed embeddings, then $P_X(m) \leq P_Y(m)$ for m large, and if equality holds for m large, then $X = Y$.

Proof: Cf.[Vak17]P490. □

Def. (5.7.3.12)[Hilbert Polynomial]. For a scheme projective over a field k of dimension r, we define the **Hilbert polynomial** P_Y as the Hilbert polynomial of its homogenous coordinate ring $\Gamma_*(Y)$. It has dimension r by(4.2.2.17).

The **degree** of Y is defined as the $r!$ times the leading coefficients of P_Y.

Prop. (5.7.3.13).

- The degree is a positive integer.
- If $Y = Y_1 \cup Y_2$ and $\dim Y_1 \cap Y_2 < r$, then $\deg Y = \deg Y_1 + \deg Y_2$.
- If H is a hypersurface whose ideal is generated by a homogeneous polynomial of degree d, then $\deg H = d$.

Proof: Cf.[Hartshorne P52]. □

Prop. (5.7.3.14). For a variety of degree k and a general linear space, the intersection has k points.

Proof: □

4 Relative Cohomology

Prop. (5.7.4.1)[Filtered Colimits]. If $f : X \to Y$ is qcqs, then $R^i f_*$ commutes with filtered colimits, by(5.3.1.6) and(5.7.1.6).

Prop. (5.7.4.2) [Sheaf Cohomology Commutes with Affine Map]. For $f : X \to Y$ affine and $\mathcal{F} \in \mathfrak{QCoh}(X)$, $H^n(Y, \mathcal{F}) = H^n(X, f_*\mathcal{F})$.

Proof: Because $R^i f_*\mathcal{F}(U) = 0$ by(5.7.1.3) and(5.3.1.7), we can then use(5.3.1.8) to conclude. □

Prop. (5.7.4.3)[Higher Direct Image Preserves Qco Sheaves]. If $f : X \to S$ is qcqs then $R^n f_*$ maps $\mathfrak{QCoh}(X)$ to $\mathfrak{QCoh}(S)$, and for $U \subset S$ affine open, $\underline{(R^p f_*\mathcal{F})|_U = (H^p(f^{-1}(U), \mathcal{F}))^\sim}$.

Proof: Firstly by(5.3.3.18), $(R^p f_*\mathcal{F})|_U = R^p f_{U*}(\mathcal{F}|_U)$, so it suffices to prove for S affine. Then $R^p f_*\mathcal{F}$ is the sheafification of the presheaf $G : U \mapsto H^p(f^{-1}(U), \mathcal{F})$ by(5.3.1.7).

If f is separated, then we can use Čech cohomology(5.7.1.2) to see that $H^p(f^{-1}(D(f)), \mathcal{F}) = H^p(X, \mathcal{F})_f$ thus G is itself a sheaf and the conclusion follows.

In general we can choose a finite affine cover U_i of X, then every intersection of U_i is quasi-compact and separated, and there is a spectral sequence convergence $H^p(\{U_i \to X\}, \mathcal{H}^q(F)) \implies H^{p+q}(X, F)$, where the left can be calculated using Čech cohomology. Taking localization w.r.t. f, we get the desired isomorphism $H^p(f^{-1}(D(f)), \mathcal{F}) = H^p(X, \mathcal{F})_f$ also by comparison(3.9.7.5). □

Prop. (5.7.4.4)[Cohomological Boundedness of Rf_*]. For a qcqs morphism $f : X \to S$, if S is qc, there is an N that for every base change f' of f, we have $R^n f'_*\mathcal{F} = 0$ for every $\mathcal{F} \in \mathfrak{QCoh}(X)$ and $n \geq N$.

In particular, if f is affine, then $R^n f'_*\mathcal{F} = 0$ for $n > 0$. And if f is projective, then $R^n f'_*\mathcal{F} = 0$ for n bigger than the maximal dimension of the fiber of f.

Proof: Check affine locally on S and use(5.7.4.3), choose a finite affine cover $\mathcal{U}$ of X. Then when n is large, $(R^n f'_*\mathcal{F})|_{U_i} = 0$ by(5.7.4.3) and(5.7.1.3) for any i, thus $R^n f'_*\mathcal{F} = 0$. For base changes, notice the cardinality of the affine cover are the same. □

Cor. (5.7.4.5). For a qc separated scheme X, the cohomology vanish for n large. And when X is separated and can be covered by r affine opens, then N can chosen to be r.

Cor. (5.7.4.6) [Projection Formula].

- Let $f : X \to Y$ be a morphism of schemes, and $\mathcal{E}$ a locally free $\mathcal{O}_Y$-module, then for any $\mathcal{F} \in \mathcal{M}od(\mathcal{O}_X)$ and any i, there are natural isomorphisms.

$$R^i f_*(\mathcal{F} \otimes f^*\mathcal{E}) \cong R^i f_*(\mathcal{F}) \otimes \mathcal{E}.$$

- If $f : X \to Y$ is a qcqs morphism of schemes, then for any $\mathcal{F} \in \mathcal{C}oh(\mathcal{O}_X), \mathcal{E} \in \mathcal{C}oh(\mathcal{O}_Y)$, there is a natural isomorphism

$$Rf_*(\mathcal{F} \otimes^L Lf^*\mathcal{E}) \cong Rf_*(\mathcal{F}) \otimes^L \mathcal{E}.$$

Proof: 1 follows from(5.3.3.20) and 2 follows from(5.8.5.8). □

<u>**Proper Morphism and** $\mathcal{C}oh(X)$</u>

Prop. (5.7.4.7)[Relative Serre Vanishing]. If $f : X \to Y$ is a proper morphism of locally Noetherian schemes, $\mathcal{I}$ an invertible sheaf on X, then the following are equivalent:

- $\mathcal{L}$ is f-ample.
- For any $\mathcal{F} \in \mathcal{C}oh(X)$, for n sufficiently large, $R^i f_*(\mathcal{F} \otimes \mathcal{I}^{\otimes n}) = 0$ and $i > 0$.
- For any Qco sheaf of ideals $\mathcal{I} \subset \mathcal{O}_X$, there exists an $n \geq 1$ that $R^1 f_*(\mathcal{I} \otimes \mathcal{L}^{\otimes n}) = 0$.

Proof: $1 \to 2$: By(5.7.4.3), this follows from(5.7.2.8). $2 \to 3$ is trivial as X is Noetherian. $3 \to 1$: Notice for any affine open subset U of Y, $U \to Y$ is qc, thus $f^{-1}(U) \to X$ is quasi-compact, thus by(5.5.1.8), a Qco sheaf of ideals $\mathcal{I}$ on $f^{-1}(U)$ can be extended to a Qco sheaf of ideals on X. Then we can use(5.7.4.3) and Leray spectral sequence to reduce to(5.7.2.8). □

Cor. (5.7.4.8). Let X be proper over a Noetherian affine scheme with an ample invertible sheaf $\mathcal{I}$, then for any finite exact sequence in $\mathcal{C}oh(X)$, if tensoring it with $\mathcal{I}^{\oplus n}$ for large n, the resulting global section is exact.

Cor. (5.7.4.9). Let X be proper over a Noetherian affine scheme with an ample invertible sheaf $\mathcal{I}$, and $\mathcal{F}, \mathcal{G} \in \mathcal{C}oh(X)$, $i \geq 0$, then for n large(depending on $\mathcal{F}, \mathcal{G}, i$),

$$\mathrm{Ext}^i(\mathcal{F}, \mathcal{G}(n)) \cong \Gamma(X, \mathcal{E}xt^i(\mathcal{F}, \mathcal{G}(n))).$$

Proof: By(5.3.3.34)(5.7.1.7), there is a spectral sequence s.t. for n large, all the small terms vanish. □

Lemma (5.7.4.10). If $f : X \to Y$ is projective and Y locally Noetherian, then for any $n \in \mathbb{N}$, $R^n f_*$ maps coherent sheaves to coherent sheaves.

Proof: By(5.7.4.3), this problem is local on the target, so we may assume that $Y = \operatorname{Spec} R$ and $X = \mathbb{P}^n_R$, in which case this follows from(5.7.2.5). □

Prop. (5.7.4.11) [Grothendieck's Coherence Theorem]. If $f : X \to Y$ is proper and Y locally Noetherian, then for any $n \in \mathbb{N}$, $R^n f_*$ maps coherent sheaves to coherent sheaves.

Proof: By(5.7.4.3), this problem is local on the target, so we may assume Y is Noetherian, and then X is also Noetherian. We prove by devissage(5.5.1.55): 1 is trivial, for 2, for any closed subscheme $i : Z \subset X$, denote $g = f|_Z$, then it suffices to find a coherent sheaf $\mathcal{G}$ on Z s.t.

1. $\mathcal{G}_\xi \cong k(\xi)$.
2. $R^p g_* \mathcal{G}$ are coherent for any $p \geq 0$.

Because then $i_*\mathcal{G}$ is a coherent sheaf on X(5.5.1.32) that $R^p f_*(i_*\mathcal{G}) = R^p g_*\mathcal{G}$ for any p by relative Leray spectral sequence(5.3.1.8) and(5.7.4.4), and also $(i_*\mathcal{G})_\xi = \mathcal{G}_\xi$.

As $g : Z \to Y$ is proper, by Chow's lemma(5.4.5.23), there is a birational, H-projective map $\pi : Z' \to Z$ over Y that Z' is projective over Y. Then there is a closed immersion $j : Z' \to \mathbb{P}^n_Y$ and an induced closed immersion $j' : Z' \to \mathbb{P}^n_Z$. Then $\mathcal{L} = j^*\mathcal{O}_{\mathbb{P}^n_Y}(1) = (j')^*\mathcal{O}_{\mathbb{P}^n_Z}(1)$ is both $g\circ\pi$-relatively ample and π-relatively ample.

Hence by relative Serre vanishing(5.7.4.7) there exists an n that $R^p\pi_*\mathcal{L}^{\otimes n} = 0$ for any $p > 0$. Let $\mathcal{G} = \pi_*\mathcal{L}^{\otimes n}$, then this $\mathcal{G}$ satisfies the conditions: $\mathcal{G}_\xi = \kappa(\xi)$ as $\pi^{-1}(U) \to U$ is an isomorphism, and from relative Leray spectral sequence

$$R^p g_* R^q \pi_* \mathcal{L}^{\otimes n} \Longrightarrow R^n (g\circ\pi)_* \mathcal{L}^{\otimes n},$$

we see $R^p g_*\mathcal{G} \cong R^p g'_*\mathcal{L}^{\otimes n}$, which are coherent by(5.7.4.10). □

Cor. (5.7.4.12) [Coherent Cohomology Finite]. If $\pi : X \to \operatorname{Spec} A$ is proper over a Noetherian affine scheme A and $\mathcal{F}$ is a coherent sheaf on X, $H^i(X, \mathcal{F})$ are finite A-modules.

Proof: By(5.7.4.3), $R^p\pi_*\mathcal{F}$ is the Qco sheaf $\widetilde{H^p(X,\mathcal{F})}$, which is coherent iff $H^p(X,\mathcal{F})$ is a finite A-module. □

Prop. (5.7.4.13). Given a proper morphism between locally Noetherian schemes $f : X \to Y$, a coherent sheaf $\mathcal{F}$ on X and a coherent sheaf of ideals $\mathcal{I}$ of $\mathcal{O}_Y$. Then $\mathcal{M} = \bigoplus_{n\geq 0} R^p f_*(\mathcal{I}^n\mathcal{F})$ is a Qco graded $\mathcal{A} = \bigoplus_{n\geq 0}\mathcal{I}^n$-module of f.t..

Proof: By(5.7.4.3), this is local on Y, so we may assume Y is affine, Cf.[Sta]02O8. □

Prop. (5.7.4.14). Let $f : X \to Y$ be a proper morphism between locally Noetherian schemes and $\mathcal{F}$ a coherent sheaf on X, $y \in Y$. Consider the infinitesimal nbhds $X_n = \operatorname{Spec}(\mathcal{O}_{Y,y}/\mathfrak{m}_y^n) \times_Y X \xrightarrow{i_n} X$ of the fiber $X_1 = X_y$, and set $\mathcal{F}_n = i_{n*}\mathcal{F}$, then

$$(R^n f_*\mathcal{F})^\wedge_y \cong \varprojlim_n H^n(X_n, \mathcal{F}_n)$$

as $\mathcal{O}^\wedge_{Y,y}$-modules.

Proof: Cf.[Sta]02OD. □

Cor. (5.7.4.15)[Support of Higher Direct Images]. Let $f : X \to Y$ be a proper morphism between locally Noetherian schemes and $y \in Y$ s.t. $\dim(X_y) = d$, then for any coherent sheaf $\mathcal{F}$ on X, $(R^p f_*\mathcal{F})_y = 0$ for $p > d$.

Proof: Cf.[Sta]02V7. □

5 Base Change

Prop. (5.7.5.1) [Flat Base Change]. For a Cartesian diagram of schemes

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ S' & \xrightarrow{g} & S \end{array}$$

If g is flat and f is qcqs, then for every Qco sheaf $\mathcal{F}$ on X with base change $\mathcal{F}'$ on X', there is a canonical isomorphism

$$g^* Rf_*\mathcal{F} \cong Rf'_*\mathcal{F}'.$$

By(5.3.3.18), when S, S' is affine, this reads:

$$H^i(X,\mathcal{F}) \otimes_A B \cong H^i(X \otimes_A B, (g')^*\mathcal{F}).$$

Proof: Firstly by(5.3.3.18)(5.7.4.3), it suffices to show for S, S' affine. If X is separated, then the then we can use Čech cohomology(5.7.1.2), and the Čech complex of K' is just the cohomology of the Čech complex tensored with B, so it commutes with taking cohomology because B is A-flat.

Now if X is only qs, then we choose a finite affine open cover $\{U_i\}$, then every intersection of U_i is quasi-compact and separated. and there is a spectral sequence convergence $H^p(\{U_i \to X\}, \mathcal{H}^q(F)) \implies H^{p+q}(X, F)$. Tensoring with B, we also get the desired isomorphism $H^i(X,\mathcal{F}) \otimes_A B \cong H^i(X \otimes_A B, (g')^*\mathcal{F})$ by comparison(3.9.7.5). □

Prop. (5.7.5.2) [Finite Locally Free Base Change]. For a Cartesian diagram of schemes

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ S' & \xrightarrow{g} & S \end{array}$$

If $S = \operatorname{Spec} A, S' = \operatorname{Spec} B$ and B is finite locally free over A, for every Qco sheaf $\mathcal{F}$ on X with base change $\mathcal{F}'$ on X', there is a canonical isomorphism

$$H^i(X,\mathcal{F}) \otimes_A B \cong H^i(X \otimes_A B, (g')^*\mathcal{F}).$$

Proof: If X is separated, then the then we can use Čech cohomology(5.7.1.2), and the Čech complex of K' is just the cohomology of the Čech complex tensored with B, so it commutes with taking cohomology because B is A-flat and tensoring a f.p. ring map commutes with colimits of rings.

In general we choose an affine open cover $\{U_i\}$, then every intersection of U_i is separated. and there is a spectral sequence convergence $H^p(\{U_i \to X\}, \mathcal{H}^q(F)) \implies H^{p+q}(X, F)$. Tensoring with B, we also get the desired isomorphism $H^i(X,\mathcal{F}) \otimes_A B \cong H^i(X \otimes_A B, (g')^*\mathcal{F})$ by comparison(3.9.7.5). □

Prop. (5.7.5.3) [Representing Higher Direct Image]. Let $f : X \to S$ be a qcqs morphism of schemes. If S is qc and separated and $\mathcal{F}$ is a Qco sheaf on X, there exists a $\mathcal{K}^\bullet \in K^+(\mathfrak{QCoh}(\mathcal{O}_S))$ s.t. for any morphism $g : S' \to S$, the complex $g^*\mathcal{K}^\bullet$ is a representative for $Rf'_*\mathcal{F}'$, where the notation is as in(5.7.5.1).

Proof: We only prove the case X is separated, the general case in [Sta]01XN.

Choose a finite affine open covering $\mathcal{U}$ of X, consider the complex of sheaves $\mathfrak{C}^\bullet(\mathcal{U},\mathcal{F}) = \mathcal{H}om^\bullet((\mathbb{Z}^\sharp_{\mathcal{U},\bullet}),\mathcal{F})$(5.3.2.1), then $\mathfrak{C}^p(\mathcal{U},\mathcal{F}) = \bigoplus_{i_0\ldots i_p} j_{i_0\ldots i_p *}\mathcal{F}_{i_0\ldots i_p}$. Then let $\check{\mathcal{C}}^\bullet(\mathcal{U},f,\mathcal{F}) = f_*\mathfrak{C}^\bullet(\mathcal{U},\mathcal{F})$. There is a natural map $\mathcal{F}\to\mathfrak{C}^\bullet(\mathcal{U},\mathcal{F})$. Now $j_{i_0\ldots i_p}$ and $f_{i_0\ldots i_p}$ are both affine by(5.4.4.88), so are their base changes, thus the higher direct image vanish. So by relative Leray spectral sequence, we see each term $j_{i_0\ldots i_p *}\mathcal{F}'_{i_0\ldots i_p}$ is f'_*-acyclic. Then by Leray's acyclicity theorem,

$$Rf'_*(\mathcal{F}') = Rf'_*(\mathfrak{C}^\bullet(\mathcal{U},\mathcal{F}))\cong \mathcal{C}^\bullet(\mathcal{U}',f',\mathcal{F}') = g^*\mathcal{C}^\bullet(\mathcal{U},f,\mathcal{F}).$$

The last equation follows from the fact $f_{i_0\ldots i_p}$ are all affine thus the base change are isomorphisms. □

Prop. (5.7.5.4) [Proper Flat Base Change]. If $f: X\to S$ is a proper morphism of f.p., then

- If E a perfect object in $D(\mathcal{O}_X)$, $\mathcal{G}\in D(\mathcal{O}_X)$ is representable by a bounded complex of f.p. $\mathcal{O}_X$-modules flat over S, then

$$Rf_*(E\otimes^L_{\mathcal{O}_X}\mathcal{G}^\bullet),\quad Rf_*R\mathcal{H}om(E,\mathcal{G}^\bullet)$$

  are perfect complexes in $D(\mathcal{O}_S)$, and its formation commutes with base change.
- If E a pseudo-coherent object in $D(\mathcal{O}_X)$, $\mathcal{G}\in D(\mathcal{O}_X)$ is representable by a bounded above complex of f.p. $\mathcal{O}_X$-modules flat over S, then $Rf_*(E\otimes^L_{\mathcal{O}_X}\mathcal{G}^\bullet)$ is a pseudo-coherent complex in $D(\mathcal{O}_S)$, and its formation commutes with base change.

Proof: Cf.[Sta]0A1H, 0A1J, 0CSC.**?** □

Cor. (5.7.5.5). Let $f: X\to S$ be a proper morphism of f.p., then

- If $E\in D(\mathcal{O}_X)$ is perfect(pseudo-coherent) and f is flat, then Rf_*E is a perfect(pseudo-coherent) object in $D(\mathcal{O}_S)$, and its formation commutes with base change.
- If $\mathcal{G}\in\mathfrak{QCoh}^{\mathrm{pf}}(\mathcal{O}_X)$ and is flat over S, then $Rf_*\mathcal{G}$ is a perfect object of $D(\mathcal{O}_S)$ and its formation commutes with base change.

Cor. (5.7.5.6). If $A\in\mathcal{CA}\mathrm{lg}$, X be a proper scheme of f.p. over A, then if $\mathcal{G}\in\mathfrak{QCoh}^{\mathrm{pf}}(\mathcal{O}_X)$ and is flat over A, there exists a finite complex of finite projective A-modules $L^\bullet$ that for any $A'\in\mathcal{CA}\mathrm{lg}_A$, $M\in\mathcal{M}\mathrm{od}_A$, by(5.7.5.5) and projection formula(5.7.4.6),

$$H^i(X_{A'},\mathcal{F}_{A'}) = H^i(L^\bullet\otimes_A A'),\quad H^i(X,\mathcal{F}\otimes_A M) = H^i(L^\bullet\otimes_A M)$$

6 Semicontinuity

Prop. (5.7.6.1). T^i is left exact iff $\operatorname{Coker} d^{i-1}$ is a projective A-module, iff it is representable by a finite A-module.

Proof: Denote $W^i = \operatorname{Coker} d^{i-1}$, then $\operatorname{Coker} d^{i-1}\otimes_A M = W^i\otimes M$, because tensoring is right exact. Thus $T^i(M) = \ker(W^i\otimes M\to L^{i+1}\otimes M)$. Then for $M'\subset M$, there is a commutative diagram

$$\begin{array}{ccccccc} 0 & \longrightarrow & T^i(M) & \longrightarrow & W^i\otimes M' & \longrightarrow & L^{i+1}\otimes M' \\ & & \downarrow{\alpha} & & \downarrow{\beta} & & \downarrow{\gamma} \\ 0 & \longrightarrow & T^i(M) & \longrightarrow & W^i\otimes M & \longrightarrow & L^{i+1}\otimes M \end{array}$$

γ is injective, so using spectral sequence, its clear α is injective iff β is injective, i.e. W^i is flat, which is equivalent to finite projective(4.3.1.7).

To prove T^i is representable, let $Q = \mathrm{Coker}(L^{i+1,*} \to W^{i,*})$, then Q is finite because W^i is finite(4.3.1.18), and $0 \to \mathrm{Hom}(Q, M) \to \mathrm{Hom}(W^{i,*}, M) \to \mathrm{Hom}(L^{i+1,*}, M)$, but by(4.3.1.19), the last two are just $W^i \otimes M$ and $L^{i+1} \otimes M$, $\mathrm{Hom}(Q, M) = T^i(M)$ by what has already be proved. □

Prop. (5.7.6.2). T^i is right exact iff the cup product $H^i(X, \mathcal{F}) \otimes_A M \to H^i(X, \mathcal{F} \otimes_A M)$ is an isomorphism for any A-module M.

Proof: Because T^i and $\otimes$ commutes with direct limit, it suffices to prove for M finite. In this case, choose a finite presentation $A^r \to A^s \to M \to 0$, then there is a diagram

$$\begin{array}{ccccccc} T^i(A) \otimes A^r & \longrightarrow & T^i(A) \otimes A^s & \longrightarrow & T^i(A) \otimes M & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow & & \\ T^i(A^r) & \longrightarrow & T^i(A^s) & \longrightarrow & T^i(M) & & \end{array}$$

The first two vertical arrows are isomorphisms, so if T^i is right exact, so does the third vertical arrow. Conversely, if $T^i(A) \otimes_A M \to T^i(M)$ are all isomorphisms, then by a similar diagram, we can show $T^i(M) \to T^i(M')$ are surjective for $M \to M'$ surjective. □

Cor. (5.7.6.3). T^i is exact iff it is right exact and $T^i(A) = H^i(X, \mathcal{F})$ is a finite projective A-modules.

Proof: When T^i is right exact, $H^i(X, \mathcal{F} \otimes_A M) \cong H^i(X, \mathcal{F}) \otimes_A M$ by(5.7.6.2), so it is exact iff $H^i(X, \mathcal{F})$ is flat. Because it is in priori finite, this is equivalent to finite projective(4.3.1.7). □

Def. (5.7.6.4). For a point $y \in \mathrm{Spec}\, A$, define $T^i_y(N) = H^i(L^\bullet_y \otimes N)$, then T^i is (left/right)exact at y iff T^i_y are all (left/right)exact(exact sequence is stalkwise(4.1.4.2)).

Prop. (5.7.6.5). If T^i is (left/right)exact at a point y, then the same is true on a nbhd of y.

Proof: From(5.7.6.1), $(\mathrm{Coker}\, d^{i-1})_y$ is a finite projective A_p module, so it is free, and it is a coherent sheaf, so it is free at a nbhd of y by(5.5.1.38), so the same is true on a nbhd of y. Now right exactness of T^i is equivalent to left exactness of T^{i+1}, and exact is left exact+right exact, so we are done. □

Prop. (5.7.6.6). T^i is right exact at y iff $H^i(X, \mathcal{F}) \otimes k(y) \to H^i(X, \mathcal{F} \otimes_A k(y))$ is surjective.

Proof: Cf.[Hartshorne P289].**?** □

Prop. (5.7.6.7) [Cohomology and Stalks]. Let $f : X \to Y$ be a proper morphism of locally Noetherian schemes and $\mathcal{F}$ is a coherent sheaf on X flat over Y, $y \in Y$, then

- If the natural map
$$\varphi^i(y) : R^i f_*(\mathcal{F}) \otimes k(y) \to H^i(X_y, \mathcal{F}_y)$$
is surjective, then it is an isomorphism, and and the same is true for y' in an open nbhd of y.
- Assume $\varphi^i(y)$ is surjective, then $\varphi^{i-1}(y)$ is also surjective iff $R^i f_*(\mathcal{F})$ is finite projective in a nbhd of y.

Proof: 1: This follows from(5.7.6.2)(5.7.6.6) and(5.7.6.5).

2: $\varphi^{i-1}(y), \varphi^i(y)$ are both surjective iff T^i and T^{i-1} are both right exact at y(5.7.6.6), which is equivalent to T^i exact at y. Then we finish by(5.7.6.3) □

Remark (5.7.6.8). How's this related to(5.7.5.5)**?**

Prop. (5.7.6.9) [Semicontinuity of Cohomology]. Let $X \to Y$ be a projective morphism of locally Noetherian schemes and $\mathcal{F}$ is a coherent sheaf on X, flat over Y, then for each i, $h^i(y, \mathcal{F}) = \dim_{k(y)} H^i(X_y, \mathcal{F}_y)$ is an upper semicontinuous function on Y.

Proof: The question is local on Y, so we may assume Y is affine Noetherian. By(5.7.5.1), $H^i(y, \mathcal{F}) = \dim_{k(y)} T^i(k(y))$. And as in the proof of(5.7.6.1), $T^i(M) = \ker(W^i \otimes M \to L^{i+1} \otimes M)$, and $W^i \to L^{i+1} \to W^{i+1} \to 0$ is exact, so $0 \to T^i(k(y)) \to W^i \otimes k(y) \to L^{i+1} \otimes k(y) \to W^{i+1} \otimes k(y) \to 0$, and counting dimension, $h^i(y, \mathcal{F}) = \dim W^i \otimes k(y) + \dim W^{i+1} \otimes k(y) - \dim L^{i+1} \otimes k(y)$. Notice the last term is constant as L^{i+1} is free A-module and the first two terms are upper semi-continuous by(5.5.1.41), thus $h^i(y, \mathcal{F})$ is upper-semicontinuous. □

Cor. (5.7.6.10) [Grauert]. If Y is integral and $h^i(y, \mathcal{F})$ is constant on Y, then $R^i f_*(\mathcal{F})$ is locally free on Y and $R^i f_*(\mathcal{F}) \otimes k(y) \cong H^i(X_y, \mathcal{F}_y)$.

Proof: Cf.[Hartshorne P288]. □

5.8 Topics in Schemes

Main references are [Sta]and [Har77].

1 Cartier Divisors

Def. (5.8.1.1) [Cartier Divisor]. A **Cartier divisor** on a scheme X is an element in $\Gamma(X, \mathcal{K}_X^*/\mathcal{O}_X^*)$.

An **effective Cartier divisor** is a Cartier divisor that is locally defined as $\{(U_i, f_i)\}$ where $f_i \in \Gamma(U_i, \mathcal{O}_{U_i})$ are nonzero-divisors, equivalently, it is a closed subscheme whose ideal sheaf is an invertible sheaf.(Notice by definition, $\mathcal{K}$ is the localization w.r.t. nonzero-divisors, and f_i is invertible in $\mathcal{K}^*$ so f_i must be nonzero-divisors.)

The group of effective Cartier divisors is denoted by $\mathrm{Cart}^{\mathrm{eff}}(X)$.

The **Cartier divisor group** CaCl is the quotient of $\Gamma(X, \mathcal{K}^*) \to \Gamma(X, \mathcal{K}^*/\mathcal{O}_X^*)$.

Prop. (5.8.1.2) [Cartier Divisor is Nowhere Dense]. Let $D \subset X$ be an effective Cartier divisor, then it is nowhere dense in X, i.e $X \backslash D \to X$ is scheme-theoretically dense.

Proof: It suffices to check affine-locally, it is qc so the scheme-theoretic closure of $\operatorname{Spec} A_f \to \operatorname{Spec} A$ is $V(\ker(A \to A_f)) = V(0)$ as f is a nonzero-divisor. □

Prop. (5.8.1.3) [Closed Subschemes and Effective Cartier Divisors]. Let X be a locally Noetherian scheme and $D \subset X$ is a closed subscheme corresponding to a Qco sheaf of ideals $\mathcal{I} \subset \mathcal{O}_X$. If for any $x \in D$, the ideal $\mathcal{I}_x \subset \mathcal{O}_{X,x}$ is generated by a single nonzero-divisor, then D is an effective Cartier divisor.

Proof: Cf.[Sta]0AG8. □

Cor. (5.8.1.4) [Prime Divisor and Effective Cartier Divisor]. Let X be a locally Noetherian scheme and D is a prime Weil divisor on X and $\mathcal{O}_{X,x}$ are UFDs for any $x \in D$, then D is an effective Cartier divisor.

Proof: For any $x \in D$, let $A = \mathcal{O}_{X,x}$, and $\mathfrak{p}$ be the prime corresponding to the generic point of D, then $\dim A_{\mathfrak{p}} = 1$, so $\mathfrak{p}$ is principle as A is a UFD, so D is an effective Cartier divisor by(5.8.1.3). □

Prop. (5.8.1.5) [Cartier-Pic]. For an integral scheme X, the homomorphism $\mathrm{CaCl}(X) \to \mathrm{Pic}(X)$(5.8.1.1)(5.5.3.10) induced from long exact sequence of $0 \to \mathcal{O}_X^* \to \mathcal{K}_X^* \to \mathcal{K}_X^*/\mathcal{O}_X^* \to 0$ is an isomorphism.

Explicitly, for a Cartier divisor $D = \{(U_i, f_i)\}$, the image is the invertible sheaf $\mathcal{O}_X(D)$(5.5.3.12).

Proof: It is clearly injective by definition, so it suffices to show any invertible sheaf can embed into the constant sheaf: for any invertible sheaf $\mathcal{L}$, tensor with $\mathcal{K}$ and restrict to the stalk of the generic point, i.e. there is a compatible choice of homomorphisms into $K(X)$. □

Prop. (5.8.1.6). If $X \in \mathrm{N}\mathcal{S}\mathrm{ch}$ and the diagonal map is affine, for a dense affine open U, if all the stalk of $X \backslash U$ are UFD, then U is the complement of an effective Cartier divisor.

Proof: The irreducible complements of $X \backslash U$ is finite and has codimension 1 by(5.6.3.5) because $U \to X$ is affine, and it is an effective Cartier divisor by(7.1.5.1)., so their sum will suffice. □

Prop. (5.8.1.7)[Pullback of Effective Cartier Divisors]. Let $f : X \to Y \in \mathcal{S}\mathrm{ch}$ and $D \in \mathrm{Cart}^{\mathrm{eff}}(Y)$, then the pullback of D via f is an effective Cartier divisor on X in the following cases:

- $f(x)\notin D$ for any $x\in \mathrm{WeakAsso}(X)$.
- $X,Y\in \mathcal{S}\mathrm{ch}^{\mathrm{int}}$ and f is dominant.
- f is flat.

Proof: 2 is a special case of 1 as a reduced scheme has no embedded points.
1 follows from(4.2.5.17).
3 is easy. □

Prop. (5.8.1.8) [Effective Cartier Divisors]. If X is a Noetherian scheme with an ample invertible sheaf $\mathcal{L}$, then any line bundle in $\mathrm{Pic}(X)$ is isomorphism to $\mathcal{O}_X(D-D')$ for some effective Cartier divisors D,D' on X.

Proof: Cf.[Sta]0AYM. □

Relative Effective Cartier Divisors

Def. (5.8.1.9) [Relative (Effective) Cartier Divisors]. Let X be a scheme over S, then a **relative effective (Cartier)divisor** on X/S is an effective Cartier divisor D on X that is flat over S.

Prop. (5.8.1.10) [Fibral Criterion of Relative Effective Divisor]. Let $f:X\to S$ be a morphism of locally Noetherian schemes locally of f.t., $D\subset X$ be a closed subscheme and $x\in D$, $s=f(x)$, then the following are equivalent:

- D is a relative effective divisor at a nbhd of x.
- X and D are flat over S at x, and the fiber D_s is a Cartier divisor on X_s at x.
- X is flat over S at x, and D is cut out by an element that is regular on the fiber X_s.

In particular, a relative Cartier divisor pair can be regarded as a family of Cartier divisors pairs.

Proof: $1\to 2$: Let $\mathcal{O}_{D,x}=b\mathcal{O}_{X,x}$, then there is an exact sequence $0\to\mathcal{O}_{X,x}\xrightarrow{b}\mathcal{O}_{X,x}\to\mathcal{O}_{D,x}\to 0$, which induces a long exact sequence

$$\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{X,x},k(s))\to\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{X,x},k(s))\to\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{D,x},k(s))\to\mathcal{O}_{X_s,x}\otimes k(s)\xrightarrow{b}\mathcal{O}_{X_s,x}\otimes k(s).$$

Because D is flat over S, $\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{D,x},k(s))=0$, thus b is regular in $\mathcal{O}_{X_s,x}$ and D_s is en effective divisor on X_s at x. Also the map $\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{X,x},k(s))\to\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{X,x},k(s))$ is surjective, which is multiplication by b, and b is in the maximal ideal, thus by Nakayama lemma, $\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{X,x},k(s))=0$. Then $\mathcal{O}_{X,x}$ is $\mathcal{O}_{S,s}$-flat by local criterion(4.4.1.16).

$2\to 3$: Let D corresponds to an ideal I in $\mathcal{O}_{X,x}$, and because D_s is effective divisor on X_s, there exists $b\in I$ s.t. the image of b in $\mathcal{O}_{X,x}\otimes k(s)$ generate the ideal of D_s. Then it suffices to show that b generates I. Notice there is an exact sequence $0\to I\to\mathcal{O}_{X,x}\to\mathcal{O}_{D,x}\to 0$, and $\mathcal{O}_{D,x}$ is flat over $\mathcal{O}_{S,s}$, thus $I\otimes k(s)\to\mathcal{O}_{X,x}\otimes k(s)$ is injective, and the image is just the ideal of D_s, thus b generates $I\otimes k(s)$. Thus by Nakayama, it also generates I.

$3\to 1$: The exact sequence $0\to I\to\mathcal{O}_{X,x}\to\mathcal{O}_{D,x}\to 0$ induces the long exact sequence

$$\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{X,x},k(s))\to\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{D,x},k(s))\to I\otimes k(s)\to\mathcal{O}_{X_s,x}\otimes k(s).$$

$I\otimes k(s)\to\mathcal{O}_{X_s,x}\otimes k(s)$ is injective because its composition with $\mathcal{O}_{X_s,x}\otimes k(s)\to I\otimes k(s)\to\mathcal{O}_{X_s,x}\otimes k(s)$ is multiplication by b, thus injective as b is regular on the fiber X_s. Thus $\mathrm{Tor}_1^{\mathcal{O}_{S,s}}(\mathcal{O}_{D,x},k(s))=0$, thus D is flat at x by local criterion(4.4.1.16). And also I is flat over $\mathcal{O}_{S,s}$. Notice $b:\mathcal{O}_{X,x}\to I$ is isomorphism after tensoring $k(x)$ and I is flat, so $\ker(b)=0$ by Nakayama, and b is regular. □

Cor. (5.8.1.11). If D, E are relative effective Cartier divisors on X/S, then $D+E$ is also a relative Cartier divisor on X/S.

Proof: This follows from item3 of(5.8.1.10). □

Prop. (5.8.1.12) [Pullback of Divisors]. For $S \in \mathcal{S}\mathrm{ch}$, $X \in \mathcal{S}\mathrm{ch}/S$ and Z an relative Cartier divisor on X/S, then for any $T \in \mathcal{S}\mathrm{ch}/S$, Z_T is a relative Cartier divisor on X_T/T.

And if $f : X\prime \to X$ is a flat morphism over S, then f^*Z is also a relative Cartier divisor on X'/S.

Proof: If $0 \to \mathcal{O}_X \xrightarrow{\mathcal{I}} \mathcal{O}_X \to i_*\mathcal{O}_Z \to 0$, then $0 \to \mathcal{O}_{X_T} \xrightarrow{\mathcal{I}_T} \mathcal{O}_{X_T} \to i_*\mathcal{O}_{Z_T} \to 0$ because $\mathcal{O}_Z$ is flat over $\mathcal{O}_S$, so $\mathcal{I}_T$ is also an effective divisor on X_T/T.

The second case is similar. □

2 Blowing Up

Blowing-up

Blowing-up serves as a way to magnify local properties to global ones.

Def. (5.8.2.1) [Blowing-Up]. Let X be a scheme and a closed subscheme $Z \subset X$ defined by $\mathcal{I}$, the **blowing up** of X along Z $\mathbf{Bl}_Z X$ is defined as the map $\beta : \mathbf{Proj}_X(\oplus_{d\geq 0}\mathcal{I}^d) \to X$.

The map $\beta : \mathbf{Bl}_Z X \to X$ pulls back Z to an effective Cartier divisor $E_Z X$, called the **exceptional divisor**, and it has the universal property that any morphism $Y \to X$ that pulls back Z to an effective Cartier divisor uniquely factors through $\mathbf{Bl}_Z X$.

Proof: Notice first an effective devisor is equivalent to an invertible sheaf of ideal. And any morphism $Z \to X$ pulls back I to the image of $f^{-1}I \otimes_{\mathcal{O}_X} \mathcal{O}_Z \to f^{-1}I \cdot \mathcal{O}_Z$. This is just $\mathcal{O}(1)$ on $\mathbf{Bl}\, X_{\mathcal{I}}$ so invertible.

For the construction, the local uniqueness will implies the existence. Notice locally $\widetilde{X}_I$ is projective over X. Now because the $Z \to X$ pulls back I to an invertible sheaf and it is generated by $f^{-1}(a_i)$, we use**??** to get another $Z \to \mathrm{Proj}^n_X$ and it factors through the closed subscheme $\widetilde{X}_I$. If there is another morphism g, then $f^{-1}I \cdot \mathcal{O}_Z = g^{-1}(\pi^{-1}I \cdot \mathcal{O}_{\widetilde{X}_I}) \cdot \mathcal{O}_Z = g^{-1}(\mathcal{O}_{\widetilde{X}_I}) \cdot \mathcal{O}_Z$ surjective, and a surjective morphism between two invertible sheave is an isomorphism, and they are both ideal sheaves, thus is the same, so this morphism is unique as it is determined by the map on $\mathcal{O}_X$**??**. □

Cor. (5.8.2.2). Let X be a scheme and $Z \subset X$.

- If Z is itself an effective Cartier divisor, then the $\mathbf{Bl}_Z X = X$.
- If $U \subset X$ is an open subscheme, then $\mathbf{Bl}_Z(U) = \beta^{-1}(U) \subset \mathbf{Bl}_Z(X)$. In particular, Blowing-up is a local construction.
- If $Z = X$, then $\mathbf{Bl}_X X = \varnothing$.
- β is an isomorphism $\beta^{-1}(X\backslash Z) \to X\backslash Z$ away from Z.
- If X is reduced, then $\mathbf{Bl}_Z X$ is also reduced.
- If X is irreducible and Z doesn't contain the generic point of X, then $\mathbf{Bl}_Z X$ is irreducible.

Proof: 1: By universal property.

2: This follows from universal property and the fact the restriction of an effective Cartier divisor is an effective Cartier divisor.

3: By universal property.

4: By item2 and 3.
5: ?
6: ? □

Cor. (5.8.2.3). $\pi : \widetilde{X}_I \to X$ is birational, proper thus surjective. If X is a (complete)variety, then so does $\widetilde{X}_I$.

Def. (5.8.2.4) [Strict Transform]. Let $Z \subset X$ is a closed subscheme and $f : Y \to X$ be a morphism, then $Y \times_X \mathbf{Bl}_Z X$ is called the **total transform** of Y, and the **strict transform** of Y is the scheme-theoretic closure of $Y \times_X \mathbf{Bl}_Z X \backslash Y \times_X E_Z X$ in $Y \times_X \mathbf{Bl}_Z X$, or equivalently the closed subscheme of $Y \times_X \mathbf{Bl}_Z X$ cut out by the Qco ideal of sections supported on $Y \times_X E_Z Y$.

Prop. (5.8.2.5) [Strict Transformation]. Let $Z \subset X$ is a closed subscheme and $f : Y \to X$ be a morphism, then the strict transform of Y is the blowing-up of Y at the closed subscheme $f^{-1}Z$.

Proof: Cf.[Sta]080E.? (Recall the definition of fiber product, we only need to check for Z,X affine and glue. For this, check $B \otimes_A (\oplus I^d) \to \oplus (IB)^d$ defines the fiber map). □

Prop. (5.8.2.6). If X is H-(quasi-)projective, then so does $\widetilde{X}_I$ and π is H-projective(5.5.2.19). And any birational projective morphism from another variety Z to X comes from a blowing-up.

Proof: Cf.[Hartshorne P166]. □

Prop. (5.8.2.7) [Exceptional Divisor]. Let E be $\pi^{-1}(x)$ for a blowing-up, called the **exceptional divisor**. Often the line bundle $\mathcal{O}_{\widetilde{X}}(E)$ associated with it is called denoted by E.

There are canonical coordinates near E: let $\widetilde{U}_i$ be $\widetilde{U} - \{(l_i = 0)\}$, then endow $\widetilde{U}_i$ with the coordinate $z(i) = (l_j/l_i, \ldots, z_i, \ldots, l_n/l_i)$, it is holomorphic to $\mathbb{C}^n$. π in this coordinate is written as $(z(1), \ldots, z(n)) \mapsto (z(i)z(1), \ldots, z(i), \ldots, z(n)z(i))$.

The transition function can be written, it is

$$\varphi_j \circ \varphi_i^{-1}((z(i)_1, \ldots, z(i)_n)) = (\frac{z(i)_1}{z(i)_j}, \ldots, \frac{1}{z(i)_j}, \ldots, z(i)_i z(i)_j, \ldots, \frac{z(i)_n}{z(i)_j}).$$

Notice it is somewhat tricky because it has two different coordinates.

The defining function of E in this coordinate is $(z(i)) = (z_i)$. So the line bundle $\mathcal{O}_{\widetilde{X}}(E)$ has transition function $g_{ij} = z(i)/z(j)$, and it can be thought of as the line bundle that has line $[l]$ at the point $(z, [l]) \in \widetilde{U}$. So it is kindof tautological, in fact its restriction on $E \cong \mathbb{CP}^{n-1}$ is just the tautological line bundle.

Prop. (5.8.2.8). The canonical line bundle $\mathcal{K}_{\widetilde{X}} = \pi^* \mathcal{K}_X + (n-1)E$, where n is the dimension of X.

Proof: Away from E, the π is a holomorphism, so It suffices to compare the two transition function of the two canonical maps near E using the coordinates in(5.8.2.7), with the local section given by $dz_1 \wedge \ldots \wedge dz_n$ and $dz(i)_1 \wedge dz(i)_n$ respectively. On $\widetilde{U}_i$, locally $dz_1 \wedge \ldots \wedge dz_n$ is pulled by π^* to the trivial bundle on U', and by calculation, $dz(j)_1 \wedge dz(j)_n = z(i)_j^{n-1} dz(i)_1 \wedge dz(i)_n$, so $\mathcal{K}_{\widetilde{X}} - (n-2)E$ has a global section $z(i)_i^{n-1} dz(i)_1 \wedge dz(i)_n$, so it is also trivial on $\widetilde{U}$, so $\mathcal{K}_{\widetilde{X}} = \pi^* \mathcal{K}_X + (n-1)E$ is true. □

Blowing up along a regular variety

Prop. (5.8.2.9). If X is a regular variety over k and Y is a regular closed subvariety defined by $\mathcal{I}$, then the blowing up along $\mathcal{I}$ is also regular, and the inverse image Y' of Y is locally principal in it. In fact, $Y' \to Y$ is isomorphic to $\mathbb{P}(\mathcal{I}/\mathcal{I}^2)$, the projective space associated to the locally free bundle $\mathcal{I}/\mathcal{I}^2$ on Y, and the normal sheaf $\mathcal{N}_{Y'/X'} \cong \mathcal{O}_{\mathbb{P}(\mathcal{I}/\mathcal{I}^2)}(-1)$.

Proof: (Imagine the blowing up of $\mathbb{A}^2$ along $\{0\}$). $X' \cong \mathrm{Proj} \oplus \mathcal{I}^d$ and $Y' \cong \mathrm{Proj} \oplus \mathcal{I}^d/\mathcal{I}^{d+1}$. Then since Y is regular, (4.3.4.17) tells us $\mathcal{I}$ is locally generated by a regular sequence and(4.3.4.16) tells $Y' = \mathbb{P}(\mathcal{I}/\mathcal{I}^2)$. Y' is regular by(4.3.5.18), and then(4.3.5.24) shows that X' is regular also. For the normal sheaf, the defining sheaf $\mathcal{I}' = \mathcal{O}_{X'}$ and then $\mathcal{I}'/\mathcal{I}'^2 = \mathcal{O}_Y(1)$, thus $\mathcal{N}_{Y'/X'} \cong \mathcal{O}_{\mathbb{P}(\mathcal{I}/\mathcal{I}^2)}(-1)$. □

Prop. (5.8.2.10). In a blowing up along a regular variety of codimension $r \geq 2$, There is an isomorphism $\mathrm{Pic}X' \cong \mathrm{Pic}X \oplus \mathbb{Z}$ induced by the Weil divisor exact sequence of $Y' \subset X'$. This is because $r \geq 2$ and (5.8.2.2).

We also have $\omega_{X'} = f^*\omega_X \otimes \mathcal{L}((r-1)Y')$ because $\mathcal{L}(Y') = \mathcal{O}(-1)$ and $\omega_Y \cong \omega_X \otimes \mathcal{L}(D) \otimes \mathcal{O}_Y$ by(5.10.1.17), so it suffice to prove $\omega_{Y'} \cong f^*\omega_X \otimes \mathcal{O}_{Y'}(-r)$. For this, notice for a closed pt of Y, the fiber is a $\mathbb{P}^{r-1}$ because $\mathcal{I}/\mathcal{I}^2$ is locally free of rank r by(5.10.1.16) and the functoriality of $\mathcal{O}(1)$.

3 Compatifications

Def. (5.8.3.1) [Compatifications]. Let $S \in \mathcal{S}\mathrm{ch}_{\mathrm{qcqs}}$, $X \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,ft}}/S$, then the category of **compatifications of** X/S is the category of pairs $(i, \overline{X})$, where $i : X \to \overline{X}$ is an immersion and $\overline{X} \to S$ is proper.

Thm. (5.8.3.2)[Nagata Compatification]. Situation as in(5.8.3.1), then X/S has a compactification.

Proof: Cf.[Sta]0F41. □

4 Limits of Schemes

Prop. (5.8.4.1) [Noetherian Reduction]. For any $S \in \mathcal{S}\mathrm{ch}_{\mathrm{qcqs}}$, there exists a direct system $(S_i, f_{ii'})$ indexed over a set I that

- $f_{ii'}$ are affine.
- S_i are of f.t. over $\mathbb{Z}$.
- $S = \varprojlim_i S_i$.

Proof: Cf.[Sta]01ZA. □

Prop. (5.8.4.2) [Characterizing Morphisms of F.P.]. Let $f : X \to S$ be a morphism of schemes, then the following are equivalent:

- f is locally of finite presentation.
- For any directed inverse system $(T_i, f_{ii'})$ in $\mathcal{A}\mathrm{ff}_S$, we have

$$\mathrm{Mor}_S(\varprojlim_i T_i, X) = \varinjlim_i \mathrm{Mor}_S(T_i, X)$$

- For any directed inverse system $(T_i, f_{ii'})$ in $\mathcal{S}\mathrm{ch}_S$ with T_i qcqs and $f_{ii'}$ affine, we have

$$\mathrm{Mor}_S(\varprojlim_i T_i, X) = \varinjlim_i \mathrm{Mor}_S(T_i, X)$$

Proof: Cf.[Sta]01ZC. □

Prop. (5.8.4.3) [Reduction to Finite Presented Morphisms]. Let $f: X \to S$ be a morphism of schemes, if X is qcqs and S is qs, then $X = \varprojlim_i X_i$ is a limit of a directed system of schemes X_i of f.p. over S with affine morphisms over S.

Proof: Cf.[Sta]09MV. □

Prop. (5.8.4.4) [Integral and Finite]. Let $f: X \to S$ be an integral morphism of schemes with S qcqs, then $X = \varprojlim_i X_i$ is a limit of a directed system of schemes X_i finite of f.p. over S with affine morphisms over S.

Proof: Consider $\mathcal{A} = f_*\mathcal{O}_X$, which is a Qco sheaf of $\mathcal{O}_S$-modules. Then $\mathcal{A} = \varinjlim \mathcal{A}_i$ is a filtered colimit of finite and f.p. $\mathcal{O}_S$-modules by(5.5.1.13). Then $X_i = \mathbf{Spec}_S(\mathcal{A}_i)$ satisfies the requirement by(5.2.7.12). □

Sheaves

5 $D_{\mathfrak{QCoh}}(X)$

Def. (5.8.5.1) [Notations]. For $X \in \mathfrak{Sch}$,

Denote $D^*_{\mathfrak{QCoh}}(X) = D^*_{\mathfrak{QCoh}(X)}(\mathfrak{Mod}(\mathcal{O}_X))$(3.9.1.8). There is a natural functor $D^*(\mathfrak{QCoh}(X)) \to D^*_{\mathfrak{QCoh}}(X)$.

Denote $D^*_{\mathfrak{Coh}}(X) = D^*_{\mathfrak{Coh}(X)}(\mathfrak{Mod}(\mathcal{O}_X))$(3.9.1.8). There is a natural functor $D^*(\mathfrak{Coh}(X)) \to D^*_{\mathfrak{Coh}}(X)$.

By(5.3.1.5), these notions are affine local.

Prop. (5.8.5.2) [Direct Sum]. Direct sum exists in $D_{\mathfrak{QCoh}}(X)$, and equals that in $D(X)$.

Proof: By(3.9.1.15), direct sum exists in $D(X)$ and are given by term-wise direct sums. Notice the direct sum of elements in $D_{\mathfrak{QCoh}}(X)$ is also in $D_{\mathfrak{QCoh}}(X)$ as direct sums are exact functor and $\mathfrak{QCoh}(X)$ is stable under direct sums. □

Prop. (5.8.5.3) [Affine Case]. Let $X = \operatorname{Spec} A$, there is a natural equivalence$\tilde{}$: $D(A) \to D(\mathfrak{QCoh}(X))$. Then the functors $R\Gamma(X, -): D_{\mathfrak{QCoh}}(X) \to D(A)$ is quasi-inverse to the inclusion functor $D^*(\mathfrak{QCoh}(X)) \to D^*_{\mathfrak{QCoh}}(X)$(5.8.5.1), and they are both isomorphism of triangulated categories.

Proof: Cf.[Sta]06Z0. □

Prop. (5.8.5.4) [Derived Pullbacks]. Let $f: X \to S$ be a qcqs morphism of schemes, then Lf^* maps $D_{\mathfrak{QCoh}}(X)$ into $D_{\mathfrak{QCoh}}(S)$, and affine locally it is just the derived tensor functor $-\otimes^L_A B: D(A) \to D(B)$ via identifications in(5.8.5.3), by(5.3.3.14)(5.3.3.15).

Prop. (5.8.5.5) [Derived Products]. For $X \in \mathfrak{Sch}$, $D_{\mathfrak{QCoh}}(X)$ is stable under derived tensor products, and affine locally it is just the derived tensor product $- \otimes^L -$ via identifications in(5.8.5.3), by(5.3.3.6)(5.3.3.15).

Prop. (5.8.5.6) [Higher Direct Images]. Let $f: X \to S$ be a qcqs morphism of schemes, then Rf_* maps $D_{\mathfrak{QCoh}}(X)$ into $D_{\mathfrak{QCoh}}(S)$. And if f is affine, affine locally it is just the restriction $D(B) \to D(A)$ via identifications in(5.8.5.3), by(5.3.1.9).

Moreover, if S is qc, then there exists a $N \in \mathbb{Z}$ s.t. $Rf_*(D^{\leq m}_{\mathfrak{QCoh}}(X)) \subset D^{\leq m+N}_{\mathfrak{QCoh}}(S)$, and this N is invariant under base change.

Proof: Cf.[Sta]08D5.**?** □

Prop. (5.8.5.7). For $f : X \to Y$ qcqs, $Rf_* : D_{\mathfrak{QCoh}}(X) \to D_{\mathfrak{QCoh}}(Y)$ preserves direct sums.

Proof: Cf.[Sta]08DZ. □

Prop. (5.8.5.8) [Projection Formula]. Let $f : X \to Y$ be a qcqs morphism of schemes and $E \in D_{\mathfrak{QCoh}}(X), K \in D_{\mathfrak{QCoh}}(Y)$, then the projection map(5.3.3.19)

$$Rf_*(E) \otimes^L_{\mathcal{O}_Y} K \to Rf_*(E \otimes^L_{\mathcal{O}_Y} Lf^*K)$$

is an isomorphism.

Proof: Cf.[Sta]08EU. □

Pseudo-Coherent and Perfect Complexes

Prop. (5.8.5.9) [Affine Case]. If $X = \operatorname{Spec} A$, $M \in D(A)$ and E is the corresponding element in $D(X)$, then

- E is an (m-)pseudo-coherent object in $D(X)$ iff M is an (m-)pseudo-coherent object in $D(A)$(4.9.5.9).
- E has Tor-amplitude in $[a, b]$ iff M has Tor amplitude in $[a, b]$.
- E is a perfect object in $D(X)$ iff M is a perfect object in $D(A)$(4.9.5.3).

Proof: Cf.[Sta]08E7, 08EB, 08E9,. □

Prop. (5.8.5.10) [Noetherian Case]. Let X be a Noetherian scheme and $\mathcal{E} \in D_{\mathfrak{QCoh}}(X)$, then the following are equivalent:

- $\mathcal{E}$ is m-pseudo-coherent.
- $\mathcal{E} \in D^-_{\mathfrak{QCoh}}(X)$ and $H^i(\mathcal{E}) \in \mathfrak{Coh}(X)$ for $i \geq m$.

In particular, E is pseudo-coherent iff $E \in D^-_{\mathfrak{Coh}}(X)$.

Proof: Cf.[Sta]08E8. □

Prop. (5.8.5.11) [$\mathcal{E}xt$]. Let $X \in \mathcal{S}\mathrm{ch}$.

1. If $X = \operatorname{Spec} A$ and $K, L \in D(A)$, then $\mathcal{E}xt^n(\widetilde{K}, \widetilde{L})$ is the sheaf extending the sheaf on the basis $D(f) \mapsto \operatorname{Ext}^n_{A_f}(K_f, L_f)$.
2. If $X = \operatorname{Spec} A$ and $K, L \in D(A)$, then $R\mathcal{H}om(\widetilde{K}, \widetilde{L}) = (R\operatorname{Hom}_A(K, L))^\sim$ iff K is pseudo-coherent and $L \in D^+(A)$, or K is perfect.
3. If $\mathcal{L} \in D_{\mathfrak{QCoh}}(X)$ and $\mathcal{K} \in D(X)$ perfect, then $R\mathcal{H}om(\mathcal{K}, \mathcal{L}) \in D_{\mathfrak{QCoh}}(X)$.
4. If $\mathcal{L} \in D^+_{\mathfrak{QCoh}}(X)$ and $\mathcal{K} \in D(X)$ pseudo-coherent, $R\mathcal{H}om(\mathcal{K}, \mathcal{L}) \in D_{\mathfrak{QCoh}}(X)$ and are locally bounded below.

Proof: 1: This follows from(5.3.3.27) as

$$H^n(R\mathcal{H}om(X_f, \widetilde{K}, \widetilde{L})) = \operatorname{Hom}_{D(\mathcal{O}_{X_f})}(\widetilde{K}_f, \widetilde{L}_f[n]) = \operatorname{Hom}_{D(A_f)}(K_f, L_f[n]) = \operatorname{Ext}^n(K_f, L_f).$$

2: This follows from(5.3.4.22).
3, 4 follows from item2,(5.3.4.22) and locality of cohomology. □

Prop. (5.8.5.12) [Criterion for Relative Perfectness over Affine Base]. Let $A \in \mathcal{C}\mathcal{A}\mathrm{lg}$ and X be a separated, flat of f.p. scheme over A, $K \in D_{\mathcal{Q}\mathcal{C}\mathrm{oh}}(X)$. If $R\Gamma(X, E \otimes^L K)$ is perfect in $D(A)$ for any perfect object $E \in D(X)$, then K is perfect over A.

Proof: Cf.[Sta]0GET. □

$\underline{D_{\mathcal{C}\mathrm{oh}}(X)}$

Prop. (5.8.5.13) [$R\mathcal{H}om$ Preserves $D_{\mathcal{C}\mathrm{oh}}(X)$]. If X is a locally Noetherian scheme and $L \in D^+_{\mathcal{C}\mathrm{oh}}(X)$ and $K \in D^-_{\mathcal{C}\mathrm{oh}}(X)$, then $R\mathcal{H}om(K, L) \in D^+_{\mathcal{C}\mathrm{oh}}(X)$.

Proof: Cf.[Sta]0D0C. □

Prop. (5.8.5.14). Let X be a Noetherian scheme, then there are natural equivalences

$$D^-(\mathcal{C}\mathrm{oh}(X)) \cong D^-_{\mathcal{C}\mathrm{oh}(X)}(\mathcal{Q}\mathcal{C}\mathrm{oh}(X)) \cong D^-_{\mathcal{C}\mathrm{oh}}(X), \quad D^b(\mathcal{C}\mathrm{oh}(X)) \cong D^b_{\mathcal{C}\mathrm{oh}}(X).$$

Proof: Cf.[Sta]0FDA, 0FDB. □

Prop. (5.8.5.15). Let S be Noetherian and $f : X \to S$ be a proper morphism, then Rf_* maps $D^b_{\mathcal{C}\mathrm{oh}}(X)$ to $D^b_{\mathcal{C}\mathrm{oh}}(S)$.

Proof: Cf.[Sta]08E2. □

Prop. (5.8.5.16) [Perfect Complexes for Regular Schemes]. If X is a Noetherian regular scheme of finite dimension, then $D^b_{\mathcal{C}\mathrm{oh}}(X)$ consists exactly of the perfect objects in $D(X)$, by(4.9.5.5) and(5.8.5.9).

Def. (5.8.5.17) [K-Groups of Schemes]. Let $X \in \mathcal{S}\mathrm{ch}$, the **Grothendieck group** of X is defined to be $K_0(X) = K_0(D_{\mathrm{perf}}(X))$. If X is locally Noetherian, also define the **Grothendieck group of coherent sheaves** on X to be $K'_0(X) = K_0(\mathcal{C}\mathrm{oh}(X))$.

Prop. (5.8.5.18). If X is Noetherian, then

$$K'_0(X) = K_0(\mathcal{C}\mathrm{oh}(X)) = K_0(D^b(\mathcal{C}\mathrm{oh}(X))) = K_0(D^b_{\mathcal{C}\mathrm{oh}}(X)).$$

In particular, there is a map $K_0(X) \to K'_0(X)$.

Proof: This follows from(3.9.1.13) and(5.8.5.14). □

Prop. (5.8.5.19) [$K_0 \cong K'_0$]. If X is a Noetherian regular scheme of finite dimension, then the map $K_0(X) \to K'_0(X)$(5.8.5.18) is an isomorphism, by(5.8.5.16).

Prop. (5.8.5.20). For $X \in \mathcal{S}\mathrm{ch}$, $- \otimes^L -$ defines a ring structure on $K_0(X)$, by(3.7.7.30) and(3.9.3.12).

Prop. (5.8.5.21). If $X = \mathrm{Spec}\, R$, then $K_0(X) = K_0(R)$. And if R is Noetherian, then $K'_0(X) = K'_0(R)$.

Proof: Cf.[Sta]0FDH. □

Prop. (5.8.5.22) [Push and Pull]. Let $f : X \to Y$ be a proper morphism of locally Noetherian schemes, then there is a map

$$f_* : K'_0(X) \to K'_0(Y) : [\mathcal{F}] \mapsto \oplus_{i \geq 0}[R^{2i} f_* \mathcal{F}] - \oplus_{i \geq 0}[R^{2i+1} f_* \mathcal{F}],$$

which is definable by(5.8.5.15). And there is an obvious map $f^* : K'_0(Y) \to K'_0(X)$. They satisfy

$$f_*(\alpha \cdot f^* \beta) = f_* \alpha \cdot \beta, \alpha \in K'_0(X), \beta \in K'_0(Y).$$

Proof: The first assertion follows from long exact sequence for Rf_*. The last assertion follows from projection formula(5.8.5.8). □

Prop. (5.8.5.23) [Lambda Operators]. Let $X \in \mathcal{S}ch$, there are functor $\lambda^r : K_0(\mathcal{C}oh^{\text{free}}(X)) \to K_0(\mathcal{C}oh^{\text{free}}(X))$ that sends $[\mathcal{E}]$ to $[\wedge^r \mathcal{E}]$.

Proof: Consider a map $c : \mathcal{C}oh^{\text{free}}(X) \to K_0(\mathcal{QC}oh^{\text{free}}(X))[t] : \mathcal{E} \mapsto \sum_{i=0}^{\infty}[\wedge^i \mathcal{E}]t^i$. It suffices to prove that for any exact sequence $0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0$, $c(\mathcal{E}) = c(\mathcal{E}')c(\mathcal{E}'')$, and then take λ^r as

$$c(M) = \sum_{r>0} \lambda^r(M)t^r.$$

To show this, notice that there is a filtration of $\wedge^r \mathcal{E}$ with quotients

$$\wedge^r \mathcal{E}', \wedge^{r-1}(\mathcal{E}') \otimes \mathcal{E}'', \ldots, \wedge^r(\mathcal{E}''),$$

by(5.5.1.26). □

Prop. (5.8.5.24) [Adam Operators]. Let $X \in \mathcal{S}ch$, then there is are **Adam operators**

$$\psi^{-1}, \psi^1, \psi^2, : K_0(X) \to K_0(X)$$

s.t. for $\mathcal{L} \in \mathrm{Pic}(X)$,

$$\psi^{-1}[\mathcal{L}] = [\mathcal{L}^{-1}], \quad \psi^1[\mathcal{L}] = [\mathcal{L}], \quad \psi^2[\mathcal{L}] = [\mathcal{L}^{\otimes 2}].$$

Proof: For any $L \in K_0(X)$, there is an action of $\{\pm 1\}$ on $L \otimes^L L$ by switching factors. Denote $(L \otimes^L L)^+, (L \otimes^L L)^-$ the fixed and anti-fixed parts**?** of $L \otimes^L L$, and define $\psi^2[L] = [(L \otimes^L L)^+] - [(L \otimes^L L)^-]$. **?** □

Coherator

Prop. (5.8.5.25) [$R\mathcal{Q}_X$].

Prop. (5.8.5.26) [$D\mathcal{Q}_X$]. Let X be a qcqs scheme, then the inclusion functor $D_{\mathcal{QC}oh}(X) \to D(X)$ has a right adjoint, called the **coherator**, denoted by $D\mathcal{Q}_X$.

Proof: Use(3.7.7.35). The conditions are satisfied as $D_{\mathcal{QC}oh}(X)$ is compactly generated and has direct sums that is preserved by inclusion by(5.8.5.30)(5.8.5.2). □

Prop. (5.8.5.27). Let $f : X \to Y$ be a morphism of qcqs schemes, then

$$Rf_* \circ D\mathcal{Q}_X = D\mathcal{Q}_Y \circ Rf_* : D(X) \to D_{\mathcal{QC}oh}(Y).$$

Proof: They are both right adjoint to $Lf^* : D_{\mathcal{QC}oh}(Y) \to D(X)$, as Lf^* maps $D_{\mathcal{QC}oh}(Y)$ into $D_{\mathcal{QC}oh}(X)$(5.8.5.4). □

Prop. (5.8.5.28) [Cohomological Boundedness of $D\mathcal{Q}_X$]. Let X be a qcqs scheme, then there exists $N \in \mathbb{Z}$ s.t. if $K \in D(X)$ satisfies $K|_U \in D^{[a,b]}(\mathcal{O}_U)$ for any affine open $U \subset X$, then $D\mathcal{Q}_X(K) \in D^{[a,b+N]}_{\mathcal{QC}oh}(X)$.

Proof: Cf.[Sta]0CSA. □

Compact Generators

Prop. (5.8.5.29) [Perfect and Compact Objects]. Let X be a qcqs scheme, then $K \in D(X)$ is perfect iff it is a compact object in $D_{\mathfrak{QCoh}}(X)$.

Proof: Cf.[Sta]09M1. □

Prop. (5.8.5.30) [$D_{\mathfrak{QCoh}}(X)$ is Compactly Generated]. There is a perfect object $P \subset D_{\mathfrak{QCoh}}(X)$ that is a generator of $D_{\mathfrak{QCoh}}(X)$(3.7.7.31).

Proof: Cf.[Sta]09IS. □

Resolution Property

Def. (5.8.5.31) [Resolution Properties]. A scheme X is said to have **resolution property** iff every $\mathcal{F} \in \mathfrak{QCoh}^{\mathrm{ft}}(X)$ is a quotient of a locally free sheaf.

Prop. (5.8.5.32). If X has an ample invertible sheaf, then X has the resolution property by(5.5.4.5). In fact, every coherent sheaf is a quotient of a finite direct sum of $\mathcal{O}_X(-n)$.

Prop. (5.8.5.33) [Regular Scheme has Resolution property]. If X is qc regular scheme with an affine diagonal, then X has the resolution property, Cf.[Sta]0F8A**?**. Conversely, if X is qcqs with the resolution property, then X has affine diagonal. Cf.[Sta]0F8C.

Prop. (5.8.5.34) [Kleiman]. If X is a qc irreducible and locally factorial scheme with affine diagonal map, then X has the resolution property.

Proof: By(5.8.1.6), we have an basis of the form X_s for $s \in \Gamma(X, \mathcal{L})$ for various invertible sheaves, then for any coherent sheaf, it is generated by f.m. sections in $\Gamma(U_i, \mathcal{F})$ and $U_i = X_s$ for $s \in \Gamma(X, \mathcal{L})$, and for each of them, we can use(5.5.3.5), we can extend these to global sections on $\Gamma(\mathcal{F} \otimes \mathcal{L}_i^{n_i})$ for n_i large. Then tensoring $\mathcal{L}_i^{-n}$, we find a $\oplus L_i^{-n_i} \to \mathcal{F}$ surjective. □

Prop. (5.8.5.35). When X has the resolution property, $\mathcal{E}xt^\bullet(-, \mathcal{G})$ is an universal δ-functor for every $\mathcal{G} \in \mathfrak{QCoh}(X)$, because locally free sheaf is adapted to $\mathcal{E}xt^\bullet(-, \mathcal{G})$ by(5.3.3.25), so we can calculate $\mathcal{E}xt(\mathcal{F}, \mathcal{G})$ using a finite locally free resolution of $\mathcal{F}$.

Prop. (5.8.5.36). If X is a qcqs scheme with the resolution property, then the map $K_0(\mathcal{V}\mathrm{ect}(X)) \to K_0(X)$ is an isomorphism.

Proof: Cf.[Sta]0FDJ. □

6 Duality for Schemes

Main references are [Hartshorne Residues and Duality, Hartshorne], [Sta]Chap48 and [Grothendieck Duality and Base Change, Conrad]

Right Adjoints of Pushforwards

Prop. (5.8.6.1) [Right Adjoints of Pushforwards Exist]. Let $f : X \to Y$ be a morphism between qcqs schemes, then the functor $Rf_* : D_{\mathfrak{QCoh}}(X) \to D_{\mathfrak{QCoh}}(Y)$ has a right adjoint, denoted by $f^\times$.

Proof: Use(3.7.7.35). The conditions are satisfied as $D_{\mathfrak{QCoh}}(X)$ is compactly generated and has direct sums by(5.8.5.30)(5.8.5.2), and Rf_* preserves direct limits(5.8.5.7). □

Prop. (5.8.6.2). Let $f: X \to Y$ be a morphism between qcqs schemes, then $f^\times$ maps $D^+_{\mathfrak{QCoh}}(Y)$ into $D^+_{\mathfrak{QCoh}}(X)$.

Proof: This follows from the fact Rf_* has finite cohomological dimension N(5.8.5.6) and(3.9.1.18). □

Prop. (5.8.6.3). Let $f: X \to Y$ be a morphism of qcqs schemes, then for $K \in D_{\mathfrak{QCoh}}(X), L \in D_{\mathfrak{QCoh}}(Y)$, there is a canonical map

$$Rf_* R\mathcal{H}om_{\mathcal{O}_X}(L, f^\times K) \to R\mathcal{H}om_{\mathcal{O}_Y}(Rf_*L, Rf_*f^\times K) \to R\mathcal{H}om_{\mathcal{O}_Y}(Rf_*L, K),$$

by(5.3.3.31) and adjunction.

Then this map becomes isomorphism after applying the coherator $D\mathfrak{Q}_X$(5.8.5.26).

Proof: By Yoneda lemma, it suffices to show that for any $M \in D_{\mathfrak{QCoh}}(Y)$,

$$\mathrm{Hom}_Y(M, Rf_* R\mathcal{H}om_{\mathcal{O}_X}(L, f^\times K)) \cong \mathrm{Hom}_Y(M, R\mathcal{H}om_{\mathcal{O}_Y}(Rf_*L, K)):$$

$$\begin{aligned}
\mathrm{Hom}_Y(M, Rf_* R\mathcal{H}om_{\mathcal{O}_X}(L, f^\times K)) &= \mathrm{Hom}_X(Lf^*M, R\mathcal{H}om_{\mathcal{O}_X}(L, f^\times K))\\
&= \mathrm{Hom}_X(Lf^*M \otimes^L L, f^\times K)\\
(\text{ as } Lf^*M \otimes^L L \in D_{\mathfrak{QCoh}}(X) \text{ by } (5.8.5.4)(5.8.5.5)) &= \mathrm{Hom}_Y(Rf_*(Lf^*M \otimes^L L), K)\\
&= \mathrm{Hom}_Y(M \otimes Rf_*L, K)\\
&= \mathrm{Hom}_Y(M, R\mathcal{H}om_{\mathcal{O}_Y}(Rf_*L, K))
\end{aligned}$$

□

Cor. (5.8.6.4). By(5.8.5.6), this adjointness is true without coheration if both $R\mathcal{H}om_{\mathcal{O}_X}(L, f^\times K)$ and $R\mathcal{H}om_{\mathcal{O}_Y}(Rf_*L, K)$ are in $D_{\mathfrak{QCoh}}(Y)$. This is the case if L, Rf_*L are perfect or $K \in D^+_{\mathfrak{QCoh}}(Y)$ and and L, Rf_*L are pseudo-coherent, by(5.8.5.11).

In particular, this holds if $f: X \to Y$ is a proper morphism of Noetherian schemes and $L \in D^-_{\mathfrak{Coh}}(X)$ and $S \in D^+_{\mathfrak{QCoh}}(S)$, by(5.8.5.15) and(5.8.5.10).

Cor. (5.8.6.5) [Global Sections]. Let $f: X \to Y$ be a morphism of qcqs schemes, then for $K \in D_{\mathfrak{QCoh}}(X), L \in D_{\mathfrak{QCoh}}(Y)$, there is a canonical isomorphism

$$R\,\mathrm{Hom}_{\mathcal{O}_X}(L, f^\times K) \to R\,\mathrm{Hom}_{\mathcal{O}_Y}(Rf_*L, Rf_*f^\times K) \to R\mathcal{H}om_{\mathcal{O}_Y}(Rf_*L, K)$$

Proof: This is because for any $E \in D(X)$, $H^i(X, E) = \mathrm{Ext}^i_X(\mathcal{O}_X, E) = \mathrm{Hom}(\mathcal{O}_X[-i], E) = \mathrm{Hom}(\mathcal{O}_X[-i], D\mathfrak{Q}(E))$ only depends on $D\mathfrak{Q}(E)$. □

Prop. (5.8.6.6) [Proper Flat $f^\times$]. Let $f: X \to Y$ be a proper flat morphism of f.p. between qcqs schemes, then $f^\times$ is compatible with base change between qcqs schemes.

Proof: Cf.[Sta]0AAB. □

Upper Shriek

Def. (5.8.6.7) [$\mathcal{S}\mathrm{ch}_S^{\mathrm{ft,sep}}$]**.** For a locally Noetherian scheme S, let $\mathcal{S}\mathrm{ch}_S^{\mathrm{ft,sep}}$ be the full subcategory of $\mathcal{S}\mathrm{ch}/S$ consisting of schemes separated of f.t. over S.

Prop. (5.8.6.8) [Lower Shriek]. Let $f : X \to Y \in \mathcal{S}\mathrm{ch}_S^{\mathrm{ft,sep}}$, take a compactification $\overline{f} : \overline{X} \to Y$ of X/Y, then we can define the functor

$$f^! : D^+_{\mathcal{QC}\mathrm{oh}}(Y) \to D^+_{\mathcal{QC}\mathrm{oh}}(X) : f^! K = \overline{f}^{\times}(K)|_X.$$

and this functor is independent of the compactification chosen.

Proof: Cf.[Sta]0AA0. □

Prop. (5.8.6.9). If $f : X \to Y, g : Y \to Z \in \mathcal{S}\mathrm{ch}_S^{\mathrm{ft,sep}}$, then there is a canonical isomorphism of functors $(g \circ f)^! \cong f^! \circ g^!$.

Proof: Cf.[Sta]0ATX. □

Prop. (5.8.6.10) [Properties of $f^!$]. Let $S \in \mathcal{S}\mathrm{ch}$ be Noetherian, then for $X, Y \in \mathcal{S}\mathrm{ch}_S^{\mathrm{ft,sep}}$,

- If $j : X \to Y$ is an open immersion, then $j^! = j^*$.
- If $i : X \to Y$ is a closed immersion, then $i^! = R\mathcal{H}om(\mathcal{O}_X, -)$.
- $f^!$ maps $D^+_{\mathcal{QC}\mathrm{oh}}(Y)$ into $D^+_{\mathcal{QC}\mathrm{oh}}(X)$.
- If $f : X \to Y$ is a local complete intersection morphism, then $f^!\mathcal{O}_Y$ is an invertible object of $D(X)$, and $f^!$ preserves perfect complexes.
- If $f : X \to Y$ is finite, then $f_* f^!(-) = R\mathcal{H}om_{\mathcal{O}_Y}(f_*\mathcal{O}_X, -)$.
- If $f : X \to Y$ is an effective Cartier divisor, then $f^!(-) = Lf^*(-) \otimes^L_{\mathcal{O}_X} \mathcal{O}_Y(-X)[-1]$.
- If $f : X \to Y$ is a Koszul regular immersion of codimension c, then $f^!(-) = Lf^*(-) \otimes^L \wedge^c \mathcal{N}[-c]$.
- If $f : X \to Y$ is smooth proper of relative dimension d, then $f^!(-) = Lf^*(-) \otimes^L \Omega^d_{X/Y}[d]$.

Proof: Cf.[Sta]0AU0, 0AA2, 0AU1, 0B6V, 0AU3.? □

Dualizing Complexes

Def. (5.8.6.11) [Dualizing Complex]. Let X be a locally Noetherian scheme, then a complex $K \in D_{\mathcal{QC}\mathrm{oh}}(X)$ is called a **dualizing complex** if it satisfies the following equivalent conditions:

- For any affine open $U = \operatorname{Spec} A \subset X$, $K|_U$ is a dualizing complex in $D(A)$.
- There exists an affine open covering $U_i = \operatorname{Spec} A_i$ of X s.t. $K|U_i$ is a dualizing complex in $D(A_i)$ for any i.

Proof: This follows from(4.9.8.2). □

Prop. (5.8.6.12) [Dualizing]. Let X be a locally Noetherian scheme and ω_X be a dualizing complex, then $D = R\mathcal{H}om_{\mathcal{O}_X}(-, \omega_X)$ is an anti-equivalence of $D_{\mathcal{QC}\mathrm{oh}}(X)$ with itself, and there is a canonical isomorphism $\mathrm{id} \cong D^{\circ 2}$.

Moreover, if X is qc, then D exchanges $D^+_{\mathcal{QC}\mathrm{oh}}(X)$ and $D^-_{\mathcal{QC}\mathrm{oh}}(X)$, and induces an equivalence $D : D^b_{\mathcal{QC}\mathrm{oh}}(X) \to D^b_{\mathcal{QC}\mathrm{oh}}(X)$.
