Preface

This is a note containing subtle or important materials I encountered while studying. I started this project in the fall of my third undergraduate year (October 2019) in Peking University, noticing that I have a poor memory and consistently forget what I have already learned. So it came to me that I can compile all the proofs of theorems I cannot recall that is hard and subtle yet appearing over and over again. But finally it turns out I want to make it as comprehensive as possible. Here it is!

I constantly add stuff to this note, and I regularly put them online. You can find the newest version released at https://math.mit.edu/~hao_peng/skyscraper.pdf. Don’t be surprised to find many sections containing only titles, and the symbol “?” means “further work required here”. If you find errors or have suggestions, please feel free to email me.

Constitutions: The following are principles of the structure of this note, but the current version is far from it. They serve as ultimate goals.

- This note should be self-contained.
- Notations should be consistent throughout the whole note.
- Propositions should be put in the (sub)section of the most advanced term appeared in the statement, or as a corollary.
- Logical order is not necessary, but vicious circles are intolerable. Although it should also be properly ordered logically in the sense that if every notion appearing is referred to its definition, the ordering has the least number of reverse cross-references (i.e. referring to definitions after it) under admissible permutation, where admissible permutation means a permutation that preserves the tree structure of this note (i.e. the tree of chapter-section-subsection-··· ordering).
- Theories should be stated at the most generality. There’s no need to give proofs for the special case but clarify the deduction from the general case, unless it is needed in the proof of the general case, then state it as a lemma.
- When facing multiple proofs, only the most elegant and essential proof should be recorded.
- References should be traced to the original author and his specific paper.
- Each section should contain less than 30 pages. Each chapter should contain less than 20 sections.

Writing Styles: The following are writing standards of this note. Main references are [CMOS] and [Poo]. Notice some rules of [Poo] remain to be discussed.

- Use less words and more math symbols and equations, and use plain English, so that even those who don’t speak English can understand without much effort.
- A theorem is a proposition that seems more important or general among others.
• A lemma is a statement that seems to be only useful proving its corresponding proposition or theorem.

• A corollary is a proposition that can be deduced quite easily from it corresponding proposition or theorem.

• A conjecture is a statement whose proof is unknown yet.

• The naming of lemmas/propositions/theorems/conjectures by multiple authors follows the lexicographical order.

Tips: This is hardly a readable note. I use it as a dictionary. It only contains materials that I’m interested in and many proofs are still missing. Hopefully I can complete them all as time goes by. The main reason why I have to latex all these materials together is that I need tons of cross-references. So I believe it’s the best way to read this book digitally, and it’s good to know how to go forwards and backwards between hyper-references on your computer. For example, on a MacOS system, the default shortcuts are \( +[ \) for Preview and \( +[ \) for Foxit Reader. Foxit reader is stable when handling a large file.

Acknowledgement: Sincere thanks to Yi Tian (田翊) for answering my questions when I was learning algebraic geometry and \( p \)-adic geometry in year 2020 when I was in Peking University. His help is fundamental. Thanks to Zhiyu Zhang (张志宇) for giving me directions on mathematical study and advices on mathematical life in year 2022 when I was in MIT.

There is already a great online book [Sta] maintained by Johan de Jong that covers considerably many of the Algebraic Geometry part of this note. I haven’t finish reading it but I reordered the materials that I learned and keep track of it in my own way. I used different paths for some proofs to optimize the proof. The idea to compile this note was inspired by [Sta]. One different feature of this note compared to [Sta] is that we want to make every proof as optimal and as general as possible, (See Constitutions above). And suggestion to optimize proofs or generalize statements is strongly encouraged.

The writing style of this note is influenced by various literature, including beautiful writings of J. S. Milne, especially [Mil17][Mil17d] and [Mil08].

Copyright issue: It should be made clear that I took proofs from many different places, so nothing in this note should be considered originated from me. Until I get a full extensive references of this note, I have few rights to the material. But I am currently too busy being a graduate student, so many references are still missing. Tell me if you think I should cite you. Nevertheless, I hope this note can contribute to my study and help anyone who read it. But it comes with no warranty, please use at your own risk.

How to cite this note: Don’t cite this note for now.
“And they said, Go to, let us build us a city and a tower, whose top may reach unto heaven; and let us make us a name, lest we be scattered abroad upon the face of the whole earth.”

–Genesis 11:1-9
### Table of Contents

**Chapter 1 – Mathematical Logic and Foundations**

1.1 Zermelo-Fraenkel Set Theory with Choice ...................................................... 1  

1.2 Model Theory ............................................................................................... 14  

**Chapter 2 – Algebras**

2.1 Group Theory ............................................................................................... 31  

2.2 Abstract Algebra .......................................................................................... 48  

2.3 Linear Algebra ............................................................................................. 73  

2.4 More on (Non-Commutative)Algebras ......................................................... 92  

2.5 Lie Algebras ................................................................................................. 108  
2.6 Infinite Dimensional Lie Algebras ................................................................. 143

2.7 Reflection Groups and Coxeter Groups .......................................................... 144

2.8 Algebraic K-Theory ....................................................................................... 155

2.9 Hopf Algebras .................................................................................................... 158
(1) Hopf Algebras. (2) Commutative Hopf Algebras. (3) Quiver Hecke Algebra.

Chapter 3 – Categories and Algebraic Topology

3.1 Categories ......................................................................................................... 165

3.2 Categorical Logic ............................................................................................ 189

3.3 Homological Algebra ....................................................................................... 197

3.4 Derived Categories ........................................................................................... 212

3.5 Differential Graded Algebras ............................................................................. 233
(1) dg-Categories. (2) Sheaves of DGAs.

3.6 Topology I ......................................................................................................... 234

3.7 Model Categories ............................................................................................ 254

3.8 Topology II ....................................................................................................... 267
(1) Topological Groups. (2) Hausdorff Geometry. (3) Spaces from Algebraic Geometry. (4) Spectral Spaces.
3.9 Algebraic Topology I: Homotopies ................................................................. 279

3.10 Algebraic Topology II: Homologies and Cohomologies ................................................................. 295

3.11 Fiber Bundles & K-Theory ......................................................................... 314

3.12 Simplicial Homotopy Theory ...................................................................... 336

3.13 Higher Topos Theory .................................................................................. 356
(1) Introduction. (2) $\infty$-Categories. (3) $\infty$-Category of $\infty$-Categories. (4) Limits and Colimits. (5) Presentable and Accessible $\infty$-Categories. (6) $\infty$-Algebras. (7) Topological Cyclic Homology Theory(Scholze).

3.14 Stable $\infty$-Categories ............................................................................... 362
(1) Stable $\infty$-Categories. (2) Monoidal $\infty$-Categories.

Chapter 4 – Commutative Algebras

4.1 Commutative Algebra I .................................................................................. 363

4.2 Commutative Algebra II .................................................................................. 379

4.3 Commutative Algebra III .............................................................................. 402

4.4 Commutative Algebra IV .............................................................................. 419

4.5 $p$-adic Commutative Algebras ...................................................................... 445
(1) $F_p$-Algebras. (2) $p$-Local Rings. (3) Witt Theory. (4) $\delta$-Rings.
4.6 Derived Commutative Algebras ................................................................. 460

4.7 Divided Power Algebras ............................................................................. 473
(1) de Rham Complex.

4.8 Almost Ring Theory .................................................................................. 482

Chapter 5 – Algebraic Geometry I: Scheme Theory

5.1 Sites, Sheaves and Stacks .......................................................................... 491

5.2 Ringed Topoi, Ringed Sites, Ringed G-Spaces and Schemes ......................... 515

5.3 Cohomology on Ringed Sites ....................................................................... 535

5.4 Properties of Schemes ................................................................................. 557

5.5 Quasi-Coherent Sheaves on Schemes .......................................................... 585

5.6 More Properties of Schemes ....................................................................... 607

5.7 Cohomology of Schemes ............................................................................. 625

5.8 Topics in Schemes ...................................................................................... 639
5.9 Resolution of Singularities .................................................................................. 659
5.10 Varieties ............................................................................................................. 660
(1) Varieties. (2) Projective Varieties. (3) Birational Geometry. (4) Others. (5) Relative
Varieties.

5.11 Curves .............................................................................................................. 667
(1) Basics. (2) Vector Bundles. (3) Singularities and \( \delta \)-Invariants. (4) Linear Series. (5) Hyper-
Curves.

5.12 K3 Surfaces ..................................................................................................... 689

Chapter 6 – Weil Cohomologies and Motives

6.1 Intersection Theory ............................................................................................ 691
for Line Bundles.

6.2 Algebraic de Rham Cohomology ........................................................................ 716
(1) de Rham Complexes. (2) De Rham Cohomologies. (3) Cup Products. (4) Poincaré Duality.

6.3 Étale Fundamental Groups .................................................................................. 719
(1) Étale Connected Components. (2) Étale Fundamental Groups. (3) Galois Inverse Problem.

6.4 Étale Cohomology Theory .................................................................................. 721
(1) Basics. (2) Constructible Sheaves. (3) Base Changes. (4) Lower Shriek Functor. (5) Co-
homology with Compact Support. (6) Finiteness Theorems. (7) \( \ell \)-adic Étale Cohomologies.
(8) Curves.

6.5 Pro-Étale Cohomology ....................................................................................... 740
(1) Introduction. (2) Ring-Theoretical Stuff.

6.6 Crystalline Cohomology .................................................................................... 742

6.7 Prismatic Cohomology ....................................................................................... 750
(1) Prisms. (2) Perfect Prisms. (3) Integral Perfectoid Rings. (4) Prismatic Site. (5) Hodge-
Tate Comparison. (6) Proof of Hodge-Tate Comparison. (7) Derived de Rham Cohomology.
(8) Derived Prismatic Cohomology. (9) \( q \)-de Rham Cohomology. (10) Étale Comparison.
(11) Almost Purity.

6.8 Motives ............................................................................................................. 767
(1) Weil Cohomology Theories. (2) Pure Motives. (3) Mixed Motives. (4) Standard Conjec-
tures.
**Chapter 7 – Algebraic Geometry II: Group Theory**

### 7.1 Group Schemes I: Structure Theory .............................................................. 777

### 7.2 Group Schemes II: Solvable Groups ...................................................................... 797

### 7.3 Group Theory III: Reductive Groups .................................................................. 809

### 7.4 Topics in Group Schemes .................................................................................. 819
1. over Finite Fields.

### 7.5 Formal Groups and $p$-Divisible Groups ........................................................... 820

### 7.6 Geometric Invariant Theory .............................................................................. 835

### 7.7 Moduli Problems .............................................................................................. 836

### 7.8 Algebraic Stacks .............................................................................................. 850

### 7.9 Group Algebraic Spaces ..................................................................................... 852
1. Quotient of Groupoids.  2. Quotients of Schemes.

### 7.10 Higher Dimensional Geometry ....................................................................... 854

**Chapter 8 – Algebraic Geometry III: Derived Algebraic Geometry**

### 8.1 Simplicial Commutative Algebras .................................................................... 855

### 8.2 Andre-Quillen-Cohomology ............................................................................ 861

### 8.3 Derived Algebraic Geometry(Lurie) ................................................................ 867
Chapter 9 – Algebraic K-Theory of Schemes

9.1 K-Theory of Schemes ................................................................................................. 869
   (1) K-Groups of Schemes.

9.2 Brauer-Grothendieck Groups .................................................................................. 870
   (1) Brauer Groups. (2) Brauer Groups of Fields. (3) Severi-Brauer Varieties. (4) Norm Residue
   Isomorphism Theorem.

Chapter 10 – Condensed Mathematics and Analysis

10.1 Profinite Cohomology .............................................................................................. 877
   (1) Group Cohomology. (2) Cohomology of Profinite Groups. (3) Galois Cohomology.

10.2 Condensed Mathematics(Scholze) ........................................................................ 889
   (1) Introduction. (2) Condensed Objects. (3) Cohomologies. (4) LCAs. (5) Solid Abelian

10.3 Topological Commutative Algebra ........................................................................ 894
   (1) Topological Abelian Groups and Rings. (2) Valuation Rings. (3) Valuations. (4) Affinoid
   Algebras. (5) Huber Rings. (6) Analytic Points and Analytic Huber Pairs. (7) Huber and

10.4 Real Analysis ........................................................................................................... 923

10.5 Complex Analysis .................................................................................................... 933
   (1) Basics. (2) Complex Integration. (3) Series and Product Developments. (4) Analytic
   Continuations. (5) Theorems. (6) Harmonic Functions. (7) Elliptic Functions. (8) Special
   Functions. (9) Multi-Variable case.

10.6 General Functional Analysis ................................................................................... 954
   (1) Topological Vector Space. (2) Completeness. (3) Dual Space. (4) Banach Space.

10.7 Archimedean Functional Analysis ........................................................................ 959
   (1) Topological Vector Space. (2) Various Spaces and Duality. (3) Convexity. (4) Duality

10.8 Archimedean Banach Algebra ................................................................................ 975
   (5) Hilbert-Schmidt Operators and Trace Classes.

10.9 Analysis on Locally Compact Groups .................................................................... 991
   (1) Locally Compact Groups. (2) Unitary Representations. (3) Locally Compact Abelian
10.10 Harmonic Analysis ................................................................. 1019
(1) Distributions. (2) Fourier Analysis on $\mathbb{R}^n$. (3) Sobolev Space. (4) Fourier Analysis on $\mathbb{T}^n$.

10.11 Differential Operators ......................................................... 1026

10.12 D-modules ............................................................................ 1034

10.13 Dynamic System .................................................................. 1035

Chapter 11 – Differential Geometry

11.1 Geometric Analysis ............................................................... 1045

11.2 Riemannian Geometry ............................................................. 1063

11.3 Low Dimensional Topology .................................................... 1079

11.4 Differential Forms in Algebraic Topology(Bott-Tu) ..................... 1082
(1) Basics.

11.5 Symplectic Geometry ............................................................. 1083
(1) Basics.

11.6 Lie Groups ............................................................................. 1084

11.7 Complex Geometry ................................................................ 1109

11.8 Kähler Geometry ................................................................. 1117
11.9 Locally Symmetric Spaces ................................................................. 1130
(1) Symmetric Spaces. (2) Decompositions of Symmetric Spaces. (3) Non-Compact Type.
(7) Quotients of Hermitian Symmetric Domains.

11.10 Compactifications of Locally Symmetric Spaces ............................... 1135

11.11 Calabi-Yau Manifolds .................................................................... 1136

Chapter 12 – Algebraic Number Theory

12.1 $p$-adic Analysis ........................................................................... 1137
(1) (Ultranormed) Valuation Theory. (2) Ultranormed Banach Spaces. (3) $p$-adic Analysis.

12.2 Algebraic Number Theory ............................................................... 1146
(5) Adele and Idele. (6) Fourier Analysis on Adeles and Ideles.

12.3 Quadratic Forms over Fields ......................................................... 1171
(1) Quadratic Forms. (2) Witt Theory. (3) Witt Ring. (4) Quaternion Algebras. (5) over
Local or Finite Fields. (6) over Global Fields. (7) Algebraic Extensions.

12.4 Cohomology of Number Fields ...................................................... 1184
(1) Abstract Class Field Theory. (2) Local Class Field Theory. (3) Global Class Field Theory.
(4) Brauer Groups of Local and Global Fields. (5) Decomposition Law. (6) L-Series and
(9) Cohomology of Global Fields.

12.5 Transcendental Number Theory ..................................................... 1201
(1) Transcendental Numbers. (2) Periods. (3) Periods and Differential Equations. (4) Periods
and L-Functions. (5) Periods and Motives.

Chapter 13 – Arithmetic Geometry

13.1 Pseudo-Algebraically Closed Fields ............................................. 1203

13.2 Diophantine Geometry .................................................................. 1204
(1) over Local Fields. (2) over Global Fields. (3) Artin’s Conjecture. (4) Weil Heights. (5) Dio-

13.3 Arithmetic of Algebraic Groups .................................................... 1216
(1) over $p$-adic Number Fields. (2) Over Global Fields. (3) over Adeles.

13.4 Arithmetic Subgroups .................................................................... 1220
(1) Arithmetic Subgroup of Lie Groups.
13.5 Arithmetic of Abelian Varieties ...................................................... 1221

13.6 Surfaces and Arithmetic Surfaces ...................................................... 1249

13.7 Reductions ..................................................................................... 1254
(1) Semistable Reductions. (2) Reduction of Curves.

13.8 Arithmetic of Elliptic Curves ............................................................ 1256

13.9 Complex Multiplication Theory ......................................................... 1280

13.10 Arithmetic Moduli of Elliptic Curves ................................................. 1290
(1) Moduli Problems.

13.11 Arithmetic of K3 Surfaces ............................................................... 1291

13.12 ℓ-adic Étale Cohomologies over Finite Fields .................................... 1292

13.13 Rational Points on Abelian Varieties ................................................. 1312

13.14 Shimura Varieties ........................................................................... 1318

13.15 Mordell-Lang Conjecture (Faltings Theorem) .................................... 1321
(1) Tate Hom Conjecture. (2) Heights of Abelian Varieties. (3) Finiteness Theorems. (4) Curves.

13.16 Tate Conjecture & Hodge Conjecture .............................................. 1325
(1) Statements. (2) over Finite Fields. (3) K3 Surfaces. (4) Hodge Conjecture.
Chapter 14 – $p$-Adic Geometry

14.1 Galois Representations .................................................................1331

14.2 $p$-adic Hodge Theory .................................................................1337
(1) Intro. (2) $(\varphi, \Gamma)$-modules. (3) Isocrystals. (4) Admissible Representations. (5) $\mathbb{C}_p$-Admissibility and Hodge-Tate Representations. (6) Sen’s Theory and Hodge-Tate Representations. (7) Admissible Representations. (8) Crystalline Representations.

14.3 $p$-adic Modular Forms ...............................................................1350

14.4 $\mathbb{F}_p$-Schemes ......................................................................1351
(1) Perfect Schemes.

14.5 Formal and Rigid Geometry .........................................................1353

14.6 $p$-adic Uniformizations ...............................................................1372
(1) Mumford Curves.

14.7 Rapoport-Zink Spaces ................................................................1373
(1) Isocrystals with Additional Structures. (2) Period Domain. (3) Algebraic Groups of EL/PEL Types.

14.8 Adic Spaces and Perfectoid Spaces (Scholze) ............................1381

14.9 Fargues-Fontaine Curve ..............................................................1406

14.10 Pro-Étale Sites on Perfectoids and Diamonds ............................1429
(1) Properties of Perfectoid Spaces. (2) Pro-Étale Site and v-Site. (3) Morphisms of v-Stacks. (4) Diamonds.
Chapter 15 – Representation Theory

15.1 Classical Representation Theory ..........................................................1441
(1) Topological Representations. (2) Linear Representation of Finite Groups. (3) Symmetric Groups. (4) Locally Profinite Groups.

15.2 Modular Representations ..................................................................1461
(1) Block Theory. (2) Unequal Characteristic. (3) Equal Characteristic.

15.3 Representations of Algebraic Groups ...............................................1462

15.4 Complex Representations of Finite Groups of Lie Type ...................1469

15.5 Bruhat-Tits Theory .......................................................................1477

15.6 Representations of (Non-Compact)Lie Groups ................................1478
(1) Basics. (2) Finite-Dimensional Representations. (3) (g, K)-Modules. (4) Unitary Representations.

15.7 Automorphic Representations of GL(n) over Archimedean Local Fields......1495

15.8 Admissible Representations of GL(n) over p-Adic Number Fields ...........1513

15.9 Cuspidal Representations ..............................................................1542
(1) GL(n). (2) SL(n).

15.10 Adelic Automorphic Representations of GL(n) .............................1543

15.11 Modular Forms .............................................................................1555

15.12 Overview of the Langlands Program .............................................1576
(1) Langlands Program. (2) Local Langlands. (3) Global Langlands Correspondence. (4) Beyond Endoscopy.
15.13 Local Langlands for GL(n) over p-Adic Fields ..................................................1580
(1) Local Langlands for p-adic GL(n). (2) Cuspidal Representations. (3) Simple Characters.
(4) Tame Lifting. (5) Description of the Langlands Correspondence.

15.14 Automorphic Forms Beyond GL(2) .......................................................................1583
(1) Automorphic Forms on Unitary Groups. (2) Quaternionic Modular Forms. (3) Theta Correspondence. (4) Weil Representations. (5) Gan-Gross-Prasad Conjecture.

15.15 Representations of Semisimple Lie Algebras and Category O .................................1589
(1) Semisimple Representations. (2) Verma Modules. (3) Weyl Character Formula. (4) Category O.

15.16 Trace Formulae ...........................................................................................................1598
(1) Introduction. (2) Trace Formulae.

Chapter 16 – L-Functions

16.1 L-Functions Attached to Motives .................................................................................1601
(1) over Finite Fields. (2) over Global Fields. (3) Motivic L-Functions. (4) Abelian Varieties.
(5) Elliptic Curves. (6) Tamagawa Number Conjecture. (7) Others.

16.2 L-Functions Attached to Automorphic Representations .............................................1607

16.3 L-Functions Attached to Galois Representations ........................................................1633

16.4 p-adic L-Functions ........................................................................................................1636
(1) p-Adic L-Functions. (2) Iwasawa Main Conjectures. (3) Iwasawa Main Conjectures for GL(2).

16.5 Heegner Points ..............................................................................................................1637

16.6 Gan-Gross-Prasad Conjecture .....................................................................................1640
(1) Introduction. (2) restriction Problems. (3) Statements. (4) Arithmetic Fundamental Lemma.

16.7 Colmez Conjecture .......................................................................................................1641
(1) Averaged Colmez Conjecture.

16.8 BSD Conjecture ..........................................................................................................1642
(1) Statements. (2) Low Rank Cases. (3) over Function Fields. (4) Motivic BSD Conjectures.
16.9 Shimura-Taniyama-Weil Conjecture .............................................................1646
(1) Modularity. (2) L-Functions. (3) Fermat’s Last Theorem.

16.10 Special Values of L-Functions .....................................................................1649
(1) Deligne Conjecture. (2) Beilinson-Bloch Conjecture. (3) Bloch-Kato Conjecture. (4) Height Pairings.

16.11 Riemann Conjecture ..........................................................................................1651
(1) Hilbert-Pólya Conjecture.

Chapter 17 – Arakelov Geometry
17.1 Arithmetic Intersection Theory .....................................................................1653
(1) Arithmetic Riemann-Roch.

17.2 Arakelov Geometry ..........................................................................................1654
(1) Metrized Line Bundles.

Chapter 18 – Theoretical Physics
18.1 Quantum Mechanics ..........................................................................................1655
(1) Basics. (2) Quantum Computations. (3) Quantum Algorithms.

18.2 Quantum Field Theory ......................................................................................1660
(1) Supersymmetric Quantum Field Theory. (2) Topological Quantum Field Theory.

Chapter 19 – Combinatorics
19.1 Combinatorics ....................................................................................................1663
(1) Graph Theory. (2) Ramsey’s Theory. (3) Polytopes. (4) Hilbert’s 3rd Problem.

Chapter 20 – Others
20.1 Elementary Mathematics ....................................................................................1671
(1) Algebra. (2) Number Theory.

20.2 French to English Dictionary ............................................................................1675

Chapter – Notations

Chapter – References

Chapter – Index
1 Mathematical Logic and Foundations

1.1 Zermelo-Fraenkel Set Theory with Choice

Main references are [H-J99], [Model Theory Marker].
Set theory is one choice of foundation of mathematics. And many propositions need efforts to be made rigorous. Another choice of foundation of mathematics is the homotopy type theory(HoTT).

1 Basic Axioms

Axiom (1.1.1.1) [Axiom of Existence]. There exists a set which has no elements.

Axiom (1.1.1.2) [Axiom of Extensionality]. If every element of $X$ is an element of $Y$ and every element of $Y$ is an element of $X$, then $X = Y$.

Cor. (1.1.1.3). There is at most one set which has no elements, it is called the empty set $\emptyset$ or 0.

Def. (1.1.1.4). Write $x \in X$ if $x$ is an element of $X$.

Def. (1.1.1.5). Write $A \subset B$ iff $\forall x, x \in A \Rightarrow x \in B$.

Axiom (1.1.1.6) [Axiom Schema of Comprehension]. For any set $A$, if $P(x)$ is a property of elements of $A$, there is a set $B$ that $x \in B$ iff $x \in A$ and $P(x)$, it is denoted by $B = \{ x \in A | P(x) \}$.

Axiom (1.1.1.7) [Axiom of Pairs]. For each $A, B$, there is a set $C$ that $x \in C$ iff $x = A$ or $x = B$.

Axiom (1.1.1.8) [Axiom of Unions]. For any set $S$, there exists a set $U$ that $x \in U$ iff $x \in A$ for some $A \in S$.

Axiom (1.1.1.9) [Axiom of Power Sets]. For any set $S$, there exists a set $P$ that $x \in P$ iff $x \subset S$.

Def. (1.1.1.10) [Successors]. The successor of a set $x$ is $S(x) = x \cup \{x\}$.

Def. (1.1.1.11) [Inductive Sets]. A set $I$ is called inductive if $0 = \emptyset \in I$ and if $n \in I$, then $n + 1 \in I$, where $n + 1 = S(n)$ the successor.

Axiom (1.1.1.12) [Axiom of infinity]. An inductive set (1.1.1.11) exists.

Def. (1.1.1.13) [Natural Numbers]. The set of natural numbers $\mathbb{N}$ is defined to be $\{ x \in I_0 | x \in I$ for all inductive set $I \}$, where $I_0$ is an inductive set given by (1.1.1.12).

Cor. (1.1.1.14) [Inductive Principle]. If $P(x)$ is a property that $P(0)$, and $P(n)$ implies $P(n + 1)$, then $P(n)$ for each natural number $n$. 
Proposition (1.1.15). \( \mathbb{N} \) is a linearly ordered set.

Proof: Cf. [Set Theory Jech P43].

Corollary (1.1.16) [Inductive Principle Second Version]. If \( P(x) \) is a property that \( P(0) \), and \( P(k) \) holds for all \( k < n \) implies \( P(n) \), then \( P(n) \) for each natural number \( n \).

Proof: Use induction principle (1.1.14) for the property \( Q(n) : P(k) \) for all \( k < n \). Then \( Q(n) \) implies \( Q(n + 1) \).

2 Cardinals

Theorem (1.1.2.1) [Cantor-Schröder-Bernstein]. If there is an injection from \( A \) to \( B \) and an injection from \( B \) to \( A \), then there is a bijection from \( A \) to \( B \). Thus the ordering of the cardinal is well-defined.

So we can denote \( |A| \leq |B| \) iff there is an injection from \( A \) to \( B \). Then if \( |A| \leq |B| \) and \( |B| \leq |A| \), then \( |A| = |B| \).

Proof: Let \( f : A \to B \), \( g : B \to A \) be injection, then use the above lemma (1.1.2.2) for \( g \circ f(A) \subset g(B) \subset A \).

Lemma (1.1.2.2). If \( A_1 \subset B \subset A \) with \( |A| = |A_1| \), then \( |A| = |B| \).

Proof: Let \( f \) be a bijection from \( A \) to \( A_1 \). Define inductively \( A_{n+1} = f(A_n) \), \( B_{n+1} = f(B_n) \). Then \( A_{n+1} \subset B_n \subset A_n \). Let \( C_n = A_n - B_n \), \( C = \cup C_n \), then \( f(C_n) = C_{n+1} \), so \( f(C) = \cup_{i \geq 0} C_i \).

Now define \( g : A \to B = f(x) \) on \( C \) and \( x \) on \( A - C \), then it is a bijection from \( A \) to \( B \).

Definition (1.1.2.3) [Cardinal Numbers]. A cardinal number is an equivalence class of sets, where equivalence is given by bijections. It is used to describe the ‘size’ of a set.

It is by the axiom of choice that any two cardinal number can be compared.

The cardinal number of \( \mathbb{N} \) is denoted by \( \aleph_0 \).

Countable and Uncountable Sets

Definition (1.1.2.4) [Countable Sets]. A set is called countable iff it has the cardinality of \( \aleph_0 \) (1.1.2.3).

It is called finite if it has the cardinality of \( n \) for some natural number \( n \). It is called uncountable iff it is not countable or finite.

Proposition (1.1.2.5). The subset or image of an at most countable set is at most countable.

Proof:

Proposition (1.1.2.6). The product of two countable sets is countable. (Use diagonal enumerating).

Proof:

Proposition (1.1.2.7). A countable union of almost countable subsets is almost countable.

Proof: It suffices to prove the countable case, the rest follows from (1.1.2.5). For this, choose an enumerating \( a_n(k) \) for each \( A_n \), the \( \cup A_n \) is the image of \( \mathbb{N} \times \mathbb{N} : (n, k) \mapsto a_n(k) \). Then it is countable by (1.1.2.6).

Proposition (1.1.2.8). The set of finite sequences and hence the set of finite subsets of a countable set is countable.

Proof: The desired set equals \( \cup_k A^k \), which is countable by (1.1.2.6) and (1.1.2.7).

1.1. ZERMELO-FRAENKEL SET THEORY WITH CHOICE

Cardinal Arithmetics

Def. (1.1.2.9). The sum, multiplication and exponentiation of two ordinal is the cardinality of the set $A \bigcup B$, $A \times B$ or $A^B$ respectively.

It is easily verified to be associative and commutative, just as usual operations.

Prop. (1.1.2.10). $\aleph_0 \times \aleph_0 = \aleph_0$ by (1.1.2.6). And $\kappa \times \kappa = \kappa$ for any infinite cardinal, if one uses the axiom of choice by (1.1.5.3).

Prop. (1.1.2.11). The image of a set $X$ has cardinals no more than $X$, if axiom of choice holds.

Proof: Use axiom of choice to choose an element from each inverse image $f^{-1}(\{x\})$, then it is an injection from $f(X)$ to $X$.

Prop. (1.1.2.12)[Cantor]. $\# P(X) = 2^{\# X}$, and $|X| < |P(X)|$.

Proof: The first is obvious, for the second, the function $x \rightarrow \{x\}$ is an injection of $X$ into $P(X)$. And there are no mapping from $X$ onto $P(X)$, because if $f$ is one, the consider $S = \{x \mid x \notin f(x)\}$, then $S$ is not in the range of $f$, because if $f(z) = S$, then $z \in S$ iff $z \notin S$, contradiction.

Prop. (1.1.2.13)[Cardinality Arithmetic of $\aleph_0$]. For cardinality arithmetics involving $\aleph_0$, Cf.[Set Theory Jech P98].

Prop. (1.1.2.14). if $|B| = 2^{\aleph_0}$ and $|A| \leq \aleph_0$, then $|B - A| = 2^{\aleph_0}$. In fact, $|B - A| = |B|$ for any $|A| < |B|$, if one uses the axiom of choice.

Proof: By (1.1.2.13), we can assume $B = \mathbb{R} \times \mathbb{R}$, then project $A$ onto the coordinate axis, then $\pi(A)$ has cardinality $\leq \aleph_0$, so there is a $x_0 \notin \pi(A)$, so $x_0 \times \mathbb{R} \subset B - A$, so $|B - A| = 2^{\mathbb{R}}$.

For the general case, ?

Conj. (1.1.2.15)[The Continuum Hypothesis]. There is no cardinal $\kappa$ that $\aleph_0 < \kappa < 2^{\aleph_0}$.

Notice $2^{\aleph_0} \geq \aleph_1$ by Cantor’s theorem (1.1.2.12), and this hypothesis is equivalent to $2^{\aleph_0} = \aleph_1$.

3 Orderings

Def. (1.1.3.1)[Ordering]. A partial ordering on a set $A$ is a relation $<$ on $A$, or equivalently a subset $C \subset A \times A$ that

- For no $x \in A$, $x < x$ holds.
- If $x < y$ and $y < z$, then $x < z$.

It is called a total ordering if moreover it satisfies

- For every $x, y \in A$ that $x \neq y$, either $x < y$ or $y < x$.

A poset is just a partially ordered set.

Def. (1.1.3.2)[Reverse Ordering]. The reverse ordering $A^{op}$ of an ordered set $A$ is the same set $A$ with the ordering reversed.

Def. (1.1.3.3)[Cofinality]. The cofinality of or a poset (i.e partially ordered set) $\alpha$ is the is the smallest cardinality $\delta$ of a cofinal subset of $\alpha$. 
Def. (1.1.3.4) [\(\kappa\)-Filtered Poset]. For a cardinal \(\kappa\), a poset is called \(\kappa\)-filtered if for any subset unbounded from above has cardinality \(\geq \kappa\).

Def. (1.1.3.5) [Directed Set]. A directed set is a poset that 3-filtered and non-empty.

Def. (1.1.3.6). In a poset \(P\), two elements \(p, q\) are called compatible if there is an \(r \in P\) that \(r < p, r < q\).

Def. (1.1.3.7) [\(\kappa\)-Chain Condition]. For a cardinal \(\kappa\), a poset \(P\) is said to satisfy the \(\kappa\)-chain condition if for any subset \(A \subset P\) that elements of \(A\) are pairwise incompatible (1.1.3.6), then \(|A| \leq \kappa\).

Total Ordering

Def. (1.1.3.8) [Well-Ordering]. A linear ordering is just a total ordering. A linear ordering is called a well-ordering if every nonempty subset has a minimal element.

Def. (1.1.3.9) [Lexicographical Ordering]. If given a family of linearly ordered set \(A_i\) indexed by a well-ordered set \(I\), then there is a linear ordering on \(\prod_I A_i\), where \((f_i) < (g_i)\) iff \((f_i) \neq (g_i)\) and for the minimal \(i_0\) (well-ordering used) that \(f_{i_0} \neq g_{i_0}, f_{i_0} < g_{i_0}\). It is called the lexicographical ordering.

Def. (1.1.3.10). An ordered set \(X\) is called dense iff for each \(a < b\), there is a \(x\) that \(a < x < b\).

Def. (1.1.3.11) [Least Upper Bound]. An ordered set \(A\) is said to have the least upper bound property if any subset \(A_0 \subset A\) bounded above has a least upper bound. It is said to satisfy the greatest lower bound property if \(A^{op}\) satisfies the least upper bound property.

Prop. (1.1.3.12) [Cantor]. Any two ordered set that is countable, dense and has no endpoints are isomorphic. In particular, any of these is isomorphic to the set of rational numbers \(\mathbb{Q}\).

Proof: We will built the isomorphism by extending partial embeddings. Let \(a_0, \ldots, a_n, \ldots\) be an ordering of \(A\), \(b_0, \ldots, b_n, \ldots\) be an ordering of \(B\), and we can alternatively extend mapping on \(a_n\) and \(b_n\), as \(A, B\) are complete without endpoints. Then we get an isomorphism of \(A\) and \(B\). \(\square\)

Cor. (1.1.3.13). Any countable linearly ordered set can be mapped isomorphically into \(\mathbb{Q}\).

Def. (1.1.3.14). A initial segment of an ordered set \(W\) is the ordered set \(W[a] = \{ x \in W \mid x < a \}\).

Lemma (1.1.3.15). If \(W\) is a well-ordered set, then any increasing function \(f : W \to W\) satisfies \(f(x) \geq x\).

Proof: If the set \(\{ x \mid f(x) < x \}\) is not empty, then it has a minimal element \(a\), then \(f(f(a)) < f(a)\), contradiction. \(\square\)

Cor. (1.1.3.16). A well-ordered set cannot be isomorphic to an initial segment of itself, and an automorphism of a well-ordered set must be identity.

Proof: Use the above lemma (1.1.3.15), if it is isomorphic to \(W[a]\), then \(f(a) < a\), contradiction. For any automorphism, \(f(x) \geq x, f^-(x) \geq x\), so \(f(x) = x\). \(\square\)
Prop.(1.1.3.17) [Comparison of Well-Orderings]. A cut of a well-ordered set is well-ordered. And for any two well-ordered sets $W_1, W_2$, either they are isomorphic, or one of them is isomorphic to a initial segment of another.

Proof: The three cases are mutually exclusive by (1.1.3.16), so it suffices to show one of them holds.

Define a set $f = \{(x, y) \in W \times W | W_1[x] \cong W_2[y]\}$. (1.1.3.16) shows $f$ is injective and monotone in both coordinates. Now we want to prove that if the domain of $f$ is not all $W_1$, then it is an initial segment, and the image is all $W_2$, this will finish the proof.

It is clearly an initial segment $W_1[a]$ because it is well-ordered and if $h : W_1[x] \cong W_2[y]$ and $x' < x$, then $h : W_1[x'] \cong W_2[h(y)]$. If the image is not all of $W_2$, then similarly the image of $f$ is an initial segment of $W_2$, $= W_2[b]$. But this means $W_1[a] \cong W_2[b]$, so $a, b$ is also in the domain(image), which is a contradiction. \qed

Complete Linear Ordering

Def.(1.1.3.18) [Complete Ordering]. A cut of an ordered set $X$ consists of two disjoint nonempty subsets $A \cup B = X$ that $a < b$ for any $a \in A, b \in B$.

It is called a Dedekind cut if $A$ doesn’t have a maximal element. It is called a gap if $A$ doesn’t have a maximal element and $B$ doesn’t have a minimal element.

An ordered set is called complete if there are no gaps.

Prop.(1.1.3.19). A complete ordered set has the least upper bound property and greatest lower bound property.

Proof: Consider the cut $A = \{x | x < a$ for some element in $T\}, B = R - A$, if $T$ is bounded above, $B$ is not empty, so this is truly a cut, and $A$ doesn’t have a maximal element, because if $x < a \in R$, then $x < \frac{x + a}{2} < a$. So by completeness of $R$, $B$ has a minimal element, that is, the supremum of $A$ exists. Similarly for the case $A$ bounded from below. \qed

Prop.(1.1.3.20) [Completion of Ordering]. There is an obvious ordering on the set $C$ of all Dedekind cuts of $X$, and $X$ embeds into $C$ by $b \mapsto \{x | x < b\} \cup \{x | x \geq b\}$.

$C$ is complete and has no endpoints, $P$ is dense in $C$, which is called a completion of $P$.

Proof: Cf.[Set Theory Jech P88]. \qed

Prop.(1.1.3.21) [Real Numbers]. $Q$ has a unique completion ordering $R$, called the set of real numbers. $R$ is not countable.

Proof: $R$ is a dense linear ordering without endpoints, so by (1.1.3.12) if it is countable then it is isomorphic to $Q$, but this is not possible because $Q$ is not complete. \qed

Prop.(1.1.3.22). $|P(\mathbb{N})| = |2^\mathbb{N}| = |R|$, which is denoted by $2^{\aleph_0}$. By(1.1.3.21), $\aleph_0 < 2^{\aleph_0}$.

Proof: The first equality is by (1.1.2.12). Now by the construction of $R$, it can be embedded into $P(\mathbb{N})$, so $|R| \leq |P(Q)| = |P(\mathbb{N})|$. Conversely, $|2^\mathbb{N}| \leq |R|$ by decimal representation, so they are equal by Bernstein(1.1.2.1). \qed
4 Ordinals

Def. (1.1.4.1)[Ordinal Numbers]. A set is called transitive iff each element of $T$ is a subset of $T$. A set $\alpha$ is called a ordinal number iff $\alpha$ is transitive and well-ordered by inclusion.

Prop. (1.1.4.2). If $\alpha$ is an ordinal, then $S(\alpha) = \alpha \cup \{\alpha\}$ is also an ordinal, obviously. Thus any natural number is an ordinal by definition.

An ordinal is called a successor ordinal iff $\alpha = S(\beta)$ for some $\beta$, and a limit ordinal otherwise.

Lemma (1.1.4.3).
1. If $\alpha$ is an ordinal, then $\alpha \notin \alpha$.
2. Every element of an ordinal is an ordinal.
3. If ordinals $\alpha \subseteq \beta$, then $\alpha \in \beta$. That is, for ordinals, $\subseteq$ is the same as $\in$.

Proof:  
1. If $\alpha \in \alpha$, then contradiction to the fact $\in$ is a ordering (1.1.4.1).
2. To show $x \in \alpha$ is transitive, it suffices to show that if $u \in v \in x$, then $u \in x$, because then $v$ is a subset of $x$. But this follows from the fact $\in$ is an ordering. And because $x \subseteq \alpha$, the inclusion of $x$ is the restriction of inclusion in $\alpha$, so it is a well-ordering.
3. Consider $\beta - \alpha$, it has a minimal element $\gamma$. Notice $\gamma \subseteq \alpha$, because otherwise there is an element of $\beta - \alpha$ smaller than $\gamma$, by definition (1.1.4.1).

Now we show $\gamma = \alpha$, then it will follow that $\alpha \in \beta$. For this, if $\delta \in \alpha$ and $\delta \notin \gamma$, then $\gamma \in \delta$ or $\gamma = \delta$. But then this implies that $\delta \in \alpha$ because $\alpha$ is an ordinal, contradicting the fact $\gamma \in \beta - \alpha$.

Prop. (1.1.4.4)[Ordinal is Well-Ordered]. Define the ordering of ordinal by $\alpha < \beta$ iff $\alpha \in \beta$. The ordering of ordinals is a total ordering and is a well-ordering.

Proof: If $\alpha \beta \in \gamma$, then $\alpha \in \gamma$ because $\gamma$ is transitive. If $\alpha \in \beta \in \alpha$, then $\alpha \in \alpha$, contradicting (1.1.4.3).

Given any two ordinals, $\alpha \cap \beta$ is also an ordinal by definition. If $\alpha \cap \beta = \beta$ or $\alpha$, then $\alpha \subseteq \beta$, hence $\alpha \in \beta$ by (1.1.4.3). If $\alpha \cap \beta \subseteq \alpha$ and $\alpha \cap \beta \subseteq \beta$, then $\alpha \cap \beta \subseteq \alpha \cap \beta$, contradiction.

Well-ordering: Given a set of ordinals, take $\alpha \in A$ and consider the set $\alpha \cap A$. If $\alpha \cap A = \emptyset$, then $\alpha$ is minimal in $A$, because otherwise some $\beta \in \alpha \cap A$. If $\alpha \cap A \neq \emptyset$, then it has a minimal element $\beta$ in the inclusion because $\alpha$ is an ordinal. Then $\beta$ is the minimal element of $A$.

Cor. (1.1.4.5)[Supremum Ordinal]. Any set of ordinals has a supremum ordinal, it is just $\cup_{\alpha \in X} \alpha$.

Proof: Firstly $\cup_{\alpha \in X} \alpha$ is transitive and it is well-ordered (for each subset $A \subset X$, choose an $\alpha \in X$ that $\alpha \cap A \neq 0$, then the minimal element of $\alpha \cap A$ is just the minimal element of $A$.) so it is an ordinal.

Now if $\alpha \in X$, then $\alpha \subset \cup X$, so $\alpha \leq \cup X$ by (1.1.4.3). And if $\alpha \in \gamma$ for some ordinal $\gamma$, then $\cup X \subseteq \gamma$. So $\cup X$ is truly the supremum.

Cor. (1.1.4.6). For any set $X$ of ordinals, there is an ordinal $\alpha$ that is not in $X$, just choose $S(\cup X)$.

Axiom (1.1.4.7)[Axiom Scheme of Replacement]. Let $P(x, y)$ be a property that for each $x$ there exists uniquely a $y$ that $P(x, y)$, then for each set $A$ there is a set $B$ that for each $x \in A$ there is an element $y \in B$ that $P(x, y)$. 

Prop. (1.1.4.8). Every well-ordered set is isomorphic to a unique ordinal. So we can regard an ordinal as an equivalence class of isomorphic well-ordered sets.

Proof: Cf. [Set Theory Jech P111]. □

Cor. (1.1.4.9) [Cardinal as Initial Ordinal]. The axiom of choice together with (1.1.4.4) asserts that every cardinal has a unique smallest ordinal, called the initial ordinal. So we can identify cardinal number $\alpha$ as an ordinal that is the initial ordinal $\omega_\alpha$ of $\alpha$. Anyway, cardinal number is fewer than ordinal numbers.

The first infinite cardinal number (or the first initial ordinal) is denoted by $\omega$ or $\aleph_0$.

Prop. (1.1.4.10) [Transfinite Induction/Recursion]. If a property defined for the set of ordinals satisfies:

1. $P(0)$.
2. $P(\alpha + 1)$ if $P(\alpha)$.
3. $P(\lambda)$ if $P(\beta)$ for all $\beta < \lambda$.
then $P$ is true for all ordinals.

Transfinite recursion:

Proof: □

Ordinal Arithmetic

Cf. [Set Theory Jech Chap5.5].

Def. (1.1.4.11). We use infinite recursion to define addition of ordinals as

- $\beta + 0 = \beta$
- $\beta + (\alpha + 1) = (\beta + \alpha) + 1$, where $\alpha + 1$ is the successor of $\alpha$.
- $\beta + \alpha = \sup\{\beta + \gamma | \gamma < \alpha\}$ for a limit ordinal $\alpha$.

The multiplication of ordinals and exponentiation of ordinals are defined similarly.

Remark (1.1.4.12) [Cardinal and Ordinal Arithmetics]. Note that the ordinal arithmetics may be smaller than the ordinal sum of the corresponding initial ordinal (1.1.4.9), because operations of initial ordinals may not be initial, the deeper reason is that the cardinal case, we can rearrange the order to get a smaller ordinal.

Prop. (1.1.4.13). The addition and multiplication of ordinals are of the order type of $\alpha \uplus \beta$ in adjunction order and $\alpha \times \beta$ in lexicographical order respectively, Cf. [Set Theory Jech P120,122]

Cantor Normal Form

Prop. (1.1.4.14) [Cantor Normal Form]. Any ordinal $\alpha$ can be expressed uniquely as the form $\alpha = \sum_{i<n} \omega^{\beta_i}$, where $\beta_0 \geq \beta_1 \geq \ldots \beta_{n-1}$ are ordinals.

Proof: Cf. [Jech Set Theory P124]. □

Prop. (1.1.4.15) [Goodstein Sequence]. The weak Goodstein sequence is a sequence that $m_2$ is any positive integer, $m_{k+1}$ is $m_k$ written in $k$-basis and replacing the base by $k + 1$, and then minus 1.
The Goodstein sequence is a sequence that \( m_2 \) is any positive integer, \( m_{k+1} = m_k \) written in \( k \)-basis and even the exponents in \( k \)-basis and and replacing the base by \( k+1 \), and then minus 1.

Then for each Goodstein sequence and weak Goodstein sequence, it reaches 1 in a finite number of times.

**Proof:** Let \( m_k = \sum k^{a_i}b_i \), then let the ordinal \( \alpha_k = \sum \omega^{a_i}b_i \). Then it is clear that \( \alpha_2 > \alpha_3 > \ldots \). But if the weak Goodstein sequence doesn’t terminate, we constructed a descending sequence of ordinals that doesn’t terminate, contradiction (choose a minimal element).

Similarly for Goodstein sequences, just replace every base \( k \) by \( \omega \).

\[ \square \]

5 Alephs

**Prop. (1.1.5.1).** For any set \( A \), there is a least ordinal that is not equipotent to any subset of \( A \), called the Hartogs number of \( A \). This is clearly an initial ordinal.

**Proof:** By axiom schema of replacement, any well-ordered subsets of \( A \) is equipotent to an ordinal, and also by axiom schema of replacement, there is a set \( H \) that for any well-ordering of subsets of \( A \) in \( P(A \times A) \), this ordered sets is equipotent to a \( \alpha \in H \). Then use (1.1.4.6) to find a minimal ordinal that is not equipotent to any subset of \( A \). In fact, this is just \( h(A) = \{ \alpha \in H | \alpha \) equipotent to some subset of \( A \} \).

\[ \square \]

**Def. (1.1.5.2) [Aleph].** The alephs for ordinal numbers are defined recursively: \( \aleph_0 = \omega \), \( \aleph_{\alpha+1} = h(\aleph_\alpha) \), and \( \aleph_\alpha = \sup \{ \aleph_\beta | \beta < \alpha \} \) for a limit ordinal \( \alpha \). By definition \( \alpha_\alpha < \aleph_\beta \) when \( \alpha < \beta \).

Then \( \aleph_\alpha \) are all infinite initial ordinal numbers, and any infinite ordinal number is of the form \( \aleph_\alpha \) for some ordinal \( \alpha \). So natural numbers together with alephs are just all the cardinal numbers.

Notice: to avoid confusion, when do arithmetic of ordinal numbers, \( \aleph_\alpha \) is written as \( \omega^{\aleph_\alpha} \).

**Proof:** Use transfinite induction on \( \alpha \). The only nontrivial case is when \( \alpha \) is a limit ordinal, where if \( \gamma < \aleph_\alpha \) and \( |\gamma| = |\aleph_\alpha| \), then there is a \( \beta < \alpha \) that \( \gamma \leq \aleph_\beta \) by definition, so \( |\aleph_\alpha| < |\gamma| \leq |\aleph_\beta| < |\aleph_\alpha| \) as \( \aleph_\beta \) is an initial ordinal.

To prove that any infinite initial ordinal is an aleph, first notice that \( \alpha < \aleph_\alpha \) by a simple transfinite induction. So we may use transfinite induction on the following assertion for \( \alpha \): if \( \Omega < \aleph_\alpha \), then there is a \( \gamma < \alpha \) that \( \Omega = \aleph_\gamma \). For this, \( \alpha = 0 \) is trivially true, if \( \alpha = \beta + 1 \), then \( \Omega < h(\aleph_\alpha) \) implies that \( |\Omega| < |\aleph_\alpha| \) by definition. Because \( \Omega \) is initial, \( \Omega = \aleph_\beta \) or \( \Omega < \aleph_\beta \), so by induction hypothesis it is true. If \( \alpha \) is a limit ordinal, then \( \Omega < \omega_\beta \) for some \( \beta < \alpha \), so also by induction hypothesis it is true.

\[ \square \]

**Aleph Arithmetics**

**Prop. (1.1.5.3).** \( \aleph_\alpha \cdot \aleph_\alpha = \aleph_\alpha \).

**Proof:** Cf. [Set Theory Jech P134].

\[ \square \]

**Cor. (1.1.5.4).** \( \aleph_\alpha \cdot \aleph_\beta = \aleph_\beta \) for \( \alpha \leq \beta \), and \( n \cdot \aleph_\beta = \aleph_\beta \).

So \( \aleph_\alpha + \aleph_\beta = \aleph_\beta \) for \( \alpha \leq \beta \), and \( n + \aleph_\beta = \aleph_\beta \).
6 Natural Numbers and Real Numbers

Prop.(1.1.6.1). \((\mathbb{N}, <)(1.1.1.15)\) is a well-ordered set.

Proof: □

Example(1.1.6.2)[Examples of Countable Sets].

- \(\mathbb{Z}\).
- \(\mathbb{Q}\).

Arithmetic of Real numbers

Prop.(1.1.6.3). The set of real numbers \(\mathbb{R}(1.1.3.21)\) can be endowed with a field structure, making it an ordered field.

Proof: Cf.[Set Theory Jech P175]. □

Prop.(1.1.6.4). \(\mathbb{R}\) satisfies the least upper bound hypothesis.

Proof: □

7 The Axiom of Choice

Def.(1.1.7.1). Let \(S\) be a system of sets, a function \(g\) defined on \(S\) is called a choice function iff \(g(X) \in X\) for each \(X \in S\).

Prop.(1.1.7.2)[Zermelo]. The following are equivalent:
1. (the axiom of choice)There exists a choice function for very system of sets.
2. (the well-ordering principle)Every set can be well-ordered.
3. (Zorn’s lemma)If every chain in a partially ordered sets has a upper bound, then the partially ordered set has a maximal element.

Proof: 2 → 1: If \(A\) is well-ordered, then \(P(A)\) clearly has a choice function, that is the minimal element of a set.
1 → 2: Use transfinite recursion, Cf.[Set Theory Jech P137].
2 → 3, 3 → 2: Cf.[Set Theory Jech P142]. □

Axiom(1.1.7.3)[the Axiom of Choice]. Any system of sets has a choice function.

Prop.(1.1.7.4). Every infinite set \(X\) has a countable subset, if the axiom of choice holds.

Proof: Choose a well-ordering of it(1.1.7.2), then it is an infinite ordinal. Then the initial segment of the first ordinal \(X[\omega]\) is a countable subset. □

Prop.(1.1.7.5). For every infinite set \(S\), there exists a unique aleph \(\aleph_\alpha\) that \(|S| = \aleph_\alpha\).

Proof: choose a well-ordering of \(S(1.1.7.2)\), then it is an infinite ordinal, and it has the same cardinality as an initial cardinal by(1.1.4.9), thus the result. □

Cor.(1.1.7.6). For any sets \(A\) and \(B\), either \(|A| \leq |B|\) or \(|B| \leq |A|\).

Proof: Because the ordinal is totally ordered(1.1.4.4). □
8 Filters and Ultrafilters

Def.(1.1.8.1)[Filter]. For a poset $P$, a filter on $P$ is a subset $F$ that
- If $p < q$ and $p \in F$, then $q \in F$.
- If $p, q \in F$, then there is an $r \in F$ that $r < p, r < q$.

Def.(1.1.8.2)[Filter on Sets]. Let $S$ be a non-empty set, a filter on $S$ is a filter $F$ on $\mathcal{P}(S)$ that
- $\emptyset \notin F$.

Def.(1.1.8.3)[Finite intersection property]. A family of subsets of a set is said to have the finite intersection property if any finite collection of elements of this family is non-empty.

Lemma(1.1.8.4). Let $G$ be a collection of subsets of $S$ that has the finite intersection property, then there is a smallest filter $F$ that $G \subset F$. It is just the collection of subsets of $S$ that contain some finite intersection set of elements of $G$.

Def.(1.1.8.5)[Ultrafilter]. An ultrafilter is a filter $F$ that for every subset $X$, $X \in F$ iff $S - X \notin F$. A prime ideal is an ideal that for every subset $X$, $X \in F$ iff $S - X \notin F$.

A ultrafilter is equivalent to a maximal filter. And it is equivalent to a $\{0, 1\}$-valued finitely additive measure on $S$.

Proof: If $F$ is an ultrafilter, then it is maximal, because any larger filter will have some $X, S - X$, thus has $\emptyset$, contradiction.

Conversely, if $F$ is maximal filter but not ultra, then there is a $X$ that $X \notin F, S - X \notin F$. Let $G = F \cup \{X\}$, then any finite intersection of elements of $G$ is not empty: $X_1 \cap \ldots \cap X_n \cap X \neq 0$ otherwise $S - X \in F$. So there is a filter containing $G$ by(1.1.8.4), contradiction. \qed

Prop.(1.1.8.6) [Pushforward of Filters]. If $\mathcal{F}$ is a (ultra)filter on $X$ and $f : X \to Y$ is a function, then $f_*(\mathcal{F}) = \{A \subset Y | f^{-1}(A) \in \mathcal{F}\}$ is a (ultra)filter on $X$, called the pushforward filter of $\mathcal{F}$.

Prop.(1.1.8.7). For an ultrafilter $\mathcal{F}$ on $X$, if $U_i \notin \mathcal{F}$, then $\sum_{i=1}^{n} U_i \notin \mathcal{F}$.

Proof: As $X - U_i \in \mathcal{F}$, there intersection are in $\mathcal{F}$, so its complement is not in $\mathcal{F}$. \qed

Prop.(1.1.8.8). Any filter can be extended to an ultrafilter(maximal filter), if the axiom of choice is used.

Proof: Use Zorn’s lemma(1.1.7.2). It suffices to prove that a union of a chain of filters is a filter, which is trivial. \qed

Cor.(1.1.8.9). Non-principal ultrafilter exists on any infinite set. And in fact, any non-principal ultrafilter contains all the cofinite sets.

For any non-principle ultrafilter, it cannot contains a single pt $\{x\}$, so it contains every cofinite set.
1.1. ZERMELO-FRAENKEL SET THEORY WITH CHOICE

Proof: Consider any ultrafilter containing the filter of cofinite sets of $S$, then it is non-principal. □

Def. (1.1.8.10) [$\kappa$-Completeness]. Let $\kappa$ be an uncountable cardinal, then a field $F$ on a set $S$ is called $\kappa$-complete if for every cardinal $\lambda < \kappa$, if $X_\alpha \in F$ for every $\alpha < \lambda$, then $\cap_{\alpha < \lambda} X_\alpha \in F$.

An $\aleph_1$-complete filter is also called a $\sigma$-complete filter.

Closed unbounded and Stationary Set

Silver’s Theorem

9 Combinatorial Set Theory

Def. (1.1.9.1) [Notations]. For a set $S$, let $[S]^r$ be the set of subsets of $S$ of order $r$. Let $\kappa, \lambda$ be cardinals, we write $\kappa \rightarrow (\lambda)^r_s$ as a shorthand for: for any set $S$ with $|S| = \kappa$ and every partition of $[S]^r$ into $s$ classes, there exists a subset $H \subset S$ that $[H]^r$ is in the same class, and $|H| \geq \lambda$.

Prop. (1.1.9.2) [Ramsey’s Theorem]. For any positive natural number $r, s$ if we color the $r$-subsets of a set with cardinality $\aleph_0$ into $s$ families, then there is a subset of cardinal $\aleph_0$ that all its $r$-subsets are colored the same.

Cor. (1.1.9.3). Every infinite linearly ordered set contains a subset isomorphic to $(\mathbb{N}, <)$ or $(\mathbb{N}, >)$.

Proof: Choose a well ordering of it. Then consider this new ordering and the original ordering. Then there is an infinite set that is compatible with the original ordering, or converse. Then its initial segment of order type $\omega_0$ satisfies the requirement. □

Def. (1.1.9.4) [Weakly Compact Cardinals]. An weakly compact cardinal is an uncountable cardinal $\kappa$ that $\kappa \rightarrow (\kappa)^r_s$ for any $r, s \in \mathbb{Z}_+$.

Prop. (1.1.9.5). Weakly compact cardinals are strongly inaccessible.

Trees

Def. (1.1.9.6). A tree is a partial ordered set $T$ that there is a minimal element $r$ and for each $x$, \{y \in T | y < x\} is finite and linearly ordered.

A tree is called of finite branched for each $x$, there is a finite set \{y_1, \ldots, y_r\} is $T$ that $y_i > x$ and if $z > x$, then $z \geq y_i$ for some $i$.

Def. (1.1.9.7) [Height]. For any node $x$, \{y \in T | y < x\} is a well-ordered set, which is isomorphic to an ordinal by (1.1.4.8), it is called the height of $x$. $T_\alpha$ denotes the set of all nodes of $T$ of order $\alpha$. The least $\alpha$ that $T_\alpha \neq \emptyset$ is called the height of $T$.

A branch is a maximal chain in $T$, its length is its ordinal. The length is always smaller than the height of the tree. If it equals the height of the tree, it is called cofinal.

Def. (1.1.9.8). A subtree is a subset $T'$ of $T$ that if $x \in T'$, $y < x$, then $x \in T'$.

An antichain of a tree $T$ is a subset $A \subset T$ that any two elements in $A$ are incomparable.

Def. (1.1.9.9). A path through $T$ is a morphism of ordering from $\omega$ to $T$. 

Lemma (1.1.9.10) [König’s Lemma]. If $T$ is an infinite finite branching tree, then there is a path through $T$.

Proof: Use recursion to choose for each $n$ an element that has infinite successors. □

Def. (1.1.9.11). An Aronszajn tree is a tree of height $\kappa$ and all its level sets are at most countable, but has no branches of length $\kappa$.

Prop. (1.1.9.12). An Aronszajn tree of height $\omega_1$ exists.

Proof: Cf. [Set Theory Jech P228]. □

10 The Axiom of Foundation

11 Large Cardinals

Def. (1.1.11.1) [Abstract Measures]. Let $S$ be a non-empty set, then an abstract measure on $S$ is a non-trivial probabilistic measure $\mu$ on the measurable space $(S, \mathcal{P}(S))$ that $\mu(\{a\}) = 0$ for any $a \in S$.

Def. (1.1.11.2) [Regular Cardinal]. A cardinal is called regular if it is not a sum of $\lambda$ cardinals $\kappa_i$ that $\lambda < \kappa$ and $\kappa_i < \kappa$.

Def. (1.1.11.3) [Strong Limit]. A cardinal $\kappa$ is called a strong limit if $2^\lambda < \kappa$ for any $\lambda < \kappa$.

Def. (1.1.11.4) [Strongly Inaccessible Cardinal]. A cardinal $\kappa$ is called strongly inaccessible (SI) if it is regular (1.1.11.2) and is a strongly limit.

Def. (1.1.11.5) [Weakly Inaccessible Cardinal]. A cardinal $\kappa$ is called weakly inaccessible if it is regular and is a limit cardinal.

Prop. (1.1.11.6) [Measure and CH]. If there exists an abstract measure on $2^{\aleph_0}$, then the Continuum Hypothesis fails.

Prop. (1.1.11.7). If there is a measure on a set $S$, then some cardinal $\kappa \leq |S|$ is weakly inaccessible.

Prop. (1.1.11.8). Let $\mu$ be a $\{0, 1\}$-valued measure on $S$, then $U = \{X \subseteq S|\mu(X) = 1\}$ is a non-principal $\sigma$-complete ultrafilter of $S$

Prop. (1.1.11.9) [Stanislaw-Ulam Dichotomy]. If there exists a measure on some set, then either there exists a $\{0, 1\}$-valued measure on some set, or there exists a measure on $2^{\aleph_0}$.

Def. (1.1.11.10) [Measurable Cardinals]. A measurable cardinal is an uncountable cardinal $\kappa$ on which there exists a non-principal $\kappa$-complete ultrafilter.

Prop. (1.1.11.11). A measurable cardinal is strongly inaccessible.

Def. (1.1.11.12) [Small Categories]. Given a regular cardinal $\kappa$, a set $S$ is called $\kappa$-small if it has cardinality smaller than $\kappa$. A category $\mathcal{C}$ is called $\kappa$-small if the set of all objects of $\mathcal{C}$ is $\kappa$-small, and the set of all morphisms of $\mathcal{C}$ is $\kappa$-small.

Throughout the whole book, we will fix a strongly inaccessible cardinal $\kappa$ and call a set or category small if it is $\kappa$-small. And a category is called essentially small if it is equivalent to a small category.

12 Forcing Construction of Cohn

Def. (1.1.12.1) [Dense Subset]. In a poset $P$, a subset $D \subseteq P$ is called dense if for any $p \in P$, there is a $q \in D$ that $q < p$. If $\mathcal{D}$ is a collection of dense subsets of $P$, a filter $G \subseteq P$ is called $\mathcal{D}$-generic if $D \cap G \neq \emptyset$ for all $D \subset \mathcal{D}$.

Prop. (1.1.12.2). If $\mathcal{D}$ is a countable collection of dense subsets of $P$, then there is a $\mathcal{D}$-generic filter $G$.

Proof: Let $\mathcal{D} = \{D_1, \ldots, D_n, \ldots\}$. Choose $p_0 \in P$, and consecutively choose $p_n \leq p_{n-1}$ that $p_n \in D_n$, and define $G = \{q | q \geq p_n$ for some $n\}$. □

Axiom (1.1.12.3) [Martin’s Axiom]. If $P$ is a partially ordered set satisfying the countable chain condition (1.1.3.7), and $D$ is a collection of dense subsets of $P$ with $|D| < 2^{\aleph_0}$, then there is a $D$-generic filter on $P$. 
1.2 Model Theory

Basic references are [Model Theory Marker] and [Mathematical Logics Hamilton]. The exercises of [Model Theory Marker] is important.

1 Mathematical Logics

Turing Machine and Computability

Prop.(1.2.1.1) [Turing Machine]. For the ring structure of \( \mathbb{N} \), there is a \( \mathcal{L} \)-formula \( \varphi(e, x, s) \) that \( \mathbb{N} \models T(e, x, s) \) iff the Turing machine coded with \( e \) halts on input \( x \) within \( s \) steps. So the set of halting computation is definable by the formula: \( \exists s \varphi(e, x, s) \).

Proof: Cf.[Models of Peano Arithmetic Kaye]. □

Def.(1.2.1.2) [Recursively Enumerable Sets]. A set \( S \) of the natural numbers is called recursively enumerable iff there is an algorithm that the set of input numbers that halts is exactly \( S \). Equivalently, a recursively enumerable set is a set that there is an algorithm that 'enumerates' the members of \( S \).

Prop.(1.2.1.3) [Hilbert’s 10-th Problem]. For any recursively enumerable set \( A \subset \mathbb{N}^n \), there is a polynomial \( P(X_1, \ldots, X_n, Y_1, \ldots, Y_m) \) that
\[
A = \{ \bar{x} \in \mathbb{N}^n : \mathbb{N} \models \exists y_1 \exists y_2 \ldots, \exists y_mp(x, \bar{y}) = 0 \}
\]

2 Structure and Theories

Basics

Def.(1.2.2.1) [Boolean Algebra]. A Boolean algebra is a set \( B \) with Boolean connectives \( \land, \lor, 0, 1 \), where:
- \( \land \) is a symmetric function \( B \times B \to B \) that \( \varphi \land \varphi = \varphi \);
- \( \lor \) is function \( B \to B \) that \( \neg \circ \lor = \text{id} \);
- 0,1 are nullary operations that \( \neg 0 = 1, \text{and} \ x \land 0 = 0, \text{and} \ x \land \neg x = 0 \).
Sometimes \( \lor \) is also used, which is defined as \( \varphi \lor \psi = \neg(\neg \varphi \land \neg \psi) \).

Prop.(1.2.2.2). The power set of any set is a Boolean algebra with \( \land = \cap \) and \( \lor(A) = X - A \).
In fact, every Boolean algebra can be embedded as a subalgebra of a power set algebra of some set by(3.6.2.16).

Def.(1.2.2.3) [Languages and Structures]. A language \( \mathcal{L} \) is a set of symbols, where a symbol is indeterminants that are labeled constant symbol \( C \), function symbol (of finite arity) \( \mathcal{F} \) or relation symbol (of finite arity) \( \mathcal{R} \).
For a language \( \mathcal{L} \), a \( \mathcal{L} \)-structure on a set \( M \) is an assignment for each constant symbol \( c \) an element \( c^M \in M \), for each function symbol \( f \) of arity \( n \) a function \( f^M : M^n \to M \), and for each
relation symbol $R$ of arity $m$ a subset $R^M \subseteq M^m$. These $c^M, f^M, R^M$ are called interpretations of $\mathcal{L}$.

And there is a natural definition of morphisms of $\mathcal{L}$-structures, and an injective morphism of $\mathcal{L}$-structures is called an embedding or a structure extension.

**Def. (1.2.2.4) [Formulae].** For a language $\mathcal{L}$, the set of **terms** is the smallest set $\mathcal{T}$ that $c \in T$ for each constant symbol $c$, $x_i \in T$ for each variable symbol, and if $t_1, \ldots, t_n \in \mathcal{T}$ and $f \in \mathcal{F}$, then the symbol $f(t_1, \ldots, t_n) \in \mathcal{F}$.

An **atomic formula** is a symbol of the form $t_1 = t_2$ or $R(t_1, \ldots, t_n)$, where $t_i$ are terms.

The set of $\mathcal{L}$-**formulae** is the smallest set $\mathcal{W}$ that any atomic formula is in $\mathcal{W}$, and if $\varphi, \psi \in \mathcal{W}$, then $\neg \varphi, \varphi \land \psi$ are in $\mathcal{W}$, and adjunction with the **qualifier symbol** $\exists x_i \varphi$ is in $\mathcal{W}$.

A **free variable in a formula** is a $x_i$ that is not qualified with $\forall$ or $\exists$, otherwise it is called bound.

A **sentence** is a formula without free variables.

A **theory** is a set of sentences in a language $\mathcal{L}$.

**Remark (1.2.2.5) [Simplifications].** $\varphi \rightarrow \psi$ is the simplification of $\neg \varphi \lor \psi$, $\varphi \leftrightarrow \psi$ is the simplification of $(\varphi \rightarrow \psi) \land (\psi \rightarrow \varphi)$.

Even $\lor$ is the simplification of $\neg (\neg \varphi \land \psi)$, and $\forall x_i \varphi$ is the simplification of $\neg (\exists x_i \neg \varphi)$.

**Def. (1.2.2.6) [First Order Logic].** A **first order logic** is a $\mathcal{L}$-structure that only elements in $M$ are quantified with $\forall$ or $\exists$. For example, "Every bounded subsets has a least upper bound" cannot be expressed as a formulae in a first order logic of $\mathbb{R}$.

**Def. (1.2.2.7) [Truth].** Let $\varphi$ be a formula with free variables $\overline{v} = (v_1, \ldots, v_m)$, then we inductively define $\mathcal{M} \models \varphi(\overline{a})$ as follows:

- If $\varphi$ is $t_1 = t_2$ where $t_1, t_2$ are terms, then $\mathcal{M} \models \varphi(\overline{a})$ if $t_1^\mathcal{M}(\overline{a}) = t_2^\mathcal{M}(\overline{a})$.
- If $\varphi$ is $R(t_1, \ldots, t_n)$, then $\mathcal{M} \models \varphi(\overline{a})$ if $(t_1^\mathcal{M}(\overline{a}), \ldots, t_n^\mathcal{M}(\overline{a})) \in R^\mathcal{M}$.
- If $\varphi$ is $\neg \psi$, then $\mathcal{M} \models \varphi(\overline{a})$ if $\mathcal{M} \not\models \psi(\overline{a})$.
- If $\varphi$ is $\psi \land \theta$, then $\mathcal{M} \models \varphi(\overline{a})$ if $\mathcal{M} \models \psi(\overline{a})$ and $\mathcal{M} \models \theta(\overline{a})$.
- If $\varphi$ is $\exists v_j \psi(\overline{v}, v_j)$, then $\mathcal{M} \models \varphi(\overline{a})$ is there is a $b \in M$ that $\mathcal{M} \models \psi(\overline{a}, b)$, and we say $\mathcal{M}$ **satisfies** $\varphi(\overline{a})$. Notice if there is no free variables, $\varphi(\overline{a})$ just writes $\varphi$.

**Def. (1.2.2.8) [Models].** If $T$ is a theory and the $\mathcal{L}$-structure $M$ satisfies all $\varphi \in T$, then $M$ is called a **model** of $T$, and writes $M \models T$.

A theory $T$ is called **satisfiable** if there is a model $\mathcal{M}$ for $T$.

A set of $\mathcal{L}$-structures $\mathcal{K}$ is called an **elementary class** if there is an $\mathcal{L}$-theory $T$ that $\mathcal{K} = \{ \mathcal{M} \mid \mathcal{M} \models T \}$.

Given a $\mathcal{L}$-structure on $M$, the **theory of $M$** is the set of all sentences true in $M$.

Two $\mathcal{L}$-structures $\mathcal{M}$ and $\mathcal{N}$ are called **elementarily equivalent**, denoted by $\mathcal{M} \equiv \mathcal{N}$, if for all $\mathcal{L}$-sentences $\varphi$, $\mathcal{M} \models \varphi \iff \mathcal{N} \models \varphi$.

**Prop. (1.2.2.9) [Quantifier-Free Formulae].** Suppose $\mathcal{M}$ is a substructure of $\mathcal{N}$ and $\overline{a}$ is a tuple in $\mathcal{M}$. If $\varphi(\overline{a})$ is a quantifier-free formula, then $\mathcal{M} \models \varphi(\overline{a})$ iff $\mathcal{N} \models \varphi(\overline{a})$.

**Proof:** Cf. [Model Theory P11].

**Prop. (1.2.2.10).** If $\mathcal{L}$-structures $\mathcal{M} \cong \mathcal{N}$, then $\mathcal{M}$ is elementarily equivalent to $\mathcal{N}$. 

\[\square\]
Proof: This seemingly trivial proposition still needs proof, and the proof uses induction, just as that of (1.2.2.9).

Def. (1.2.2.11) [Logical Consequence]. Let \( T \) be an \( \mathcal{L} \)-theory and \( \varphi \) an \( \mathcal{L} \)-sentence, then \( \varphi \) is called a **logical consequence** of \( T \), writes \( T \models \varphi \), if for any \( \mathcal{L} \)-structure \( \mathcal{M} \) that \( \mathcal{M} \models T \), \( \mathcal{M} \models \varphi \).

**Definable Sets and Interpretability**

Def. (1.2.2.12). Let \( \mathcal{M} \) be an \( \mathcal{L} \)-structure, a subset \( X \) of \( \mathcal{M}^n \) is called **definable** iff there is an \( \mathcal{L} \)-formula \( \varphi(v_1, \ldots, v_n, w_1, \ldots, w_m) \) and a tuple \( \bar{b} \in \mathcal{M}^m \) that \( X = \{ \bar{a} \in \mathcal{M}^n : \mathcal{M} \models \varphi(\bar{a}, \bar{b}) \} \). Moreover if \( A \subset M \), \( X \) is called **\( A \)-definable** iff \( y_i \in A \).

Prop. (1.2.2.13) [Examples of Definable Sets]. The definability of some sets are often nontrivial, using many number theories. For example, Cf. [Marker P20].

Prop. (1.2.2.14). There is an inductive characterization of definable sets, Cf. [Marker P22].

Prop. (1.2.2.15). If \( \mathcal{M} \) is an \( \mathcal{L} \)-structure, If \( X \subset \mathcal{M}^n \) is \( A \)-definable, then very \( \mathcal{L} \)-automorphism of \( \mathcal{M} \) that fixes \( A \) pointwise will fixes \( X \) setwise.

Proof: For an automorphism \( \tau \) of \( \mathcal{M} \), \( \mathcal{M} \models \varphi(\bar{b}, \bar{a}) \) iff \( \mathcal{M} \models \varphi(\tau(\bar{b}), \tau(\bar{a})) = \varphi(\tau(\bar{b}), \bar{a}) \).

Cor. (1.2.2.16). \( \mathbb{R} \) is not definable in \( \mathbb{C} \).

Proof: If \( \mathbb{R} \) is definable, it is definable over a finite set \( A \subset \mathbb{C} \), Let \( r, s \) be algebraically independent over \( A \) and \( r \in \mathbb{R}, s \notin \mathbb{R} \). This can be done, otherwise \( \mathbb{C} \) or \( \mathbb{R} \) is finite transcendental over \( \mathbb{Q} \), then \( |\mathbb{C}| = |\mathbb{Q}|(2.2.6.3) \), which is impossible by (1.1.3.21). Then there is an automorphism \( \sigma \) of \( \mathbb{C} \) fixing \( A \) that \( \sigma(r) = s \), so \( \mathbb{R} \) is not definable by (1.2.2.15).

Def. (1.2.2.17) [Definably Interpretability]. An \( \mathcal{L}_0 \)-structure \( \mathcal{N} \) is called **definably interpreted** in an \( \mathcal{L} \)-structure \( \mathcal{M} \) if there is a definable set \( X \subset \mathcal{M}^n \) that we can interpret the symbols of \( \mathcal{L}_0 \) as definable subsets and functions of \( X \) and the resulting \( \mathcal{L}_0 \)-structure is isomorphic to \( \mathcal{N} \).

The usual example is that the group structure of \( GL_2(K) \) is definably interpreted in the ring structure of a field.

Def. (1.2.2.18) [Interpretability and Quotient Construction]. An \( \mathcal{L}_0 \)-structure \( \mathcal{N} \) is called **interpretable** in an \( \mathcal{L} \)-structure \( \mathcal{M} \) iff there is a definable set \( X \subset \mathcal{M}^n \) and a definable equivalence relation \( E \) on \( X \), that we can interpret the symbols of \( \mathcal{L}_0 \) as definable subsets and functions of \( X/E \) and the resulting \( \mathcal{L}_0 \)-structure is isomorphic to \( \mathcal{N} \).

The usual example is that the set structure of a projective space is interpretable in the ring structure of a field.

Prop. (1.2.2.19). Any structure for a countable language can be interpreted in a graph.

Proof:
3 Some Theories Often Used

Def. (1.2.3.1) [Languages].
- \( L_r \) is defined to be the language of rings.
- \( L_{or} \) is defined to be the language of ordered rings.

Def. (1.2.3.2) [Theories].
- \( ACF \) is defined to be the theory of alg.closed fields, w.r.t \( L_r \).
- \( ACF_p \) is defined to be the theory of alg.closed fields of char \( p \).
- \( DAG \) is defined to be the theory of non-trivial torsion-free divisible Abelian groups, w.r.t. \( L_r \).
- \( DLO \) is the theory of dense linear orders without endpoints.
- \( ODAG \) is the theory of nontrivial divisible Abelian groups.
- \( RCF \) is the theory of real closed fields w.r.t \( L_{or} \).

4 Basis Techniques

Def. (1.2.4.1) [Definitions for Theories]. A theory \( T \) is said to have the witness property iff whenever \( \varphi(v) \) is an \( L \)-formula with one free variable \( v \), there is a constant symbol \( c \) that \( T \models (\exists v \varphi(v) \rightarrow \varphi(c)) \).

A theory \( T \) is called maximal iff for any \( L \)-sentence, either \( \varphi \in T \) or \( \neg \varphi \in T \).

A theory \( T \) is called complete iff for any \( L \)-sentence, either \( T \models \varphi \) or \( T \models \neg \varphi \).

Def. (1.2.4.2) [Proof System]. A proof of a \( L \)-sentence \( \varphi \) from a theory \( T \), denoted by \( T \vdash \varphi \), is a

Prop. (1.2.4.4). If \( L \) is a recursive language and \( T \) is a recursive \( L \)-structure, then \( \{ \varphi | T \vdash \varphi \} \) is recursively enumerable.

Prop. (1.2.4.5). The halting computation set is not computable.

Cor. (1.2.4.6). The full theory \( Th(\mathbb{N}) \) of the ring structure of \( \mathbb{N} \) is undecidable.
Proof: If such an algorithm exists, then we can use it to compute whether the sentence
\[ \varphi(e, x) = \exists s T((1 + \ldots + 1, 1 + \ldots + 1, s)) \]
is computable. Then this will contradicts the fact that halting computation set is not computable (1.2.4.5).

\[ \square \]

Prop. (1.2.4.7) [Gödel's Completeness Theorem]. Let \( T \) be an \( \mathcal{L} \)-theory and \( \varphi \) is an \( \mathcal{L} \)-sentence, then \( T \models \varphi \) iff \( T \vdash \varphi \).

Proof: ?

\[ \square \]

Cor. (1.2.4.8) [Consistent and Satisfiable]. A theory \( T \) is consistent iff it is satisfiable.

Proof: If \( T \) is satisfiable, then it is clearly consistent, and if \( T \) is not satisfiable, then there are no models for \( T \), so \( T \models \neg \forall \varphi \) by definition, so \( T \vdash \varphi \) by Gödel’s completeness theorem.

\[ \square \]

Cor. (1.2.4.9) [Lemma on Constants]. Suppose \( T \vdash \varphi(\bar{c}) \) and \( \bar{c} \) is a tuple of constants not appearing in \( T \), then \( T \vdash \forall x \varphi(x) \).

Proof: We use the Gödel’s completeness theorem (1.2.4.7), and notice this theorem is obviously true for \( \vdash \) replaced by \( \models \). Notice we can add the constants to \( \mathcal{L} \), thus \( \varphi(\bar{c}) \) has no free variables.

\[ \square \]

Ultraproducts of Theories

Def. (1.2.4.10) [Ultraproducts of Theories]. If \( M_i, i \in I \) is a collection of \( \mathcal{L} \)-structures and \( \mathcal{F} \) is an ultrafilter on \( I \), then the ultraproduct \( \prod_I M_i / \mathcal{F} \) of \( M_i \) is a \( \mathcal{L} \)-structure defined as:

- The underlying set \( M = \prod M_i / \sim \), where \( (a_i) \sim (b_i) \) iff \( \{ i \in I | a_i = b_i \} \in \mathcal{F} \), which is an equivalent relation.
- If \( c \) is a constant symbol, then \( c^M = (c^{M_i}) \).
- If \( f \) is a function symbol, then \( f^M([a_{i1}], \ldots, [a_{in}]) = [f^{M_i}(a_{i1}, \ldots, a_{in})] \).
- If \( R \) is a relation symbol, then \( ([a_{i1}], \ldots, [a_{in}]) \in R^M \) iff \( \{ i \in I | (a_{i1}, \ldots, a_{in}) \in R^{M_i} \} \in \mathcal{F} \).

Prop. (1.2.4.11) [Łoś Theorem]. Let \( M_i, i \in I \) be \( \mathcal{L} \)-structures and \( \mathcal{F} \) be an ultrafilter on \( I \). Let \( \varphi(\bar{x}) \) be a first-order logic formula in the free variables \( \bar{x} \), and let \( (a_i) \) be a tuple of elements from \( \prod_I M_i / \mathcal{F} \), then
\[ \prod_I M_i / \mathcal{F} \models \varphi([a_i]) \iff \{ i \in I | M_i | \models \varphi_i(\bar{a}) \} \in \mathcal{F}. \]

Proof: The proof is by induction, which is routine, Cf.[Model Theory for Algebra and Algebraic Geometry, P22].

\[ \square \]

Cor. (1.2.4.12). An ultraproduct of models for a theory \( T \) is also a model for \( T \).

Cor. (1.2.4.13) [Non-Standard Model for \( Th(R) \)]. Consider \( R \) in the language \( \mathcal{L}_r \), where \( \mathcal{L}_r \) is the language of rings, (i.e., the ring structure), let \( \mathcal{F} \) be a non-principle ultrafilter on \( \mathbb{N}(1.1.8.9) \), and consider the ultraproduct \( \mathcal{R} = \prod_{i \in \mathbb{N}} R / \mathcal{F} \), which is called an ultrapower of \( R \).

Notice each factor satisfies \( Th(R) \), so \( \mathcal{R} \) also satisfies \( Th(R) \).
Cor. (1.2.4.14). Using ultraproduct construction, we can find a field of characteristic 0 that has exactly one algebraic extension in each degree.

Proof: Just use the field model \( \mathbb{F}_p \) for all \( p \) and construct their ultraproduct w.r.t. a non-principal ultrafilter. □

Prop. (1.2.4.15) [Keiler-Shelah Theorem]. Two \( L \)-structures \( \mathcal{M} \) and \( \mathcal{N} \) are elementary equivalent iff there is an index set \( I \) and an ultrafilter \( \mathcal{F} \) on \( I \) that \( \prod_{I} M / \mathcal{F} \cong \prod_{I} N / \mathcal{F} \).

Proof: Cf.[C. C. Chang and H. J. Keisler, Model Theory 6.1.15]. □

Compactness Theorem and Henkin Construction

Lemma (1.2.4.16). Suppose \( T \) is a maximal and finitely satisfiable \( L \)-theory with the witness property, then \( T \) is satisfiable. In fact, \( T \) has \( \kappa \) constant symbols, then there is a model \( \mathcal{M} \models T \) that \( |\mathcal{M}| \leq \kappa \).

Proof: Cf.[Marker, P35]. □

Lemma (1.2.4.17). Let \( L \) be a finitely satisfiable \( L \)-theory, then there is a language \( L \subset L^* \) and a \( T \subset T^* \) a finitely satisfiable \( L^* \)-theory that any \( L^* \)-theory extending \( T^* \) has the witness property. And we can choose \( |L^*| = |L| + \aleph_0 \).

Proof: We first show there is a language \( L \subset L_1 \) and a finitely satisfiable \( L_1 \)-theory \( T \subset T_1 \) that witnesses all \( L \)-formulae: We add a constant symbol \( c_\varphi \) for each \( L \)-formula \( \varphi \), and add sentences \((\exists v \varphi(v)) \rightarrow \varphi(c_\varphi)\) to \( T \), then this \( T_1 \) is finitely satisfiable, because for any finite subset \( \Delta \) of \( T_1 \), only f.m. constant symbols appear, and we have a model \( \mathcal{M} \) for \( \Delta \cap T \), thus we can interpret \( c_\varphi \) as the element \( a \) that \( \mathcal{M} \models \varphi(a) \), if \( \mathcal{M} \models \exists v \varphi(v) \). Now we can inductively define \( L_n, T_n \), and consider their union, then this satisfies the desired conditions. And the cardinality is also clear. □

Lemma (1.2.4.18). If \( T \) is a finitely satisfiable \( L \)-theory, then there is a maximal (1.2.4.1) finitely satisfiable \( L \)-theory \( L \subset L' \).

Proof: it is easy to construct a maximal satisfiable \( L \)-theory, and it is truly maximal in sense of (1.2.4.1): for any sentence \( \varphi \), if \( T \cup \varphi \) is not finitely satisfiable, there is a finite set \( \Delta \subset T \) that \( \Delta \models \neg \varphi \). Then we claim \( T \cup \neg \varphi \) is finitely satisfiable: for another finite set \( \Sigma \), because \( \Delta \cup \Sigma \) is finitely satisfiable and \( \Delta \models \neg \varphi \), \( \Sigma \cup \neg \varphi \) is satisfiable. □

Prop. (1.2.4.19) [Strong Compactness Theorem]. If \( T \) is a finitely satisfiable \( L \)-theory and \( \kappa \) is an infinite cardinal that \( \kappa > |L| \), then there is a model of \( T \) of cardinality at most \( \kappa \).

Proof: By (1.2.4.17), we get a desired language \( L^* \) of cardinality \( \leq \kappa \), and a theory \( T^* \), and by (1.2.4.18), we can assume \( T^* \) is maximal and finitely satisfiable, and it has the witness property. Then (1.2.4.16) says there is a model of cardinality \( \leq \kappa \). □

Cor. (1.2.4.20) [Compactness Theorem]. A theory \( T \) is satisfiable iff every finite subset of \( T \) is satisfiable.

Remark (1.2.4.21). Notice the compactness theorem is also a consequence of the completeness theorem (1.2.4.7): if \( T \) is not satisfiable, then it is not consistent by (1.2.4.8). Let \( \sigma \) be a proof of a contradiction in \( T \), then \( \sigma \) consists of f.m. sentences in \( T \), which consists of a finite unsatisfiable subset \( T_0 \) of \( T \).
It is clear provable using ultrafilters: If there is a family of structures \( \{M_\Delta\} \) indexed by the collection of all finite subsets of \( T \), with \( M_\Delta \models \Delta \) for all \( \Delta \in I \) where \( I \) is the set of all finite subsets of \( T \).

Then we want to find an ultrafilter \( F \) on \( I \) that for all \( \varphi \in T \), \( \{\Delta | \Delta \models \varphi \} \in F \), then we can use Leo's theorem (1.2.4.11) to show that \( \prod_I M_\Delta / F \) is a model for all \( \varphi \in T \). Now in fact we make pick a ultrafilter over the filter generated by all the \( A_\varphi = \{\Delta | \varphi \in \Delta \} \), because \( M_\Delta \models \Delta \). In fact, this is the case because \( A_\varphi \) has the finite intersection property trivially.

**Cor. (1.2.4.22).** If \( T \models \varphi \), then \( \Delta \models \varphi \) for some finite \( \Delta \subset T \).

*Proof:* If not, then \( \Delta \cup \{\neg \varphi \} \) is satisfiable for all finite \( \Delta \subset T \), so \( T \cup \{\neg \varphi \} \) is finitely satisfiable, thus satisfiable by compactness theorem, but this cannot be true because \( T \models \varphi \). \( \square \)

**Cor. (1.2.4.23) [Torsion Elements].** Let \( L \) be a language containing \( \{\cdot, e\} \), the language of groups, and \( T \) is a theory extending the theory of groups, let \( \varphi(v) \) be an \( L \)-formula. If for any \( n \) there is a \( G_n \models T \) and \( G_n \) has an element of finite order greater than \( n \), then there is an \( L \)-structure \( G \) that \( G \models T \) and \( G \) has an element of infinite order.

In particular, there is no formula that defines the torsion elements in any models for \( T \).

*Proof:* Consider a new language \( L^* = L \cup \{c\} \), and \( T^* \) an \( L^\ast \)-theory that

\[
T^* = T \cup \{ \varphi(c) \} \cup \{ (\underbrace{\cdots c \cdots c}_{n \text{-times}} = e) \},
\]

then the theory \( T^* \) is finitely satisfiable by hypothesis, so \( T^* \) is satisfiable by compactness theorem. \( \square \)

**Cor. (1.2.4.24) [Larger than All Natural Number].** Consider \( L \) the language of ordered rings, let \( Th(\mathbb{N}) \) be the theory of \( \mathbb{N} \), then there is an \( L \)-structure \( M \models Th(\mathbb{N}) \) and \( M \) has an element that is larger than every natural number.

*Proof:* The same proof as that of (1.2.4.23), but use

\[
T^* = Th(\mathbb{N}) \cup \{ 1 + \cdots + 1 < c \}^{n \text{-times}}
\]

\( \square \)

**Prop. (1.2.4.25) [Model of a Given Cardinality].** If \( T \) is an \( L \)-theory with infinite models, then if \( \kappa \) is an infinite cardinal that \( \kappa \geq |L| \), then there is a model of \( T \) of cardinality \( \kappa \).

*Proof:* Let \( L^* = L \cup \{c_\alpha : \alpha < \kappa\} \), where \( c_\alpha \) are pairwise different new constants, and \( T^* \) be the \( L^\ast \) theory \( T \cup \{c_\alpha \neq c_\beta, \alpha < \beta < \kappa\} \), then any model for \( T^* \) must has cardinality \( \geq \kappa \). But then we use strong compactness theorem (1.2.4.19), it suffices to show \( T^* \) is finitely satisfiable: for any finite \( \Delta \subset T^* \), there are only f.m. new constant symbols, thus we can use the infinite model \( M \) to interpret the constant symbols randomly, thus we are done. \( \square \)
1.2. MODEL THEORY

**Complete Theories**

**Def.(1.2.4.26).** Let \( \kappa \) be an infinite cardinal and \( T \) is a theory with models of size \( \kappa \). \( T \) is called \( \kappa \)-categorical iff any two models of \( T \) of cardinality \( \kappa \) are isomorphic.

**Prop.(1.2.4.27).** The theory of torsion-free divisible Abelian groups is \( \kappa \)-categorical for all \( \kappa > \aleph_0 \).

*Proof:* A torsion-free Abelian group is just a vector space over \( \mathbb{Q} \). Thus the conclusion is trivial, just notice for a cardinal \( \kappa > \aleph_0 \), a vector space of dimension \( \kappa \) has cardinality \( \kappa \). \( \square \)

**Prop.(1.2.4.28)[Vaught’s Test].** Let \( T \) be a satisfiable theory with no finite models, if \( L \) is \( \kappa \)-categorical for some \( \kappa \geq |L| \), then \( T \) is complete.

*Proof:* If there is a sentence \( \varphi \) that \( T \not\models \varphi \) and \( T \not\models \neg \varphi \), so \( T_0 = T \cup \{ \varphi \} \) and \( T_1 = T \cup \{ \neg \varphi \} \) is satisfiable. They both have infinite models by hypothesis, so by (1.2.4.25) there are models of cardinal \( \kappa \) for \( T_0 \) and \( T_1 \), but they cannot be isomorphic, contradiction. So \( T \) is complete. \( \square \)

**Prop.(1.2.4.29)[Recurve Complete Satisfiable is Decidable].** If \( T \) is a recursive complete satisfiable theory in a recursive language \( L \), then \( T \) is decidable.

*Proof:* Because \( T \) is satisfiable, The set of all \( \varphi \) that \( M \models \varphi \) and the set of all \( \varphi \) that \( M \models \neg \varphi \) are disjoint, and their sum is the set of all sentences by completeness. By Gödel’s completeness theorem, this is equivalent to \( M \vdash \varphi \) or \( M \vdash \neg \varphi \). Then by (1.2.4.4), they are both enumerable, so it is decidable by definition. \( \square \)

**Up and Down(of Cardinality)**

**Def.(1.2.4.30)[Elementary Embedding].** An \( L \)-structure embedding \( j : M \to N \) is called an elementary embedding, denoted by \( M \prec N \), if for any \( L \)-formula \( \varphi \),

\[
M \models \varphi(\pi) \iff N \models \varphi(j(\pi)).
\]

Notice that one way implication is sufficient, because we can use negation.

Isomorphisms are elementary embeddings by (1.2.2.10).

**Def.(1.2.4.31)[Diagrams].** Let \( M \) be an \( L \)-structure, then we can add to \( L \) constant symbols for each element of \( M \), and the class \( \text{Diag}(M) \) of atomic diagrams of \( M \) is sentences of the form \( \varphi(m_1, \ldots, m_n) \), where \( \varphi \) is an atomic \( L \)-formula or the negation of an atomic \( L \)-formula, and \( M \models \varphi(m_1, \ldots, m_n) \). And the class \( \text{Diag}_{el}(M) \) of elementary diagrams of \( M \) is sentences of the form \( \varphi(m_1, \ldots, m_n) \) where \( \varphi \) is an \( L \)-formula that \( M \models \varphi(m_1, \ldots, m_n) \).

**Prop.(1.2.4.32)[Diagrams and Embedding].** The diagram and elementary diagram is very important in constructing embeddings of theories: Let \( N \) be an \( L_M \)-structure, then:

- If \( N \models \text{Diag}(M) \), there is an \( L \)-embedding \( M \subset N \).
- If \( N \models \text{Diag}_{el}(M) \), there is an elementary \( L \)-embedding \( M \prec N \).

**Prop.(1.2.4.33)[Upward Löwenheim-Skolem Theorem].** Let \( M \) be an infinite \( L \)-structure and \( \kappa \) be an infinite cardinal that \( \kappa \geq |M| + |L| \), then there is an \( L \)-structure \( N \) of cardinality \( \kappa \) that \( M \) embeds into \( N \).

*Proof:* \( \text{Diag}_{el}(M) \) is clearly satisfiable, so by (1.2.4.25), there is an \( L^* \)-model \( N \) of cardinality \( \kappa \) that \( M \prec N \). \( \square \)
Prop. (1.2.4.34) [Tarski-Vaught Test]. A substructure $\mathcal{M}$ of a structure $\mathcal{N}$ is an elementary substructure iff for any formula $\varphi(v, \overline{w})$ and $\overline{a} \in M$, if there is $b \in N$ that $\mathcal{N} \models \varphi(b, \overline{a})$, then there is a $c \in M$ that $\mathcal{N} \models \varphi(c, \overline{a})$.

Proof: Cf. [Marker P45]. □

Prop. (1.2.4.35) [(Downward) Löwenheim-Skolem Theorem]. Suppose $\mathcal{M}$ is an $\mathcal{L}$-structure and $X \subseteq \mathcal{M}$, then there is an elementary submodel $\mathcal{N}$ that $X \subseteq \mathcal{N}$ and $|\mathcal{N}| \leq |X| + |\mathcal{L}| + \aleph_0$.

Proof: Cf. [Marker P46]. □

Def. (1.2.4.36) [Universal Sentences]. A universal sentence is a sentence of the form $\forall v \varphi(v)$, where $\varphi$ is quantifier-free.

For a theory $T$, denote by $T_{\forall}$ the set of all of the universal sentences $\varphi$ that $T \models \varphi$.

A $\mathcal{L}$-theory $T$ is said to have a universal axiomatization iff there is a set of universal $\mathcal{L}$-sentences $\Gamma$ that $\mathcal{M} \models T$ iff $\mathcal{M} \models \Gamma$.

Prop. (1.2.4.37) [Universal Axiomation]. An $\mathcal{L}$-theory $T$ has a universal axiomatization iff for any $\mathcal{N} \subseteq \mathcal{M}$, if $\mathcal{M} \models T$, then $\mathcal{N} \models T$.

Proof: Cf. [Marker P47]. □

Prop. (1.2.4.38) [Universal Consequences]. If $T$ is an $\mathcal{L}$-theory, then $A \models T_{\forall}$ iff there is an $\mathcal{M} \models T$ that $A \subseteq \mathcal{M}$.

Proof: If $A \subseteq \mathcal{M}$, then $A \models T_{\forall}$, by (1.2.4.37). Conversely, if $A \models T_{\forall}$, then consider $\text{Diag}(A)$, then it suffices to show $\text{Diag}(A)$ is satisfiable. If it is not, then by compactness theorem (1.2.4.20) there is a finite set that is not satisfiable, and the part coming from diagrams of $M$ can be expressed by a single formula $\chi(\overline{a})$, where $\chi$ is quantifier-free, $\overline{a} \in M$, $\mathcal{M} \models \chi(\overline{a})$, and we are saying that $T \cup \{\chi(\overline{a})\}$ is not satisfiable, then $T \models \neg \chi(\overline{a})$.

Now $T \models \forall \overline{a} \neg \chi(\overline{a})$ as $\mathcal{L}$-theory because $\overline{a}$ can be designated arbitrarily, but this sentence is in $T_{\forall}$, thus $\mathcal{M} \models \forall \overline{a} \neg \chi(\overline{a})$, in particular, $\mathcal{M} \models \neg \varphi(\overline{a})$, contradiction. □

Prop. (1.2.4.39) [Elementary Chain]. If $\mathcal{M}_i$ is a chain of $\mathcal{L}$-structures that $\mathcal{M}_i \prec \mathcal{M}_j$ for any $i < j$, then we can define there union $\mathcal{M} = \cup \mathcal{M}_i$. Then $\mathcal{M}$ is an elementary extension of each $\mathcal{M}_i$.

Proof: Use induction on formulas to show that

$$\mathcal{M}_i \models \varphi(\overline{a}_i) \iff \mathcal{M} \models \varphi(\overline{a})$$

for all $\mathcal{L}$-formulas $\varphi$. This is true for quantifier-free formula by (1.2.2.9), and if this is true for $\varphi, \psi$, then this is true for $\neg \varphi$ and $\varphi \land \psi$. For the sentence $\varphi = \exists v \psi(v, \overline{w})$, if $\mathcal{M}_i \models \psi(b, \overline{a})$ for some $b$, then so does $\mathcal{M}$. Conversely, if $\mathcal{M} \models \psi(b, \overline{a})$ for some $b$, then $b \in \mathcal{M}_j$ for some $j$, then $\mathcal{M}_j \models \varphi$, by the condition, $\mathcal{M}_i \models \varphi$ also. □

Back and Forth Argument

Cf. [Marker Chap2.4]. Some deep ideas are involved.

Prop. (1.2.4.40) [Cantor]. The theory $DL0(1.2.3.2)$ is $\aleph_0$-categorical and complete.

Proof: It is $\aleph_0$-categorical by (1.1.3.12), and it is complete, by Vaught’s test (1.2.4.28), as it has no finite models. □
5 Quantifier Elimination

**Def.(1.2.5.1)** [Quantifier Elimination]. A theory is said to have quantifier elimination if for each formula \( \varphi(\overline{v}) \), there is a quantifier-free formula \( \psi(\overline{v}) \) such that \( T \models \forall \overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v})) \).

**Lemma (1.2.5.2)**. Suppose \( \mathcal{L} \) contains a constant symbol \( c \), \( T \) is an \( \mathcal{L} \)-theory, and \( \varphi(\overline{v}) \) is an \( \mathcal{L} \)-formula, then the following are equivalent:

1. There is a quantifier-free \( \mathcal{L} \)-formula \( \psi(\overline{v}) \) such that \( T \models \forall \overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v})) \).
2. If \( M, N \) are models of \( T \), and \( A \) is an \( \mathcal{L} \)-structure that \( A \subset M \cap N \), then for all \( \overline{v} \in A \), \( N \models \varphi(\overline{v}) \iff M \models \varphi(\overline{v}) \).

**Proof**: 1 \( \rightarrow \) 2 is clear, because a quantifier-free formula \( \psi(\overline{v}) \) is preserved under substructure by (1.2.2.9).

2 \( \rightarrow \) 1. Cf.[Marker, P74]. \( \Box \)

**Lemma (1.2.5.3)**. Let \( T \) be an \( \mathcal{L} \)-theory that for any quantifier-free \( \mathcal{L} \)-formula \( \theta(\overline{v},w) \), there is a quantifier-free formula \( \psi(\overline{v}) \) that \( T \models \forall \overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v})) \), then \( T \) has quantifier elimination.

**Proof**: We want to show for each formula \( \varphi(\overline{v}) \), there is a quantifier-free formula \( \psi(\overline{v}) \) such that \( T \models \forall \overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v})) \), and we use induction on the complexity of \( \varphi \).

If \( \varphi \) is quantifier-free, this is trivial. If \( \varphi = \neg \theta_0 \) or \( \varphi = \theta_0 \land \theta_1 \), then we are easily done. If \( \psi(\overline{v}) = \exists w \theta(\overline{v},w) \), and \( T \models \forall \overline{v}(\theta(\overline{v},w) \leftrightarrow \psi_0(\overline{v},w)) \), then \( T \models \forall \overline{v}(\varphi(\overline{v}) \leftrightarrow \exists w \psi_0(\overline{v},w)) \). But the assumption shows there is a quantifier-free \( \psi \) such that \( T \models \forall \overline{v}(\exists w \theta(\overline{v},w) \leftrightarrow \psi(\overline{v})) \), and then \( T \models \forall \overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v})) \). \( \Box \)

**Prop.(1.2.5.4)** [Criterion for Quantifier Elimination]. Combining (1.2.5.2) and (1.2.5.3), we get: If \( T \) is an \( \mathcal{L} \)-theory that for all quantifier-free \( \mathcal{L} \)-formula \( \varphi(\overline{v},w) \) and models \( M, N \models T \), and \( A \subset M \cap N, \overline{v} \in A \), and if there is \( b \in M \) that \( M \models \varphi(\overline{v},b) \) will imply there is \( c \in N \) that \( N \models \varphi(\overline{v},c) \), then \( T \) is quantifier-free.

**Def.(1.2.5.5)** [Algebraically Prime Models]. A theory \( T \) is said to have algebraically prime models if for any \( A \models T \) and an embedding \( i : A \to M \) that for any other \( N \models T \), any embedding \( j : A \to N \) factors through \( i \).

**Def.(1.2.5.6)** [Simply Closed Model]. If \( M, N \) are models of \( T \), and \( M \subset N \), then \( M \) is called simply closed in \( N \), denoted by \( M \prec_s N \), iff for any quantifier-free formula \( \varphi(\overline{v},w) \) and \( \overline{v} \in M^n \), if \( N \models \exists w \varphi(\overline{v},w) \), then so does \( M \).

**Prop.(1.2.5.7)** [Quantifier Elimination Test]. If \( T \) is an \( \mathcal{L} \)-theory that has algebraically prime models, and any inclusion of models for \( T \) is simply closed, then \( T \) has quantifier elimination.

**Proof**: This is an immediate consequence of (1.2.5.4). \( \Box \)

**Def.(1.2.5.8)** [Model Complete]. An \( \mathcal{L} \)-theory \( T \) is called model complete if \( M \prec N \) whenever \( M \subset N \). A complete theory is clearly model complete.

**Prop.(1.2.5.9)**. If \( T \) has quantifier elimination, then \( T \) is model complete.

**Proof**: If \( M \subset N \), let \( \varphi(\overline{v}) \) be an \( \mathcal{L} \)-formula, and \( \overline{v} \in M \), then there is a quantifier-free formula \( \psi(\overline{v}) \) such that \( T \models \forall \overline{v}(\varphi(\overline{v}) \leftrightarrow \psi(\overline{v})) \). By (1.2.2.9), the formula \( \psi(\overline{v}) \) passes between \( M \) and \( N \), so \( M \models \varphi(\overline{v}) \iff M \models \psi(\overline{v}) \iff N \models \psi(\overline{v}) \iff N \models \varphi(\overline{v}) \). \( \Box \)
**Prop.(1.2.5.10) [Minimal Model and Completeness].** If $T$ is model-complete and there is a minimal model $M_0$ that $M_0$ embeds into every model of $T$, then $T$ is complete.

*Proof:* Clearly any model is elementary equivalent to $M_0$, thus clearly $T$ is complete. □

**Prop.(1.2.5.11) [Eliminating Algorithm].** Let $T$ be a decidable theory with quantifier elimination, then there is an algorithm to find the elimination $\psi$ of a given formula $\varphi$.

*Proof:* We just need to find a quantifier-free $\psi$ that $T \models \forall \varphi(\varphi(\sigma) \leftrightarrow \psi(\sigma))$. This an effective search because $T$ is decidable, and we can eventually find $\psi$ because $T$ has quantifier elimination. □

**Examples of Quantifier Elimination**

**Prop.(1.2.5.12).** The theory $DLO(1.2.3.2)$ has quantifier elimination.

*Proof:* Cf.[Marker P72]. □

**Lemma(1.2.5.13).** $DAG(1.2.3.2)$ has algebraically prime models.

*Proof:* This is just the alg.closure of the quotient field of an integral domain. □

**Prop.(1.2.5.14).** $DAG$ has quantifier elimination.

*Proof:* We use(1.2.5.7) By?? $DAG$ has algebraically prime models, thus it suffices to show any inclusion of models for $DAG(1.2.3.2)$ is simply closed: For any torsion-free divisible Abelian groups $H \subset G$, $\varphi(\bar{a}, w)$ quantifier-free, $\bar{a} \in H$, $b \in G$ that $G \models \varphi(\bar{a}, w)$. Then $\varphi$ is a disjunction of conjunctions of atomic or negated atomic formulas, and we need to prove $H \models \varphi(\bar{a}, w)$.

So we may assume $\varphi$ is conjunction of atomic formulas and negated atomic formulas:

$$\varphi(\bar{a}, w) \leftrightarrow \bigwedge(g_i + m_i w = 0) \land \bigwedge(h_i + m'_i w \neq 0).$$

If any $m_i \neq 0$, then $b \in H$. If all $m_i = 0$, then there are only f.m. constraints, and there is $b' \in H$ that $H \models \varphi(\bar{a}, b')$ because $H$ is infinite. □

**Cor.(1.2.5.15).** The theory $DAG$ is complete, by(1.2.5.10), as $(\mathbb{Q}, +, 0)$ embeds in every model of $DAG$, and(1.2.5.14)(1.2.5.9).

**Prop.(1.2.5.16).** The theory $ODAG$ is a complete theory with quantifier elimination. In particular, any ordered divisible Abelian group is elementarily equivalent to $(\mathbb{Q}, +, <)$, by completeness.

*Proof:* Cf.[Marker, P80]. □

**Prop.(1.2.5.17) [Presburger Arithmetic].** Presburger arithmetic is a complete decidable theory with quantifier elimination in the language $\mathcal{L}^*$.

*Proof:* Cf.[Marker, P84]? □

**Strongly Minimal Theory**

**Def.(1.2.5.18) [Strongly Minimal Theory].** A theory $T$ is called strongly minimal iff for any $\mathcal{M} \models T$, every definable subset of $\mathcal{M}$ is either finite or cofinite.

**Prop.(1.2.5.19).** $DAG(1.2.3.2)$ is strongly minimal.

*Proof:* Cf.[Marker P78]. □
6 Algebraically Closed Fields

Lemma (1.2.6.1). $ACF_p(1.2.3.2)$ is $\kappa$-categorical for all uncountable cardinal $\kappa$.

Proof: Because two alg.closed field of the same transcendental degree over the base field is isomorphic??. The conclusion follows as an alg.closed field of transcendence degree $\kappa$ has cardinality $\kappa + \aleph_0$.

Prop. (1.2.6.2). The theory $ACF_p$ is complete, by (1.2.6.1) and (1.2.4.28).

Cor. (1.2.6.3). $ACF_p$ is decidable, in particular, $\text{Th}(\mathbb{C})$, the first-order theory of the fields of complex numbers, is decidable.

Proof: $ACF_p$ is complete by (1.2.6.1) and (1.2.4.28), it is clearly recursive, and it is clearly satisfiable, so use (1.2.4.29).

Prop. (1.2.6.4) [First order Lefschetz Principle]. Let $\varphi$ be a sentence in the language of rings, the following are equivalent:
1. $\varphi$ is true in $\mathbb{C}$.
2. $\varphi$ is true in every(some) alg.closed field of char 0.
3. For $p$ large/there exists arbitrary large $p$, $\varphi$ is true in any alg.closed field of char $p$.

Proof: 1, 2 are equivalent because $ACF_p$ is complete (1.2.6.2) and use Gödel’s completeness theorem. If 2 is true, then $ACT_0 \models \varphi$, so by (1.2.4.22), then some $\Delta \models \varphi$. So for $p$ sufficiently large, $ACF_p \models \Delta$, so $ACF_p \models \varphi$ for $p$ large.
If $ACF_0 \models \neg \varphi$, then $ACF_0 \models \neg \exists \varphi$ by completeness (1.2.6.2), so by above argument, $ACF_p \models \neg \exists \varphi$ for $p$ large, contradiction.

Cor. (1.2.6.5) [Ax]. Any injective polynomial map from $\mathbb{C}^n$ to $\mathbb{C}^n$ is surjective.

Proof: By Lefschetz principle (1.2.6.4), it suffices to show this for $(\mathbb{F}_p)^{alg}$ for $p$ large. If this is not true, then choose the coefficients of the coordinate map of $f$, and the coordinates of an element that is not in the image, then the subfield $k$ they generated is algebraic over $\mathbb{F}_p$, so it is finite, and clearly $f$ is also surjective on $k^n$, contradiction.

Cor. (1.2.6.6). Let $K \subset L$ be alg.closed fields, and $V, W$ be varieties defined over $K$, and $f$ is a polynomial isomorphism of $V$ and $W$ over $L$, then there is a polynomial isomorphism of $V$ and $W$ over $K$.

Proof: Let $f$ have degree $d$. Then we can write a formula $\Psi$ saying that there is an embedding of $K$ into $M$ and there is a polynomial bijection of $V$ and $W$ over $M$, then $L \models \Psi$, and because $ACF$ is complete (1.2.6.2), $K \models \Psi$, too. Thus there is also an isomorphism over $K$.

Prop. (1.2.6.7). $ACF_\forall$ is the theory of integral domains.

Proof: Clearly a ring is a subring of an alg.closed field iff it is an integral domain, so the result follows from (1.2.4.38).

Prop. (1.2.6.8). $ACF$ has qualifier elimination.
Proof: Use (1.2.5.5), clearly it has algebraically prime models (1.2.6.7), and we need to check simply closedness.

For this, if \( K \subset L \), notice that a quantifier-free formula \( \varphi \) is just a conjunction of some polynomial functions and negation of polynomial functions, with their coefficients in \( K \). If there are some polynomial, then the solution \( b \) of \( \varphi \) in \( L \) is algebraic over \( K \), thus in \( K \) because \( K \) is alg.closed. Now if it is just negations of polynomials, then clearly \( \varphi \) is true in \( K \) for some \( c \in K \), because \( K \) is alg.closed thus infinite. \( \Box \)

Cor. (1.2.6.9). \( ACF \) is model-complete, by (1.2.5.9).

Lemma (1.2.6.10). Let \( K \) be a field, then the subsets of \( K^n \) defined by atomic formulas are exactly Zariski closed subsets. And a subset of \( K^n \) that is quantifier-definable iff it is a Boolean combination of Zariski closed subsets (constructible). (Clear).

Prop. (1.2.6.11). \( ACF \) is strongly minimal.

Proof: Because by quantifier elimination (1.2.6.8), every definable set is a finite Boolean combination of sets of the form \( V(p) = 0 \), where \( p \in K[X] \), but \( V(p) \) is either finite or all of \( K \). \( \square \)

Elimination of Imaginaries in Alg.Closed Fields

Def. (1.2.6.12) [Algebraicity]. Let \( M \) be an \( L \)-structure and \( A \subset M \), then for \( b \in M \), \( b \in acl(A) \) if there is a formula \( \varphi(x, \overline{y}) \) and \( \pi \in A \) that \( M \models \varphi(b, \pi) \), and \( \{ x \in M | M \models \varphi(x, \pi) \} \) is finite.

Def. (1.2.6.13) [Algebraicity over Equivalence Class]. Let \( M \) be an \( L \)-structure and \( E \) a definable equivalence relation on \( M^n \), then we say a element \( c \in M \) is algebraic over \( \overline{a}/E, b_1, \ldots, b_m \) if there is a formula \( \varphi(c, \overline{y}, \overline{\pi}) \) that

1. \( M \models \varphi(c, \overline{a}, \overline{b}) \).
2. If \( \overline{a} E \overline{a}' \), then \( M \models \varphi(c, \overline{a}, \overline{b}) \iff \varphi(c, \overline{a}', \overline{b}) \).
3. \( \{ x | M \models \varphi(x, \overline{\pi}, \overline{b}) \} \) is finite.

And a sequence \( \overline{c} \) is called algebraic over \( a/E, b_1, \ldots, b_m \) iff each coordinate is.

Lemma (1.2.6.14). Suppose \( \overline{c} \) is algebraic over \( \overline{a}/E, \overline{d}, \overline{b} \), and \( \overline{b} \) is algebraic over \( \overline{a}/E, \overline{d} \), then \( \overline{c} \) is also algebraic over \( \overline{a}/E, \overline{d} \).

Proof: Cf. [Marker, P92]. \( \square \)

Lemma (1.2.6.15). Suppose \( K \) is an alg.closed field and \( E \) is a definable equivalence relation on \( K^n \), and \( \psi(\overline{x}, \overline{y}, \overline{d}) \) defines \( E \). If \( \overline{a} \in K^n \), then there is a \( \overline{c} \in K^n \) algebraic over \( \overline{a}/E, \overline{d} \) s.t. \( \overline{c} E \overline{a} \).

Proof: Cf. [Marker, P92]. \( \square \)

Prop. (1.2.6.16) [Elimination of Imaginaries]. Let \( K \) be an alg.closed field, \( A \subset K \), and \( E \) is an \( A \)-definable equivalence relation on \( K^n \), then for some \( l \) there is an \( A \)-definable function \( f : K^n \to K^l \) that \( x E \overline{y} \iff f(\overline{x}) = f(\overline{y}) \).

Proof: Cf. [Marker, P92]. \( \square \)
7 Real Closed Fields

Prop. (1.2.7.1). The class of real closed fields is an elementary class (1.2.2.8) of $L_r$-structures.
Proof: The real closed fields are axiomatized by:
- Axioms for fields.
- For each $n \geq 1$, the sentence $\forall x_1 \ldots \forall x_n (x_1^2 + \ldots + x_n^2 + 1 \neq 0)$.
- $\forall x \exists y (y^2 = x \lor y^2 + x = 0)$.
- For each $n \geq 0$, the sentence $\forall x_1 \ldots \forall x_n \exists y (y^{2n+1} + \sum_{i=0}^{2n} x_i y^i = 0)$.
These truly axiomatize real closed fields, by (2.2.9.7).

Prop. (1.2.7.2). Let $F$ be a real closed field, then the definable sets in $F^n$ w.r.t the $L_{or}$ is also definable w.r.t. $L_r$.
Proof: Because we can replace all instances $t_i < t_j$ by $\exists v (v \neq 0 \land t_i + v^2 = t_j)$.

Prop. (1.2.7.3). $RCF$ is the theory of ordered integral domains (easy).

Cor. (1.2.7.4). $RCF$ has algebraically prime models.
Proof: Let $D$ be an ordered domain, and let $R$ be a real closure of the fraction field of $D$ compatible with the ordering of $D$. Let $F$ be another real closed field extension of $D$, then let $K$ be the algebraic closure of the fraction field of $D$ in $F$, then $K$ is a real closed field by (2.2.9.7), then by (2.2.9.12) there is an isomorphism of $R \cong K$ extending $D \to K$, thus embeds $R$ into $F$ extending $D \to F$.

Prop. (1.2.7.5). $RCF$ has quantifier elimination (w.r.t. $L_{or}$).
Proof: Use (1.2.5.5), it has algebraically prime models by (1.2.7.4), and we need to check simply closedness: Let $F \subset K$ be RCFs, $\varphi(v,\overline{a})$ be a quantifier-free formula and let $\overline{a} \in F, b \in K$ that $K \models \varphi(b,\overline{a})$. Then there are polynomials that

$$\varphi(v,\overline{a}) \leftrightarrow (\bigwedge p_i(v) = 0 \land \bigwedge q_i(v) > 0).$$

If any $p_i \neq 0$, then $b$ is algebraic over $F$, but then $b \in F$ because $F$ is real closed. So we may assume $\varphi(v,\overline{a}) \leftrightarrow \bigwedge q_i(v) > 0)$. Then because $q_i(b) > 0$ and $q_i$ has f.m. zeros, by intermediate property (2.2.9.9), we can find a nbhd of $b$ that is interval with endpoints in $F$ that $q_i > 0$, and because $F$ is dense (char 0), there is an element $b'$ that $F \models \varphi(b',\overline{a})$.

Cor. (1.2.7.6). $RCF$ is complete and decidable. Thus it is just the theory of $(\mathbb{R},+,-,\cdot,\langle\rangle)$, and it is decidable.
Proof: It is model-complete by (1.2.5.9), and it has a minimal model that is the field $\mathbb{R}_{alg}$ of algebraic numbers in $\mathbb{R}$, then it is complete by (1.2.5.10). It is decidable by (1.2.4.29).

Prop. (1.2.7.7) $[RCF$ is O-Minimal]. The theory $RCF(1.2.3.2)$ is o-minimal.
Proof: Because $RCF$ has quantifier elimination, every definable set of a real closed field $R$ is semialgebraic, thus it is clearly a disjoint union of intervals and points.
Semia
gebraic Sets

Def. (1.2.7.8) [Semia
gebraic Sets]. Let $F$ be an ordered field, then $X \subset F^n$ is called semi-
gebraic if there it is a Boolean combination of sets of the form $\{ \bar{x} | p(\bar{x}) > 0 \}$, where $p(\overline{X}) \subset F[\overline{X}]$.

Prop. (1.2.7.9) [Tarski-Seidenberg Theorem]. If $F$ is a real closed field, the semialgebraic sets are closed under projection.

Proof: This is because quantifier elimination (1.2.7.5) implies semialgebraic sets are just definable
sets, and the projection of a definable set is also definable. □

Cor. (1.2.7.10). The composite of two semialgebraic functions are semialgebraic.

Prop. (1.2.7.11) [Closure of Semialgebraic Sets]. Let $F$ be a real closed field and $A \subset F^n$ be semialgebraic, then the closure of $A$ in the Euclidean topology is also semialgebraic.

Proof: The closure of $A$ is defined by

$$\{ \bar{x} | \forall \varepsilon > 0, \exists \bar{y} \in A, d(\bar{x}, \bar{y}) < \varepsilon \}. $$

Thus it is definable, and thus semialgebraic by quantifier elimination (1.2.7.5). □

Prop. (1.2.7.12). Let $F$ be a real closed field and $X \subset F^n$ be closed and bounded, $f$ be a continuous semialgebraic function, then $f(X)$ is closed and bounded.

Proof: If $F = \mathbb{R}$, then this follows from (3.6.5.2) that $X$ is compact hence the image is also compact hence closed and bounded. As we can formulate a sentence asserting the conclusion. Thus the theorem follows as $RCF$ is complete (1.2.7.6). □

Lemma (1.2.7.13). For $R$ a real closed field and $f : R \to R$ semialgebraic, then for any interval $U$ there is an element $x$ that $f$ is continuous at $x$.

Proof: It suffices to prove for $R = \mathbb{R}$ by completeness of $RCF$. If there is an interval that $f$ has
finite range, then the inverse image of some point $b$ is infinite, but also definable, so by $o$-minimality
contains an interval that $f$ is constant, hence continuous.

Otherwise, we inductively choose a chain of intervals: $V_0 = U$, and the image of $V_n$ is definable thus contains an interval of length at most $1/n$, by $o$-minimality and our assumption. Now for the same reason the inverse image of this interval contains an interval, called $V_{n+1}$, s.t. $V_{n+1} \subset V_n$, then $\cap V_n = \cap V_n \neq \varnothing$ because $\mathbb{R}$ is locally compact. For any $x \in V$, it is easy to see $f$ is continuous at $x$. □

Prop. (1.2.7.14). For $R$ a real closed field and $f : R \to R$ semialgebraic, then $f$ is discontinuous only at f.m. points.

Proof: The discontinuous points of $f$ is definable by

$$D = \{ x | F |= \exists \varepsilon > 0 \forall \delta > 0 \exists y | x - y| < \delta \land |f(x) - f(y)| > \varepsilon \},$$

thus it is a finite union of intervals and points, by $o$-minimality (1.2.7.7), but it must be f.m. points, by (1.2.7.13). □

Def. (1.2.7.15). We can naturally define the notion of definably connected and definably arcwise connected sets in $R^n$. 

Def.(1.2.7.16)[Cells]. For an real closed field $F$, we inductively define $n$-cells:

- $X \subset F^m$ is a 0-cell if it is a single point.
- If $X \subset F^m$ is an $n$-cell and $f : X \to F$ is a continuous definable function, then $Y = \{(\overline{a}, y) | \overline{a} \in X \}$ is an $n$-cell.
- If $X \subset F^m$ is an $n$-cell and $f, g$ are either continuous functions from $X$ to $F$ or constants $\pm \infty$, then $Y = \{(x, y) | x \in X \land f(x) < y < g(x)\}$ is an $n + 1$-cell.

Prop.(1.2.7.17)[Uniform Bounding]. Let $X \subset F^{m+1}$ be semialgebraic, then there is a natural number $N$ that if $\overline{a} \in F^n$ and $X_{\overline{a}} = \{y | (\overline{a}, y) \in X\}$ is finite, then $|X_{\overline{a}}| < N$.

Proof: First notice $X_{\overline{a}}$ is definable, thus by $o$-minimality, $\{\overline{a}||X_{\overline{a}}| < \infty\}$ is definable, thus we may assume these are all of $X$.

Now let $\Gamma$ be the theory

$$RCF + Diag(F) + \exists y_1, y_2, \ldots, y_m[\bigwedge_{i < j} y_i \neq y_j \land \bigwedge y_i \in X_{\overline{a}}]$$

where $m \in \mathbb{N}$, and $c_1, \ldots, c_n$ are new constants. (Notice $y_i \in X_{\overline{a}}$ is a sentence).

Then $\Gamma$ is not satisfiable, because otherwise there is an embedding $F \subset K$, and by model completeness $F \prec K$, thus there is no $\overline{a}$ that $X_{\overline{a}}$ is infinite, because it is definable, contradiction.

Then by compactness theorem, there is some f.m. sentences of $\Gamma$ that is unsatisfiable, thus the conclusion follows.

Prop.(1.2.7.18)[Cell Decomposition]. Let $F$ be a real closed field, then any semialgebraic set $X \subset F^m$ is a finite disjoint union of cells.

Proof: Cf.[Marker, P103].

8 $O$-Minimal Structures

Cf.[O-Minimal Structures].

Def.(1.2.8.1)[O-Minimal Structure]. An ordered structure is called $o$-minimal if any definable set is a finite union of intervals with endpoints in $M \cup \{\pm \infty\}$ and points.

Def.(1.2.8.2)[General O-Minimal Expansions]. A structure expanding the real closed field $R$ is a collection $\mathcal{S} = (\mathcal{S}^n)$, where $\mathcal{S}^n$ is a family of subsets of $R^n$, that

- Algebraic subsets are in $\mathcal{S}$.
- Each $\mathcal{S}^n$ is a Boolean subalgebra of the powerset of $R^n$.
- $\mathcal{S}$ is stable under Cartesian product and projection.

And $\mathcal{S}^n$ are called the definable subsets of $R^n$. And this structure is called $o$-minimal if moreover each subset in $\mathcal{S}^1$ is a finite unions of intervals and points.
2  Algebras

2.1 Group Theory

Main References are [Finite Groups, Issac], [Lan05] and [代数学引论，丁石孙].

1 Notations

Notations(2.1.1.1). • Use notations defined in ??.

2 Magmas

Def.(2.1.2.1)[Binary Operators]. A binary operator on a set $X$ is a map $\circ : X \times X \to X$.

Def.(2.1.2.2)[Unital Operator]. A unital binary operator on a set $X$ is a map $\circ : X \times X \to X$ that has a left and right identity element $1_\circ$.

Prop.(2.1.2.3)[Associative Operators]. An associative operator on a set $X$ is an operator $\circ : X \times X \to X$ s.t. $(x \circ y) \circ z = x \circ (y \circ z)$ for any $x, y, z \in X$.

Def.(2.1.2.4)[Magma]. A magma is a set $X$ with a binary operator $\circ : X \times X \to X$. A unital magma is a magma that the operator is unital. It is called Abelian if $x \circ y = y \circ x$ for any $x, y \in X$.

Prop.(2.1.2.5)[Eckmann-Hilton argument]. If $\circ$ and $\otimes$ are two unital binary operators on a set that commute with each other: $(a \otimes b) \circ (c \otimes d) = (a \circ c) \otimes (b \circ d)$, then they are equal and in fact commutative and associative.

Proof: Firstly the units coincide, because

$$1_\circ = 1_\circ \circ 1_\circ = (1_\otimes \circ 1_\otimes) \circ (1_\otimes \circ 1_\otimes) = (1_\circ \circ 1_\circ) \circ (1_\circ \circ 1_\circ) = 1_\otimes \otimes 1_\otimes = 1_\otimes.$$  

Next

$$a \circ b = (1 \otimes a) \circ (b \otimes 1) = (1 \circ b) \otimes (a \circ 1) = b \otimes a = (b \circ 1) \otimes (1 \circ a) = (b \otimes 1) \circ (1 \otimes a) = b \circ a.$$  

Thus $\circ$ and $\otimes$ coincide and are commutative. Finally for associativity:

$$(a \otimes b) \otimes c = (a \otimes b) \otimes (1 \otimes c) = (a \otimes 1) \otimes (b \otimes c) = a \otimes (b \otimes c).$$  

□

Def.(2.1.2.6)[Monoid]. A monoid is an associative unital magma $(X, \circ)$.

3 Groups

Def. (2.1.3.1) [Groups]. The category of Groups is denoted by $\mathfrak{G}_{\text{rp}}$.

Def. (2.1.3.2) [Generators]. Let $G \in \mathfrak{G}_{\text{rp}}$ and $S \subset G$, then $S$ is said to be a set of generator for $G$ if the only subgroup of $G$ containing $S$ is $G$.

Def. (2.1.3.3) [Normal Subgroups]. A normal subgroup of a group $G$ is a subgroup $N$ that if $x \in G$, then $x^{-1}N x = N$.

Def. (2.1.3.4) [Simple Groups]. A simple group is a group that has no normal subgroups.

Def. (2.1.3.5) [Finitely Generated Group]. A group $G$ is called finitely generated if there is a finite subset $S$ that the only subgroup containing $S$ is $G$ itself.

Def. (2.1.3.6) [Product Subgroups]. Let $G$ be a group and $N, H$ be subgroups such that $N$ is normal in $G$, then $NH = \{x \in G | x = nh, n \in N, h \in H\}$ is a subgroup of $G$, called the product subgroup.

Def. (2.1.3.7) [Coset]. Let $G$ be a group and $H$ a subgroup. Consider the equivalence relation on $G$ s.t. $x \sim y$ iff $x = yh$ for some $h \in H$, then the equivalence classes is denoted by $G / H$, called the right coset of $H$ in $G$. And $G$ acts on this set by left translation.

Prop. (2.1.3.8) [Fundamental Isomorphisms]. Let $G$ be a group and $N, H$ be subgroups such that $N$ is normal in $G$, then

- there is a natural isomorphism $G / NH \cong (G / N) / (H / H \cap N)$ as sets, and if $H$ is also normal, this is an isomorphism of groups.
- there is a natural isomorphism of groups: $H / N \cap H \cong NH / N$.

Proof: 1: Consider the natural isomorphism $N \mapsto NH / H : n \mapsto nH$, then it is a group homomorphism, and the kernel is $N \cap H$, thus we are done.

Cor. (2.1.3.9). if $H_1, H_2$ are subgroups of a group $G$ that has finite indexes, then $H_1 \cap H_2$ also has finite index in $G$.

Prop. (2.1.3.11). If a finite group $G$ has an automorphism $\alpha$ that $\alpha^2 = id$ and $\alpha$ has no fixed point other than $e$, then $G$ is an Abelian group of odd order.
Proof: $G$ is clearly of odd order. Consider the map $g \mapsto \alpha(g)g^{-1}$, then it is injective, hence it is also surjective, and consider $\alpha(\alpha(g)g^{-1}) = g\alpha(g)^{-1} = (\alpha(g)g^{-1})^{-1}$, thus $\alpha(h) = h^{-1}$ for all $h \in G$, thus clearly $G$ is Abelian. \hfill \Box

Prop.(2.1.3.12). If $H$ is a subgroup of a finite group $G$, then $G \neq \bigcup g^{-1}Hg$.

Proof: There are at most $|G\lhd H|$ different summands in the right hand side, so it doesn’t have enough elements. \hfill \Box

Prop.(2.1.3.13). If $G$ is a f.g. group\(^{(2.1.3.5)}\) and $H$ is a group of finite index in $G$, then $H$ is f.g.

Proof: Suppose $G$ has generators $g_i$, we may add their inverses to it, and let $Ht_1, \ldots, Ht_m$ are all the right cosets with $t_1 = 1$, then there are $h_{ij}$ that $t_i g_j = h_{ij} t_{kij}$, then we claim $H$ is generated by $h_{ij}$.

For this, consider any $h = \prod g_i$, then $g_1 = h_{1t} t_{k_1t}$, and we can do this from left to right. Now $h = \prod h_{i_{ij}} t_o$, then $t_o$ must by 1, and we are done. \hfill \Box

Prop.(2.1.3.14). Let $\varphi : G \to H$ be a map of sets between groups s.t. $\# \text{Im}(\varphi) = \infty$, and for each $g \in G$, there is a set $S(g) \in H$ that $\varphi(h)\varphi(g) = \varphi(hg)$ for any $h$ s.t. $\varphi(h) \notin S(g)$, then $\varphi$ is a homomorphism.

Proof: For $g, h \in G$, take $f$ s.t. $\varphi(f) \notin S(g) \cup \varphi(g)^{-1} S(h) \cup \{\varphi(gh)\}$. Then

$$\varphi(f)\varphi(g)\varphi(h) = \varphi(fg)\varphi(h) = \varphi(fgh) = \varphi(f)\varphi(gh),$$

thus $\varphi(g)\varphi(h) = \varphi(gh)$. \hfill \Box

4 Abelian Groups

Remark(2.1.4.1). An Abelian group is the same as a module over $\mathbb{Z}$. Thus the theory of commutative algebra applies in this case.

Prop.(2.1.4.2)[Abelianization]. There is a functor from the category of Abelian semi-groups to the category of Abelian groups that is left adjoint to the forgetful functor, called the Abelianization.

Proof: Define $A'$ to be the quotient

$$\bigoplus_{(a,b) \in A^2} \mathbb{Z} \to \bigoplus_{x \in A} \mathbb{Z} \to A' \to 0,$$

where $1_{(a,b)}$ is mapped to $1_a + 1_b - 1_{a+b}$. Then it can be seen this satisfies the universal property and it is functorial in $A$. \hfill \Box

Prop.(2.1.4.3)[Classifying F.g. Abelian Groups]. Any finitely generated Abelian group is of the form

$$\mathbb{Z}^r \bigoplus_{p_i \text{ primes}} \mathbb{Z}/(p_i^{a_i}),$$

Proof: As $\mathbb{Z}$ is PID, the classifying theorem follows immediately from(2.2.4.21): \hfill \Box
Prop. (2.1.4.4) [Baer-Specker Group]. The group $\prod^N \mathbb{Z}$ is called the Baer-Specker group. Then the natural homomorphism

$$\text{Hom}(\prod^N \mathbb{Z}, \mathbb{Z}) \to \prod^N \mathbb{Z}$$

is injective with image $\bigoplus^N \mathbb{Z}$. In particular, by countability argument, $\prod^N \mathbb{Z}$ is not a free group (4.3.1.5). Moreover, any infinite direct product of $\mathbb{Z}$ is not free, because otherwise the subgroup $\prod^N \mathbb{Z}$ would be free.

Proof: The natural homomorphism is the composite?

$$\text{Hom}(\prod^N \mathbb{Z}, \mathbb{Z}) \xrightarrow{\text{?}} \text{Hom}(\#^N \mathbb{Z}, \mathbb{Z}) \xrightarrow{\eta} \prod^N \mathbb{Z}.$$ 

Thus the assertion follows from (2.1.6.6) and (2.1.6.5).

□

Remark (2.1.4.5). This can be proven in other ways, like using condensed mathematics.

Forms on Abelian Groups

Def. (2.1.4.6) [Quadratic Forms]. For $A \in \text{Ab}$, a function $d : A \to \mathbb{R}$ is called a quadratic form if

- $d(\alpha) = d(-\alpha)$ for any $\alpha \in A$.
- The form $B_d : A \times A \to \mathbb{R}$ $(\alpha, \beta) \mapsto [d(\alpha + \beta) - d(\alpha) - d(\beta)]/2$ is bilinear.

It is called positive semi-definite if moreover $d(\alpha) \geq 0$. And positive-definite if moreover $d(\alpha) = 0 \iff \alpha = 0$.

Prop. (2.1.4.7) [Cauchy-Schwartz]. Let $A$ be an Abelian group and $d$ a positive semi-definite quadratic form over $A$, then

$$|d(\alpha - \beta) - d(\alpha) - d(\beta)| \leq 2\sqrt{d(\alpha)d(\beta)}.$$ 

Proof: Consider the bilinear form $B_d$, then

$$0 \leq d(m\alpha - n\beta) = m^2d(\alpha) + n^2d(\beta) - 2mnB_d(\alpha, \beta).$$

This is true for any $m, n \in \mathbb{Z}$, thus the discriminant $B_d(\alpha, \beta)^2 \leq d(\alpha)d(\beta)$. □

Prop. (2.1.4.8). If $M, N$ are Abelian groups and $d$ is a quadratic form on $M \times N$ s.t. $d(0 \times N) = d(M \times 0) = 0$, then $d$ is bilinear in both $M$ and $N$.

Proof: The bilinear form associated to $d$ satisfies $B_d((a, 0), (0, b)) = d(a, b)$, thus it is clear $d$ is bilinear in $M$ and $N$. □

Def. (2.1.4.9) [Polarization]. Let $\Gamma$ be an Abelian group and $h : \Gamma \to \mathbb{R}$ is a function, then the $r$-th polarization function $P_r(h) : \Gamma^r \to \mathbb{R}$ is defined to be

$$P_r(h)(x_1, \ldots, x_r) = \frac{1}{r!} \sum_{I \subseteq \{1, \ldots, r\}} (-1)^{r - \#I} \prod_{i \in I} x_i.$$ 

Lemma (2.1.4.10).
Proposition 2.1.4.11. There is a natural isomorphism of additive groups

\[ \bigoplus_{j=0}^{r-1} \text{Sym}^j \Gamma^r \cong \{ h : \Gamma \to \mathbb{R} \mid P_r(h) = 0 \} : (A_0, \ldots, A_{r-1}) \mapsto \sum_{i=0}^{r-1} \Delta A_i. \]

Proof: This is an injective map by (2.1.4.10), and for any \( h \) that \( P_r(h) = 0 \), By (2.1.4.10) item 1, this means \( A_{r-1} = P_{r-1}(h) \in \text{Sym}^{-1}\Gamma^r \). Let \( h' = h - \Delta A_{r-1} \), then (2.1.4.10) item 4 shows \( P_{r-1}(h') = 0 \), thus we can use induction to show \( h' = \sum_{i=1}^{r-2} \Delta A_i \), thus \( h = \sum_{i=1}^{r-1} \Delta A_i \).

Proposition 2.1.4.12. Let \( \Gamma \) be an Abelian group, for functions \( h_1, h_2 : \Gamma \to \mathbb{R} \), let \( h_1 = h_2 + O(1) \) denote the fact that \( |h_1 - h_2| \) is bounded on \( \Gamma \). Then there is a natural isomorphism of additive groups:

\[ \bigoplus_{j=0}^{r-1} \text{Sym}^j \Gamma^r \cong \{ h : \Gamma \to \mathbb{R} \mid P_r(h) = O(1) \} / O(1) : (A_0, \ldots, A_{r-1}) \mapsto h(x) = A_0 + A_1(x) + \ldots + A_{r-1}(x, \ldots, x). \]

Proof: The map is injective by (2.1.4.11). To show surjectivity:

By hypothesis and (2.1.4.10), there exists \( C > 0 \) s.t.

\[ |P_{r-1}(h(x_0 + x_1, x_2, \ldots, x_{r-1}) - P_{r-1}(h(x_0, x_2, \ldots, x_{r-1}) - P_{r-1}(h(x_1, x_2, \ldots, x_{r-1})| \leq C. \]

So

\[ |P_{r-1}(h(2^N x_1, x_2, \ldots, x_{r-1}) - 2P_{r-1}(h(2^{N-1} x_1, x_2, \ldots, x_{r-1})| \leq C \]

for any \( N \), and by iterating,

\[ |P_{r-1}(h(2^N x_1, 2^N x_2, \ldots, x_{r-1}) - 2^{r-1}P_{r-1}(h(2^{N-1} x_1, 2^{N-1} x_2, \ldots, 2^{N-1} x_{r-1})| \leq (2^{r-1} - 1)C. \]

Thus

\[ A_{r-1}(x_1, \ldots, x_{r-1}) = \lim_{N \to \infty} \frac{P_{r-1}(h(2^N x_1, 2^N x_2, \ldots, x_{r-1})}{2^{N(r-1)}} \]

exists, and it is clear that \( A_{r-1} \in \text{Sym}^{r-1}\Gamma^r \) and \( A_{r-1}(x_1, \ldots, x_{r-1}) - P_{r-1}(h(x_1, \ldots, x_{r-1}) \leq 2^{r-1}C. \)

Let \( h' = h - \Delta A_{r-1} \), then \( P_{r-1}h' = P_{r-1}h - A_{r-1} = O(1) \), thus we can use induction to show \( h' = \sum_{i=1}^{r-2} \Delta A_i + O(1) \), thus \( h = \sum_{i=1}^{r-1} \Delta A_i + O(1) \).

Corollary 2.1.4.13. Let \( \Gamma \) be an Abelian group and \( h : \Gamma \to \mathbb{R} \) be a function on an Abelian group \( \Gamma \) that

\[ h(\sum_{i=1}^{3} x_i) = \sum_{1 \leq i < j \leq 3} h(x_i + x_j) - \sum_{i=1}^{3} h(x_i) + O(1), \]

then there exists a unique symmetric bilinear pairing \( b \) on \( \Gamma \) and \( l \) a homomorphism \( \Gamma \to \mathbb{R} \), that

\[ h(x) = \frac{1}{2} b(x, x) + l(x) + O(1). \]
Prop.\,(2.1.4.14). Let $M$ be an Abelian group and $b : M \times M \to \mathbb{R}$ is a bilinear form on $M$ that $\text{rad}(B) = 0$, so $b$ defines a bilinear form on $B_\mathbb{Z} : M \otimes \mathbb{Z} \to \mathbb{R}$. Then $b_\mathbb{R}$ is positive-definite iff for any f.g. subgroup $M'$ of $M$ and $C > 0$, $\{ x \in M' | b(x, x) \leq C \}$ is finite.

Proof: We may assume $M$ is f.g.. As $M/M_{\text{tor}}$ is torsion-free, it is a lattice in $M_\mathbb{R}(1.2.3.29)$. Assume $b_\mathbb{R}$ is positive-definite, then it defines a topology on $M_\mathbb{R}$, then $\{ x \in M' | b_\mathbb{R}(x, x) \leq C \}$ is finite because it is a compact discrete set.

Conversely, if $\{ x \in M' | b(x, x) \leq C \}$ is finite and $b_\mathbb{R}$ is not positive-definite, then it is at least semi-positive definite. If $b_\mathbb{R}(y, y) = 0$, then by Cauchy-Schwartz inequality (2.1.4.7), $y$ is in the radical of $b_\mathbb{R}$. By hypothesis $y \notin M_\mathbb{Q}$.

Now choose a basis $e_1, \ldots, e_n$ of $M$, for any $n > 1$, there is a $y_n \in M$ s.t.

$$y_n - ny \in S = \{ \sum \alpha_i e_i | 0 \leq \alpha_i \leq 1 \},$$

and we can use induction.

$$b_\mathbb{R}(y_n, y_n) = b_\mathbb{R}(y_n - ny, y_n - ny)$$

is bounded by the maximal value of $b_\mathbb{R}$ on $S$. These $y_n$ are all different because $y \notin M_\mathbb{Q}$, thus contradicting the hypothesis. \hfill \Box

Prop.\,(2.1.4.15). Let $M \in \text{Ab}$ s.t. $\#M/\#M < \infty$ for some $n \geq 2$ and there is a positive semi-definite symmetric bilinear form $B$ on $M$ s.t. $\{ x \in M | B(x, x) \leq C \}$ is finite for any $C > 0$, then $M$ is f.g..

Proof: Choose a set of generators $\{ x_i \}$ for $M/\#M$. Now there is a constant $C$ that whenever $(x, x) \geq C$,

$$(x - x_i, x - x_i) < 2(x, x), \forall i,$$

because by Cauchy-Schwartz inequality (2.1.4.7), $(x - x_i, x - x_i)$ is similar to $(x, x)$ when $(x, x)$ is large.

Now let $\Gamma = \{ x_1, \ldots, x_s \} \cup \{ x \in \Gamma | (x, x) < C \}$. Then $\Gamma$ is finite by hypothesis. We prove $\Gamma$ generates $M$: Consider the infimum $C_0$ of $(x, x)$ that $x$ is not generated by $M$, then there is a $x$ that $C_0 \leq (x, x) < 2C_0$. Obviously $C_0 \geq C$. Let $x = x_i + ny$ for some $x_i \in \Gamma, y \in M$, then

$$(y, y) = \frac{1}{n^2}(x - x_i, x - x_i) < \frac{2}{n^2}(x, x) \leq \frac{1}{2}(x, x) < C_0.$$

Thus by minimality of $C_0$, $y \in \Gamma$, thus $x \in \Gamma$. \hfill \Box

Def.\,(2.1.4.16)[Lagrangian Decomposition]. Let $A$ be a f.g. Abelian group and $\Gamma : A \times A \to \mathbb{Q}/\mathbb{Z}$ is a bilinear alternating non-degenerate pairing, then a Lagrangian decomposition of $A$ is an Abelian subgroup $B \subset A$ s.t. $\Gamma|_B = 0$, called an isotropic subgroup of $A$, such that $A \cong B \oplus \hat{B}$, and $\Gamma$ is given by

$$\Gamma((x, \chi), (y, \psi)) = \chi(y) \psi(x)^{-1}.$$

Prop.\,(2.1.4.17). Let $A$ be a f.g. Abelian group and $\Gamma : A \times A \to \mathbb{Q}/\mathbb{Z}$ is a bilinear alternating non-degenerate pairing, then $A$ admits a Lagrangian decomposition.

In particular, if $\#A < \infty$, then $\#A$ is a perfect square.

Proof: Because $A$ is f.g., take $x, y$ in $A$ s.t. $\Gamma(x, y)$ has the maximal denominator, then it is easy to see that for any $z \in A$, $z - ax - by \in \text{span}(x, y)_\perp$ for some $a, b \in \mathbb{Z}$, so $A = \text{span}(a, b) \oplus \text{span}(a, b)_\perp$, and we can use induction. \hfill \Box
Finite Abelian Groups

**Prop.(2.1.4.18)** [Characterizing Finite Cyclic Groups]. Let \( G \in \text{Ab}^{\text{fin}} \) that \( \#\{x \in G | x^d = 1 \} \leq d \) for any \( d \geq 1 \), then \( G \) is cyclic.

*Proof:* Consider the subset \( G_d \) of elements of order \( d \), if it is non-empty, choose \( y \in G_d \), then \( \# \langle y \rangle \geq d \), thus \( \langle y \rangle = \{ x \in G | x^d = 1 \} \), which means \( \#G_d \leq \varphi(d) \). Then \( |G| = \sum_{d|n} \#G_d \leq \sum_{d|n} \varphi(d) = n \). Thus \( G_n \neq \emptyset \), which means \( G \) is cyclic. \( \square \)

**Cor.(2.1.4.19).** Any finite subgroup of the multiplicative group of a field is cyclic.

5 Automorphism Group

**Prop.(2.1.5.1).** Any group of order \( > 2 \) have at least 2 automorphisms.

*Proof:* Assume the contrary, consider its inner automorphism, then it is Abelian, and then multiplying by \( p \) for \( p \) large prime is not identity, Then \( |G||p - 1 \) for such \( G \). Now it is clear \( |G| = 2 \), because otherwise we can choose \( p \equiv 2 \mod |G| \). \( \square \)

**Def.(2.1.5.2).** A group is called **complete** if all automorphisms of \( G \) are inner.

**Prop.(2.1.5.3).** \( S_n \) is the automorphism group of \( A_n \) for \( n = 5 \) or \( n \geq 7 \).

*Proof:* \( \square \)

**Prop.(2.1.5.4).** If \( G \) is a non-Abelian simple group, then \( \text{Aut}(G) \) is a complete group.

**Prop.(2.1.5.5).** \( S_n \) are complete groups except for \( S_5 \).

*Proof:* \( S_n \) is the automorphism group of \( A_n \) for \( n = 5 \) or \( n \geq 7 \) by(2.1.5.3), thus it is complete by(2.1.5.4). \( \square \)

**Prop.(2.1.5.6)** [Wielandt]. If \( G \) is a finite group with trivial center, then the sequence

\[
G < \text{Aut}(G) < \text{Aut}(\text{Aut}(G)) < \ldots
\]

must terminate in finite steps.

*Proof:* \( \square \)

6 Free Groups and Presentations

**Def.(2.1.6.1)** [Free Groups]. There is a **free group** functor \( F : \text{Set} \rightarrow \text{Grp} \) that is left adjoint to the forgetful functor.

The image of the set \( [n - 1] \) is denoted by \( F_n \).

*Proof:* For the existence of \( F \), Cf.[Lan05]P66. \( \square \)

**Prop.(2.1.6.2)** [Nielsen-Schreier]. A subgroup \( H \) of a free group \( G \) is a free group. Moreover, a subgroup \( H \) of finite index \( m \) in \( F_n \) is isomorphic to \( F_{1 + m(n-1)} \).
Proof: A free group is the fundamental group of a graph $X$ which is a wedge sum of circles, and there is a covering $X_H \to X$ the $\pi_1(X_H) = H$ by (3.11.1.28). And if $H$ is of index $m$ in a free group $G$, $X_H \to X$ has degree $m$ by (19.1.1.5). Now (19.1.1.5) shows $H = \pi_1(X_H)$ is a free group, and the final assertion follows by comparing two ways of counting Euler number $\chi$. □

Prop. (2.1.6.3). Use the same method as in (2.1.6.2), we can determine all the subgroups of index 2 in $F_2$.

Proof: □

Def. (2.1.6.4) [Earring Group]. For any $n \in \mathbb{Z}_+$, there are group homomorphisms $F_n \to F_{n-1}$ corresponding to the map of sets

$$[n-1] \to F_{n-1} : i \mapsto \begin{cases} [i] & , i \leq n-2 \\ 1 & , i = n-1 \end{cases}.$$ 

The Earring group $\#^{\mathbb{N}}\mathbb{Z}$ is defined to be the subgroup of

$$\lim_{\xrightarrow{n \in \mathbb{N}}} F_n$$

consisting of elements $(w_0, w_1, \ldots, w_n, \ldots)$ s.t. if each $w_n$ is a reduced word, then for any $k \in \mathbb{Z}_+$, the number of $[k]^\pm$ appearing in $w_n$ stablizes.

Prop. (2.1.6.5). The natural homomorphism

$$\eta : \text{Hom}(\#^{\mathbb{N}}\mathbb{Z}, \mathbb{Z}) \to \prod_{\mathbb{N}} \mathbb{Z}$$

is injective with image $\oplus^{\mathbb{N}}\mathbb{Z}$.

Prop. (2.1.6.6). There is a natural group homomorphism $\varepsilon : \#^{\mathbb{N}}\mathbb{Z} \to \prod_{\mathbb{N}} \mathbb{Z}$ that is surjective.

Proof: The $k$-th coordinate of this map is given by omitting all the elements that is not $[k]$. It is clearly surjective. □

Prop. (2.1.6.7) [Smith]. $\#^{\mathbb{N}}\mathbb{Z}$ is not a free group.

List of Presentations of Important Groups

Prop. (2.1.6.8). Let $F$ be a field, then $SL(2, F)$ has a representation as:

$$\langle t(y), n(z), w_1 \rangle, \quad y \in F^*, z \in F$$

quotient the relations:

$$t(y_1)t(y_2) = t(y_1y_2), \quad n(z_1)n(z_2) = n(z_1 + z_2), \quad t(y)n(z)t(y)^{-1} = n(y^2z), \quad w_1t(y)w_1 = t(-y^{-1}).$$
\[w_1 n(z) w_1 = t(-z^{-1}) n(-z) w_1 n(-z^{-1}), \ z \in F^*,\]

And the isomorphism is given by \( \Phi \):

\[t(y) \mapsto \begin{bmatrix} y & \ y^{-1} \end{bmatrix}, \ n(z) \mapsto \begin{bmatrix} 1 & z \end{bmatrix}, \ w_1 \mapsto \begin{bmatrix} -1 & 1 \end{bmatrix}.\]

**Proof:** The map vanishes on the relations is direct calculation. An inverse of \( \Phi \) is constructed by

\[\Psi \left( \begin{bmatrix} a & b \\ c & d \end{bmatrix} \right) = \begin{cases} n(a/c) t(-c^{-1}) w_1 n(d/c) & c \neq 0 \\ t(a n(b/a)) & c = 0 \end{cases}\]

The verification of the inverse is verified by direct calculation. □

**Prop.(2.1.6.9).** Let \( F \) be a field, then \( SL(2, F) \) is generated by \( N(F) \) and any element in \( SL(F) \backslash N(F) \).

**Proof:** Take this element in \( G(F) \backslash B(F) \), left and right multiplying by elements in \( N(F) \), we see it contains some \( \begin{bmatrix} a & -a^{-1} \\ \ a^{-1} & 1 \end{bmatrix} \), then it contains \( \begin{bmatrix} a & -a^{-1} \\ \ a^{-1} & 1 \end{bmatrix}^{-1} N(F) \begin{bmatrix} a & -a^{-1} \end{bmatrix} = \begin{bmatrix} 1 & * \\ 0 & 1 \end{bmatrix} \). Then it contains \( N(F) \begin{bmatrix} a & -a^{-1} \end{bmatrix} = \begin{bmatrix} * & -a^{-1} \end{bmatrix} \). Left multiplying by \( \begin{bmatrix} 1 & * \\ 0 & 1 \end{bmatrix} \) and right multiplying by \( N(F) \), we see it contains all diagonal matrices in \( SL(2, F) \). So it contains \( SL(2, F) \), by Bruhat decomposition. □

**Prop.(2.1.6.10).** \( SL(2, \mathbb{Z}) \) is generated by \( S = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, T = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \) with relations

\[S^4 = 1, \quad (ST)^3 = S^2\]

**Proof:** [Serre, Trees, P81]. □

**Cor.(2.1.6.11) [Modular Group].** \( PSL_2(\mathbb{Z}) = SL_2(\mathbb{Z})/\{\pm 1\} \) is generated by \( S = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, T = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \) with relations

\[S^2 = 1, \quad (ST)^3 = 1.\]

**Prop.(2.1.6.12) [Braid Group].** The **Braid group** \( B_n \), defined by \( B_n = \pi_1(\mathbb{C}^n \backslash \bigoplus \{z_i = z_j\}/S^n) \) has a presentation by \( b_i, i = 1, \ldots, n-1 \) and relations

- if \( |i - j| \geq 2 \), then \( b_i b_j = b_j b_i \),
- \( b_i b_{i+1} b_i = b_{i+1} b_i b_{i+1} \).

**Proof:** □

**Cor.(2.1.6.13) [Pure braids].** Due to the covering map \( \mathbb{C}^n \backslash \bigoplus \{z_i = z_j\} \to \mathbb{C}^n \backslash \bigoplus \{z_i = z_j\}/S^n \) with fiber \( S^n \), there is a map \( B_n \to S_n \) which is easily seen to be surjective and with kernel \( P_n = \pi_1(\mathbb{C}^n \backslash \bigoplus \{z_i = z_j\}), \) called the group of **pure braids**.

**Prop.(2.1.6.14).** There is a group homomorphism \( B_3 \to PSL_2(\mathbb{Z}) \) that maps \( a = \sigma_1 \sigma_2 \sigma_1 \) to \( S \) and \( b = \sigma_1 \sigma_2 \) to \( T \). The kernel of this map is the group generated by \( c = a^2 = b^3 \).
7 Sylow Theory

Prop. (2.1.7.1) [Class Equation]. For a finite group $G$, if $G_x = C((x))$, then

$$|G| = |C(G)| + \sum |G|/|G_x|$$

where the summation is over non-trivial conjugate classes of $G$.

*Proof:* Consider the left action of $G$ on itself, and calculate elements. □

Cor. (2.1.7.2) [$p$-Groups are Solvable]. If $G$ is a $p$-group, then $G$ has a non-trivial center. In particular, any $p$-group is solvable.

Cor. (2.1.7.3). If $p||G|$, then $G$ has an element of order $p$.

*Proof:* Follows from Sylow theory and any $p$-group has a non-trivial center. □

Lemma (2.1.7.4). For any $p$-group $G$ acting on a finite set $X$, $|X| \equiv X^G \mod p$ (trivial).

Prop. (2.1.7.5) [Sylow Theorem]. For a finite group of order $|G| = p^k m$.

- There is a Sylow $p$-group.
- For a Sylow $p$-subgroup, any $p$-subgroup is contained in a conjugate of $P$. In particular, any two Sylow $p$-subgroups are conjugate.
- The number of Sylow $p$-groups $n_p$ satisfies: $n_p|m, n_p \equiv 1 \mod p$.

*Proof:* 1: Use induction, let $Z = C(G)$, if $p||Z|$, then $Z$ contains a cyclic group of order $p$. Choose a $p$-Sylow subgroup of $G/C$, then its inverse image in $G$ is a $p$-Sylow subgroup. If $Z$ is prime to $p$, consider the conjugate action of $G$ on $G - Z$, then some conjugacy class has order prime to $p$, by (2.1.7.4), then the stabilizer $H$ of this class satisfies $|G : H|$ is prime to $p$. Thus $H$ contains a $p$-Sylow subgroup by induction.

2: If $Q$ is a $p$-subgroup, then $Q$ acts on $G/P$ by left translation, so it has a fixed element by (2.1.7.4), $QxP = xP$ for some $x$, thus $Q \subseteq xPx^{-1}$.

3: $n_p|m$ by considering the conjugate action of $P$ on the set of conjugates of $P$, then as in the proof of item 2, $P$ is the only fixed element, so $n_p \equiv 1 \mod p$ by (2.1.7.4). □

Lemma (2.1.7.6). If $G$ has a sylow subgroup $H$ that $|G/H|!$ is not divisible by $|G|$, then $G$ is not simple.

*Proof:* Consider the conjugate action of $G$ on the conjugacy classes of $H$, then it is a group homomorphism of $G$ into a subgroup of $S_{|G/H|}$, but the hypothesis shows that it is not injective, thus the kernel is non-trivial normal. □

Prop. (2.1.7.7) [Frattini Argument]. If $G$ is a finite subgroup, $N$ is normal in $G$ and $P$ is a Sylow subgroup of $N$, then $NN_G(P) = G$.

*Proof:* For any element $g \in G$, consider $g^{-1}Pg \subset N$ is a Sylow subgroup of $N$, thus by Sylow theorem (2.1.7.5), there is a $n \in N$ that $g^{-1}Pg = n^{-1}Pn$, thus $gn^{-1} \in N_G(P)$, thus $g \in NN_G(P)$. □

8 Split Extension

Prop. (2.1.8.1) [Cyclic Central Extension Split]. If there is an exact sequence $0 \to \mathbb{Z} \to G \to C \to 0$ where $\mathbb{Z} \subset C(G)$ and $C$ is cyclic, then $G$ is Abelian.

Proof: This is because we can choose an inverse image of a generator of $C$. □

Prop. (2.1.8.2) [Schur-Zassenhaus]. An exact sequence of finite groups $0 \to A \to E \to G \to 0$ must split when $|A|$ and $|G|$ are relatively prime.

Proof: □

Prop. (2.1.8.3). Let $\alpha, \beta : G \to \text{Aut}(H)$ be two actions of $G$ on $H$, then theirs semiproduct sequences

$$1 \to H \to G \rtimes H \to G \to 1$$

are isomorphic iff $\alpha, \beta$ are equivalent modulo $\text{Inn}(H)$.

9 Subnormality

Def. (2.1.9.1) [Normal Series]. A subnormal series of a group $G$ is a descending chain of groups:

$$G = G_0 \triangleright G_1 \triangleright \ldots \triangleright G_r = \{e\}$$

that $G_{k+1}$ is normal in $G_k$. It is called a composite series iff each $G_k/G_{k+1}$ is simple.

Lemma (2.1.9.2) [Butterfly Lemma]. Let $H_1, H_2$ be subgroups of a group $G$, $N_1, N_2$ are normal subgroups of $H_1$ and $H_2$, then there is a canonical isomorphism of groups:

$$N_1(H_1 \cap H_2)/N_1(H_1 \cap N_2) \cong N_2(H_2 \cap H_1)/N_2(H_2 \cap N_1).$$

Prop. (2.1.9.3) [Schreier]. Any two subnormal series of a group $G$ have a common refinement.

Proof: □

Cor. (2.1.9.4) [Jordan-Hölder]. For any two composition series $G = G_0 \triangleright G_1 \triangleright \ldots \triangleright G_r = \{e\}$, $G = G'_0 \triangleright G'_1 \triangleright \ldots \triangleright G'_{r'} = \{e\}$, there $r = r'$, and there exists a permutation $\sigma \in S_{r-1}$ s.t. $G_i/G_{i+1} \cong G'_{\sigma(i)}/G'_{\sigma(i)+1}$.

Def. (2.1.9.5) [Central Series]. A central series of a group $G$ is an ascending chain of groups:

$$\{e\} = Z_0 < G_1 < \ldots < G_r = G$$

that $Z_{k+1}/Z_k$ is in the center of $G/Z_k$.

Prop. (2.1.9.6). A group is

- solvable iff it has a normal series that $G_i/G_{i+1}$ is Abelian.
- nilpotent iff it has an upper central series.

Proof: □
Def. (2.1.9.7) [Supersolvable Groups]. A group $G$ is called a **supersolvable group** iff it has a normal series that $G_i/G_{i+1}$ is cyclic.

If $G$ is finite, this notion is equivalent to solvable.

**Lemma (2.1.9.8) [p-Group is Nilpotent].** Any $p$-group is nilpotent.

**Proof:** Using induction by (2.1.7.2), we see it has a central series, thus nilpotent (2.1.9.6). □

**Prop. (2.1.9.9) [Nilpotent Finite Groups].** If $G$ is a finite group, then the following are equivalent:

- $G$ is nilpotent.
- $N_G(H) > H$ for every proper subgroup $H < G$.
- Every maximal subgroup of $G$ is normal.
- Every Sylow subgroup of $G$ is normal.
- $G$ is a direct product of its non-trivial Sylow subgroups.

**Proof:**

1 $\rightarrow$ 2: Choose a central series $Z_n$, let $Z_n \subset H$ and $Z_{n+1} \not\subset H$, then $[Z_{n+1}, H] \subset [Z_{n+1}, G] \subset Z_{n+1} \subset H$, thus $Z_{n+1} \subset N_G(H)$.

2 $\rightarrow$ 3, 4 $\rightarrow$ 5: trivial.

3 $\rightarrow$ 4 For any $p$-Sylow subgroup $G$, if $N_G(P)$ is proper subgroup, then it is contained in some maximal subgroup $M$, and $M$ is normal, thus by Frattini argument (2.1.7.7), $G = N_G(P)M = M$, contradiction.

5 $\rightarrow$ 1: By lemma (2.1.9.8). □

**Prop. (2.1.9.10) [Jordan-Horder].** For a finite group $G$, any two of its composite series has the same length, then the quotient groups $G_k/G_{k+1}$ are in bijection with each other as sets.

**Proof:** Cf. [代数学引论 P89]. □

**Prop. (2.1.9.11) [Minimal Normal Subgroup].** The minimal normal subgroup $N$ of a finite group $G$ is a direct product of simple groups $L^n$.

**Proof:** Let $N_1$ be a maximal normal subgroup of $N$, then $N/N_1$ is simple, and let $N_i$ be the conjugates of $N_1$ in $G$, then they are all maximal normal subgroup of $N$. the simple groups $N/N_i$ are mutually isomorphic, and $\cap N_i = 1$ by the minimality of $N$.

Now we use induction to prove $N/N_1 \cap \ldots \cap N_i$ is isomorphic to a product of $N/N_1$, which will finish the proof.

Now assume $N_1 \cap \ldots \cap N_{i-1} \not\subset N_i$, then $(N_1 \cap \ldots \cap N_{i-1})N_i = N$, and notice

$N/N_1 \cap \ldots \cap N_i \cong N_1 \cap \ldots \cap N_{i-1}/N_1 \cap \ldots \cap N_i \cong N_1 \times N_i \times N_1 \cap \ldots \cap N_i \cong N/N_1 \times N/N_1 \cap \ldots \cap N_i.$

□

**Prop. (2.1.9.12).** If a finite group $|G| = \prod p_i$, where $p_i$ are different primes that $\prod p_i$ and $\prod (p_i - 1)$ are coprime, then $G$ is cyclic.

**Proof:** We prove all the Sylow groups are normal. Choose the maximal Sylow group $A_n$, then it is normal by Sylow theorem, and other Sylow groups act by conjugation is trivial (consider the center (2.1.7.2), then the center of the quotient, and so on), hence $A_n$ is in the center. Now consider the quotient, by induction it is cyclic, hence this is a central extension of a cyclic group, hence $G$ is Abelian (2.1.8.1), so cyclic. □
Prop. (2.1.9.13). If $G$ is a finite group and $p$ is the minimal prime number of $|G|$, then all subgroups $N$ of $G$ of index $p$ is normal.

Proof: Consider the left action of $G$ on $G/H$, then the kernel is $\cap a^{-1}Ha$, which is the maximal normal subgroup contained in $H$. Now this is group homomorphism of $G$ into $S_p$, thus it has kernel at lest $|G|/p$, so the kernel equals $H$, showing $H$ is normal. □

Prop. (2.1.9.14) [Burnside’s Theorem]. If $p, q$ are primes, then any finite groups of order $p^aq^b$ is solvable.

Proof: Cf. [Serre Linear representations of finite groups, P65]. □

Prop. (2.1.9.15) [Thompson]. A finite group is not solvable iff there exist non-trivial elements $x, y, z$ of coprime orders $a, b, c$ that $xy = z$.

Prop. (2.1.9.16) [Feit-Thompson]. All finite groups that has odd order is solvable.

Proof: □

10 Commutators

Def. (2.1.10.1) [Notation].
- $[a, b] = a^{-1}b^{-1}ab$.
- $x^y = y^{-1}xy$.

Prop. (2.1.10.2) [Commutator relations].

Def. (2.1.10.3) [Metabelian Groups]. A metabelian group is a group $G$ that $G'$ is Abelian.

Prop. (2.1.10.4). If $G = AB$ where $A, B$ are Abelian, then $[G, G] = [A, B]$ and $G$ is metabelian.

Proof: The first one is easy to verify, the second because if we let $b^{a_1} = a_2b_2$, $a^{b_1} = b_3a_3$, then

$[a, b]^{a_1b_1} = [a, b^{a_1}]^{b_1} = [a, b]^{b_1} = [a^{b_1}, b_2] = [a_3, b_2]$

and similarly, $[a, b]^{b_1a_1} = [a_3, b_2]$, so we have $[a, b]$ commutes with $[b_1^{-1}, a_1^{-1}]$, which shows $[A, B]$ is Abelian. □

Prop. (2.1.10.5). If $G$ is a metabelian finite group, then the transfer of $Ver: G \rightarrow G'$ is trivial map.
13 Classification of Finite Groups

Thm.(2.1.13.1)[Classification of Finite Simple Groups]. Every finite simple group is one of the following:

- $\mathbb{Z}/(p)$.
- $A_n$.
- 16 infinite family of finite groups of Lie type.
- 26 exceptional groups, called sporadic simple groups.

Proof: A full list is in https://brauer.maths.qmul.ac.uk/Atlas/v3/? □

Prop.(2.1.13.2)[Monster Group]. The largest sporadic simple group is called the Monster group $M$.

$$\#M = 2^{46} \cdot 3^{20} \cdot 5^9 \cdot 7^6 \cdot 11^2 \cdot 13^3 \cdot 17 \cdot 19 \cdot 23 \cdot 29 \cdot 31 \cdot 41 \cdot 47 \cdot 59 \cdot 71.$$  □

Prop.(2.1.13.3)[Happy Family]. There are 20 sporadic groups appearing as a subquotient of $M$, and they form a set called the happy family. The remaining 6 groups are known as the pariah groups, including the Lyons group, Janko groups $J_1, J_3, J_4$, Rudvalis group and the O’Nan group $ON$.

Prop.(2.1.13.4)[Baby Monster Group]. The second largest sporadic simple group is called the baby Monster group $B$.

Def.(2.1.13.5)[O’Nan Group].

Prop.(2.1.13.6). The O’Nan group has size

$$\#ON = 2^9 \cdot 3^4 \cdot 5 \cdot 7^3 \cdot 11 \cdot 19 \cdot 31.$$  □

Prop.(2.1.13.7)[Classification of Small Groups].

1. A group $G$ of prime order $p$ or order $p^2$ is Abelian.
2. A group $G$ of order $p^a q^b$ that it has $q^b$ $p$-Sylow subgroups, then its $q$-Sylow subgroup is normal thus it is not simple.
3. A non-Abelian group $G$ of order 6 is isomorphic to $S_3$.
4. Any non-Abelian group of order 8 is isomorphic to $D_4$ or quadratic numbers $Q$.
5. A group of order smaller than 60 is solvable.
6. Any simple group $G$ of order 60 is isomorphic to $A_5$.
7. A group of order 148 is not simple, by (2.1.7.6) applied to the 37-Sylow subgroup.
8. A group of order 150 is not simple, by (2.1.7.6) applied to the 5-Sylow subgroup.

Proof:  
1. Because $G$ has non-trivial center $Z$ by (2.1.7.2), if $Z = G$, then it is Abelian, otherwise the $|Z| = p$, and the quotient $G/Z$ is cyclic, thus $G$ is Abelian by (2.1.8.1).
2. Calculating elements.

3. Consider its normal 3-Sylow group, then the quotient is cyclic thus $G$ is semi-product which must by $S_3$ when non-Abelian.

4.

5.

6. Consider $G$ has 6 5-Sylow groups, thus there are 24 elements of order 5.
$G$ has 4 or 10 3-Sylow subgroups, if it have 4 3-Sylow subgroups, then the normalizer contains a 5-Sylow subgroup, so we have a subgroup of order 15, which must by $\mathbb{Z}/15$, so it contains a normal 5-Sylow subgroup, which shows there are at most $60/15 = 4$ 5-Sylow subgroups, contradiction.
So we have 10 3-Sylow subgroups, which shows there are at most 15 elements of order 2 or 4. So we have 3 or 5 2-Sylow subgroups. If it is 3, then we can do the same as that for 3-Sylow to construct a 20-order group and reach contradiction.
So now it have 5 2-Sylow subgroups, and then we consider the conjugate action on Sylow subgroups, which is transitive, so it has trivial kernel, and $G \hookrightarrow S_5$. Now $G = [G, G] \subset [S_5, S_5] = A_5$.

Prop.(2.1.13.8). There is a group that is group that $a^3 = 1$ for any $a \in G$, but is not Abelian. It is the uni-upper-triangular matrices in $M_3(\mathbb{F}_3)$.

14 Profinite Groups

Basic references are [Neukirch Cohomology of Number Fields], [Serre Galois Cohomology] [Profinite Groups Zalesskii] and [Shatz Profinite Groups, Arithmetic and Geometry].

Def.(2.1.14.1) [Profinite Groups]. A profinite group is a topological group that is an inverse limit of finite discrete groups.

Lemma(2.1.14.2). For a compact totally disconnected group $G$, any nbhd $U$ of $e$ contains a normal open subgroup.

Proof: $U$ contains a precompact nbhd of $e$, then by(3.8.1.24), $U$ contains an open subgroup $V$, so by(3.8.1.6), there is a nbhd $V'$ of $e$ that $xV'x^{-1} \subset V$ for all $x \in G$, this says $\bigcap x^{-1}Vx$ is open, so it is an open normal subgroup.

Prop.(2.1.14.3)[Profinite Compact and Totally Disconnected]. A profinite group is the same thing as a totally disconnected, compact Hausdorff topological group. In particular, $G \cong \varprojlim G/U$ where $U$ runs over all open normal subgroups of $G$.

Proof: One way is because $\lim G_i$ is a closed subgroup of $\prod G_i$ which by Tychonoff’s theorem is compact.

Conversely, by(2.1.14.2), $G$ has a basis of $e$ consisting of normal open subgroups, and by(3.8.1.23), the intersection of open normal subgroups is $\{e\}$. For any open normal subgroup $N$ of $G$, $G/N$ is compact discrete hence finite, the map $G \rightarrow \varprojlim G/N$ is continuous and has dense image, but $G$ is compact and the right is Hausdorff, so the image is closed, hence it is surjective. It is injective because $\cap N = \{e\}$. Hence $G \cong \varprojlim G/N$. □
Cor. (2.1.14.4). A closed subgroup of a profinite group is profinite, and a quotient group is profinite.

A direct product of profinite groups are profinite, and so the inverse limit profinite groups are profinite, as it is a closed subgroup of a direct product.

Proof: The closed subgroup is totally disconnected by (3.6.1.26).

To show the quotient group is totally disconnected, by (3.8.1.23), it suffice to prove $H$ is intersection of compact open nbhds in $G/H$. If $x \notin H$, then there is an open subgroup $U$ disjoint from $xH$ by (3.8.1.7), so it is closed hence compact. So $UH$ is a compact nbhd of $H$ in $G/H$ that doesn’t contains $xH$, hence the result. □

Cor. (2.1.14.5). A closed subgroup of a profinite group is a intersection of open normal subgroups of $G$ containing it, as $G/H$ is profinite and as in the proof of (2.1.14.3), $H$ is the intersection of open normal subgroups of $G/H$.

Prop. (2.1.14.6). For $G \in \text{Prof}$, if $U_\alpha$ is the system of open normal subgroups of $G$, and $H$ is a closed subgroup of $G$, then there is a natural isomorphism of topological groups

$$H \cong \lim_{\leftarrow} H/H \cap U_\alpha,$$

and if $H$ is normal, then there is a natural isomorphism of topological groups

$$G/H \cong \lim_{\leftarrow} G/HU_\alpha.$$

Prop. (2.1.14.7). Any infinite profinite groups is uncountable.

Proof: [Profinite Groups Zalesskii] Prop2.3.1. □

Prop. (2.1.14.8). The category of profinite Abelian groups is Pontryagin dual to the category of torsion abelian group. (not that hard to verify).

Proof: □

Pro-$p$-Groups

Def. (2.1.14.9) [Surnatural Number]. To consider indexes of closed subgroups of a profinite group, the notion of surnatural numbers are needed. A surnatural number is a formal product $\prod_p p^{n_p}$, $n_p \in \mathbb{N} \cup \{0, \infty\}$.

For a closed subgroup $H$ of a profinite group $G$, $[G : H]$ is defined to be the least common multiple of $[G/U : H/H \cap U]$ where $U$ goes over all open normal subgroups of $G$. This also equals the least common multiple of $[G : V]$ for $V$ open containing $H$ (because for any such $V$, there is an open normal subgroup $U$ that $HU \subset V$ (3.8.1.6)).

Proof: $[G/U : K/K \cap U] = [G/U : H/H \cap U][H/H \cap U : K/K \cap U][G : H][H : K]$, giving one way of inequality. For the converse, Cf.[Etale Cohomology Fulei P150]. The quotient case is trivial. If $[G : H]$ is finite, then For the final assertion, notice for a open subgroup $V$, $G - V$ is compact, so $H_i \subset V$ if $\cap H_i \subset V$ for some $i$.\hfill\Box

Def. (2.1.14.11) [Pro-$p$-Group]. A profinite group $G$ is called a pro-$p$-group iff $[G : 1]$ is a power of $p$.

Given a profinite group, a closed subgroup $H$ is called Sylow pro-$p$-subgroup of $G$ if $H$ is pro-$p$ and $[G : H]$ is prime to $p$.\hfill\Box

Prop. (2.1.14.12). A profinite group $G$ is a pro-$p$-group iff it is an inverse limit of finite $p$-groups. In particular, any finite quotient of a pro-$p$-group is a $p$-group.\hfill\Box

Prop. (2.1.14.13) [Sylow Pro-$p$-Group Exists].\hfill\Box

Prop. (2.1.14.14). Any pro-$p$ subgroup $H$ of $G$ is contained in a Sylow $p$-subgroup of $G$, and any two Sylow $p$-subgroups are conjugate. And a surjective morphism of profinite groups maps a pro-$p$ group to a pro-$p$ group.\hfill\Box

Prop. (2.1.14.15). For a pro-$p$ group $G$, any nonzero simple $p$-torsion $G$-module is isomorphic to $\mathbb{Z}/p\mathbb{Z}$ with trivial $G$-action.\hfill\Box
2.2 Abstract Algebra

References are [Lan05], [Rom07] and [Finite Groups Issac].

This section differs from sections on Commutative Algebras because it contains more basic, but maybe non-commutative properties. This section differs from sections on Group Theory because it concerns objects with more structure than a group.

Notations (2.2.0.1).
- Use notations defined in Group Theory.

1 Rings

Basics

Def. (2.2.1.1) [Rings]. A ring is an Abelian group \((R, +)\) together with a multiplication map 
\[ \times : R \times R \to R \]
s.t.
- \((R, \times)\) is a monoid.
- For any \(x, y, z \in R\),
  \[ x(y + z) = xy + xz, \quad z(x + y) = zx + zy \]

A commutative ring is a ring that the multiplication is commutative. The category of rings is denoted by \(\mathcal{R}\)ing, the category of commutative rings is denoted by \(\mathcal{C}\)Ring.

Def. (2.2.1.2). \(R \in \mathcal{R}\)ing is called
- a simple ring if it has no non-trivial two-sided ideals.
- a domain or an integral ring if whenever \(ab = 0\), \(a = 0\) or \(b = 0\).
- reduced if it has no non-zero nilpotent element.
- Dedekind-finite if for any \(a, b \in R\), \(ab = 1 \Rightarrow ba = 1\).

Def. (2.2.1.3) [Fields]. A field is a commutative ring that every non-zero element has an inverse. The category of fields is denoted by \(\mathcal{F}\)ield.

Prop. (2.2.1.4) [Characteristic]. For \(R \neq 0 \in \mathcal{R}\)ing, there exists at most one \(p \in \mathbb{P}\) s.t. \(p \cdot 1 = 0 \in k\).
If such a \(p\) exists, denote char \(k = p\), otherwise denote char \(k = 0\).

Prop. (2.2.1.5). If \(1 - ab\) is left(right) invertible in a unital ring \(R\), then so is \(1 - ba\), and
\[ (1 - ba)^{-1} = 1 + b(1 - ab)^{-1}a. \]

Proof: Direct Calculation. \(\square\)

Prop. (2.2.1.6) [Kaplansky]. If \(a\) has a right inverse by no left inverse in a ring, then \(a\) has infinitely many right inverses.

Proof: If \(ab = 1\), then in fact \(b + (1 - ba)a^n\) are right inverses for \(a\) for any \(n \geq 0\), and they are distinct, because if \(b + (1 - ba)a^n = b + (1 - ba)a^m\), then \((1 - ba)a^n = (1 - ba)a^m\). And by multiplying \(b\) on the right, we get \((1 - ba)a^{n - m} = 1 - ba\), so \((1 - ba)a^{n - m - 1} + b)a = 1. \(\square\)
2.2. ABSTRACT ALGEBRA

Division Rings

Def. (2.2.1.7)[Division Rings]. A skew field (or division ring) is a unital ring that every non-zero element is invertible (but may not be commutative).

Prop. (2.2.1.8)[Wedderburn]. A finite division ring $D$ is a field.

Proof: Use the class equation for the invertible elements of $D$, if it is not isomorphic, consider the center $Z(D)$ of $D$, let $|Z(D)| = z$, then it is a field, and any other centralizer can be seen as a vector space over $Z(D)$, let it of dimension $k$, then $z^n - 1 = z - 1 + \sum \frac{z^n - 1}{z_k - 1}$. But then let $\Psi_n$ be the cyclotomic polynomial of degree $n$, then $\Psi_n(z)$ divides $z - 1$. But this is not true, as it is bigger. □

Prop. (2.2.1.9). If $D$ is a f.d. division algebra over $\mathbb{R}$, then it is isomorphic to $\mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$.

Proof: Cf. [Advanced Linear Algebra P466]. □

Prop. (2.2.1.10). Let $k \in \text{Field}, k = \mathbb{F}$, then any division ring $A$ over $k$ with dimension $< \#k$ is isomorphic to $k$.

In particular, a division ring $A$ of at most countable dimension over $\mathbb{C}$ is isomorphic to $\mathbb{C}$.

Proof: Notice it suffices to find an eigenvalue of $\varphi: A \to A$ for each $\varphi \in A$. But $\{(\varphi - a)^{-1}\}$ is a uncountable set of elements of $A$, so some $\sum a_i(\varphi - c_i)^{-1} = 0$, spanning the expression, we see $\prod_k(\varphi - \mu_k) = 0$, so some $\varphi - \mu_k = 0$, contradiction. □

Prop. (2.2.1.11)[Hua Equation]. In a division ring $D$, if $a, b \neq 0$ and $ab \neq 1$, then

$$a - (a^{-1} + (b^{-1} - a)^{-1})^{-1} = aba$$

Proof: suffices to show

$$1 = (1 - ab)a(a^{-1} + (b^{-1} - a)^{-1}) = (1 - ab)(1 + a(b^{-1} - a)^{-1}).$$

But this is equal to

$$(1 - ab)(1 - (b^{-1} - a)(b^{-1} - a)^{-1} + b^{-1}(b^{-1} - a)^{-1}) = (1 - ab)(1 - ab)^{-1} = 1.$$ □

Others

Prop. (2.2.1.12). If $R \in \text{Ring}, \#R = p^2$, then $R$ is commutative.

Proof: Consider the center of $R$, it is non-trivial because □

Prop. (2.2.1.13). Let $A, A'$ be $k$-algebras and $B, B'$ subalgebras of $A, A'$ with centralizers $C, C'$, then the centralizer of $B \otimes_k B' \subset A \otimes_k A'$ is $C \otimes_k C'$.

Proof: It suffices to show that $C \otimes_k A' \cap A \otimes_k C' = C \otimes_k C'$, which is clear because they are flat over $k$. □
2 Polynomials

**Prop.(2.2.2.1) [Descartes’s Rule of Sign]**. Let \( p(x) = a_0 x^b_0 + a_1 x^b_1 + \cdots + a_n x^b_n \) be a real polynomial with nonzero \( a_i \), where \( A_0 < B_1 < \cdots < b_n \), then the number of positive roots of \( p(x) \) has the same parity with the number of consecutive changes of signs of \( (a_k)_{k=0,\ldots,n} \).

**Proof**: Lemma: when \( a_0 a_n > 0 \), the number of positive roots are even and when \( a_0 a_n < 0 \), it is odd. This is seen by consider \( p(0) \) and \( p(\infty) \).

Then we consider the derivative \( p' \) and use induction. Denote the number of changing sign by \( v(p) \) and the number of positive roots by \( z(p) \), then if \( z_0 a_1 > 0 \), then \( v(p) = v(p') \) and \( z(p) = \equiv z(p') \mod 2 \).

Then we have \( z(p) = v(p) \mod 2 \) and middle value theorem shows that \( z(p') \leq z(p) - 1 \), hence by induction and parity argument, we have \( v(p) \geq z(p) \).

If \( a_0 a_1 < 0 \), then the same method shows that \( v(p) = v(p') + 1 \geq z(p') + 1 \geq z(p') \) and the have the same parity by the lemma.

**□**

**Cor.(2.2.2.3)**. If \( f(x) = a_n x^n + \cdots + a_0 \), then for any \( n + 1 \) different integers \( a_0, \ldots, a_n \), there exists some \( |f(a_i)| \geq \frac{n!}{2^n}|a_n| \).

**Proof**: Use Lagrange interpolation and consider the leading coefficient.

**□**

**Prop.(2.2.2.4)**. If a degree \( n \) polynomial \( p \) satisfies \( p(n) = 2^n \) for \( n = 0, 1, \ldots, n \), then \( p(n+1) = 2^{n+1} - 1 \).

**Proof**: The polynomial in search is \( p(x) = \sum_{k=0}^{n} \binom{n}{k} \).

**□**

**Prop.(2.2.2.5) [Combinatorial Nullstellensatz]**. If \( F \) is a field, \( a_i \) are \( n + 1 \) elements of \( K \), \( b_i \) are \( n + 1 \) elements of \( K \), then there is a unique polynomial \( f \) of degree no greater than \( n \) that \( f(a_i) = b_i \).

**Proof**: The polynomial in search is \( f(x) = \sum \prod_{j \neq i} b_j - a_j \).

It is a polynomial of degree smaller than \( n + 1 \), and it satisfies the hypothesis. And clearly there is at most one such polynomial, otherwise their difference has \( n + 1 \) zeros.

**□**

**Cor.(2.2.2.6) [Combinatorial Nullstellensatz]**. If \( F \) is a field and \( f \in F[X_1, \ldots, X_n] \) is a polynomial. Let \( S_1, \ldots, S_n \) be nonempty finite subsets of \( F \) and \( g_i = \prod_{s \in S_i} (x_i - s) \), then if \( f \) vanishes at the common zeros of \( g_i \), then there are polynomials \( h_i \in F[X_1, \ldots, X_n] \) that \( \deg h_i \leq \deg F - \deg g_i \) and \( g = \sum g \).

**Proof**: The proof is very simple, just replace terms of \( f \) by lower degree terms, using equation of \( g_i \), then we get a polynomial that has degree in \( x_i \) smaller than \( |S_i| \) and vanish on \( S_1 \times \ldots \times S_n \), so it must be 0, as easily checked.

**□**

**Remark (2.2.2.7)**. For many combinatorial applications of the combinatorial nullstellensatz, Cf.[Combinatorial Nullstellensatz].
Irreducibility

**Prop. (2.2.2.8).** If \( f = a_n x^n + \ldots + a_1 x + p \in \mathbb{Z}[X] \) satisfies \( p \) is a prime and \( \sum |a_i| < p \), then \( f \) is irreducible in \( p \).

**Proof:** The ideal is that all of its roots has norm bigger than 1, because otherwise \( p = |\sum a_k x^k| \leq \sum |a_k| < p \), contradiction. So if now \( f = gh \), then \( g, h \) all have roots with norm greater than 1, in particular it has constant coefficients norm greater than 1, which is a contradiction because \( p \) is a prime. \( \square \)

**Prop. (2.2.2.9).** The cyclotomic polynomial \( \Psi_n(x) \) is irreducible over \( \mathbb{Z} \).

**Proof:** It suffices to show that for any irreducible factor \( f \mid \Psi_n(x) \), if \( \xi \) is a root of \( f \) and \( (p, n) = 1 \), then \( \xi^p \) is also a root of \( f \). Cf.[Lan05]. \( \square \)

Diophantine Equations

**Prop. (2.2.2.10) [Fermat’s Equation in Function Case].** If \( n \geq 2 \), then the only non-trivial solution to the equation in \( \mathbb{C}[t] \) of

\[
X^n + Y^n = Z^n
\]

is \( n = 2, X = (a^2 - b^2)/2, Y = ab, Z = (a^2 + b^2)/2 \).

**Proof:** The \( n = 2 \) case is easy. If \( n > 2 \), we show there are no non-trivial solutions: Differentiate it to get:

\[
X^{n-1}X' + Y^{n-1}Y' = Z^{n-1}Z',
\]

And cancelling \( X^{n-1} \), we get

\[
Y^{n-1}(X'Y - Y'X) = Z^{n-1}(X'Z - Z'X).
\]

Now \( X'Z - Z'X \neq 0 \) because \( X, Z \) are not linearly equivalent, and \( Y, Z \) is coprime, so \( Y^{n-1}|X'Z - Z'X \). But then if we assume \( \dim Y \geq \dim X \), then \( (n-1) \dim Y \leq 2 \dim Y - 1 \), which means \( n < 2 \). \( \square \)

**Resultants**

**Def. (2.2.2.11)[Resultants].** Over a commutative ring \( R \), the **resultant** \( \text{res}(A, B) \) of two polynomials \( A, B \) of degree \( d, e \) respectively is the determinant of the linear map

\[
W_e \times W_d \to W_{d+e} : (X, Y) \mapsto AX + BY,
\]

where \( W_t \) is the free module of polynomials of degree \( < t \).

**Prop. (2.2.2.12).** The resultant can be seen as the determinant of the matrix with values the coefficient of \( A \) or \( B \) in different places, multiplying \( X^s \)s with different degree and add to the last row, we can get \( A \cdot X^s \)s and \( B \cdot X^s \)s, so: \( \text{res}(A, B) = AC + BD \) for some \( C, D \).

Now if \( R \subset S \) and \( A, B \) has common roots in \( S \), then \( \text{res}(A, B) = 0 \).

**Cor. (2.2.2.13).** Resultant is stable under Euclidean division, so it can be seen as a suitable division remainder of the two polynomial.
Prop. (2.2.2.14). When $R \subset L$ a field and $A, B$ decompose into linear factors in $L$, let $t_i$ be roots of $A$ and $u_j$ be roots of $B$, then

\[
\text{res}(A, B) = v_0^d w_0^e \prod_{i=1}^{d} \prod_{j=0}^{e} (t_i - u_j)
\]

Proof: See the resultant as polynomials of the roots of $A$ and $B$, then we proved that if they has the same root, then $\text{res} = 0$, so it is divisible by $(t_i - u_j)$ for all $i, j$. Then notice the RHS is homogenous of degree $d$ in $u_j$ and homogenous of degree $e$ in $t_i$, so does res. So they are equal. □

Invariant Theory

Prop. (2.2.2.15) [Elementary Symmetric Polynomial]. For $n$ indeterminants $x_i$, define the elementary polynomials

\[
\sigma_k = \sum_{1 \leq i_1 < \ldots < i_k \leq n} x_{i_1} x_{i_2} \ldots x_{i_k} \in \mathbb{Z}[x_1, \ldots, x_n]
\]

where for $k > n$ this expression means 0. Then any symmetric polynomial is a polynomial of the fundamental symmetric polynomials.

Proof: Set the first coordinate to 0, then the rest is a polynomial of the fundamental symmetric polynomials by induction, $f(0, x) = h(\sigma_1, \ldots, \sigma_n)$, then consider $f - h$, with $h$ the same expression but $x_n$ is included, we get it is a symmetric polynomial, and it is divisible by $x_1$, thus also divisible by $\prod x_i$, thus divide it by $\prod x_i$ and use induction, we get $f$ is a polynomial of elementary symmetric polynomials. □

Prop. (2.2.2.16) [Newton Identities]. For $n$ indeterminants $x_i$, define

\[
s_k = \begin{cases} 
\sum x_i^k, & k \geq 0 \\
0, & k < 0
\end{cases} \in \mathbb{Z}[x_1, \ldots, x_n],
\]

then there are Newton Identities:

\[
s_k - \sigma_1 s_{k-1} + \ldots + (-1)^n \sigma_n s_{k-n} = 0.
\]

Proof: The case of $k \geq n$ is simple. Now if $k < n$, then we prove by induction on $n$: If $n$ is already proven, then the term is 0 if one of them is 0, but this implies that this equation is divisible by $\prod_{i=1}^{k+1} x_i$, but is has degree $k \leq n$, so it must by 0. □

Prop. (2.2.2.17) [Chern Polynomials]. By (2.2.2.16) and induction there are polynomials $P_k \in \mathbb{Z}[x_1, \ldots, x_k]$ s.t. $P_k(\sigma_1, \ldots, \sigma_k) = s_k, k \geq 0$, called the Chern polynomials. Then they satisfy:

\[
\log(1 + c_1 + c_2 + \ldots + c_n + \ldots) = \sum_{p \geq 1} (-1)^{p-1} \frac{pP_p}{p} \in \mathbb{Q}[c_1, \ldots, c_n, \ldots]
\]

In particular, we can easily calculate via homogeneity that

\[
P_1 = c_1, \quad P_2 = c_1^2 - 2c_2, \quad P_3 = c_1^3 - 3c_1c_2 + 3c_3, \quad P_4 = c_1^4 - 4c_1^2c_2 + 4c_1c_3 + 2c_2^2 - 4c_4.
\]
Proof: We can define elementary power series
\[ \sigma_k = \sum_{1 \leq i_1 < \cdots < i_k} x_{i_1} x_{i_2} \cdots x_{i_k} \in \mathbb{Z}[[x_1, \ldots, x_n, \ldots]], \]
and also
\[ s_k = \begin{cases} \sum x_i^k, & k \geq 0 \\ 0, & k < 0 \end{cases} \in \mathbb{Z}[[x_1, \ldots, x_n, \ldots]]. \]
Then the Newton identities also holds by taking limits. There is an injection
\[ Q[[c_1, \ldots, c_n, \ldots]] \rightarrow Q[[x_1, \ldots, x_n, \ldots]] : c_i \mapsto \sigma_i, \]
and the LHS is mapped to
\[ \log \left( \prod_i (1 + x_i) \right) = \prod_i \log (1 + x_i) = \sum_{p \geq 1} (-1)^p \frac{s_p}{p} \]
is the image of the RHS. \( \square \)

Prop. (2.2.2.18)[Todd Polynomials]. There are Todd polynomials \( Q_p \in \mathbb{Z}[\sigma_1, \ldots, \sigma_p], p \geq 1 \) s.t.
\[ \text{Todd}(x_1, \ldots, x_n, \ldots) = \prod_{i=1}^{n} \frac{x_i}{1 - e^{-x_i}} = 1 + \sum_{p \geq 1} \frac{Q_p}{p!} \in \mathbb{Q}[[x_1, x_2, \ldots]] \]
for any \( n \in \mathbb{Z}_+, \) and
\[ Q_1 = c_1, \quad Q_2 = c_1^2 + c_2, \quad Q_3 = c_1 c_2, \quad Q_4 = -c_1^4 + 4 c_1^2 c_2 + 3 c_2^2 + c - 1 c_3 - c_4. \]

Proof: \( ? \) \( \square \)

Prop. (2.2.2.19)[Conjugate Invariant Polynomials]. Any polynomial on the entries of matrixes \( M_n(k) \) that is invariant under conjugation is generated by coefficients of \( \det(\lambda I + X) \) and can also be generated by \( \text{tr}(X^k) \).

Proof: We notice that the matrixes having disjoint eigenvalues is dense in \( M_n(k) \), thus the restriction of the polynomial on these matrixes is a symmetric polynomial(2.2.2.15) thus identical to a polynomial described above. Hence they are equal. \( \square \)

Prop. (2.2.2.20). For any polynomial on the entries of matrixes \( M_n(k) \) that \( f(BA) = f(A) \) for \( B \in O(n) \), there is a polynomial \( F \) that \( f(A) = F(A^*A) \). Cf.[Heat Equation and the Index Theorem Atiyah P323].

Prop. (2.2.2.21)[Weyl]. Any linear map \( f \) from \( (\mathbb{R}^m)^\otimes n \) to \( R \) that is \( O(m, \mathbb{R}) \)-equivariant is a linear combinations of maps of the form:
\[ v_1 \otimes v_2 \otimes \cdots \otimes v_n \mapsto \langle v_{i_1}, v_{i_2} \rangle \langle v_{i_3}, v_{i_4} \rangle \cdots \langle v_{i_{n-1}}, v_{i_n} \rangle. \]
Where \( i_1, \ldots, i_n \) is a permutation of \( 1, 2, \cdots, n \) when \( n \) is even and when \( n \) is odd, \( f \) must be 0.

Proof: Cf.[Heat Equation and the Index Theorem]. \( \square \)
3 Commutative Rings

Bézout Domain

Def. (2.2.3.1) [Bézout Domains]. A Bézout domain is an integral domain that any sum of two principal domains is also principal.

Prop. (2.2.3.2). The localization of a Bézout domain is Bézout. A local ring is Bézout iff it is a valuation ring by (10.3.2.8).

UFDs

Def. (2.2.3.3) [UFDs]. A non-zero element $x$ in a domain $R$ is called irreducible iff for any $y, z \in R$ that $x = yz$, either $y$ or $z$ is a unit.

A non-zero element $x$ in a domain $R$ is called a prime iff $(x)$ is a prime ideal. Every prime is irreducible.

A domain $R$ is called a UFD iff every non-zero element $x \in R$ has a factorization into irreducibles, unique up to units.

Prop. (2.2.3.4). if $R$ is Noetherian domain, then each element has a decomposition into irreducible.

Proof: Trace the decomposition inductively, if it doesn’t stop, then it contradicts with Noetherian hypothesis. □

Prop. (2.2.3.5). An integral domain $R$ is a UFD iff each element $x$ factors into irreducibles, and every irreducible element is a prime. Also this is equivalent to every non-zero element factors into prime elements.

Proof: If $R$ is a UFD, then if $x$ is irreducible, if $ab \in (x)$, $ab = xc$, then $x$ is one irreducible in the decomposition of $a$ and $b$, by UFD, so $a \in (x)$ or $b \in (x)$, and $(x)$ is a prime ideal.

Conversely, if there are two decompositions $\prod a_i = \prod b_j$, then some $b_j \in (a_i)$ by primeness of $(a_i)$, so $b_j = a_iu$, so $u$ must by units, so by induction, this two decompositions are the same.

If every element factors into prime elements, then an irreducible element is a prime because it factors as a product of primes, and notice every prime is irreducible (2.2.3.3). □

Prop. (2.2.3.6) [Kaplansky]. An integral domain $R$ is UFD iff every non-zero prime ideal contains a non-zero principle prime ideal. In particular, any prime of height 1 is principal.

Proof: If $R$ is a UFD, let $p$ be a non-zero prime ideal, choose $a \neq 0 \in p$, and write $a = \pi_1 \ldots \pi_n$ as a product of irreducibles. Then $\pi_i \in p$ for some $i$, so $p$ contains the prime ideal $(\pi_i)(2.2.3.5)$.

Conversely, let $S$ be the set of all finite products of prime ideals of $R$, then $S$ is a multiplicative set of $R$. For any non-zero element $a \in R$, if $(a) \cap S = \emptyset$, then there is a prime ideal $P$ containing $(a)$ and is maximal among those avoiding elements of $S$. Then $P$ contains a non-zero prime $\pi$, contradiction. So $(a) \cap S \neq \emptyset$. Let $b \in R$ that $ab = \pi_1 \ldots \pi_n$, then we show $a \in S$ by induction on $n$.

If $n = 1$, then $a$ is a unit or a prime, so we are done. For general $n$, if $\pi_k | b$ for some $k$, then $b = \pi_kc$, and $ac = \pi_1 \ldots \pi_{k-1}\pi_{k+1} \ldots \pi_n$, then $a \in S$ by induction hypothesis. Otherwise $\pi_k | a$ for all $k$, thus $a = \pi_1 \ldots \pi_n c$ and $1 = bc$, thus $c$ is a unit and $a \in S$.

Thus we proved that every non-zero element is a product of prime elements, so $R$ is a UFD by (2.2.3.5). □
Prop. (2.2.3.7). A polynomial ring over a UFD is a UFD.

Proof: □

Prop. (2.2.3.8). Let \( k \) be a field, then the power series \( k[[X_1, \ldots, X_n]] \) is a UFD.

Proof: Cf.[Algebra Lang P209]. □

Remark (2.2.3.9). WARNING: if \( A \) is a UFD, \( A[[X]] \) may not be a UFD. Cf.[Matsumura, Commutative Ring Theory, P165].

Prop. (2.2.3.10)[Gauss Lemma].

Prop. (2.2.3.11)[Nagata]. If \( A \) is a Noetherian domain and \( x \in A \) is a prime element s.t. \( A[\frac{1}{x}] \) is a UFD, then \( A \) is a UFD.

Proof: \( A[\frac{1}{x}] \) is normal by (4.3.5.2), and \( A \) is also normal: If \( a \in \text{Frac}(A) \) is integral over \( A \), then \( a = r/x^m \) for some \( m \in \mathbb{Z}, r \in A \setminus \{x\} \). If \( a \notin A \), then \( r \in x \), contradiction.

Then we can use (6.1.2.25) to show that \( \text{Cl(Spec A)} \) = 0, and then \( A \) is a UFD by (6.1.5.6). □

Prop. (2.2.3.12). For a field \( k \) of characteristic \( \neq 2 \) and \( n \geq m \geq 5 \), \( A = k[x_1, \ldots, x_n]/(-x_1^2 + x_2^2 + \ldots + x_m^2) \) is a UFD.

Proof: \( A \cong k[x_1, \ldots, x_n]/(x_1x_2 + x_3^2 + \ldots + x_m^2) \), and \( (x_2) \) is a prime ideal of \( A \) s.t. \( A[\frac{1}{x_2}] \) is a UFD by (2.2.3.7), so \( A \) is a UFD by Nagata’s lemma (2.2.3.11). □

Prop. (2.2.3.13)[Quadratic Extension of UFDs]. If \( A \in \mathbb{C}\text{Alg} \) is an integral domain and \( Z^2 - gZ + f \) doesn’t have a root in \( \text{Frac}(A) \), then \( A[Z]/(Z^2 - gZ - f) \) is integral and normal.

Proof: If \( (a + bZ)(c + dZ) = 0 \), then by hypothesis \( ad + bc + bdf = 0 \). Then \( b(fd^2 - c^2 - cdg) = 0 \), so \( b = 0 \) or \( c = d \) by hypothesis. If \( (c, d) \neq (0, 0) \), then \( ac = ad = 0 \), so \( a = b = 0 \). □

PID

Def. (2.2.3.14)[Euclidean Domain].

Prop. (2.2.3.15)[Euclidean Domain is PID]. An euclidean domain is a PID.

Proof: □

Cor. (2.2.3.16). If \( K \) is a field, then \( K[X] \) is a PID.

Prop. (2.2.3.17)[Chinese Remainder Theorem].

Prop. (2.2.3.18)[PID Structures]. In a PID,
- An element \( t \) is irreducible iff \( (t) \) is maximal.
- A PID is UFD hence Noetherian.
- An element \( t \) is irreducible iff it is a prime.

Proof: 1: By (2.2.3.6).
2: By (2.2.3.6).
3: By item 2 and (2.2.3.4). □
4 Module Theory

Def. (2.2.4.1) [Modules]. For \( R \in \mathcal{R} \), a (left)\( R \)-module is defined to be \( \mathbb{?} \). The category of \( R \)-modules is denoted by \( \mathbf{Mod}_R \).

Left modules are preferred. There are several proposition that is written in favor of right modules, they should be rectified.

Def. (2.2.4.2) [Finite Modules]. For \( R \in \mathcal{R} \), a finite \( R \)-module is an \( R \)-module \( M \) that there is a surjection \( R^n \to M \) for some \( n \geq 0 \).

Prop. (2.2.4.3). Let \( R \) be a nonzero commutative ring and \( M \) be an \( R \)-module generated by \( n - 1 \) elements, then any \( R \)-module map \( R^n \to M \) has a nonzero kernel.

Proof: Choose a surjection \( R^{n-1} \to M \), then the map \( R^n \to M \) can be extended to a map \( R^n \to R^{n-1} \). It suffices to assume \( M = R^n \). This map is represented by a matrix. If some entry \( a_{ij} = a \) is nilpotent, then we can localize \( R \) to \( \mathcal{R}_a \) that \( a \) is a unit. We can assume \( a_{11} = a \), and apply elementary row and column transformation to make \( A = \text{diag}(1, B) \), then we finish by induction. Now if all \( a_{ij} \) are nilpotent, then \( I = (a_{ij}) \) is nilpotent, and if \( m \) is the maximal integer that \( I^m \neq 0 \), then \( (I^m)^{\leq n} \) is contained in the kernel of this morphism.

Cor. (2.2.4.4) [Rank of Free Modules]. If \( M \) is a free module over a nonzero commutative ring \( R \), then any basis of \( M \) of the same cardinality, called the rank of \( M \), and any spanning subset of \( M \) has greater cardinalities. In particular, \( R^m \neq R^n \) as \( R \)-modules.

Prop. (2.2.4.5) [Fitting Lemma]. For an endomorphism \( T \) of a \( R \)-module \( M \), if we denote \( p \) the minimal integer that \( R(T^p) = R(T^{p+1}) \) and \( q \) the minimal integer that \( N(T^q) = N(T^{q+1}) \). Then the morphisms are stable afterward. Then if there is a \( m, n \) that \( R(T^m) \oplus N(T^n) = X \) for a \( R \)-module endomorphism \( T \in \text{End}(M) \), then \( p, q < \infty \) and they are equal. Moreover, if we know \( p, q < \infty \), then we have \( R(T^p) \oplus N(T^q) = M \).

Proof: We notice that

\[
T^i : N(T^{i+j})/N(T^i) \to R(T^i) \cap N(T^i), \quad T^i : M/(R(T^i) + N(T^i)) \to R(T^i)/R(T^{i+j})
\]

are isomorphisms. Thus \( R(T^m) \oplus N(T^n) = X \) shows \( q \leq m \) and \( p \leq n \), thus we have \( R(T^p) \oplus N(T^q) = M \), which implies \( p \geq q \) and \( q \geq p \). Thus the result. The rest also follows easily from these isomorphisms.

Prop. (2.2.4.6) [Nakayama]. If \( M \) is a finite \( A \)-module, and \( I \subset A \) is an ideal that \( IM = M \), then there is an \( a \in 1 + I \) that \( aM = 0 \).

In particular, if \( I \subset \text{rad}(A) \), then \( a \) is a unit (4.2.6.2), so \( M = 0 \).

Proof: Because \( M = IM \), choose a set of generators \( \{x_i\} \) of \( M \), then \( x_i = \sum a_{ij}x_j \), where \( a_{ij} \in I \). Then if the matrix \( M = (\delta_{ij} - a_{ij}) \), then \( Mx_i = 0 \). So taking the adjoint matrix, then \( \text{det}(M)x_i = 0 \). Notice \( \text{det}(M) \) is a morphism. But the determinant must be element like \( 1 + k, k \in I \), so we are done.

Cor. (2.2.4.7). If \( M \) is a finite \( A \)-module, \( N \) a submodule and \( M = \text{rad}(A)M + N \), then \( M = N \).

Cor. (2.2.4.8). If a finite \( R \)-module \( M \) satisfies \( M \otimes_R k(p) = 0 \), then there is a \( f \notin p \) that \( M_f = 0 \).
Proof: Because $M_p = 0$, and the support of $M$ is closed (finiteness used).

Cor. (2.2.4.9). If an endomorphism $\varphi$ of a finite module $M$ over $R$ is surjective, then it is injective.

Proof: This endomorphism makes $M$ a finite module over $R[X]$ by letting $X$ act by $\varphi$. So the hypothesis shows $IM = M$ where $I = (x) \subset R[x]$. Then Nakayama (2.2.4.6) shows there are some $(1 + f(X)X)M = 0$. Thus for any $m \in M$ that $X(m) = 0$, $m = 0$, so $\varphi$ is injective.

Prop. (2.2.4.10). If $A \in \text{Ring }/\mathbb{C}$ and $\alpha \in A$ is not nilpotent, then there exists a simple $A$-module $M$ that $\alpha|_M \neq 0$.

Proof: First we claim that there is some $\lambda \neq 0 \in \mathbb{C}$ that $\alpha - \lambda$ is not invertible in $A$, this is nearly the same as the proof of (2.2.1.10), noticing that $\alpha$ is not nilpotent. Now we can take $M = A/(\alpha - \lambda)A$, then $\alpha 1 = \lambda \neq 0$.

Prop. (2.2.4.11) [Jordan-Horder]. Cf. (2.1.9.10).

Tensor Module and Hom Module

Def. (2.2.4.12) [Hom Module]. If $B$ is an $R$-$S$-bimodule and $C$ is a $T$-$S$-bimodule, then $\text{Hom}_S(B, C)$ is naturally a $T-R$-module given by the action $(tfr)(b) = tf(rb)$.

Dually, if $B$ is an $S-R$-bimodule and $C$ is a $T$-$S$-bimodule, then $\text{Hom}_S(B, C)$ is naturally an $R-T$-bimodule given by the action $(rft)(b) = f(br)t$.

Def. (2.2.4.13) [Tensor Product]. Given a ring $R$, a $T-R$-bimodule $A$ and an $R$-$S$-bimodule $B$, their tensor product is a $T-S$-bimodule defined by universal properties: $A \times B \to A \otimes_R B$ is a $T$-$S$-bimodule map, and any $T$-$S$-bimodule map $A \times B \to C$ to a $T$-$S$-bimodule $C$ factors uniquely through $A \otimes_R B \to C$.

The tensor product can be constructed as:

There is an adjoint:

$$- \otimes_R B : T \text{Mod}_R \leftrightarrow T \text{Mod}_S : \text{Hom}_S(B, -) .$$

In particular, tensoring commutes with colimits.

Similarly, there is an adjoint:

$$A \otimes_R - : R \text{Mod}_S \leftrightarrow T \text{Mod}_R : \text{Hom}_T(A, -) .$$

Proof: We need to give an isomorphism

$$\tau : \text{Hom}_S(A \otimes_R B, C) \cong \text{Hom}_R(A, \text{Hom}_S(B, C)).$$

Given $f \in \text{Hom}_S(A \otimes_R B, C)$, we define

$$\tau(f) : A \to \text{Hom}_S(B, C) : (\tau(f)a)(b) = f(a \otimes b).$$

and conversely, for $g \in \text{Hom}_R(A, \text{Hom}_S(B, C))$,

$$\tau^{-1}(g)(a \otimes b) = (g(a))(b).$$

The verifications is routine and the isomorphism for left modules is dual.
Prop. (2.2.4.14)[(Co)Induced Modules]. Given a ring homomorphism $S \to R$, then $R$ is a $S - R$-bimodule as well as a $R-S$-bimodule, then we define:

- $f^* : R\text{Mod} \to S\text{Mod} : f^* M = S M = \text{Hom}_R(R, M) = R \otimes_R M$ (2.2.4.12)(2.2.4.13), the restriction.

- $f_1 : S\text{Mod} \to R\text{Mod} : f_1 M = R \otimes_S M$ is the induced module, it is left adjoint to restriction, by (2.2.4.13).

- $f_* : S\text{Mod} \to R\text{Mod} : f_* M = \text{Hom}_S(R, M)$ is the coinduced module, it is right adjoint to restriction, by (2.2.4.13).

Dually for left modules, we define:

- $f^* : \text{Mod}_R \to \text{Mod}_S : f^* M = M_S = \text{Hom}_R(R, M) = M \otimes_R R$ (2.2.4.12)(2.2.4.13), the restriction.

- $f_1 : \text{Mod}_S \to \text{Mod}_R : f_1 M = M \otimes_S R$ is the induced module, it is left adjoint to restriction, by (2.2.4.13).

- $f_* : \text{Mod}_S \to \text{Mod}_R : f_* M = \text{Hom}_S(R, M)$ is the coinduced module, it is right adjoint to restriction, by (2.2.4.13).

Def. (2.2.4.15)[Algebras]. For $R \in \mathbb{C}\text{Ring}$, a(n) (commutative/unital/associative) algebra over $R$ is a (commutative/unital/associative)magma object in the monoidal category $\text{(Mod}_R, \otimes)$.

The category of $R$-algebras is denoted by $\text{Alg}_R$. The category of commutative $R$-algebras is denoted by $\mathbb{C}\text{Alg}_R$, the category of commutative unital associative algebra over $R$ is denoted by $\mathbb{C}\text{Ring}_R$. Notice $\mathbb{C}\text{Ring}_R \cong \mathbb{C}\text{Ring}/R$.

Torsion-Free Modules

Def. (2.2.4.16)[Torsion-Free Modules]. Let $R$ be a ring, an $R$-module $M$ is called torsion-free iff there are no non-zero divisor $x \in R, 0 \neq f \in M$ that $xf = 0$.

Prop. (2.2.4.17). If $0 \to M_1 \to M_2 \to M_3$ and $M_1, M_3$ are torsion-free, then $M_2$ is torsion-free. Torsion-free is a stalk-wise property (4.1.4.2).

Proof: Trivial. □

Prop. (2.2.4.18). Let $M$ be a finite $R$-module, then $M$ is torsion-free if it is a submodule of a finite free module.

Proof: One direction is trivial, for the other, if $M$ is torsion-free, then $M \subset M \otimes_R K$, and $M \otimes_R K$ is a finite $K$-vector space, with basis $e_i$. Now let $x_i$ be a basis of $M$, let $x_i = \sum a_{ij}b_{ij}e_j$, then let $e = \prod_{ij} b_{ij}$, then $M \subset Re_1/b \oplus \ldots \oplus Re_n/b$. □

Prop. (2.2.4.19). If $M, N$ are $R$-modules that $M$ is torsion-free, then $\text{Hom}(N, M)$ is torsion free.

Proof: Choose a surjection $\bigoplus_I R \to N \to 0$, then $\text{Hom}(N, M) \hookrightarrow \prod_I M$ is torsion free. □

Modules over PID or Bézout Domains

Prop. (2.2.4.20)[Modules over a Bézout domain]. Let $R$ be a Bézout domain, then

- any finite submodule of a free module over $R$ is finite free.
any f.p. \( R \)-module \( M \) is a summand of a free \( R \)-module and \( M_{\text{tor}} \), where \( M_{\text{tor}} = \oplus R/(f_i) \) where \( f_i \in R^* \).

**Proof:** Cf.[Sta]0ASU. \( \square \)

**Prop. (2.2.4.21) [Classification of Modules over PID].**
1. Every submodule of a free module over a PID is free of smaller rank. Thus a projective module over a PID is free.
2. Every finite torsion-free module over a PID is free.
3. Every finite module over a PID has a primary decomposition \( M = \oplus_i R/(q_i) \), where \( (q_i) \) is primary ideals.

So projective \( \iff \) free \( \iff \) torsion-free (when f.g.).

**Proof:**
1: Choose a well ordering on the basis of \( F \), let \( F_i \) is the submodule generated by \( e_j, j \leq i \). Then \( \pi_j(P \cap F_i) \subset R \) is a module of the form \( (a_i) \), thus choose \( u_i \in P \) that \( p_i(u_i) = a_i \). Then \( u_i \) is a basis for \( P \): they are linearly independent, because for any finite linear combination that are 0, the maximal coordinate are 0. It also spans \( P \), because we can choose an element in \( P - \{u_i\} \) whose maximal nonzero coordinate \( \alpha \) is minimal among them, by well-orderedness. But we can subtract a multiple of \( u_\alpha \), thus producing a smaller element, contradiction.

2: If it is finite torsion-free, then it is a submodule of a finite free module(2.2.4.18), so it is free by item 1.

3: Follows immediately from(4.2.5.34) and(2.2.3.18).

**Prop. (2.2.4.22) [Primary Cyclic Decomposition].** There is a primary cyclic decomposition theorem for a torsion module \( M \) over a PID \( R \). Thus the multisets of elementary divisors of \( M \) is a complete set of invariants for \( M \).

**Proof:** Cf.[Advanced Linear Algebra P153]. \( \square \)

**Cor. (2.2.4.23) [Invariant Factor Decomposition].** By reordering the cyclic decomposition, we can get the invariant factor decomposition of \( M \), there are scalars \( d_m | d_{m-1} | \ldots | d_1 \) that are called the invariant factors of \( M \).

**Proof:** Cf.[Advanced Linear Algebra P157]. \( \square \)

**Cor. (2.2.4.24) [Elementary Factor Theorem].** Let \( F \) be a free module over a PID \( R \), and let \( M \) be a f.g. submodule\( \neq 0 \), then there exists a basis \( B \) of \( F \), elements \( e_1, \ldots, e_m \) in this basis, and non-zero elements \( a_1, \ldots, a_m \in R \) that

- the elements \( a_1 e_1, \ldots, a_m e_m \) forms a basis of \( M \).
- \( a_i | a_{i+1} \).

And these \( a_i \) are uniquely determined up to units.

**Transfinite Direct Sum Dévissage of Modules**

**Def. (2.2.4.25) [Direct Sum Dévissage of Modules].** Let \( M \) be a module over a ring \( R \), then a direct sum dévissage is a family of submodules \( M_\alpha \) indexed by an ordinal \( S \) such that

- \( M_0 = 0 \).
- if \( \alpha + 1 \in S \), then \( M_\alpha \) is a direct sum of \( M_{\alpha + 1} \).
• if $\alpha$ is a limit ordinal, then $M_\alpha = \bigcup_{\beta < \alpha} M_\beta$.

• $\bigcup_{\alpha \in S} M_\alpha = M$.

If moreover, for any $\alpha \in S, \alpha + 1 \in S$, $M_{\alpha + 1}/M_\alpha$ is countably generated, then $M_\alpha$ is called a Kaplansky dévissage of $M$.

**Prop.(2.2.4.26).** Let $M_\alpha$ be a direct sum dévissage of $M$, then $M \cong \bigoplus_{\alpha \in S, \alpha + 1 \in S} M_{\alpha + 1}/M_\alpha$.

**Proof:** Cf. [Sta]058V.

**Cor.(2.2.4.27).** $M$ is a direct sum of countably generated modules iff $M$ admits a Kaplansky dévissage.

**Prop.(2.2.4.28).** Suppose $M$ is a direct sum of countably generated modules and $P$ is a direct sum of $M$, then $P$ is also a direct sum of countably generated modules.

**Proof:** Cf.[Sta]058X.

**Prop.(2.2.4.29)[Direct Summand Criterion of Free Modules].** Let $M$ be a countably generated $R$-module that for any direct summand $N$ of $M$ and an element $x \in N$, $x$ is contained in a free direct summand of $N$, then $M$ is free.

**Proof:** Let $x_1, x_2, \ldots$ be a countable set of generators for $M$, then we can use inductions to find free submodules $F_1, F_2, \ldots$ of $M$ s.t. $\bigoplus_{i=1}^n F_i$ are direct summands of $M$ and contains $x_1, \ldots, x_n$ for any $n$, thus $M = \bigoplus F_i$ is free.

## 5 Field Extensions

**Prop.(2.2.5.1) [Artin].** If $G$ is a monoid and $K$ is a field, any distinct characters of $G$ in $K$ are linearly independent over $K$.

**Proof:** Consider the minimal length of linear combination that is 0, then we multiply a suitable $z$ in it, then we can can cancel a character, contradicting the minimality.

**Cor.(2.2.5.2).** If $\alpha_i$ are different elements in $K$ and there are element $a_i$ that $\sum a_i \alpha_i^v = 0$ for every $v \geq 0$, then $a_i = 0$ for all $n$. (Seen as characters from $\mathbb{Z}_{\geq 0} \to K$).

**Def.(2.2.5.3)[Composition of Fields Extensions].**

**Field Extensions**

**Def.(2.2.5.4) [Distinguished Class of Extensions].** A family $L$ of extensions are called distinguished iff

- It is closed under base change.
- $E/F/K \in L$ iff $F/K \in L$ and $E/F \in L$.

**Def.(2.2.5.5) [Algebraic Extensions].** An algebraic extension is a field extension $L/K$ s.t. for any element $\alpha \in L$, there exists a nonzero polynomial $f(X) \in K[X]$ s.t. $f(\alpha) = 0$.

**Prop.(2.2.5.6).** The family of finite extensions form a distinguished class.

The family of algebraic extensions form a distinguished class.

The family of f.g. extensions form a distinguished class.
Proof: Finite case is trivial. For the alg. extensions, for \( k \subset F \subset E \), for any \( \alpha \in E \), \( \alpha \) satisfies an polynomial function with f.m coefficients in \( F \), the coefficients form a subfield \( F_0 \) of \( F \) which is finite over \( k \), so \( k \subset F_0 \subset F_0(\alpha) \) is a finite tower, so it is finite, hence algebraic. The base change is easy to check.

For f.g. extensions, it suffice to check composition:?

Prop. (2.2.5.7). For an alg.extension \( k \subset E \), any injective field map \( E \to E \) over \( k \) is an automorphism. (This is because it induce a permutation of any \( \alpha \) with its conjugates in \( E \), so it is surjective).

Lemma (2.2.5.8). Let \( f \in k[X] \) be a polynomial of degree \( \geq 1 \), then there is a field \( K \) that \( f \) has a root in \( K \). Hence for any finite set of polynomials, there is a field \( K \) that all of them have roots in \( K \).

Proof: Cf. [Algebra Lang P231].

Lemma (2.2.5.9). For any \( k \in \text{Field} \), there exists \( K \in \text{Field} \) s.t. \( k \subset K, K = K \).

Proof: Firstly, we construct a field that every polynomial in \( k[X] \) of degree \( \geq 1 \) has a root. Consider the polynomial ring \( k[X_f] \), where there is a indeterminant \( X_f \) for each \( f \in k[X] \) of deg \( \geq 1 \). Then the ideal generated by \( f(X_f) \) is not a unit ideal, which can be seen by constructing a finite field extension that \( f_i \) all have a root in it (2.2.5.8).

So if \( \mathfrak{m} \) is a maximal ideal containing all \( f(X_f) \), then the quotient field is a field that all \( f \) have a root(\( X_f \)).

So now if we construct inductively like this, and consider their union, then it is clearly a field and any polynomial of degree \( \geq 1 \) have a root in it.

Prop. (2.2.5.10) [Algebraic Closure]. For any field \( K \). There exists uniquely an alg.closed field \( K/k \) that is algebraic over \( K \), up to isomorphism over \( k \), called the algebraic closure of \( k \), denoted by \( \overline{k} \).

Proof: Let \( E \) be a field that is alg.closed and contains \( k \) by (2.2.5.9). Let \( k^a \) be the union of subextensions that are algebraic over \( k \). \( k^a \) is a field, by (2.2.5.6), and \( k^a \) is alg.closed, because if \( f(X) \) is a polynomial of degree \( \geq 1 \) in \( k^a[X] \), then it has a root \( \alpha \in E \), and \( \alpha \) is algebraic over \( k^a \), so \( \alpha \in k^a \).

Prop. (2.2.5.11) [Finite Algebraic Extensions]. Let \( L/K \) be a field extension and \( F/L \) be a finite extension, then there is a finite extension \( F'/K \) s.t. \( F = LF' \).

Proof: Take a generator \( x_i \) of \( F/L \), then \( x_i \) are algebraic over \( L \), thus there are polynomials \( f_i \in L[X] \) s.t. \( f_i(x_i) = 0 \). Let \( F' \) be the fields over \( K \) generated by all the coefficients of \( f_i \)'s, then \( F = LF' \).

Prop. (2.2.5.12). If \( E/F \) is an algebraic field extension, then for any \( R \) that \( E \subset R \subset F \), \( R \) is a field.

Proof: If \( \alpha \in R \), then \( \alpha \) is algebraic over \( E \), so there is a relation \( \alpha^n + \ldots + a_0 = 0 \), so \( \alpha^{-1} = -a_0^{-1}(a_1 + \ldots \alpha^{n-1}) \in R \).
Normal & Separable Extensions

Def. (2.2.5.13) [Normal Extensions]. A field extension $K/k$ in $\bar{k}$ is called normal extension iff it satisfied the following equivalent conditions:

- Any embedding of $K$ into $\bar{k}$ induce an automorphism on $K$.
- $K$ is the splitting field of a family of polynomials in $k[X]$.
- Every irreducible polynomial in $k[X]$ that has a root in $K$ splits in $K$.

Proof: Cf. [Algebra Lang P237].

Prop. (2.2.5.14). Normal extension are stable under base change and composition, by the first definition of (2.2.5.13).

Def. (2.2.5.15) [Normal Closure]. For any field extension $F/K$, there is a field extension $E/F$ that $E/K$ is normal, called the normal closure of $F/K$. It is the composite of conjugates of $F/K$.

Def. (2.2.5.16) [Separable Degree]. Define the separable degree $[E : k]_s$ of an extension $E/k$ as the cardinality of embedding of $E$ into $\bar{k}$. Separable degree commutes with composition, and when $E/k$ is finite, $[E : k]_s \leq [E : k]$.

Def. (2.2.5.17) [Separable Polynomials]. A finite extension is called a separable extension iff $[E : k]_s = [E : k]$, an algebraic number $\alpha$ over $k$ is called separable over $K$ iff $k(\alpha)/k$ is separable. A polynomial $f \in k[X]$ is called a separable polynomial iff it has no multiple roots in $\bar{k}$.

Def. (2.2.5.18) [Separable Extensions]. An algebraic extension $E/k$ is called a separable extension iff it satisfies the following equivalent conditions:

- every f.g. subfield is separable over $k$, (this is compatible because subfield of a finite separable extension is separable, by the compatibility of separable degree).
- Every element of $E$ is separable.
- It is generated by a family of separable elements.

Proof: If $E/k$ is separable and $k \subset k(\alpha) \subset E$, then by (2.2.5.17), $k(\alpha)$ is separable. And if it is generated by a family of separable elements $\{\alpha_i\}$, then any f.g. subfield can are f.g. by elements $\{\alpha_i\}$. Now it is a tower of separable extensions, hence separable by the compatibility of separable degree.

Prop. (2.2.5.19). Separable extensions form a distinguished class.

Proof: Cf. [Algebra Lang P241].

Prop. (2.2.5.20) [Primitive element Theorem]. A finite extension $E/k$ is primitive iff there are only f.m. middle fields. And if $E/k$ is separable, this is satisfied.

Proof: If $k$ is finite, this is simple. Assume $k$ infinite, for any two elements $\alpha, \beta$, consider $k(\alpha + c, \beta)$, if there is only finitely many middle fields, there exists two that is equal, so $k(\alpha, \beta) = k(\gamma)$. Proceeding inductively, $E$ is primitive.

Conversely, if $k(\alpha) = E$, every middle field corresponds to a divisor of the irreducible polynomial of $\alpha$. This map is injective, because for any $g_F$, degree of $\alpha$ over $F$ is the same over the degree over the coefficient field of $g_F$, so it must be equal to $F$. 

If \( E/k \) is separable, Let

\[
P(X) = \prod_{i \neq j} (\sigma_i \alpha + X \sigma_i \beta - \sigma_j \alpha - X \sigma_j \beta)
\]

for different embedding \( \sigma_i, \sigma_j \) of \( E(\alpha, \beta) \) into \( k^{\text{alg}} \). Then it is not identically zero, thus there exists \( c \) that \( \sigma_i(\alpha + c \beta) \) is all distinct, thus generate \( K(\alpha, \beta) \). \( \square \)

**Inseparable Extensions**

**Prop. (2.2.5.21).** Any irreducible polynomial of fields of characteristic 0 is separable and if \( \text{char} = p \), then all roots have the same multiplicity and thus \( [k(\alpha) : k] = p^n [k(\alpha) : k] \) for some \( n \).

**Proof:** All roots have the same multiplicity because there are Galois actions. If the multiplicity is not 1, the derivative \( f' \) is zero, otherwise \( f \) is not irreducible. Then \( f(X) = g(X^p) \). We can choose \( f(X) = h(X^{p^n}) \) with \( h \) separable, then \( [k(\alpha) : k(\alpha^p^n)] = p^n \), thus the result. \( \square \)

**Def. (2.2.5.22).** The **inseparable degree** \( [E : k]_s \) is defined as the quotient \( [E : k]/[E : k]_s \). An algebraic element \( \alpha \) is called **purely inseparable** over \( k \) iff there is a \( n \) that \( \alpha^{p^n} \in k \).

**Def. (2.2.5.23).** An extension is called **purely inseparable** if it satisfies the following equivalent conditions:

- \( [E : k]_s = 1 \).
- Every element \( \alpha \) of \( E \) is purely inseparable over \( k \).
- For every \( \alpha \in E \), the irreducible equation of \( \alpha \) over \( k \) is of type \( X^{p^n} - a \).
- It is generated by a family of purely inseparable elements.

**Proof:** Cf. [Algebra Lang P249]. \( \square \)

**Cor. (2.2.5.24).** A field over \( \mathbb{F}_p \) is perfect iff there are no purely inseparable extensions of it.

**Cor. (2.2.5.25) [Perfect Closure].** For any field \( k \) of char \( p \), there is a unique purely inseparable field extension \( k^{\text{perf}}/k \) that \( k^{\text{perf}} \) is perfect, called the **perfect closure** of \( k \). It is generated by adding all the \( p^n \)-th roots to \( k \).

**Prop. (2.2.5.26).** Purely inseparably extensions form a distinguished class.

**Proof:** Cf. [Algebra Lang P250]. \( \square \)

**Prop. (2.2.5.27).** If \( E/k \) is algebraic and \( E_0 \) be the maximal separable extension contained in \( E \), then \( E/E_0 \) is purely inseparable. And if \( E/k \) is normal, then \( E_0/k \) is normal, too.

**Proof:** By the proof of (2.2.5.21), any \( \alpha \) has a \( p^n \) that \( \alpha^{p^n} \) that \( \alpha^{p^n} \) is separable, hence it is purely inseparable over \( E_0 \) by (2.2.5.23). \( E_0/k \) is normal because any \( \sigma \) maps \( E \) to itself, and \( E_0 \) to \( \sigma(E_0) \in E \) separable, hence \( \sigma(E_0) \subset E_0 \). \( \square \)
Trace and Norm

Prop. (2.2.5.28) [Trace and Norm]. Let \( L/K \) be a finite field extension and \( \Sigma \) be the set of embeddings \( \sigma : L \to \overline{K} \), then define the **trace map** \( \text{tr}_{L/K} : L \to K : x \mapsto [L : K] \sum_{\sigma \in \Sigma} \sigma(x) \) and the **norm map** \( N_{L/K} : L \to K : x \mapsto (\prod_{\sigma \in \Sigma} \sigma(x))^{[L : K]} \).

Prop. (2.2.5.29). Let \( L/K \) be a field extension,

- The norm induces a multiplicative homomorphism \( L^* \to K^* \), and the trace induces an additive homomorphism \( L \to K \).
- If \( E/F/K \) are field extensions, then \( N_{E/K} = N_{F/K} \circ N_{E/F} \), and \( \text{tr}_{E/K} = \text{tr}_{F/K} \circ \text{tr}_{E/F} \).
- If \( L = K(\alpha) \) and \( F = \text{Irr}(\alpha, k; X) = X^n - a_{n-1}X^{n-1} + \ldots + (-1)^n a_0 \), then
  \[
  N_{L/K}(\alpha) = a_0, \quad \text{tr}_{L/K}(\alpha) = a_{n-1}.
  \]

Prop. (2.2.5.30) [Calculating Dual Basis]. Let \( L = K(\alpha) \) be a finite separable extension, let \( f(X) = \text{Irr}(\alpha, k; X) \), and

\[
\frac{f(X)}{X - \alpha} = \beta_0 + \beta_1 X + \ldots + \beta_{n-1} X^{n-1},
\]

then the dual basis of \((1, \alpha, \ldots, \alpha^{n-1})\) w.r.t. the trace form (2.2.5.32) is

\[
\frac{\beta_0}{f'(\alpha)}, \ldots, \frac{\beta_{n-1}}{f'(\alpha)}.
\]

Proof: Denote the roots of \( f \) be \( \alpha_i \), then they are pairwise different, and

\[
\sum_i \frac{f(X)}{X - \alpha_i} \frac{\alpha_i^r}{f'(\alpha_i)} = X^r
\]

for all \( r \) by Lagrange interpolation (2.2.2.2). But this is equivalent to

\[
\text{tr}
\left(\frac{\alpha_i^r \beta_j}{f'(\alpha)}\right) = \delta_{ij}
\]

Prop. (2.2.5.31). Let \( L/K \) be a field extension, then \( x \in L \) acts on \( L \) via multiplication \( T_x \). Then

\[
\det(T_x) = N_{L/K}(x), \quad \text{tr}(T_x) = \text{tr}_{L/K}(x).
\]

Proof: Let \( F = K(x) \subset L \), and \( p(X) \) be the minimal monic polynomial of \( x \), then \( \text{char}(T_x; X) = \text{char}(T_x|K; X)^{[L:K(x)]} \), thus we are done by (2.2.5.29).

Prop. (2.2.5.32) [Trace Form]. If \( L/K \) is a finite extension, consider the pairing

\[
Q_{L/K} : L \times L \to K : (x, y) \mapsto \text{tr}(xy)
\]

called the **trace form**. Then the following are equivalent:
Prop. (2.2.6.2).

Def. (2.2.6.1) [Transcendental Basis].

Prop. (2.2.5.34).

Def. (2.2.5.33) [Discriminant of a Basis].

We define $x$ self algebraically independent. So

If $L/K$ is inseparable, then by (2.2.5.29), if we consider $L/K'/K$ that $L/K'$ is purely inseparable of degree $p$, then it is generated by some equation $x^p - a$, and the root is $\alpha$. Then $L = K'(\alpha)$ and the minimal polynomial of $\alpha^i, 0 \leq i \leq p - 1$ is $x^p - a^i$, so $\text{tr}(\alpha^i) = 0$, and $\text{tr} L/K = 0$.

If $L/K$ is separable, $\text{tr}_{L/K} \neq 0$ by the linear independence of characters (2.2.7.3). □

Def. (2.2.5.33) [Discriminant of a Basis]. Let $\alpha_i$ be a basis of a separable extension $L/K$, then the discriminant of the basis $d(\alpha_1, \ldots, \alpha_n)$ is defined to be $\det(\sigma_i(\alpha_j))^2$. Clearly, $d(\alpha_1, \ldots, \alpha_n)$ is invariant under the Galois action of $L/K$, thus it is an element of $K$.

Prop. (2.2.5.34). Notice $\text{tr}_{L/K}(\alpha_i \alpha_j) = \sum_k \sigma_k(\alpha_i) \sigma_i(\alpha_j)$, thus $(\text{tr}_{L/K}(\alpha_i \alpha_j))$ is the product of the matrices $(\sigma_k \alpha_i)^t$ and $(\sigma_k \alpha_j)$, thus

$$d(\alpha_1, \ldots, \alpha_n) = \det(\text{tr}_{L/K}(\alpha_i \alpha_j)).$$

So the discriminant of $\{\alpha_1, \ldots, \alpha_n\}$ is the Gram matrix of the trace norm w.r.t. this basis (2.3.8.24). In particular, by (2.2.5.32),

$$d(\alpha_1, \ldots, \alpha_n) \neq 0.$$ 

6 Transcendental extension

Def. (2.2.6.1) [Transcendental Basis]. Let $K$ be an extension of a field $k$, a transcendental base is an algebraically independent set that any element is algebraic over it.

Given any algebraically independent set $S \subset T$ a set over which $K$ is algebraic, $S$ can be extended to a transcendental base contained in $T$, by Zorn’s lemma. In particular, a transcendental basis exists.

Prop. (2.2.6.2). Any two transcendental bases have the same cardinality, called the transcendental degree of $K/k$, denoted by $\text{tr deg}_k(K)$.

Proof: If $K/k$ has a finite transcendental basis, then let $X = \{x_1, \ldots, x_m\}$ transcendental base of minimal number, $S = \{w_1, \ldots, w_n\}$ an algebraically independent set. If $n > m$, we proceed by changing one element in $X$ a time using induction and prove that $K$ is algebraic over $\{w_1, \ldots, w_r, x_{r+1}, \ldots, x_m\}$, contradiction.

Because $w_{r+1}$ is algebraic over $\{w_1, \ldots, w_r, x_{r+1}, \ldots, x_n\}$, we have a minimal polynomial

$$f = \sum g_j(w_{r+1}, w_1, \ldots, w_r, x_{r+2}, \ldots, x_m)x_j^{r+1}$$

s.t. $f(w_{r+1}, w_1, \ldots, x_m) = 0$ (after possibly renumbering $x_i$, this $x$ must exists because $S$ is itself algebraically independent). So $x_r$ is algebraic over $\{w_1, \ldots, w_r, x_{r+1}, \ldots, x_n\}$, hence $K$ is independent over it, too.

If $K/k$ has an infinite basis $B$, let $B'$ be another basis, then for any $\alpha \in B^*$, there is a finite set $B_\alpha \subset B$ that $\alpha$ is algebraic over $k(B_\alpha)$, because algebraic equation involves f.m. generators. Then we define $B^* = \cup_{\alpha \in B^*}$, then it has cardinality smaller than $B'$. But $B^* = B$, because for any $\beta \in B$, $\beta$ is algebraic over $B'$ which is algebraic over $k(B^*)$, thus $\beta$ is algebraic over $k(B^*)$, thus $\beta \in B^*$. □
Prop. (2.2.6.3). If $K$ is of finite transcendental degree over $k$, then $|K| = |k|$.

Proof: We find a purely transcendental $L/k$ that $K/L$ is algebraic, then the element of $L$ are all polynomials of finite indeterminants of elements of $k$, so $|L| = |k|$ by (1.1.5.4), and similarly $|K| = |L|$.

Prop. (2.2.6.4). Two alg.closed field of the same transcendental degree over base field is isomorphic.

Proof: We define a bijection of the transcendental basis, and then extend it to an isomorphism of fields, by adjunction of algebraic numbers using Zorn's lemma.

Prop. (2.2.6.5) [Lüroth]. The automorphism group of $K(T)$ is $PGL_2(K)$.

Proof: Consider $\theta = \sigma(x) = \frac{f(x)}{g(x)}$, then $x$ is algebraic over $K(\theta): \theta g(x) - f(x) = 0$. Now $x$ is transcendental over $K$, thus $\theta$ is transcendental over $K$ as well. Now the minimal polynomial of $x$ over $K(\theta)$ is just $\theta g(x) - f(x)$, because it is irreducible, as it is linear over $\theta$. But $K(x) = K(\theta)$, thus the polynomial must have degree 1, so $f(x), g(x)$ is of degree 1. Now the rest is clear.

Prop. (2.2.6.6) [Lüroth]. Any subfield $K \nsubseteq L \subset K(T)$ is of the form $K(u)$ where $u \in K(X)$ is transcendental over $K$.

Proof: It is clearly transcendental over $K$, so this follows from (5.11.1.17) and Riemann-Hurwitz (5.11.1.32), notice that the field extension is separable by (4.3.9.4): The non-singular complete curve corresponding to $L$ has genus 0, and it has a rational point, so isomorphic to $\mathbb{P}^1_k$ (5.11.8.2).

7 Galois Theory

Def. (2.2.7.1) [Galois Extension]. A Galois field extension is a field extension that is both normal and separable.

Def. (2.2.7.2) [Galois Closures]. Let $F/K$ be a separable extension, then the normal closure $E/K$ is also separable, called the Galois closure of $F/K$.

In particular, the maximal separable extension $k^{\text{sep}}/k$, called the separable closure of $k$, is Galois over $k$, and $\text{Gal}(k^{\text{sep}}/k)$ is denoted by $\text{Gal}_k$.

Prop. (2.2.7.3) [Algebraic Independence, Artin]. Let $L$ be a field, $G$ be a monoid and $\chi_i: G \to L$ be multiplicative maps, then $\chi_i$ are linearly independent over $L$.

Proof: Let $\sum_{i=1}^n a_i \chi_i = 0$ and $a_i \neq 0$ for any $i$, we use induction to derive contradictions: for all $i$, $n = 1$ is trivial, and for general $n$, assume $a_1, a_2 \neq 0$, then the two equations $\chi_1(h) \neq \chi_2(h)$, then $\sum_{i=1}^n a_i \chi_i(hg) = 0$ and $\sum_{i=1}^n a_i \chi_i(g) = 0$ gives us a equation with smaller $n$, thus we are done.

Prop. (2.2.7.4) [Galois Main Theorem, Artin]. Let $G$ be a finite group of automorphisms of $K$. Then $K/K^G$ is Galois of Galois group $G$.

Proof: For every element $x$, set $\{\sigma_1 x, \ldots, \sigma_r x\}$ be distinct conjugates, then $f(X) = \prod_{i=1}^r (X - \sigma_i x)$ shows that $K$ is separable and normal over $K^G$. And primitive element theorem shows that $[K : K^G] \leq |G|$, so it must equals $G$. 

Prop. (2.2.7.5). If \( L/K \) is a finite Galois extension, then there is an isomorphism:

\[
L \otimes_K L \cong L \times L \times \ldots \times L : (a, b) \mapsto (ab, a\sigma_1(b), \ldots, a\sigma_{n-1}(b))
\]

where \( \sigma_i \) are Galois elements.

Proof: Choose a primitive element \( x \) and its minimal polynomial \( f(x) \), then \( L \cong K[X]/(f) \), and \( L \otimes_K L \cong L[X]/(f) \), but \( f \) decomposes completely in \( L[X] \), thus by Chinese remainder theorem (2.2.3.17), the given map is an isomorphism of rings.

Prop. (2.2.7.6) [Infinite Galois Theorem]. The middle fields correspond to the closed subgp of \( G(L/K) \).

Proof: The highlight is that \( G(L/L^n) = H \) for a closed subgp \( H \) of \( G(L/K) \). If \( \sigma \) fixes \( L^n \) but is not in \( H \), because for every finite field \( M \), \( H \cdot G(L/M) \) corresponds to \( M/(M \cap L^n) \), so \( \sigma G(L/M) \cap H \neq \emptyset \). So \( \sigma \) is in the closure of \( H \) thus in \( H \).

Prop. (2.2.7.7) [Normal Basis Theorem]. For a finite Galois extension, normal basis exists.

Proof: Finite case: The Galois group is cyclic, and the linear independent of characters shows that the minimal polynomial of \( \sigma \) is \( n \)-dimensional thus equals \( X^n - 1 \). Regard \( L \) as a \( K[X] \) module thus by (2.2.4.21) is a direct sum of modules of the form \( K[X]/(f(x)) \), \( f(x)|X^n - 1 \) and the minimal polynomial for the action of \( X \) is \( X^n - 1 \). So it must be isomorphic to \( K(X)/(X^n - 1) \).

Infinite Case: Let

\[
f([X_\sigma]) = \det(t_{\sigma_i, \sigma_j}), \quad t_{\sigma, \tau} = X_{\sigma^{-1}\tau}
\]

We see \( f \neq 0 \) by substituting 1 for \( X_{id} \) and 0 otherwise. So it won’t vanish for all \( x \) if we substitute \( X_\sigma = \sigma(x) \) because \( [\sigma(x)] \) is pairwisely different. Thus there exists \( w \) s.t.

\[
\det(\sigma^{-1}\tau(w)) \neq 0.
\]

Now if

\[
\sum a_{\tau}(w) = 0, \quad a_{\sigma} \in K,
\]

act by \( \sigma \) for all \( \sigma \), we get \( [\sigma^{-1}\tau(w)][a_{\sigma}] = 0 \), thus \( [a_{\sigma}] = 0 \).

Prop. (2.2.7.8) [Kummer Theory]. Let \( K \) be a field and containing the set \( n \)-th roots of unity \( \mu_n \) where \( n \in \mathbb{Z} \cap K^* \), a Kummer extension \( L/K \) of exponent \( n \) is a Galois extension that the Galois group is Abelian of exponent \( n \).

Then there is an inclusion preserving isomorphism between the lattice of Kummer extensions \( L \) over \( K \) and the lattice of subgroups of \( K^\times \) containing \( (K^\times)^n \):

\[
L \mapsto \Delta = (L^\times)^n \cap K^\times, \quad \Delta \mapsto K(\sqrt[n]{\Delta}).
\]

And \( \Delta/(K^\times)^n \) is isomorphic to \( \text{Gal}(L/K)^\vee = \text{Hom}(\text{Gal}(L/K), \mathbb{Q}/\mathbb{Z}) \).

Proof: The Galois cohomology of the Kummer sequence \( 1 \to \mu_n \to L^\times \xrightarrow{n} (L^\times)^n \to 0 \) says

\[
1 \to K^\times \xrightarrow{n} (L^\times)^n \cap K^\times \xrightarrow{\delta} H^1(\text{Gal}(L/K), \mu_n) \to H^1(\text{Gal}(L/K), L^\times) = 1 (10.1.3.2)
\]

And \( \text{Gal}(L/K) \) acts trivially on \( \mu_n \subset K^* \), so

\[
H^1(\text{Gal}(L/K), \mu_n) = \text{Hom}(\text{Gal}(L/K), \mathbb{Q}/\mathbb{Z})
\]
and
\[ \delta : a \mapsto \chi_a(\sigma) = \sigma(\sqrt[n]{a})/\sqrt[n]{a} \in \mu_n. \]

Now let \( L/K \) be the maximal Kummer extension of exponent \( n \), then \((L^\times)^n = K^\times\). So the assertion follows from Galois theory on applied to \( L/K \).

\[ \square \]

**Prop. (2.2.7.9) [Finite Fields].** \( \text{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) = \mathbb{Z}/(n) \) and is generated by the Frobenius.

**Proof:**

**Prop. (2.2.7.10) [Artin-Schreier Theory].** Let \( K \) be a field of characteristic \( p > 0 \) containing \( \mathbb{F}_q \), where \( q = p^k \), an Artin-Schreier extension \( L/K \) of exponent \( q \) is a Galois extension that the Galois group is Abelian of exponent \( q \).

Then there is an inclusion preserving isomorphism between the lattice of Artin-Schreier extensions \( L \) over \( K \) of exponent \( q \) and the lattice of subgroups of \( W_{p,k}^+(K) \) containing \((W_{p,k}^+(\text{Frob}_p^k) - \text{id})(W_{p,k}^+(K)):\)

\[ L \mapsto \Delta = (W_{p,k}^+(\text{Frob}_p^k) - \text{id})(W_{p,k}^+(L)) \cap W_{p,k}^+(K), \]
\[ \Delta \mapsto K\{b_{i_1}, \ldots, b_{i_k}| b_i = (b_{i_1}, \ldots, b_{i_k}), W_{p,k}^+(\text{Frob}_p^k)(b) - b \in \Delta\}. \]

And \( \Delta/(W_{p,k}^+(\text{Frob}_p^k) - \text{id})(W_{p,k}^+(K)) \) is isomorphic to \( \text{Gal}(L/K)^\vee = \text{Hom}(\text{Gal}(L/K), \mathbb{Q}/\mathbb{Z}) \).

**Proof:** The Galois cohomology of this exact sequence

\[ 0 \to W_{p,k}^+(\mathbb{F}_q) \to W_{p,k}^+(L) \xrightarrow{W_{p,k}^+(\text{Frob}_p^k) - \text{id}} (W_{p,k}^+(\text{Frob}_p^k) - \text{id})(W_{p,k}^+(L)) \to 0, \]

says

\[ 1 \to W_{p,k}^+(K) \xrightarrow{W_{p,k}^+(\text{Frob}_p^k) - \text{id}} (W_{p,k}^+(\text{Frob}_p^k) - \text{id})(W_{p,k}^+(L)) \cap W_{p,k}^+(K) \]
\[ \xrightarrow{\delta} H^1(\text{Gal}(L/K), W_{p,k}^+(\mathbb{F}_q)) \to H^1(\text{Gal}(L/K), W_{p,k}^+(L)) = 0(10.1.3.3) \]

And \( \text{Gal}(L/K) \) acts trivially on \( W_{p,k}^+(\mathbb{F}_q) \), so by (4.5.3.22),

\[ H^1(\text{Gal}(L/K), W_{p,k}^+(\mathbb{F}_q)) = \text{Hom}(\text{Gal}(L/K), \mathbb{Q}/\mathbb{Z}) \]

and

\[ \delta : a \mapsto \chi_a(\sigma) = \sigma(b) - b \in W_{p,k}^+(\mathbb{F}_q), \quad W_{p,k}^+(\text{Frob}_p^k)(b) - b = a. \]

Next we prove for any \( b = (b_1, \ldots, b_k), W_{p,k}^+(\text{Frob}_p^k)(b) - b \in W_{p,k}^+(K), K\{b_1, \ldots, b_k\}/K \) is Abelian of exponent \( q \). Let \( K_i = K(\{b_1, \ldots, b_i\}) \). By (4.5.3.4),

\[ (b_1^q, \ldots, b_k^q) - (b_1, \ldots, b_k) \in W_{p,k}^+(K) \]

implies \( b_i^q - b_i \in K_{i-1} \). Thus \( K_i/K_{i-1} \) is an Artin-Schreier extension of exponent \( p \). As the Galois action is always of the form \( \sigma(s) - s \in \mathbb{F}_q \) for any \( \sigma \in \text{Gal}(K_k/K) \) and \( s \in K_k \), we see \( K_k/K \) is also Artin-Schreier of exponent \( q = p^k \).

Now let \( L/K \) be the maximal Artin-Schreier extension of exponent \( q \), then \((W_{p,k}^+(\text{Frob}_p^k) - \text{id})(W_{p,k}^+(L)) = W_{p,k}^+(K) \). So the assertion follows from Galois theory on applied to \( L/K \).

\[ \square \]
Cor. (2.2.7.11) [Artin-Schreier of Exponent $p$]. Let $K$ be a field of characteristic $p > 0$, then there is an inclusion preserving isomorphism between the lattice of Artin-Schreier extensions $L$ over $K$ of exponent $p$ and the lattice of subgroups of $K^+$ containing $\{x^p - x| x \in K\}$:

$$L \mapsto \Delta = \{x^p - x| x \in L\} \cap K,$$

$$\Delta \mapsto K(\{b| b^p - b \in \Delta\}).$$

And $\Delta/\{x^p - x| x \in K\}$ is isomorphic to $\text{Gal}(L/K)^\vee = \text{Hom}(\text{Gal}(L/K), \mathbb{Q}/\mathbb{Z})$.

8 Ordered Rings

Def. (2.2.8.1) [Ordered Rings]. An ordered ring is a ring $R$ together with a subset $P \subset R$ that $R$ is a disjoint union $P \bigcup \{0\} \bigcup (-P)$, and if $x, y \in P$, then $x + y, xy \in P$. Elements in $P$ are called positive elements.

An ordered field is an ordered ring that is also a field. An orderable ring/field is a ring/field that can be given an ordered structure.

Prop. (2.2.8.2). An orderable field has char0, because $0 \notin P \cup (-P)$.

A square $> 0$ in an ordered field (trivial).

Def. (2.2.8.3) [Convex Subgroup]. Let $\Gamma$ be an ordered Abelian group (2.2.8.1), then a convex subgroup of $\Gamma$ is a subgroup $\Delta$ that if $a < b < c$ and $a, c \in \Delta$, then $b \in \Delta$. Notice this is in fact equivalent to if $0 < c \in \Delta$, then $0 < b < c$ are also in $\Delta$.

Prop. (2.2.8.4) [Height]. The set of all convex subgroups of $\Gamma$ is well-ordered, and its ordinal is called the height of $\Gamma$.

Proof: If $\Delta_1, \Delta_2$ don’t contains each other, let $a \in \Delta_1 - \Delta_2$ and $b \in \Delta_2 - \Delta_1$, then changing $\pm a, \pm b$, we may assume $0 < a < b$, so $a \in \Delta_2$, contradiction. \qed

Prop. (2.2.8.5) [Height 1 Case]. Let $\Gamma$ be an ordered Abelian group, then the following are equivalent:

1. $\text{ht}(\Gamma) = 1$.
2. for all $a, b \in \Gamma$ that $a > 0$ and $b \geq 0$, there is an integer $n$ that $b \leq na$.
3. there exists an injection from $\Gamma$ to $\mathbb{R}$.

Proof: $3 \rightarrow 1$ is easy.

1 $\rightarrow$ 2: Consider the convex subgroup generated by $a$, then it is $\Delta$ by height condition, so $b$ must by in it, i.e. $b \leq na$ for some $n$.

2 $\rightarrow$ 3: Choose an $a > 0$, let the injection $\varphi$ given by $\varphi(b) = \sup\{\frac{b}{k}| na \leq kb\}$ for $b > 0$ and extends to negative elements.

It is easily verified that $\varphi(c) + \varphi(b) \leq \varphi(c + b)$, and if $\varphi(c) + \varphi(b) < \varphi(c + b)$, choose a rational approximation of them, and multiply to get integers, then if $k(c+b) \leq \varphi(c+b)ka > \varphi(b)a + \varphi(c)a + a$, then either $kc \geq \varphi(c)ka + a$ or $kb \geq \varphi(b)ka + a$, contradiction.

So this map is truly a morphism of ordered Abelian groups, and it is injective because if $b > 0$, then by 2, there must be an $n$ that $a \leq nb$, so $\varphi(b) \geq 1/n$. \qed
9 Real Fields

Def.(2.2.9.1)[Real Fields]. A field \( K \) is called real if \(-1\) is not a sum of squares in \( K \). A field \( K \) is called real closed iff it is real, and any alg.extension that is real must be itself. An ordered field is clearly a real field by (2.2.8.2), the converse is in fact true, by (2.2.9.11). In particular, a real field is of characteristic 0.

Prop.(2.2.9.2). If \( K \) is real, \( a \in K \), and \( -a \) cannot both be sum of squares. If \( -a \) is not a sum of squares in \( K \), then \( K(\sqrt{a}) \) is real. Hence either \( K(\sqrt{a}) \) or \( K(\sqrt{-a}) \) is real.

Proof: Suppose \( K(\sqrt{a}) \) is not real. If \( a \) is a square, then \( K(\sqrt{a}) = K \) is real. So \( a \) is not a square,

\[
-1 = \sum (b_i + c_i \sqrt{a})^2 = \sum (b_i^2 + c_i^2 + 2b_i c_i \sqrt{a})
\]

Since \( \sqrt{a} \notin K \), \( -1 = \sum (b_i^2 + c_i^2) \), so

\[
-a = \frac{1 + \sum b_i^2}{\sum c_i^2}
\]

This implies that \( -a \) is a sum of squares. \( \square \)

Prop.(2.2.9.3). If the minimal polynomial \( f \) of an \( \alpha \) algebraic over a real field \( K \) is of odd degree, then \( K(\alpha) \) is real.

Proof: If \( K(\alpha) \) is not real, then \( -1 = \sum g_i(X)^2 + h(X)f(X) \), where \( g_i \) has degree smaller than \( n \).

This can happen if \( h(X) \) has degree odd and \( \leq n - 2 \). Then if \( \beta \) is a root of \( h \), then \( K(\beta) \) is also not real. So the proof is finished if we use induction. \( \square \)

Def.(2.2.9.4)[Real Closure Exists]. For any real field \( K \), there exists a real closure \( K^a \) of \( K \).

That is, it is real closed and algebraic over \( K \).

Proof: This is an easy consequence of Zorn’s lemma. \( \square \)

Cor.(2.2.9.5)[Real Closed Fields Unique Ordering]. There exists a unique ordering on a real closed field \( R \). The elements \( > 0 \) are just the squares in \( R \). Now every real closed field is assumed to have this ordering tacitly. In particular, any real closed field has char0, so does any real field.

Proof: The set of finite sum of squares in \( R \) is closed under addition and multiplication, and all of them are squares, by (2.2.9.2) and maximality of \( R \). Also by (2.2.9.2) either \( a \) is a square or \( -a \) is a square, but not simultaneously. So it is truly an order on \( R \). \( \square \)

Prop.(2.2.9.6)[Fundamental Theorem of Algebra]. For a field \( R \), \( R \) is real closed iff \( R \neq R[i] \) and \( \overline{R} = R(i) \).

Proof: One direction is trivial, the other follows from the lemma below (2.2.9.7), it satisfies the condition by (2.2.9.2) and maximality. \( \square \)

Lemma(2.2.9.7)[Equivalent Definition of Real Closed Fields]. If \( R \) is a real field that: for all \( a \in R, \sqrt{a} \in R \) or \( \sqrt{-a} \in R \), and any polynomial of odd degree has a root in \( R \), then \( K = R(i) \) is alg.closed.
Proof: For any order of $R$, the first condition in fact says that any $a > 0$ in $R$ is a square. Now $rac{a + \sqrt{a^2 + b^2}}{2}$ is non-negative, so there is a $c^2 = \frac{a + \sqrt{a^2 + b^2}}{2}$, that is $(c + \frac{b}{2c})^2 = a + bi$, so $K$ has all squares.

As $R$ is of char0(2.2.9.5)(2.2.8.2), so it suffices to show any Galois extension $L/K$ is trivial. Let $G = G(L/R)$, and $H$ be its 2-Sylow subgroup, then $G = H$ by condition. Now if $G_1 = G(L/K)$, then $G_1$ is nontrivial, because otherwise there is a subgroup of index 2, then its fixed field is a square extension of $K$, which is impossible by what we have proved. So $G = G_1$, that is $L = K$. □

Cor. (2.2.9.8) [Complex Numbers is Alg.Closed]. $\mathbb{C} = \mathbb{R}[i]$ is alg.closed.

Prop. (2.2.9.9) [Intermediate Property]. An ordered field is real closed iff it has the intermediate property.

Proof: If $R$ is real closed, as $R[i]$ is alg.closed(2.2.9.6), $f$ can be decomposed into factors of degree 1 or 2. For a factor $X^2 + \alpha X + \beta$, 4$\beta > \alpha^2$, otherwise it has a root hence not irreducible. So the change of sign is because of a linear factor, the rest is easy.

Conversely, if it has the intermediate property, then for $a > 0$, consider $p(X) = X^2 - a$, then $p(0) < 0, p(a + 1) > 0$, so $p$ has a root, that is, $a$ is a square. For a polynomial of odd degree, for $M$ large enough, $f(M) > 0, f(-M) < 0$, so $f$ has a root. So by(2.2.9.7) $R$ is real closed. □

Prop. (2.2.9.10) [Artin-Schreier]. If $K$ is separably closed and $F$ is a subfield of finite index in $K$, then $F = K$ or $F$ is real closed and $K = F(i)$.

Proof: Cf.[Lan05]P299.

Real Fields and Order

Prop. (2.2.9.11) [Real Field and Order]. If $R$ is a real field, then it is orderable, in fact, if $-a$ is not a sum of squares in $F$, then there is an ordering that $a > 0$. So a real field is equivalent to an orderable field.

Proof: By(2.2.9.2), $F(\sqrt{a})$ is real, so it has a real closure(2.2.9.4) and has the induced order(2.2.9.5), and $a > 0$ because it is a square(2.2.8.2). □

Prop. (2.2.9.12) [Existence and Uniqueness of Real Closure]. For any ordered field $F$, there is a unique real closure $R$ of $F$ that every positive element of $F$ is a square in $R$, thus the ordering is compatible.

Proof: The existence is by adding all the square roots of elements> 0 to $F$, the resulting field is real closed because of(2.2.9.2) and the fact a union of real fields(2.2.9.2) is real.

The uniqueness: because an ordered field is of char0(2.2.8.2), so the primitive element theorem(2.2.5.20) applies that each finite subextension of $R_0$ is of the form $F(\alpha)$, where $\alpha$ is a root of an irreducible separable polynomial $f$. Then the roots of $f$ are different so can be ordered $\alpha_1 < \ldots < \alpha_n$. Similarly, $f$ has the same number of different roots in $R_1 \beta_1 < \ldots < \beta_n$ by(2.2.9.14), so there is a map $h: \alpha_i \to \beta_i$, and it is the unique map that a ordered map from $F(\alpha)$ to $R_1$ extending id on $F$ can be. it is this uniqueness that makes us able to use Zorn’s lemma to show that there is a maximal ordered map, must be a map from $R_0$ to $R_1$, which is an isomorphism, by primitive element theorem again. □

Prop. (2.2.9.13) [Sturm’s Algorithm]. Cf.[Model Theory Marker P327].
Cor. (2.2.9.14). If $F$ is an ordered field and $R_0, R_1$ be two real closure of $F$ that is compatible with the ordering, then any irreducible polynomial has the same number of roots in $R_0$ and $R_1$.

Proof: Cf.[Model Theory Marker P328].

Prop. (2.2.9.15)[Hilbert’s 17th Problem]. If $f$ is a positive semidefinite rational function over a real closed field $F$, then $f$ is a sum of squares of rational functions.

Proof: Let $f(X_1, \ldots, X_n)$ be a positive semidefinite rational function, if $f$ is not a sum of squares of rational functions, then by (2.2.9.11), there is an ordering on $F(X)$ that $f < 0$. Let $R$ be a real closure of $F(X)$, then $R \models \exists \bar{v} F(\bar{v}) < 0$, as $F(X) < 0$. But $RCR$ is complete, by (1.2.7.6), thus $F \models \exists \bar{v} F(\bar{v}) < 0$ also, contradiction.
2.3 Linear Algebra

Main references are [H-K71], [线性代数 谢启鸿], [Rom07] and [Determinant, 高等代数 notes, 安金鹏].

In this section, the category of vector spaces over a field $k$ is studied, without considering any topology on $K$ or $V$. More generally, the category of free modules over a commutative unital ring $R$ is studied.

Def. (2.3.0.1) [Notations]. Throughout this section, $k$ denote a field.

1 Basics

Def. (2.3.1.1) [Vector Spaces].

Def. (2.3.1.2) [Linear Operators]. A linear operator on a $R$-module $V$ is an element of the endomorphism ring $\text{End}_R(V)$

Def. (2.3.1.3) [Basis]. Let $R$ be a field, then the sets $S$ that are linearly independent over $R$ has maximal objects by Zorn’s lemma, and such a maximal object must span $M$, called a basis of $M$.

Prop. (2.3.1.4) [Dimension]. All basis of a linear $k$-vector space $V$ have the same cardinality, this cardinality is called the dimension $\dim_k(V)$ of $V$. This follows immediately from (2.2.4.4).

Prop. (2.3.1.5) [Canonical way of Writing a Basis]. After so many years, I still find it confusing to write a basis and observing change of basis, so I will write it here:

A vector should always be written vertically, and so a basis should be $\overrightarrow{e} = (e_1, \ldots, e_n)(\text{horizontal})$, and a vector with basis $\overrightarrow{d}$ (vertical) is in fact $\overrightarrow{e} \overrightarrow{d}$.

A change of basis should be written $\overrightarrow{e}' = ea$, with $a \in GL_n$, and then if an operator has matrix $A$ w.r.t. the basis $\overrightarrow{e}$, it then map in the basis $\overrightarrow{e}' v = \overrightarrow{e}' x = \overrightarrow{e} a x \mapsto \overrightarrow{e} Aax = \overrightarrow{e} a^{-1} Aax$, so it has matrix $a^{-1} Aa$ w.r.t the basis $\overrightarrow{e}'$.

Prop. (2.3.1.6) [Extension of Basis].

Proof: \hfill \Box

Prop. (2.3.1.7). Let $F$ is a subfield of $K$ and $U$ is a $K$-vector space with a $F$-subspace $U'$. Then if every finite $F$-linearly independent subset of $U'$ is $K$-linearly independent, then $\dim_F(U') \leq \dim_K(U)$.

Proof: If the converse is true, there is a $F$-basis $u_j'$ of $U'$, then some of $u_j'$ is $K$-linearly dependent, contradiction. \hfill \Box

Def. (2.3.1.8) [Matrices]. Let $R$ be a commutative ring, the set of matrices of size $m \times n$ over $R$ is an (non-commutative) algebra $M_{m \times n}(R)$ over $R$ whose underlying module is $R^\otimes_{n2} = \oplus_{1 \leq i \leq m, 1 \leq j \leq n} e_{ij} R$, and the algebra structure is given by

$e_{ij} e_{ij} = e_{ik}$.

An element $A = \sum_{1 \leq i \leq m, 1 \leq j \leq n} a_{ij} e_{ij} \in M_{m \times n}(R)$ is denoted by $A = (a_{ij})$. 
Prop. (2.3.1.9). $A, B$ are two $n \times n$-matrices, if $1 - AB$ is invertible, then so does $1 - BA$, and
\[(1 - BA)^{-1} = 1 + B(1 - AB)^{-1}A.\]

Proof: Immediate from (2.2.1.5) or (2.3.10.12).

Cor. (2.3.1.10). $AB$ and $BA$ has the same characteristic polynomials.

Prop. (2.3.1.11). For a ring $R$, there is an isomorphism of rings
\[M_n(R) \cong M_n(R^{op}).\]

The isomorphism is given by $A \mapsto A^t$.

Def. (2.3.1.12) [Notation for Matrix Group]. Let $R$ be a ring, denote
- $GL(n, R)$ be the subgroup of $\text{End}_R(\oplus R^\oplus n)$ consisting of invertible matrices.
- $SL(n, R)$ be the subgroup of $GL(n, R)$ consisting of matrices of determinant 1 (2.3.10.1).
- $U_n(R)$ be the subgroup of $GL(n, R)$ consisting of upper-triangular matrices.
- $P_n(R)$ be the subgroup of $GL(n, R)$ consisting of matrices $A = (a_{ij})$ that $a_{ni} = 0$ for $i < n$.
- $Q_n(R)$ be the subgroup of $GL(n, R)$ consisting of matrices $A = (a_{ij})$ that $a_{ni} = 0$ for $i < n$ and $a_{nn} = 1$.

Prop. (2.3.1.13). Let $K$ be a topological field, there is a decomposition of spaces
\[U_n(K) \setminus GL(n, K) \cong GL(1, K) \times U_2(K) \setminus GL(2, K) \times \ldots \times Q_n(K) \setminus GL(n, K)\]
where $GL(n - 1, K)$ embeds $GL(n, K)$ obviously.

Remark (2.3.1.14). This is wrong.

Proof: By induction, it suffices to show
\[U_n(K) \setminus GL(n, K) \times U_{n-1}(K) \setminus GL(n-1, K) \times Q_n(K) \times GL(n, K).\]
Consider the map $GL(n - 1, K) \times GL(n, K) \to U_n(K) \setminus GL(n, K) : (x, y) \mapsto xy$, then $x_1y_1 = x_2y_2$ iff $x_1y_1 = ux_2y_2$ for some $u \in U_n(K)$, iff $y_1y_2^{-1} = x_1^{-1}ux_2$. This is possible iff $y_1y_2^{-1} \in Q_n$, and for all $(y_1, y_2)$ that $y_1y_2^{-1} \in Q_n$, $x_1y_1 = ux_2y_2$ iff $x_1 = ux_2y_2y_2^{-1}$. □

2 Rank

Prop. (2.3.2.1) [Rank Nullity Theorem]. Let $T : V \to W$ be a linear map between vector spaces, then rank$(T) + \dim \text{Nul}(T) = V$.

Proof: This follows from the exact sequence $0 \to \ker(T) \to V \to \text{Im}(T) \to 0$. □

Prop. (2.3.2.2) [Row Rank equals Column Rank]. The row rank of a $m \times n$ matrix $A$ is the same as the column rank.

Proof: Let $A$ be the matrix of a linear map $T : V \to W$, then column rank equals the range of $T$, and the row rank equals the range of $T^t$, so they are equal by (2.3.3.7). □
Prop. (2.3.2.3) [Sylvester’s Inequality]. For $U$ a $m \times n$ matrix and $V$ a $n \times k$ matrix,

$$\text{Rank}(UV) \geq \text{Rank}(U) + \text{Rank}(V) - n$$

Proof: This comes from $\dim \ker fg \leq \dim \ker f + \dim \ker g$, which is because $\ker fg = g^{-1}(\ker f)$.

Prop. (2.3.2.4) [Finite Field General Linear Group]. Over finite field $\mathbb{F}_p$, $|GL_n(\mathbb{F}_p)| = (p^n - 1)(p^n - p)\ldots(p^n - p^{n-1})$.

Proof: This is because choose the rows are equivalent to choosing a basis for $V = \oplus_{i=1}^n \mathbb{F}_p$, and when choosing $n$-th row, it suffices to avoid an element in the span of the first $n - 1$ rows.

Prop. (2.3.2.5) [Wedge and Rank]. Let $T : V \to V'$ be a linear map, then $\wedge^k(T) = 0$ iff $\text{rank}(T) < k$.

Proof: If $\text{rank}(T) < k$, then $\text{Im}(\wedge^k(T)) \subset \wedge^k \text{Im}(T) = 0$. Conversely, if $\text{rank}(T) \geq k$, choose $\{Te_1, \ldots, Te_k\}$ linearly independent, then $T(e_1 \wedge \ldots \wedge e_k) = Te_1 \wedge \ldots \wedge Te_k \neq 0$.

3 Dual spaces

Def. (2.3.3.1) [Dual Spaces]. Let $V$ be a vector space over a field $k$, the set of linear functionals on $V$ with value in $k$ form another vector space, which is denoted by $V^*$, called the dual space of $V$.

Def. (2.3.3.2) [Annihilator]. Let $V$ be a vector space and $W \subset V$ a subspace, then the annihilator $W^\perp$ is the subspace of $W^*$ consisting of linear functionals $l$ on $V$ s.t. $l(W) = 0$.

Def. (2.3.3.3) [Dual Basis]. Let $V \in \text{Vect}_k$ and $(e_1, \ldots, e_n)$ is a basis of $V$, then there exists unique elements $\alpha_1, \ldots, \alpha_n$ of $V^*$ s.t. $(e_i, \alpha_j) = \delta_{ij}$. Any such elements $\alpha_1, \ldots, \alpha_n$ constitute a basis for $V^*$, and is called the dual basis of $(e_1, \ldots, e_n)$.

Prop. (2.3.3.4) [Dimension of the Annihilator]. Let $W \subset V$ be f.d. vector spaces, then $\dim W + \dim W^\perp = \dim V$.

Proof: Let $\{e_1, \ldots, e_k\}$ be a basis of $W$ and extend it to a basis $\{e_1, \ldots, e_k, e_{k+1}, \ldots, e_n\}$ of $V$ by (2.3.1.6). Consider the dual space $e_1^*, \ldots, e^*_n$, then the annihilator of $W$ is just span$\{e_{k+1}^*, \ldots, e^*_n\}$. Thus $k + (n - k) = n = \dim V$.

Def. (2.3.3.5) [Transpose]. Let $T : V \to W$ be a linear map of f.d. vector spaces, then $T$ induces a map $T^t : W^* \to V^*$ given by $T^t(l) = l \circ T$. This is a linear map, called the transpose of $T$.

Prop. (2.3.3.6) [Adjoint Map and Transpose]. Let $T : V \to W$ be a linear map of f.d. vector spaces, such that w.r.t. a basis $\{e_1, \ldots, e_n\}$ of $V$ and $\{f_1, \ldots, f_m\}$ of $W$, $T$ is given by matrix $A = (a_{ij})$. Then w.r.t. the dual basis $\{f_1^*, \ldots, f^*_m\}$ of $W^*$, $\{e_1^*, \ldots, e^*_n\}$ of $V^*$, the transpose map (2.3.3.5) $T^t : W^* \to V^*$ is given by the a matrix $A^t = (b_{ij})$, where $b_{ij} = a_{ji}$. $A^t$ is called the transpose matrix of $A$.

Proof: $(e_j, T^t(f^*_i)) = \langle Te_j, f^*_i \rangle = a_{ji}$, thus $b_{ij} = a_{ji}$.

Prop. (2.3.3.7) [Transpose Range Nullity Duality]. Let $f : V \to V'$ be a linear map between f.d. vector spaces over a field $k$, then

- $\text{rank}(T^t) = \text{rank}(T)$. 

• The range of $T^t$ is the annihilator of the null space of $T$.

Proof: 1: Notice that $T^t(g) = 0$ iff $\langle g, T(v) \rangle = 0$ for any $v \in V$, thus the null space of $T^t$ is just the annihilator of the range of $T$, which equals $\dim(V' - \text{rank}(T))$ by (2.3.3.4). But this space has dimension $\dim \ker(T^t) = \dim V' - \text{rank}(T')$, so $\text{rank}(T) = \text{rank}(T^t)$.

2: This follows from the fact that $(T^t)^t = T$ and the argument above. □

Cor. (2.3.3.8). A linear map between f.d. vector spaces is surjective iff its transpose is injective.

Prop. (2.3.3.9) [Infinite Dual space]. If $\dim_K V$ is not finite, then $\dim_K V < \dim_K V^*$.

Proof: Notice $\text{Hom}(\oplus_{i \in I} K e_i, K) = \prod K e_i^*$.

We prove first that if $|K|$ is at most countable, then $|V| = |I|$. Notice the set $S_n(I)$ of all $n$-element subsets of $I$ is of the same cardinality of $I(1.1.5.3)$. And the finite sums of $K$ and $e_i$ can be seen as a subset of $S_n(I) \times K^n$, so it has the same cardinality of $I$.

Now we can prove if $|K|$ is at most countable, then $\dim V < \dim V^*$. This is because $V^*$ equals the functions from $V$ to $K$, which is bigger than the functions from $V$ to $\{0, 1\}$, which is the power set of $V$, so having cardinality $2^{|V|}$ which is bigger than $|V|$, by Cantor theorem (1.1.2.12).

Now generally, $K$ is not countable, but it has a base field $F$, which is countable, so we consider the $F$-vector space $W = \oplus_{i \in I} F e_i$, then $\dim_F W = \dim_K V$, and $\dim_F W < \dim_F W^*$. If we can show $\dim_F W^* \leq \dim_K V^*$, then we are done.

For this, first consider the natural $F$-linear mapping $W^* \to V^*$, which is clearly an imbedding. Now we want to use (2.3.1.7), so we check the conditions, for $F$-linearly independent $\varphi_1, \ldots, \varphi_n$, if $\sum c_i \varphi_i = 0$, $c_i \in K$, then if we can find $w_k \in W$ that $\varphi_i(w_j) = \delta_{ij}$, then this is a contradiction. But this is true, by a simple argument, using the $F$-linearity of $F$. □

4 Rational Form and Jordan Form

Prop. (2.3.4.1) [Elementary and Invariant Factors]. A linear operator in $L(V)$ is equivalent to a $K[X]$-module structure on $V$, and two operators are similar iff the module structure are isomorphic.

As $K[X]$ is a PID, the elementary factors, invariant factors, cyclic and elementary decomposition theorems (2.2.4.22) can be applied to the case.

Proof: Cf. [Advanced Linear Algebra P168]. □

Cor. (2.3.4.2) [Jordan Forms].

• For a matrix over an alg.closed field, it is similar to a matrix of blocks $\lambda_i I + N, N x_i = x_i + 1$, called the Jordan form.

• For a real matrix, it is similar to a matrix of blocks of the above form together with $\begin{bmatrix} a & -b \\ b & a \end{bmatrix}$ on the diagonal and $I_{2 \times 2}$ on the lower side.

Proof: 1: Over an alg.closed field, the elementary factors are all of the form $(x - c_i)^{m_{ij}}$. Now in the basis $v, (T - c_i)v, \ldots, (T - c_i)^{m_i - 1}v$, the matrix is just the Jordan form.

2: Over $R$, the elementary factors are all of the form $(x - c_i)^{m_{ij}}$ and $((x - a)^2 + b^2)^{m_{ij}}$. Then complexify it and consider a cyclic vector $v$, for $(T - (a + bi)I)$, let $v_{n+1} = (T - (a + bi)I) v_n$, and let $v_n = X_n + iY_n$, then it can be verified that $T$ is of the Jordan form given in the basis $X_i, Y_i$. □
Def. (2.3.4.3) [Companion matrix]. The companion matrix for a monic polynomial \( p(x) = x^n + a_{n-1}x^{n-1} + \ldots + a_0 \in F[X] \) is the matrix

\[
T_{p(x)} = \begin{bmatrix}
0 & 0 & \cdots & 0 & -a_0 \\
1 & 0 & \cdots & 0 & -a_1 \\
0 & 1 & \ddots & \vdots \\
\vdots & \vdots & \ddots & 0 \\
0 & 0 & \cdots & 1 & -a_{n-1}
\end{bmatrix}
\]

Prop. (2.3.4.4) [Companion Matrix is Nonderogatory]. An operator is cyclic iff it is similar to a companion matrix.

A companion matrix is nonderogatory (2.3.5.2). In fact, the minimal polynomial and the maximal polynomial of the companion matrix of \( p(X) \) are both \( p(X) \).

Proof: The operator of the companion matrix is an operator \( A \) with a basis \( \{ v, Av, A^2v, \ldots, A^{n-1}v \} \) and \( A^nv = -\sum_{i<n} a_i A^i v \), which just equivalent to the fact the action of \( A \) is cyclic.

The determinant of \( T_{p(X)} \) equals \( p(X) \) by (2.3.4.13), and for the minimal polynomial, in the basis of \( \{ v, Av, A^2v, \ldots, A^{n-1}v \} \), clearly for a polynomial \( f(X) \) of degree \( m < n \), \( f(A)v \neq 0 \), and \( p(A)v = \sum_{i<n} a_i A^i v + A^nv = 0 \). So the minimal polynomial of \( A \) is \( p(X) \). \( \square \)

Prop. (2.3.4.5) [Rational Canonical Form]. Every matrix is similar to splint of companion matrices (2.3.4.3) corresponding to its elementary divisors.

Prop. (2.3.4.6) [Invariant Factor Form]. Every matrix is similar to splint of companion matrices, corresponding to its invariant factors.

Computing the Invariant Factors

Def. (2.3.4.7) [Elementary Row Operation]. An elementary row operation for a matrix \( M \) over an algebra \( A \) is one of the following:

- Multiplying one row of \( M \) by a non-zero scalar in \( A \).
- plus the \( r \)-th row by \( c \)-times the \( s \)-th row, where \( c \) is invariant \( A \).

And an elementary matrix is a matrix obtained by the identity matrix by an elementary row operation.

Two matrix is called row equivalent iff they can be connected by f.m. elementary row operations, and this is equivalent to \( M = PN \), where \( P \) is a product of f.m. elementary matrices, because left multiplication by an elementary matrix is equivalent to an elementary row operation.

Similarly we can define elementary column operations.

Lemma (2.3.4.8). The elementary row operation change the determinant only by an invariant element in \( A \). (Clear).

Prop. (2.3.4.9). Let \( P \) be a matrix with entries in \( F[X] \), then the following are equivalent:

- \( P \) is invertible.
- The determinant is a nonzero scalar.
- \( P \) is row equivalent to identity matrix.
• $P$ is a product of elementary matrices.

Proof: The only hard part is $2 \rightarrow 3$: this is because it has determinant in $F^*$, thus the greatest common divisor of the first column is a scalar, thus we can use row operation to make it $(1, 0, \ldots, 0)'$, and then we can continue to make it a upper triangular matrix with 1 in the diagonal, and also kill the upper half part. So it is row equivalent to the identity matrix. □

Cor.(2.3.4.10). Let $M, N$ be two matrices with entries in $F[X]$, then they are equivalent iff $N = PM$ for some $P$ that has determinant in $F$.

Def.(2.3.4.11). We call $M, N$ equivalent iff $M, N$ are connected by a sequence of elementary row operations and column operations. This is equivalent to $M = PNQ$ for $P, Q$ invertible matrices in $M_n(F[X])$.

Prop.(2.3.4.12)[Normal Form of Companion Matrix]. For a monic polynomial $p(X)$, consider its companion matrix $T_p$, then the matrix $xI - T_p \in M_n(F[X])$ is equivalent to $\text{diag}(p(X), 1, \ldots, 1)$.

Proof: Clear, if one reduces the $x$ in the diagonal from the bottom row to the top row one by one. □

Cor.(2.3.4.13). For a companion matrix $A$ of $p$, $\det(xI - A) = p$.

Proof: This is from (2.3.4.8), and the fact both the side are monic polynomials. □

Def.(2.3.4.14)[Smith Normal Form]. A matrix in $M_n(F[X])$ is called a Smith normal form iff it is diagonal and diagonal entries $f_i \in F[X]$ is monic and satisfies $f_k$ divides $f_{k+1}$.

Prop.(2.3.4.15). Any matrix $M$ with entries in $F[X]$ is equivalent to a unique Smith normal form.

Proof: This is immediate from (11.6.6.7) applied to the PID $F[X]$ (2.2.3.16). □

Cor.(2.3.4.16)[Computing Invariant Factors]. The diagonal entries of the Smith form of the matrix $xI - M \in M_n(F[X])$ are just the invariant factors of $M$.

Proof: This is because of the uniqueness of Smith form (2.3.4.15) and the invariant factor (2.3.4.6) and (2.3.4.12). □

Applications

Prop.(2.3.4.17). For any two matrices $A, B \in M_{n \times n}(K)$, $(AB)^n$ and $(BA)^n$ are similar.

Proof: It suffices to show that they have the same elementary factors. Notice that for any irreducible polynomial $p$, if $p \neq x$, then if $p^k(AB)v = 0$, then $p^k(BA)Bv = 0$, if $p^k(NA)v = 0$, then $p^k(AB)Av = 0$. Thus there are maps $B : N(p^k(AB)) \rightarrow N(p^k(BA))$ and $A : N(p^k(BA)) \rightarrow N(p^k(AB))$. Now their composition are both injective, thus they have the same dimension.

And for $p = x$, these two both have nullity as the multiplicity of 0 in the charpoly of $AB, BA$ (2.3.10.13), thus the same. So they have the same elementary factors, thus similar. □

Prop.(2.3.4.18)[Matrix Similar to Transpose]. Any matrix is similar to its transpose.

Proof: This is because the invariant factors can be computed using the greatest common divisors of minors by (2.3.4.15) and (2.3.4.16), and they are clearly invariant under conjugation. □
5 Minimal and Characteristic Polynomials

Def. (2.3.5.1) [Minimal Polynomials]. The minimal polynomial of a matrix $A$ is the polynomial $p$ of minimal degree that $p(A) = 0$. It is equivalent to the maximal invariant factor of $A$, by (2.3.4.1).

Def. (2.3.5.2) [Non-derogatory Operator]. An operator is called nonderogatory iff it has only one invariant factor.

Prop. (2.3.5.3) [Generalized Cayley-Hamilton]. The characteristic polynomial of $A$ is the product of the elementary divisors of $A$, thus the characteristic polynomial and minimal polynomial (2.3.5.1) of $A$ have the same set of irreducible factors, but may not with the same multiplicity. In particular, the characteristic polynomial is divisible the minimal polynomial.

Proof: Because charpoly and minipoly are both invariant under similarity, assume $A$ is in rational form (2.3.4.5), so the result follows from (2.3.4.4). \qed

Prop. (2.3.5.4). The linear functor $X \to AX - XC$ is an isomorphism iff the minimal polynomial of $A$ and $C$ has not common factor.

Proof: Notice if $AX = XC$, then we have $P(A)X = XP(C)$ for every polynomial $P$, in, particular for the minimal polynomials of $A$ and $C$, thus $P(C)$ is non-invertible and $A, C$ has a characteristic value in common. Conversely, if they have a characteristic value, then we upper triangularize $A$ to see clearly that there is a $X$ that $AX = XC$ ($X$ has only the first row). \qed

Characteristic Polynomial Images

In this subsubsection, we consider the set of characteristic polynomials of elements in a subgroup of $GL(n, k)$ as a whole.

6 Diagonalization and Triangulation

Prop. (2.3.6.1). If a linear map has matrix form $T$ in a basis $(X_i)$ and there is another basis $(Y_i)$ that $(Y_i) = (X_i)P$, then it has matrix form $PTP^{-1}$ in the basis $(Y_i)$. In particular, if $T$ can be diagonalized, with eigenvectors $(X_i)$, then $T = (X_i)D(X_i)^{-1}$.

Prop. (2.3.6.2) [Relation with Minimal Polynomial].
- An $n \times n$-matrix $A$ is upper-triangular over a field $K$ iff its minimal polynomial is a product of linear factors.
- An $n \times n$-matrix $A$ is diagonalizable over a field $K$ iff its minimal polynomial is a product of linear factors with no multiple roots.

Proof: 1: If it is upper-triangular, its minimal polynomial is a product of factors because its characteristic polynomial does (2.3.5.3). Conversely, we can find an eigenvector for $A$, then we quotient this vector and use induction.

2: If it is diagonalizable, then the minimal polynomial is clearly polynomials. Conversely, its elementary factors are all linear factors, thus its Jordan form is just diagonal (2.3.4.2). \qed

Cor. (2.3.6.3) [Upper Triangulation Alg.Closed Field]. If $K$ is alg.closed, then any $n \times n$-matrix $A$ is upper-triangular over $K$. Similarly, it is lower-triangular.
Proof: It suffices to find a flag that is stabilized by $A$. And for this, it suffices to find an eigenvector of $A$. This is clear, as the characteristic polynomial of $A$ has a root in $K$.

Prop.(2.3.6.4) [Simultaneously Triangulable]. If $A_i$ is a commutating family of upper-triangulable $n \times n$-matrices, then they are simultaneously triangulable.

Proof: As in the proof of (2.3.6.3), by induction, it suffices to show there is a common eigenvector. Now assume there are f.m. matrices in $F$, we induct on the number of matrices to show there is an eigenvector. Let $\lambda$ be an eigenvalue of $A_1$ because it is upper-triangulable, then $N(A_1 - \lambda I)$ is invariant under $F$, and all the matrices are upper-triangulable on $N(A_1 - \lambda I)$, which is seen by intersecting the flag with $N(A_1 - \lambda I)$. So by induction, there is a common eigenvector for $F$.

Prop.(2.3.6.5) [Simultaneously Diagonalizable]. If $A_i$ is a commutating family of diagonalizable $n \times n$-matrices, then they are simultaneously diagonalizable.

If $A_i$ is a commutating family of real symmetric matrixes, then they are simultaneously orthogonally diagonalizable.

Proof: We may assume there are f.m. matrices and use induction. Consider the diagonal decomposition $V_i$ of $V$ for $A_1$, then each $V_i$ is invariant under $F$. Notice then each $A_i$ is diagonalizable on $V_i$, thus by induction, $F$ is simultaneously diagonalizable on each $V_i$, then $F$ is simultaneously diagonalizable.

For the second, induction on the numbers of matrices. If some matrix is $cI$, then clear, if some are not $cI$, then choose its eigenvalue decomposition, we conclude by induction hypothesis.

Prop.(2.3.6.6) [Invariance of Field Extension]. Let $A \in M_n(F)$, and $E$ be the subfield generated by the entries of $A$, then the invariant factors of $A$ are polynomials over $E$. In particular, two matrix are similar over the smallest field that they are defined.

Proof: Clear, because we know how an irreducible polynomial over $E$ factors through $\overline{E}$.

Prop.(2.3.6.7) [Jordan Decomposition]. Let $k$ be a perfect field and $A \in M_n(k)$, then there exists unique matrices $A_s, A_n$ that $A_s$ is semisimple, $A_n$ is nilpotent, $A = A_s + A_n$, and $A_s, A_n$ are polynomials of $A$ in particular, $A_s$ commutes with $A_n$.

Moreover, if $A$ is invertible, then there exists unique matrices $A_s, A_u$ that $A_s$ is semisimple, $A_u$ is unipotent, $A = A_s \cdot A_u$, and $A_s, A_u$ are polynomials of $A$, in particular, $A_s$ commutes with $A_u$.

Proof: If $k$ is alg.closed, then use (2.3.6.3). And Lagrange interpolation shows $A_s, A_n$ are polynomials in $A$. For the uniqueness, notice that because they are polynomials in $A$, if there are two sets of Jordan decompositions $A = A_s + A_n = A_s' + A_n'$, then $(A_s - A_{s}') = (A_n' - A_n)$, but the sum of commuting semisimple/nilpotent matrices is semisimple/nilpotent, so it is semisimple and nilpotent, so it can only be 0, so $A_s = A_{s}'$.

In general, because $k$ is perfect, taking a Galois field extension $k'/k$ containing all eigenvalues of $A$, then $A = A_s + A_n$ where $A_s, A_n$ has entries in $k'$. But then taking Galois action and using the uniqueness, $A_s, A_n$ has entries in $k$.

Finally, by the Galois action again, $A_s, A_n$ are polynomials in $A$.

If $A$ is invertible, then $A_s$ is also invertible, seen by base change to alg.closure. Then $A = A_s(1 + A_s^{-1}A_n)$, where $1 + A_s^{-1}A_n$ is unipotent.

Prop.(2.3.6.8). If $T$ is a diagonalizable operator on a subspace $V$, then for any invariant subspace $V'$, $T|_{V'}$ is also diagonalizable.

Proof: Use the eigenvalue decomposition $V = \oplus_i V_{\lambda_i}$, then $V' = \oplus_i (V_{\lambda_i} \cap V')$, which is because if $\sum v_i \in V'$, where $v_i$ are in different eigenspaces, then each $v_i \in V'$. 

\[\square\]
7 Positivity(Inner Spaces)

Def. (2.3.7.1) [Inner Spaces]. A real inner space is a f.d. real quadratic space that $B(v, v) > 0$ for $v \neq 0$. It is necessarily non-degenerate.

A complex inner space is a f.d. Hermitian space $V$ that $B(v, v) > 0$ for $v \neq 0$.

Prop. (2.3.7.2). An inner metric on a vector space will induce an inner metric on the dual space, that is, asserting the dual basis of an orthonormal basis to be orthonormal. On an arbitrary basis, the matrix on the dual basis is written as $A^{-1}$ because we can write $A = P^tP$, and the dual basis transformation is like $(P^t)^{-1}$, so the metric matrix is $A^{-1}$.

Prop. (2.3.7.3) [Positivity and Principal Minors]. A matrix is positive symmetric (Hermitian) iff it is symmetric, and all its upper principle minors has positive determinants.

A positive symmetric (Hermitian) matrix is equivalent to a real (complex) inner space.

Proof: Cf. [Hoffman P328].

Cor. (2.3.7.5) [Gordan’s Theorem]. exactly one of the following has a solution:

$\left\{\begin{array}{ll}
AX > 0 \\
Y^tA = 0, Y \geq 0, Y \neq 0
\end{array}\right.$

Proof: If both have a solution, then $0 = Y^tAX > 0$, contradiction. If the first has no solution, then $A'x = e, z \geq 0$, where $A' = [A, -A, -I]$ has no solution, by Farkas’ lemma, there is a solution of $Y^tA' \leq 0$ and $Y^tb = 0$. Which shows that $Y^tA = 0$ and $Y \neq 0$.

Cor. (2.3.7.6). For any subspace in $\mathbb{R}^m$, either it has an intersection with the open first quadrant, or its orthogonal complement has an intersection with the closed first quadrant minus 0. (Regard it has the image of a $AX$).

8 Bilinear & Hermitian Forms

Prop. (2.3.8.1) [Hermitian Forms]. A complex vector space $V$ is equivalent to a real vector space with an endomorphism $J$ that $J^2 = -1$, by $i$ acting by $J$.

A Hermitian form on $(V, J)$ is an $\mathbb{R}$-bilinear mapping $(-, -) : V \times V \to \mathbb{C}$ that satisfies

$(Ju, v) = i(u, v), \quad (u, v) = (v, u)$.

If we write $(u, v) = \varphi(u, v) - i\psi(u, v)$, then

- $\varphi$ is symmetric, $\varphi(Ju, Jv) = \varphi(u, v)$.
- $\psi$ is alternating, $\psi(Ju, Jv) = \psi(u, v)$. 
• \( \psi(u,v) = -\varphi(u,Jv), \varphi(u,v) = \psi(u,Jv) \).

Conversely, if \( \varphi \) satisfies this condition, then

\[
(u,v) = \varphi(u,v) + i\varphi(u,Jv).
\]

is a Hermitian form. Also \((-,-)\) is positive or non-singular iff \( \varphi \) is.

**Lemma (2.3.8.2).** Any eigenvalue of a Hermitian (e.g., real symmetric) matrix \( M \) is real.

**Proof:** Consider the bilinear form defined by the matrix \( M \), then if \( x \) is an eigenvector with eigenvalue \( \lambda \), then \( \lambda(x,x) = (Hx,x) = (x,Hx) = \overline{\lambda}(x,x) \), so if \( \lambda \) is not real, \( x = 0 \).

**Prop. (2.3.8.3) [Principal Axis Theorem].** A symmetric matrix \( A \) is orthogonally diagonalizable. Similarly, a Hermitian matrix is unitarily diagonalizable.

**Proof:** Firstly, we can find an eigenvector of \( A \): Only the real case needs proof, and this is because any eigenvalue of \( A \) is real (2.3.8.2).

Let \( v \) be an eigenvector of \( A \) of length 1, then the orthogonal complement of \( v \) is preserved by \( A \), so we can use induction to find an orthonormal basis consisting of eigenvectors of \( A \), then these together with \( v \) forms an orthonormal basis consisting of eigenvectors of \( A \).

**Prop. (2.3.8.4) [Complex Normal operators].** More generally, a normal operator over \( \mathbb{C} \) is unitarily diagonalizable using resolution of identity (10.8.4.3) because the spectrum are discrete thus the point projection is orthogonal.

**Prop. (2.3.8.5) [Gram-Schmidt].** Any symmetric matrix over fields of characteristic \( \neq 2 \) is congruent to a diagonal matrix.

**Proof:** Any symmetric matrix defines a bilinear form on \( V \). If \( B \) is not identically 0, then there is a \( x \) that \( x^tBx \neq 0 \), by polarization identity. Then \( W = \{Kx\} \) is non-degenerate, so we have \( W \oplus W^\perp = V \) by (12.3.1.8). And by induction, we are done.

**Prop. (2.3.8.6) [Antonne-Takagi].** For any complex symmetric matrix \( A \), there is unitarily matrix \( U \) that \( UAU^t \) is a real diagonal matrix with non-negative entries.

**Proof:** Consider \( B = A^*A \) is Hermitian and positive-semi-definite, thus there is a unitary matrix \( V \) that \( V^*BV \) is diagonal with non-negative real entries by (2.3.8.3). Now \( C = V^tAV \) is complex symmetric with \( C^*C \) real diagonal. If we let \( C = X + iY \), then \( XY = YX \). So by (2.3.6.5), there is a real orthogonal matrix \( W \) that \( WXW^t \) and \( WYW^t \) are diagonal. Now set \( U = VW^t \), which is unitary, \( UAU^t \) is complex diagonal. And easily we can modify the diagonal entries to be non-negative.

**Prop. (2.3.8.7) [Skew-Symmetric Forms].** For any f.d. skew-symmetric vector space \( V \) over a field \( k \) with \( \text{char} \ k \neq 2 \), then there exists a basis \( \{x_1, \ldots, x_r, y_1, \ldots, y_r, z_1, \ldots, z_k\} \) s.t. \( (x_i, y_i) = -(y_i, x_i) = 1 \), and the inner product of other pairs in this basis vanish. In particular, if \( V \) is non-degenerate, then \( \dim V \) is even.

**Proof:** Use induction on \( \dim V \). If \( \dim V = 0 \), this is clear. For \( \dim V > 0 \), if there exists a pair \( (x,y) \neq 0 \), then we can take \( (x,y) = 1 \), and we can look at the complement \( \{x,y\}^\perp \subset V \) and use induction.
Prop. (2.3.8.8). Given a bilinear form on a field, the relation of orthogonality is symmetric iff it is symmetric or alternating, i.e. $B(x, x) = 0$.

Proof: Let $w = B(x, z)y - B(x, y)z$, then $B(x, w) = 0$, hence we have $B(w, x) = 0$, that is

$$B(x, z)B(y, x) - B(x, y)B(z, x) = 0.$$  

Let $z = x$, then $B(x, x)[B(x, y) - B(y, x)] = 0$.

If some $B(u, v) \neq B(v, u)$ and $B(w, w) \neq 0$, then $B(u, u) = B(v, v) = 0, B(w, v) = B(v, w), B(w, u) = B(u, w)$. Let $x = u$ or $v$ se get $B(w, v) = B(v, w) = 0 = B(w, u) = B(u, w)$. Now $B(u, w + v) \neq B(w + v, u)$, hence $B(w + v, w + v) = 0 = B(w, w)$, contradiction. $\square$

Prop. (2.3.8.9). If $B$ is a non-degenerate bilinear form on an associative algebra $V$, choose a basis $x_i$ of $V$, then choose a dual basis $y_i$, then $\sum x_i \otimes y_i \in T(V)$ is independent of $x_i$ chosen.

Proof: Let $V^\vee$ be the dual of the vector space $V$. There is an isomorphism $V \otimes V^\vee \cong \text{End}(V)$ given by mapping $(v, f)$ to the operator $v' \mapsto f(v')v$. The non-degenerate bilinear form induces naturally an isomorphism $\beta : V \cong V^\vee : v \mapsto (., v)$. Then under the isomorphisms

$$\text{End}(V) \cong V \otimes V^\vee \cong V \otimes V,$$

where the second isomorphism is $(\text{id}_V, \beta^{-1})$. The identity map $\text{id}_V \in \text{End}(V)$ is send to $\sum x_i \otimes y_i \in T(V)$, so $\sum x_i \otimes y_i$ is independent of the basis chosen. $\square$

Symmetric Bilinear Forms

For symmetric bilinear forms and more about quadratic forms, see 12.3.

Real Spectral Theory

Remark (2.3.8.10). The general spectral theory applies to this case.

Prop. (2.3.8.11). For a normal operator $N$ on a real inner product space, $N\alpha = 0$ iff $N^t\alpha = 0$. In particular, $N$ and $N^t$ has the same number of eigenvalues and dimension of eigenspaces.

Proof: This is because

$$(N\alpha, N\alpha) = (N^tN\alpha, \alpha) = (NN^t\alpha, \alpha) = (N^t\alpha, N^t\alpha).$$  

$\square$

Cor. (2.3.8.12). For a normal operator $N$ on a real inner product space, $\text{Im}(N) = \ker(N)^\perp$.

Proof: $\text{Im}(N) = \ker(N^*) = \ker(N)$. $\square$

Cor. (2.3.8.13). For a normal operator $N$ on a real inner product space, if $N^2\alpha = 0$, then $N\alpha = 0$.

Proof: This is because $N\alpha \in \ker(N) \cap \text{Im}(N) = \emptyset$. $\square$

Lemma (2.3.8.14). If $f, g$ are relatively prime polynomials and $T$ is a normal operator, $f(T)\alpha = 0$ and $g(T)\beta = 0$, then $\alpha$ is orthogonal to $\beta$.  

$\square$
Proof: Choose polynomials $a, b$ that $af + bg = 1$, then $\alpha = b(T)g(T)\alpha$, and
\[(\alpha, \beta) = (b(T)g(T)\alpha, \beta) = (b(T)\alpha, g(T)^*\beta)\]
Notice $g(T)$ is also normal, and $g(T)\beta = 0$, thus by (2.3.8.11) $g(T)^*\beta = 0$. Thus $\alpha, \beta$ are orthogonal. $\square$

**Lemma (2.3.8.15).** Let $V$ be a real inner product space and $S$ an operator that $S^2 = -1$. Suppose $\alpha \in V$ and $S\alpha = -\beta$, then
\[
S^*\alpha = \beta, \quad S^*\beta = -\alpha,
\]
$\alpha, \beta$ are orthogonal, and $||\alpha|| = ||\beta||$.

**Proof:** Because $\alpha, \beta$ are orthogonal, and $\alpha \perp \beta$, and $S\alpha = -\beta$. Let $V = \ker(p_1(T))$, then $V$ is invariant under $T$, and $W = \sum V_j$ is orthogonal to $W_j$ by (2.3.8.14).

The restriction of $T$ on $W_i$ has minimal polynomial $p_i$. If $p_i$ has degree 1, then $T$ is a scalar on $W_i$. If $p_i$ has degree 2, then $p_i = (x - a)^2 + b^2$ for some $a, b \in \mathbb{R}, b \neq 0$. Then we choose a maximal $k$ that there exists subspaces $V_j \in W_i, j \leq k$ that
- $\dim V_j = 2$.
- $V_j$ are pairwise orthogonal.
- $V_j$ is invariant under $T, T^*$, and $T|_{V_j}$ is orthogonal congruent to $\begin{bmatrix} a_i & b_i \\ -b_i & a_i \end{bmatrix}$.

Then denote $W = \bigoplus_{j=1}^k V_j$, we prove that $W = V$: Suppose not, then $W^{\perp} \neq 0$ is invariant under $T$ and $T^*$. Denote $S = b^{-1}(T - a)$, then $S^2 + 1 = 0$. Let $\alpha \neq 0 \in W^{\perp}$, then $S\beta = -S\alpha$, then $S\alpha = \alpha, \alpha, \beta \in W^{\perp}$. Since $T = aI + bS$, we have
\[
T\alpha = a\alpha - b\beta, \quad T\beta = b\alpha + a\beta.
\]
Now lemma (2.3.8.15) implies $\{\alpha, \beta\}$ is invariant under $S, S^*$ thus also $T, T^*$, so this gives another $V_{k+1}$, contradiction. $\square$
Cor. (2.3.8.17) [Unitary Equivalence of Normal Operators]. Let $T, T'$ be real (complex) normal matrices, then $T$ is orthogonally (unitarily) congruent to $T'$ iff $T$ and $T'$ have the same characteristic polynomial.

Proof: This follows from (2.3.8.16) (or (2.3.8.4)). □

Cor. (2.3.8.18) [Complex Structure Form]. A real normal matrix $J$ s.t. $J^2 + 1 = 0$ is orthogonal congruent to $\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}_n$.

In particular, as such $J$ is equivalent to a complex structure on $\mathbb{R}^n$, so the set of complex structures is bijective to $O(n)/U(\frac{n}{2})$ thus can be endowed with a structure of a homogenous space.

Proof: This is because $J$ and $\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}_n$ are both normal and they have the same characteristic polynomial, by (2.3.5.3). □

Def. (2.3.8.19) [Cayley-transformation]. For a field $k$ of char $k \neq 2$ and a matrix $P \in M_n(k)$ that has no eigenvalue $-1$, there is a Cayley transformation $A = \frac{1 - P}{1 + P}$. $1 + A$ is invertible, and

$$P = \frac{1 - A}{1 + A}.$$

Then $A$ is skew-symmetric iff $P$ is orthogonal.

Proof: If $Av = -v$, then $v - Pv = -v - Pv$, so $2v = 0$, so $v = 0$. So $A + 1$ is invertible.

If $P$ is orthogonal, then $A^t = \frac{1 - P^t}{1 + P^t} = \frac{1 - P^{-1}}{1 + P^{-1}} = -A$. Conversely, if $A^t = -A$, then $P^t = \frac{1 + A}{1 - A} = P^{-1}$. □

Prop. (2.3.8.20). If char $k \neq 2$ and $P$ is an orthogonal matrix of odd dimension, then det $P$ is an eigenvalue of $P$.

Proof: multiplying by $-1$, we can assume det $P = -1$. Consider the Cayley transformation (2.3.8.19), then

$$\text{det } P = \text{det}(1 - A) \text{det}(1 + A)^{-1} = \text{det}(1 - A)^t \text{det}(1 + A)^{-1} = 1.$$

Contradiction. □

Hermitian Spaces

Def. (2.3.8.21) [Hermitian Space]. Let $E$ be a field, $F$ a Galois extension of $E$ of degree 2 with involution $x \mapsto \overline{x}$ or $E \oplus E$ with involution $(x, y) = (y, x)$.

Then a Hermitian space over $F/E$ is a free $F$-module $V$ with a $E$-map $(\cdot, \cdot) : V \times V \to F$ s.t.

- $(cx, y) = (x, cy) = c(x, y)$ for $c \in F$.
- $(x, y) = (y, x)$.
- the pairing is non-degenerate.

Def. (2.3.8.22) [Hermitian Transpose]. Let $L : V \to W$ be a map between Hermitian spaces, then there is a Hermitian transpose $F$-anti-linear map $L^* : W^* \to V^*$ that satisfies

$$(Lu, w) = (u, L^* w).$$

As the pairing on $V$ is non-degenerate, this is map is uniquely determined.
Def. (2.3.8.23) [Hermitian Matrix]. A Hermitian matrix is a matrix $A \in M_{n \times n}(F)$ that satisfies $A^t = \overline{A}$.

Prop. (2.3.8.24) [Gram Matrix]. Let $V$ be a $n$-dimensional vector space with a canonical basis $e_1, \ldots, e_n$, then a $n \times n$ symmetric (Hermitian) matrix $M$ defines a bilinear (sesqui-linear) form $B$ on $V$ by $(x, y) \mapsto x^t My(x^t My)$. Conversely, for any bilinear (sesqui-linear) form $B$ on $V$, let $M = (a_{ij})$ where $a_{ij} = (e_i, e_j)$, then $M$ is symmetric (Hermitian) matrix, called the Gram matrix of $B$.

so we will interchange freely between a symmetric (Hermitian) matrix and a bilinear (sesqui-linear) form on $V$.

Proof: Trivial. □

9 Tensor Algebras

Def. (2.3.9.1) [Tensor Algebras]. The tensor product and tensor algebras of modules are defined in (2.2.4.13) and (4.1.1.20). In this subsection, we focus on tensor algebras of vector spaces.

Def. (2.3.9.2) [Symmetrized Tensors]. Let $V$ be a vector field over a field of characteristic 0, for any $n$, we define a multilinear map

\[ V^n \rightarrow T^n(V) : (v_1, \ldots, v_n) \mapsto \frac{1}{n!} \sum_{\sigma \in S_n} v_{\sigma(1)} \otimes \cdots \otimes v_{\sigma(n)}. \]

and descends to a linear map $\sigma : S^n(V) \rightarrow T^n(V)$, called the symmetrizer. Elements in $\text{Im}(\sigma) = \tilde{S}^n(V)$ is called symmetrized tensors.

Then $\sigma^2 = \sigma$, and $\ker(\sigma) = I \cap T^n$, where $I = \ker(T(V) \rightarrow \text{Sym}(V))$. In particular,

\[ T^n(V) = \tilde{S}^n(V) \oplus (T^n(V) \cap I). \]

Proof: $\sigma^2 = \sigma$ is easy. So $V = \text{Im}(\sigma) \oplus \ker(\sigma)$. Now $T^n(V) \cap I \subset \ker(\sigma)$, and because $\text{Im}(\sigma) \rightarrow S^n(V)$ is surjective, $T^n(V) \cap I = \ker(\sigma)$. □

Def. (2.3.9.3) [Anti-Symmetrized Tensors]. Let $V$ be a vector field over a field of characteristic 0, for any $n$, we define a multilinear map

\[ V^n \rightarrow T^n(V) : (v_1, \ldots, v_n) \mapsto \frac{1}{n!} \sum_{\sigma \in S_n} \text{sgn}(\sigma)v_{\sigma(1)} \otimes \cdots \otimes v_{\sigma(n)}. \]

and descends to a linear map $\tau : \wedge^n(V) \rightarrow T^n(V)$, called the anti-symmetrizer. Elements in $\text{Im}(\tau) = \tilde{\wedge}^n(V)$ is called anti-symmetrized tensors.

Then $\tau^2 = \tau$, and $\ker(\tau) = I \cap T^n$, where $I = \ker(T(V) \rightarrow \wedge(V))$. In particular,

\[ T^n(V) = \tilde{\wedge}^n(V) \oplus (T^n(V) \cap I). \]

Proof: $\tau^2 = \tau$ is easy. So $V = \text{Im}(\sigma) \oplus \ker(\sigma)$. Now $T^n(V) \cap I \subset \ker(\sigma)$, and because $\text{Im}(\sigma) \rightarrow S^n(V)$ is surjective, $T^n(V) \cap I = \ker(\sigma)$. □
10 Determinant and Trace

Def. (2.3.10.1)[Determinant]. For a linear operator $T \in L(V)$, as $\dim \wedge^n V^* = 1$, the determinant $\det(T) \in R$ is defined by $\wedge^n (T^t) = \det(T) \cdot \text{id}_{\wedge^n V^*}$. That is: $L(T\alpha_1, \ldots, T\alpha_n) = \det TL(\alpha_1, \ldots, \alpha_n)$. And the determinant of a matrix is defined by the linear operator it associates in a canonical basis.

Prop. (2.3.10.2)[Properties of Determinants].
1. $\det(\text{id}_V) = 1$.
2. $\det(UV) = \det U \cdot \det V$.
3. $T$ is invertible iff $\det T$ is invertible, in which case $\det(T^{-1}) = (\det T)^{-1}$.
4. If $\{\alpha_1, \ldots, \alpha_n\}$ is a basis for $V$, and $f_i$ is its dual basis, then $\det T = f_1 \wedge \ldots \wedge f_n(T\alpha_1, \ldots T\alpha_n)$.

Proof: All these are not hard. □

Cor. (2.3.10.3). $\det(P^{-1}AP) = \det(A)$.

Prop. (2.3.10.4). $\det T = \det T^t$.

Proof: Use (2.3.10.2), if $\{\alpha_1, \ldots, \alpha_n\}$ is a basis for $V$, and $f_i$ is its dual basis, then $\det T^t = f_1 \wedge \ldots \wedge f_n(T^t f_1, \ldots, T^t f_n) = f_1 \wedge \ldots \wedge f_n(T \alpha_1, \ldots T \alpha_n) = \det T$ □

Prop. (2.3.10.5)[Expansion of Determinants]. If $A_i$ be the $i$-th column of $A$, then $\det A = f_1 \wedge \ldots \wedge f_n(A \varepsilon_1, \ldots, A \varepsilon_n) = f_1 \wedge \ldots \wedge f_n(A_1, \ldots, A_n) = \sum_{\sigma \in S_n} \text{sgn}(\sigma) \prod_{1 \leq i \leq n} A_{\sigma(i)} i$.

Prop. (2.3.10.6). For a matrix, the determinant satisfies the following properties:
1. adding a multiple of a column/row to another column/row, the determinant doesn’t change.
2. Multiplying a row or a column with a scalar, then the determinant multiplies with this scalar.
3. Changing two rows or two columns makes the determinant multiply by $-1$.

Proof: All this follows from 4 of (2.3.10.2). Notice the last one follows from the first two. □

Prop. (2.3.10.7)[Laplacian Expansion Formula]. Cf.[Determinant 安金鹏 P15].

Prop. (2.3.10.8). Adjunction matrix, Cf.[Determinant 安金鹏 P16].

Proof: □

Cor. (2.3.10.9). If $AB = 1$, then $BA = 1$.

Prop. (2.3.10.10)[Cramer’s Rule]. Cf.[Determinant 安金鹏 P16].

Prop. (2.3.10.11)[Binet’s Formula]. Let $F/E$ be a Hermitian pair, $A \in M_{n \times m}(F)$, then $\det(A^*A) = \sum_{I \in \{0, \ldots, n\}, \# I = m} |\det(A_I)|^2$. 

Proof: □
Proof: Let \( L : F^m \to F^n \) be the corresponding map, then \( \wedge^n(L^*) \circ \wedge^n(L) = \wedge^n(L^* \circ L) \). In the canonical basis, the matrices for \( \wedge^n(L^*)(\text{resp. } \wedge^n(L)) \) have only one column(\text{resp. one row}) with entries \( \det(A_I) \) by definition(2.3.10.1), thus the assertion follows by(2.3.10.1) again. □

Prop. (2.3.10.12)[Sylvester’s Determinant Identity]. If \( A \) and \( B \) are matrices of sizes \( m \times n \) and \( n \times m \), then

\[
\det(I_m + AB) = \det(I_n + BA)
\]

Proof: Notice

\[
\begin{pmatrix} 1 & A \\ B & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ B & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 - BA \end{pmatrix} \begin{pmatrix} 1 & A \\ 0 & 1 \end{pmatrix}
\]

\[
= \begin{pmatrix} 1 & A \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 - BA & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ B & 1 \end{pmatrix}
\]

and use(2.3.10.2). □

Cor. (2.3.10.13). Multiplying by \( x \), we see that the characteristic polynomial of \( AB \) and \( BA \) are the same.

Remark(2.3.10.14). There is another proof in case \( m = n \): It suffices to show

\[
\det(I + (A + xI)(B + xI)) = \det(I + (B + xI)(A + xI)).
\]

But notice \( A + xI \) and \( B + xI \) are invertible in \( M_{n \times n}(K(X)) \), thus

\[
\det(I + (A + xI)(B + xI)) = \det((A + xI)((A + xI)^{-1} + (B + xI))) = \det(I + (B + xI)(A + xI)).
\]

Prop. (2.3.10.15).

\[
\det \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \det(A) \det(D - CA^{-1}B).
\]

Proof: As before, consider \( \det \begin{bmatrix} A + xI & B \\ C & D + xI \end{bmatrix} \), then \( A + xI \) is invertible, and this equals

\[
\det \begin{bmatrix} A + xI & B \\ C & D + xI - C(A + xI)^{-1}B \end{bmatrix} = \det(A + xI) \det(D + xI - C(A + xI)^{-1}B).
\]

Letting \( x = 0 \), we get the desired result. □

Prop. (2.3.10.16) [Symplectic Group Determinant]. The determinant of a symplectic matrix \( \in \text{Sp}(2n, \mathbb{R}) \) has determinant 1.

Proof: A symplectic matrix preserves the symplectic structure thus the symplectic form \( \omega \), hence preserves \( \omega^n \) which is \( n! \) times the volume form, so it has determinant 1 by definition(2.3.10.1). □

Prop. (2.3.10.17) [Vandermonde Matrix]. The \( n \times n \) Vandermonde matrix, with the \( k \)-th row \( (1, x_k, \ldots, x_k^n) \), has determinant \( \prod_{i<j}(x_i - x_j) \). So it is invertible when \( x_i \) are pairwisely different.

Proof: Eliminate the first row by adding columns. □
Prop. (2.3.10.18) [Pfaffian]. There is a polynomial $\text{Pf}$ called Pfaffian s.t. $\det M = \text{Pf}(M)^2$ for a skew-symmetric matrix. This is because a skew symmetric is equal to $A^t \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}^k A$ for $A$ an orthogonal matrix (2.3.8.3), so it has determinant $(\det A)^2$ and $A$ and depends polynomially on the entries of $M$.

Cor. (2.3.10.19).

$\text{Pf}(A^t MA) = \det A \cdot \text{Pf}(M)$.

Because we only need to consider the sign and it is determined by letting $A = \text{id}$.

Traces

Def. (2.3.10.20) [Trace]. For a $n \times n$-matrix $A$, define its trace $\text{tr}(A)$ to be the minus of the coefficient of $x^{n-1}$ in $\det(xI - A)$. It is clear that $\text{tr}(A) = \sum_{i=1}^n a_{ii}$, and by (2.3.10.3) that traces are invariant under conjugacy.

Prop. (2.3.10.21). $\text{tr}(AB) = \text{tr}(BA)$.

Proof: This is because $\det(x - AB) = \det(x - BA)$ by Sylvester determinant identity (2.3.10.12).

Prop. (2.3.10.22) [Trace Formula]. For $V \in \text{Vect}/k, F \in \text{End}(V), d \in \mathbb{Z}_+$,

$$t \frac{d}{dt} \log \det(1 - FT)^{d-1} = \sum_{i \geq 1} d \text{tr}(F^i|V)T^i + 1 + T k[[T]].$$

In particular, if char $k = 0$,

$$\det(1 - FT)^d|V|^{-1} = \exp\left(\sum_{i \geq 1} \text{tr}(F^i|V)\frac{T^d}{i}\right) + 1 + T k[[T]].$$

Proof: Pass to $\overline{k}$ and let $k_1, \ldots, k_r$ be the eigenvalues of $F$.

11 (Real) Quaternion Algebra

Remark (2.3.11.1). The argument below are largely true for any skew field.

Def. (2.3.11.2) [Real Quaternion Algebra]. The real quaternion algebra $\mathbb{H}$ is the space $\mathbb{R}\{1, i, j, k\}$ subjects to the relations

$$ij = -ji = k, jk = -kj = i, ki = -ik = j, i^2 = j^2 = k^2 = -1.$$

In fact, by (12.3.5.6), any quaternion algebra over $\mathbb{R}$ is isomorphic to $\mathbb{H}$.

Prop. (2.3.11.3) [Module of Quaternion Algebras]. There is an involution on $\mathbb{H}$ that $\overline{x} = \frac{a + bi + cj + dk}{a - bi - cj - dk} = a - bi - cj - dk$. Then we define a the module of $x \in \mathbb{H}$ as

$$|x|^2 = x\overline{x} = \overline{x}x = a^2 + b^2 + c^2 + d^2.$$

Then every non-zero element of $\mathbb{H}$ is invertible. In particular, it is a skew field.
Prop. (2.3.11.4). H is isomorphic to subalgebra of matrices in $M(2, \mathbb{C})$ consisting of elements of the form
\[
\left\{ \begin{bmatrix} \alpha & -\overline{\beta} \\ \beta & \overline{\alpha} \end{bmatrix} \right\} | \alpha, \beta \in \mathbb{C} \}
\]

Prop. (2.3.11.5). The center of H is $\mathbb{R}$, by (12.3.4.3).

Prop. (2.3.11.6) [Invertible Quaternion Matrices]. Denote $GL(n, \mathbb{H})$ the set of invertible matrices in $M_n(\mathbb{H})$. If $A \in M_n(\mathbb{H})$, $A$ acts on $\mathbb{H}^n$, and determines a complex matrix $A'$ in $M_{2n}(\mathbb{C})$.

- If $A, B \in M_n(\mathbb{H})$ satisfies $AB = 1$, then $BA = 1$.
- $A \in M = GL(n, \mathbb{H})$ iff $A' \in GL(2n, \mathbb{C})$. In particular if we define the determinant of $A \in M_n(\mathbb{H})$ as the determinant of $A'$, then $\det(A) \neq 0$ iff $A$ is invertible.

Proof: 1: $(AB)' = A'B'$, thus $M_n(\mathbb{H})$ is a subalgebra of $M_{2n}(\mathbb{C})$. Thus $B'A' = 1$ by (2.3.10.9).

2: If $A'$ is invertible, then $A$ is a bijection, thus there are vectors $v_1, \ldots, v_n$ that $Av_i = e_i$. This means
\[
(v_1, \ldots, v_n)A = 1.
\]
Thus by item 1 $A$ is invertible. \(\square\)

Def. (2.3.11.7) [Sesquilinear Form on $\mathbb{H}^n$]. Let $V = \mathbb{H}^n$, then a sesquilinear form on $\mathbb{H}^n$ is a bi-additive function $(\cdot, \cdot) : V \times V \rightarrow \mathbb{H}$ such that
\[
(x\alpha, y\beta) = \overline{\pi}(x, y)\beta, \quad \alpha, \beta \in \mathbb{H}.
\]

Moreover if it is called a Hermitian form iff $(x, y) = \overline{(y, x)}$, and skew-Hermitian iff $(x, y) = -(y, x)$.

Prop. (2.3.11.8) [Quaternion Hermitian Forms].

- Every non-degenerate Hermitian quaternion form is of the form
\[
(x, y) = \overline{x}_1y_1 + \ldots + \overline{x}_py_p - \overline{x}_{p+1}y_{p+1} - \ldots - \overline{x}_ny_n
\]
in some basis. And $p$ is uniquely determined.

- Every non-degenerate skew-Hermitian quaternion form is of the form
\[
(x, y) = \overline{x}_1y_1 + \ldots + \overline{x}_ny_n
\]
in some basis.

Proof: Firstly, there are some $v$ that $(v, v) \neq 0$: If $(v, v) = 0$ for all $v$, then $(x, y) + (y, x) = 0$ for all $x, y$. If it is skew-Hermitian, this means $(x, y)$ is real, which is impossible, unless $(x, y) = 0$. If it is Hermitian, this means $(x, y)$ is imaginary, but $(x, y\overline{i}), (x, y\overline{j}), (x, y\overline{k})$ are all imaginary, thus $(x, y) = 0$.

Then choose this $v$, and take the orthogonal complement of $v$, then by induction we can find $v_1, \ldots, v_n$ that is mutually orthogonal.

If it is Hermitian, then $(v_i, v_i) \in \mathbb{R}$, thus we can find some $t_i \in \mathbb{R}$ that $(tv_i, tv_i) = \pm 1$. $2p$ is the multiplicity of the eigenvalue 1 of the eigenspace of to the matrix corresponding to the form, so $p$ is uniquely defined.

If it is skew-Hermitian, then $(v_i, v_i)$ is imaginary, thus by (11.6.4.3), there are $u_i \in \mathbb{H}$ that $(u_i, v_i, u_i, v_i) = \overline{u}_i(v_i, v_i)u_i = j$. \(\square\)
Cor. (2.3.11.9).
- Every non-degenerate Hermitian quaternion form is of the form
  \[(x, y) = B_1(x, y) + jB_2(x, y)\]
in some basis, where \(B_1(x, y)\) is the usual canonical Hermitian form of signature \((2p, 2q)\), and \(B_2\) is the usual canonical skew-symmetric bilinear form. Also \(B_2(x, y) = B_1(xj, y)\).

- Every non-degenerate skew-Hermitian quaternion form is of the form
  \[(x, y) = B_1(x, y) + jB_2(x, y)\]
in some basis, where \(B_1(x, y)\) is the usual canonical skew-Hermitian form that \(iB_1\) is Hermitian of signature \((n, -n)\), and \(B_2\) is the usual canonical symmetric bilinear form. Also \(B_2(x, y) = B_1(xj, y)\) in some basis.

12 Others

Prop. (2.3.12.1). Let \(H^* = \bigoplus_{i=0}^{2d} H^i\) be a graded algebra over a field s.t. \(\dim H^i < \infty\) for each \(i\). Assume that for each \(0 \leq i \leq 2d\), there is a perfect pairing
\[H^i \times H^{2d-i} \to K\]
induced from an isomorphism \(\text{tr} : H^{2d} \cong K\), Let \(\varphi\) be a ring endomorphism of \(H^*\) that satisfies
- \(\varphi(H^i) \subset H^i\),
- \(\varphi_{2d} = \text{id}\)

Then each \(\varphi_i\) is invertible, and \(\varphi_i^{-1} = \varphi_{2d-i}^t\), where \(\varphi_{2d-i}^t\) is the transpose of \(\varphi_{2d-i}\) w.r.t. the perfect pairing \(H^i \times H^{2d-i} \to K\).

Proof: Let \(a \in H^i\) be any element, if \(a \neq 0\), then because the pairing \(H^i \times H^{2d-i} \to K\) is perfect, there exists some \(b \in H^{2d-i}\) s.t. \(ab \neq 0\). Thus \(\varphi_i(a)\varphi_{2d-i}(b) \neq 0\), thus \(\varphi_i\) is injective. Now \(\text{tr}(\varphi_i^{-1}(a)b) = \text{tr}(\varphi_{2d}(\varphi_i^{-1}(a)b)) = \text{tr}(a\varphi_{2d-i}(b))\), thus \(\varphi_i^{-1} = \varphi_{2d-i}^t\). \(\Box\)
2.4 More on (Non-Commutative) Algebras

Notations (2.4.0.1).

- Use notations defined in Abstract Algebra.

1 Semisimplicity

Def. (2.4.1.1). For \( R \in \mathfrak{Ring} \), a simple \( R \)-module is a \( E \in \Mod_R \) that no submodules other than 0 and \( E \). It is called faithful iff there is no nonzero element \( a \in R \) that \( ax = 0 \) for any \( x \in E \).

- It is called non-degenerate if \( RE = E \).

Prop. (2.4.1.2) [Shur’s lemma]. For \( R \in \mathfrak{Ring} \) and \( E \) a simple \( R \)-module, \( \text{End}_R(E) \) is a division ring, this is because the kernel and image are all 0 or \( E \).

Cor. (2.4.1.3) [Uniqueness of Decomposition of Modules]. If an \( R \)-module \( E \) can be written as a finite direct sum of simple \( R \)-modules in multiple ways, then the multiplicity of the irreducible modules appearing in it is uniquely determined.

Proof: Cf. [Lang, Algebra, P643]

Def. (2.4.1.4) [Semisimple Modules]. For \( R \in \mathfrak{Ring} \), a semisimple \( R \)-module is a \( E \in \Mod_R \) iff it satisfies the following equivalent conditions:

- It is a sum of simple modules.
- It is a direct sum of simple modules.
- Any submodule \( F \) of \( E \) has a complement in \( E \).

Proof: 3 \( \rightarrow \) 2: By Zorn’s lemma, it suffices to show any non-zero semisimple module contains a simple submodule: Take a \( m \neq 0 \in M \), then we may assume \( M = Rm \), and by Zorn’s lemma there is a maximal submodule \( N \) that \( m \notin N \), and let \( N \oplus N' = M \), then we show \( N' \) is simple. because any submodule \( N'' \) satisfies \( m \in N \oplus N'' \) thus \( N'' = N' \).

2 \( \rightarrow \) 1 is immediate, it suffices to show 1 \( \rightarrow \) 3: for any submodule \( N \subset M \), consider all the simple modules that intersect \( N \) trivially, denote their sum by \( V \), I claim \( N \oplus V = M \), otherwise, let \( S \) be a simple submodule that contained in \( N + V \), then \( S \cap (N + V) = 0 \), so \( N \cap (S + V) = 0 \), contradicting the maximality.

Cor. (2.4.1.5). For \( R \in \mathfrak{Ring} \), any submodule and quotient module of a semisimple \( R \)-module is semisimple.

Proof: The quotient is clearly a sum of simple modules, and for a submodule, its submodule has a complement.

Density Theorems

Def. (2.4.1.6). If \( E \) be a semisimple \( R \)-module, let \( R' = \text{End}_R(E) \), then \( E \) is also a \( R' \)-module, where the action is given by \( (\varphi, x) \rightarrow \varphi(x) \). Then any element of \( R \) defines an element of \( \text{End}_{R'}(E) \) by left multiplication. If we called \( \text{End}_{R'}(E) \) the bicommutant of \( E \) over \( R \), then
Lemma (2.4.1.7). For a module $E$ over $R$, let $\text{End}_{R'}(E)$ be the bicommutant. If $f \in \text{End}_{R'}(E)$ and $x \in E$, then there is an element $\alpha \in R$ that $\alpha x = f(x)$.

Proof: Since $E$ is semisimple, write $E = Rx \oplus F$, and let $\pi$ be the projection unto $Rx$, then $\pi \in \text{End}_R(E)$, and $f(x) = f(\pi(x)) = \pi f(x) \in Rx$. □

Prop. (2.4.1.8) [Jacobson Density Theorem]. Let $E$ be semisimple over $R$ and let $R' = \text{End}_R(E)$. If $f \in \text{End}_{R'}(E)$ and $x_1, \ldots, x_n \in E$, then there is an element $\alpha \in R$ that $\alpha x_i = f(x_i)$ for all $i$.

In particular, if $E$ is f.g. over $R'$, the natural map $R \to \text{End}_{R'}(E)$ is surjective.

Proof: Consider $f^n \in \text{End}_R(E^n)$, then it is just a $n \times n$ matrix with entries in $R'$.

Consider the lemma (2.4.1.7) shows there is an $\alpha \in R$ that

$$(\alpha x_1, \ldots, \alpha x_n) = (f(x_1), \ldots, f(x_n))$$

which is the result. □

Cor. (2.4.1.9) [Wedderburn Theorem]. Let $R \in \mathfrak{Ring}$ and $E$ is a faithful simple $R$-module. Let $D = \text{End}_R(E)$. If $E$ is of f.g. over $D$, then $R = \text{End}_k(E)$.

Proof: The density theorem (2.4.1.8) and the fact $E$ is f.g. over $D$ shows that $R \to \text{End}_k(E)$ is surjective, and also injective because it is faithful, thus $R = \text{End}_k(E)$. □

Cor. (2.4.1.10) [Burnside’s Theorem]. Let $E$ is an $R$-module that is f.d over an alg.closed field $k$ and $R$ is a subalgebra of $\text{End}_k(E)$. If $E$ is simple as an $R$-module, then $R = \text{End}_k(E)$.

Proof: It follows from Shur’s lemma (2.4.1.12) and (2.2.1.10) $R' = \text{End}_R(E)$ is just $k$, so we can use Wedderburn’s theorem (2.4.1.9). □

Cor. (2.4.1.11) [F.d. Simple Module over Commutative Algebra]. If $R$ is commutative and $E$ is a simple $R$-module of f.d. over an alg.closed field $k$, then $E$ is of 1-dimensional.

Proof: The theorem shows the image of $R$ in $\text{End}_k(E)$ is all of $\text{End}_k(E)$, but Shur’s lemma (2.4.1.12) and (2.2.1.10) that the image of $R$ consists of scalars, thus $\dim_k E = 1$. □

Prop. (2.4.1.12) [Projection Operators]. Let $k$ be a field and $R$ is a $k$-algebra. If $V_1, \ldots, V_n$ are pairwise non-isomorphic simple $R$-modules of f.d. over $k$, then there exists elements $e_i$ in $R$ that acts as identity on $V_i$ and 0 on other $V_j$.

Proof: This is an immediate consequence of Jacobson density theorem (2.4.1.8) applied to the projection operator on $\oplus_i V_i$. □

Prop. (2.4.1.13) [Characters Determine F.D. Representations (Bourbaki)]. Let $R$ be an algebra over a field $k$ of char0, $E_1, E_2$ be two f.d. semisimple $R$-module over $k$, then if the character $\chi_1 = \chi_2$, then the $R$-modules $E_1, E_2$ are isomorphic.

Proof: $E, F$ are isomorphic to direct sums of simple $R$-modules, so it suffices to show the multiplicities $m, n$ of any simple module $V$ is the same. We can find an element $e$ that is identity on $E$ and 0 on other simple modules $V_i$ by (2.4.1.12), thus the trace of $e$ on $E, F$ are $m \dim_k(V), n \dim_k(V)$ respectively, thus $m = n$ because $k$ is of char0. □
Def. (2.4.1.14) [Matrix Coefficients]. For an algebra $R$ and an $R$-module $M$ over a field $k$, then a matrix coefficient of $M$ is a function $c : R \to k$ of the form $c(r) = L(rx)$, where $L$ is a linear functional on $M$ and $x \in M$.

Cor. (2.4.1.15). If $R$ is an algebra over a field $k$ and two simple $R$-modules that is f.d. over $k$ have a nonzero matrix coefficient in common, then they are isomorphic.

Proof: Let $c(r) = L_1(rx_1) = L_2(rx_2)$. If they are non-isomorphic, then we can find a $e \in R$ that is identity on $M_1$ and $0$ on $M_2$ by (2.4.12). Let $c(u) \neq 0$, then
\[
    c(ue) = L_1(ue x_1) = L_1(u x_1) = c(u) \neq 0, \quad c(ue) = L_2(ue x_2) = L_2(0) = 0
\]
contradiction.

Prop. (2.4.1.16) [Simple Modules of Tensor Product]. Let $A, B$ be algebras over a field $\Omega$, $R = A \otimes B$, then:

- If $P$ be a simple $R$-module of f.d. over $\Omega$, then there is a simple $A$-module $M$ and a simple $B$-module $N$ that $P$ is isomorphic to a quotient of $M \otimes N$. Also the isomorphism classes of $M, N$ are uniquely determined.

- If $\Omega$ is alg.closed and $M, N$ are simple modules of $A, B$ of f.d. over $\Omega$, then $M \otimes N$ is a simple module over $A \otimes B$.

Proof: 1: because $P$ is f.d., it contains a simple $A$-module $M$. Let $N_1 = \text{Hom}_A(M, P)$, then it is a $B$-module as $A, B$ commutes in $A \otimes B$. Then we can define a map $\lambda : M \otimes N_1 \to P$, which is a $A \otimes B$-module morphism. Now $N_1$ is also of f.d., so it contains a simple $B$-module $N$, and $\lambda$ is clearly non-zero on $M \otimes N$, thus its image is all of $P$, as $P$ is simple.

For the uniqueness, let $d = \dim N$, then $P$ is isomorphic to $k \leq d$ copies of $M$ as an $A$-module, so the isomorphism class of $M$ is determined, so does that of $N$.

2: Consider the map of $A, B$ to $\text{End}_\Omega(M), \text{End}_\Omega(N)$ are surjective by (2.4.10). Then it suffices to show that $M \otimes N$ are simple over $\text{End}_\Omega(M) \otimes \text{End}_\Omega(N)$, but this is just $\text{End}_\Omega(M \otimes N)$, over which $M \otimes N$ is clearly simple.

Semisimple Rings and Simple Rings

Def. (2.4.1.17) [Semisimple Ring]. A (left) semisimple ring is a ring $R$ s.t. it is a (left)semisimple module over itself. In (2.4.1.23), we will see a semisimple ring is semisimple in both sides.

Prop. (2.4.1.18). Any semisimple ring is left Artinian and Noetherian.

Proof: Consider the decomposition $R = \bigoplus_{\alpha} \mathcal{A}_\alpha$, where $\mathcal{A}_\alpha$ are simple left $R$-ideals. Then by considering the decomposition of $1 \in R$, clearly this is a finite sum. The rest is easy.

Prop. (2.4.1.19). If $R$ is a semisimple ring, then any $R$-module is semisimple.

Proof: Any $R$-module is a quotient of a free $R$-module, thus semisimple, by (2.4.15).

Prop. (2.4.1.20). $R$ is semisimple iff all $R$-modules are projective.

Proof: If $R$ is left-semisimple, for any $R$-module $P$ and an exact sequence
\[
    0 \to N \to M \to P \to 0
\]
by (2.4.1.19), there is a complement of $N$ in $M$, thus this sequence splits and $P$ is projective. The converse is also clear that any submodule of any $R$-module has a complement.
Lemma (2.4.1.21). Let $D$ be a division ring and $R = M_n(D)$, then
- $R$ is simple, left semisimple and left Noetherian.
- $R$ has a unique left simple module $V$, and $R$ acts faithfully on $V$, with $R \cong nV$.
- $\text{End}_R(V) \cong D$.

Proof: Cf. [Lam, P31].

Prop. (2.4.1.22) [Wedderburn-Artin]. Any left semisimple ring is of the form $R \cong \text{Mat}(n_1, D_1) \times \cdots \times \text{Mat}(n_r, D_r)$, and $D_i$ are uniquely determined division rings. There are exactly $r$ different left simple $R$-modules and $D_i$ are uniquely determined.

Proof: Consider the decomposition $R \cong n_1V_1 \oplus \cdots \oplus n_rV_r$ where $V_i$ are simple left $R$-modules. Then we can use Schur’s lemma (2.4.1.2) and (2.4.1.21) to calculate the endomorphism ring, so:

$$R \cong \text{End}(n_1V) \times \cdots \times \text{End}(n_rV_r) \cong \text{Mat}(n_1, D_1) \times \cdots \times \text{Mat}(n_r, D_r).$$

For the uniqueness, we use (2.4.1.21), which shows $D_i$ and $V_i$ both can be recovered.

Cor. (2.4.1.23). $R \in \text{Ring}$ is left semisimple iff it is right semisimple. ((2.3.1.11) is used).

Cor. (2.4.1.24). A semisimple commutative ring is a finite direct product of fields.

Def. (2.4.1.25) [Semisimple Categories]. Let $k \in \text{Field}$ and $\mathcal{A}$ a $k$-linear Abelian category that End$(X)$ are all finite $k$-modules for $X \in \mathcal{A}$, then $\mathcal{A}$ is semisimple iff End$(X)$ is a semisimple $k$-algebra for any $X$.

Proof: If $\mathcal{A}$ is semisimple, then any $X \in \mathcal{A}$ is a direct sum of simple objects, so End$(X)$ is semisimple.

Conversely, if End$(X)$ is semisimple thus a product of matrix algebras over division algebras, so $X$ can be indecomposable only if End$(X)$ is a division algebra. Now if $f : M \to N$ is a morphism of indecomposable objects, if there is a map $g : N \to M$ that $g \circ f \neq 0$, then $g \circ f$ is an automorphism of $M$, and $(g \circ f)^{-1} \circ g$ is a right inverse to $f$, so $N$ is a direct sum of $M$, and thus $f$ is an isomorphism because $M$ is indecomposable.

Now it suffices to show any indecomposable object is simple. If $M$ is an indecomposable object properly contained in another indecomposable object, then

$$\begin{bmatrix} 0 & 0 \\ \text{Hom}(M, N) & 0 \end{bmatrix} \subset \begin{bmatrix} \text{End}(M) & \text{Hom}(N, N) \\ \text{Hom}(M, N) & \text{End}(N) \end{bmatrix} = \text{End}(M \oplus N)$$

is a two sided nilpotent nonzero ideal, contradicting the fact End$(M \oplus N)$ is semisimple.

Prop. (2.4.1.26) [Semisimplicity and Base Change]. If $A \in \text{Alg}_k$ and $A \otimes_k K$ is semisimple for some field extension $K/k$, then $A$ is semisimple. Conversely, if $A$ is semisimple, then $A \otimes_k K$ is semisimple for every separable field extension $K/k$.

Prop. (2.4.1.27) [Characters Determine F.D. Representations]. If \( R \) is a semisimple ring over a field \( k \) of characteristic 0, then its f.d. representations are determined by their characters, by (2.4.1.13).

Prop. (2.4.1.28) [Simple Artinian Algebras]. For a simple ring \( R(2.2.1.2) \), the following are equivalent:

- \( R \) is left semisimple.
- \( R \) is left Artinian.
- \( R \) has a minimal left ideal.
- \( R \cong \text{Mat}(n,D) \) for some division ring \( D \).

Proof: The equivalence of 1, 4 is by Wedderburn theorem (2.4.1.22) and (2.4.1.21). 2 \( \rightarrow \) 3 is easy, and for 1 \( \rightarrow \) 2, \( R \) is a finite direct sum of minimal ideals by Wedderburn theorem (2.4.1.22), so it is Artinian.

For 3 \( \rightarrow \) 1, consider all the ideals in \( R \) that is isomorphic to the minimal ideal \( \mathfrak{A} \), then it is also a right ideal of \( R \), so equals \( R \), hence \( R \) is semisimple. \( \square \)

Cor. (2.4.1.29). And finite simple \( k \)-algebra \( A \) is of the form \( M_n(D) \) where \( D \) is a finite division ring over \( k \). This is because \( A \) is clearly left Artinian.

Prop. (2.4.1.30) [Double Centralizer Property]. Let \( R \) be a simple ring and \( \mathfrak{A} \) a nonzero left ideal. Let \( D = \text{End}_R(\mathfrak{A}) \), then the natural map \( f : R \rightarrow \text{End}(\mathfrak{A}_D) \) is an isomorphism.

Proof: since \( R \) is simple, \( f \) is injective. To show it is surjective, let \( E = \text{End}(\mathfrak{A}_D) \), then for any \( a, r \in \mathfrak{A} \) and \( h \in E \), we have \( h(ra) = h(r)a \), thus

\[(h \cdot f(r))a = h(ra) = h(r)a = f(h(r))a\]

which shows \( f(R) \) is a left ideal in \( E \). And because \( \mathfrak{A}R = R \), we have \( f(R) = f(\mathfrak{A})f(R) \), then

\[Ef(R) = Ef(\mathfrak{A})f(R) \subset f(\mathfrak{A})f(R) = f(R)\]

which shows \( f(R) \) is a left ideal in \( E \), and it contains 1, so \( f(R) = E \). \( \square \)

2 Jacobson Radical Theory

Def. (2.4.2.1) [Jacobson Radical]. For \( R \in \mathfrak{Ring} \), the Jacobson radical is defined to be the intersection of all maximal left ideals in \( R \).

- \( R \) is called Jacobson semisimple if \( \text{rad } R = 0 \).
- \( R \) is called semi-local if \( \overline{R} = R/\text{rad } R \) is semisimple.
- \( R \) is called semi-primary if \( R \) is semi-local and \( \text{rad } R \) is nilpotent.

Prop. (2.4.2.2) [Characterizing Jacobson Radicals]. For \( y \in R \), the following are equivalent:

- \( y \in \text{rad } R \).
- \( 1 - xy \) is left-invertible for any \( x \in R \).
- \( yM = 0 \) for any simple left \( R \)-module \( M \).
- \( 1 - xyz \) is invertible for any \( x, z \in R \).
Prop. (2.4.2.6) [Artinian Radical Nilpotent].

In a left Artinian ring, rad $R$ is the largest nilpotent left ideal, and it is also the largest nilpotent right ideal.

Proof: By the above lemma, it suffices to show $J = \text{rad } R$ is nilpotent. By Artinian property, the descending chain $J \supset J^2 \supset J^3 \supset \ldots$ is stabilizing, so there exists $k$ s.t. $J^k = J^{k+1} = I$. Then $I = 0$, because otherwise we can choose a minimal non-left ideal $\mathfrak{A}$ s.t. $IA = 0$. Then if $a \neq 0 \in \mathfrak{A}$,

$$I(Ia) = I^2a = Ia = 0,$$

so $\mathfrak{A} = Ia$, and $a = ya$ for some $y \in J$, so $(1-y)a = 0$. But $1-y$ is a unit by (2.4.2.2), contradiction. □

Cor. (2.4.2.7). In a left Artinian ring, any 1-sided locally nilpotent ideal is nilpotent. By left Artinian, there is a $k$ that $(\text{rad } R)^k = (\text{rad } R)^{k+1} = I$. Now if $I \neq 0$, then we can choose a minimal left ideal $\mathfrak{A}$ that $I\mathfrak{A} \neq 0$ by Artinian property. Now there is an $a \in \mathfrak{A}$ that $Ia \neq 0$, so $I(Ia) = Ia \neq 0$, so $Ia = \mathfrak{A}$ and $a = ya$ for some $y \in I$. But $1-y$ is invertible, so $a = 0$, contradiction.

Prop. (2.4.2.8) [Semisimplicity and Jacobson Semisimplicity]. For $R \in \text{Ring}$, the following are equivalent:

- $R$ is semisimple.
- $R$ is Jacobson semisimple and left Artinian.
- $R$ is Jacobson semisimple and satisfies DCC on principal left ideals.

Proof: 1 → 2: $R$ is left Artinian by (2.4.1.18), and consider $R = \text{rad } R \oplus \mathfrak{B}$, then $\mathfrak{B}$ is contained in a maximal left ideal $\mathfrak{m}$, which cannot contain $\text{rad } R$, unless $\text{rad } R = 0$.

3 → 1: 3 implies that any left ideal $\mathfrak{A}$ contains a minimal left ideal $I$ (the minimal principal one), and every minimal left ideal $I$ is a direct summand of $R$ (by choosing the maximal left ideal $\mathfrak{m}$ not containing $I$, because $I \oplus \mathfrak{m} = R$).

Then we can deduce 1: If $R$ is not semisimple, then take a minimal left ideal $\mathfrak{B}_1$, then $R = \mathfrak{B}_1 \oplus \mathfrak{A}_1$, and $\mathfrak{A}_1 \neq 0$ otherwise $R$ is semisimple, and we can choose a minimal left ideal $\mathfrak{B}_2 \subset \mathfrak{A}_1$, then $\mathfrak{A}_1 = \mathfrak{B}_2 \oplus \mathfrak{A}_2$. Continuing this way, we get a chain of left ideals $\mathfrak{A}_1 \supset \mathfrak{A}_2 \supset \ldots$, and they are both principal because they are direct summands of $R$, contradicting item 3. □
Prop. (2.4.2.9) [Hokins-Levitzki Theorem]. Let $R$ be a semi-primary ring (2.4.2.1), then for any $R$-module $M$, the following are equivalent:

- $M$ is Noetherian.
- $M$ is Artinian.
- $M$ has a composition series.

In particular, a ring is left Artinian iff it is left Noetherian and semi-primary.

Proof: It suffices to prove if $M$ is Noetherian or Artinian, $M$ has a composition series. Denote $J = \sqrt{R}$, then $J^n$ for some $n > 0$. We consider

$$0 \subset J^{n-1}M \subset \cdots \subset JM \subset M,$$

and the quotient $J^{k-1}M/J^kM$ is Artinian or Noetherian over $\overline{R} = R/\sqrt{R}$ which is semisimple, so it is a direct sum of simple modules, and the sum is finite, so there is a composition series.

The last assertion: A left Artinian ring is semi-primary, by (2.4.2.6) and (2.4.2.8). So the assertion follows from the equivalence of item 1 and 2. □

Lemma (2.4.2.10). Let $x \in \sqrt{R}$ where $R$ is a $k$-algebra, then $x$ is algebraic over $k$ iff $x$ is nilpotent.

Proof: One direction is trivial. For the other, if $x^r + a_1x^{r+1} + \cdots + a_nx^{r+n} = 0$, then because $1 + a_1x^1 + \cdots + a_nx^n$ is invertible, we have $x^r = 0$. □

Prop. (2.4.2.11) [Amitsur]. Suppose $k$ is a field and $R$ is a $k$-algebra that $\dim_k R < |k|$, then $\sqrt{R}$ is the largest locally nilpotent ideal of $R$.

Proof: If $|k| < \infty$, then $R$ is Artinian, so $\sqrt{R}$ is nilpotent by (2.4.2.6), and it is the largest by (2.4.2.6) again. Suppose now $k$ is infinite. By the lemma above, it suffices to show every $r \in \sqrt{R}$ is algebraic over $k$. Notice that $a - r$ is invertible for $a \in k^*$, and $\{(a - r)^{-1}\}$ cannot be $k$-linearly independent because $\dim_k R < |k|$, so there is a dependence relation

$$\sum_{i=1}^n b_i(a_i - r)^{-1} = 0.$$

Hence $r$ is algebraic over $k$. □

Prop. (2.4.2.12) [Amitsur]. Let $R$ be a ring and $S = R[T]$. Let $J = \sqrt{S}$ and $N = R \cap J$, then $N$ is a locally nilpotent ideal in $R$, and $J = N[T]$. In particular, if $R$ is Jacobson semisimple, then $S$ is also Jacobson semisimple (2.4.2.5).

Proof: Cf. [Lam, P71]. □

Lemma (2.4.2.13). Let $R$ be a $k$-algebra and $K/k$ is a separable algebraic field extension, then if $R$ is Jacobson semisimple, so is $R \otimes_k K$.

Proof: Cf. [Lam, P76]. □

Prop. (2.4.2.14) [Jacobson Radical Under Base Change of Fields]. Let $R$ be a $k$-algebra and $K/k$ a separable algebraic extension, then $\sqrt{R \otimes_k K} = (\sqrt{R}) \otimes_k K$.

Proof: Cf. [Lam, P76]. □
3 Finite Semisimple \( k \)-Algebras

Reference for this subsection is [Sta] Chap 11.

**Def. (2.4.3.1) [Azumaya Algebras].** A central \( k \)-algebra is an algebra \( A \) that the center of \( A \) is the image of \( k \rightarrow A \).

**Def. (2.4.3.2) [Azumaya Algebras].** An Azumaya algebra over \( k \) is defined to be a finite central \( k \)-algebra. The category of Azumaya algebras over \( k \) is denoted by \( \text{Az} k \).

**Lemma (2.4.3.3).** Let \( D \) be a division ring with central field \( k \) and \( A \in \text{Ring} / k \), then any two-sided ideal \( I \) of \( A \otimes k D \) is of the form \( J \otimes k D \) for some two-sided ideal \( J \) of \( A \). In particular, if \( A \) is simple, then \( A \otimes k D \) is also simple.

*Proof:* Cf. [Sta] 074C.

**Lemma (2.4.3.4).** Let \( R \in \text{Ring} \) and \( n \in \mathbb{Z}_+ \), then
- The functors \( M \mapsto M \oplus n, N \mapsto e_{11} n \) defines an equivalence of categories between \( \text{Mod}_R \) and \( \text{Mod}_{\text{Mat}(n,R)} \).
- Any two-sided ideal of \( \text{Mat}(n,R) \) is of the form \( \text{Mat}(n,I) \) for some two-sided ideal \( I \) of \( R \).
- Then center of \( \text{Mat}(n,R) \) is the equal to the center of \( R \).

**Prop. (2.4.3.5).** if \( A, A' \) are two simple \( k \)-algebras that \( A \) is finite central over \( k \), then \( A \otimes_k A' \) is simple.

*Proof:* Let \( A' \) be finite central over \( k \), then by (2.4.1.28), \( A' \cong \text{Mat}(n,D) \) for some finite central division algebra over \( k \). Then
\[
A \otimes_k A' \cong \text{Mat}(n,A \otimes D),
\]
which is simple by (2.4.3.3) and (2.4.3.4).

**Cor. (2.4.3.6).** The tensor product of two Azumaya \( k \)-algebras is an Azumaya \( k \)-algebra.

*Proof:* Combine the proposition with (2.2.1.13).

**Cor. (2.4.3.7) [Base Change].** If \( k \in \text{Field} \) and \( A \in \text{Ring} / k \), then for any field extension \( k'/k \), \( A \otimes_k k' \in \text{Az} k' \) iff \( A \in \text{Az} k \).

*Proof:* Combine (2.2.1.13) with (2.4.3.5).

**Prop. (2.4.3.8) [Skolem-Noether].** Let \( A \) be a finite central simple \( k \)-algebra and \( B \) is a simple \( k \)-algebra that \( f, g : B \rightarrow A \) are two \( k \)-algebra homomorphisms. Then there exists an invertible element \( x \in A \) that \( f = x^{-1} g x \).

*Proof:* Choose a simple \( A \)-module \( M \), then \( L = \text{End}_A(M) \) is a skew field, and \( M \) has two \( B \otimes_k L^{\text{op}} \) structures by \( f \) and \( g \). The \( k \)-algebra \( B \otimes_k L^{\text{op}} \) is simple by (2.4.3.5), and also \( B \) is finite simple because there is a \( k \)-homomorphism \( B \rightarrow A \), so \( B \otimes_k L^{\text{op}} \) is finite simple, thus the two \( B \otimes_k L^{\text{op}} \) structures on \( M \) are isomorphic, which means there is a \( \varphi : M \rightarrow M \) intertwining these two structures. But \( \varphi \) commutes with \( L \), meaning that \( \varphi \) is just multiplying by some \( x \in A \), so \( x \) is what we want.

**Cor. (2.4.3.9).** Let \( A \) be a finite simple \( k \)-algebra, then any automorphism of \( A \) is inner.

*Proof:* Because the center of \( A \) is a finite field extension \( k' \) of \( k \) that \( A \) is central simple over \( k' \), thus the Skolem-Noether theorem applies.
Splitting Fields

Prop. (2.4.3.10)[Centralizer Theorem]. Let \( k \in \text{Field} \) and \( A \in \text{Az}_k \), and \( B \) a simple sub \( k \)-algebra of \( A \), then

- \( C = C_A(B) \) is also simple.
- \( \dim_k A = \dim_k B \cdot \dim_k C \).
- \( C_A(C) = B \).

Proof: Cf.[Sta]074T.

Cor. (2.4.3.11). Let \( k \in \text{Field} \) and \( B \subset A \in \text{Az}_k \), then \( C = C_A(B) \) is also in \( \text{Az}_k \), and \( A \cong B \otimes_k C \).

In particular, if a division ring \( D \) is of f.d. over its center \( k \), then \( D \in \text{Az}_k \), and \( \dim_k D \) is a square.

Proof: \( \dim_k A = \dim_k (B \otimes_k C) \) by (2.4.3.10), and \( B \otimes_k C \) is simple by (2.4.3.5), so the natural map \( B \otimes_k C \to A \) is an isomorphism, and the center of \( C \) is \( k \) by (2.4.3.5).

Prop. (2.4.3.12). For \( k \in \text{Field} \), \( A \in \text{Az}_k \), If \( K \subset A \) is a sub \( k \)-field, then the following are equivalent:

- \( \dim_k A = [K : k]^2 \).
- \( C_A K = K \).
- \( K \) is a maximal commutative subring of \( A \).

Proof: 1, 2 are equivalent by (2.4.3.10), and 2, 3 are clearly equivalent, as \( C_A K \) is a commutative subring containing \( K \).

Cor. (2.4.3.13). If \( D \) is a division ring with center \( k \), then every maximal subfield of \( D \) satisfies \( \dim_k A = [K : k]^2 \).

Proof: This is because any commutative subring of \( A \) is a field.

Def. (2.4.3.14)[Splitting Fields]. For \( k \in \text{Field} \) and \( B \) a finite semisimple \( k \)-algebra, then \( B \) is said to split if \( B \) is isomorphic to a product of matrix algebras over \( k \). A field extension \( K/k \) is called a splitting field of \( B \) if \( B_K \) is split.

Prop. (2.4.3.15). If \( k \in \text{Field}, k = \overline{k} \), then any finite semisimple \( k \)-algebra is split.

Proof: This follows from (2.4.1.22) and (2.2.1.10).

Cor. (2.4.3.16)[Central Simple Algebras are of Square Dimensions]. Let \( k \in \text{Field}, A \in \text{Az}_k \), then \( \dim_k A \) is a square.

Proof: This is true because \( A \otimes_k \overline{k} \) is a matrix algebra.

Prop. (2.4.3.17)[Maximal Subfields are Splitting]. Let \( k \in \text{Field}, A \in \text{Az}_k, k'/k \) a finite field extension, then \( k \) is a splitting field of \( A \) iff there exists a \( B \in \text{Az}_k \) similar to \( A \)? s.t. \( k' \subset B \) and \( \dim_k B = [k' : k]^2 \).

In particular, if \( D \) is a division ring, any maximal subfield of \( D \) is a splitting field of \( D \), by (2.4.3.12).

Proof: Cf.[Sta]074Z.
Cor. (2.4.3.18). If \( k \in \text{Field} \) and \( D \) is a central division ring with \( \dim_k D = d^2, d \in \mathbb{Z}_+ \) by (2.4.3.16), then for any splitting field \( k'/k, d|([k': k]) \).

**Proof:** By (2.4.3.17), there exists \( B \in \text{Az}_k \) similar to \( D \) s.t. \( \dim_k B = [k': k]^2 \). Then it follows from (9.2.2.1) that \( B \cong \text{Mat}(n, D) \) for some \( n \in \mathbb{Z}_+ \). Then \( n^2d^2 = [k': k]^2 \), so \( d|[k': k] \). \( \square \)

Prop. (2.4.3.19) [Galois Splitting Fields, Noether-Köthe]. If \( k \in \text{Field} \) and \( D \) is a central division ring over \( k \), then there exists a maximal subfield \( K \subset D \) s.t. \( K/k \) is finite separable. In particular, by (9.2.2.1)(2.4.3.17), any central simple algebra has a finite Galois splitting field.

**Proof:** Notice it suffices to prove that: if \( D \neq k \), there exists \( \alpha \in D \setminus k \) s.t. \( k(\alpha)/k \) is separable. This is because if we find such \( \alpha \), then \( D' = C_D(\alpha) \) is another simple division algebra with center \( k(\alpha) \), by (2.4.3.10), so we can use induction on \( D'/k(\alpha) \).

We may assume \( k \) is non-perfect of characteristic \( p \in \mathbb{P} \), thus an infinite field. Suppose we cannot find such an element, then every element satisfies an equation of the form \( T^{p^r} - a = 0 \), where \( a \in k \). And because \( \dim_k D < \infty \), there exists an \( r \) s.t. \( x^{p^r} \in k \) for any \( x \in D \). Then we can use the fact \( \#k = \infty \) to show that \( x^{p^r} \in \overline{k} \) for any \( x \in D \otimes_k \overline{k} \). But then every \( p^r \)-th power of \( D \otimes_k \overline{k} \cong \text{Mat}(n, \overline{k}) \) is central, which is not true, as \( n > 1 \) and we can take \( e_{11} \).

**Cor. (2.4.3.20).** Let \( k \in \text{Field} \), then for \( A \in \text{Ring}/k \), \( A \in \text{Az}_k \) iff \( A \otimes_k \text{sep} \cong \text{Mat}(n, k\text{sep}) \) for some \( n \in \mathbb{Z}_+ \), by (2.4.3.7).

Def. (2.4.3.21) [Reduced Degree]. For \( k \in \text{Field} \) and \( B \) a finite semisimple \( k \)-algebra, suppose \( B = \prod_i B_i \) where \( B_i \) are simple \( k \)-algebras with center \( k_i \), define the **reduced degree** of \( B \) over \( k \) to be

\[
[B : k]_{\text{red}} = \sum_i [B_i : k_i]^{1/2}[k_i : k],
\]

which is an integer by (2.4.3.16). And for any field extension \( k'/k \),

\[
[B_{k'} : k']_{\text{red}} = [B : k]_{\text{red}}.
\]

**Proof:** ? Why invariant? \( \square \)

Prop. (2.4.3.22). For \( k \in \text{Field} \) and \( B \) a finite semisimple \( k \)-algebra, any maximal étale \( k \)-subalgebra of \( B \) has rank \( [B : k]_{\text{red}} \) over \( k \).

**Proof:** This follows from (2.4.3.13). \( \square \)

Prop. (2.4.3.23). For \( k \in \text{Field} \) and \( B \) a finite semisimple \( k \)-algebra, then for any faithful \( B \)-module \( M \),

\[\dim_k M \geq [B : k]_{\text{red}}.\]

And the equality holds iff \( B \) is split.

**Proof:** This is clear from (2.4.1.21). \( \square \)

Prop. (2.4.3.24). If \( k \in \text{Field} \) and \( A \in \text{Az}_k \), then \( A \otimes_k A^{\text{op}} \cong \text{Mat}(n, k) \), where \( n = \dim_k A \).

**Proof:** There is a map \( A \otimes_k A^{\text{op}} \to \text{End}_k(A) : (a \otimes a') \mapsto (x \mapsto axa') \). By (2.4.3.6), \( A \otimes_k A^{\text{op}} \) is simple, thus this is an injective map, but both sides have the same dimension, thus this is an isomorphism. \( \square \)
Finite Semisimple $k$-Algebras with Involution

**Def. (2.4.3.25) [Involution].** Let $*$ be an involution on a semisimple algebra $B$ over a field $k$. It is called an **involution of first kind** if it fixes elements in the center of $B$. It is called an **involution of second kind** otherwise.

**Prop. (2.4.3.26) [Decomposition].** Let $(B, *)$ be a f.d. semisimple $k$-algebra with an involution, if $k$ is alg.closed and has characteristic 0, then it decomposes as products of pairs of the following types:

- $(A): M_n(k) \times M_n(k), (a, b)^* = (b^t, a^t)$.
- $(C): M_n(k), b^* = b^t$.
- $(BD): M_{2n}(k), b^* = Jb^tJ^{-1}$, where $J = \begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}$.

**Proof:** Let $B = B_1 \times \ldots \times B_r$ be the decomposition into products of simple $k$-algebras, where $B_i$ are the minimal two-sided ideals of $B$. Applying $*$, $B = B_1^* \times \ldots \times B_r^*$ so $B_i^*$ is a permutation of $B_i$, so $B$ is a product of algebras either simple or product of two simple algebras that $*$ interchanges them.

If $B$ is simple, then $B \cong M_n(k)$ as $k$ is alg.closed, so $b^* = ub^tu^{-1}$ for some $u \in M_n(k)$ by Skolem-Noether (2.4.3.8). Then $b = b^{**} = (u^t u^{-1})^{-1}bu^t u^{-1}$, so $u^t u^{-1}$ is in the center, denote it by $c$, then $u^t = cu$, $u = c^2 u$, so $c = \pm 1$, and $u$ is symmetric or skew-symmetric. Up to a congruence, we see the situation is $(C)$ or $(BD)$.

The other case is also easy. \qed

4 Idempotented Algebras

**Lemma (2.4.4.1).** Let $R$ be a ring and $e, f$ be idempotents of $R$ that $ef = fe = e$, then $f = e + e'$, where $e'$ is an idempotent and $M[f] = M[e] \oplus M[e']$.

Moreover, if $R$ is an algebra over an alg.closed field $k$ and $M[e]$ is a simple $R[e]$-module of f.d. over $k$, then $\dim \text{Hom}_{R[e]}(M[e], M[f]) = 1$.

**Proof:** Let $e' = f - e$, then it is easily verified to be an idempotent, and $ee' = e'e = 0$, thus $M[f] = M[e] \oplus M[e']$ is clear.

For the second, because $R[e]$ acts by 0 in $R[e']$, $\text{Hom}_{R[e]}(M[e], M[f]) = \text{Hom}_{R[e]}(M[e], M[e])$ has dimension 1, by Shur’s lemma (2.4.1.2) and (2.2.1.10). \qed

**Def. (2.4.4.2) [Idempotented Algebra].** An **idempotented algebra** $\mathcal{H}$ is an algebra over a field $k$ together with a set $\mathcal{E}$ of idempotents that if $e_1, e_2 \in \mathcal{E}$, then there exists $e_0 \in \mathcal{E}$ such that

$$e_0 e_1 = e_1 e_0 = e_1, e_0 e_2 = e_2 e_0 = e_2,$$

and also for any $\varphi \in \mathcal{H}$, there exists $e \in \mathcal{E}$ that $e \varphi = \varphi e = \varphi$.

We can define a partial order on $\mathcal{E}$: $e < f$ iff $ef = fe = f$, then this order is cofinal.

If $e$ is an idempotent, denote $\mathcal{H}[e] = e \mathcal{H} e$, which is a subring of $\mathcal{H}$ with unit $e$. Also if $M$ is an $\mathcal{H}$-module, we denote $M[e]$ the $R[e]$-module $eM$.

**Prop. (2.4.4.3).** If $0 \rightarrow M_1 \rightarrow M_2 \rightarrow M_3 \rightarrow 0$ is an exact sequence of $\mathcal{H}$-modules, $e \in \mathcal{E}$, then $0 \rightarrow M_1[e] \rightarrow M_2[e] \rightarrow M_3[e] \rightarrow 0$ is also exact.

**Proof:** Because tensoring an idempotent is exact. \qed
Def. (2.4.4.4) [Smooth Representations of Idempotented Algebras]. Let \((\mathcal{H}, \mathcal{E})\) be an idempotented algebra, a smooth \(\mathcal{H}\)-module \(M\) is an \(\mathcal{H}\)-module \(M = \bigcup_{e \in \mathcal{E}} M[e]\), and an admissible \(\mathcal{H}\)-module is a smooth \(\mathcal{H}\)-module that each \(M[e]\) is of f.d. over \(k\).

A smooth \(\mathcal{H}\)-module is clearly non-degenerate.

Def. (2.4.4.5) [Contragradient Module]. If \(M\) be a smooth \(\mathcal{H}\)-module, then we can define a contragradient \(\hat{M}\) of \(M\), which is the smooth \(\mathcal{H}\)-module consisting of smooth vectors in \(M^*\), where the action is defined as \(((\varphi)m)(m) = \lambda(x)m\). Notice if \(M\) is admissible, then so does \(\hat{M}\), because an element in \(M[e]\) is determined by its restriction on \(M[\ell(e)]\), so \(\hat{M}[e]\) is of f.d. if \(M[\ell(e)]\) does.

Prop. (2.4.4.6) [Simpleness Checked on Idempotents]. Let \(M\) be a non-zero module over an idempotented algebra \((\mathcal{H}, \mathcal{E})\) over \(C\), \(\mathcal{E}^0\) be a cofinal subset of \(\mathcal{E}\), then \(M\) is a simple \(\mathcal{H}\)-module iff \(M[e]\) is simple \(\mathcal{H}[e]\)-modules for any \(e \in \mathcal{E}^0\).

Proof: If there exists a proper \(\mathcal{H}\)-submodule \(M_1\) of \(M\), then \(M/M_1 = M_2\), then \(M[e]/M_1[e] = M_2[e]\) for all \(e\) by (2.4.4.3). Thus we can choose \(e\) s.t. \(M_1[e] \neq 0, M_2[e] \neq 0\), thus \(M[e]\) is reducible. Conversely, If \(W_0 \subset M[e_K]\) is a proper non-zero \(\mathcal{H}[e_K]\)-submodule, then \([\pi(\mathcal{H})W_0][e] = W_0\), thus \(\pi(\mathcal{H})W_0\) is a proper submodule of \(M\).

Prop. (2.4.4.7) [Isomorphism Checked on Idempotents]. Let \(V_1, V_2\) be two simple admissible modules over an idempotented algebra \((\mathcal{H}, \mathcal{E})\), if \(e \in E\) that \(V_1[e] \cong V_2[e] \neq 0\), then \(V_1 \cong V_2\).

Proof: Choose an isomorphism \(j: V_1[e] \rightarrow V_2[e]\), then the subspace \(V' = \{(x, xj) \subseteq V_1[e] \oplus V_2[e] \subset V_1 \oplus V_2\) is a \(\mathcal{H}[e]\)-submodule. Let \(V = \pi(\mathcal{H})V'\), then \(V[e] = V'\), so \(V\) is not contained or contains any of \(V_1\) or \(V_2\), thus \(V \cap V_1 = V \cap V_2 = 0\) as \(V_i\) are irreducible. Thus the projections \(V \rightarrow V_1, V \rightarrow V_2\) are isomorphisms as \(V_i\) are irreducible, and \(V_1 \cong V_2\).

Prop. (2.4.4.8) [Extension Theorem]. Let \((\mathcal{H}, \mathcal{E})\) be an idempotented algebra and \(e \in E\). If \(V_e\) is a simple \(\mathcal{H}[e]\)-module, then there is a simple \(\mathcal{H}\)-module \(V\) that \(V[e] = V_e\).

Proof: Let \(V_e \cong \mathcal{H}[e]/I\), where \(I\) is a left ideal of \(V_e\). Let \(E_1, E_2\) be the module generated by \(I\) and \(\mathcal{H}[e]\) in \(\mathcal{H}\) by left action of \(\mathcal{H}\), then \(E_1[e] = I\) and \(E_2[e] = \mathcal{H}[e]\), thus \((E_3 = E_1/E_2)[e] \cong V_e\) by (2.4.4.3). Now if \(E'\) is a submodule of \(E_3\), then either \(E'[e] = 0\) thus \((E_3/E')[e] \cong L\), or \(E'[e] = L\), thus \(E' = E_3\) by (2.4.4.7). Thus if we choose the proper submodule \(E'\) that \(E_3/E'\) is irreducible by (15.1.1.21), then \(E_3/E'[e] = L\).

Prop. (2.4.4.9). If \(\mathcal{H}\) is an idempotented algebra, then \(\mathcal{M}(\mathcal{H})\) has enough projectives.

Proof: For any idempotent \(e \in \mathcal{H}\), consider the module \(\mathcal{H}e\), then it is projective, because \(\text{Hom}_{\mathcal{H}}(\mathcal{H}e, X) = e.X\), thus it is clearly exact. Now any \(m \in V\) has an idempotent \(e \in \mathcal{H}\) that \(ev = v(\text{use definition})\). Thus by taking the direct sum, we are done.

### Spherical Idempotents

Def. (2.4.4.10) [Spherical Idempotents]. Let \((\mathcal{H}, \mathcal{E})\) be an idempotented algebra over a field \(\Omega\). Then an idempotent \(e \in \mathcal{E}\) is called spherical idempotent if there exists an anti-involution \(\iota: \mathcal{H} \rightarrow \mathcal{H}\) that \(\iota(x) = x\) for any \(x \in \mathcal{H}[e^0]\). Notice this implies \(\mathcal{H}[e^0]\) is commutative, as \(xy = \iota(xy) = yx\).
Def. (2.4.4.11) [Spherical Vectors]. Let \( e^0 \) be a spherical idempotent of the idempotented algebra \((\mathcal{H}, \mathcal{E})\) and \( \iota \) is the corresponding involution. If \( M \) is an admissible \( \mathcal{H} \)-module, then a spherical (unramified) module is a \( \mathcal{H} \)-module \( M \) that \( M[e^0] \neq 0 \), and elements in \( M[e^0] \) are called spherical vectors.

Then if \( M \) is simple and spherical, then \( M \) has at most one spherical vector up to scalar, and \( \hat{M} \) is also spherical. Thus the space of spherical vectors is fixed by \( \mathcal{H}[e^0] \), and the action of \( \mathcal{H}[e^0] \) on that defines a spherical character.

Proof: In fact, \( M[e^0] \) is a simple \( \mathcal{H}[e^0] \)-module(2.4.4.6), and is of f.d., and \( \mathcal{H}[e^0] \) is commutative(2.4.4.10), so(2.4.1.11) shows it is of dimension 1. so if \( m^0 \neq 0 \in M[e^0] \), then we can define a \( \hat{m}^0 \neq 0 \in M[e^0] \) as:

\[ e^0 m = \hat{m}^0(m) \cdot m^0. \]

Prop. (2.4.4.12) [Isomorphism Checked on Spherical Idempotents]. Let \((\mathcal{H}, \mathcal{E})\) be an idempotented algebra over a field \( \Omega \) and \( e^0 \) is a spherical idempotent. If \( M, N \) are simple admissible spherical \( \mathcal{H} \)-modules that \( M[e^0] \cong N[e^0] \) over \( \mathcal{H}[e^0] \), then \( M \cong N \) as \( \mathcal{H} \)-modules.

Proof: This follows from(2.4.4.7).

Restricted Tensor Product

Def. (2.4.4.13) [Restricted Tensor Product]. Give an infinite number of vector spaces \( V_v \) indexed by a set \( \Sigma \) and elements \( x_v^0 \in V_v \) be given for a.e. \( v \), we can define the restricted tensor product \( \bigotimes V_v \) as the direct limit

\[ \lim_{S \subseteq \Sigma \text{ finite}} \bigotimes_{v \in S} V_v. \]

It can be thought of as the vector spaces spanned by all symbols \( \otimes_v x_v \) where \( x_v = x_v^0 \) for a.e. \( v \).

Notice if \( V_v \) are idempotented algebras and \( x_v^0 \in V_v \) are idempotents for a.e. \( v \), then \( \prod V_v \) also has a natural idempotented algebra structure.

Def. (2.4.4.14) [Tensor Product Module of Idempotented Algebras]. Given a set of idempotented algebras \( (\mathcal{H}_v, \mathcal{E}_v) \) and specify an idempotent \( e_v^0 \) for a.e. \( v \). Let \( M_v \) be \( \mathcal{H}_v \)-modules over \( k \) for all \( v \), and assume \( M_v[e_v^0] \) be of dimension 1 a.e. \( v \), and specify a.e. a non-zero element \( m_v^0 \in M_v[e_v^0] \)

Then we can define tensor product(2.4.4.13) \( \prod \mathcal{H}_v \) which is an idempotented algebra and \( \prod M_v \).

Then we can define an restricted tensor module structure of \( M_v \) over \( \prod \mathcal{H}_v \) by the action

\[ (\otimes_v \varphi_v)x_v = \otimes_v (\varphi_v)x_v. \]

Lemma (2.4.4.15) [Simple Module of Tensor Product]. Let \( (\mathcal{H}_1, \mathcal{E}_1), (\mathcal{H}_2, \mathcal{E}_2) \) be idempotented algebras over an alg.closed field \( \Omega \), and let \((\mathcal{H}, \mathcal{E})\) be the tensor product. If \( M_1, M_2 \) are simple admissible modules over \( \mathcal{H}_1, \mathcal{H}_2 \), respectively, then \( M_1 \otimes M_2 \) are simple admissible modules over \( \mathcal{H}_1 \otimes \mathcal{H}_2 \), and any simple admissible module over \( \mathcal{H} \) comes uniquely from a pair \( (M_1, M_2) \) like this.

Proof: If \( M_1, M_2 \) are simple admissible over \( H_1, H_2 \) respectively, then if \( e_1 \in \mathcal{E}_1, e_2 \in \mathcal{E}_2 \), then \( (M_1 \otimes M_2)(e_1 \otimes e_2) = M_1[e_1] \otimes M_2[e_2] \) is simple and of f.d. by(2.4.4.6) and(2.4.1.16), so \( M_1 \otimes M_2 \) is simple by(2.4.4.6).
Now if $M$ is simple admissible over $\mathcal{H}_1 \otimes \mathcal{H}_2$, then we find an $e_1^0 \otimes e_2^0 \in \mathcal{E}$ that $M[e_1^0 \otimes e_2^0] \neq 0$. Let $\mathcal{E}_i^0 = \{ e_i \in \mathcal{E}_i | e_i < e_i^0 \}$, then $\mathcal{E}_i^0$ is cofinal in $\mathcal{E}_i$. Then for any $e_i \in \mathcal{E}_i^0$, $M[e_1 \otimes e_2]$ is non-zero thus simple, thus it is of the form

$$M[e_1 \otimes e_2] = M_1(e_1, e_2) \otimes M_2(e_1, e_2)$$

where $M_i(e_1, e_2)$ are simple $\mathcal{H}[e_i]$-modules by (2.4.1.16).

Now we show that $M_2(e_1, e_2)$ depends only on $e_1$: it suffices to show $M_2(e_1, e_2) = M_2(f_1, e_2)$ for $f_1 < e_1$. For this, notice that for any idempotents $g_1, g_2$,

$$M[g_1 \otimes g_2] = M_1(g_1, g_2) \otimes M_2(g_1, g_2)$$

is a finite direct sum of simple modules $M_2(g_1, g_2)$ as an $\mathcal{H}_2[g_2]$-module. Notice that by (2.4.4.1), $M[e_1 \otimes e_2] = M[f_1 \otimes e_2] \oplus M[e' \otimes e_2]$ for $e' = f_1 - e_1$, so by (2.4.1.3), $M_2(f_1, e_2) = M_2(e_1, e_2)$.

Similarly we know $M_1(e_1, e_2)$ only depends on $e_1$.

Next we have:

$$\dim_k \text{Hom}_{\mathcal{H}_1}[e_1](M_1[e_1], M_1[f_1]) \geq 1, \quad f_1 \leq e_1.$$ 

and similar for $\mathcal{H}_2$. For this, it suffices to prove that $\dim_k \text{Hom}_{\mathcal{H}_1}[e_1](M[e_1 \otimes e_2], M[f_1 \otimes e_2]) \geq 1$, by what we just said, but this is by the decomposition

$$M[e_1 \otimes e_2] = M[f_1 \otimes e_2] \oplus M[e' \otimes e_2]$$

above. But

$$\dim_k \text{Hom}_{\mathcal{H}_1}[e_1] \otimes \mathcal{H}_2[e_2] \cdot (M_1(e_1) \otimes M_2(e_2), M_1(f_1) \otimes M_2(f_2)) = 1, \quad f_1 \leq e_1, f_2 \leq e_2$$

by (2.4.4.1), so the $\geq$ above should change to $=.$

Now we know the homomorphism is of dimension 1, we want to choose a family of maps that is compatible for $g_1 \leq f_1 \leq e_1 \leq e_0^1$. For this, we can choose the maps $\lambda(e_1, e_0^1)$ arbitrarily, then choose $\lambda(e_1, f_1)$ to be compatible with $\lambda(e_1, e_0^1)$ and $\lambda(f_1, e_0^1)$, then these are compatible choices. Hence we can define a direct limit

$$M_1 = \lim_{\rightarrow (e_0^1)^{op}} M(e_1).$$

It is easy to see $M_1(e_1) \to M_1$ are all injective, and $M_1(e_1) = M[e_1]$. Similarly, we can define an $M_2$ that $M_2[e_2] = M_2(e_2)$.

Finally, we have

$$M[e_1 \otimes e_2] = M_1[e_1] \otimes M_2[e_2] = (M_1 \otimes M_2)[e_1 \otimes e_2]$$

for all $e_1 \in \mathcal{E}_1^0, e_2 \in \mathcal{E}_2^0$, thus $M \cong M_1 \otimes M_2$ by (2.4.4.7).

As for the uniqueness of $M_1, M_2$, notice the decomposition of $M[e_1 \otimes e_2]$ is unique by (2.4.1.16), so $M_i[e_i]$ is uniquely determined, thus by (2.4.4.7) $M_i$ are determined.

Prop. (2.4.4.16) [Flath Theorem]. Let $(\mathcal{H}_c, \mathcal{E}_v)$ be an indexed family of idempotent $k$-algebras, and for a.e. $v$ let $e_v^0 \in \mathcal{E}_v$ be a spherical idempotent. Let $(\mathcal{H}, \mathcal{E})$ be the restricted tensor product of $\mathcal{H}_c$ w.r.t. $e_v^0$, which is an idempotent algebra. For each $v \in \Omega$, there is a simple $\mathcal{H}_v$-module $M_v$ and for a.e. $v$ we specify a non-zero spherical vector. Let $\otimes_v M_v$ be the tensor product module, then it is a simple admissible $\mathcal{H}$-module, and every simple admissible module is of this type, with $M_v$ uniquely determined.
Proof: Firstly the tensor product is simple and admissible: For any idempotent $e = \otimes e_v \in \mathcal{E}$, there is a finite set $S$ that if $v \notin S$, then $e_v = e_v^0$, hence for these $v \dim M_v[e_v] = 1$. Then

$$M[e] = \otimes_{v \in S} M_v[e_v].$$

which is simple of f.d. by (2.4.4.15), so $M$ is simple admissible by (2.4.4.6).

Conversely, for any simple $\mathcal{H}$-module $M$, we need to show it is a tensor product. If there are only f.m. indices, then this follows from (2.4.4.15).

Suppose first that $e_0^v$ is defined and spherical for all $v$, and $e = \otimes e_0^v$, and $M[e] \neq 0$. Then $\dim M[e] = 1$ (2.4.4.11). Let $m$ be a spherical vector, then there is a ring homomorphism $\gamma : \mathcal{H}[e] \rightarrow k$ defined by $hm = \gamma(h)m$. Because $\mathcal{H}[e] = \otimes'_v M_v[e_0^v]$, we have

$$\gamma(\otimes_v h_v) = \prod_v \gamma_v(h_v).$$

Now if we decompose $\mathcal{H} = \mathcal{H}_v \otimes \mathcal{H}_v'$, then by (2.4.4.15), there exists simple admissible module $M_v$ over $\mathcal{H}_v$, $M_v'$ over $\mathcal{H}_v'$ respectively, that $M = M_v \otimes M_v'$, thus $M[e] = M_v[e_0^v] \otimes M_v'[e_0^v]$. Now consider $M_v$ for all $v$, and $N = \otimes'_v M_v$ w.r.t. $m_v$, then it is simple admissible $\mathcal{H}$-module, and we have $N[e] = \otimes'_v M_v[e_0^v] \cong M[e]$ as $\mathcal{H}[e]$-modules of dimension 1, which is because they are both simple and have the same character

$$\gamma(\otimes_v h_v) = \prod_v \gamma_v(h_v).$$

Hence $M \cong N$, by (2.4.4.12).

Now the general case follows from the two situations above: choose $e \in \mathcal{E}$ that $M[e] \neq 0$, then let $S$ be large that for $v \notin S$, $e_v = e_v^0$. Then we decompose $\mathcal{H}$ as $\mathcal{H} = \otimes_{v \in S} \mathcal{H}_v \otimes (\otimes_{v \notin S} H_v)$, then

$$M = \bigotimes_{v \in S} M_v \otimes M_v' = \bigotimes_{v \in S} M_v \otimes (\bigotimes_{v \notin S} M_v) = \otimes_{v \notin S} M_v.$$

□

5 Miscellaneous

Lemma (2.4.5.1). Let $R$ be a (possibly non-commutative) unital ring of characteristic 0 with the following properties:

- $R$ has no zero-divisors,
- rankZ $R \leq 4$,
- $R$ has an involution $(-)^\wedge : R \rightarrow R^{\text{op}}$,
- For any $\alpha \in R$, $\alpha \bar{\alpha} \in \mathbb{N}$, and $\alpha \bar{\alpha} = 0$ iff $\alpha = 0$.

Then $R$ is isomorphic to exactly one of the following:

- \Z.
- an order in an imaginary quadratic extension over \Q.
- an order in a definite quaternion algebra over \Q.

And the third case won’t happen in characteristic 0, by (13.8.1.24).
Proof: It suffices to show $K = R \otimes_{\mathbb{Z}} \mathbb{Q}$ is either $\mathbb{Q}$, an imaginary quadratic field or a definite quaternion algebra. For $\alpha \in K$, denote $N\alpha = \alpha \hat{\alpha}$, $\text{tr} \alpha = \alpha + \hat{\alpha}$, then $\text{tr} \alpha = 1 + N\alpha - N(1 - \alpha) \in \mathbb{Q}$.

Assume $K \neq \mathbb{Q}$, let $\alpha \in K \setminus \mathbb{Q}$. We may replace $\alpha$ by $\alpha - \frac{1}{2} \text{tr} \alpha$ to assume $\text{tr} \alpha = 0$, then $\alpha^2 = -N\alpha < 0 \in \mathbb{Z}$. So $\mathbb{Q}(\alpha)$ is an imaginary quadratic field.

Assume $K \neq \mathbb{Q}(\alpha)$, let $\beta \in K \setminus \mathbb{Q}(\alpha)$. We may replace $\beta$ by $\beta - \frac{1}{2} \text{tr} \beta - \frac{\text{tr}(\alpha \beta)}{\alpha^2} \alpha$ to assume $\text{tr}(\beta) = \text{tr}(\alpha \beta) = 0$. Hence $\beta^2 = -N\beta < 0 \in \mathbb{Z}$, and $\alpha \beta = -\beta \alpha$. So $\mathbb{Q}(\alpha, \beta)$ is a definite quadratic extension of $\mathbb{Q}$. Then $K = \mathbb{Q}(\alpha, \beta)$ because they are has rank 4 over $\mathbb{Z}$. $\square$

2.5 Lie Algebras

Basic references are [Car05], [Ser87], [Mil13], [Kna96], [Lie Algebras and Lie Groups Serre], and [Eti21].

In this section, if not otherwise pointed out, $k$ is assumed to be a field of char0 or just $C$.

1 Basics

Def.(2.5.1.1)[Lie Algebras]. A Lie algebra $L$ is an non-associative algebra over a field $k$ with a bilinear Lie bracket operation that satisfies:

$$[x, x] = 0, \quad [xyz] = [[xy]z] + [yzx]$$ (Jacobi Identities).

It is easily deduced that $[xy] = -[yx]$.

Denote $\text{ad}_x(y) = [xy]$, then $\text{ad}_x$ are all derivatives of $L$.

An element $x \in \mathfrak{g}$ is called nilpotent or semisimple if $\text{ad}_x$ is nilpotent or semisimple.

Prop.(2.5.1.2)[Associative Algebra]. For any associative algebra $A$ over $k$, it can be given naturally a Lie algebra structure by defining $[xy] = xy - yx$. In this way, we get a natural functor $\text{AssAlg}_k \to \text{Lie}_k: A \mapsto [A]$.

Prop.(2.5.1.3)[Derivatives form a Lie Algebra]. Given a $k$-algebra $A$, the set of derivatives $\text{Der}_k(A) = \text{Der}_k(A, A)$ is a Lie algebra under the associative bracket.

Proof: \[ [D_1, D_2](ab) = D_1(D_2(a)b + aD_2(b)) - D_2(D_1(a)b + aD_1(b)) = D_1D_2(a)b + D_2(a)D_1(b) + D_1(a)D_2(b) + aD_1D_2(b) - (D_2D_1(a)b + D_1(a)D_2(b) + D_2(a)D_1(b) + aD_2D_1(b)) = [D_1, D_2](a)b + a[D_1, D_2](b) \]

□

Prop.(2.5.1.4)[Base Change of Fields]. Let $\mathfrak{a}$ be a subalgebra of a Lie algebra $\mathfrak{g}$ over $k$, and $k'/k$ a field extension, then $\mathfrak{a}_{k'}$ is a subalgebra of $\mathfrak{g}_{k'}$, and

$$N_{\mathfrak{g}_{k'}}(\mathfrak{a}_{k'}) = N_{\mathfrak{g}}(\mathfrak{a})_{k'},$$

$$e_{\mathfrak{g}_{k'}}(\mathfrak{a}_{k'}) = e_{\mathfrak{g}}(\mathfrak{a})_{k'}.$$

Proof: This is because the normalizer and centralizer is defined by linear equations with coefficients in $k$, thus the vector space is defined over $k$.

□

Prop.(2.5.1.5). Let $D$ be a derivative of a $k$-algebra $A$ that is nilpotent, then $e^D$ is an automorphism of $A$(as an algebra).

Proof: Routine calculation.

□

Def.(2.5.1.6)[Semidirect Product of Lie Algebras]. Let $\mathfrak{g}, \mathfrak{h}$ be Lie algebras and $\tau: \mathfrak{g} \to \text{Der}(\mathfrak{h})$, then we can define a semi-direct product Lie algebra $\mathfrak{g} \ltimes \mathfrak{h}$ that is isomorphic to $\mathfrak{g} \oplus \mathfrak{h}$ as vector spaces, and $\mathfrak{g}, \mathfrak{h}$ are subalgebras of $\mathfrak{g} \ltimes \mathfrak{h}$, with $[g, h] = \tau(g)(h)$. It can be shown that this is truly a Lie algebra.
Def. (2.5.1.7) [Elementary Automorphisms]. Let \( g \) be a Lie algebra, a \textbf{special automorphism} is an automorphism of \( g \) of the form \( e^{ad_x} \), where \( x \) is in the nilpotent radical (2.5.1.34).

The group of \textbf{elementary automorphisms} is the subgroup of the automorphism group of \( g \) generated by the automorphisms of the form \( e^{ad_x} \) where \( ad(x) \) is nilpotent.

Def. (2.5.1.8) [Ideals]. A subspace \( a \subset g \) is called an \textbf{ideal} of \( g \) iff \([g,a] \subset a\). If \( I \) is an ideal of \( L \), then \( L/I \) can be made into a Lie algebra by defining \([I + x, I + y] = I + [xy]\).

Def. (2.5.1.9) [Center]. The \textbf{center} of a Lie algebra \( g \) is the elements \( a \) that \( ad a = 0 \). It is an ideal.

Def. (2.5.1.10) [Simple Lie Algebras]. A Lie algebra \( g \) is called \textbf{simple} if it is not 1-dimensional and it has no nontrivial ideal.

Def. (2.5.1.11) [Lie Algebra of Affine Maps]. Let \( V \) be a f.d. \( k \)-vector space. If we regard \( V \) as a commutative algebra, then \( \text{Der}_k(V) = \mathfrak{gl}_V \). Then \( V \times \mathfrak{gl}_V \) is a Lie algebra, denoted by \( \mathfrak{af}(V) \).

Let \( V' = V \oplus k \), and let \( \mathfrak{h} = \{ w \in \mathfrak{gl}_V, |w(V') \subset V \} \), which is a Lie subalgebra of \( \mathfrak{gl}_V \). If we define

\[
\eta : \mathfrak{h} \to \mathfrak{gl}_V : \eta(w) = w|_V, \quad \zeta : \mathfrak{h} \to V : \zeta(w) = w(0,1),
\]

then \((\eta, \zeta)\) defines a Lie algebra homomorphism from \( \mathfrak{h} \) to \( \mathfrak{af}(V) \). This map is bijective, with the inverse given by sending \((v, f) \in \mathfrak{af}(V)\) to the morphism

\[
(v', c) \mapsto (f(v') + cv, 0).
\]

Lemma (2.5.1.12). Let \( \lambda, \mu \in k \) and \( x, y, z \in g \), then we have

\[
(ad(x) - \lambda - \mu)^m[y, z] = \sum_{i=1}^m \left( \begin{array}{c} m \\ i \end{array} \right) [(ad(x) - \lambda)^iy, (ad(x) - \mu)^m-i]z].
\]

Proof:

\[
(ad(x) - \lambda - \mu)^m[y, z] = \sum_{p+q+r+s=m} (-1)^{r+s} \frac{m!}{p!q!r!s!} \lambda^r \mu^s [(ad x)^p(y), (ad x)^q(z)]
\]

\[
= \sum_{k+l=m} \frac{m!}{k!l!} [(ad(x) - \lambda)^ky, (ad(x) - \mu)^lz]
\]

\( \square \)

Def. (2.5.1.13) [Killing Form]. A bilinear form \( B \) on \( g \) is called \textbf{invariant} if \( B([x, y], z) + B(x, [y, z]) = 0 \).

The \textbf{Killing form} on a Lie algebra \( g \) of f.d. is the invariant symmetric bilinear form defined by

\( B(x, y) = \text{tr}(ad x \circ ad y) \).

If \( a \) is an ideal of a Lie algebra \( g \), then the Killing form on \( a \) is that of the Killing form on \( a \) as a Lie algebra. This is linear algebra.

Prop. (2.5.1.14). Any invariant symmetric bilinear form on a \textbf{simple} Lie algebra \( g \) is a multiple of the Killing form.

Prop. (2.5.1.15). A subalgebra \( h \) of a Lie algebra \( g \) is commutative if it consists of semisimple elements.
Proof: For an element \( x \in \mathfrak{h} \), we need to show that \( \text{ad}_\mathfrak{a}(x) = 0 \). If it is not, because \( \text{ad}_\mathfrak{h}(x) \) is semisimple by (2.3.6.8), there is a nonzero eigenvector \( y \) at least after a base change, so \([x, y] = cy, y \neq 0 \in \mathfrak{h} \). So \( \text{ad}(y)(x) = -cy \), and \( \text{ad}(y)^2(x) = 0 \), so \( \text{ad}(y) \) is non-semisimple on the subspace \( \{x, y\} \), which means \( \text{ad}(y) \) is non-semisimple on \( \mathfrak{q} \), by (2.3.6.8) again. \( \square \)

Lemma (2.5.1.16). If \( \mathfrak{g} \subset \mathfrak{g}_n \) is a Lie subalgebra, and \( a \in \mathfrak{g} \) is a nilpotent matrix, then \( \text{ad}(a) \) is also nilpotent.

Proof: This is because \( \text{ad}(a) = l(a) - g(a) \), where \( l(a) \) is left multiplication and \( r(a) \) is right multiplication. The left and right multiplication commutes, so it is clear \( \text{ad}(a)^{2n} = 0 \) if \( \text{ad}(a)^n = 0 \). \( \square \)

Nilpotent and Solvable Lie Algebras

Def. (2.5.1.17)[Nilpotent and Solvable Lie Algebras]. Let \( \mathfrak{g} \) be a Lie algebra, the lower central series of \( \mathfrak{g} \) is the descending sequence of ideals of \( \mathfrak{g} \) defined inductively by \( C^1\mathfrak{g} = \mathfrak{g} \) and \( C^n\mathfrak{g} = [\mathfrak{g}, C^{n-1}\mathfrak{g}] \).

Let \( \mathfrak{g} \) be a Lie algebra, the derived series of \( \mathfrak{g} \) is the descending sequence of ideals of \( \mathfrak{g} \) defined inductively by \( D^1\mathfrak{g} = \mathfrak{g} \) and \( D^n\mathfrak{g} = [D^{n-1}\mathfrak{g}, D^{n-1}\mathfrak{g}] \).

A Lie algebra is called nilpotent if there is an \( n \) that \( C^n\mathfrak{g} = 0 \). This is equivalent to \( \text{ad} x_1 \text{ad} x_2 \ldots \text{ad} x_n = 0 \) for any \( n \) element \( x_1, \ldots, x_n \). It is called solvable if \( D^n = 0 \) for some \( n \). It is clear that \( D^n \subset C^n \), so nilpotent Lie algebra is solvable.

Prop. (2.5.1.18). The lower central series satisfies: \([C^n\mathfrak{g}, C^m\mathfrak{g}] \subset C^{m+n}\mathfrak{g}\).

The operation of taking derived series or lower central series commutes with base change of fields.

Proof: Prove by induction on \( n \): \( n = 0, 1 \) is trivial, and if the assertion is true for \( n \geq k \), then for \( n = k + 1 \), \([C^n\mathfrak{g}, C^m\mathfrak{g}] \subset [\mathfrak{g}, [C^{n-1}\mathfrak{g}, C^m\mathfrak{g}]] + [C^{n-1}\mathfrak{g}, C^{m+1}\mathfrak{g}] \subset C^{m+n}\mathfrak{g}\). \( \square \)

Cor. (2.5.1.19). Let \( \mathfrak{g} \) be a Lie algebra over a field \( k \), and \( k'/k \) is a field extension, then \( \mathfrak{g} \) is solvable/nilpotent iff \( \mathfrak{g} \otimes_k k' \) is solvable/nilpotent.

Prop. (2.5.1.20). If \( \mathfrak{g} \) is a nilpotent Lie algebra, then for any subalgebra \( \mathfrak{h} \subseteq \mathfrak{g} \), \( N_{\mathfrak{g}}(\mathfrak{h}) \neq \mathfrak{h} \).

Proof: Because \( \mathfrak{g}^n = 0 \) for some \( n \), take \( n \) to be the maximal one that \( \mathfrak{h} \not\subset \mathfrak{g}^n \), then \( [\mathfrak{g}^n, \mathfrak{h}] \subset \mathfrak{g}^{n+1} \subset \mathfrak{h} \), so \( \mathfrak{g}^n \subset N_{\mathfrak{g}}(\mathfrak{h}) \), so \( N_{\mathfrak{g}}(\mathfrak{h}) \neq \mathfrak{h} \). \( \square \)

Prop. (2.5.1.21). Subalgebras, quotient algebras and extension algebras of solvable algebras are solvable.

Proof: Let \( \mathfrak{h} \subset \mathfrak{g} \), then \( D^n(\mathfrak{h}) \subset D^n(\mathfrak{g}) \), so if \( \mathfrak{g} \) is solvable, then so is \( \mathfrak{h} \). Also the quotient is clearly solvable. For an extension of Lie algebras

\[ 0 \rightarrow \mathfrak{h} \rightarrow \mathfrak{g} \rightarrow r \rightarrow 0, \]

if \( \mathfrak{h}, r \) are both solvable, let \( D^m(\mathfrak{h}) = 0, D^n(r) = 0 \), then the image of \( D^n(\mathfrak{g}) \) is 0 in \( r \), so \( D^n(\mathfrak{g}) \subset \mathfrak{h} \), so \( D^{m+n}(\mathfrak{g}) = 0 \). \( \square \)

Cor. (2.5.1.22)[Radical]. If \( \mathfrak{a}, \mathfrak{b} \) are solvable ideals of a Lie algebra \( \mathfrak{g} \), then the ideal \( \mathfrak{a} + \mathfrak{b} \) is also solvable, because \( 0 \rightarrow \mathfrak{a} \rightarrow \mathfrak{a} + \mathfrak{b} \rightarrow \mathfrak{b}/\mathfrak{a} \cap \mathfrak{b} \).

Let \( \mathfrak{r} \subset \mathfrak{g} \) be the sum of all solvable ideals of \( \mathfrak{g} \), called the radical \( \text{Rad}(\mathfrak{g}) \). When \( \mathfrak{g} \) is of f.d., this is the maximal solvable ideal.
Def. (2.5.1.23) [Semisimple Lie Algebra]. A Lie algebra \( L \) is called **semisimple** if \( \text{Rad} \ L = 0 \), or equivalently \( \mathfrak{g} \) has no solvable ideals or no commutative ideals. Notice \( L/\text{Rad}(L) \) is semisimple, by (2.5.1.22).

Prop. (2.5.1.24) [Lie]. Let \( \mathfrak{g} \subseteq \mathfrak{gl}(V) \) be a solvable lie algebra over an alg.closed field \( k \) of char\(0\), then \( \mathfrak{g} \) is upper triangular. Equivalently, there exists a vector \( v \in V \) which is a common eigenvector for all \( X \in \mathfrak{g} \), and moreover equivalently, any irreducible representation of \( \mathfrak{g} \) is 1-dimensional.

**Proof:** Idea is to prove by induction on dimension of \( \mathfrak{g} \).

Produce a codimension 1 ideal \( \mathfrak{h} \) of \( \mathfrak{g} \). Let \( \mathfrak{g} \) be generated (as a vector space) by \( \mathfrak{h} \) and \( Y \). Being a subalgebra of solvable algebra \( \mathfrak{g} \), \( \mathfrak{h} \) is itself a solvable lie algebra. Apply induction step on \( \mathfrak{h} \) and choose \( v \in V \) such that \( v \) is an eigenvector for all \( X \in \mathfrak{h} \).

The idea is to consider set \( W \) all common eigenvectors of elements of \( \mathfrak{h} \) and produce an eigenvector of \( Y \) from this \( W \). Let

\[
W = \{ v \in V | X(v) = \lambda(X)v \; \forall \; X \in \mathfrak{h} \; \text{for a fixed} \; \lambda(X) \in \mathbb{C} \}.
\]

Suppose \( W \) is an invariant subspace of \( Y \), we then have restriction map \( Y : W \to W \). As we are in complex vector space (algebraically closed) there exists an eigenvector for \( Y \) in \( W \) say \( w_0 \). Thus, \( w_0 \) is common eigenvector for all elements of \( \mathfrak{g} \).

It remains to show that \( W \) is an invariant subspace of \( Y \) i.e., \( Y(w) \in W \) for all \( w \in W \) i.e., given \( X \in \mathfrak{h} \), we need to have \( X(Y(w)) = \lambda(X)Y(w) \).

Let \( w \in W \), we have

\[
X(Y(w)) = Y(X(w)) + [X,Y](w) = Y(\lambda(X)w) + \lambda([X,Y])w = \lambda(X)Y(w) + \lambda([X,Y])w.
\]

This is almost the same as what we want but with an extra term \( \lambda([X,Y])w \). Suppose we prove \( \lambda([X,Y]) = 0 \) for all \( X \in \mathfrak{h} \) then we are done.

Then considers subspace \( U \) spanned by elements \( \{w, Y(w), Y^2(w), \cdots\} \) and then says that \( U \) is invariant subspace of each element of \( \mathfrak{h} \) and (assuming \( n \) is the smallest integer such that \( Y^{n+1}w \) is in the subspace generated by \( \{w, Y(w), \cdots, Y^n(w)\} \)) representation of an element \( Z \) of \( \mathfrak{h} \) with the basis \( \{w, Y(w), \cdots, Y^n(w)\} \) is an upper triangular matrix with \( \lambda(Z) \) in the diagonal. So, \( \text{tr}(Z) = n\lambda(Z) \).

So, \( \text{tr}([X,Y]) = n\lambda([X,Y]) \). As \( [X,Y] = XY - YX \), we have \( \text{tr}([X,Y]) = \text{tr}(XY) - \text{tr}(YX) = 0 \). Thus, \( \lambda([X,Y]) = 0 \) and we are done. \( \square \)

Cor. (2.5.1.25). If \( \mathfrak{g} \) is a solvable algebra over an alg.closed field \( k \) of char \(0\), then all irreducible representations of \( \mathfrak{g} \) is of dimension \( 1 \).

Cor. (2.5.1.26). \( \mathfrak{g} \) is a solvable algebra iff \( [\mathfrak{g}, \mathfrak{g}] \) is nilpotent.

**Proof:** If \([\mathfrak{g}, \mathfrak{g}]\) is nilpotent, then clearly \( \mathfrak{g} \) is solvable. Conversely, if \( \mathfrak{g} \) is solvable, we need to prove \([\mathfrak{g}, \mathfrak{g}]\) is nilpotent. For this, we can assume \( k \) is alg.closed, and then \( \text{ad}(\mathfrak{g}) \subseteq \mathfrak{b}_g \) for some basis, thus \( \text{ad}(\mathfrak{g}, \mathfrak{g}) \subseteq \mathfrak{n}_g \) is nilpotent, and the kernel of \( \text{ad} \) is an Abelian subalgebra, so \([\mathfrak{g}, \mathfrak{g}]\) is nilpotent. \( \square \)

Cor. (2.5.1.27). If \( \mathfrak{g} \) is a Lie subalgebra of \( \mathfrak{gl}_n(k) \) where \( k \) is an alg.closed field of char\(0\), then

\[
\mathfrak{g} \text{ is solvable} \iff \text{tr}(xy) = 0, \; \forall \; x \in \mathfrak{g}, \; y \in [\mathfrak{g}, \mathfrak{g}].
\]
Proof: Firstly if $\mathfrak{g}$ is solvable, then by Lie’s theorem, we can assume $\mathfrak{g} \in \mathfrak{b}_V$ the upper-triangular matrices, so $[\mathfrak{g}, \mathfrak{g}] \in \mathfrak{n}_V$ is nilpotent, and so $xy \in \mathfrak{n}_V$ is also nilpotent, and $\text{tr}(xy) = 0$.

Conversely, if $\text{tr}(xy) = 0$ for all $x \in \mathfrak{g}, y \in [\mathfrak{g}, \mathfrak{g}]$, we only need to prove $[\mathfrak{g}, \mathfrak{g}]$ is solvable, so we may change $\mathfrak{g}$ to $[\mathfrak{g}, \mathfrak{g}]$ and assume $\text{tr}(xy) = 0$ for all $x, y \in \mathfrak{g}$.

Now to show $\mathfrak{g}$ is solvable, it suffices to show $[\mathfrak{g}, \mathfrak{g}]$ is nilpotent, or by Engel’s theorem\ref{2.5.1.29} all $x \in [\mathfrak{g}, \mathfrak{g}]$ defines a nilpotent endomorphism on $V$. Choose a basis that $x$ is upper-triangular by\ref{2.3.6.3}, and let $x_s$ be the semisimple part of $x$, then it suffices to show $x_s = 0$, or equivalently $\text{tr}(\bar{x}_s x) = 0$. To show this, notice $x \in [\mathfrak{g}, \mathfrak{g}]$, so it suffices to show $\text{tr}(\bar{x}_s[y, z]) = 0$ for any $y, z$. But this equals $\text{tr}([\bar{x}_s, y], z)$. Finally, this is 0 because of the hypothesis and the fact $\bar{x}_s$ is a polynomial in $x$\ref{2.3.6.7} so $[\bar{x}_s, y] \in \mathfrak{g}$.

\begin{corollary}[Cartan’s Criteria for Solvability] A Lie algebra $\mathfrak{g}$ over a field of characteristic 0 is solvable if $\kappa_\mathfrak{g}(x, y)$ for any $x \in \mathfrak{g}, y \in [\mathfrak{g}, \mathfrak{g}]$, where $\kappa$ is the Killing form.

Proof: By\ref{2.5.1.19}, it suffices to show for $k$ alg.closed. Because the kernel of the adjoint map is the center of $\mathfrak{g}$, so $\mathfrak{g}$ is solvable iff $\text{ad}(\mathfrak{g})$ is solvable.

\end{corollary}

\begin{proposition}[Engel] If $(\mathfrak{V}, \rho)$ is a representation of a Lie algebra $\mathfrak{g}$ that $\rho(x)$ is nilpotent for all $x \in \mathfrak{g}$, then there is a basis of $\rho(\mathfrak{g})$ contained in $\mathfrak{n}_V$, in particular $\mathfrak{g}$ is nilpotent.

Proof: It suffices to show if a sub-Lie algebra of $\mathfrak{gl}_V$ consists of nilpotent elements, then there is a common 0-eigenvector. Use Induction, choose a maximal subalgebra $K$ of $L$, then notice the normalizer of $K$ in $L$ is strictly containing $K$, because we can let $K$ acts by adjoint on $L/K$, and notice $\text{ad} x = \lambda_x - \rho_x$ is nilpotent for $x$ a nilpotent matrix, so by induction hypothesis there is an $x \in L$ that $[x, K] \subset K$. But $K$ is maximal, so it must be of codimension 1, and $L = K + Fz$. The 0-eigenvectors for $K$ is a nonzero subspace by induction hypothesis. Now this space is invariant under $z$: for any $h \in K$,

$$h(z(v)) = [h, z](v) + zh(v) = 0.$$ 

So now a 0-eigenvector for $z$ in this space will suffice.

\end{proposition}

\begin{corollary}[2.5.1.30] If all elements of $L$ are ad-nilpotent (i.e. $\text{ad} x = 0$), then $L$ is nilpotent. Equivalently, elements of $L$ has a common 0-eigenvector.

Proof: Consider $\text{ad} : \mathfrak{g} \rightarrow \mathfrak{gl}_\mathfrak{g}$, then the image is nilpotent by Engel’s theorem\ref{2.5.1.29}, and the kernel of ad is the center of $\mathfrak{g}$, so $\mathfrak{g}$ is also nilpotent.

\end{corollary}

\begin{corollary}[2.5.1.31] Let $\mathfrak{a}$ be an ideal of a Lie algebra $\mathfrak{g}$. Then $\mathfrak{a}$ is nilpotent if $\text{ad}\mathfrak{a}(a)$ is nilpotent for any $a \in \mathfrak{a}$.

Proof: If $\text{ad}\mathfrak{a}(a)$ is nilpotent for any $a \in \mathfrak{a}$, then also $\text{ad}\mathfrak{a}(a)$ is nilpotent, so $\mathfrak{a}$ is nilpotent by Engel’s theorem. Conversely, if $\mathfrak{a}$ is nilpotent, then $\text{ad}\mathfrak{a}(a)$ is nilpotent for any $a \in \mathfrak{a}$. And $\text{ad}(\mathfrak{a})(\mathfrak{g}) \subset \mathfrak{a}$, so $\text{ad}\mathfrak{a}(a)$ is nilpotent.

\end{corollary}

\begin{corollary}[2.5.1.32] The sum of two nilpotent ideals of $\mathfrak{g}$ is nilpotent.

Proof: We need to show for any $a \in \mathfrak{a}, b \in \mathfrak{b}$, $\text{ad}\mathfrak{a}(a + b)$ is nilpotent. For this, we need to factor $\mathfrak{g}$ as Jordan sequence $0 \subset \mathfrak{g}_1 \subset \mathfrak{g}_2 \subset \ldots \subset \mathfrak{g}_n = \mathfrak{g}$ over itself via the adjoint representation, then I claim that $\text{ad}(a)(\mathfrak{g}_k) \subset \mathfrak{g}_{k-1}$. Because $V = \mathfrak{g}_k/\mathfrak{g}_{k-1}$ is simple, let $V' \subset V$ consists of vectors $v$ that $a(v) = 0$ for any $a \in \mathfrak{a}$, then it is non-empty by Engel’s theorem, and also it is invariant under action of $\mathfrak{g}$: $a(gv) = [a, g](v) + g(av) = 0$. So it is all of $V$.

Then, we have $\text{ad}(a + b)(\mathfrak{g}_k) \subset \mathfrak{g}_{k-1}$, thus $\text{ad}(a + b)$ is nilpotent.
**Cor. (2.5.1.33)** [Maximal Nilpotent Ideal]. For any Lie algebra \( \mathfrak{g} \), there exists a maximal nilpotent ideal, denoted by \( \mathfrak{n} \).

**Def. (2.5.1.34)** [Nilpotent Radical]. The nilpotent radical \( \mathfrak{s} = s(\mathfrak{g}) \) of a Lie algebra is the intersection of the kernels of simple representations of \( \mathfrak{g} \).

\( \mathfrak{s} \) is nilpotent for any f.d. representation of \( \mathfrak{g} \), in particular the adjoint representation of \( \mathfrak{g} \). Thus it is nilpotent, by (2.5.1.31).

**Lemma (2.5.1.35).** Let \( \mathfrak{g} \subset \mathfrak{gl}_V \) be a subalgebra, and let \( \mathfrak{a} \) a commutative ideal of \( \mathfrak{g} \). If \( V \) is simple as a \( \mathfrak{g} \)-module, then \( [\mathfrak{g}, \mathfrak{a}] \cap \mathfrak{a} = 0 \).

**Proof:** Cf. [Mil13] P58.

**Prop. (2.5.1.36).** Let \( \mathfrak{g} \) be a Lie algebra, and \( \mathfrak{r} \) its radical, \( \mathfrak{s} \) it nilpotent radical, then

\[
\mathfrak{s} = D(\mathfrak{g}) \cap \mathfrak{r} = [\mathfrak{g}, \mathfrak{r}].
\]

In particular, \( [\mathfrak{g}, \mathfrak{r}] \) is nilpotent (2.5.1.34).

**Proof:** To show \( D(\mathfrak{g}) \cap \mathfrak{r} \subset \mathfrak{s} \), we need to show that \( \rho(D(\mathfrak{g}) \cap \mathfrak{r}) = 0 \) for any simple representation \( \rho \). Because \( \mathfrak{r} \) is solvable, let \( r \) be the smallest integer that \( \rho(D^r(\mathfrak{r})) = 0 \), then \( \mathfrak{a} = \rho(D^r(\mathfrak{r})) \) is a commutative ideal of \( \rho(\mathfrak{g}) \). Hence by (2.5.1.35) \( D(\rho(\mathfrak{g})) \cap \mathfrak{a} = 0 \), so \( \rho(D(\mathfrak{g}) \cap D^r(\mathfrak{r})) = 0 \). Now if \( r > 0 \), then \( \rho(D^r(\mathfrak{r})) = 0 \), contradicting the minimality of \( r \), so \( \rho(D(\mathfrak{g}) \cap r) = 0 \).

To show \( \mathfrak{s} \subset [\mathfrak{g}, \mathfrak{r}] \), let \( \mathfrak{q} = \mathfrak{g}/[\mathfrak{g}, \mathfrak{r}] \), and \( f \) the quotient map. Then because the kernel is solvable, \( f(r) \) is the radical of \( \mathfrak{q} \) (2.5.1.22), but it is also contained in the center of \( \mathfrak{q} \), so \( \mathfrak{q} \) is reductive, and thus has a faithful semisimple representation (2.5.4.4), then the kernel of this representation is just \([\mathfrak{g}, \mathfrak{r}]\), showing that \( \mathfrak{s} \subset [\mathfrak{g}, \mathfrak{r}] \).

**Def. (2.5.1.37)** [Levi Subalgebras]. Let \( \mathfrak{g} \) be a Lie algebra and \( \mathfrak{r} \) its radical, then a Lie subalgebra \( \mathfrak{s} \) is called a Levi subalgebra if \( \mathfrak{g} = \mathfrak{r} \oplus \mathfrak{s} \).

**Prop. (2.5.1.38)** [Levi-Malcev]. Every Lie algebra over a field \( k \) of char0 has a Levi subalgebra, and any two Levi subalgebras of \( \mathfrak{g} \) are conjugate by a special automorphism of \( \mathfrak{g} \) (2.5.1.7).

**Proof:** If \( \mathfrak{q} \) is reductive, then Levi subalgebra exists uniquely, by (2.5.4.2) and (2.5.4.3).

If \( \mathfrak{r} \) is a minimal ideal of \( \mathfrak{g} \), then \( [\mathfrak{g}, \mathfrak{r}] = \mathfrak{r} \), and \( [\mathfrak{r}, \mathfrak{r}] = 0 = Z(\mathfrak{g}) \). Consider the adjoint action of \( \mathfrak{g} \) on \( \text{End}_k(\mathfrak{g}) \). Also consider the subspaces \( V, W \) of \( \text{End}_k(\mathfrak{g}) \), where \( V \) is the subspace of maps from \( \mathfrak{g} \) to \( \mathfrak{r} \) that restriction to \( \mathfrak{r} \) is a constant multiple of identity, and \( W \) is the subspaces of \( V \) consisting of maps vanishing on \( \mathfrak{r} \). Both of \( V, W \) are invariant under action of \( \mathfrak{g} \).

Let \( \varphi : \mathfrak{r} \to \mathfrak{g} \) be the adjoint action, which is injective and has image \( P \subset W \). Also \( \Psi \) is invariant under action of \( \mathfrak{g} \) (because \( \mathfrak{r} \) is an ideal).

For \( x \in \mathfrak{r}, y \in \mathfrak{g}, \alpha \in V \), \( (zx)(y) = [x, \alpha(y)] - \alpha([x, y]) = -\lambda(\alpha)[x, y], \) so \( x\alpha = \text{ad}(\lambda(\alpha)x) \), which means elements of \( r \) map \( V \) into \( P \). Thus now \( \mathfrak{r} \) acts trivially on \( V/P \), and \( W/P \) is invariant under the action of \( \mathfrak{g}/\mathfrak{r} \), which is a semisimple Lie algebra. Thus by Weyl’s theorem (15.15.1.2), there exists a \( \mathfrak{g} \)-stable line \( L \) that \( V/P = W/P \oplus L \). But \( \mathfrak{g} \) acts trivially on \( L \) by (15.15.1.1).

Let \( \alpha_0 \) generates \( L \) and normalized that \( \lambda(\alpha) = 1 \), then \( \mathfrak{g}\alpha_0 \in P \), We consider the map \( \mathfrak{g} \xrightarrow{g \mapsto g\alpha_0} P \xrightarrow{\varphi^{-1}} \mathfrak{r} \), whose restriction to \( \mathfrak{r} \) is the identity map, so its kernel is a Levi subgroup for \( \mathfrak{r} \).

Still in this case, let \( \mathfrak{s}' \) be a second Levi subgroup for \( \mathfrak{r} \). For each \( x \in \mathfrak{s}' \), there is a unique \( h(x) \in \mathfrak{r} \) that \( x + h(x) \in \mathfrak{s} \). Hence this \( h \) satisfies \( h([x, y]) = [h(x), y] + [x, h(y)] \). But then
by (15.15.1.3), \( h(x) = [a, x] \) for some \( a \in \mathfrak{r} \). Then \( 1 + \text{ad}(a) \) maps \( \mathfrak{s} \) to \( \mathfrak{s}' \), and \( \text{ad}(a)^2 = 0 \) because \( \mathfrak{r} \) is commutative. And \( \mathfrak{r} = [\mathfrak{r}, \mathfrak{g}] \), so \( a \) is in the nilpotent radical of \( \mathfrak{g} \), thus \( \mathfrak{s}, \mathfrak{s}' \) are conjugate by a special automorphism.

For the general case, we can use induction on the dimension of \( \mathfrak{g} \). After the first two cases, we can assume that \( [\mathfrak{g}, \mathfrak{r}] \neq 0 \) and \( \mathfrak{r} \) contains a proper non-trivial ideal. As \( [\mathfrak{g}, \mathfrak{r}] \) is nilpotent (2.5.1.36), its center is non-zero. So we can choose a maximal ideal \( \mathfrak{m} \) contained in the center of \( [\mathfrak{g}, \mathfrak{r}] \), and \( \mathfrak{m} \neq \mathfrak{r} \). Now \( \mathfrak{g}/\mathfrak{m} \) has radical \( \mathfrak{r}/\mathfrak{m} \) because \( \mathfrak{m} \) is solvable, so we can apply induction to find a Levi subgroup \( \mathfrak{h}' \) for \( \mathfrak{g}/\mathfrak{m} \) in \( \mathfrak{g}/\mathfrak{m} \), and let \( \mathfrak{h}'' \) be its preimage in \( \mathfrak{g} \). Then \( \mathfrak{h}'' \) has radical \( \mathfrak{m} \), and thus by induction there is a Levi subgroup \( \mathfrak{h} \) for \( \mathfrak{m} \) in \( \mathfrak{h}'' \), and this \( \mathfrak{h} \) is a Levi subgroup for \( \mathfrak{r} \) in \( \mathfrak{g} \). Similarly any two such Levi subgroups are conjugate by a special automorphism.

This has another cohomological proof in [Etingof, Section 48].

2 Semisimple Lie Algebra

Prop. (2.5.2.1) [Cartan-Killing Criteria for Semisimplicity]. A f.d. Lie algebra \( \mathfrak{g} \) is semisimple iff its Killing form (2.5.1.13) is non-degenerate.

\textbf{Proof:} If \( \mathfrak{g} \) is semisimple, then the adjoint representation is faithful, thus by (2.5.9.6) the Killing form is non-degenerate. Conversely, if the Killing form is non-degenerate and \( \mathfrak{a} \) is a commutative ideal of \( \mathfrak{g} \) and \( a \in \mathfrak{a}, g \in \mathfrak{g} \), then \( (\text{ad}a \circ \text{ad}g)^2 = 0 \), so \( \text{ad}a \circ \text{ad}g \) is nilpotent and has trace 0. So \( a \in \mathfrak{g}^\perp \), which is 0 because the Killing form is non-degenerate.

Cor. (2.5.2.2). Let \( \mathfrak{a} \) be a semisimple ideal of a Lie algebra \( \mathfrak{g} \), then the orthogonal space \( \mathfrak{a}' \) w.r.t the Killing form is an ideal and is a complement for \( \mathfrak{a} \) in \( \mathfrak{g} \), and \( \mathfrak{g} \cong \mathfrak{a} \times \mathfrak{a}' \).

\textbf{Proof:} \( \mathfrak{a}^\perp \) is an ideal because the Killing form is invariant. The Killing form of \( \mathfrak{a} \) is the restriction of the Killing form of \( \mathfrak{g} \) (2.5.1.13), so \( \mathfrak{a} \cap \mathfrak{a}' = 0 \) because \( \kappa_{\mathfrak{a}} \) is non-degenerate.

Cor. (2.5.2.3). A Lie algebra is semisimple iff it is isomorphic to a product of simple algebras \( \mathfrak{g} = \mathfrak{a}_1 \times \cdots \times \mathfrak{a}_r \), and these \( \mathfrak{a}_i \) are all its minimal ideals, (Not only up to isomorphism).

\textbf{Proof:} The Killing form of \( \mathfrak{a} \cap \mathfrak{a}' \perp = 0 \), thus it is solvable, by (2.5.1.28), and then 0, so we can continue the decomposition.

For any minimal nonzero ideal \( \mathfrak{a} \subset \mathfrak{g} \), then \([\mathfrak{g}, \mathfrak{a}] \) is an ideal contained in \( \mathfrak{a} \) which is nonzero because \( \mathfrak{g} \) has trivial center. Then

\[ \mathfrak{a} = [\mathfrak{g}, \mathfrak{a}] = \bigoplus_i [\mathfrak{a}, \mathfrak{a}_i] \]

so \( \mathfrak{a} \subset [\mathfrak{a}, \mathfrak{a}_i] \subset \mathfrak{a}_i \), and then \( \mathfrak{a} = \mathfrak{a}_i \) by simplicity.

Cor. (2.5.2.4). If \( \mathfrak{g} \) is semisimple, then \([\mathfrak{g}, \mathfrak{g}] = \mathfrak{g} \).

Cor. (2.5.2.5). Let \( \mathfrak{g} \) be a Lie algebra over a field \( k \) and \( k'/k \) is a field extension, then \( \mathfrak{g} \) is semisimple iff \( \mathfrak{g} \otimes_k k' \) is semisimple.

Prop. (2.5.2.6) [Examples of Semisimple Lie Algebras].

- The subalgebra \( \mathfrak{sl}(V) \) of all elements of \( \text{End}(V) \) of trace 0 is semisimple.

Prop. (2.5.2.7). If \( L \) is semisimple, then every derivative of \( L \) is inner.

\textbf{Proof:} This is a special case of (15.15.1.3) applied to the adjoint representation.
Prop. (2.5.2.8). If \( \mathfrak{g} \) is a semisimple algebra of \( \mathfrak{gl}_n(k) \) where \( k \) is a field of \( \text{char} 0 \), then it contains the semisimple and nilpotent parts of each of its elements under the Jordan decomposition (2.3.6.7).

Proof: We may assume \( k \) is alg. closed, because the Jordan decomposition is invariant of the field that contains \( \mathfrak{g} \), and an element is contained in a vector space can be checked after base change to a larger field. For any subspace \( W \subset V \), let \( \mathfrak{g}_W = \{ \alpha \in \mathfrak{gl}_V | \alpha(W) \subset W, \text{tr}(\alpha|W) = 0 \} \), then if \( \mathfrak{g}_W \subset W \), then \( \mathfrak{g} \subset \mathfrak{g}_W \), because every element of \( \mathfrak{g} \) is a sum of brackets by (2.5.2.4), thus have zero trace. Now consider

\[
\mathfrak{g}' = \bigcap_{\mathfrak{g}_W \subset W} \mathfrak{g}_W.
\]

If \( x \in \mathfrak{g}' \), then so does \( x_s \) and \( x_n \), because they are polynomials in \( x \) without constant terms, and \( \text{ad}(x)_s = \text{ad}(x_n) \).

So it suffices to show that \( \mathfrak{g} = \mathfrak{g}' \). We claim that \( \mathfrak{g}' = \mathfrak{g} \): As \( \mathfrak{g} \) is a semisimple ideal of \( \mathfrak{g}' \), by (2.5.2.2), we have a decomposition

\[
\mathfrak{g}' = \mathfrak{g} \oplus \mathfrak{g}^\perp.
\]

Let \( \alpha \in \mathfrak{g}^\perp \) and \( W \) a simple \( \mathfrak{g} \)-module of \( V \), then \( \alpha \) acts on \( W \) as a scalar, which must be 0 because \( \alpha \in \mathfrak{g}_W \) and \( k \) has char 0. As \( W \) is a sum of simple \( \mathfrak{g} \)-modules by Weyl’s theorem (15.15.1.2), we get the desired conclusion.

Prop. (2.5.2.9) [Abstract Jordan Decomposition]. A semisimple/nilpotent element \( x \) in a Lie algebra \( \mathfrak{g} \) is an element that \( \rho(x) \) is semisimple/nilpotent for any representation \( (V, \rho) \) of \( \mathfrak{g} \). And \( x = x_s + x_n \) is called a Jordan decomposition iff \( \rho(x) = \rho(x_s) + \rho(x_n) \) is a Jordan decomposition (2.3.6.7) for any representation \( \rho \) of \( \mathfrak{g} \).

Every element of a semisimple Lie algebra \( \mathfrak{g} \) over a field of characteristic 0 has a unique Jordan decomposition, and \( x = x_s + x_n \) is a Jordan decomposition if \( \rho(x) = \rho(x_s) + \rho(x_n) \) is a Jordan decomposition for one faithful representation \( \rho \) of \( \mathfrak{g} \). In particular, this holds for the adjoint representation \( \text{ad} \).

Proof: Let \( x \in \mathfrak{g} \) and \( (V, \rho) \) a faithful representation of \( \mathfrak{g} \) (for example the adjoint representation), then there is at most one \( x = x_s + x_n \) that \( \rho(x) = \rho(x_s) + \rho(x_n) \) is the Jordan decomposition, which proves the uniqueness.

Now for any \( x \in \mathfrak{g} \), as (2.5.2.8) shows, there do exist two elements that \( \rho(x) = \rho(x_s) + \rho(x_n) \). But then it can be checked directly \( \text{ad}(x) = \text{ad}(x_s) + \text{ad}(x_n) \) is the Jordan decomposition of \( \text{ad}(x) \) as an endomorphism of \( \mathfrak{g} \), by (2.5.1.16). As the adjoint representation is faithful, this shows the Jordan decomposition is independent of the faithful representation chosen.

Now every representation is a subrepresentation of a faithful representation, so we can prove the existence.

Simple Lie Algebras

Main references are [Car05]Chap8 and [Kna96], more data about simple Lie algebras can be found in [Kna96]P508.

Def. (2.5.2.10) [Lie Algebras of Type \( A_n \): \( \mathfrak{sl}(n + 1, \mathbb{C}) \)].

Def. (2.5.2.11) [Lie Algebras of Type \( A_1 \)]. \( A_1 \) is also called \( \mathfrak{sl}_2(\mathbb{C}) \). It has a basis \( f, h, e \) with

\[
[he] = 2e, \quad [hf] = -2f, \quad [ef] = h.
\]
In matrix form,
\[
    h = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad e = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad f = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}.
\]

It can also be realized by
\[
    H = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}, \quad R = \frac{1}{2} \begin{bmatrix} 1 & i \\ i & -1 \end{bmatrix}, \quad L = \frac{1}{2} \begin{bmatrix} 1 & -i \\ -i & -1 \end{bmatrix}.
\]

These two representation differ by a conjugation by the Cayley transformation \( C = -\frac{1+i}{2} \begin{bmatrix} i & 1 \\ i & -1 \end{bmatrix} \).

It is simple by \(?\). The subalgebra \( \mathfrak{b} \) generated by \( X \) and \( H \) is solvable, called the canonical Borel subalgebra of \( \mathfrak{sl}_2 \).

**Proof:**

\[\square\]

**Prop.(2.5.2.12)** [Lie Algebras of Type \( B_n \): \( \mathfrak{so}(2n+1, \mathbb{C}) \)].

**Prop.(2.5.2.13)** [Lie Algebras of Type \( C_n \): \( \mathfrak{sp}(n, \mathbb{C}) \)].

**Prop.(2.5.2.14)** [Lie Algebras of Type \( D_n \): \( \mathfrak{so}(2n, \mathbb{C}) \)].

**Prop.(2.5.2.15)** [Lie Algebras of Type \( G_2 \)].

**Prop.(2.5.2.16)** [Lie Algebras of Type \( F_4 \)].

**Prop.(2.5.2.17)** [Lie Algebras of Type \( E_8 \)].

**Prop.(2.5.2.18)** [Classification of F.D. Complex Simple Lie Algebras].

**Prop.(2.5.2.19)** [Group Automorphisms of Simple Lie Algebras], Cf.[Carter, P184].

**Prop.(2.5.2.20).** \( \mathfrak{sl}_2(k) \) is simple if \( k \) has characteristic \( \neq 2 \).

**Def.(2.5.2.21)** [Exponent]. Let \( \mathfrak{g} \) be a simple Lie algebra,
\[
    e = \sum e_i, \quad h = 2\rho^\vee = \sum_i (2\rho^\vee, \alpha_i) h_i, \quad f = \sum_i (2\rho^\vee, \omega_i) f_i,
\]

then by definition, \([h, e] = 2e, [e, f] = h\), and
\[
    [h, f] = \sum_i \sum_j (2\rho^\vee, \alpha_i)(\alpha_j)(2\rho^\vee, \omega_j) f_j
    = \sum_j [(\sum_i (2\rho^\vee, \alpha_i))(2\rho^\vee, \omega_j)] f_j
    = \sum_j (2\rho^\vee, \alpha_j)(2\rho^\vee, \omega_j)f_j
    = -2f.
\]

So \( \{h, e, f\} \) is a \( \mathfrak{sl}_2 \)-tuple, called the principal \( \mathfrak{sl}_2 \)-subalgebra of \( \mathfrak{g} \). The highest weights of subrepresentation of the adjoint action of this subalgebra on \( \mathfrak{g} \) is called the exponents of \( \mathfrak{g} \), counted with multiplicity.

Equivalently, as \( h|_{\mathfrak{g}^0} = \text{ht}(\alpha) \text{id} \), if \( r_m \) is the number of roots of \( \mathfrak{g} \) of height \( m \), the exponents of \( \mathfrak{g} \) is the numbers \( m \) that \( r_m > r_{m+1} \).
Cor. (2.5.2.22). While \( r_m = 0 \) for \( m \) large and \( r_1 = r(\mathfrak{g}) \), there are \( r \) exponents of \( \mathfrak{g} \). Since the roots of height 2 are all \( \alpha_i + \alpha_j \) where \( i, j \) are connected by an edge in the Dynkin diagram, thus \( r_2 = r - 1 \), thus \( 1 = m_1 \leq \ldots \leq m_r \), \( \sum_{i=1}^r = |R^+| \). And \( \mathfrak{g} \cong \oplus_{r=1}^r L_{2m_i+1} \) as a representation of the principal \( \mathfrak{sl}_2 \)-subalgebra.

Prop. (2.5.2.23) [Exponents of Simple Lie Algebras]. Let \( \mathfrak{g} \) be a Lie algebra, the exponents are.
- \( A_n \): 1, 2, \ldots, \( n \).
- \( B_n \): 1, 3, \ldots, 2\( n \) − 1.
- \( C_n \): 1, 3, \ldots, 2\( n \) − 1.
- \( D_n \): 1, 3, \ldots, 2\( n \) − 3 and \( n \).
- \( G_2 \): 1, 5.
- \( F_4 \): 1, 5, 7, 11.
- \( E_6 \): 1, 4, 5, 7, 8, 11.

3 Cartan Subalgebras

Lie algebras in this subsection are assumed to be of f.d..

Def. (2.5.3.1) [Cartan Subalgebras]. A Cartan subalgebra of a Lie algebra \( \mathfrak{g} \) is a nilpotent subalgebra \( \mathfrak{h} \) that equals to its own normalizer in \( \mathfrak{g} \).

Remark (2.5.3.2). As a proper subalgebra of a nilpotent algebra is never its own normalizer (2.5.1.20), a Cartan subalgebra is a maximal nilpotent subalgebra, but a maximal nilpotent subalgebra may not be a Cartan subalgebra.

If \( k'/k \) is a field extension, then \( \mathfrak{h} \) is a Cartan subalgebra of \( \mathfrak{g} \) iff \( \mathfrak{h}_{k'} \) is a Cartan subalgebra of \( \mathfrak{g}_{k'} \). This is because being nilpotent and the normalizer is also compatible with base change (2.5.1.4).

Prop. (2.5.3.3) [Diagonal Cartan Algebra]. Let \( \mathfrak{g} \subset \mathfrak{gl}_V \) be a subalgebra containing a diagonal matrix \( a = \text{diag}(a_1, \ldots, a_n) \) with distinct \( a_i \), and let \( \mathfrak{h} \) be the subspace of all diagonal matrices in \( \mathfrak{g} \), then \( \mathfrak{h} \) is a Cartan subalgebra of \( \mathfrak{g} \).

Proof: Firstly \( \mathfrak{h} \) is Abelian, and if \( b = \sum b_{ij} e_{ij} \in N_\mathfrak{g}(\mathfrak{h}) \), then \( [a, b] \in \mathfrak{h} \). But
\[
[a, b] = \sum_{ij} (a_{ii} - a_{jj}) b_{ij} e_{ij}
\]
is in \( \mathfrak{h} \) iff \( b \) is diagonal, or \( b \in \mathfrak{h} \), so \( \mathfrak{h} = N_\mathfrak{g}(\mathfrak{h}) \) and \( \mathfrak{h} \) is a Cartan subalgebra. \( \square \)

Def. (2.5.3.4) [Regular Elements]. Let \( \mathfrak{g} \) be a f.d. Lie algebra, for any \( x \in \mathfrak{g} \), let \( P_x(T) \) be the characteristic polynomial of \( \text{ad}(x) \):
\[
P_x(T) = \det(T - \text{ad}(x)) = T^m + a_{m-1}(x)T^{m-1} + \ldots + a_0(x).
\]
Then the rank of \( \mathfrak{g} \) is the minimal \( n \) that \( n(x) \neq 0 \) for some \( x \in \mathfrak{g} \). A regular element is an element \( x \in \mathfrak{g} \) that \( a_n(x) \neq 0 \).
Prop. (2.5.3.5) [Regular Elements and Cartan Subalgebras]. For any regular element \( x \in \mathfrak{g} \), the nilspace \( \mathfrak{g}_x^0 \) is a Cartan subalgebra of \( \mathfrak{g} \).

**Proof:** Let
\[
U_1 = \{ y \in \mathfrak{g}_x^0 | \text{ad}_\mathfrak{g} (y)|_{\mathfrak{g}_x^0} \text{ is not nilpotent} \},
\]
\[
U_2 = \{ y \in \mathfrak{g}_x^0 | \text{ad}_\mathfrak{g} (y)|_{(\mathfrak{g}/\mathfrak{g}_x^0)} \text{ is invertible} \}.
\]
They are both Zariski open subsets of \( \mathfrak{g}_x^0 \). According to Engel’s theorem (2.5.1.29), to show \( \mathfrak{g} \) is nilpotent, it suffices to show that \( U_1 \) is empty. \( U_2 \) is non-empty because it contains \( x \), so if \( U_1 \) is non-empty, \( U_1 \cap U_2 \) is non-empty and there is a \( y \in U_1 \cap U_2 \). For this \( y \), \( n(y) < \dim \mathfrak{g}_x^0 = n(x) \), contradicting the regularity of \( x \).

It remains to show that \( \mathfrak{g}_x^0 \) is its own normalizer. If \( z \) normalizes \( \mathfrak{g}_x^0 \), then \([z, x] \in \mathfrak{g}_x^0\), which means \((\text{ad}(x))^n[z, x] = 0\), so \( \text{ad}(x)^{n+1}(z) = 0 \), thus \( z \in \mathfrak{g}_x^0 \).

Cor. (2.5.3.6) [Cartan Subalgebras Exist]. Let \( \mathfrak{g} \) be a Lie algebra over an infinity field \( k \) contains some Cartan subalgebra, and when \( k \) is alg.closed, all Cartan subalgebras come from some regular element, by (2.5.3.13).

**Proof:** Regular elements exist because \( k \) is infinite.

Cor. (2.5.3.7). Every Lie algebra over an infinite field is a sum of Cartan subalgebras.

**Proof:** This is because the sum of Cartan subalgebras is a vector space thus Zariski closed but it contains all regular elements, which is a Zariski open subset.

Cor. (2.5.3.8). Let \( \mathfrak{a} \) be a subalgebra of a Lie algebra \( \mathfrak{g} \) that \( \text{ad}_\mathfrak{g} (a) \) is semisimple for any \( a \in \mathfrak{a} \), then \( \mathfrak{a} \) is contained in a Cartan subalgebra of \( \mathfrak{g} \).

**Proof:** Cf.[Mil13]P81.

Prop. (2.5.3.9). Let \( \mathfrak{h} \) be a Cartan subalgebra of \( \mathfrak{g} \) over an alg.closed field \( k \). Consider the generalized eigenvalue decomposition (2.5.3.12), if \( x \in \mathfrak{g}^a \), then \( \text{ad}(x)(\mathfrak{g}^b) \in \mathfrak{g}^{a+b}(2.5.1.12) \), and thus \( \text{ad}(x) \) is nilpotent. Let \( E(\mathfrak{h}) \) be the subgroup of the group of elementary automorphisms (2.5.1.7) of \( \mathfrak{g} \) generated by the set of all the automorphisms \( e^{\text{ad}(x)} \), where \( x \in \mathfrak{g}^a \) for some \( \alpha \in \mathfrak{h}^* \backslash 0 \).

Now let \( \mathfrak{h}, \mathfrak{h}' \) be two Cartan subalgebras of \( \mathfrak{g} \), then there exists \( u \in E(\mathfrak{h}), u' \in E(\mathfrak{h}') \) that \( u(\mathfrak{h}) = u'(\mathfrak{h}') \).

**Proof:** Number the elements of \( \mathfrak{h}^* \backslash 0 \) as \( \alpha_1, \ldots, \alpha_n \), and consider the map
\[
f : \mathfrak{g}^{\alpha_1} \times \cdots \times \mathfrak{g}^{\alpha_n} \times \mathfrak{h} \to \mathfrak{g} : (x_1, \ldots, x_n, h) \mapsto e^{\text{ad}(x_1)} \cdots e^{\text{ad}(x_n)} h.
\]
Given a \( h_0 \in \mathfrak{h} \), it can be shown that
\[
(df)_{(0 \ldots, 0, h_0)} : (x_1, \ldots, x_n, h) \mapsto h + \sum_i [x_i, h_0] .
\]
Thus if we choose a regular \( h_0 \in \mathfrak{h} \), then \((df)_{(0 \ldots, 0, h_0)}\) is surjective from \( \mathfrak{g} \) to \( \mathfrak{g} \). Thus \( E(\mathfrak{h})\mathfrak{h}_r \) contains a dense open subset of \( \mathfrak{g} \). Similarly, \( E(\mathfrak{h}')\mathfrak{h}'_r \) contains a dense open subset of \( \mathfrak{g} \). So their intersection is not empty, i.e. \( u(h) = u'(h') \) for some \( u, u', h, h' \). Now
\[
u(\mathfrak{h}) = u(\mathfrak{h}_r^0) = \mathfrak{h}_r^0 = u(\mathfrak{h}') = u'(\mathfrak{h}_r^0) = u'(\mathfrak{h}')
\]
\[\Box\]
Cor. (2.5.3.10). All Cartan subalgebras in a Lie algebra have the same dimension, which is the rank of $\mathfrak{g}$ (2.5.3.4).

Proof: Because we can take a base change to an alg. closed field, under which a Cartan subalgebra is also a Cartan subalgebra by (2.5.3.2), then they have the same rank. □

Cor. (2.5.3.11) [Cartan Subalgebras are Conjugate]. Any two Cartan subalgebras of a f.d. Lie algebra over an alg. closed field $k$ are conjugate by an elementary automorphism (2.5.1.7).

Cartan Subalgebra of Semisimple Lie Algebras

Lemma (2.5.3.12) [Decomposition w.r.t. a Cartan Subalgebra]. Let $\mathfrak{h}$ be a Cartan subalgebra of a semisimple Lie algebra $\mathfrak{g}$, and assume that

$$\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha \in \mathfrak{h}^* \setminus 0} \mathfrak{g}^\alpha.$$ 

where $R = R(\mathfrak{g}, \mathfrak{h})$ is called the root system associated to $(\mathfrak{g}, \mathfrak{h})$. This is true, for example, when $k$ is alg. closed, by (2.5.9.10). (See (2.5.3.21) for when this decomposition is possible).

Cor. (2.5.3.13). If $k$ is alg. closed, the set $\mathfrak{h}_r$ of regular elements $h$ in $\mathfrak{h}$ that $\mathfrak{g}_h^0 = \mathfrak{h}$ is open and dense in $\mathfrak{h}$ in the Zariski topology.

Proof: The condition is equivalent to $\prod_{\alpha \in \mathfrak{h}^* \setminus 0} \alpha(h) \neq 0$, which is an open condition. □

Lemma (2.5.3.14). In the decomposition above, if $\alpha + \beta \neq 0$, then $\mathfrak{g}^\alpha$ and $\mathfrak{g}^\beta$ is orthogonal w.r.t. the Killing form.

Proof: $\text{ad}(x)\text{ad}(y)\mathfrak{g}^\gamma \subset \mathfrak{g}^{\alpha + \beta + \gamma}$, so if $\alpha + \beta \neq 0$, then $\text{ad}(x)\text{ad}(y)$ is nilpotent, thus $\kappa(x, y) = 0$. □

Prop. (2.5.3.15) [Cartan Subalgebras of Semisimple Lie Algebras]. Let $\mathfrak{h}$ be a Cartan subalgebra of a semisimple Lie algebra $\mathfrak{g}$, then

- Every element of $\mathfrak{h}$ is semisimple. In particular, $\mathfrak{h}$ is commutative (2.5.1.15).
- The centralizer of $\mathfrak{h}$ in $\mathfrak{g}$ is $\mathfrak{h}$.
- The restriction of the Killing form to $\mathfrak{h}$ is non-degenerate.

Proof: By (2.5.3.2), it suffices to prove this after $k$ is replaced by its alg. closure, so the generalized eigenvalue decomposition (2.5.3.12) holds. We prove 3 first: by (2.5.3.14), $\mathfrak{h}$ is orthogonal to all $[\mathfrak{h}, x]$ for any $x$. But if $x \in \mathfrak{g}^{\alpha}$, we can see that $[\mathfrak{h}, x] = \mathfrak{g}^\alpha$, so $\mathfrak{h}$ is orthogonal to all $\bigoplus \mathfrak{g}^\alpha$, so $\kappa$ must be non-degenerate on $\mathfrak{h}$.

Because $\mathfrak{g}$ has trivial center, the adjoint representation realizes $\mathfrak{h}$ as a subalgebra of $\mathfrak{gl}_\mathfrak{g}$, and Lie’s theorem (2.5.1.24) shows there is a basis that $\mathfrak{h} \subset \mathfrak{h}_\mathfrak{g}$, hence $\text{ad}([\mathfrak{h}, \mathfrak{h}]) \subset \mathfrak{n}_\mathfrak{g}$, and so $\text{tr}(\mathfrak{h}, [\mathfrak{h}, \mathfrak{h}]) = 0$. As $\kappa$ is non-degenerate on $\mathfrak{h}$, $[\mathfrak{h}, \mathfrak{h}] = 0$, thus $\mathfrak{h}$ is commutative. Now $\mathfrak{h} \subset c_\mathfrak{g}(\mathfrak{h}) \subset N_\mathfrak{g}(\mathfrak{h})$, thus $\mathfrak{h} = c_\mathfrak{g}(\mathfrak{h})$.

If $x \in \mathfrak{h}$, and $x = x_s + x_n$ is the Jordan decomposition (2.5.2.9), then $\text{ad}(x_n)$ are polynomials of $\text{ad}(x)$ thus lies in $\mathfrak{h}$. Now $\text{ad}(x_n)$ commutes with all $\text{ad}(y)$ for $y \in \mathfrak{h}$, thus $\text{ad}(y)\text{ad}(x_n)$ is nilpotent, thus $\kappa(y, x_n) = 0$. Thus $x_n = 0$ as $\kappa$ is non-degenerate on $\mathfrak{h}$. □
Cor. (2.5.3.16) [Cartan Subalgebra Maximal Abelian]. The Cartan subalgebras of a semisimple Lie algebra are the maximal subalgebras consisting of semisimple elements (2.5.2.9), and they are maximal Abelian subalgebras.

WARNING: maximal Abelian subalgebra may not be Cartan subalgebras, as they may contain non-semisimple elements.

Proof: A subalgebra consisting of semisimple elements is contained in a Cartan subalgebra, by (2.5.3.8).

Conversely, if \( h \subset h' \) and \( h \) is a Cartan subalgebra and \( h' \) consists of semisimple elements, then by (2.5.1.15), \( h' \) is commutative, and thus \( h' \subset c_{g}(h) \), so \( h = h' \).

Cartan subalgebras are Abelian by (2.5.3.15), and the are maximal Abelian because they are self-centralizing.

□

Cor. (2.5.3.17). Every regular element is semisimple, because it is contained in a Cartan subalgebra by (2.5.3.5).

Split Semisimple Lie Algebras

Def. (2.5.3.18) [Split Semisimple Lie Algebras]. A split Cartan subalgebra of a semisimple Lie algebra \( g \) over a field \( k \) is a Cartan subalgebra that all the eigenvalues of the linear maps \( \text{ad}(h) \) lies in \( k \) for all \( h \in h \). A split semisimple Lie algebra is a pair \((g, h)\) where \( g \) is semisimple and \( h \) is a split Cartan subalgebra.

Remark (2.5.3.19). For example, the diagonal matrices in \( \mathfrak{sI}_n \) is a splitting Cartan subalgebra over any field.

\( \mathfrak{sI}_2(\mathbb{R}) \) has a non-split Cartan subalgebra \( \left\{ \begin{bmatrix} 0 & -a \\ a & 0 \end{bmatrix} \mid a \in \mathbb{R} \right\} \).

Prop. (2.5.3.20). Let \( \alpha \) be a root of the split semisimple Lie algebra \((g, h)\), then

- The subspaces \( g^\alpha \) and \( h_\alpha = [g^\alpha, g^{-\alpha}] \) are both 1-dimensional.
- There is a unique element \( h_\alpha \in h_\alpha \) such that \( \alpha(h_\alpha) = 2 \), and \( (h_\alpha, h_\alpha) \neq 0 \).
- For each nonzero \( x_\alpha \in g^\alpha \), there is a \( y_\alpha \in g^{-\alpha} \) such that
  \[
  [x_\alpha, y_\alpha] = h_\alpha, \quad [h_\alpha, x_\alpha] = 2x_\alpha, \quad [h_\alpha, y_\alpha] = -2y_\alpha.
  \]
  i.e. \( \mathfrak{s}_\alpha = \{x_\alpha, y_\alpha, h_\alpha\} \cong \mathfrak{sI}_2 \).
- \( k\alpha \) is a root iff \( k = 0, \pm 1 \).

Proof: Define \( h_\alpha = [g^\alpha, g^{-\alpha}] \subset h \). Because the Killing form is non-degenerate on \( h \), we can define for each \( \alpha \in R \) a unique element \( h^\alpha \in h \) that \( \alpha(h) = k(h, h^\alpha) \) for all \( h \in h \). Then \( h_\alpha \) is the subspace spanned by \( h^\alpha \): This is because for \( x \in g^\alpha, y \in g^{-\alpha} \),

\[
\kappa(h, [x, y]) = \kappa([h, x], y) = \alpha(x)\kappa(x, y)
\]

so \([x, y] = \kappa(x, y)h^\alpha \). Combine this with the fact \( \kappa(g^\alpha, g^{-\alpha}) \neq 0 \), we get the fact \( h_\alpha = kh^\alpha \) is 1-dimensional.

Next, there is a unique element \( h_\alpha \in h_\alpha \) that \( \alpha(h_\alpha) = 2 \). For this, it suffices to show that \( \alpha \) doesn’t vanish on \( h_\alpha \): Otherwise let \( x \in g^\alpha \) and \( y \in g^{-\alpha} \) that \([x, y] = h \neq 0 \), then \([h, x] = 0 \).
\(\alpha(h)x = 0 = [h,y]\). So \(\{x,y,h\}\) spans a solvable subalgebra \(\mathfrak{a}\) of \(\mathfrak{g}\). As \(h \in [\alpha,\alpha]\). By Lie’s theorem, \(\rho(h)\) is nilpotent for any representation \(\rho\) of \(\alpha\). But \(h\) is in the Cartan subalgebra so \(\text{ad}(h)\) is semisimple \((2.5.3.15)\), so \(h = 0\), contradiction.

If \((h_\alpha,h_\alpha) = 0\), let \(h_\alpha = [x_\alpha,y_\alpha]\) for \(x_\alpha \in \mathfrak{g}^\alpha, y_\alpha \in \mathfrak{g}^{-\alpha}\), then \(\{x_\alpha,y_\alpha,h_\alpha\}\) is solvable, so by Lie’s theorem, there is a basis of \(\mathfrak{g}\) that the adjoint action is upper-triangular (when pass to the alg. closure). But then \(\text{ad}(h_\alpha)\) is nilpotent, but it is also semisimple, so \(h_\alpha = 0\), contradiction.

Because \(x_\alpha \neq 0\), there exists a unique \(y_\alpha \in \mathfrak{g}^{-\alpha}\) that \([x_\alpha,y_\alpha] = h_\alpha\). Now \([h_\alpha,x_\alpha] = \alpha(h_\alpha)x_\alpha = 2x_\alpha, [h_\alpha,y_\alpha] = -\alpha(h_\alpha)y_\alpha = -2y_\alpha\).

Finally, \(\mathfrak{h}_\alpha \oplus \oplus_{k \neq 0} \mathfrak{g}^{2k\alpha}\) is a subrepresentation of \(x_\alpha, y_\alpha, h_\alpha \cong \mathfrak{sl}_2\), so if \(\mathfrak{g}^{2\alpha} \neq 0\), then \(\text{ad}(x_\alpha)\) induces an isomorphism \(\mathfrak{g}^\alpha \cong \mathfrak{g}^{2\alpha}\) by the representation theory of \(\mathfrak{sl}_2(15.15.1.11)\). But \(\mathfrak{g}^\alpha\) is generated by \(x_\alpha\), contradiction. So \(\mathfrak{g}^{k\alpha} \neq 0\) only for \(k = 0, \pm1\).

**Prop. (2.5.3.21) [Root Decompositions]**. If \(\mathfrak{h}\) is a split Cartan subalgebra, then \(\text{ad}(\mathfrak{h})\) is a commuting family of semisimple endomorphisms with eigenvalues in \(k(2.5.3.15)\). so the decomposition

\[
\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha \in R} \mathfrak{g}^\alpha
\]

holds as in \((2.5.3.12)\). And it is in fact an eigenvalue decomposition, not only generalized eigenvalue decomposition, by \((2.5.3.20)\).

Then \(R\) is a reduced root system \((2.7.2.2)\) in \(\mathfrak{h}^\vee\), with \(s_\alpha(\beta) = -\beta(h_\alpha)\alpha\). In particular, \(\alpha^\vee = h_\alpha\).

**Proof**: Firstly \(R\) spans \(\mathfrak{h}^\vee\): if \(h \in \mathfrak{h}\) lies in the center of all \(\alpha \in R\), then \([h,\mathfrak{g}^\alpha] = 0\) for all \(\alpha \in R\), and as \([h,\mathfrak{h}] = 0\), this means \(h\) is in the center of \(\mathfrak{g}\), which is trivial, so \(h = 0\). So \(R\) spans \(\mathfrak{h}^\vee\).

We need to prove that if \(\alpha, \beta \in R\), then \(\beta(h_\alpha) \in \mathbb{Z}\) and \(\beta(h_\alpha) \in R\). For this, regard \(\mathfrak{g}\) as a \(\mathfrak{s}_\alpha\)-module \((2.5.3.20)\) under the adjoint action, then the assertion follows from the representation theory of \(\mathfrak{sl}_2(15.15.1.11)\): \(h_\alpha\) acts on \(\mathfrak{g}^\beta\) by \(\beta(h_\alpha)\), and \(y_\alpha^n\) induces an isomorphism \(\mathfrak{g}^\beta \cong \mathfrak{g}^{\beta - n\alpha}\).

Finally, \(R\) is reduced by \((2.5.3.20)\).

**Prop. (2.5.3.22) [Splitting Cartan Subalgebras are Conjugate]**. The group of elementary automorphisms of \(\mathfrak{g}(2.5.1.7)\) acts transitively on the set of pairs \((\mathfrak{b},\mathfrak{h})\) consisting of a Borel subalgebra \((2.5.4.7)\) and a splitting Cartan subalgebra of \(\mathfrak{g}\).

**Prop. (2.5.3.23) [Jacobson-Morozov]**. Let \(\mathfrak{g}\) be a semisimple Lie algebra and \(e \in \mathfrak{g}\) nilpotent, then there exists a homomorphism \(\mathfrak{sl}_2 \rightarrow \mathfrak{g}\) mapping \(X\) to \(e\).

**Recovering Split Semisimple Lie Algebras from Dynkin Diagrams**

Main references are [Car05]Chap7.

**Def. (2.5.3.24) [Cartan Matrix]**. Let \((\mathfrak{g},\mathfrak{h})\) be a split semisimple Lie algebra with root system \(R\), with notations in \((2.5.3.20)\), define the Cartan matrix of \(\mathfrak{g}\) to be the Cartan matrix \(A\) of \(R\), \(A = (a_{ij})\), where \(a_{ij} = \alpha_j(h_\alpha)\), where \(\{\alpha_1, \ldots, \alpha_n\}\) is a base \(S\) of \(R\).

**Prop. (2.5.3.25) [Serre Relations]**. Let \((\mathfrak{g},\mathfrak{h})\) be a split semisimple Lie algebra with root system \(R\) and a base \(S\), and Cartan matrix \(A = (a_{ij})\). Denote \(\mathfrak{n}_\pm = \oplus_{\alpha \in R^\pm} \mathfrak{g}^\alpha\), then \(\mathfrak{g} = \mathfrak{n}_- \oplus \mathfrak{h} \oplus \mathfrak{n}_+\). Take \(e_i \in \mathfrak{g}^{\alpha_i}, f_i \in \mathfrak{g}^{-\alpha_i}\) s.t. \([e_i,f_i,h_i = [e_i,f_i]] = \mathfrak{s}_i\) is a \(\mathfrak{sl}_2\)-triple \((2.5.3.20)\). Then
• \(e_i, f_i, h_i\) generate \(\mathfrak{g}\).

• (Serre Relations):

\[
[h_i, h_j] = 0, \quad [h_i, e_j] = a_{ij}, \quad [h_i, f_j] = -a_{ij}f_j, \quad [e_i, f_j] = \delta_{ij}h_i,
\]

\[
(\text{ad}(e_i))^{1-a_{ij}}e_j = 0, \quad (\text{ad}(f_i))^{1-a_{ij}}f_j = 0, \quad i \neq j
\]

**Proof:**

1: Because \(\mathfrak{h}_i\) generate \(\mathfrak{h}\), it suffices to show \(e_i\) generate \(\mathfrak{n}_+\), then dually \(f_i\) generate \(\mathfrak{n}_-\). We prove any \(\mathfrak{g}^\alpha\) is in the span by induction on the height of \(\alpha\). If \(\alpha = \sum n_i\alpha_i\), where \(n_i > 0\), then \(0 < \langle \alpha, \alpha \rangle = \sum n_i\langle \alpha, \alpha_i \rangle\), thus \((\alpha, \alpha_i) > 0\) for some \(i\), thus by (2.7.2.21) \(\alpha - \alpha_i\) is a root, and the representation theory of \(\mathfrak{s}_i\) shows \(e_i\) induces an isomorphism \(\mathfrak{g}^{\alpha - \alpha_i} \cong \mathfrak{g}^\alpha\). So we are done.

2: Only the last two assertions need a proof. The irreducible \(\mathfrak{s}_i\) representation generated by \(e_j\) satisfies \([f_i, e_j] = 0, [h_i, e_j] = a_{ij}\), thus this submodule is isomorphic to \(W_{a_{ij}}\), and \((\text{ad}(e_i))^{1-a_{ij}}e_j = 0\). The \(f_i\) case is similar. \(\square\)

**Prop. (2.5.3.26) [Criterion of Semisimplicity].** Let \(\mathfrak{g}\) be a Lie algebra and \(\mathfrak{h}\) a commutative Lie subalgebra. If

- there is a decomposition

\[
\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha \in R} \mathfrak{g}^\alpha,
\]

where \(R \subseteq \mathfrak{h}^\vee\) is the finite set of \(\alpha \in \mathfrak{h}^\vee \setminus \{0\}\) that \(\mathfrak{g}^\alpha \neq 0\), and \(\dim \mathfrak{g}^\alpha = 1\) for all \(\alpha \in R\).

- \(R\) generates \(\mathfrak{h}^\vee\).

- If \(\alpha \in R\), then \(-\alpha \in R\), and \([\mathfrak{g}^\alpha, \mathfrak{g}^{-\alpha}], \mathfrak{g}^\alpha) \neq 0\).

Then \(\mathfrak{g}\) is semisimple and \(\mathfrak{h}\) is a split Cartan subalgebra of \(\mathfrak{g}\) with root system \(R\).

**Proof:** If \(I\) is a commutative ideal of \(\mathfrak{g}\), by action of \(\mathfrak{h}\), we can assume that \(\mathfrak{g}^\alpha \subseteq I\) for some \(\alpha\). If \(\alpha \neq 0\), then \(\mathfrak{g}^\alpha\) and \([\mathfrak{g}^{-\alpha}, \mathfrak{g}^\alpha] \subseteq I\), so \([\mathfrak{g}^\alpha, \mathfrak{g}^{-\alpha}, \mathfrak{g}^\alpha] = 0\), contradiction. If \(I \subseteq \mathfrak{h}\), then by the hypothesis some \(\alpha(I) \neq 0\), so \(\mathfrak{g}^\alpha = [I, \mathfrak{g}^\alpha] \subseteq \mathfrak{g}^\alpha\), contradiction. So \(I = 0\).

\(\mathfrak{h}\) consists of semisimple elements and it is its own centralizer, so it is a Cartan subalgebra by (2.5.3.16). It is clearly split. \(\square\)

**Cor. (2.5.3.27) [Criterion of Simplicity].** Let \((\mathfrak{g}, \mathfrak{h})\) be a split semisimple Lie algebra. A decomposition \(\mathfrak{g} = \mathfrak{g}_1 \oplus \mathfrak{g}_2\) of Lie algebras defines a decomposition \((\mathfrak{g}, \mathfrak{h}) = (\mathfrak{g}_1, \mathfrak{h}_1) \oplus (\mathfrak{g}_2, \mathfrak{h}_2)\), and hence a decomposition of the root system \(R(\mathfrak{g}, \mathfrak{h})\).

In particular, if the root system \(R(\mathfrak{g}, \mathfrak{h})\) is indecomposable, then \(\mathfrak{g}\) is simple.

**Proof:** Let

\[
\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha \in R} \mathfrak{g}^\alpha, \quad \mathfrak{g}_1 = \mathfrak{h}_1 \oplus \bigoplus_{\alpha \in R_1} \mathfrak{g}_1^\alpha, \quad \mathfrak{g}_2 = \mathfrak{h}_2 \oplus \bigoplus_{\alpha \in R_2} \mathfrak{g}_2^\alpha
\]

be the eigenvalue decomposition of \(\mathfrak{g}, \mathfrak{g}_1, \mathfrak{g}_2\) w.r.t. the adjoint action of \(\mathfrak{h}\), then \(\mathfrak{h} = \mathfrak{h}_1 \oplus \mathfrak{h}_2\), and \(R = R_1 \sqcup R_2\). \(\square\)

**Prop. (2.5.3.28) [Serre Presentations].** Let \(\mathfrak{g}(R)\) be the Lie algebra generated by \(e_i, f_i, h_i\) with defining relations as in (2.5.3.25), then

- The Lie subalgebra \(\mathfrak{n}_+\) generated by \(e_i\) has \((\text{ad}(e_i))^{1-a_{ij}}(e_j) = 0\) as defining relations. The Lie subalgebra \(\mathfrak{n}_-\) generated by \(f_i\) has \((\text{ad}(f_i))^{1-a_{ij}}(f_j) = 0\) as defining relations. And \(h_i\) are linearly independent.
We prove by induction on the height of the $s = \alpha \in Q$ statement is clear as $\alpha$ is of f.d.

Thus we have a decomposition
\[
\tilde{g}(R) = \tilde{n}_+ \oplus \tilde{h} \oplus \tilde{n}_-
\]
by degree, and clearly $\tilde{n}_+$ is generated by $e_i$, $\tilde{h}$ is generated by $h_i$ and $\tilde{n}_-$ is generated by $f_i$.

Now I claim that $\tilde{n}_+$ is a free Lie algebra on generators $e_i$, $\tilde{n}_-$ is a free Lie algebra on generators $f_i$ and $h_i$ are linearly independent. It suffices to prove for $e_i$, and $f_i$ is true with the dual polarization. For this, let $b'$ be a vector space with basis $h'_i$, and consider the Lie algebra $\alpha = FL_r \times b'$, where $FL_r$ is the free Lie algebra generated by $f'_i$, and $b'$ acts on $FL_r$ by $[h'_i, f'_j] = -a_{ij} f'_j$, then $U = U(\alpha) = k(f'_1, \ldots, f'_n) \times k[h'_1, \ldots, h'_n]$, and there is an action of $\tilde{g}(R)$ on $U$ that is defined on the generators as follows: if $w = f'_{j_1} \ldots f'_{j_k}$ is a word in $f'_i$ of weight $\alpha$ and $P \in k[h'_1, \ldots, h'_n]$, then
\[
h_i(w \otimes P) = w \otimes (h'_i - \alpha(h_i))P
\]
\[
f_i(w \otimes P) = fw \otimes P
\]
\[
e_i(f'_{j_1} \ldots f'_{j_k} \otimes P) = \sum_{k|j_k = i} f'_{j_1} \ldots f'_{j_{k-1}} f'_{j_k} (h'_i - (\alpha_{j_{k+1}} + \ldots + \alpha_{j_n})(h'_i))P.
\]

It can be shown that this is truly a representation, and then it induces a map $\tilde{g}(R) \to U : x \mapsto x(1)$, and this maps Lie polynomials of $f$ in $\tilde{n}_+$ to Lie polynomials of $f'_i$, and $h$ to $h'_i$, so the assertions are true.

1: Now consider the elements $S^+_{ij} = (ad e_i)^1 - a_{ij} e_j \in \tilde{n}_+$ and $S^-_{ij} = (ad f_i)^1 - a_{ij} f_j \in \tilde{n}_-$. Then $[f_k, S^+_{ij}] = 0$: If $k \neq i, j$, then this is true, and if $k = j$, then $[f_j[e_i e_j]] = [e_i f_j e_j] = [h_j e_i] = a_{ji} e_i$, thus $[f_j (ad e_i)^r(e_j)] = 0$ for $r \geq 2$. If $a_{ij} \geq -1$, then this is true, and if $a_{ij} = 0$, then $a_{ji} = 0$ too, so the assertion is also true. If $k = i$, then we can prove by induction that $[f_i (ad e_i)^r(e_j)] = -r(a_{ij} + r - 1)(ad e_i)^{-1}(e_j)$. Thus $[f_i (ad e_i)^1 - a_{ij} (e_j)] = 0$, too.

So by induction we see that the ideals $I^+ \in \tilde{n}_+$ generated by such $S^+_{ij}$ is ideals $I^+ = I^+ \oplus I^-$, which implies the assertion.

2: The Serre relations shows that $e_j$ generates the representation $W_{-a_{ij}}$ of $s_i$ for $j \geq i$, and so does $f_j$. Also $e_i, f_i, h_i$ generate $W_2$, and $h_j$ generates $W_0$ or $W_0 \oplus W_2$, so $g(R)$ is a sum of f.d. modules over $s_1$, as the module generated by $\{a, b\}$ is a subquotient of $V \oplus W$ the modules generated by $\{a\}$ and $\{b\}$.

3: $g(R) = \oplus_{\alpha \in Q} g_{\alpha}$, where $g_{\alpha}$ is the subspace of $g(R)$ of weight $\alpha$. Then $g_{\alpha} \neq 0$ only if $\alpha \in Q_+$ or $Q_-$, and each $g_{\alpha}$ is of f.d.. Now we show that $g_R \neq 0$ only if $\alpha \in R \cup \{0\}$, which will suffice. We prove by induction on the height of $\alpha$: the height 1 case is trivial, and if $\alpha = ke_i$, then the statement is clear as $g^{ke_i} = 0$ for $k \geq 2$, because $n_\alpha$ is generated by $e_i$. If it is not of the form $\alpha = ke_i$, $\langle \alpha, \alpha \rangle > 0$ for some $i$, so by the representation theory of $s_1 \cong sl_2$, $g^{k_{\alpha}} \neq 0$, where $s_{\alpha} = \alpha - \alpha_i \alpha_i / 2 \not\in Q_-$, thus $s_{\alpha} \in Q_+$, and then by induction hypothesis $s_{\alpha} \in R$, so $\alpha \in R$. 

\[2.5. \text{LIE ALGEBRAS}\]
4: \( \widehat{g}(R)^\alpha \) is 1-dimensional for any \( \alpha \), so this is also true for \( g(R)^\alpha \). Then \( g(R) \) is semisimple with root system \( R \) by (2.5.3.26).

\[ \square \]

Cor. (2.5.3.29) [Classification of Split Simple Lie Algebras]. By 2, split simple Lie algebras over \( k \) are in bijection with Dynkin diagrams \( A_l, l \geq 1, B_l, l \geq 2, C_l, l \geq 3, D_l, l \geq 4 \) and \( E_6, E_7, E_8, F_4, G_2 \), by (2.7.3.5).

Notations for Split Semisimple Lie algebras

Def. (2.5.3.30) [Notations for a Split Semisimple Lie Algebra]. Let \( (g, h) \) be a split semisimple Lie algebra, then

- Its (positive/negative) root system is denoted by \((R^+/R^-)R\).
- Notation for root system is the same as in (2.7.4.1).
- \( g \) has a weight decomposition \( g = h \oplus_{\alpha \in R} g^\alpha \).
- \( x_\alpha \in g^\alpha, y_\alpha \in g^{-\alpha} \), where \( \alpha \in R^+ \).
- \( \mathfrak{s}_i = \{x_i, y_i, h_i\} \) is a \( \mathfrak{sl}_2 \)-triple, where \( x_i \in g^{\alpha_i}, y_i \in g^{-\alpha_i} \) (2.5.3.20).
- \( \alpha_i^\vee = h_i(2.5.3.21) \).

4 Reductive Lie Algebra

Def. (2.5.4.1) [Reductive Lie Algebra]. A Lie algebra is called reductive if \( \text{rad}(L) = Z(L) \), or equivalently \( Z(L) \subset \text{rad}(L) \).

Prop. (2.5.4.2). The following conditions on a Lie algebra \( g \) are equivalent:

- \( g \) is reductive.
- The adjoint representation of \( g \) is semisimple.
- \( g \) is a product of a commutative Lie algebra \( c \) and a semisimple Lie algebra \( b \).

Proof: 1 \( \rightarrow \) 2: The adjoint representation factors through the center of \( g \), which is also the radical of \( g \), so it is a representation of \( g/\text{rad}(g) \), which is semisimple (2.5.1.23), so Weyl’s theorem (15.15.1.2) shows the adjoint representation is semisimple.

2 \( \rightarrow \) 3: If the adjoint representation is semisimple, then \( g \) decomposes as a sum of minimal nonzero ideals \( a_i \) of \( g \), and then \( g \) is a product of these \( a_i \). Let \( c \) be the product of the one-dimensional ideals, then \( c \) is in the center thus commutative, and \( b \) the product of the remaining ideals, then \( b \) is semisimple because it has no solvable ideals.

3 \( \rightarrow \) 1 is trivial. \( \square \)

Cor. (2.5.4.3). The decomposition of \( g \) into a product of commutative Lie algebra and a semisimple Lie algebra is unique: in fact \( c \) is the center of \( g \), and \( b = [g, g] \), by (2.5.2.4).

Prop. (2.5.4.4). A Lie algebra \( g \) is reductive iff it has a faithful semisimple representation iff it has a trivial nilpotent radical (2.5.1.34).

Proof: If \( g \) has a faithful semisimple representation, then the nilpotent radical \( s = 0 \), thus by (2.5.1.36), \( r \) is in the center of \( g \), thus \( g \) is reductive.
Conversely, if \( g \) is reductive, then we need to show \( g \) has a faithful semisimple representation: For this, we can take the tensor product of the trivial representation of the commutative part and the adjoint representation of the semisimple part (2.5.2.3).

The last assertion is clear from (2.5.1.36).

\[ \text{Cor. (2.5.4.5) [Trace Form Criterion for Reductiveness]. If the trace form } B_{\rho}(2.5.9.5) \text{ is non-degenerate for some representation } (\rho, V) \text{ of } g, \text{ then } g \text{ is reductive.} \]

\[ \text{Proof: If } x \in \mathfrak{s}, \text{ then } \rho(x) = 0, \text{ thus } B_{\rho}(x, y) = 0 \text{ for any } y, \text{ thus } x = 0. \text{ So } \mathfrak{s} = 0, \text{ and } g \text{ is reductive.} \]

\[ \text{Cor. (2.5.4.6) [Classical Lie Algebras are Reductive]. All classical Lie groups over } \mathbb{R} \text{ or } \mathbb{C} \text{ are reductive.} \]

\[ \text{Proof: Apply (2.5.4.5) their standard representations.} \]

\[ \text{Def. (2.5.4.7) [Borel Subalgebras]. Let } g \text{ be a split reductive Lie algebra and } \mathfrak{h} \text{ a Cartan subalgebra with a system of positive roots } \Pi, \text{ and consider the corresponding triangular decomposition } g = n_- \oplus \mathfrak{h} \oplus n_+(2.5.3.21). \text{ Denote } b_+ = \mathfrak{h} \oplus n_+, \text{ and call any Lie subalgebra of } g \text{ conjugate to } b_+ \text{ a borel subalgebra of } g. \text{ The definition is independent of the choice of the Cartan subalgebra } \mathfrak{h}, \text{ by (2.5.3.22).} \]

5 Compact Lie Algebras

Main references are [李群讲义, 项武义] and [Kna96].

\[ \text{Def. (2.5.5.1) [Compact Lie Algebras]. A compact Lie algebra is Lie algebra that is the Lie algebra of a compact Lie group.} \]

\[ \text{Prop. (2.5.5.2) [Killing Form of Compact Lie Algebra]. The Killing form of a compact Lie algebra } g \text{ is negatively semi-definite, with the kernel the center of } g. \]

\[ \text{Proof: Choose an invariant inner product on } g \text{ w.r.t. the adjoint representation of } G \text{ by (10.9.4.1). Take derivative w.r.t the equation } (\text{Ad}(g)Y, \text{Ad}(g)Z) = (Y, Z), \text{ we get by (11.6.1.12),} \]

\[ (\text{ad}(X)Y, Z) + (Y, \text{ad}(X)Z) = 0. \]

so \( \text{ad}(X) \) is skew-symmetric w.r.t. this inner product, thus the eigenvalues are all purely imaginary. Then \( B(x, x) = \text{tr}(\text{ad}(x) \text{ ad}(x)) \leq 0. \)

\[ \text{Cor. (2.5.5.3) [Compact Lie Algebra is Reductive]. A compact Lie algebra } g \text{ is reductive.} \]

\[ \text{Proof: Because of the invariant inner form, any ideal } \mathfrak{a} \text{ of } g \text{ has a complement } \mathfrak{a}^\perp, \text{ thus the adjoint representation of } g \text{ is semisimple, thus } g \text{ is reductive (2.5.4.2).} \]

\[ \text{Cor. (2.5.5.4) [Compact Lie algebra Elements Semisimple]. For a compact Lie algebra } g, \text{ every element is semisimple, and the eigenvalues of any adjoint operator } \text{ad}(x) \text{ is purely imaginary.} \]

\[ \text{Proof: Because the Killing form is negative definite, thus its negation is an inner product on } g, \text{ and } \text{ad}(x) \text{ acts by skew-Hermitian matrices, thus has purely imaginary eigenvalues.} \]

\[ \text{Prop. (2.5.5.5). If } g \text{ is reductive and the Killing form is negative definite on } [g, g], \text{ then } g \text{ is compact.} \]
Proof: For the commutative part we can take the torus \((S^1)^n\), so it suffices to prove the semisimple case: for this, we consider \(\text{Int}(g)^0 \subset GL(g)\), it is contained in \(O(g)\) with the inner product defined by the negation of the Killing form, thus it is compact. And the Lie algebra of it is \(\text{Der}(g) = \text{ad}(g)(2.5.2.7)\).

\[\square\]

Prop.(2.5.5.6)[Representation of Compact Lie Algebras]. Let \(g\) be a compact Lie algebra that is the Lie algebra of a simply-connected compact Lie group, then \(\text{Rep}(g)\) is semisimple.

Proof: \[\square\]

6 Singular element

Introduction

Singular element in \(g\) is a linear space and is defined by some homogenous ideal in \(S(g)\).

The paper [Singular element] of Kostant tells in fact it is defined by some \(r\)-homogenous functions \(M_r\) in \(S(g)\), and further describes the properties of this ideal such as the \(G\)-module decomposition and as span of determinant minors.

Preliminary

Let complex simple Lie algebra \(g = \text{Lie} G, n = l + 2r\). The non-degenerate Killing form \(B \triangleq (x, y)\) on \(g\) generate a nonsingular pair on \(S(g)\) and \(\land(g)\) by

\[
(x_1 \cdots x_k, y_1 \cdots y_k) = \sum_{\sigma \in \Sigma_k} (x_1, y_{\sigma(1)}) \cdots (x_k, y_{\sigma(k)})
\]

\[
(x_1 \land \cdots \land x_k, y_1 \land \cdots \land y_k) = \sum_{\sigma \in \Sigma_k} sg(\sigma)(x_1, y_{\sigma(1)}) \cdots (x_k, y_{\sigma(k)})
\]

So \(g \leftrightarrow g', S(g) \leftrightarrow S(g') \leftrightarrow\) polynomial functions on \(g\); and \(S(g)\) and \(\land(g)\) are \(g\) thus \(G\) modules extending the adjoint representation.

Recall that \(\delta\) and \(\partial\) are called \(B\)-dual if \((\delta x, y) = (x, \partial y)\). Set antiderivation \(-d\ \mathcal{B}\)-dual to the operator

\[
\partial(x_1 \land \cdots \land x_p) = \sum_{i<j} (-1)^{i+j+1}[x_i, x_j] \land x_1 \land \cdots \hat{x}_i \land \cdots \hat{x}_j \land \cdots \land x_p
\]

on \(\land(g)\) and antiderivation \(\epsilon(u)\ \mathcal{B}\)-dual to the operator \(\epsilon(u)v = u \land v\) on \(\land(g)\).

Element \(v\) of \(S(g)\) are called invariant iff \(gv = v, \forall g \in G\) and element \(u\) of \(S(g)\) are called harmonic iff \((u, v) = 0, \forall v\) invariant and no constant term.

Denote by \(J, H\) respectively the graded subspace of invariant and harmonic elements, then:

Prop.(2.5.6.1)[Separation of Variables (in [Kos63])]. \(S(g) \cong J \otimes H\).

the Ideal of Sing \(g\)

In the projection \(\tau : T(g) \rightarrow U(g)\), PBW theorem asserts that \(S(g) \rightarrow U(g)\) is an isomorphism. Denote:

\[
\Gamma = \tau|_{S(g)} \circ \tau
\]

\(\Gamma\) is a \(G\)-map (as a consequence of the next prop).
Denote by $\Gamma_{2r,2}$ the subgroup of permutation that preserves the set of unordered pairs \{(1, 2), (3, 4), \ldots, (2r-1, 2r)\} and let $\Pi_r$ be a left coset representative of $\Gamma_{2r,2}$ in $\Gamma_{2r}$ that $sg(\Pi_r) = 1$

In [Amitsur-Levitski], Kostant proved:

**Prop. (2.5.6.2)** [in *Kos81*].

\[
\Gamma(\wedge^2(\mathfrak{g})) = R^k \in S^k(\mathfrak{g})
\]

\[
\Gamma(x_1 \wedge \cdots \wedge x_k) \mapsto \sum_{v \in \Pi_k} [x_v(1), x_v(2)] \cdots [x_v(2k-1), x_v(2k)]
\]

**Prop. (2.5.6.3)** [in *Kos81*].

\[
M = R^r \in H^r
\]

so it consists of harmonic functions.

Let $w \in \wedge^2 \mathfrak{g}$ of rank $k$ standardized as $v_1 \wedge v_2 + \cdots + v_{2k-1} \wedge v_{2k}$. Let

\[
\text{Rad}w = \{y \in \mathfrak{g}|\iota(y)w = 0\} = \{y \in \mathfrak{g}|(w, \epsilon(y)z) = 0, \forall z\}
\]

then $w$ of rank $2k \iff w^k \neq 0 \& w^{k+1} = 0 \iff \dim \text{Rad}w = n - 2k$.

**Lemma (2.5.6.4).**

\[
\iota(y)dx = [y, x]
\]

Thus

\[
\text{Rad}dx = \mathfrak{g}^x, \text{ Sing}\mathfrak{g} = \{x \in \mathfrak{g}|(dx)^r = 0\}.
\]

**Proof:** $(\iota(y)dx, z) = (dx, y \wedge z) = (x, -[y, z]) = ([y, x], z)$

So in order to find the module $M$, it's the best to find the dual of

\[
\gamma : S(\mathfrak{g}) \rightarrow \wedge^{\text{even}} \mathfrak{g} : x \rightarrow -dx
\]

Luckily:

**Prop. (2.5.6.5)** [in *Kos81*]. $\gamma$ is $B$ dual to $\Gamma$, in particular,

\[
(\Gamma(\zeta), x) = \left(\frac{-1}{r!}\right)(\zeta, (dx)^r) \ (\forall \zeta \in \wedge^2 \mathfrak{g} \text{ and } x \in \mathfrak{g})
\]

So: $f(x) = 0, \forall f \in M \iff x \in \text{Sing}\mathfrak{g}$.

**Cor. (2.5.6.6).** Let $\alpha$ be a CSA of $\mathfrak{g}, \Delta_+(\alpha)$ be the positive roots, then

\[
f|\alpha = C_f \cdot \prod_{\beta \in \Delta_+(\alpha)} \beta \quad (\forall f \in M)
\]

**Proof:** This is because that an element in a CSA is singular iff it commutes with an element outside this CSA, and taking root decomposition, this is equivalent to annihilated by a root, and by counting degree, the cor follows. □

By propositions of [[[Kos59]]] a regular nilpotent element $e$ is uniquely in a nilpotent radical $n$ of a Borel subalgebra and that $\mathfrak{g}^e \cap [n, n] = (\text{Sing}\mathfrak{g}) \cap \mathfrak{g}^e$. So there is a linear function $\xi$ on $\mathfrak{g}^e$ that $\ker \xi = (\text{Sing}\mathfrak{g}) \cap \mathfrak{g}^e$. Thus:
Cor. (2.5.6.7). \( f|g^e = C_f \cdot \xi^r \quad (\forall f \in M) \).

Proof: By counting degree, the same reason as before.
Now we think of a natural question: Can singular elements be defined by functions of even lower degree? The answer is NO.

Prop. (2.5.6.8). Assume \( 0 \neq f \) homogenous vanishes on \( \text{Sing}_g \), then deg \( f \geq r \)

Proof: By the last cor, if \( f \) has degre less than \( r \) then \( f \) vanish on any CSA, but semisimple regular element, thus CSAs are Zariski dense in \( g \) (this is because semisimple element are defined by a polynomial), so \( f = 0 \).

Thus we have established that \( \text{Sing}_g \) is an algebraic set defined by a set of harmonic \( r \)-homogenous functions on \( g \) and not by functions of degree lower than \( r \).

Next we offer a different formation of \( M \).

\[ M \text{ as minors of determinants} \]

For a \( B \) dual basis \( y_i, w_j \), define a derivation

\[ d_W(f \otimes u) = \sum^n_i \partial_{y_i} f \otimes \epsilon(w_i)u \quad \text{on} \quad S(g) \otimes \wedge g. \]

Here \( \partial_{x_i} \) is defined as \( \sum a_i \frac{\partial}{\partial x_i} \) for a standard basis \( x_i \) of \( g \). It’s easy to verify that \( d_W \) is well defined and is a \( G \)-map (Take a different basis \( Aw_i \) and \( Bz_i \), then \( AB^t = I \), substitute into the formula of \( d_W \), it doesn’t change).

**Chevalley Thm** tells us \( J \) is a polynomial ring \( \mathbb{C}[p_1, \ldots, p_l] \), where \( p_i \) are homogenous polynomials of fixed degree \( d_i \) and \( \sum^l_i (d_j - 1) = r \). So:

\[ d_W p_1(x) \wedge \ldots \wedge d_W p_l(x) = \sum_{1 \leq i_1 < \ldots < i_n \leq n} \phi(y_{i_1}, \ldots, y_{i_n}) w_{i_1} \wedge \ldots \wedge w_{i_n} \]

Where \( \phi(y_{i_1}, \ldots, y_{i_n}) = \det \partial_{y_i} p_j \) is homogenous of degree \( r \). (counting degree).

To see this, notice that \( f \otimes u \) acts as a function from \( g \) to \( \wedge g : f \otimes u(x) = f(x)u \). So:

\[ d_W p_j(x) = \sum^n_{i=1} \partial_{z_i} p_j(x) w_i. \]

Prop. (2.5.6.9). For any CSA \( \mathfrak{h} \) of \( g \) and a basis \( \{v_i\} \) of \( \mathfrak{h}, \forall x \in \mathfrak{h}, \)

\[ d_W p_1(x) \wedge \ldots \wedge d_W p_l(x) = \kappa \cdot \prod_{\phi \in \Delta^+} \phi(y)v_1 \wedge \ldots \wedge v_l \]

Lemma (2.5.6.10) [in [Kos63]], \( \{d_W p_1(x), \ldots, d_W p_l(x)\} \) is linearly independant iff \( x \in \text{Reg}_g \).

Proof: Notice that \( d_W p_j \) is a \( g \)-map, \( d_W p_j = d_W p_j([y, x]) \) so \( d_W p_j(x) \) commutes with \( g^x \); so
\( \in g^x \). Then the \( \text{lm} \) tells us when \( y \) is regular, \( d_W p_j(y) \) forms a basis of \( g^y \). Considering in \( g^y \), \( x \) is regular iff \( \prod_{\phi \in \Delta^+} \phi(x) \neq 0 \), the prop follows.

Next we give an explicit expression for \( \gamma \).

It can be verified (taking a \( z_i \) basis) that \( dx = \frac{1}{2} \sum^n_{i=1} w_i \wedge [z_i, x] \).
2.5. LIE ALGEBRAS

Now \( x \in \mathfrak{h} \),

\[
dx = \sum_{\phi \in \Delta^+} \phi(x) e_\phi \wedge f_{-\phi}
\]

(just take the basis \( w_i \) and \( z_i \) as a standard basis of \( \mathfrak{g} \) consisting of \( \{h_i, \ldots, h_l, e_\phi, f_\phi\} \))

So

\[
\gamma_r(x^r) = r!(\lambda - 1)^r \prod_{\phi \in \Delta^+} \phi(x) e_\phi \wedge f_{-\phi}
\]

Let \( \mu = i^r v_1 \wedge \cdots \wedge v_l \wedge \prod_{\phi \in \Delta^+} e_\phi \wedge f_{-\phi} \) then \( (\mu, \mu) = 1 \).

Denote \( v^* = \iota(v) \mu \) for \( v \in \wedge \mathfrak{g} \), then

\[
(v_1 \wedge \cdots \wedge v_l)^* = i^r \prod_{\phi \in \Delta^+} e_\phi \wedge f_{-\phi} = \kappa \gamma_r(x^r)
\]

(notice that \( \iota(u) \iota(v) = \iota(v \wedge u) \) and use \( \text{ln } 1 \))

Prop.(2.5.6.11). \( (dW p_1(x) \wedge \cdots \wedge dW p_l(x))^* = \kappa \gamma_r(x^r) \neq 0 \).

Proof: For \( y \in \mathfrak{h} \) regular, this follows from previous calculations, and notice both side are \( G \)-maps, and semisimple regular elements are Zariski open, conclusion follows. \( \square \)

Lemma(2.5.6.12). \( (s, t) = (s^*, t^*) \), so that \( -^* \) is a \( \mathcal{B} \)-isomorphism.

Prop.(2.5.6.13). Let \( \{w_1, \ldots, w_{2r}\} \) be linearly independent and \( \{u_1, \ldots, u_l\} \) be a basis of \( \{w_1, \ldots, w_{2r}\}^\perp \), then

\[
\Gamma(w_1 \wedge \cdots \wedge w_{2r}) = \kappa_1 \det \partial_{u_j} p_j \neq 0
\]

Thus, \( M \) is the span of all the minors \( \det \partial_{u_j} p_j \).

Proof: By the preceding props,

\[
\det \partial_{u_j} p_j = \phi(u_1, \ldots, u_l)(x) = (dW p_1(x) \wedge \cdots \wedge dW p_l(x), u_1 \wedge \cdots \wedge u_l) = ((dW p_1(x) \wedge \cdots \wedge dW p_l(x))^*, (u_1 \wedge \cdots \wedge u_l)^*) = \kappa \kappa_2(\phi_r(x^r), w_1 \wedge \cdots \wedge w_{2r}) = \kappa^{-1} \Gamma(w_1 \wedge \cdots \wedge w_{2r})(x).
\]

\( \square \)

\( G \)-module structure of \( M \)

Now we show the \( G \)-module structure of \( M \).

Let \( \theta \) be the derivative that \( \theta(x)(y) = [x, y] \) on \( \mathfrak{g} \). \( \text{Cas} = \sum_{i=1}^n \theta(z_i) \theta(w_i) \).

It’s in fact just the action of the Casimir element in center of \( U(\mathfrak{g}) \). Let \( m_l \) and \( M_l \) be the maximal eigenvalue and eigenspace of \( \text{Cas} \).

For a commutative Lie subalgebra \( c \) of rank \( l \), denote by \( [c] \) the line it defines on \( \wedge^l \mathfrak{g} \). The span of these \( [c] \) is denoted \( A_l \). Notice that \( \mathfrak{g}^y \subset A_l \) for a regular \( y \), and \( A_l \) is a \( G \)-submodule.
Prop. (2.5.6.14)[in [Kos65]].
\[ A_I = M_l; \quad m_I = l. \]

An ideal in a Borel subalgebra of \( \mathfrak{g} \) is necessarily spanned by root vectors and a prop of [[K-W09]] says any ideal of \( \dim I \) is (denoted by \( I \)) in fact abelian.

A prop in [[Kos65]] asserts that for two different ideals \( \Phi_1, \Phi_2 \), sum of their weight vectors \( \langle \Phi \rangle \) is distinct.

So \( G[\Phi_i] \) is an irreducible \( G \)-module \( V_\Phi \) with highest weight \( \langle \Phi \rangle \) and \( V_\Phi \) are inequivalent \( G \)-modules (because an irreducible representation have only one highest vector).

Prop. (2.5.6.15)[in [Kos65]].
\[ M_I = \bigoplus_{\Phi \in I} V_\Phi \bigoplus V_\Phi. \]

Now denote \( M_{2r} \) image of \( M_l \) under the isomorphism \( u \rightarrow u^* \), then

Prop. (2.5.6.16)[in [K-W09]]. \( M_I \) is the span of \( G \cdot [\mathfrak{g}^x] \) for \( x \) regular.

but by precious prop,
\[ [\mathfrak{g}^x] = \mathbb{C} W p_1(x) \wedge \ldots \wedge p_l(x). \]

thus \( M_{2r} \) is the span of \( G \cdot (\gamma_r(\frac{x^t}{1!})), x \) regular.

Prop. (2.5.6.17) [Final]. \( \Gamma|_{M_{2r}} : M_{2r} \rightarrow M \) is an isomorphism and \( M \cong M_{2r} \cong M_I = A_I \) as \( G \)-module.

So \( M \) is a multiplicity one module with \( |I| \) irreducible components.

Proof: Notice that \( \Gamma(\zeta)(x) = (\zeta, \gamma_r(\frac{x^t}{1!})) \) and \( M_{2r} \) is the span of \( G \cdot (\gamma_r(\frac{x^t}{1!})) \), the first part follows, and the rest is a recapitulation of previous props. \( \square \)

7 Real Lie Algebra

Prop. (2.5.7.1)[Passage from Real to Complex]. If \( g_\mathbb{R} \) is a Lie algebra over \( \mathbb{R} \) and \( \mathfrak{g} = g_\mathbb{R} \otimes \mathbb{C} \) its complexification, then \( g_\mathbb{R} \) is Abelian/nilpotent/solvable/semisimple iff \( \mathfrak{g} \) does.

Def. (2.5.7.2). A compact real form is a real subalgebra \( \mathfrak{l} \) of \( \mathfrak{g} \) s.t. \( \mathfrak{g} \) is the complexification of \( \mathfrak{l} \) and \( \mathfrak{l} \) is the lie algebra of a compact simply-connected Lie group.

Prop. (2.5.7.3). A real Lie algebra is compact iff there exists an invariant inner product iff the Killing form is negative definite.

Proof: One direction is easy, just use the average method to find a \( G \)-invariant inner product and then take derivative. For the other direction, the identity shows that a complement of an ideal is an ideal so \( \mathfrak{g} \) is decomposed into simple lie groups and reduce to the case that \( \mathfrak{g} \) is simple. The ideal is to show that \( \mathfrak{g} \cong \ad(\mathfrak{g}) \) is the whole outer derivative group \( \partial(\mathfrak{g}) \)(the following lm). So \( \mathfrak{g} \) equals to the identity component of \( \text{Aut}(\mathfrak{g}) \) which is a closed subgroup thus closed but it is also a subgroup of the compact group \( O(\mathfrak{g}) \) thus it is compact. \( \square \)

Lemma (2.5.7.4). If a real semisimple Lie algebra \( X \) has an invariant inner product, then every outer derivative is inner. (In fact, this is true by Cartan Criterion for semisimplicity (2.5.2.7)).
Proof: since \( \text{ad}(X) \) is skew-symmetric, it’s diagonalizable and its eigenvalue is pure imaginary, so the Killing form of \( X \) is negative definite. Now choose the complement \( \mathfrak{a} \) of \( \text{ad}(X) \) in \( \partial(X) \), then \( \mathfrak{a} \cap X = 0 \). Thus for \( D \in \mathfrak{a} \), \( \text{ad}(D(g)) = [D, \text{ad}(g)] = 0 \) for all \( g \) in \( X \), so \( D = 0 \), thus \( \text{ad}(X) = \partial(X) \). □

Prop. (2.5.7.5).

1. The complexification of the Lie algebra of a connected compact Lie group is reductive.

2. A complex Lie algebra is semisimple iff it is isomorphic to the complexification of the Lie algebra of a simply-connected compact Lie group. i.e. every complex semisimple Lie algebra has a compact real form.

Proof: 1: Because a connected compact Lie group is completely reducible so does the Lie algebra and so does the complexification. So it is reductive by (2.5.4.1). 2: Cf.[Varadarajan Lie Groups Lie algebras and Their Representations]. The idea is to find a real form whose corresponding simply-connected group is compact. □

Prop. (2.5.7.6). If \( \mathfrak{g} \) is the Lie algebra of a matrix Lie group \( G \), then:

1. every Cartan subalgebra comes from a maximal commutative subalgebra of a compact real form and any two Cartan subalgebras are conjugate under the Ad-action of \( G \).

2. any two compact real form is conjugate under the Ad-action of \( G \).

3. any two maximal commutative subalgebra of a compact real form is conjugate under the Ad-action of the corresponding compact compact subgroup.

Prop. (2.5.7.7). A real Lie algebra is semisimple iff its complexification is semisimple. Cf.[Varadarajan].

Cor. (2.5.7.8). The real Lie algebra of a compact simply-connected group is semisimple.

Note: For the classification of real semisimple Lie algebras, Cf.[李群讲义项武义 §6]

Prop. (2.5.7.9). If a complex representation of a Lie group admits an invariant bilinear form, then it is non-degenerate and unique. In fact, this is equivalent to a \( G \)-map from \( V \) to \( V^* \). Thus there is unique invariant inner product in a compact real form by the preceding proposition.

8 Universal Constructions

In this subsection \( k \) can be a field of any characteristics.

Def. (2.5.8.1) [Universal Enveloping Algebra]. The universal enveloping algebra of a Lie algebra \( \mathfrak{g} \) is defined to be

\[
U(\mathfrak{g}) = T(\mathfrak{g})/J, \quad T(\mathfrak{g}) = \bigoplus_{n=0}^{\infty} \mathfrak{g}^\otimes n
\]

which is a graded algebra \( T(\mathfrak{g}) \) quotienting the ideal \( J = \langle x \otimes y - y \otimes x - [xy] \rangle \).

There is a natural linear map \( \sigma : \mathfrak{g} \to U(\mathfrak{g}) \).

Prop. (2.5.8.2). The universal enveloping algebra \( U : \mathfrak{g} \mapsto U(\mathfrak{g}) \) defines a functor \( \text{LieAlg} \to \text{Alg}^{asso} \) that is left adjoint to the canonical functor \( \text{Alg}^{asso}_k \to \text{LieAlg}_k(2.5.1.2) \).
Proof: For any associative algebra $A$ and a morphism of Lie algebras $q \to [A]$, there is easily seen a morphism $U(q) \to A$, and it is unique. 

Cor. (2.5.8.3) [Representation as Modules]. A representation of $g(2.5.12.4)$ is the same as a representation of $U(q)$.

Prop. (2.5.8.4) [Poincaré-Birkhoff-Witt]. Let $q$ be a Lie algebra, define a filtration on $U(q)$ by assigning $F_n U(q) = \text{the image of } \bigoplus_{i=0}^{k} q^{\otimes i}$ in $U(q)$. We have $[F_1 U(q), F_2 U(q)] \subset F_{i+j-1} U(q)$, thus $g r U(q)$ has a graded commutative ring structure. Thus there is an algebra homomorphism $S(q) \to g r U(q)$, and this homomorphism is an isomorphism.

If $q$ has a basis $\{x_i\}, i \in I$, and is an order on $I$, then $U(q)$ has a basis consisting of elements $\{x_{i_1}^{r_1} \cdots x_{i_k}^{r_k}\}$ where $i_1 < i_2 < \ldots < i_r$.

Proof: We assign any monomial $a_{i_1} \ldots a_{i_n}$ in $g_s$ a pair $(k, N)$ where $k$ is the number of factors in a monomial and $N$ is the number of inversions (meaning the number of pairs $1 \leq r, s \leq n$ that $i_r > i_s$), pairs $(k, N)$ are lexicographical ordered. Let $T^{(k,N)}$ be the space of $T(q)$ generated by monomials of index $(k, N)$, $T^k = \bigcup_{N=1}^{\infty} T^{(k,N)}$, and $U^{(k,N)}$, $U^k$ the space of $T(q)$ the image of $T^{(k,N)}, T^k$ in $U(q)$. We will use induction on $(k, N)$. Notice for any $k$, $T^k = T^{(k,N)}$ for $N$ large.

To show that the monomials in $(*)$ generates $U(q)$, if we have a monomial $a_{i_1} a_{i_2} \ldots a_{i_n}, a_{i_{s+1}} \ldots a_{i_k}$ that $i_s > i_{s+1}$, then

$$a_{i_1} a_{i_2} \ldots a_{i_s} a_{i_{s+1}} \ldots a_{i_k} = a_{i_1} a_{i_2} \ldots (a_{i_{s+1}} a_{i_s}) + [a_{i_s}, a_{i_{s+1}}] \ldots a_{i_k},$$

which is in $\bigcup_{N=1}^{\infty} U^{(k',N')}$ for simplicity.

To show that the monomials are linearly independent, we first show that there is a linear map

$$\theta: T(q) \to R = C[z_i]_{i \in I}$$

satisfying the following conditions:

$$\theta(a_{i_1} \ldots a_{i_n}) = z_{i_1} \ldots z_{i_n}, \text{if } i_1 \leq i_2 \ldots \leq i_n, \quad (**)$$

$$\theta(a_1 \ldots a_k a_{i_{k+1}} \ldots a_{i_n}) = \theta(a_1 \ldots a_{i_{k+1}} a_{i_k} \ldots a_{i_n}) + \theta(a_1 \ldots [a_{i_k}, a_{i_{k+1}}] \ldots a_{i_n}). \quad (***)$$

We construct this map by construction on $\bigcup_{(k',N') \leq (k,N)} U^{(k',N')}$ and use induction on $(kN)$. For $k = 0$, let $\theta(1) = 1$. If $\theta$ is defined for any monomials of index $(k, N)$ that $k < n$, define $\theta$ on $T^{n,0}$ by $\theta(a_{i_1} \ldots a_{i_n}) = z_{i_1} \ldots z_{i_n}$, then it satisfies $(**)$.

And if $\theta$ is already defined for any $T^{n,k}$ that $k < i$, suppose that the monomial $a_{i_1} \ldots a_{i_n}$ has index $(n, i)$, then there is a smallest $k$ that $a_{i_1} \ldots a_{i_{k+1}} a_{i_k} \ldots a_{i_n}$ has index $i - 1$. Then we define

$$\theta(a_{i_1} \ldots a_{i_n}) = \theta(a_{i_1} \ldots a_{i_{k+1}} a_{i_k} \ldots a_{i_n}) + \theta(a_{i_1} \ldots [a_{i_k}, a_{i_{k+1}}] \ldots a_{i_n}).$$

Now we need to check that this definition satisfies $(***)$;

If there is another $k'$ that $i_{k'} > i_{k'+1}$, then $k < k'$. Suppose first that $k + 1 < k'$, let $a_{i_k} = a, a_{i_{k+1}} = b, a_{i_{k'}} = c, a_{i_{k'+1}} = d$, then

$$\theta(\ldots ab \ldots cd \ldots) = \theta(\ldots ba \ldots cd \ldots) + \theta(\ldots [a, b] \ldots cd \ldots)$$
\begin{align*}
\theta(\ldots ba \cdots dc \ldots) + \theta(\ldots ba \ldots [cd] \ldots) + \theta(\ldots [ab] \ldots dc \ldots) + \theta(\ldots [ab] \ldots [cd] \ldots) \\
= \theta(\ldots ab \ldots dc \ldots) + \theta(\ldots ab \ldots [cd] \ldots)
\end{align*}

where the terms except the first one are all in \(\cup_{\langle k'\rangle < \langle k\rangle} T^{(k',N')}\) so the equalities come from induction hypothesis. So it satisfies (** *).

Suppose next that \(k' = k + 1\), let \(a_{i_k} = a, a_{i_{k+1}} = b, a_{i_{k+2}} = c\), then

\begin{align*}
\theta(\ldots abc \ldots) &= \theta(\ldots bac \ldots) + \theta(\ldots [ab]c \ldots) \\
&= \theta(\ldots bca \ldots) + \theta(\ldots [bc]a \ldots) + \theta(\ldots [ac]b \ldots) + \theta(\ldots [ac]c \ldots) \\
&= \theta(\ldots cab \ldots) + \theta(\ldots [ac]b \ldots) + \theta(\ldots [ac]c \ldots) \\
&= \theta(\ldots acb \ldots) + \theta(\ldots [ac]b \ldots)
\end{align*}

where the terms except the first one are all in \(\cup_{\langle k'\rangle < \langle k\rangle} T^{(k',N')}\) so the equalities come from induction hypothesis, and in the third equality we used the Jacobi identity. So it satisfies (** *).

Now all elements in \(J\) is a linear combination of elements of the form

\[a_1 \ldots a_{i_k} a_{i_{k+1}} \ldots a_{i_n} - a_1 \ldots a_{i_k+1} a_{i_k} \ldots a_{i_n} - a_1 \ldots [a_{i_k} a_{i_{k+1}}] \ldots a_{i_n},\]

so the map \(\theta\) factors through \(T(\mathfrak{g}) \to U(\mathfrak{g})\) to a map \(\overline{\theta} : U(\mathfrak{g}) \to R\), and the elements \(a_{i_1} a_{i_2} \ldots a_{i_k}, i_1 \leq i_2 \leq \ldots \leq i_k\) are mapped to \(z_{i_1} \ldots z_{i_n}\), which are linearly independent in \(R\), so the elements \(a_{i_1} a_{i_2} \ldots a_{i_k}, i_1 \leq i_2 \leq \ldots \leq i_k\) are also linearly independent in \(U(\mathfrak{g})\). \(\square\)

**Cor. (2.5.8.5).** The map \(\mathfrak{g} \to U(\mathfrak{g})\) is injective.

**Cor. (2.5.8.6).** \(U(\mathfrak{g})\) has no zero-divisors.

**Proof:** We can use the identities \(x \otimes y - y \otimes x = [xy]\) to make any element in their right representations under the PBW prop(2.5.8.4), so it is clear that the product of two nonzero elements cannot be 0. \(\square\)

**Cor. (2.5.8.7).** If \(\mathfrak{h} \subset \mathfrak{g}\), then the subalgebra of \(U(\mathfrak{g})\) generated by \(\mathfrak{h}\) is isomorphic to \(U(\mathfrak{h})\).

**Proof:** There is a natural map \(U(\mathfrak{h}) \to U(\mathfrak{g})\), and the image is just the subgroup generated by \(\mathfrak{h}\). The PBW theorem shows this map is injective. \(\square\)

**Cor. (2.5.8.8).** If \(\mathfrak{g} = \mathfrak{a} \times \mathfrak{b}\), then \(U(\mathfrak{g}) = U(\mathfrak{a}) \otimes U(\mathfrak{b})\).

**Def. (2.5.8.9)[Coproduct of \(U(\mathfrak{g})\)].** Let \(\mathfrak{g}\) be a Lie algebra, there is a coproduct \(\Delta\) on \(T(\mathfrak{g})\) defined by \(\Delta(g) = g \otimes 1 + 1 \otimes g\). This coproduct descends to a coproduct \(\Delta : U(\mathfrak{g}) \to U(\mathfrak{g}) \otimes U(\mathfrak{g})\).

**Proof:** It suffices to check that \(\Delta(J) \subset J \otimes T(\mathfrak{g}) + T(\mathfrak{g}) \otimes J\), and this is because

\begin{align*}
\Delta(x \otimes y - y \otimes x - [xy]) &= (x \otimes 1 + 1 \otimes x)(y \otimes 1 + 1 \otimes y) - (y \otimes 1 + 1 \otimes y)(x \otimes 1 + 1 \otimes x) - ([xy] \otimes 1 + 1 \otimes [xy]) \\
&= (x \otimes y - y \otimes x - [xy]) \otimes 1 + 1 \otimes (x \otimes y - y \otimes x - [xy])
\end{align*}

\(\square\)

**Prop. (2.5.8.10)[\(\mathfrak{g}\)-Module Structure].** Let \(\mathfrak{g}\) be a Lie algebra, then \(T(\mathfrak{g})\) is a \(\mathfrak{g}\)-module, and this action descends to a \(\mathfrak{g}\)-module structure on \(U(\mathfrak{g})\).
Proof: It suffices to show that $\mathfrak{g}J \subset J$ and $\mathfrak{g}I \subset I$:

$$y(a \otimes b - b \otimes a - [ab]) = [ya] \otimes b + a \otimes [yb] - [yb] \otimes a - b \otimes [ya] - [y[ab]]$$

$$= [ya] \otimes b - b \otimes [ya] - [[ya]b] + a \otimes [yb] - [yb] \otimes a - [a[yb]]$$

\[\square\]

Prop. (2.5.8.11) [Transpose]. There is an anti-automorphism $u \mapsto u^t$ of $U(\mathfrak{g})$ that $X^t = -X$ for $X \in \mathfrak{g}$.

Proof: We first extend this $t$ to an automorphism of $T(\mathfrak{g})$, then we compose with the obvious anti-automorphism $T(\mathfrak{g}) \to T(\mathfrak{g})$. Then we check that this map descends to $U(\mathfrak{g})$: $(X \otimes Y - Y \otimes X - [X,Y])^t = Y \otimes X - X \otimes Y - [Y,X] \in J$, so $J^t \in J$.

\[\square\]

Prop. (2.5.8.12) [Graded Algebra of $U(\mathfrak{g})$]. Let $L$ be a Lie algebra, if we let $S(L) = T(L)/(x \otimes y - y \otimes x)$ be the universal symmetric algebra of $L$, then it is a graded algebra. There is a filtered structure on $U(L)$ given by $U_i = \{\text{subalgebra generated by } a_1a_2 \ldots a_j, j \leq i\}$, then the associated graded algebra of $U(L)$ is isomorphic to $S(L)$ by PBW theorem.

Cor. (2.5.8.13). If $W$ is a subspace of $T^n(L)$ that is sent isomorphically onto $S^n(L)$, then the image of $W$ is a complement of $U_n(L)$ complementary to $U_{n-1}(L)$.

Cor. (2.5.8.14) [Symmetrization Map]. Over a field of characteristic 0, the symmetrization map $\sigma : S(\mathfrak{g}) \to T(\mathfrak{g}) \to U(\mathfrak{g})$ (2.3.9.2) is an isomorphism of $\mathfrak{g}$-modules that

$$U^n(\mathfrak{g}) = \sigma(S^n(\mathfrak{g})) \oplus U^{n-1}(\mathfrak{g}).$$

Proof: It is clearly an isomorphism of vector spaces. It suffices to show the map is compatible with $\mathfrak{g}$-actions: Because

$$\sigma(y_1 \ldots y_n) = \frac{1}{n!} \sum_{\sigma \in \Sigma_n} y_{\sigma(1)} \ldots y_{\sigma(n)},$$

$$\sigma(g(y_1 \ldots y_n)) = \sigma([gy_1] \ldots y_n + \ldots + y_1 \ldots [gy_n])$$

$$= \frac{1}{n!} \sum_{\sigma \in \Sigma_n} ([gy_{\sigma(1)}] \ldots y_{\sigma(n)} + \ldots + y_{\sigma(1)} \ldots [gy_{\sigma(n)}])$$

$$= g(\frac{1}{n!} \sum_{\sigma \in \Sigma_n} y_{\sigma(1)} \ldots y_{\sigma(n)})$$

\[\square\]

Prop. (2.5.8.15). If $\mathfrak{g}$ is a Lie algebra over a field $k$ of characteristic 0, then the set of primitive elements (2.9.1.3) are just $\mathfrak{g}$.

Proof: If $f$ is primitive, then the leading term $f_0$ of $f$ is also primitive in $grU(\mathfrak{g}) \cong S(\mathfrak{g})$. Now consider $S(g) \xrightarrow{\Delta} S(\mathfrak{g}) \otimes S(\mathfrak{g}) \xrightarrow{\mu} S(\mathfrak{g})$, then if $f$ is of degree $n$, then $2^n f_0 = 2 f_0$, which means $n = 1$. So $f = c + f_0$, and $c = 0$.

\[\square\]

Prop. (2.5.8.16) [$U(\mathfrak{g})$ is Noetherian]. For a f.d. Lie algebra $\mathfrak{g}$, $U(\mathfrak{g})$ is left Noetherian.

Proof: This is because the graded stricture on $U(\mathfrak{g})$ satisfies $gr U(\mathfrak{g}) \cong S(\mathfrak{g}) \cong \mathbb{C}[X_1, \ldots, X_n]$ is Noetherian, so $U(\mathfrak{g})$ is Noetherian itself.
Free Lie Algebras

Def. (2.5.8.17) [Free Lie Algebra]. Let $X$ be a set, then we define the free Lie algebra $\text{FL}(X)$ to be the intersection of Lie subalgebras in $[F(X)]$ containing $\sigma(X)$, where $F(X)$ is the free algebra generated by $X$.

Then the free Lie algebra $\text{FL} : X \mapsto \text{FL}(X)$ defines a functor $\text{Set} \to \text{LieAlg}$ that is left adjoint to the forgetful functor.

Proof: We need to show that for any Lie algebra $L$ and a map fo sets $\theta : X \to L$, there is a unique $\varphi$ completing the upper left triangular diagram:

$$
\begin{array}{ccc}
X & \xrightarrow{i} & \text{FL}(X) \\
\downarrow{\theta} & & \downarrow{\varphi} \\
L & \xrightarrow{\varphi} & U(L)
\end{array}
$$

Notice $\varphi^{-1}(\sigma(L))$ is a Lie algebra containing $X$ thus containing $\text{FL}(X)$, so it induces a $\varphi$.

And for the uniqueness, if there are two $\varphi_1, \varphi_2$, then the element that they coincide is a Lie algebra containing $X$, thus containing $\text{FL}(X)$, so $\varphi_1 = \varphi_2$. 

\[\square\]

Cor. (2.5.8.18). $U(\text{FL}(X)) \cong FX$ for any set $X$.

Proof: Because $U \circ \text{FL}$ and $F$ are both left adjoint to the forgetful functor $\text{AssAlg} \to \text{Set}$. 

Center of $U(\mathfrak{g})$

Prop. (2.5.8.19) [g Action on U(g)]. $\mathfrak{g}$ acts on $T(\mathfrak{g})$ by adjoint (2.5.9.2), and notice

$$
\text{ad}(z)(x \otimes y - y \otimes x - [xy]) = [zx] \otimes y + x \otimes [zy] - [zy] \otimes x - y \otimes [zx] - [z[xy]] \in J,
$$

so the action of $\mathfrak{g}$ descends to an action on $U(\mathfrak{g})$.

In fact, this action is inner: $\text{ad}(g)(z) = gz - zg$ for $z \in U(\mathfrak{g})$. In particular,

$$
Z(U(\mathfrak{g})) = U(\mathfrak{g})^{\text{ad}(\mathfrak{g})}.
$$

Invariant Polynomials

Prop. (2.5.8.20) [Chevalley]. The center of the universal enveloping algebra is isomorphic to the polynomial ring over $\mathbb{C}$ of $l$ elements, where $L$ is a semisimple lie algebra of rank $l$. In particular, The center for $\mathfrak{sl}_2$ is the algebra generated by the Casimir element $1/2h^2 + ef + fe$.

Proof: Because there is a commutative diagram of isomorphisms of algebras:

$$
\begin{array}{ccc}
S(L)^G & \xrightarrow{\alpha} & P(L)^G \\
\downarrow{\eta} & & \downarrow{\phi} \\
S(H)^W & \xrightarrow{\beta} & P(H)^W
\end{array}
$$

Where $P$ is the polynomial ring $\cong S(L^*)$, the horizontal is Killing isomorphisms and vertical is the restriction maps. Cf.[Carter prop 13.32]?
The twisted Harish-Chandra map gives an isomorphism of algebras $Z(L) \rightarrow S(H)^W$ (It just maps $z \in Z(L)$ to its pure $H$ part and transform every indeterminants $h_i$ to $h_i - 1$). e.g. $z = h^2 + 2h + 1 + 4fe \in Z(\mathfrak{sl}_2)$ is mapped to $h^2$ in $S(H)$. And $P(H)^W$ is isomorphic to a polynomial ring in $l$ generators over $\mathbb{C}$.

**Def. (2.5.8.21) [Casimir Element].** If $L$ is semisimple Lie algebra, by (2.5.2.1) the Killing form is non-degenerate, thus we choose a basis $x_i$ of $L$ and a dual basis $y_i$, then $c = \sum x_i y_i$ is independent of $x_i$ chosen by (2.3.8.9), and is called the Casimir element of $U(L)$.

**Prop. (2.5.8.22).** The Casimir element lies in the center of $U(L)$.

**Proof: □**

**Prop. (2.5.8.23) [Quillen’s lm].** If $K$ is an alg.closed field of char 0 that $\mathfrak{g}$ is a f.d. Lie algebra over $K$. If $U = U(\mathfrak{g})$ is its universal enveloping algebra, then for any irreducible $U$-module $M$, $\text{End}_U(M) = K$.

**Miscellaneous**

**Prop. (2.5.8.24) [Grading on $U(\mathfrak{sl}_2(\mathbb{C}))$].** Let $H, R, L$ be a basis of $\mathfrak{sl}_2(\mathbb{C})$(2.5.2.11), if we define a grading as $\text{deg } R = 1, \text{deg } H = 0, \text{deg } L = -1$, then this is descends to a grading on $U(\mathfrak{g})$, and the degree 0 part is the ring $\mathcal{R} = \mathbb{C}[\Delta, H]$. Also, there is a decomposition:

$$U(\mathfrak{g}) = \bigoplus_{i \geq 0} L^i \mathcal{R} \oplus \bigoplus_{i > 0} R^i \mathcal{R}.$$  

9 Representations

**Def. (2.5.9.1) [Representations].** A representation of a Lie algebra $\mathfrak{g}$ over a vector space $V$ is a Lie homomorphism $\mathfrak{g} \rightarrow \mathfrak{gl}_V$.

**Def. (2.5.9.2) [Tensor Product of Representations].** Let $(V_1, \pi_1), (V_2, \pi_2)$ be two representations of a Lie algebra $\mathfrak{g}$, then $(V_1 \otimes V_2, \pi_1 \otimes \pi_2)$ is a representation of $\mathfrak{g}$ given by

$$(\pi_1 \otimes \pi_2)(g)(v_1 \otimes v_2) = \pi_1(g)v_1 \otimes v_2 + v_1 \otimes \pi_2(g)v_2.$$  

**Def. (2.5.9.3) [Representation on Tensor Algebras].** If $(V, \rho)$ is a representation of $\mathfrak{g}$, then $\mathfrak{g}$ acts on $T(V)$ via (2.5.9.2). Also, the ideals $I, J$ are invariant under action of $\mathfrak{g}$, thus the representation extends to $\text{Sym}(V)$ and $\wedge(V)$. Also it preserves degree, thus it induces representations on $\text{Sym}^k(V)$ and $\wedge^k(V)$.

**Proof:**

$$g(a \otimes a) = g(a) \otimes a + a \otimes g(a) = (a + g(a)) \otimes (a + g(a)) - a \otimes a - g(a) \otimes g(a)$$

and

$$g(a \otimes b - b \otimes a) = g(a) \otimes b + a \otimes g(b) - g(b) \otimes a - b \otimes g(a) = g(a) \otimes b - b \otimes g(a) + a \otimes g(b) - g(b) \otimes a$$  

□
Def. (2.5.9.4) [Dual Representation]. If \((\varphi, V)\) is a representation of \(g\), we define the **dual representation** \((\varphi^*, V^\vee)\) as
\[
(\varphi^*(g)(v^*), v) = (v^*, \varphi(g)v).
\]

Def. (2.5.9.5) [Trace Form]. The **trace form** of a representation \((V, \rho)\) of a Lie algebra \(g\) is an invariant symmetric form \(\beta_\rho\) defined by \((x, y) \mapsto \text{tr}(\rho(x) \circ \rho(y))\).

**Proof:** It is invariant because
\[
\text{tr}(\rho([x, y]) \circ \rho(z)) = \text{tr}(\rho(x)\rho(y)\rho(z)) - \text{tr}(\rho(y)\rho(x)\rho(z)) = \text{tr}(\rho(x)\rho(y)\rho(z)) - \text{tr}(\rho(x)\rho(z)\rho(y)) = \text{tr}(\rho(x)\rho([y, z])).
\]

Prop. (2.5.9.6). If \(\rho\) is a faithful representation of \(g\) and \(g\) is semisimple, then \(\beta_\rho\) is non-degenerate.

**Proof:** The Cartan’s criteria (2.5.1.27) shows \(g^\perp\) is a solvable sub-Lie algebra, so it must be 0 as \(g\) is semisimple (2.5.1.23). □

Prop. (2.5.9.7). Let \(L\) be a simple lie algebra, then any two non-degenerate symmetric invariant bilinear forms on \(L\) is proportional. Because any of this form corresponds to a \(L\)-morphism from \(L\) to \(L^*\). In particular, when \(L \subset gl_n\), the usual trace is proportional to the Killing form.

**Remark (2.5.9.8) [Rep(\(g\)].** Let \(g\) be a Lie algebra over a field \(k\), let Rep(\(g\)) denote the category of f.d. representations of \(g\).

Prop. (2.5.9.9) [Schur’s Lemma]. Let \(g\) be a finite Lie algebra, \(M\) be an irreducible \(g\)-module, then \(\dim M\) is countable. In particular, Shur’s lemma holds by (15.1.1.9).

**Proof:** It is of countable dimensional because \(\dim U(g)\) is countable. □

Prop. (2.5.9.10) [Generalized Eigenspace Decomposition for Nilpotent Lie Algebras]. Assume \(k\) is alg.closed, and \(g\) is a nilpotent algebra, and \((V, \rho)\) is a representation of \(g\), then there is a generalized eigenspace decomposition
\[
V = \bigoplus_{\lambda \in g^*} V^\lambda,
\]
where \(V^\lambda\) are the generalized eigenspaces, and they are stable under action of \(g\).

**Proof:** We use an induction argument:

If each \(a \in \mathfrak{h}\) has only one eigenvalue, then \(V\) is the generalized eigenspace \(V^\lambda\) for some function \(\lambda\) on \(\mathfrak{h}\). Then it suffices to show that \(\lambda\) is linear. But this is because by Lie’s theorem elements of \(\mathfrak{h}\) has a common eigenvector.

If for some \(a_0\), \(\text{ad}(a_0)\) has two eigenvalues. Now \(\mathfrak{h}\) is nilpotent, so \(\mathfrak{h} \subset \mathfrak{h}^0\), and hence \(\pi(h)V^{a_0}_\lambda \subset V^{a_0}_\lambda\) for any \(\lambda\) by (2.5.1.12).

As \(k\) is alg.closed, \(V\) can be written as a sum of generalized eigenspaces of \(a_0\), and each generalized eigenspace is a subrepresentation of \(\mathfrak{h}\), thus we can use induction. □
Def. (2.5.9.11) [Casimir Operator]. Let \( g \) be a semisimple Lie algebra of dimension \( n \), and \( \beta : g \times g \to k \) a non-degenerate invariant bilinear form on \( g \). Let \( e_i \) be a basis of \( g \) and \( e'_i \) be the dual basis under \( \beta \), then \( c = \sum e_i e'_i \in U(g) \) is independent of the basis, and lies in the center of \( U(g) \).

Now the trace form \( \beta_V \) for a faithful representation \( g \to gl_V \) of \( g \) is non-degenerate and invariant \((2.5.9.6)\), then the corresponding elements \( c'_\rho \) is called the Casimir element of \((V, \rho)\), and the action \( c_V \) of \( c'_\rho \) on \( V \) is called the Casimir operator of \((V, \rho)\).

The Casimir operator \( c_V \) is a \( g \)-module homomorphism, and has trace \( n \).

\( \square \)

Def. (2.5.9.12) [Unimodular Lie Algebras]. A f.d Lie algebra \( g \) is called unimodular if \( \wedge \text{ad} \) is a trivial representation of \( g \).

Prop. (2.5.9.13).

- If \( g = [g, g] \), then \( g \) is unimodular.
- If \( g \) is nilpotent, then \( g \) is unimodular.
- If \( g_1, g_2 \) is nilpotent, then \( g_1 \oplus g_2 \) is unimodular.
- If \( g \) is reductive, then \( g \) is unimodular.

Lemma (2.5.9.14) [Zassenhaus]. Let \( g \) be a Lie algebra and \( g' \) an ideal of \( g \). A representation \( \rho' \) of \( g' \) extends to a representation \( \rho \) of \( g \) that \( n_{\rho'}(g') \subset n_{\rho}(g) \) if there exists a Lie subalgebra \( h \) of \( g \) that \( g = g' \oplus h \) and \( [h, g'] \subset n_{\rho'}(g') \). If moreover \( \text{ad}_g(x)|_{g'} \) is nilpotent for all \( x \in h \), then \( \rho \) can be chosen that \( h \subset n_{\rho}(g) \).

\( \square \)

Prop. (2.5.9.15) [Nilpotent Representation Extension]. Let \( g \) be a Lie algebra, \( \alpha \) a nilpotent ideal of \( g \), and \( \rho \) a representation of \( \alpha \) that \( \rho(x) \) is nilpotent for all \( x \in \alpha \). Then \( \rho \) extends to a representation \( \rho' \) of \( g' \) that \( \rho'(x) \) is nilpotent for all \( x \in n \) the largest nilpotent ideal of \( g \).

\( \square \)

Thm. (2.5.9.16) [Ado]. Let \( g \) be a Lie algebra over a field \( k \) of char\(0\), then there exists a faithful representation \( \rho \) of \( g \) that \( \rho(n) \) consists of nilpotent endomorphisms, where \( n \) is the largest nilpotent radical. If \( g \) is of f.d., then this representation can be chosen to be of f.d.. In particular, any finite dimensional Lie algebra can be embedded in some \( gl(n, k) \).

\( \square \)
Remark (2.5.9.17). In fact, this is true for Lie algebras over a field of char $p$, too, Cf.[JACOBSON, N. 1962. Lie algebras.] Chap 6.3.

**Semisimple Representations**

For representations of a semisimple Lie algebra, See 15.15.

10 Lie Algebra Cohomology

Main references are [Wei94] and [Eti21].

**Prop. (2.5.10.1)** [Chevalley-Eilenberg resolution].

11 Amitsur-Levitski

**Preliminary**

Notice that in this paper, Kostant considers **reductive** lie groups. But in the range of this paper, the abelian part makes no contribution in the alternative part because they commutes with all elements. So We well just consider a **semisimple** Lie algebra in order to get a non-degenerate Killing form.

**Prop. (2.5.11.1).**

\[
\Gamma(\wedge^{2k}(\mathfrak{g})) = R^k \subset S^k(\mathfrak{g})
\]

\[
\Gamma(x_1 \wedge \cdots \wedge x_k) = \sum_{v \in \Pi_k} [x_v(1), x_v(2)] \cdots [x_v(2k-1), x_v(2k)]
\]

**Proof:** The proof is in fact simple, just notice that for every $v \in \Pi_k$ a representative of the subgroup $\Sigma_{2k,2}$ permuting the unordered pairs $\{(1,2), (3,4), \ldots, (2k-1,2k)\}$, the element in $v\Sigma_{2k,2}$ in fact combine in pairs to $[x_{v(2i-1)}, x_{v(2i)}]$ and together the $k!$ permutation of them compose a $[x_{v(1)}, x_{v(2)}] \cdots [x_{v(2k-1)}, x_{v(2k)}]$. \hfill \Box

Later he finds the dual of $\Gamma$, that is:

**Prop. (2.5.11.2).** $\gamma$ is $B$ dual to $\Gamma$,

\[
(\Gamma(\zeta), y_1 \cdots y_r) = (-1)^r (\zeta, dy_1 \wedge \cdots \wedge dy_r) \quad \forall \zeta \in \wedge^{2r}\mathfrak{g} \text{ and } y_i \in \mathfrak{g}.
\]

In particular,

\[
\Gamma(\zeta)(x) = \frac{(-1)^r}{r!} (\zeta, (dx)^r) \quad \forall \zeta \in \wedge^{2r}\mathfrak{g} \text{ and } x \in \mathfrak{g}.
\]

For the proof just notice that $(-dw, x_i \wedge x_j) = (w_i, [x_i, x_j])$ and

\[
(x_1 \otimes \cdots \otimes x_r, y_1 \otimes \cdots \otimes y_r) = \sum_{\sigma} (x_1, y_{\sigma(1)}) \cdots (x_r, y_{\sigma(r)})
\]

So dim of $R^k$ equals the dim of image of $\gamma_r$, that is, spanned by $(dx)^k$(because they are dual).

We say that a representation of $\mathfrak{g}$ satisfies m-fold standard identity if the alternating sum of any m elements of image of $\mathfrak{g}$ is 0. Obviously, this is equivalent to:

\[
\tau(R^k(\mathfrak{g})) \subset \ker \pi_V
\]
Now let \( o(g) \) be the maximum rank of \( dw, w \in g \), then by the discussion of the first paper, when \( g \) is semisimple, \( o(g) = r \). So the \( 2r \)-identity is satisfied by any representation of \( g \).

Furthermore, a prop of [Harish-Chandra] assert for any nonzero element \( u \in U(g) \), there is a representation such that \( \pi(U) \neq 0 \). So this is a sharp bound for general representations.

But one might naturally ask: Can we find the specific bound for a particular representation of a specific \( g \)? The answer is YES.

**Prop. (2.5.11.3).** \( \gamma \) vanishes on the ideal \( J_+ \cdot S(g) \).

**Proof:** The proof comes from the observation \( \pi \) is a \( G \)-map and by Cartan-Koszul theory, invariant elements in \( \wedge g \) are naturally isomorphic to the cohomology of \( g \) and \( \gamma(w) = -dw \) is clearly exact, thus \( \gamma(w_1 w_2 \ldots w_i) = \gamma(w_1) \wedge \cdots \wedge \gamma(w_i) \) is exact too. So \( \gamma(w) = 0 \).

**Cor. (2.5.11.4).** \( M = R^r \in H^r \), so it consists of harmonic functions.

**Proof:** \( (u, \Gamma(y)) = (\gamma(u), y) = 0 \) \( \forall u \) invariant, by Thm; so \( R^k = \text{Image} \Gamma \) is harmonic.

**Generalized Amitsur-Levitski**

Let \( E^k \subset U(g) \) be spanned by \( y^k, y \) nilpotent in \( g \), and \( Z \) the center.

In [Kos97] Kostant proved that the PBW isomorphism \( \delta : S(g) \to U(g) \) induces \( J, \delta(H) = E \).

So \( \tau : T(g) \to U(g) \) induces

\[
\tau(A^{2k}(g)) = \delta(R^k(g)) \subset E^k.
\]

Define \( \epsilon(\pi) \) the minimum integer \( k \) that \( \pi(y)^k = 0, \forall y \) nilpotent in \( g \). Then clearly:

**Prop. (2.5.11.5)[Generalized Amitsur-Levitski].** \( \pi \) satisfies the \( 2\epsilon(\pi) \)-fold standard identity.

**Prop. (2.5.11.6).** If \( \pi \) satisfies the \( m \)-identity, it satisfies the \( m + 1 \)-identity (By taking a summation on a fixed first element \( \sigma(1) \)).

**Prop. (2.5.11.7).**

- Let \( \pi \) be the natural representation of \( gl_n \) on \( \mathbb{C}^n \) then \( \epsilon(\pi) = n \).

- If \( n \) even and \( \pi \) the natural representation of skew-symmetric matrices on \( \mathbb{C}^n \) then \( \epsilon(\pi) = n - 1 \).

From this one derives the classical Amitsur-Levitski prop that \( GL_n(\mathbb{C}) \) satisfies the \( n \)-fold standard identity.

**Proof:**

1: the abstract Jordan decomposition which assures \( x \) is nilpotent in \( gl_n \) if \( \pi(x) \) is nilpotent.

2: comes from the Lacobson-Morosov Thm that any nilpotent element of \( g \) is contained in a \( sl_2 \)-triple. Thus we only need to show that \( W \) is reducible considered as this \( sl_2 \)-triple-module.

But then an irreducible representation of \( sl_2 \) preserves a non-degenerate bilinear form it must be odd dimensional cause a non-degenerate bilinear form is equivalent to a \( g \)-map from \( V \) to \( V^* \).

And there can be constructed an anti-symmetric form defined on the \( sl_2 \)-representation on \( \text{Sym}_{2k}[x, y] \) by (2.5.11.9), so there can’t exist symmetric \( g \)-invariant form. So this representation must be reducible.
Cor. (2.5.11.8) [Classical Amitsur-Levitski]. By (2.5.11.5),

\[ [[x_1, x_2, \ldots, x_n]] = \sum_{\sigma} \text{sgn}(\sigma)x_{\sigma(1)}x_{\sigma(2)}\cdots x_{\sigma(k)} = 0 \quad \forall x_i \in \mathfrak{gl}_n \]

called \textit{n-fold standard identity}.

Prop. (2.5.11.9). For a construction of the anti-symmetric form, notice

\[ \pi(g)f(x_1, x_2) = f(g_{11}x_1 + g_{12}x_2, g_{21}x_1 + g_{22}x_2). \]

Set

\[ v_k = \left(\begin{array}{c} m \\ k \end{array}\right)x_1^{m-k}x_2^k, \quad \Omega(v_k, v_{m-k}) = (-1)^k \left(\begin{array}{c} m \\ k \end{array}\right). \]

One verifies:

\[ \Omega(g \cdot u, g \cdot v) = (\det g)^m \Omega(u, v) \quad \forall g \in GL(2, \mathbb{C}) \]

So when \( m = n - 1 \) is odd, this is a symplectic form preserved by \( \mathfrak{sl}_2 \).

A computable Formula

Finally, Kostant gave a computable formula for determining \( \epsilon(\pi) \). Clearly we just need to consider irreducible representation.

Let \( \pi_\lambda \) be the irreducible representation of highest weight \( \lambda \), then the dual representation \( \pi_\lambda' \) has highest weight the negative of the lowest weight of \( \pi_\lambda \), that is, \( -w_0(\gamma) \).

But then \( \lambda + \lambda' \) is a sum of simple positive roots. \( \lambda + \lambda' = \sum_{i=1}^n m_i \alpha_i \). Put \( \epsilon(\lambda) = 1 + \sum_{i=1}^n m_i \). Then:

Prop. (2.5.11.10). \( \epsilon(\pi_\lambda) = \epsilon(\lambda) \).

\textit{Proof:} Just choose a \( \mathfrak{sl}_2 \)-triple \( \{e, x, f\} \) with \( \alpha(x) = 2 \ \forall \alpha \) simple root. Then \( \lambda(x) \) and \( -\lambda'(x) \) are respectively the maximal and minimal eigenvalues of \( \pi(x) \). \( (\lambda + \lambda')(x) = 2(\epsilon(\lambda) - 1) \). Thus \( f \) has nilpotent degree \( \epsilon(\lambda) \). And any nilpotent element action increases the eigenvalue of an eigenvector of \( x \) by at least 2, the prop follows. \( \square \)

Further Work

(cf. [Pro76]) Another different proof of the Amitsur-Levitski theorem is given by Kostant using techniques related to \textit{trace identities}. It turns out that method sheds more light. Later is studied the polynomial of matrices invariant under the conjugation action.

Artin conjectured that all the invariants is polynomials of the Trace polynomial \( Tr(A_1A_2\cdots A_n) \) (Proved)

And further, the relations among these invariant all turned out to be consequences of the prop of Hamilton-Cayley. All this is made into the \textit{Invariant Theory}.

Prop. (2.5.11.11) [Interesting results].

1. If an algebra over a field of characteristic 0 satisfies the identity \( X^n = 0 \), then it satisfies all the identities of \( n \times n \) matrices.

2. The space of multilinear identities of degree \( m \) of \( n \times n \) matrices can be described completely in terms of Young diagrams.
12 Lie $p$-Algebras

Remark (2.5.12.1). In this subsection, let $k$ be a field of characteristic $p$.

Def. (2.5.12.2) [Lie $p$-Algebras]. Let $x_0, x_1$ be elements of a Lie algebra over $k$ of characteristic $p$, then for $0 < r < p$, let $s_r(x, x_1)$ denote $\frac{1}{r}$ times coefficient of $t^{r-1}$ in the expression of $\text{ad}^{p-1}_{x+y}(x)$.

Then a Lie $p$-algebra is a Lie algebra $\mathfrak{g}$ over $k$ equipped with a map $x \mapsto x[p]: \mathfrak{g} \rightarrow \mathfrak{g}$ such that

- $(cx)^{[p]} = c^px^{[p]}$ where $c \in k$.
- $\text{ad}(x^{[p]}) = (\text{ad}(x))^{p}$.
- $(x+y)^{[p]} = x^{[p]} + y^{[p]} + \sum_{i=1}^{p-1} s_r(x, y)$.

Example (2.5.12.3). If $L$ is an Abelian Lie algebra, then it can be regarded as a Lie $p$-algebra by assigning $x[p] = 0$.

If $A$ is an associative algebra, then it can be given a Lie $p$-algebra structure by assigning $x[p] = x^p$.

Proof: To show $A$ is a Lie $p$-algebra, we check $\text{ad}(x)^p(y) = (l_x - r_x)^p(y) = l^p_x - r^p_x(y) = \text{ad}(x^p)(y)$.

Prop. (2.5.12.4) [Representations]. A representation of a Lie $p$-algebra $\mathfrak{g}$ over a $k$-vector space $V$ is a homomorphism $\mathfrak{g} \rightarrow \mathfrak{gl}_V$ of Lie $p$-algebras.

Def. (2.5.12.5) [Universal Enveloping $p$-Algebra]. The universal enveloping $p$-algebra of a Lie $p$-algebra $\mathfrak{g}$ is defined to be

$$U[p](\mathfrak{g}) = T(\mathfrak{g})/J[p], \quad T(\mathfrak{g}) = \bigoplus_{n=0}^{\infty} \mathfrak{g}^\otimes n$$

which is a graded algebra $T(\mathfrak{g})$ quotients the ideal $J = \{x \otimes y - y \otimes x - [xy], x^\otimes p - x^{[p]}\}$.

There is a natural linear map $\sigma: \mathfrak{g} \rightarrow U[p](\mathfrak{g})$.

Prop. (2.5.12.6). The universal enveloping $p$-algebra $U[p]: \mathfrak{g} \mapsto U[p](\mathfrak{g})$ defines a functor LieAlg $\rightarrow$ AssAlg that is left adjoint to the canonical functor $\text{AssAlg}_k \rightarrow \text{LieAlg}_k(2.5.12.3)$.

Proof: For any associative algebra $A$ and a morphism of Lie $p$-algebras $\mathfrak{g} \rightarrow [A]$, there is easily seen a morphism $U[p](\mathfrak{g}) \rightarrow A$, and it is unique.

Cor. (2.5.12.7) [Representation as Modules]. A representation of $\mathfrak{g}(2.5.12.4)$ is same as a representation of $U[p](\mathfrak{g})$.

Prop. (2.5.12.8). Let $e_i$ be a $k$-vector space basis of $\mathfrak{g}$, then the monomials

$$\{e_{i_1}^{n_1} e_{i_2}^{n_2} \cdots e_{i_r}^{n_r} | i_1 < i_2 < \ldots < i_r, 0 < n_{i_k} < p\}$$

for different $r$ form a basis of $U[p](\mathfrak{g})$.

Proof: This is a consequence of PBW theorem (2.5.8.4).

Cor. (2.5.12.9). If $\mathfrak{g}$ is of finite dimensional over $k$, then so does $U[p](\mathfrak{g})$, and the map $i: \mathfrak{g} \rightarrow U[p](\mathfrak{g})$ is injective.
2.6 Infinite Dimensional Lie Algebras

References are [What is moonshine?], [Vertex Operator Algebras and the Monster], [Infinite-Dimensional Lie Algebras, Kac], [Car05].

1 Kac-Moody Algebras
2 Vertex Operator Algebras
3 Moonshine Conjectures

Thm. (2.6.3.1) [Monstrous Moonshine]. There is a naturally defined graded infinite dimensional module, called the Monstrous module $V = \bigoplus_{n \in \mathbb{Z}} V_n$ of the monster group $M$ s.t. for any $g \in M$, the Mckay-Thompson series

$$T_g(\tau) = \sum_{n \geq -1} \text{tr}(g|V_n)e^{2\pi inr}$$

is a Hauptmodul for a discrete subgroup $\Gamma \subset SL(2,\mathbb{Z})$ of genus 0 and period $r$ at the cusp.

Proof: Cf.[Borcherds, 1992]

Prop. (2.6.3.2) [Duncan-Mertens-Ono, 2017]. There exists an infinite dimensional module $V = \bigoplus_{n>0, n \equiv 0, 3 \mod 4} V_n$ of the O'Nan group (2.1.13.5) ON s.t. for any $g \in ON$, the Mckay-Thompson series

$$F_g(\tau) = q^{-4} + 2 + \sum_{n>0} \text{tr}(g|V_n)e^{2\pi inr}$$

is a meromorphic modular form of weight $\frac{3}{2}$ on $\Gamma_0(4N)$, where $N$ is the order of $g$.

Proof:
2.7 Reflection Groups and Coxeter Groups

Main references are [Hum90], [Ser87], [Kna96].

Notations (2.7.0.1).
- Let $k \in \text{Field}$, char $k = 0$, $V \in \text{Vect}_k$.

1 Reflection Groups

Def. (2.7.1.1) [Reflections]. Let $V \in \text{Vect}^d / k$, a reflection on $V$ is a linear transformation $s \in \text{End}(V)$ that has $d - 1$ eigenvalues 1 and one eigenvalue $-1$.

Prop. (2.7.1.2). Let $\alpha \in V$ and $\alpha^\vee \in V^\vee$ that $(\alpha, \alpha^\vee) = 2$, then

$$s_\alpha : x \mapsto x - (x, \alpha^\vee)\alpha$$

is a reflection, and every reflection with vector $\alpha$ is of this form.

Proof: Clearly $s_\alpha$ is a reflection, and if $s$ is any reflection, then $\alpha^\vee$ is the composition of the quotient map $V \to V/H$ with the map $V/H \to F$ sending $\alpha + H$ to 1. □

Lemma (2.7.1.3). Let $R \subset V$ be a set s.t. span$\{R\} = V$, then for any $\alpha \in V$, there exists at most one reflection $s$ with vector $\alpha$ that $s(R) \subset R$.

Proof: Let $s, s'$ be two such reflections, then $t = ss'$ is an automorphism that is identity on both $F\alpha$ and $V/F\alpha$. So $(t - 1)^2 = 0$ on $V$. So the minimal polynomial of $T$ divides $(T - 1)^2$. Also because $R$ is finite there exists an $m$ that $t^m = 1$ on $R$ thus on $V$, so $t = 1$ as the greatest divisor of $(T - 1)^2$ and $T^m - 1$ is $T - 1$. □

Lemma (2.7.1.4). Let $V$ be an inner product space, then for any vector $\alpha$, there exists a unique reflection $s_\alpha$ that respects the inner product, which is

$$s_\alpha(x) = x - 2\frac{(x, \alpha)}{(\alpha, \alpha)}\alpha.$$

Def. (2.7.1.5) [Reflection Groups]. $\Gamma \leq \text{GL}(n, k)$ is called a reflection group if it is generated by reflections.

Thm. (2.7.1.6) [Shephard-Todd-Chevalley]. Let $\Gamma \leq \text{GL}(n, k)$, then $\Gamma$ is a reflection group iff $k[X_1, \ldots, X_n]^\Gamma$ is a polynomial ring. And in this case,
- There are homogenous alg.ind polynomials $p_1, \ldots, p_r$, $d_i = \deg(p_i)$, $d_1 \leq d_2 \leq \ldots \leq d_r$ s.t. $k[X_1, \ldots, X_n]^\Gamma = k[p_1, \ldots, p_r]$.
- $\frac{1}{\# \Gamma} \sum_{\gamma \in \Gamma} \frac{\text{tr}(\gamma)}{\det(1 - \gamma T)} = \prod_{i=1}^r \frac{1}{1 - Td_i} \in k(T)$.
- $(d_1, \ldots, d_r)$ are determined by $\Gamma$.
- $\# \Gamma = \prod_i d_i$, and $\Gamma$ contains $\sum_i (d_i - 1)$ reflections.
- If $\Gamma$ is an irreducible subgroup of $\text{GL}(n, k)$, then it is an abstractly irreducible group, and $Z(\Gamma)$ is cyclic of order $\text{pgcd}(d_1, \ldots, d_r)$.

Proof: □
2 Root Systems

Def. (2.7.2.1) [Root System]. A subset $R$ of a vector space $V$ over $F$ is called a root system if
- $R$ spans $V$ and doesn’t contain 0.
- For each $\alpha \in R$, there exists a unique reflection $s_\alpha = \text{id} - \alpha^\vee \otimes \alpha$ with vector $\alpha$ that $s_\alpha(R) \subset R$.
- For any $\alpha, \beta \in R$, $s_\alpha(\beta) - \beta$ is a multiple of $\alpha$, or equivalently $\alpha^\vee(\beta) \in \mathbb{Z}$.

Elements of $R$ are called the roots of $R$, and dimension of $V$ is called the dimension of the root system. And the subgroup of $GL(V)$ generated by all $s_\alpha$ is called the Weyl group of $R$. The Weyl subgroup is a finite group, as a subgroup of the group of permutations of $R$.

A root system is called indecomposable iff it cannot be written as a direct sum of two root systems.

Def. (2.7.2.2) [Reduced Root System]. Let $\alpha, \beta$ be roots that are multiples of each other, then $\beta = c\alpha$ for some $c \in F$, then $2(\beta, \alpha^\vee) = 2c \in \mathbb{Z}$, also $2c^{-1} \in \mathbb{Z}$, so $c \in \{-1, -1/2, 1/2, 1\}$. A reduced root system is a root system that there are no roots $\alpha, \beta$ that $\alpha = 2\beta$.

Prop. (2.7.2.3) [Invariant Quadratic Form]. Let $R$ be a root system in $V$, then there is a positive bilinear form in $V$ that is invariant under the action of the Weyl group of $R$.

Notice that for such a bilinear form, the reflection must be of the form given in (2.7.1.4), or in other words, $\alpha^\vee(\beta) = \left(\frac{2\alpha}{(\alpha, \alpha)}, \beta\right)$.

Proof: This follows entirely because the Weyl group of $R$ is finite, as we can take the average of any positive bilinear form under the action of reflections.

Def. (2.7.2.4) [Dual Root System]. Let $R$ be a root system in $V$, the set of dual vectors $\alpha^\vee$ for $\alpha \in R$ is also a root system in $V^\vee$, called the dual system of $R$. And it has the same Weyl group as $R$.

Moreover, $R^\vee \cong R$.

Proof: Take an invariant quadratic form on $V(2.7.2.3)$, then it gives an isomorphism $V \rightarrow V^\vee$. Then $\alpha^\vee$ corresponds to $\frac{2\alpha}{(\alpha, \alpha)}$ under this isomorphism, and there obviously generates $V$. If $\alpha^\vee \in R^\vee$, we can take the corresponding reflection to be $s_{\alpha^\vee} = 1 - \alpha \otimes \alpha^\vee$. Then

$$s_{\alpha^\vee}(\beta^\vee)(x) = (\beta^\vee - \beta^\vee(\alpha)\alpha^\vee)(x)$$

$$= (x, 2\beta/(\beta, \beta)) - \frac{(\alpha, \beta)}{(\beta, \beta)}(x, 2\alpha/(\alpha, \alpha))$$

$$= (x, \frac{2(\beta - \alpha(\alpha, \beta)/(\alpha, \alpha))}{(\beta, \beta)})$$

$$= (x, \frac{2s_\alpha(\beta)}{(\beta, \beta)}) = (s_\alpha(\beta))^\vee(x).$$

So $s_{\alpha^\vee}(\beta^\vee) = (s_\alpha(\beta))^\vee \in R^\vee$. In this way, we see $\alpha^\vee \vee = \alpha$, and $s_{\alpha^\vee}(\beta^\vee) - \beta^\vee = \beta^\vee(\alpha)\alpha^\vee$ is an integral multiple of $\alpha^\vee$. Also it can be seen easily from the formula above that the Weyl group is the same as the Weyl group of $R$.

Prop. (2.7.2.5) [Real Root Systems]. Let $R$ be a roots system in a vector space $V$ over a field $F$, and let $V_0$ be the $\mathbb{Q}$-vector space spanned by $R$, then $R$ is a root system in $V_0$ and $V_0 \otimes_{\mathbb{Q}} F \cong V$.

So from now on we focus on a real root system.
Proof: The non-trivial part is that the isomorphism $V_0 \otimes \mathbb{Q} \mathbb{F} \cong V$. The natural map $i : V_0 \otimes \mathbb{Q} \mathbb{F} \to V$ is surjective because $R$ generates $V$, and consider its transpose

$$i^* : V^\vee \to V_0^\vee \otimes \mathbb{Q} \mathbb{F},$$

then we can see that this maps $\alpha^\vee$ to $\alpha_0^\vee$, and $R_0^\vee$ is a root system in $V_0^\vee$, thus $\alpha_0^\vee$ generates $V_0^\vee$, and $i^*$ is surjective, showing $i$ is injective. \qed

**Def. (2.7.2.6)** [Base]. A subset $S \subset R$ is called a base of $R$ if every elements of $R$ can be written uniquely as a linear integral combination of elements of $S$ with the same sign.

If $S$ is a base of $R$, then we let $R^+$ denote the set of $R$ that is non-negative integral combinations of elements of $S$, called the positive roots of $R$, and $R^-$ the set of $R$ that is non-positive integral combinations of elements of $S$, called the negative roots of $R$. $R = R^+ \sqcup R^-.$

**Prop. (2.7.2.7)** [Base exists]. Let $t \in V^\vee$ be an element that $t(\alpha) \neq 0$ for all $\alpha \in R$. Let $R_t^+(R_t^-)$ be the set of all $\alpha \in R$ that $t(\alpha) > 0(<0)$, then $R = R_t^+ \cup R_t^-$. An element of $R_t^+$ is called indecomposable if it cannot be written as the sum of two elements in $R_t^+$. Let $S_t$ be the set of indecomposable elements of $R_t^+$, then $S_t$ is a base of $R$.

In particular, every root system $(R,V)$ contains a base. And if $S$ is a base and $t \in V^\vee$ that $t(S) > 0$, then $S = S_t$.

**Proof:** Cf.[Ser87]P38. \qed

**Cor. (2.7.2.8).** If $t \in V^\vee$ and $S_t$ is a basis of $V$ contained in $R_t^+$ that attains the minimal value of $t$ in $R_t^+$, then $S_t$ is a base of $R$.

**Prop. (2.7.2.9).** Let $S$ be a base of a root system $(R,V)$, then every positive root $\beta$ can be written as

$$\beta = \alpha_1 + \ldots + \alpha_k$$

in such a way that all the partial sums are roots.

**Proof:** Cf.[Ser87]P40. \qed

**Prop. (2.7.2.10).** Let $R$ be a reduced root system and $S$ a base, then for any $\alpha \in S$,

$$s_\alpha(R^+ \setminus \{\alpha\}) = R^+ \setminus \{\alpha\}.$$ 

In particular if $\rho = \frac{1}{2}(\sum_{\alpha \in R^+} \alpha)$, then $s_\alpha \rho = \rho - \alpha$.

**Proof:** If $\beta \in R^+$, then $s_\alpha(\beta) = \beta - c\alpha$ for some $c > 0$, Thus $s_\alpha(\beta) \in R^-$ iff $\beta = \alpha$. \qed

**Prop. (2.7.2.11)** [Base and Dual System]. Let $R$ be a reduced system and $S$ a base, then $S^\vee$ is a base of $R^\vee$.

**Proof:** By the isomorphism between $V$ and $V^\vee$, it suffices to show the vectors $\{\alpha^\vee, \alpha \in S\}$ is a base for $R^* = \{\alpha^\vee, \alpha \in R\}$. But it is clear if $S$ is a base corresponding to a vector $t \in V^*$, then $\{\alpha^\vee, \alpha \in S\}$ is the extremal vectors corresponding to $t$ too, so it is a base by(2.7.2.7). \qed
2.7. REFLECTION GROUPS AND COXETER GROUPS

Property of the Weyl Group

Prop. (2.7.2.12) [Weyl Group and Bases]. Let \( W \) be the Weyl group of a reduced root system \( R \) and \( S \) a base of \( R \), then
1. For any \( t \in V^* \), there exists \( w \in W \) that \( (w(t),\alpha) \geq 0 \) for all \( \alpha \in S \).
2. \( W \) acts transitively on the set of bases of \( R \).
3. For each \( \beta \in R \), there exists some \( w \in W \) that \( w(\beta) \in S \).
4. The group \( W \) is generated by \( s_\alpha \) where \( \alpha \in S \).
5. \( W \) acts simply transitively on the set of bases of \( R \).

Proof: We can in fact prove this for \( W_S \) the group generated by \( s_\alpha \) where \( \alpha \in S \).

1. Let \( \rho \) be defined in (2.7.2.10), and choose an element \( w \in W_S \) that \( w(t)(\rho) \) is maximal, then \( w(t)(\rho) \geq w(t)s_\alpha(\rho) = w(t)(\rho) - w(t)(\alpha) \). So \( (w(t),\alpha) \geq 0 \).
2. Let \( S' \) be a base and \( t' \in V^* \) that \( t'(S') > 0(2.7.2.7) \). Also by 1 we can find \( w \in W \) that \( w(t)(\alpha) \geq 0 \) for all \( \alpha \in S \). And in fact \( w(t)(\alpha) > 0 \) for all \( \alpha \in S \). So \( S = S t, S' = S_{w(t)} \). Thus \( w \) sends \( S' \) to \( S \).
3. Finally we prove that \( W_S = W \): because for any \( \beta \in R \), there exists \( w \in W_S \) that \( w(\beta) \in S \), so \( s_\beta = w^{-1}s_{w(\beta)}w \in W_S \).
4: See [Ser87]P70.

Def. (2.7.2.13) [Length]. Let \( w \in W \), define the length of \( w \) to be the minimal number \( m \) that \( w \) can be written as a product of \( m \) simple reflections \( s_i \).

Prop. (2.7.2.14). Let \( R \) be a root system with Weyl group \( W \), \( w \in W \).
- Let \( n(w) \) be the number of elements \( \alpha \in R^+ \) that \( w(\alpha) \in R^- \), then \( n(w) = l(w) \).
- There is a unique element \( w_0 \in W \) with length \( |R^+| \).
- \( w_0(R^+) = R^- \), and \( w_0^2 = \text{id} \).

Proof: 1: Cf.[Carter, P63].
2: By (2.7.2.12) there is a unique element \( w_0 \in W \) mapping \( S \) to \( -S \), and it has maximal length \( |R^+| \) by item1.
3: \( w_0^2(R^+) = R^- \), thus \( l(w_0^2) = 0 \) and \( w_0^2 = \text{id} \).

Def. (2.7.2.15) [Weyl Chambers]. Let \( (V,R) \) be a real root system, then a Weyl chamber is a connected component of \( V \setminus \bigcup_{\alpha \in R} H_\alpha \), where \( H_\alpha \) is the fixed hyperplane of vectors fixed by \( s_\alpha \).

Prop. (2.7.2.16). The Weyl group \( W \) acts transitively on the set of Weyl chambers of \( R \).

Proof: To show the action is transitive, if two Weyl chambers \( C, C' \) are adjacent with a common face \( F \subset H_\alpha \), then clearly \( s_\alpha(C) = C' \). In general, choose two generic vector in \( C, C' \) and connect them, then \( C, C' \) can be connected by adjacent chambers.
If \( w \in W \) satisfies \( w(C) = C \), we may assume \( C \) is the fundamental Weyl chamber, then \( w(S) = S \), so by (2.7.2.14), \( l(w) = 0 \), so \( w = \text{id} \).

Def. (2.7.2.17) [Height of Weights]. Let \( \alpha = \sum n_i\alpha_i \in R \), then the height of roots \( \alpha \) is denoted by \( \text{ht}(\alpha) = \sum n_i \).
Prop. (2.7.2.18) [Highest Root]. Let \((R, V)\) be a root system and \(S\) a base. If \(S\) is indecomposable, then there exists a root \(\bar{\alpha} = \sum_{\alpha \in S} n_\alpha \alpha\) that for any other root \(\sum_{\alpha \in S} m_\alpha \alpha, n_\alpha \geq m_\alpha\).

Proof: □

Def. (2.7.2.19) [Kostant’s Partition Function]. Let \(R\) be a root system, the Kostant’s partition function \(\Psi\) is a function on \(Q(R)\) that \(\Psi(\alpha)\) equals the number of ways to write \(\alpha\) as an unordered sum of positive roots in \(R^+\).

**Cartan Matrix and Dynkin Diagrams**

Prop. (2.7.2.20) [Angles Between Roots]. Let \(\alpha, \beta\) be two non-propositional roots in a root system \(R\), then we can put \(n(\alpha, \beta) = \alpha^\vee(\beta) = 2(\alpha, \beta)/(\alpha, \alpha)\). Then \(n(\alpha, \beta)\) are integers(2.7.2.1), and \(n(\alpha, \beta)n(\beta, \alpha) = 4 \cos^2 \varphi_{\alpha,\beta}\), where \(\varphi_{\alpha,\beta}\) is the angle between these two vectors. Then because \(4 \cos^2 \varphi_{\alpha,\beta}\) is an integer, it can only take values 0, 1, 2, 3. Then there are only 7 possibilities of the angles between \(\alpha, \beta\), and if \(\alpha, \beta\) are not orthogonal, their ration of lengths are determined also by the angle.

Prop. (2.7.2.21) [String of Roots]. If \(\alpha, \beta\) are not proportional and \(n(\beta, \alpha) > 0\), then \(\alpha - \beta\) is a root.

In particular, for \(\alpha, \beta \in S\) where \(S\) is a base of \(R\), \(n(\alpha, \beta) \leq 0\).

Proof: (2.7.2.20) shows \(n(\beta, \alpha) = 1\) or \(n(\alpha, \beta) = 1\). Now \(\alpha - \beta = s_\beta(\alpha)\) or \(-s_\alpha(\beta)\) is a root of \(R\). □

Def. (2.7.2.22) [Cartan Matrix]. Let \(R\) be a root system with a base \(S\). Then the Cartan matrix is \((n(\alpha, \beta))_{\alpha, \beta \in S}(2.7.2.20)\).

Prop. (2.7.2.23). The Cartan matrix depends only on \((V, R)\) and not on \(S\), and if \(R\) is reduced, \(R\) is determined by its Cartan matrix up to isomorphisms.

Proof: The first assertion follows from(2.7.2.12) as every two bases are conjugate. The Cartan matrix determines \(R\) because it determined the inner product between roots in a basis of \(V\). □

Prop. (2.7.2.24). Let \(E\) be the group of automorphisms of \(S\) that leaves that Cartan matrix invariant, then it can be identified with the set of automorphisms of \(R\) that leave the base \(S\) invariant. Then the group \(\text{Aut}(R)\) is isomorphic to the semi-product \(E \ltimes W\).

Proof: Let \(W\) is generated by \(s_\alpha\) so invariant under \(\text{Aut}(R)\). Now if \(u \in \text{Aut}(R)\), then \(u(S)\) is a base of \(R\), so there exists some \(w \in W\) that \(w(u(S)) = S\), thus \(u \in EW\). Also if \(w \in W \cap E\), then □

Def. (2.7.2.25) [Coxeter graph]. A coxeter graph is a finite graph that each pair of distinct vertices are connected by 0, 1, 2 or 3 vertices.

Def. (2.7.2.26) [Coxeter Graph associated to a Root System]. Let \((R, V)\) be a root system and \(S\) a base of \(R\), then the associated coxeter graph is a graph whose nodes are indexed by the elements of \(S\), and two distinct nodes \(\alpha, \beta\) are connected by \(a(\beta, \alpha)a(\alpha, \beta) = 4 \cos^2 \varphi_{\alpha,\beta}\) edges(2.7.2.20). This is independent of the choice of \(S\), by(2.7.2.23).

Prop. (2.7.2.27). \(R\) is indecomposable iff the Coxeter graph is connected.

Proof: By the formula in(2.7.1.4), \(R\) is decomposable iff \(R = R_1 \sqcup R_2\) where \(R_1, R_2\) are orthogonal to each other. Then this is equivalent to \(\varphi_{\alpha,\beta} = \pi/2\) for any \(\alpha \in R_1, \beta \in R_2\). □
3 Simple Root System

Lemma (2.7.3.1) [Listing of Indecomposable Root Systems]. The coxeter graphs $\Gamma$ arising from indecomposable root systems are exactly the graphs $A_n(n \geq 1), B_n(n \geq 2), D_n(n \geq 4), E_6, E_7, E_8, F_4, G_2$. (graphs are given in [Etingod, Lie algebras]P109.)

Proof: The existence is these types are given by (2.7.3.2).

For the converse, notice first that for a graph with vertices $v_i$ and $v_j$, $v_i, v_j$ are connected with $A_{ij}$ edges, the quadratic form

$$Q(x_1, \ldots, x_n) = \sum_{i=1}^{n} x_i^2 - \sum_{1 \leq i < j \leq n} \sqrt{A_{ij}}x_ix_j = \| \sum x_i v_i \|^2$$

is positive definite.

Next we show some constraints on the graph:

- Any subgraph of the coxeter graph, it can be shown that the corresponding quadratic form is also positive definite, in particular non-degenerate.
- If it is a tree: If it contains a circle, consider the subgraph of the circle, then the corresponding quadratic form vanishes on $(1, 1, \ldots, 1)$, contradiction.
- It doesn’t contains subgraphs listed in P77 of [Car05].

Now if $\Gamma$ contains a triple edge, then it must be $G_2$, otherwise it must contain a $\hat{G}_2$. If $\Gamma$ contains no triple edges, then it contains at most one double edge, otherwise it contains some $\hat{C}_l, l \geq 2$. If it contains only one double edge, then it contains no branch points, otherwise it contains some $\hat{B}_l, l \geq 3$, so it is a chain with an edge added. If the double edge is in one end, then it is $B_l$ for some $l \geq 3$, otherwise it must by $F_4$, in order not to contain $\hat{F}_4$.

Now we assume $\Gamma$ contains only simple edges. If it contains no branch point, then it is $A_l$ for some $l \geq 1$. But $\Gamma$ contains at most one branch point, and only 3 edges, otherwise it contains some $\hat{D}_l, l \geq 4$. If $\Gamma$ has only one branch point, then the graph is a center with three branches. One of the branch must be a single vertex, otherwise it contains a $\hat{E}_6$. Then a second branch must has $\leq 2$ vertices, otherwise it contains a $\hat{E}_7$. If the second branch has a single vertex, then $\Gamma \cong D_l$ for some $l \geq 4$. If the second branch has two vertices, then the third branch has $\leq 4$ vertices, otherwise it contains some $\hat{E}_8$. So $\Gamma \cong E_6, E_7$ or $E_8$. \qed

Prop. (2.7.3.2) [Listing of Indecomposable Root Systems]. Let $e_n$ be the standard basis of $\mathbb{R}^n$ with the standard bilinear form, and let $L_n$ be the subgroup generated by $e_n$. Then

- $A_n$: Let $V$ be the hyperplane of $\mathbb{R}^{n+1}$ orthogonal to the vector $e_1 + \ldots + e_{n+1}$, and $R$ be the subset of $L_{n+1} \cap V$ consisting of vectors of length $\sqrt{2}$. Then $(R, V)$ is a root system, and the Weyl group is the permutation group $S_n$ of $e_1, \ldots, e_{n+1}$. The polarization with $t(e_i) = n+1-i$ gives a base consisting of $\{e_i - e_{i+1}, i = 1, \ldots, n\}$ by (2.7.2.8).

- $B_n$: Let $V = \mathbb{R}^n$ and $R$ be the subset of $L_n$ consisting of vectors of length 1 or $\sqrt{2}$. Then $(R, V)$ is a root system, and the Weyl group is the permutation and sign changes of the vectors $e_i$, isomorphic to $\mathbb{Z}_2^n \times S_n$. The polarization with $t(e_i) = n+1-i$ gives a base consisting of $\{e_1 - e_2, \ldots, e_{n-1} - e_n, e_n\}$ by (2.7.2.8).

- $C_n$: Let $C_n$ be the dual system of $B_n(2.7.2.4)$, which by the invariant form isomorphic to the set of $\mathbb{R}^n$ consisting of vectors $\pm e_i \pm e_j, \pm 2e_i$. It has the same Weyl group as $B_n$. It has a base consisting of $\{e_1 - e_2, \ldots, e_{n-1} - e_n, 2e_n\}$ by (2.7.2.8).
• $D_n$: Let $V = \mathbb{R}^n$ and $R$ be the set of all vectors of $L_n$ of length $\sqrt{2}$. The Weyl group consists of permutations and sign changes of an even number of the vectors $e_i$. The polarization with $t(e_i) = n - i$ gives a base consisting of $\{e_1 - e_2, \ldots, e_{n-1} - e_n, e_n - e_1 + e_{n-1}\}$.

• $G_2$: Let $V = \mathbb{R}[\omega]$ and $R$ be the subset of $\mathbb{Z}[\omega]$ of norm 1 or 3. The Weyl group is isomorphic to the dihedral group. It clearly has a base consisting of $\{1, \omega - 1\}$.

• $F_4$: Let $V = \mathbb{R}^4$, and let $R$ be the set of vectors $\{\pm e_i, \pm e_i \pm e_j, \frac{1}{2}(\pm e_1 \pm e_2 \pm e_3 \pm e_4)\}$. It can be shown this is a root system. The polarization with

$$t(e_1) = 8, t(e_2) = 3, t(e_3) = 2, t(e_3) = 1,$$

gives a base consisting of $\{e_2 - e_3, e_3 - e_4, e_4, \frac{1}{2}(e_1 - e_2 - e_3 - e_4)\}$.

• $E_8$: Let $V = \mathbb{R}^8$ and

$$R_{E_8} = \{\pm e_i \pm e_j, i \neq j\} \cup \left\{\frac{1}{2}\sum_{i=1}^{8} \pm e_i\right\} \text{with even number of minus signs}\}.$$

The polarization with

$$t(e_1) = 23, t(e_2) = 6, t(e_3) = 5, \ldots, t(e_8) = 0$$

gives a base consisting of $\{e_2 - e_3, \ldots, e_7 - e_8, e_7 + e_8, \frac{1}{2}(e_1 - e_2 - \ldots - e_7 + e_8)\}$.

• $E_7$: $E_7$ is the intersection of $E_8$ with the hypersurface $\sum x_i = 0$, so

$$R_{E_7} = \{\pm(e_i - e_j), i \neq j\} \cup \left\{\frac{1}{2}\sum_{i=1}^{8} \pm e_i\right\} \text{with 4 minus signs}\}.$$

The polarization with

$$t(e_1) = 18, t(e_2) = 7, t(e_3) = 6, \ldots, t(e_8) = 1$$

gives a base consisting of $\{e_2 - e_3, \ldots, e_7 - e_8, \frac{1}{2}(e_1 - e_2 - e_3 - e_4 - e_5 + e_6 + e_7 + e_8)\}$.

• $E_6$: $E_6$ is the intersection of $E_7$ with the hypersurface $x_7 + x_8 = 0$.

$$R_{E_6} = \{\pm(e_i - e_j)|i \neq j \leq 6\} \cup \{\pm(e_7 - e_8)\} \cup \left\{\frac{1}{2}(\pm e_1 \pm e_2 \pm \ldots \pm e_7) \pm \frac{1}{2}(e_7 - e_8)\right\} \text{with 3 minus signs before } v_i, i \leq 6\}.$$

The polarization

$$t(e_1) = 11, t(e_2) = 4, t(e_3) = 3, t(e_4) = 2, t(e_5) = 1, t(e_6) = 0, t(e_7) = 4, t(e_8) = 3$$

gives a base consisting of $\{e_2 - e_3, \ldots, e_5 - e_6, e_7 - e_8, \frac{1}{2}(e_1 - e_2 - e_3 - e_4 - e_5 + e_6 - e_7 + e_8)\}$.

$$A_n^\vee \cong A_n, B_n^\vee \cong C_n, D_n^\vee \cong D_n, G_2^\vee \cong G_2, F_4^\vee \cong F_4, E_8^\vee \cong E_8, E_7^\vee \cong E_7, E_6^\vee \cong E_6.$$  

Remark (2.7.3.3). The polarizations $t$ are intimately related to the averaged coroot $\rho^\vee(2.7.3.12)$.

Def. (2.7.3.4) [Dynkin Diagram]. The coxeter graph cannot determine the root system up to isomorphism, because it cannot distinguish between $n(\alpha, \beta)$, $n(\beta, \alpha)$. So there is a Dynkin diagram which is constructed from the coxeter diagram by adding a vector from the longer vector to the shorter vector when $n(\alpha, \beta)n(\beta, \alpha) = 2$ or 3.
Prop. (2.7.3.5) [Listing of Dynkin Diagrams]. The Dynkin diagrams arising from indecomposable root systems are exactly the diagrams $A_n (n \geq 1), B_n (n \geq 2), C_n (n \geq 3), D_n (n \geq 4), E_6, E_7, E_8, F_4, G_2$. (Graphs are given in [Etingof, Lie algebras] P109.)

Proof: This follows easily from (2.7.3.1) and (2.7.3.2). \hfill \Box

Prop. (2.7.3.6) [Non-Reduced Root Systems]. For any $n \geq 1$, there is exactly one non-reduced indecomposable root system of rank $n$, which is $BC_n$, the union of $B_n$ and $C_n$ in (2.7.3.2).

Cor. (2.7.3.7). Cf. [Kna96] P139.

Weight Lattices

Def. (2.7.3.8) [Weight Lattice]. Let $(R, V)$ be a root system, we can define the root lattice as the $\mathbb{Z}$-lattice $Q(R)$ generated by $R$, and also the weight lattice $P(R) = \{ x \in V | \alpha^\vee (x) \in \mathbb{Z}, \forall \alpha \in R \}$ $P(R)$ has a generator by fundamental weights $\omega_i$ that $(\omega_i, \alpha_j^\vee) = \delta_{ij}$. Then $Q(R) \subset P(R)$, and $[P(R) : Q(R)]$ is finite as they are both complete lattices.

Prop. (2.7.3.9). Let $\rho = 1/2 \sum_i \alpha_i$, then $\rho = \sum_i \omega_i$.

Proof: It follows from (2.7.2.10) that $s_\alpha \rho = \rho - \alpha$, so $(\rho, \alpha_i^\vee) = 1$, thus $\rho = \sum_i \omega_i$ by definition (2.7.2.10). \hfill \Box

Prop. (2.7.3.10) [Weight Lattices of Indecomposable Root Systems]. Let $R$ be a root system, notation as in (2.7.3.2),

- $A_n$: $\alpha_i^\vee = \alpha_i$ for $i \leq n$, so $\omega_i = \left(\frac{n+i}{n+1}, \ldots, \frac{n+1}{n+2}, \ldots, \frac{n+1}{n+1}\right)$ $(i \text{ terms})$ for $1 \leq i \leq n$. Then $P = \{ (x_i) \in \mathbb{R}^n | x_i - x_j \in \mathbb{Z} \sum x_i = 0 \}, Q = \{ (x_i) \in \mathbb{Z}^n | \sum x_i = 0, \}$ and $P/Q \cong \mathbb{Z}/(n+1)\mathbb{Z}$.

- $B_n$: $\alpha_i^\vee = \alpha_i$ for $i < n$ and $\omega_n = (\frac{1}{2}, \ldots, \frac{1}{2})$. Then $P = \mathbb{Z}^n$ and $Q = \mathbb{Z}^n \cup \left(\frac{1}{2}, \ldots, \frac{1}{2}\right) + \mathbb{Z}^{n}, P/Q \cong \mathbb{Z}/2\mathbb{Z}$.

- $C_n$: $\alpha_i^\vee = \alpha_i$ for $i < n$ and $\omega_n = (\frac{1}{2}, \ldots, \frac{1}{2})$. Then $P = \{ (x_i) \in \mathbb{Z}^n | \sum x_i = 2 \mathbb{Z} \}$ and $Q = \mathbb{Z}^n, P/Q \cong \mathbb{Z}/2\mathbb{Z}$.

- $D_n$: $\alpha_i^\vee = \alpha_i$ for $i \leq n$, so $\omega_i = (1, \ldots, 1, 0, 0, \ldots, 0) (i\ \text{ones})$ for $1 \leq i \leq n-2$, $\omega_{n-1} = (1, 2, 1, \ldots, 1), \omega_n = (1, 2, 1, \ldots, 1, 2)$. So $P/Q \cong (\mathbb{Z}/2\mathbb{Z})^2$ for even $n$ and $\mathbb{Z}/4\mathbb{Z}$ for $n$ odd.

- $G_2$: It is clear $\omega_1 = \omega + 1, \omega_2 = 2\omega + 1$. Then $P = Q = \mathbb{Z}[\omega]$.

- $F_4$: $\omega_1 = (1, 1, 0, 0), \omega_2 = (2, 1, 1, 0), \omega_3 = (\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2}), \omega_4 = (1, 0, 0, 0)$. So $P = Q = \frac{1}{2}\mathbb{Z}^4$.

- $E_8$: $\omega_1 = (1, 1, 0, \ldots, 0), S = Q = \{ (x_1, \ldots, x_8) | x_i \in \mathbb{Z} \text{ or } x_i \in \frac{1}{2} \mathbb{Z}, \sum x_i \in 2\mathbb{Z} \}$.

- $E_7$: $P/Q \cong \mathbb{Z}/2\mathbb{Z}$.

- $E_6$: $\omega_1 = (1, 1, 0, \ldots, 0), P/Q \cong \mathbb{Z}/3\mathbb{Z}$.

Proof: \hfill \Box

Prop. (2.7.3.11) [Maximal Roots]. For $A_n$, the maximal root is $\theta = e_1 - e_{n+1} = \alpha_1 + \ldots + \alpha_n = \omega_1 + \omega_n$. For $C_n$, the maximal root is $\theta = 2e_1 = 2\alpha_1 + \ldots + 2\alpha_{n-1} + \alpha_n = 2w_1$.

But for any other indecomposable root system $R$, the maximal root $\theta$ is a fundamental root:

- $B_n$: $\theta = e_1 + e_2 = \alpha_1 + 2\alpha_2 + \ldots + 2\alpha_{n-1} = \omega_2$.

- $D_n$: $\theta = e_1 + e_2 = \alpha_1 + 2\alpha_2 + \ldots + 2\alpha_{n-2} + \alpha_{n-1} + \alpha_n = \omega_2$. 

• $G_2$: $\theta = 2\omega + 1 = 3\alpha_1 + 2\alpha_2 = \omega_2$.
• $F_4$: $\theta = e_1 + e_2 = 2\alpha_1 + 3\alpha_2 + 4\alpha_3 + 2\alpha_4 = \omega_1$.
• $E_8$: $\theta = e_1 + e_2 = 2\alpha_1 + 3\alpha_2 + 4\alpha_3 + 5\alpha_4 + 6\alpha_5 + 4\epsilon_6 + 3e_7 + 2e_8 = \omega_1$.
• $E_7$: $\theta = e_1 - e_8 = \alpha_1 + 2\alpha_2 + 3\alpha_3 + 4\alpha_4 + 3\alpha_5 + 2\alpha_6 + 2\alpha_7 = \omega_6$.
• $E_6$: $\theta = e_1 - e_8 = \alpha_1 + 2\alpha_2 + 3\alpha_3 + 2\alpha_4 + \alpha_5 + 2\alpha_6 = \omega_4$.

Prop. (2.7.3.12) [$\rho$ and $\rho^\vee$]. $\rho^\vee$ is $\rho$ of the dual system $R^\vee$. Under the identification of $V$ and $V^*$, If $(R, S)$ is simply laced, then $R \cong R^\vee$ via $\alpha \mapsto \alpha^\vee$, so by (2.7.3.10),

- $A_n: \rho_{A_n} = \rho_{A_n}^\vee = (\frac{n}{2}, \frac{n-2}{2}, \ldots, -\frac{n}{2}) = \sum_i \frac{i(n+1-i)}{2} \alpha_i$.
- $B_n: \rho_{B_n} = \rho_{B_n}^\vee = (\frac{2n-1}{2}, \frac{2n-3}{2}, \ldots, \frac{1}{2}) = \sum_i \frac{i(n-i)}{2} \alpha_i$.
- $C_n: \rho_{C_n} = \rho_{C_n}^\vee = (n, n-1, \ldots, 1) = \sum_{i \leq n} \frac{i(2n+1-i)}{2} \alpha_i + \frac{n(n+1)}{4} \alpha_n$.
- $D_n: \rho_{D_n} = \rho_{D_n}^\vee = (n-1, n-2, \ldots, 0) = \sum_{i \leq n-2} \frac{i(2n-1-i)}{2} \alpha_i + \frac{1}{2} \alpha_{n-1} + \frac{n(n-1)}{4} \alpha_n$.
- $G_2: \rho_{G_2} = 3\omega + 2 = 5\alpha + 3\beta, \rho_{G_2}^\vee = \frac{10}{3}\omega + \frac{8}{3} = 6\alpha + \frac{10}{3}\beta$.
- $F_4: \rho_{F_4} = (\frac{11}{2}, \frac{5}{2}, \frac{3}{2}, \frac{1}{2}), \rho_{F_4}^\vee = (8, 3, 2, 1)$.
- $E_6: \rho_{E_6} = \rho_{E_6}^\vee = (23, 6, 5, 4, 3, 2, 1, 0)$.
- $E_7: \rho_{E_7} = \rho_{E_7}^\vee = (18, 7, 6, \ldots, 1) - (\frac{23}{4}, \ldots, \frac{23}{4})$.
- $E_8: \rho_{E_8} = \rho_{E_8}^\vee = (\frac{15}{2}, \frac{1}{2}, -\frac{1}{2}, -\frac{3}{2}, -\frac{5}{2}, -\frac{7}{2}, -\frac{1}{2}, -\frac{1}{2})$.

Def. (2.7.3.13) [Coxeter Numbers]. Let $(R, S)$ be an indecomposable root system, defined the Coxeter root to be $h_R = (\theta, \rho^\vee) + 1 = \text{ht}(\theta) + 1$, and the dual Coxeter number $h_R^\vee = (\rho, (\theta)^\vee) + 1$. Clearly if $(R, S)$ is simply laced, then $R \cong R^\vee$ via $\alpha \mapsto \alpha^\vee$, so if $\theta = \sum m_i \alpha_i$, then $\theta^\vee = \sum m_i \alpha_i^\vee$, so $h_R^\vee = h_R = \sum m_i + 1$.

Prop. (2.7.3.14) [Listing of Coxeter Numbers]. We can determine the Coxeter numbers and dual coxeter numbers of indecomposable root systems:

- $h_{A_n} = h_{A_n}^\vee = n + 1$.
- $h_{B_n} = 2n$, and $\theta^\vee = e_1 + e_2 = \alpha_1^\vee + 2\alpha_2^\vee + \ldots + \alpha_n^\vee$, so $h_{B_n}^\vee = 2n - 1$.
- $h_{C_n} = 2n$, and $\theta^\vee = e_1 = \alpha_1^\vee + \ldots + \alpha_n^\vee$, so $h_{C_n}^\vee = n + 1$.
- $h_{D_n} = h_{D_n}^\vee = 2n - 2$.
- $h_{G_2} = 6$, and $\theta^\vee = \frac{2}{3}(2\omega + 3) = \alpha_1^\vee + 2\alpha_2^\vee$, so $h_{G_2}^\vee = 4$.
- $h_{F_4} = 12$, and $\theta^\vee = e_1 + e_2 = 2\alpha_1^\vee + 3\alpha_2^\vee + 2\alpha_3^\vee + \alpha_4^\vee$, so $h_{F_4}^\vee = 9$.
- $h_{E_6} = h_{E_6}^\vee = 30$.
- $h_{E_7} = h_{E_7}^\vee = 18$.
- $h_{E_8} = h_{E_8}^\vee = 12$.

Minuscule Weights

Def. (2.7.3.15) [Minuscule Weights]. Let $(R, S)$ be a root system, then a dominant weight $\omega$ is called minuscule if $(\omega, \beta^\vee) \leq 1$ for any positive coroot $\beta^\vee$. 
Prop. (2.7.3.16) [Minuscule and Fundamental Weights]. Let $\theta^\vee = \sum m_i \alpha_i^\vee$ the maximal coroot, where $m_i$ are positive integers, and $m_i = (\omega_i, \theta^\vee)$. Then any minuscule weight is fundamental, and a fundamental weight $\omega_i$ is minuscule if $m_i = 1$.

Proof: The definition of minuscule weight requires $m_i \leq 1$, and any other coroot is of the form $\beta^\vee = \sum n_i \alpha_i^\vee$, where $n_i \leq m_i$, so $n_i = (\omega_i, \beta^\vee) \leq 1$. \hfill $\square$

Lemma (2.7.3.17). If $\omega \in Q$ and $|(\omega, \beta^\vee)| \leq 1$ for any coroot $\beta$, then $\omega = 0$.

Proof: If not, choose a counterexample $\omega = \sum m_i \alpha_i$ with $\sum |m_i| > 0$ minimum, then $(\omega, \omega) = \sum m_i (\omega, \alpha_i^\vee) > 0$, so changing $\omega$ to $-\omega$ if necessary, we can assume $m_i > 0$, $(\omega, \alpha_i^\vee) > 0$ for some $i$, so $(\omega, \alpha_i^\vee) = 1$, and $s_i \omega = \omega - \alpha_i$ is another counterexample with smaller $|m_i|$, contradiction. \hfill $\square$

Prop. (2.7.3.18). The following are equivalent for a dominant integral weight $\omega$ of a root system:

- $\omega$ is minuscule (2.7.3.15).
- If $\lambda$ is a dominant integral weight and $\omega - \lambda \in Q^+$, then $\lambda = \omega$.

Proof: Cf. [Etingof, P141]? \hfill $\square$

Prop. (2.7.3.19) [Number of Minuscule Roots]. Every coset in $P/Q$ contains a unique minuscule weight. This gives a bijection between the $P/Q$ and the set of minuscule weights. In particular, the number of minuscule weights equals the determinant of the Cartan matrix.

Proof: For any $a \in P$, let $C = a + Q$ be a coset, let $\omega \in C \cap P^+$ be an element with minimum $(\omega, \rho)$, then for any dominant weight $\lambda < \omega \in C$, $(\omega - \lambda, \rho) \geq 0$, so $\lambda = \omega$. Thus $\omega$ is minuscule (2.7.3.18).

Conversely, if $\omega_1 \neq \omega_2 \in C$ are minuscule, then by (2.7.3.17), there is a positive coroot $\beta^\vee$ that $|(\omega_1 - \omega_2, \beta)| > 2$. But then as $\omega_1, \omega_2$ are both dominant, $|(\omega_1 - \omega_2, \beta)| \leq 1$, contradiction. \hfill $\square$

Cor. (2.7.3.20) [Listing of Minuscule Weights]. By (2.7.3.19) and (2.7.3.2)(2.7.3.10), we can determine minuscule weights for indecomposable root system $(R, S)$,

- $A_n$: $P/Q \cong \mathbb{Z}/(n + 1)\mathbb{Z}$, so it has $n + 1$ minuscule weight, which are all the fundamental weights $\omega_i$ and 0.
- $B_n$: $P/Q \cong \mathbb{Z}/2\mathbb{Z}$, so there is exactly one non-zero minuscule weight, which is $\omega_n = (\frac{1}{2}, \ldots, \frac{1}{2})$, by (2.7.3.18).
- $C_n$: $P/Q \cong \mathbb{Z}/2\mathbb{Z}$, so there is exactly one non-zero minuscule weight, which is $\omega_n = (1, 0, \ldots, 0)$, by (2.7.3.18). The corresponding fundamental representation is the standard representation of $\mathfrak{sp}_{2n}$.
- $D_n$: $|P/Q| = 4$, so there are exactly 3 non-zero minuscule weights, which are $\omega_1, \omega_{n-1}$ and $\omega_n$, with corresponding fundamental representations of dimension $2n, 2^{n-1}, 2^{n-1}$. This is because the maximal coroot $\beta^\vee = \alpha_1^\vee + 2\alpha_2^\vee + \ldots + 2\alpha_{n-2}^\vee + \alpha_{n-1}^\vee + \alpha_n^\vee$.
- $G_2$: $|P/Q| = 1$, so there are no non-zero minuscule weights.
- $F_4$: There are no non-zero minuscule weights.
- $E_8$: There are no non-zero minuscule weights.
- $E_7$: $P/Q \cong \mathbb{Z}/2\mathbb{Z}$, so there is exactly one non-zero minuscule weight.
- $E_6$: $P/Q \cong \mathbb{Z}/3\mathbb{Z}$, so there are exactly two non-zero minuscule weights.
Prop. (2.7.3.21) \([w_0]\). Notice \(-w_0\) is an automorphism of \((R, S)\) that permutes fundamental weights and simple roots, so it induces an automorphism of the Dynkin diagram of \(R\). So if the Dynkin diagram of \(g\) has no non-trivial automorphism, \(w_0 = -1\). This is case for \(R = A_1, B_n, C_n, G_2, F_4, E_7\) and \(E_8\).

For \(D_n\), if \(n\) is even, then \(-1 \in W\) so \(w_0 = -1\). If \(n\) is odd, then \(w_0(e_i) = -e_i\) for \(i < n\) and \(w_0(e_n) = e_n\).

Notice also each \(s_i\) acts trivially on \(P / Q\), so \(-w_0\) acts by \(-1\) on \(P / Q\). For \(A_n, n \geq 2\), \(P / Q \cong \mathbb{Z} / (n + 1)\mathbb{Z}\), thus \(-w_0\) is the flip of the chain. Likewise for \(E_6\), \(P / Q \cong \mathbb{Z} / 3\mathbb{Z}\), thus \(-w_0\) flips the two minuscule weights. But for \(D_n\), \(P / Q \cong \mathbb{Z} / 2\mathbb{Z} \times \mathbb{Z} / 2\mathbb{Z}\) for \(n\) even and \(P / Q \cong \mathbb{Z} / 4\mathbb{Z}\) for \(n\) odd, so \(-w_0\) preserves the minuscule weights or flip \(w_{n-1}\) and \(w_n\).

4 Notations for a Root System

Def. (2.7.4.1) [Notations for a Root System]. Let \((R, S)\) be a root system, then

- \(R^+ / R^-\) is the positive/negative roots w.r.t. \(S\).
- \(S = \{\alpha_1, \ldots, \alpha_r\}\).
- \(s_i\) is the reflection w.r.t. \(\alpha_i\).
- \(\theta\) is the maximal root.
- \(\theta^\vee\) is the maximal coroot (maximal root of the dual root system). (It may not be dual to \(\theta\))
- \(\rho = \frac{1}{2} \sum_i \alpha_i = \sum \omega_i\).
- \(\rho^\vee\) is \(\rho\) of the dual system \(R^\vee\).
- The height of weights is defined as in (2.7.2.17).
- \(W\) is the Weyl group.
- \(w_0 \in W\) is the unique element with length \(|R^+|\) (2.7.2.14).
- \(n_{ij}\) is the Cartan number \(n(\alpha_i, \alpha_j)\).
- \(Q(R)\) is the root lattice (2.7.3.8).
- \(P(R)\) is the weight lattice, generated by the fundamental weights \(\omega_i\) (2.7.3.8).
- \(P^+(R)\) is the dominant integral weights.
- \(\mathcal{P}\) is the Kostant partition function on \(Q(R)\).
2.8 Algebraic K-Theory

Main references are [Algebraic K-Theory of Fields, Suslin, in Proc. ICM 1986, P222-244] and [G-S17].

1 Milnor K-Groups of Fields

Def.(2.8.1.1) $[K_0]$. The Grothendieck group $K_0(A)$ for a ring $A$ is the free group generated by f.g. projective module over $A$ modulo exact sequences. Then we have $P \sim Q$ iff $P \oplus A^n \cong Q \oplus A^n$ for some $n$. This is a functor $\mathcal{C}_{\text{Alg}} \to \mathcal{A}_{\text{Ab}}$.

Def.(2.8.1.2) [Milnor K-Groups]. For $k \in \text{Field}$, define the $n$-th Milnor K-group to be the groups

\[ K_0^{\text{Mil}}(k) = \mathbb{Z}, \quad K_1^{\text{Mil}}(k) = k^\times, \quad K_n^{\text{Mil}}(k) = (k^\times)^{\otimes n}/\{a_1 \otimes \ldots \otimes a_n \mid \exists 1 \leq i < j \leq n, a_i + a_j = 1\}, n \geq 2 \]

The elements in $K_n^{\text{Mil}}(k)$ are called symbols, and the class of $a_1 \otimes \ldots \otimes a_m$ is denoted by $\{a_1, \ldots, a_n\}$.

Prop.(2.8.1.3) [Total Milnor K-Groups]. For $m, n \in \mathbb{N}$, the tensor product $(k^\times)^{\otimes m} \times (k^\times)^{\otimes n} \to (k^\times)^{\otimes (m+n)}$ induces a surjective map

\[ K_m^{\text{Mil}}(k) \otimes K_m^{\text{Mil}}(k) \to K_{m+n}^{\text{Mil}}(k), \]

which induces a graded group structure on

\[ K_*^{\text{Mil}}(k) = \bigoplus_{n \in \mathbb{N}} K_n^{\text{Mil}}(k). \]

Then $K_*^{\text{Mil}}(k)$ is graded commutative.

Proof: Firstly we show that $\{x, -x\} = 0$: Because

\[ \{x, -x\} + \{x, -(1 - x)x^{-1}\} = \{x, 1 - x\} = 0, \]

Thus

\[ \{x, -x\} = -\{x, 1 - x^{-1}\} = \{x^{-1}, 1 - x^{-1}\} = 0. \]

Then the general case follows by induction. □

Prop.(2.8.1.4) [Finite Fields]. If $k \in \text{Field}$, $\# k < \infty$, for any $n \geq 2$, $K_n^{\text{Mil}}(k) = 0$.

Proof: By(2.8.1.3), it suffices to show that $K_2^{\text{Mil}}(k) = 0$. And if $\omega$ is a generator of the cyclic group $k^\times$, then it suffices to show that $\{\omega, \omega\} = \{\omega, -1\} = 0$. If $\# k = 2^m$, then

\[ 0 = \{1, \omega\} = \{\omega^{2^m-1}, \omega\} = (2^m - 1)\{\omega, \omega\}, \]

thus we are done. And if char $k \neq 2$, then we can find two non-squares in $k^\times$ s.t. $a + b = 1$. Then

\[ 0 = \{a, b\} = \{\omega^i, \omega^k\} = kl\{\omega, \omega\}, \]

so $\{\omega, \omega\} = 0$. □
Def. (2.8.1.5) [Residue Maps and Specialization Maps]. Let \((R, K, k)\) be a DVR, then for any \(n \in \mathbb{Z}_+\), there exists a unique homomorphism
\[ \partial^\text{Mil}_n : K_n^\text{Mil}(K) \to K_{n-1}^\text{Mil}(k) \]

s.t. for any uniformizer \(\varpi\) and units \(u_1, \ldots, u_{n-1} \in R^*\),
\[ \partial^\text{Mil}_n(\{\varpi, u_1, \ldots, u_{n-1}\}) = \{\overline{u}_1, \ldots, \overline{u}_{n-1}\}. \]

Moreover, for any uniformizer \(\varpi\) and \(n \in \mathbb{Z}_+\), there exists a specialization map
\[ s^\text{Mil}_{\varpi} : K_n^\text{Mil}(K) \to K_n^\text{Mil}(k) \]

s.t.
\[ s^\text{Mil}_{\varpi}(\{\varpi^1 u_1, \ldots, \varpi^n u_n\}) = \{\overline{u}_1, \ldots, \overline{u}_n\} \]

for any \(u_1, \ldots, u_n \in R^*\).

Cor. (2.8.1.6). \(\partial^\text{Mil}_n(\{a, b\}) = (-1)^{v(a)v(b)}a^{-v(b)}b^{v(a)}\).

Proof:

Thm. (2.8.1.7) [Berrick-Keating]. Let \(R, S \in \text{Ring} \) and \(U \in \text{Mod}_{R,S}\), let \(T = \begin{bmatrix} R & U \\ S & \end{bmatrix} \in \text{Ring}\), then the map
\[ \pi_i : K_i(T) \to K_i(T) \oplus K_i(S) \]

is an isomorphism for any \(i \in \mathbb{Z}\).

Prop. (2.8.1.8) [Matsumoto]. For \(k \in \text{Field}\), \(K_2^\text{Mil}(k) \cong K_2(k)\).

Proof:

2 Bloch-Kato Conjecture

Lemma (2.8.2.1) [Hilbert’s Theorem90 for \(K_2\)]. Let \(K/k\) be a cyclic Galois field extension with a generator \(\sigma \in \text{Gal}(K/k)\), then the complex
\[ K_2^\text{Mil}(K) \xrightarrow{\sigma^{-1}} K_2^\text{Mil}(K) \xrightarrow{\text{Nm}_{K/k}} K_2^\text{Mil}(k) \]

is exact.

Prop. (2.8.2.2) [Galois Symbols]. Let \( k \in \text{Field}, m \in \mathbb{Z} \cap k^\times, n \in \mathbb{Z}_+ \), the boundary map
\[
\partial k^\times \to H^1(k, \mu_m)
\]
induces a map
\[
\partial^n : (k^\times)^{\otimes n} \to (H^1(k, \mu_m))^{\otimes n} \cup H^n(k, \mu_m^{\otimes n}),
\]
and this map factors through \( K_n^{\text{Mil}}(k) \) and gives a Galois symbol map
\[
h_{k,m}^n : K_n^{\text{Mil}}(k) \to H^n(k, \mu_m^{\otimes n}).
\]

**Proof:** To show this map factors through \( K_n^{\text{Mil}}(k) \), it suffices to show for \( n = 2 \) and \( \partial^2(a \otimes (1-a)) = 0 \). Take an irreducible factorization
\[
x^m - a = \prod_l f_l \in k[x],
\]
and let \( \alpha_l \) be a root of \( f_l \) in \( k_{\text{sep}}, K_l = k(\alpha_l) \), then
\[
(1 - a) = \prod_l \text{Nm}_{K_l/k}(1 - \alpha_l).
\]
and
\[
\partial^2(a \otimes (1-a)) = \sum_l \partial^2(a \otimes \text{Nm}_{K_l/k}(1 - \alpha_l)).
\]
But
\[
\partial^2(a \otimes \text{Nm}_{K_l/k}(1 - \alpha_l)) = \partial(a) \cup \partial(\text{Nm}_{K_l/k}(1 - \alpha_l)) = \partial(a) \cup \text{cor}^K_{\alpha_l} \text{res}^K_{K_l}(a) \cup (1 - \alpha_l) = \text{cor}(\text{res}^K_{K_l}(a) \cup (1 - \alpha_l))
\]
But by definition \( a \in (K_l^\times)^m \), so \( \partial_{K_l}(a) = 0 \), by (10.1.3.9). Thus \( \partial^2(a \otimes (1-a)) = 0 \). \( \square \)

Thm. (2.8.2.3) [Bloch-Kato Conjecture, Voevodsky-Rost/Merkurjev-Suslin]. Situation as in (2.8.2.2), the Galois symbol (2.8.2.2) induces an isomorphism
\[
K_n^{\text{Mil}}(k)/mK_n^{\text{Mil}}(k) \xrightarrow{\cong} H^n(k, \mu_m^{\otimes n}).
\]

**Proof:** The \( n = 1 \) case follows from (10.1.3.9).
For the \( n = 2 \) case? \( \square \)

## 2.9 Hopf Algebras

Main references are [Quantum Groups, Drinfeld], [A Brief Introduction To Quantum Groups Pavel Etingof And Mykola Semenyakin].

### 1 Hopf Algebras

#### Coalgebras and Bialgebras

**Def.(2.9.1.1) [Coalgebras].** Let $R$ be a commutative ring, a **coalgebra** is a monoid object in the category $\text{Mod}^R_R$.

**Remark(2.9.1.2) [Yoneda Interpretation].** We do not need to verify all the relations defining a coalgebra $C$, whenever we have a functorial monoidal structure on all the set $\text{Hom}_R(H,T)$, we immediately recover the maps

- (Comultiplication): $\mu : C \to C \otimes_R C$ as $i_1 \cdot i_2$ in $\text{Hom}_R(C,C \otimes C)$,
- (Counit): $\varepsilon : C \to R$ as $1$ in $\text{Hom}_R(C,R) = C^\vee$.

by Yoneda lemma.

$C^\vee$ is an monoid by definition, and $C$ is called **cocommutative** iff $C^\vee$ is commutative.

**Def.(2.9.1.3) [Primitive Elements].** Let $H$ be a coalgebra over $R$, an element $x \in H$ is called **primitive** if $\mu(x) = 1 \otimes x + x \otimes 1$. It is called **group-like** if $\Delta(x) = x \otimes x$.

**Def.(2.9.1.4) [Bialgebras].** Let $R$ be a commutative ring, a **bialgebra** is a monoid object in the category of coalgebras over $R$. Equivalently, in the Yoneda interpretation, $C$ is an $R$-algebra that $\Delta$ is a homomorphism of algebras.

**Def.(2.9.1.5) [Hopf Algebra].** A **Hopf algebra** over a commutative algebra $R$ is a bialgebra $A$ together with a $R$-linear map $S : A \to A$ that satisfies:

$$m \circ (\text{id} \otimes S) \circ \mu = m \circ (S \otimes \text{id}) \circ \mu = \eta \circ \varepsilon : A \to A.$$ 

If $S^2 = \text{id}_A$, then $A$ is called an **involutive Hopf algebra**.

**Prop.(2.9.1.6).** In a Hopf algebra, $S$ is an anti-homomorphism both for the algebra structure and coalgebra structure.

**Example(2.9.1.7) [Group Algebras].** Let $\Gamma$ be a group, the group algebra $R[\Gamma]$ with the coalgebra structure

$$\mu : R[\Gamma] \to R[\Gamma] \times R[\Gamma] : g \mapsto g \otimes g, \varepsilon : R[\Gamma] \rightarrow R : \sum a_g g \mapsto \sum a_g$$

and

$$S : R[\Gamma] \to R[\Gamma] : g \mapsto g$$

is a Hopf algebra.

**Def.(2.9.1.8) [Dual Hoof Algebra].** Let $H$ be a Hopf algebra, matrix coefficients. $H^0$.

**Prop.(2.9.1.9).** $\text{Rep}(H) = \text{Mod}_{H^0}$. 

Co-modules

**Def. (2.9.1.10) [Co-Module].** Let $A$ be a coalgebra over a field $k$, then a right **co-module** is a $k$-vector space $V$ together with a $k$-linear map $\rho : V \to V \otimes A$ that satisfies

$$(\text{id}_V \otimes \mu) \circ \rho = (\rho \otimes \text{id}_A) \circ \rho, \quad (\text{id}_V \otimes \varepsilon) \circ \rho = \text{id}_V.$$

The map $\rho$ is called the **co-action**, and a $k$-subspace $W \subset V$ that $\rho(W) \subset W \otimes A$ is called a **sub-comodule** of $V$.

**Def. (2.9.1.11) [Tensor Product of Co-modules].**

Topologists’ Hopf Algebras

**Def. (2.9.1.12) [Topologist’s Hopf Algebra].** A **topologist’s Hopf algebra** over a commutative ring $R$ is a unital magma object in the dual category of graded algebras with $0$-degree term $R$, given by maps $\Delta : A \to A \otimes A$, and $\varepsilon : A \to R$ the canonical projection map. So in particular, $\Delta$ is of the form

$$\Delta(\alpha) = 1 \otimes \alpha + \alpha \otimes 1 + \sum_i \alpha'_i \otimes \alpha''_i, |\alpha'_i| > 0, |\alpha''_i| > 0.$$

**Prop. (2.9.1.13).** The tensor product of two topologists’ Hopf algebra is a topologists’ Hopf algebra.

**Prop. (2.9.1.14).** Let $F$ be a field, then $F[\alpha]/(\alpha^n)$, where $\alpha$ is placed at even dimension or $F$ has characteristic $2$, is a topologists’ Hopf algebra iff $F$ has positive characteristic $p$ and $n$ is a power of $p$.

**Proof:** By definition, it is easy to see that $\alpha$ is primitive, thus

$$\Delta(\alpha^n) = 0 = \sum_{0 < i < n} \binom{n}{i} \alpha^i.$$

Which then implies that $n$ is a $p$-power. □

**Prop. (2.9.1.15) [Hopf-Borel].** Let $A$ be a topologists’ Hopf algebra over a perfect field $K$, and $A$ is of f.d. in each degree, then:

- If $K$ has characteristic $0$, $A$ is isomorphic as an algebra to the tensor product of an exterior product of odd-dimensional generators and a polynomial ring of even-dimensional generators.
- If $K$ has characteristic $p$, then $A$ is isomorphic as an algebra to the tensor product of algebras of the following types:
  - $K[\alpha]$, where $\alpha$ is even-dimensional if $p \neq 2$.
  - $\wedge K[\alpha]$ where $\alpha$ is odd-dimensional.
  - $K[\alpha]/(\alpha^{p^i})$, where $\alpha$ is even-dimensional if $p \neq 2$.

**Proof:** We only prove the 0-characteristic case, Cf. [Hat02]P285. □
2 Commutative Hopf Algebras

Prop. (2.9.2.1) [Commutative Hopf Algebra]. Let $R$ be a commutative ring, a commutative Hopf algebra is equivalent to a cogroup object in $\mathcal{C}\text{Alg}_R$. A homomorphism of Hopf algebras is a morphism of algebras that represents a natural transformation of functors from $\mathcal{C}\text{Alg}_R$ to $\mathcal{S}\text{rp}$.

*Proof:* The critical point is to look at the definition of Hopf algebra. In this case, $S$ is a homomorphism of algebras (2.9.1.6), and notice tensor product is just the product in the dual category, and $m : A \otimes A \to A$ is the diagonal in the dual category, thus a cogroup object is a map $\Delta : A \to A \otimes A$ together with a map $\text{inv} : A \to A$ that

$$m \circ (\text{id} \otimes \text{inv}) \circ \Delta = m \circ (\text{inv} \otimes \text{id}) \circ \Delta = \text{id} : A \to A,$$

which is exactly the definition of the Hopf algebra (2.9.1.5).

Cor. (2.9.2.2) [Yoneda Interpretation]. We do not need to verify all the relations defining a Hopf algebra $H$, whenever we have a functorial commutative group structure on all the set $\text{Hom}(H,T)$, we immediately recover the maps:

- (Comultiplication): $\mu : H \to H \otimes R H$ as $i_1 \cdot i_2$ in $\text{Hom}(H,H \otimes H)$,
- (Antipode): $\iota : H \to H$ as inv in $\text{Hom}(H,H)$,
- (Counit): $\varepsilon : H \to R$ as 1 in $\text{Hom}(H,R) = H^\vee$.

by Yoneda lemma.

For convenience, we denote the structure maps $\eta_H : R \to H, \mu : H \times R H \to H, (-)^{-1} : H \to H$.

Prop. (2.9.2.3) [Group Algebras]. Let $\Gamma$ be a commutative group, then the group algebra $R[\Gamma]$ (2.9.1.7) represents the group functor that maps a commutative $R$-algebra $S$ to the commutative group $\text{Hom}(\text{grp} (\Gamma), S)$.

Cor. (2.9.2.4) [Multiplicative Groups]. $G_{m,R} = R[t,t^{-1}]$ is a Hopf algebra that represents the group functor of multiplicative groups on $\mathcal{C}\text{Alg}_R$.

Cor. (2.9.2.5) [Roots of Unity $\mu_{n,R}$]. Let $\Gamma \cong \mathbb{Z}/n\mathbb{Z}$, then $R[\Gamma] \cong R[t]/(t^n - 1)$ is a Hopf algebra that represents the group functor of multiplicative groups of $n$-th roots of unity on $\mathcal{C}\text{Alg}_R$.

Prop. (2.9.2.6) [Additive Groups]. $R[t]$ can be given a Hopf algebra structure that represents the group functor that maps a commutative $R$-algebra $S$ to the additive group $S^+$.

Def. (2.9.2.7) [$G_{(a,b),R}$]. Given elements $a, b \in R$ that $ab = 2$, for any commutative $R$-algebra $S$, the group $G_{(a,b),R}(S)$ of elements $x$ of $S$ that $x^2 + ax = 0$ is a group under the mapping $(m, n) \mapsto m + n + bmn$. Notice the inverse of $m$ is $m$ itself. Then $R[t]/(t^2 + at)$ can be given a Hopf algebra that represents the functor $S \mapsto G_{(a,b),R}(S)$.

Def. (2.9.2.8) [$V_\alpha$]. Let $V$ be a vector space over $k$, then $\text{Sym}(V^\vee)$ can be given a Hopf algebra structure representation the functor $V_\alpha : R \mapsto R \otimes_k V \cong \text{Hom}_k(V^\vee, R)$.

Def. (2.9.2.9) [Locally Constant Functions]. Let $\Gamma$ be a group, then $\Gamma_R = \prod_{\gamma \in \Gamma} R$ represents the group functor that maps an $R$-algebra $T$ to the group of locally constant functions on $\text{Spec} R$ with value in $\Gamma$. 
Remark (2.9.2.10). To illustrate the philosophy of (7.1.1.2), we figure out the Hopf structure of the local constant functions: a map \( \prod_{\gamma \in E} R \to T \) is equivalent to a set of idempotents \( e_\gamma \) of \( T \) that \( \sum e_\gamma = 1 \). This is equivalent to a locally constant function on \( \text{Spec} \, T \) that takes value \( \gamma \) on \( V(e_\gamma) \). Then the product takes values \( \gamma \delta \) on \( V(e_\gamma \otimes e_\delta) \subset \text{Spec} \, T \otimes T \), or equivalently takes values \( \gamma \) on \( V(\sum_{gg' = \gamma} e_g \otimes e_{g'}) \), so \( \Delta(e_\gamma) = \sum_{gg' = \gamma} e_g \otimes e_{g'} \).

Lemma (2.9.2.11) [Modulo \( \ker(\varepsilon) \)]. For a Hopf algebra \( A \) over \( R \), the comultiplication and counit are determined by \( \ker \varepsilon \):

- \( R \oplus \ker \varepsilon \to A : (a,b) \mapsto a + b \) is an isomorphism of \( R \)-modules.
- \( \mu(a) \equiv -\varepsilon(a) + a \otimes 1 + 1 \otimes a \mod \ker \varepsilon \otimes R \ker \varepsilon \).
- \( \iota(a) \equiv -a \mod (\ker \varepsilon)^2 \) for \( a \in \ker \varepsilon \).

Proof: 1: this is because the counit \( 0 \to \ker \varepsilon \to A \to R \to 0 \) has an inverse by the \( R \)-algebra map \( R \to S \).

2: item 1 allows us to write

\[ A \otimes_R A = R \oplus (\ker \varepsilon \otimes_R R) \oplus (R \otimes_R \ker \varepsilon) \oplus (\ker \varepsilon \otimes \ker \varepsilon) \]

so for \( a \in A \),

\[ \mu(a) = b + c \otimes 1 + 1 \otimes d + z \]

where \( b, c, d \in \ker \varepsilon, z \in \ker \varepsilon \otimes \ker \varepsilon \). Then \( a = (\varepsilon \otimes \text{id}_A)(b + c \otimes 1 + 1 \otimes d + z) = b + d \), and also \( a = b + c \). Applying \( \varepsilon \) shows \( b = \varepsilon(a) \), and thus

\[ \mu(a) = \varepsilon(a) + (a - \varepsilon(a)) \otimes 1 + 1 \otimes (a - \varepsilon(a)) + z = -\varepsilon(a) + a \otimes 1 + 1 \otimes a + z. \]

3: Let \( \iota(a) = b + c \) where \( b, c \in \ker \varepsilon \), then

\[ \varepsilon(a) = (\text{multi})(\iota \otimes \text{id})(-\varepsilon(a) + a \otimes 1 + 1 \otimes a + z) = -\varepsilon(a) + \iota(a) + a + (\text{multi})(\iota \otimes \text{id})(z) \]

so for \( a \in \ker \varepsilon \), \( \iota(a) \equiv -a \mod (\ker \varepsilon)^2 \), as \( (\text{multi})(\iota \otimes \text{id})(z) \in (\ker \varepsilon)^2 \), because \( \iota \) commutes with \( \varepsilon \).

Def. (2.9.2.12) [Hopf Ideal and Quotient Hopf Algebra]. Let \( A \) be a Hopf algebra, then a quotient Hopf algebra is a quotient \( A/I \) that has a Hopf algebra structure compatible with that of \( A \). In other words, there are commutative diagrams

\[
\begin{align*}
A \xrightarrow{\mu} A \otimes_R A & \quad \xrightarrow{\varepsilon} R \quad \xrightarrow{\iota} A \\
A/I & \xrightarrow{\text{proj}} A/I \otimes_R A/I & \xrightarrow{\text{restr}} A/I \\
\end{align*}
\]

In particular, quotient Hopf algebra corresponds to ideals of \( A \) that

\[ \mu(I) \subset \ker(A \otimes_R A \to A/I \otimes_R A/I), \quad \varepsilon(I) = 0, \quad \iota(I) \subset I, \]

called Hopf ideals of \( A \).

Remark (2.9.2.13) [Examples]. If \( \Gamma' \) is a subgroup of a commutative group \( \Gamma \), then \( R[\Gamma] \) has a quotient Hopf algebra \( R[\Gamma/\Gamma'] \). In particular, \( R[t]/(t^n - 1) \) is a quotient Hopf algebra of \( R[t,t^{-1}] \).
Prop. (2.9.2.14) [Hopf Ideals of Additive Groups]. Let \( f = \sum_{i=0}^{d} a_i t^i \in R[t] \) be a monic polynomial \( \neq t \), then \( (f) \) is a Hopf ideal of \( R[t] \) iff \( R \) is of char \( p > 0 \) and the derivative \( f' = 0 \).

**Proof:** We check conditions in (2.9.2.12), the first says \( \sum a_i (t \otimes 1 + 1 \otimes t)^i \) vanishes in \( R[t]/(f) \otimes_R R[t] \). But \( f \) is monic, so this is equivalent to \( a_i \binom{i}{j} = 0 \) for any \( 0 < j < i \leq d \). But we have \( \gcd_{0<j<i}(i) = p \) if \( i = p^r \) for some \( r \geq 1 \) and 1 otherwise, so \( a_d = 0 \) unless \( d \) is a power of \( p \), and \( p = 0 \in R \) because \( a_d = 1 \). In particular, \( f = \sum_{i=0}^{d} b_i t^{p^i} \), and it automatically satisfies the other two conditions. \( \square \)

Cor. (2.9.2.15) \([\alpha_{p', R}]\). Let \( R \) be a commutative ring of char \( p > 0 \), then the quotient Hopf algebra \( R[t]/(t^{p'}) \) corresponding to the Hopf ideal \( (t^{p'}) \) is denoted by \( \alpha_{p', R} \).

**WARNING:** \( \alpha_{p', R} \) is isomorphic to \( \mu_{p', R} \) as \( R \)-algebras, but they are not isomorphic as Hopf algebras.

Prop. (2.9.2.16) [Irreducibility of Hopf Algebras]. Let \( k \) be a field, then the following Hopf algebra contains no proper Hopf ideals:

- \( G_{a, k} \) if char \( R = 0 \).
- \( \alpha_{p, k} \) if char \( R = p > 0 \).

**Proof:** Any Hopf ideal to \( k[t] \) is principal, thus this proposition follows from (2.9.2.14). \( \square \)

Def. (2.9.2.17) [Cokernel Hopf Algebra]. Let \( A \to B \) be a homomorphism of Hopf Algebras over \( R \), then the **cokernel Hopf algebra** is the algebra \( B \otimes_A R = B/B \otimes_A \ker(\varepsilon_A) \), which represents the functor of kernels of \( \text{Hom}_R(B, T) \to \text{Hom}_R(A, T) \), thus is a Hopf algebra.

Lemma (2.9.2.18). A Hopf algebra over a field \( k \) is direct limit of Hopf algebra of f.t. over \( k \).

Def. (2.9.2.19) [Group-Like Elements]. Let \( A \) be a Hopf algebra, then a **group-like element** \( a \in A \) is an invertible element that satisfies \( \mu(a) = a \otimes a \in A \otimes A \).

If \( a \) is a group-like element in a Hopf algebra \( A \), then \( a = (\varepsilon, \text{id})\mu(a) = \varepsilon(a)a \), so \( \varepsilon(a) = 1 \).

Prop. (2.9.2.20) [Group-Like Elements are Linearly Independent]. Let \( A \) be a Hopf algebra over a field \( k \), then the set of group-like elements are linearly independent over \( k \).

**Proof:** If \( e = \sum a_i e_i \) that \( e, e_i \) are all group-like elements, then

\[
\mu(e) = e \otimes e = \sum c_i c_j e_i \otimes e_j = \sum c_i \mu(e_i) = \sum c_i e_i \otimes e_i
\]

so \( c_i^2 = c_i \) and \( c_i e_j = 0 \). Now also notice \( 1 = \varepsilon(e) = \sum c_i \varepsilon(e_i) = \sum c_i (2.9.2.19) \), contradiction. \( \square \)

Cor. (2.9.2.21). The set of group-like elements in the Hopf algebra \( k[\Gamma](2.9.2.3) \) are just the set \( \Gamma \subset k[\Gamma] \).

Prop. (2.9.2.22) [Cartier Theorem]. A Hopf algebra \( A \) over a field \( k \) of characteristic 0 is reduced.

**Proof:** We can base change to the algebraic closure \( \overline{k} \) of \( k \) and assume \( k \) is alg. closed. Because reducedness is stalkwise and Hilbert’s Nullstellensatz, it suffices to show \( A_s \) is reduced at each \( s \in G(k) \). The translation by \( g \in G(k) \) acts transitively on \( G(k) \), so it suffices to show it vanishes at the kernel of the counit map \( \ker(\varepsilon) \). Cf. [Jakob, Stix].

We may assume by taking direct limits that \( A \) is f.g. over \( k \). Let \( \mathfrak{m} \) be the kernel of the counit \( \varepsilon : A \to k \), then \( \mathfrak{m}/\mathfrak{m}^2 \) is a f.g. \( k \)-vector space with a basis lifting to \( x_1, \ldots, x_r \in \mathfrak{m} \).

We prove that \( \text{gr}_\mathfrak{m}(A) \) is a polynomial ring in \( x_i \), Cf. [Shatz]. \( \square \)
Prop. (2.9.2.23) [Faithfully Flatness]. If $A \subset B$ are f.g. Hopf algebras over a field $k$, then $B$ is f.f. over $A$.

Proof: Cf. [Milne, P73]. □

Cor. (2.9.2.24). If $A \subset B$ are Hopf algebras that $B$ is an integral domain, and let $K, L$ be their fraction field, then $B \cap L = A$. In particular, if $K = L$, then $A = B$.

Proof: Since $A \to B$ is f.f. by (2.9.2.23), $cB \cap A = cA$ for any $c \in A$ by (2.9.2.23). Thus if $a/c \in B$ for $a, c \in A$, then $a \in cB \cap A = cA$, so $a/c \in A$. □

3 Quiver Hecke Algebra

Cf. [Bru13].
3 Categories and Algebraic Topology

3.1 Categories

Main references are [?], [Coend Calculus, Fosco Loregian].

1 Basics

Def.(3.1.1.1)[Category]. A category $\mathcal{C}$ consists of the following data:

- A set $\text{Ob}(\mathcal{C})$ of objects of $\mathcal{C}$.
- For any $x, y \in \text{Ob}(\mathcal{C})$ a set $\text{Mor}(x, y)$ of morphisms from $x$ to $y$.
- For any $(x, y, z) \in \text{Ob}(\mathcal{C})$, a map of sets $\circ : \text{Mor}(y, z) \times \text{Mor}(x, y) \to \text{Mor}(x, z)$, called the composition law of $\mathcal{C}$.

that satisfies:
- (Identity) For any $x \in \text{Ob}(\mathcal{C})$, there exists an element $\text{id}_x \in \text{Mor}(x, x)$ s.t. $\text{id}_x \circ \varphi = \varphi$, $\psi \circ \text{id}_x = \psi$ whenever these compositions make sense. It is clear such an element is unique.
- (Associativity) $(\varphi \circ \psi) \circ \chi = \varphi \circ (\psi \circ \chi)$ whenever these compositions make sense.

Remark(3.1.1.2). Let $\mathcal{C}$ be a category, we will sometimes say $x \in \mathcal{C}$ to mean that $x$ is an element of $\text{Ob}(\mathcal{C})$ and $f : x \to y \in \mathcal{C}$ or $f$ is a morphism in $\mathcal{C}$ to mean: $x, y \in \text{Ob}(\mathcal{C})$ and $f \in \text{Mor}(x, y)$. Hopefully this won’t make any confusions.

Def.(3.1.1.3)[Dual Categories]. Let $\mathcal{C}$ be a category, then the dual category of $\mathcal{C}$ is a category $\mathcal{C}^{\text{op}}$ with

- $\text{Ob}(\mathcal{C}^{\text{op}}) = \text{Ob}(\mathcal{C})$.
- For $x, y \in \text{Ob}(\mathcal{C}^{\text{op}}) = \text{Ob}(\mathcal{C})$, $\text{Mor}_{\mathcal{C}^{\text{op}}}(x, y) = \text{Mor}_{\mathcal{C}}(y, x)$.
- The composition law of $\mathcal{C}^{\text{op}}$ is induced from that of $\mathcal{C}$.

Def.(3.1.1.4)[Isomorphisms]. Let $\mathcal{C}$ be a category, an isomorphism in $\mathcal{C}$ is a morphism $\varphi \in \text{Mor}(x, y)$ in $\mathcal{C}$ s.t. there exists a morphism $\psi \in \text{Mor}(y, x)$ s.t. $\varphi \circ \psi = \text{id}_y$ and $\psi \circ \varphi = \text{id}_x$. It is clear that such a $\psi$ is unique, and if it exists, it is called the inverse morphism of $\varphi$.

For $x, y \in \mathcal{C}$, if there exists an isomorphism in $\text{Mor}(x, y)$, $x, y$ are said to be equivalent objects.

Def.(3.1.1.5)[Functors]. Let $\mathcal{C}, \mathcal{C}'$ be categories, a functor $F$ from $\mathcal{C} \to \mathcal{C}'$ consists of the following data:

- a morphism of sets $\text{Ob}(\mathcal{C}) \to \text{Ob}(\mathcal{C}') : x \mapsto F(x)$.
- for any $x, y \in \text{Ob}(\mathcal{C})$, a morphism of sets $\text{Mor}(x, y) \to \text{Mor}(F(x), F(y)) : f \mapsto F(f)$.

that satisfies:
• $F(\text{id}_x) = \text{id}_{F(x)}$.

• $F(\varphi \circ \psi) = F(\varphi) \circ F(\psi)$ whenever $\varphi \circ \psi$ is defined.

A **contravariant functor** from $\mathcal{C}$ to $\mathcal{C}'$ is defined to be a functor from $\mathcal{C}^{\text{op}}$ to $\mathcal{C}'$.

**Def. (3.1.1.6)** [$\text{id}_\mathcal{C}$]. For any category $\mathcal{C}$, there exists a trivial functor $\text{id}_\mathcal{C} : \mathcal{C} \to \mathcal{C}$.

**Def. (3.1.1.7)** [Natural Transformations]. Let $\mathcal{C}, \mathcal{C}'$ be categories and $F, G : \mathcal{C} \to \mathcal{C}'$ be functors between categories, then a **natural transformation** $\eta$ from $F$ to $G$ consists of an element $\eta_x$ for each $x \in \text{Ob}(\mathcal{C})$ s.t. for any $f : x \to y \in \mathcal{C}$, the following diagram is commutative:

$$
\begin{array}{ccc}
F(x) & \xrightarrow{F(f)} & F(y) \\
\downarrow{\eta_x} & & \downarrow{\eta_y} \\
G(x) & \xrightarrow{G(f)} & G(y)
\end{array}
$$

Then for any two categories $\mathcal{C}, \mathcal{C}'$, there is a category $\text{Fun}(\mathcal{C}, \mathcal{C}')$ consisting of the set of functors from $\mathcal{C}$ to $\mathcal{C}'$, and natural transformations as morphisms between functors.

**Def. (3.1.1.8)** [Initial Objects]. An **initial object** in a category $\mathcal{C}$ is an object $\varnothing$ s.t. for any $X \in \mathcal{C}$, there exists a unique morphism $\varnothing \to X$. A **final object** is an initial object in $\mathcal{C}^{\text{op}}$. Initial and final objects are unique up to unique isomorphisms.

An object that is both initial and final is called a **zero object**.

**Def. (3.1.1.9)** [Filtered Categories]. A **filtered category** is a category $\mathcal{I}$ that:

- It is nonempty.

- for any $a, b \in \mathcal{I}$, there is some $c \in \mathcal{I}$ with morphisms $a \to c, b \to c$

- for any two morphisms $a, b : x \to y$, there is a morphism $c : y \to z$ that $c \circ a = c \circ b$.

**Def. (3.1.1.10)** [Fully Faithful Functors]. A functor of category $F : \mathcal{C} \to \mathcal{D}$ is called:

- a **full/faithful functor** if for any $x, y \in \text{Ob}(\mathcal{C})$, $F : \text{Hom}(X, Y) \to \text{Hom}(F(x), F(y))$ is surjective/injective.

- an **essentially surjective functor** if any object of $\mathcal{D}$ is equivalent to some $f(x)$, where $x \in \mathcal{C}$.

- an **equivalence** if there is a functor $G : \mathcal{D} \to \mathcal{C}$ that $F \circ G \cong \text{id}_\mathcal{D}$ and $G \circ F \cong \text{id}_\mathcal{C}$.

**Prop. (3.1.1.11)** [Category Equivalences]. A Functor $\mathcal{C} \to \mathcal{D}$ is an equivalence if and only if it’s fully faithful and essentially surjective.

**Proof:** There exist an object $G(X) \in \mathcal{C}$ and an isomorphism $\xi_X : FG(X) \to X$ for every $X \in \mathcal{D}$. Because $F$ is fully faithful, there exists a unique morphism $G(f) : G(X) \to G(Y)$ such that $F(G(f)) = \xi_Y^{-1} \circ f \circ \xi_X$ for every morphism $f : X \to Y$ in $\mathcal{D}$. Thus we obtain a functor $G : \mathcal{C} \to \mathcal{D}$ as well as a natural isomorphism $\xi : F \circ G \to \text{Id}_\mathcal{D}$. Moreover, the isomorphism $\xi_{F(Z)} : FGF(Z) \to F(Z)$ decides an isomorphism $\eta_Z : GF(Z) \to Z$ for every $Z \in \mathcal{C}$. This yields a natural isomorphism $\eta : G \circ F \to \text{Id}_\mathcal{C}$. $\square$

**Def. (3.1.1.12)** [Setoids]. A **setoid** is a category that is equivalent to a category that has only the identity morphisms.

**Def. (3.1.1.13)** [Groupoids]. A **groupoid** is a category that all morphisms are isomorphisms.
Prop. (3.1.1.14) [Equivalence Relations]. An equivalence relation is a groupoid that 
\( \# \text{Mor}_\mathcal{C}(x, y) \leq 1 \) for any \( x, y \in \mathcal{C} \).

Prop. (3.1.1.15). A category is equivalent to a setoid iff it is an equivalence relation.

Proof: \( \square \)

Def. (3.1.1.16) [Subcategories]. Let \( \mathcal{C} \) be a category, a subcategory \( \mathcal{C}' \) of \( \mathcal{C} \) is a category together 
with a functor \( F : \mathcal{C}' \to \mathcal{C} \) s.t. \( F : \text{Ob}(\mathcal{C}') \to \text{Ob}(\mathcal{C}) \) is injective and \( F \) is faithful. And it is called a 
full subcategory if \( F \) is fully faithful. It is called a strictly full subcategory if for any \( y \in \mathcal{C} \), 
\( y \) is equivalent to some \( F(x), x \in \text{Ob}(\mathcal{C}') \) iff \( y \in F(\mathcal{C}') \).

Def. (3.1.1.17) [Comma Categories]. For a category \( \mathcal{C} \) and an object \( S \), the 
comma category \( \mathcal{C} / S \) is defined to be the category of arrows \( T \to S \) with the arrows being compatible arrows over \( S \).

Def. (3.1.1.18) [Category of Arrows]. For a category \( \mathcal{C} \), the category of arrows \( \text{Arr}(\mathcal{C}) \) is a category 
whose objects are arrows in \( \mathcal{C} \) and a morphism \( f \to g \) is a commutative diagram

\[
\begin{array}{ccc}
A & \xrightarrow{h} & B \\
\downarrow f & & \downarrow g \\
A' & \xleftarrow{k} & B'
\end{array}
\]

Def. (3.1.1.19) [Twisted Arrow Category]. For a category \( \mathcal{C} \), the category of twisted arrows \( \text{TW}(\mathcal{C}) \) 
is a category whose objects are arrows in \( \mathcal{C} \) and a morphism \( f \to g \) is a diagram

\[
\begin{array}{ccc}
A & \xleftarrow{h} & B \\
\downarrow f & & \downarrow g \\
A' & \xrightarrow{k} & B'
\end{array}
\]

Def. (3.1.1.20) [Final Objects]. An object \( Z \) of a category is called a final object if 
\( \# \text{Hom}(X, Z) = 1 \) for any object \( X \). It is called weakly final if \( \text{Hom}(X, Z) \neq \emptyset \) for every object \( X \). 
Dually an object is called (weakly) initial if it is (weakly) initial as an object of \( \mathcal{C}^{\text{op}} \).

Def. (3.1.1.21) [Epimorphisms and Monomorphisms]. An epimorphism in a category is a morphism \( X \to Y \) that the map 
\( \text{Hom}(Y, Z) \to \text{Hom}(X, Z) \) induced by composition is injective. Dually, an 
monomorphism is an epimorphism in the dual category.

Def. (3.1.1.22) [Projective and Injective]. A projective object \( X \) in a category is an object that for any epimorphism \( (3.1.1.21) \) \( Y \to Z \), \( \text{Hom}(X, Y) \to \text{Hom}(X, Z) \) is surjective. Dually, an 
injective object \( X \) is a projective object in the dual category.

Def. (3.1.1.23) [Retract]. A morphism \( f \) in a category \( \mathcal{C} \) is called a retract of \( g \) if there are morphisms 
\( F, G : f \to g \) in \( \text{Mor}(\mathcal{C})(3.1.1.18) \) that \( G \circ F = \text{id}_f \).

Def. (3.1.1.24) [Equivalence relations]. For \( \mathcal{C} \in \text{Cat} \) has finite products, \( X_0 \in \mathcal{C} \), an equivalence 
relation on \( X_0 \) is a tuple \((X_1, u)\), where \( X_1 \in \mathcal{PSh}(\mathcal{C}) \) and \( u \in \text{Hom}(X_1, X_0 \times X_0) \) s.t for any 
\( X \in \mathcal{C} \), the map 
\[
\bar{X}_1(T) \xrightarrow{u} \bar{X}_0(T) \times \bar{X}_0(T)
\]
is a bijection of \( \bar{X}_1(T) \) onto the graph of an equivalence relation on \( \bar{X}_1(T) \). Similarly, we can define 
pre-relations on \( X_0 \), relations on \( X_0 \) and pre-equivalence relations on \( X_0 \).
Prop. (3.1.1.25) [Involutions]. Situation as in (3.1.1.24), then there is a morphism \( \sigma : F_0 \rightarrow F_0 \), \( \sigma^2 = \text{id}, u_0 \circ \sigma = u_1, u_1 \circ \sigma = u_0 \), by the symmetry in the definition of equivalence relations.

Def. (3.1.1.26) [Categorical Quotients]. Situation as in (3.1.1.24), for an equivalence relation \( u : X_1 \rightarrow X_0 \times X_0 \), a morphism \( v : X_0 \rightarrow X \) is called a categorical quotient if
- \( u \) factors through \( v : X_0 \rightarrow X \), and \( u : X_1 \rightarrow X_0 \times X_0 \) is an isomorphism.
- For any \( T \in \mathcal{C} \), there is a cokernel sequence
  \[
  \text{Mor}(X, T) \rightarrow \text{Mor}(X_0, T) \cong \text{Mor}(X_1, T)
  \]
  is exact.

Representable Functors

Def. (3.1.1.27) [Presheaves]. A presheaf on a category \( \mathcal{C} \) is defined to be a contravariant functor from \( \mathcal{C} \) to \( \text{Set} \). The category of presheaves on \( \mathcal{C} \) is denoted by \( \mathcal{P}\text{sh}(\mathcal{C}) \).

Prop. (3.1.1.28) [Representability Criterion]. Let \( \mathcal{C} \) be a complete category, \( F : \mathcal{C} \rightarrow \text{Set} \) be a functor. Assume that \( F \) commutes with limits, and the category \( \mathcal{I} \) of pairs \((x, f)\) where \( x \in \mathcal{C}, f \in F(x) \) has a cofinal family of objects indexed by a set \( I \), then \( F \) is representable, i.e. there is an object \( x \) that \( F(y) = \text{Mor}_\mathcal{C}(x, y) \), functorial in \( y \).

\[\text{Proof:} \quad \text{Because} \ \mathcal{C} \ \text{has small limits, let} \ \mathcal{I}' \ \text{be the full subcategory of} \ \mathcal{I} \ \text{generated by} \ (x_i, f_i), \ \text{set} \ x = \text{lim}_{(x_i, f_i) \in \mathcal{I}} x_i. \ \text{As} \ F \ \text{commutes with limits,} \ F(x) = \text{lim}_{(x_i, f_i) \in \mathcal{I}} F(x_i). \ \text{Hence there is a universal element} \ f \in F(x) \ \text{that maps to} \ f_i \ \text{under} \ F(x \rightarrow x_i). \ \text{f induces a natural transformation} \ \xi : \text{Mor}_\mathcal{C}(x, -) \rightarrow F(-).
\]

The assumption shows \( \xi \) is surjective. Now let \( x' \rightarrow x \) be the equalizer of all maps \( \varphi : x \rightarrow x \) that \( F(\varphi)f = f \), then there is a \( f' \in F(x') \) mapping to \( f \). Then the transformation \( \xi' \) defined by \( f' \) is also surjective. Now we also want to show it is injective: if \( a, b \in \text{Mor}_\mathcal{C}(x', y) \) mapsto the same element, then we consider the equalizer \( e' : x'' \rightarrow x' \) of \( a, b \), then the assumption and the fact \( F \) commutes with equalizer shows there is a \( f'' \in F(x'') \) mapping to \( f' \).

By universality consider a morphism \( \psi : x \rightarrow x'' \) that \( F(\psi)f = f'' \), then \( e \circ e' \circ \psi \) is a morphism \( x \rightarrow x \) that fixes \( f \), thus by construction \( ee'\psi e = e \), so \( e'\psi e = \text{id} \), because \( e \) is a monomorphism. Then \( e' \) is an epimorphism, thus \( a = b \).

\[\square\]

Adjunctions

Def. (3.1.1.29). Two functors \( f : \mathcal{C} \rightarrow \mathcal{D}, \ g : \mathcal{D} \rightarrow \mathcal{C} \) are called an adjunction pair iff there is a natural isomorphism of functors:

\[\mathcal{C}^{op} \times \mathcal{D} \rightarrow \text{Set} : \text{Hom}(f(-), -) \cong \text{Hom}(-, g(-)).\]

Equivalently this means that for any \( X_1 \rightarrow X_2 \in \mathcal{C}, Y_1 \rightarrow Y_2 \in \mathcal{D}, \)
\[
\begin{array}{ccc}
  f(X_1) & \longrightarrow & Y_1 \\
  \downarrow & & \downarrow \\
  f(X_2) & \longrightarrow & Y_2
\end{array}
\]

\[\square\]
is commutative iff its corresponding map

\[
\begin{array}{ccc}
X_1 & \longrightarrow & g(Y_1) \\
\downarrow & & \downarrow \\
X_2 & \longrightarrow & g(Y_2)
\end{array}
\]

is commutative.

Denoted an adjunction pair by \((f, g) : \mathcal{C} \rightleftarrows \mathcal{D}\).

**Prop. (3.1.1.30)**[Units and Counits]. If \(f, g\) are adjoints, then there are natural transformations \(u : \text{id} \to gf\), and \(v : fg \to \text{id}\), called the **unit/counit maps**. They satisfies \(f \overset{\sim}{\rightleftarrows} fgf \overset{\sim}{\rightarrow} f\) is id, and \(g \overset{\sim}{\rightleftarrows} gfg \overset{\sim}{\rightarrow} f\) is id.

Conversely, if there are natural morphisms \(u, v\) satisfying these two identities, then \((f, g)\) is an adjunction, by

\[
\text{Hom}(fX, Y) \to \text{Hom}(gfX, gY) \to \text{Hom}(X, gY) \to \text{Hom}(fX, fgY) \to \text{Hom}(fX, Y).
\]

**Proof:** 

\[\square\]

**Lemma(3.1.1.31).** Let \((f, g)\) be an adjunction pair, then

- If \(g \circ f\) is fully faithful, then \(f\) is fully faithful.
- If \(f \circ g\) is fully faithful, then \(g\) is fully faithful.

**Proof:** Cf.[Sta]0FWV. 

\[\square\]

**Prop. (3.1.1.32).** Let \((f, g)\) be an adjunction pair, then

- \(f\) is fully faithful iff \(u : \text{id} \to gf\) is an isomorphism.
- \(g\) is fully faithful iff \(v : fg \to \text{id}\) is an isomorphism.

**Proof:** 1: If \(\text{id} \cong gf\), then \(gf\) is fully faithful, so \(f\) is fully faithful by(3.1.1.31). If \(f\) is fully faithful, then for any \(X, Y\),

\[
\text{Hom}(X, Y) \xrightarrow{u} H(X, gfY) \cong H(fX, fY) \cong H(X, Y)
\]

is a canonical isomorphism, so \(u\) is an isomorphism.

2 is dual to 1. 

\[\square\]

**Cor. (3.1.1.33)**[Units and Equivalences]. Let \((F, G)\) be an adjunction pair, then the following are equivalent:

- \(F, G\) are both fully faithful.
- the unit and counit are both isomorphisms.
- \(F, G\) defines an equivalence of categories.

**Proof:** 1 \(\to\) 2 \(\to\) 3 follow from(3.1.1.32). And 3 \(\to\) 1 is clear. 

\[\square\]

**Prop. (3.1.1.34)**[Adjunction Preserves (Co)Limits]. A right adjoint functor is left exact and it preserves injectives if its left adjoint is exact.

A left adjoint functor is right exact and it preserves projectives if its right adjoint is exact.
Prop. (3.1.1.35) [Adjoint Functor Theorem]. Let \( G : \mathcal{C} \to \mathcal{D} \) be a functor, assume \( \mathcal{C} \) is complete and \( G \) commutes with colimits. Assume for every \( y \in \mathcal{D} \), the category of pairs \((x, f)\) where \( x \in \mathcal{C} \) and \( f \in \text{Mor}_\mathcal{D}(y, G(x)) \) has a cofinal family of objects indexed by a set \( I \), then \( G \) has a left adjoint. Similarly the dual statement holds.

Proof: The assumption shows that for any \( y \in \mathcal{D} \), the functor \( x \mapsto \text{Mor}_\mathcal{D}(y, G(x)) \) satisfies the condition of (3.1.1.28), thus it is representable by an object denoted by \( F(y) \). By Yoneda lemma, \( F \) underlies a functor, and this functor is a left adjoint of \( G \). □

Prop. (3.1.1.36) [Examples of Adjunction pairs].
- The valuation at \( k \)-th coordinate is left adjoint to the functor \( k^*(A) i = \prod_{\text{Hom}_i,k} A \) and is exact. So \( k_* \) preserves injectives.
- The sheaf \( \Gamma \) functor is right adjoint to the constant sheaf functor over arbitrary site.
- The inclusion functor is right adjoint to the shification functor over arbitrary site.
- The forgetful functor is right adjoint to the Shification functor, and shification is exact, so it preserves injectives.
- The stalk functor is left adjoint to the skyscraper sheaf operator.

Limits and Colimits

Prop. (3.1.1.37) [Products and Equalizers Implies Limits]. If a category admits arbitrary (resp. finite) products and equalizers, then it admits arbitrary (resp. finite) limits. Dually a category that admits coproducts and coequalizers admits all colimits.

Proof: The limits over a category \( \mathcal{C} \) is an equalizer of products over the category of arrows in \( \mathcal{C} \). □

Def. (3.1.1.38) [Exact Functor]. A functor \( F : \mathcal{C} \to \mathcal{D} \) is called an left exact functor if it maps finite limits to finite limits. It is called a right exact functor if it maps finite colimits to finite colimits. It is called an exact functor if it is both left exact and right exact.

Def. (3.1.1.39) [(Co)Complete Category]. A category is called (co)complete if it has all small (co)limits.

Def. (3.1.1.40) [Inverse System]. An inverse system in \( \mathcal{C} \) is a diagram \( Z^\text{op}_+ \to \mathcal{C} \), where \( Z_+ \) is the category of non-negative integers with a unique morphism \( n \to m \) iff \( n \leq m \).

Prop. (3.1.1.41) [Equivalent Inverse System]. Two inverse systems \( \{A_n\}, \{B_n\} \) are called equivalent if there are two non-decreasing unbounded maps \( \alpha, \beta : Z_+ \to Z_+ \) and maps \( \alpha : A_n \to B_{\alpha(n)}, \beta : B_n \to A_{\beta(n)} \) that is compatible with the transition maps and for any \( n \), there is a \( m \) large that \( A_m \to A_{\beta(m)} \to A_n \) coincide with the transition map \( A_m \to A_n \), and similar for \( B_n \). And similarly for colimits.

The limit for two inverse systems are the same, and similarly for colimits.

Prop. (3.1.1.42). Any presheaf on a small category is a colimit of representable sheaves \( h_X \). (Consider all \( h_X \to F \) and take colimit, prove it is isomorphism).

Prop. (3.1.1.43) [Filtered Colimit of Sets].
Prop. (3.1.1.44) [Cofiltered Limits of Sets]. A cofiltered limit of nonempty sets is nonempty.

Proof: Cf. [Sta]086J □

Def. (3.1.1.45) [Mittag-Leffler]. If \((A_i, \varphi_{ji})\) is a directed inverse system of sets over \(I\), then it is said to satisfy the Mittag-Leffler condition if \(\varphi_{ji}(A_j) \in A_i\) stabilizes. This is clearly true if \(\varphi_{ji}\) is surjective for any \(i, j\).

Prop. (3.1.1.46). If \((A_n)\) where \(n \in \mathbb{Z}\) is a Mittag-Leffler inverse system of nonempty sets, then \(\lim A_i\) is also nonempty.

Proof: Let \(A'_{j} = \cap_{j \geq i} \varphi_{ji} A_{j}\), then \((A'_{j})\) is a filtered system that the transition maps are all surjective, and clearly \(\lim A_{j} = \lim A'_{j}\), so it is nonempty by (3.1.1.44). □

Fiber Product

Prop. (3.1.1.47). For a category \(C\), the following are equivalent:

- It has arbitrary limits.
- It has arbitrary products and equalizer.
- It has arbitrary products and fibered products.

Proof: 1 \(\rightarrow\) 2, 1 \(\rightarrow\) 3 is trivial. 3 \(\rightarrow\) 2: The equalizer for \(f, g : X \rightarrow Y\) can be constructed as the base change of \(Y \rightarrow Y \otimes Y\) along \((f, g) : X \rightarrow Y \times Y\). 2 \(\rightarrow\) 1: for any diagram \(F : I \rightarrow C\), the fibered pullback can be constructed as the equalizer of two morphisms:

\[
\begin{align*}
  s, t : & \prod_{i \in Ob(I)} F(i) \rightarrow \prod_{f : i \rightarrow k \in Mor(I)} F(k) \\
  \text{where } \pi_{(f : j \rightarrow k)} s = \pi_{k}, \text{ and } \pi_{(f : j \rightarrow k)} t = (Ff)\pi_{j}.
\end{align*}
\]

\(□\)

Prop. (3.1.1.48) [Diagonal Base Change]. The diagonal commutes with base change:

\[
\begin{array}{ccc}
X \times_Y Z & \xrightarrow{\Delta} & (X \times_Y Z) \times_Z (X \times_Y Z) \\
\downarrow & & \downarrow \\
X & \xrightarrow{\Delta} & X \times_Y X
\end{array}
\]

Proof: □

Prop. (3.1.1.49). \((X \times_Y Z) \times_S (Z \times_F W) = (X \times_S Z) \times_{E \times_S F} (Y \times_S W)\).

Proof: □

Prop. (3.1.1.50). For \(f : X \rightarrow T\) and \(g : Y \rightarrow T\) and \(h : T \rightarrow S\), \(X \times_T Y = T \times_X S\) \((X \times_S Y)\). In particular, \(X \times_T Y \rightarrow X \times_S Y\) is a base change of \(T \rightarrow T \times_S T\).

Proof: For any object \(U\),

\[
\text{Hom}(U, X \times_T Y) = \{s : U \rightarrow X, t : U \rightarrow Y | f \circ s = g \circ t\},
\]

\[
\text{Hom}(U, T \times_T S(X \times_S Y)) = \{r : U \rightarrow T, s : U \rightarrow X, t : U \rightarrow Y | h \circ f \circ s = h \circ g \circ t, r = g \circ t, r = f \circ s\},
\]

so they are functorially isomorphic. Then by Yoneda lemma we have the desired isomorphism. □
Prop. (3.1.1.51). The diagonal map \( X \to X \times_Y X \) is an isomorphism iff \( X \to Y \) is monomorphism. (Because this is equivalent to \( \text{pr}_1 = \text{pr}_2 \)).

Def. (3.1.1.52) [Mapping graph]. Let \( f : X \to Y \) be a morphism in a category with fiber products and finite products, then the mapping graph \( \Gamma_f \) of \( f \) is defined to be the pullback

\[
\begin{array}{c}
\Gamma_f \to X \times Y \\
\downarrow \\
Y \to Y \times Y
\end{array}
\]

it can be seen that \( \Gamma_f \) is isomorphic to \( X \).

Localizations

Def. (3.1.1.53) [Localizing Categories]. Let \( \mathcal{C} \) be a category and \( S \) be a class of morphisms, then a functor \( F : \mathcal{C} \to \mathcal{D} \) is called the localizing category of \( \mathcal{C} \) w.r.t \( S \) if it maps morphisms in \( S \) to isomorphisms, and any other functor with this property factors uniquely through \( F \).

Def. (3.1.1.54) [Localizing Systems]. A class of morphisms \( S \) in a category is called a left (resp. right) localizing system if:

- (LS1): \( S \) is closed under composition and contains all the identities.
- (LS2): for every \( s \in S \) and \( f \) with the same source (resp. target), there is a \( t \in S \) and a \( g \), s.t. \( t \circ f = g \circ s \) (resp. \( f \circ t = s \circ g \)).
- (LS3): the existence of a \( t \in S \) s.t. \( ft = gt \) implies (resp. is implied by) the existence of a \( s \in S \) s.t. \( sf = sg \).

It is called localizing system if it is both left localizing and right localizing.

Def. (3.1.1.55) [Saturated Localizing Systems]. Let \( S \) be a localizing system, then it is called a saturated localizing system moreover it satisfies

- if \( f, g, h \in S \) and \( fg, gh \in S \), then \( g \in S \).

Def. (3.1.1.56) [Gabriel-Zisman Localization]. Cf. [Sta]04VD.

Cor. (3.1.1.57). If \( \mathcal{C} \) is a category and \( S \) is a left localizing system, then the rule \( X \mapsto X, (f : X \to Y) \mapsto \text{id}^{-1} f \) is a functor \( \mathcal{Q} : \mathcal{C} \to S^{-1}\mathcal{C} \) that represents \( S^{-1}\mathcal{C} \) as a localizing category of \( \mathcal{C} \) w.r.t \( S \)(3.1.1.53). And \( Q \) preserves finite colimits.

The dual is true for a right localizing system \( S \).

Proof: Cf.[[Sta]04VG], [[Sta]05Q2].

Cor. (3.1.1.58). If \( \mathcal{C} \) is a category and \( S \) is a localizing system, then the left localizing category and the right localizing category is canonically isomorphic, by the universal property(3.1.1.53).

Prop. (3.1.1.59) [Saturation]. If \( S \) is a localizing system in a category \( \mathcal{C} \), then the morphisms in \( \mathcal{C} \) that is mapped to an isomorphism in \( S^{-1}\mathcal{C} \) is the smallest saturated localizing system containing \( S \), called the saturation of \( S \).

Proof: Cf.[[Sta]05Q9].

Prop. (3.1.1.60) [Full Subcategories of Localized Categories]. If \( S \) is a left localizing system in a category \( \mathcal{C} \), \( \mathcal{C}' \) is a full subcategory of \( \mathcal{C} \) and \( S' \) is a left localizing system of \( \mathcal{C}' \) that \( S' \subset S \). If for any \( s : X \to Y \in S \) and \( X \in \mathcal{C}' \), there is a morphism \( t : Y \to Z \) that \( Z \in \mathcal{C}' \) and \( t \circ s \in S' \), then the natural functor \( (S')^{-1}\mathcal{C}' \to S^{-1}\mathcal{C} \) is fully faithful. And the dual is true for right localizing systems.

Proof: This is not hard from the Gabriel-Zisman localization description(3.1.1.56).
3.1. CATEGORIES

**Group Objects**

**Def. (3.1.1.61) [Group Object].** In a category \( C \) with finite products and a final object \( e \), a(n) **(Abelian)group object** is an object \( G \) that \( h_G \) is a functor from \( C \) to \( \mathcal{G} \text{rp} \) (resp. \( \mathcal{A} \text{b} \)). And a homomorphism of group objects is a natural transformation as a functor from \( C \) to \( \mathcal{G} \text{rp} \).

This is in fact equivalent to a morphism \( m_G : G \times G \to G \) and \( i_G : G \to G, e_G : e \to G \) that satisfy the desired commuting diagrams.

**Def. (3.1.1.62) [Group Action].** A **(left)action** of a group object \( G \) on an object \( X \) is a map of presheaves \( h_G \times h_X \to h_X \) that for any \( U \), \( h_G(U) \times h_X(U) \to h_X(U) \) is a group action. This is equivalent to a morphism \( \mu : G \times X \to X \) that satisfies the desired commuting diagrams.

**Prop. (3.1.1.63).** Let \( \mu : G \times X \to X \) be an action of a group object \( G \) on an object \( X \), there is a commutative diagram

\[
\begin{array}{ccc}
G \times X & \xrightarrow{(g,x)\mapsto(g,gx)} & G \times X \\
\downarrow{(g,x)\mapsto gx} & & \downarrow{\pi_2} \\
X & \xrightarrow{id} & X
\end{array}
\]

and the horizontal maps are isomorphisms.

**Cor. (3.1.1.64).** Considering the action of \( G \) on itself, we get

\[
\begin{array}{ccc}
G \times G & \xrightarrow{(g,h)\mapsto(g,gh)} & G \times G \\
\downarrow{m} & & \downarrow{\pi_2} \\
G & \xrightarrow{id} & G
\end{array}
\]

and the horizontal maps are isomorphisms.

**Prop. (3.1.1.65).** A unital magma object \( G \) in the category of groups is an Abelian group.

**Proof:** A unital magma object structure endows \( G \) with maps \( (\tilde{m}, \tilde{e}) \), and \( \tilde{m}(ab, cd) = \tilde{m}(a, c)\tilde{m}(b, d) \), because \( \tilde{m} \) is a morphism of groups. So we can use Eckmann-Hilton argument\(^2\) to show the category multiplication is the same as the group multiplication. So the commutativity of \( \tilde{m} \) with the inverse \( i \) implies that it is Abelian. \( \square \)

**Prop. (3.1.1.66).** A right-lax monoidal functor (3.1.4.10) between Cartesian monoidal structures maps a unital magma object to a unital magma object.

**Def. (3.1.1.67) [Categorical Quotient].** Let \( C \) be a category with finite products, \( G \) be a group object in \( C \), \( G \times X \to X \) is a left action (3.1.1.62), then a morphism \( X \to Y \) is called the **categorical quotient** of \( X \) iff \( Y \) is the coequalizer of \( G \times X \xrightarrow{\rho} X \). It is called the **universal categorical quotient** of \( X \) iff its product with \( S \) is the categorical quotient for each element \( S \in C \), in the category \( C/\Sigma \).
2 Ends and Coends

Def. (3.1.2.1) [Dinatural Transformation]. Given categories $\mathcal{C}, \mathcal{D}$ and functor $P, Q : \mathcal{C}^{op} \times \mathcal{C} \to \mathcal{D}$, then a dinatural transformation $\alpha : P \to Q$ is a family of arrows $\alpha_C : P(C, C) \to Q(C, C)$ where $C \in \mathcal{C}$ that for any arrow $C \to C' \in \mathcal{C}$, there is a commutative diagram

\[
P(C', C) \xrightarrow{\alpha_C} P(C, C) \xrightarrow{\alpha_{C'}} Q(C', C) \xrightarrow{} Q(C, C')
\]

Def. (3.1.2.2) [Wedge and Cowedge]. Let $P : \mathcal{C}^{op} \times \mathcal{C} \to \mathcal{D}$ be a functor, then a wedge for $P$ is a binatural functor $\Delta_D \to P$, where $D$ is an object of $\mathcal{C}$. Similarly a cowedge is a binatural functor $P \to \Delta_D$.

Def. (3.1.2.3) [End and Coend]. For a functor $P : \mathcal{C}^{op} \times \mathcal{C} \to \mathcal{D}$, the wedges and cowedges of $P$ form categories, and we define end of $P$ is just a terminal wedge, denoted by $\int^\mathcal{C} P(C, C)$, and the coend of $P$ is the initial cowedge, denoted by $\int_\mathcal{C} P(C, C)$.

Ends and coends are functorial w.r.t natural transformations.

Prop. (3.1.2.4) [Ends as Colimits]. There is a morphism

\[
F \mapsto \overline{F} : \text{Fun}(\mathcal{C}^{op} \times \mathcal{C}, \mathcal{D}) \to \text{Fun}(\text{Tw}(\mathcal{C}), \mathcal{D})
\]

where we maps $f : C \to C'$ to $F(C, C')$. Then it can be checked that

\[
\int^\mathcal{C} F(C, C) = \lim_{\text{Tw}(\mathcal{C})} \overline{F}, \quad \int_\mathcal{C} F(C, C) = \colim_{\text{Tw}(\mathcal{C})} \overline{F}.
\]

Cor. (3.1.2.5). A functor that preserves (co)limits preserves (co)ends.

Cor. (3.1.2.6). For an object $D \in \mathcal{D}$, we have isomorphisms:

\[
\text{Hom}(\int^\mathcal{C} F(C, C), D) \cong \int_C \text{Hom}(F(C, C), D),
\]

\[
\text{Hom}(D, \int_\mathcal{C} F(C, C)) \cong \int_C \text{Hom}(D, F(C, C)).
\]

Prop. (3.1.2.7) [Fubini]. Cf.[Coend Calculus, P20].

Prop. (3.1.2.8) [Natural Transformation as Ends]. Let $F, G : \mathcal{C} \to \mathcal{D}$ be functors, then the set of natural transformations is an coend.

\[
\text{Map}(F, G) \cong \int^\mathcal{C} \text{Hom}_{\mathcal{D}}(FC, GC)
\]

Kan Extension

Cf.[All Concepts are Kan Extensions].
Def. (3.1.2.9) [Kan Extensions]. Given functors $F : \mathcal{C} \to \mathcal{E}$ and $K : \mathcal{C} \to \mathcal{D}$, a left Kan extension of $F$ along $K$ is a functor $\text{Lan}_K F : \mathcal{D} \to \mathcal{E}$ together with a natural transformation $\eta : F \to \text{Lan}_K F \circ K$ that for any other pair $(G : \mathcal{D} \to \mathcal{E}, \gamma : F \to G \circ K)$, $\gamma$ factors uniquely through $\eta$.

Dually, a right Kan extension of $F$ over $K$ is equivalent to a left Kan extension of $F^{\text{op}}$ over $K^{\text{op}}$.

Prop. (3.1.2.10) [(Co)Limits as Kan Extensions]. If $\mathcal{D}$ is the final category 1, then the left Kan extension is just the colimit of the diagram defined by $F$, and the right Kan extension is just the limit of the diagram defined by $F$.

Prop. (3.1.2.11) [Yoneda Lemma]. $h_X : Y \mapsto \text{Hom}(Y, X)$ is a presheaf, and $\text{Hom}(h_X, F) \cong F(X)$ for any presheaf $F$.

So $X \to h_X$ is a fully faithful embedding from $\mathcal{C}$ to $\hat{\mathcal{C}} = \text{Func}(\mathcal{C}^{\text{op}}, \text{Set})$. In particular, if a $X \to Y$ induces isomorphism $\text{Hom}(W, X) \to \text{Hom}(W, Y)$ for every $W$, then $X \cong Y$.

So we can regard $C$ as a fully faithful subcategory of $\hat{\mathcal{C}}$.

Proof: The map $\text{Hom}(h_X, F) \to F(X)$ maps a $u$ to $u(X)(\text{id}_X)$. And the inverse map is defined to be $x \in F(X) \mapsto (s \in \text{Hom}(Y, X) \mapsto s^*(x) \in F(Y)) \in \text{Hom}(h_X, F)$.

Cor. (3.1.2.12). A universal object for a presheaf $F$ is a pair $(X, \zeta)$ that $\zeta \in F(X)$ with the property that for any $U$ and a $\sigma \in F()$, there is a unique arrow $U \to X$ that $Ff(\zeta) = \sigma$.

In fact, a universal object is equivalent to an isomorphism $h_X \cong F$, and this makes it easy to check whether a presheaf $F$ is representable.

Prop. (3.1.2.13) [Presheaves as Colimits of Presentable Presheaves]. Any presheaf of sets in $C$ is a colimit of presentable presheaves of $C$. More precisely, there is an isomorphism $F \cong \lim_{h_X \to F} h_X$.

From this we see that any morphism $\hat{C} \to D$ is determined by its restriction on $C$.

Proof: For any presheaf $G$, there is a morphism $\text{Hom}(F, G) \to \text{Hom}(\lim_{h_X \to F} h_X, G)$, i.e. a set of sections $f_s \in G(X)$ for every $h_X \to F$, that if $t \circ u = s$, then $u^*(f_t) = f_s$. Conversely, by Yoneda lemma, this just says that there is a morphism of presheaves $F \to G : F(X) \to G(X) : s \mapsto f_s$.

Cor. (3.1.2.14) [Kan Extension]. For a cocomplete category $\mathcal{D}$, there is a natural bijection between functor $\hat{\mathcal{C}} \to \mathcal{D}$ that commutes with colimits and functors $\mathcal{C} \to \mathcal{D}$ by Yoneda embedding.

Proof: For this, we only have to notice the functor $\mathcal{D} \to \hat{\mathcal{C}} : D \mapsto \text{Hom}(FX, D)$ is right adjoint to $F : \hat{\mathcal{C}} \to \mathcal{D}$ when $F$ is defined by colimit as in (3.1.2.13).

Cor. (3.1.2.15). Any contravariant functor $F : \hat{\mathcal{C}} \to \text{Set}$ that take colimits to limits, $F$ is representable. (Just use $G$ in the last proof, $F$ is representable by $G(\text{pt})$).

Def. (3.1.2.16) [$J$-Free Diagram]. For a cocomplete category $\mathcal{C}$ and a small category $J$, let $J^\delta$ be the subcategory of $J$ that has the same objects but only the identity morphisms, then an $J$-diagram in $\mathcal{C}$ is called $J$-free iff it is a left Kan extension of some diagram $J^\delta \to \mathcal{C}$. 
3 2-Categories

Remark (3.1.3.1)[2-Categories]. 2-categories are defined as in (3.13.2.25).

Def. (3.1.3.2) [(2, 1)-Categories]. A (2, 1)-category is a 2-category that all the 2-morphisms (corresponding to a 2-simplex) are isomorphisms.

Def. (3.1.3.3) [Final Objects]. A final object in a (2, 1)-category is an object \( x \) that for any object \( y \) there is a morphism \( y \to x \), and any two morphisms \( y \to x \) are isomorphic by a unique 2-morphism.

Lemma (3.1.3.4) [2-Commutative diagrams]. Let \( C \) be a 2-category, and \( g : y \to z, f : x \to z \) are arrows in \( C \), then the diagrams in \( C \):

\[
\begin{array}{ccc}
w & \xrightarrow{a} & x \\
\downarrow{b} & & \downarrow{f} \\
y & \xrightarrow{g} & z
\end{array}
\]

together with a 2-morphism from \( gb \) to \( fa \), naturally form a 2-category. A diagrams with invertible 2-morphisms are called 2-commutative diagram in \( C \).

Def. (3.1.3.5) [2-Fibered Products]. Let \( C \) be a 2-category, and \( g : y \to z, f : x \to z \) are arrows in \( C \), a 2-fibered product of \( f, g \) is a final object in the (2, 1)-category of 2-commutative diagrams as defined in (3.1.3.4), and it is denoted by \( x \times_z y \).

4 Monoidal Categories

Main references are [Tensor Categories, Etingof], [Lur09].

Def. (3.1.4.1) [Monoidal Category]. A monoidal category is a category \( \mathcal{C} \) with a functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) and a unit object 1 together with isomorphisms

\[
\eta_{A,B,C} : (A \otimes B) \otimes C \to A \otimes (B \otimes C), \quad \alpha_A : A \otimes 1 \to A, \quad \beta_A : 1 \otimes A \to A
\]

that satisfies the following commutative diagrams: Cf.[HTT, P791]. (Pentagon diagram)

Def. (3.1.4.2) [Dual and Opposed Category]. Let \( \mathcal{C} \) be a monoidal category, then the opposed category \( \mathcal{C}^{opp} \) is the same category as \( \mathcal{C} \) with the tensoring switched, which is also a monoidal category.

The dual category \( \mathcal{C}^{opp} \) with the same tensoring is also a monoidal category.

Def. (3.1.4.3). A strict monoidal category is a monoidal category that the isomorphisms above are all identities.

Prop. (3.1.4.4) [Mac Lane Coherence]. In a monoidal category, any two morphisms between two bracketings of a product \( X_1 \otimes \ldots X_n \) constructed using the isomorphisms \( \eta_{A,B,C} \) are equal. Also if some \( X_i \) are 1, then we can also use \( \alpha_A \) and \( \beta_A \).

Prop. (3.1.4.5) [Cartesian Monoidal Category]. For a category that has finite products, the product makes \( \mathcal{C} \) a symmetric monoidal category, called the Cartesian monoidal structure.

The Cartesian monoidal structure of the category of sets the default monoidal structure.

Prop. (3.1.4.6). For any category \( \mathcal{C} \), the category \( \mathcal{C}[\mathcal{C}, \mathcal{C}] \) of endofunctors has a natural monoidal structure.
Def. (3.1.4.7) [Closedness]. A monoidal category $(\mathcal{C}, \otimes)$ is called **left-closed** if for every $A \in \mathcal{C}$, the functor $N \mapsto A \otimes N$ has a right adjoint $Y \mapsto A^Y$ (or denoted by $\text{Hom}(A, Y)$ when $\mathcal{C}$ is symmetric). Dually it is called **right-closed** if $\mathcal{C}^{op}$ is left-closed. It is called **closed** if it is both left-closed and right-closed.

For a Cartesian monoidal category $\mathcal{C}$, $\mathcal{C}$ is called **Cartesian closed** if it is closed for the Cartesian monoidal structure.

Def. (3.1.4.8) [Reflexive Objects]. Let $(\mathcal{C}, \otimes)$ be a symmetric monoidal category that is closed, then we denote $\text{Hom}(Y, 1)$ by $Y^\vee$, then there is a natural map $Y \to (Y^\vee)^\vee$. If such a map is reflexive, then $Y$ is called a **reflexive object**.

Prop. (3.1.4.9). If $\mathcal{C}$ is closed, then

$$
\lim_{A_i} B \cong \lim \text{lim} (A_i B) \quad A (\lim_{B_i} A) \cong \lim \text{lim} (A B_i)
$$

**Proof:** Because $\mathcal{C}$ is closed, left and right tensor $A \otimes -$ and $- \otimes A$ are both left adjoints thus commutes with colimits. Now $B \mapsto A B$ is a right adjoint, thus it commutes with limits. And for any $C \in \mathcal{C}$,

$$
\text{Hom}(C, \lim_{A_i} B) \cong \text{Hom}(C \otimes (\lim_{A_i} B), B) \cong \lim \text{Hom}(C \otimes A_i, B)
$$

$$
\cong \lim B \text{Hom}(C \otimes A_i, B) \cong \lim \text{Hom}(A_i B) \cong \text{Hom}(C, \lim (A_i B))
$$

so $\lim_{A_i} B \cong \lim (A_i B)$ by Yoneda lemma.

Def. (3.1.4.10) [Monoidal Functor]. Let $(\mathcal{C}, \otimes), (\mathcal{D}, \otimes)$ be monoidal categories, then a **right-lax monoidal functor** from $\mathcal{C}$ to $\mathcal{D}$ is a functor $G$ together with morphisms $\gamma_{A,B}: G(A) \otimes G(B) \to G(A \otimes B)$ for any $A, B \in \mathcal{C}$ and a morphism $e : 1_{\mathcal{D}} \to G(1_\mathcal{C})$ that satisfies the following compatibility conditions: (Hexagon diagram).

Moreover, it is called a **monoidal functor** if $\gamma_{A,B}$ and $e$ are all isomorphisms.

Def. (3.1.4.11) [Equivalence of Monoidal Categories]. An equivalence of monoidal categories is a map that is an equivalence of categories as well as a monoidal functor.

Prop. (3.1.4.12) [Mac Lane Strictness]. Any monoidal category is equivalent to a strict monoidal category.

Prop. (3.1.4.13) [Examples]. For a monoidal category $(\mathcal{C}, \otimes)$, the functor $X \mapsto \text{Hom}(1, X)$ is a right-lax monoidal functor from $\mathcal{C}$ to $\text{Set}(3.1.4.5)$.

The morphism $\pi_0 : A \mapsto \pi_0(A)$ is a monoidal functor from the category of topological spaces $\text{Top}$ to the category $\text{Set}$ because it commutes with products.

**Proof:**

Symmetric Monoidal Categories

Def. (3.1.4.14) [Symmetric Monoidal Category]. A symmetric monoidal category is a monoidal category $(\mathcal{C}, \otimes)$ together with a natural transformation $\psi$ between $\otimes$ and $\otimes \circ \sigma : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ that $\psi^2 = \text{id}$ and the following commutative hexagon diagram is commutative:

A **symmetric monoidal functor** between symmetric monoidal categories are required to commutes with the braiding.
Rigid Monoidal Categories

Def. (3.1.4.15) [Duals]. Let \( C \) be a monoidal category and \( V \in C \), a left dual of \( V \) is an element \( V^* \) together with maps
\[
ev_V : V^* \otimes V \to 1, \quad coev_V : 1 \to V \otimes V^*
\]
that satisfies
\[
V \to V \otimes V^* \otimes V, \quad V^* \to V^* \otimes V \otimes V^* \to V^*
\]
are identities.

Similarly we can define right dual. if \( Y \) is a left/right dual to \( X \), then \( X \) is right/left dual to \( Y \).

Def. (3.1.4.16) [Dual Morphisms]. Let \( f : X \to Y \) be a morphism and \( X^*, Y^* \) the left duals of \( X \) and \( Y \), then there is a natural left dual map: \( f^* : Y^* \to X^* \) given by
\[
Y^* \to Y^* \otimes X \otimes X^* \to Y^* \otimes Y \otimes X^* \to X^*.
\]

Prop. (3.1.4.17). Let \( F : C \to D \) be a monoidal functor of monoidal categories, \( X \in C \) is an object with left dual \( X^* \). Then \( F(X^*) \) is a left dual of \( F(X) \) with evaluation and coevaluation maps
\[
ev_{F(X)} : F(X^*) \otimes F(X) \to F(X^* \otimes X) \to F(1_C) \to 1_D,
\]
\[
coev_{F(X)} : 1_D \to F(1_C) \to F(X \otimes X^*) \to F(X) \otimes F(X^*).
\]
and similarly for right duals.

Prop. (3.1.4.18) [Adjointness]. Let \( C \) be a monoidal category and \( V \in C \) with left dual \( V^* \), then there are natural adjunction maps
\[
\text{Hom}(U \otimes V, W) \cong \text{Hom}(U, W \otimes V^*), \quad \text{Hom}(V^* \otimes U, W) \cong \text{Hom}(U, V \otimes W).
\]

Proof: The first adjunction map is given by \( f \mapsto (f \otimes \text{id}_{V^*}) \circ (\text{id}_U \otimes coev_V) \), and the inverse given by \( g \mapsto (W \otimes ev_V) \circ (g \otimes \text{id}_{V^*}) \). The verification and the second one: \( \square \)

Cor. (3.1.4.19). In particular, we can use Yoneda lemma to show the left/right adjoints are unique if they exist.

Def. (3.1.4.20) [Rigid Tensor Categories]. Let \( C \) be a monoidal category, an element \( X \in C \) is called rigid if it has left and right duals. A rigid monoidal category is a monoidal category that every object is rigid. In particular, by (3.1.4.18), a rigid monoidal category is closed.

Prop. (3.1.4.21). If \( C \) is a rigid tensor category, then the functor
\[
\text{Equivalence of } C^{op} \text{ and } C^{opp}.
\]

Cor. (3.1.4.22). Any natural transformation of monoidal functors between rigid monoidal categories is an isomorphism.

Proof: Cf. [Milne, Tannakian Categories, P13]. \( \square \)

Prop. (3.1.4.23) [Trace and Rank]. Let \( C \) be a rigid symmetric monoidal category, we can define a trace morphism
\[
\text{tr}_X : \text{End}(X) \to \text{End}(1) : f \mapsto 1 \to X \otimes X^* \xrightarrow{f \otimes \text{id}} X \otimes X^* \to X^* \otimes X \to 1
\]
And the dimension of \( X \) is defined to be \( \text{tr}_X(\text{id}_X) \in \text{End}(1) \).
Invertible Objects and Grothendieck Categories

Def. (3.1.4.24) [Invertible Objects]. An invertible object in a monoidal category is a rigid object $L$ that the evaluation maps and coevaluation maps are all isomorphisms.

Tensor Categories

Def. (3.1.4.25) [Tensor Categories]. A tensor category over a field $k$ is an Artinian Abelian category over $k$ together with a rigid monoidal structure that is bilinear and satisfies $\text{End}(1) = k$.

A tensor functor is a functor between tensor categories that is additive and monoidal.

Prop. (3.1.4.26) [End(1)]. If $\mathcal{C}$ is a rigid additive tensor category, then $\text{End}(1)$ is a ring that acts on objects $X \in \mathcal{C}$ via $X \cong 1 \otimes X$. The action of $\text{End}(1)$ commutes with $\text{End}(X)$, in particular, $\text{End}(1)$ is commutative and $\mathcal{C}$ is $\text{End}(1)$-linear.

Prop. (3.1.4.27) [Abelian Rigid Tensor Category Exact]. If $\mathcal{C}$ is an rigid Abelian tensor category, then $\otimes$ commutes with inverse limits and direct limits in each variable.

Proof: It commutes with direct limits because it is left adjoint to the Hom functor, and it commutes with inverse limits by considering the opposite category (3.1.4.21).

Prop. (3.1.4.28). $\dim(X \otimes Y) = \dim X \cdot \dim Y$. If there is an exact sequence $0 \rightarrow X \rightarrow Z \rightarrow Y \rightarrow 0$, then $\dim(Z) = \dim(X) + \dim(Y)$.

Prop. (3.1.4.29) [Decompositions]. Let $(\mathcal{C}, \otimes)$ be a rigid Abelian tensor category and if $U$ is a subobject of 1, then $1 = U \oplus U^\perp$ where $U^\perp = \ker(1 \rightarrow U^\vee)$. Consequently, 1 is a simple object iff $\text{End}(1)$ is a field. And any rigid tensor category can be decomposed as rigid Abelian tensor categories $\mathcal{C}_I$ with $\text{End}(1_I)$ being fields.

Proof: Let $V = \text{Coker}(U \rightarrow 1)$, by tensoring $0 \rightarrow U \rightarrow 1 \rightarrow V \rightarrow 0$ with $U \hookrightarrow 1$, we get exact sequences

$$
\begin{array}{cccccc}
0 & \rightarrow & U & \rightarrow & 1 & \rightarrow & V & \rightarrow & 0 \\
\uparrow & & \uparrow & & \uparrow & & \uparrow \\
0 & \rightarrow & U \otimes U & \rightarrow & U & \rightarrow & V \otimes U & \rightarrow & 0
\end{array}
$$

thus $V \otimes U = 0$ and $U \otimes U = U$ via $1 \otimes 1 \cong 1$.

For the rest, Cf. [Tannakian Categories, Milne, P14].

Def. (3.1.4.30) [Associative Algebra in a Symmetric Tensor Category].

Prop. (3.1.4.31) [Fiber Functors]. If a symmetric tensor category admits an additive monoidal functor from $\mathcal{C} \rightarrow \text{Vect}_k$, then it is unique up to isomorphisms. Such a functor is called a fiber functor.

Def. (3.1.4.32) [Tannakian Categories]. A Tannakian category is a symmetric tensor category $\mathcal{C}$ over $k$ which admits a fiber functor $F : \mathcal{C} \rightarrow \text{Vect}_k$.

Prop. (3.1.4.33). An Tannakian category is equivalent to the symmetric tensor category $\text{Rep}(G)$ for an affine group scheme $G$, and $G$ is uniquely defined up to inner automorphisms.
5 Enriched Category

Def. (3.1.5.1) [Enriched Category]. Given a monoidal category \((\mathcal{C}, \otimes)\), an enriched category \(\mathcal{D}\) over \(\mathcal{C}\) consists of the following data:

- a collection of objects.
- For objects \(X, Y \in \mathcal{D}\), a mapping object \(\text{Map}_\mathcal{D}(X, Y) \subseteq \mathcal{C}\).
- For objects \(X, Y, Z \in \mathcal{D}\), a composite map \(\text{Map}(X, Y) \otimes \text{Map}(Y, Z) \to \text{Map}(X, Z)\) that is associative.
- For every \(X \in D\), a morphism \(1 \mapsto \text{Map}(X, X)\) that satisfies the commutative diagrams of the identity morphism.

Def. (3.1.5.2) [Category of Enriched Categories]. We can naturally define morphisms and natural transformations of categories enriched over a monoidal category \(\mathcal{C}\).

Prop. (3.1.5.3) [Transfer of Enriched Structure]. Given a right-lax monoidal functor between monoidal categories \(F : \mathcal{C} \to \mathcal{C}'\) and a category \(\mathcal{D}\) enriched over \(\mathcal{C}\), we may obtain a category \(F(\mathcal{D})\) enriched over \(\mathcal{C}'\) by asserting \(\text{Map}_{F(\mathcal{D})}(X, Y) = F(\text{Map}(X, Y))\). It is an enriched category just by the definition of right-lax monoidal functors.

Prop. (3.1.5.4) [Underlying Category]. For a category enriched \(\mathcal{D}\) over \(\mathcal{C}\), by (3.1.4.13), we can transfer the structure via \(\mathcal{C} \to \text{Set} : X \mapsto \text{Hom}(1, X)\), and the resulting category is called the underlying category of \(\mathcal{D}\).

Prop. (3.1.5.5).

- A category enriched in the Cartesian monoidal structure of the category of sets is just a usual category.
- A right-closed monoidal category is enriched over itself if we define \(\text{Map}(X, Y) = Y^X\). (Check).

Def. (3.1.5.6) [Tensored Category]. Let \(\mathcal{C}\) be a right-closed monoidal category and \(\mathcal{D}\) a category enriched over \(\mathcal{C}\), then \(\mathcal{D}\) is called tensored over \(\mathcal{C}\) if for any \(C \in \mathcal{C}\) and \(X \in \mathcal{D}\), there is an isomorphism of functors

\[
\eta : \text{Map}_\mathcal{D}(X, -)^C \cong \text{Map}_\mathcal{D}(X \otimes C, -).
\]

for some element \(X \otimes C \in \mathcal{D}\).

In particular, this implies \(\text{Hom}_\mathcal{C}(C, \text{Map}(X, Y)) \cong \text{Hom}_\mathcal{D}(X \otimes C, Y)\), thus \(X \otimes C\) is determined up to a unique isomorphism, and the map \((X, C) \mapsto X \otimes C\) defines a functor \(\mathcal{D} \times \mathcal{C} \to \mathcal{D}\) that there are natural morphisms

\[
X \otimes (C \otimes D) \cong (X \otimes C) \otimes D.
\]

Dually, if \(\mathcal{C}\) is left-closed and there is an object \(^C X\) that there is an isomorphism of functors

\[
^C \text{Map}(-, X) \cong \text{Map}(-, ^C X)
\]

then \(\mathcal{D}\) is called cotensored over \(\mathcal{C}\).

Proof: \(\square\)

Prop. (3.1.5.7). If \(\mathcal{C}\) is a right-closed monoidal category, then it is naturally tensored over itself, as defined in (3.1.5.5).
6 Others

Def. (3.1.6.1) [Compact Objects]. Fix a regular cardinal $\kappa$. Let $\mathcal{C}$ be a category that admits small colimits, and $J$ be a $\kappa$-filtered poset and a diagram $\{Y_\alpha\}$ indexed by $J$, then for $X \in \mathcal{C}$, there is a natural map

$$\lim \hom(X, Y_j) \to \hom(X, \lim Y_j).$$

$X$ is called $\kappa$-compact if this is an isomorphism for any $\kappa$-filtered diagram $J$. $X$ is called small if it is $\kappa$-compact for some small regular cardinal $\kappa$.

Def. (3.1.6.2) [Presentable Category]. Fix a regular cardinal $\kappa$, a regular category is a category $\mathcal{C}$ that satisfies:

- $\mathcal{C}$ admits all small colimits.
- $\mathcal{C}$ is generated by a small set $S$ of objects of $\mathcal{C}$ under small colimits.
- Any object of $\mathcal{C}$ is small.
- For $X,Y \in \mathcal{C}$, $\hom(X,Y)$ is small.

Remark (3.1.6.3). HTT Chap5.5 has a $\infty$-generalization of this notion.

Lifting Property and Small Object Argument

Def. (3.1.6.4) [lifting Properties]. Let $\mathcal{C}$ be a category and $p: A \to B, q: X \to Y$ be morphisms, then $p$ is said to have left lifting property w.r.t $q$ and $q$ is said to have right lifting property w.r.t $p$ if given any diagram

$$\begin{array}{ccc}
A & \to & X \\
\downarrow & & \downarrow \\
B & \to & Y
\end{array}$$

there is a dotted arrow completing the diagram.

For a set $A$ of morphisms of $\mathcal{C}$, let $l(A)$ denote the morphisms that have left lifting property w.r.t $A$ and $r(A)$ the morphisms that have right lifting property w.r.t $A$.

Def. (3.1.6.5) [Weakly Saturated Class]. Let $\mathcal{C}$ be a category with all small colimits, then a class of morphisms of $\mathcal{C}$ is called weakly saturated if it satisfies:

- Closed under pushout.
- Closed under transfinite composition: Let $\alpha$ be an ordinal and $\{D_\beta\}_{\beta<\alpha}$ be a system of objects in $\mathcal{C}_{C\downarrow}$ indexed by $\alpha$. For $\beta < \alpha$, let $D_{\leq \beta}$ be the colimit of system $\{D_\gamma\}_{\gamma<\beta}$ in $\mathcal{C}_{C\downarrow}$, then if each $D_{\leq \beta} \to D_\beta$ is in $S$, then $C \to D_{\leq \alpha}$ is in $S$.
- Closed under Retraction: In the category of morphisms of $\mathcal{C}$, if there is a morphism $F : f \to g, G : g \to f$ that $G \circ F = \text{id}$, and $g \in S$, then $f \in S$.

Cor. (3.1.6.6). The second condition implies all isomorphisms are in $S$, and $S$ is closed under composition.

Prop. (3.1.6.7) [Lifting and Retraction]. For a diagram $\begin{array}{ccc}
X & \to & X \\
\downarrow & & \downarrow \\
Z & \to & Y
\end{array}$ represents $p$ as a retraction of $u$, as the diagram $\begin{array}{ccc}
X & \to & Z \\
\downarrow & & \downarrow \\
Y & \to & Y
\end{array}$ shows.
Dually a diagram:

\[
\begin{array}{c}
X \xrightarrow{i} Y \\
\downarrow q \quad s \quad \downarrow f \\
Z \quad \quad Z \\
\end{array}
\]

represents \( q \) as a retraction of \( i \).

**Prop. (3.1.6.8) [Small Object Argument].** Let \( \mathcal{C} \) be a presentable category and \( A_0 = \{ \varphi_i : C_i \to D_i \} \) be a small collection of morphisms in \( \mathcal{C} \), then there is a morphism \( T : \mathcal{C}[1] \to \mathcal{C}[2] \) taking morphisms \( f : X \to Z \) in \( \mathcal{C} \) to the diagram

\[
\begin{array}{c}
Y \\
\downarrow f' \\
X \xrightarrow{f} Z
\end{array}
\]

That \( f' \) belongs to the weakly saturated class generated by \( A_0 \) and \( f'' \in r(A_0) \).

Moreover, if \( \kappa \) is a regular cardinal that each \( C_i, D_i \) is \( \kappa \)-compact, then \( T \) commutes with \( \kappa \)-filtered colimits.

**Proof:** Cf. [HTT, P788]. \( \square \)

**Lemma (3.1.6.9).** \( l(A) \) is weakly saturated for any set of morphisms \( A \)(Clear).

**Cor. (3.1.6.10) [Generated Weakly Saturated Class].** For any presentable category \( \mathcal{C} \) and \( A \) a set of morphisms in \( \mathcal{C} \), \( l(r(A)) \) is the smallest weakly saturated class of morphisms containing \( A \).

**Proof:** One direction of inclusion is by (3.1.6.9), for the other, if \( f : X \to Z \in l(r(A)) \), then there is a factorization \( X \xrightarrow{f'} Y \xrightarrow{f''} Z \), where \( f' \in A \) and \( f'' \in r(A) \), thus \( f \in l(f'') \), thus \( f \) is retraction of \( f' \):

\[
\begin{array}{c}
X \xrightarrow{f'} Y \\
\downarrow f' \quad g \quad f'' \quad \downarrow f'' \\
Z \quad \quad Z \quad Y \quad Z
\end{array}
\]

Thus \( f \in A \). \( \square \)

**Trees**

Cf. [HTT, Appendix]

**7 Fibered Categories**

**Categories of Categories**

**Def. (3.1.7.1) [2-Category of Categories over Categories].** There is a 2-category of categories over \( \mathcal{C} \), where the 1-morphisms are morphisms of categories over \( \mathcal{C} \) and the 2-morphisms are base-preserving natural transformations.

Two categories over \( \mathcal{C} \) are called **equivalent** if they are equivalent in this 2-category.

**Prop. (3.1.7.2) [2-Fibered Products in the Categories of Categories].** 2-fibered products exists in the categories of categories.

**Proof:** Let \( F : A \to \mathcal{C}, G : B \to \mathcal{C} \) be functors, then we can define a category \( A \times_\mathcal{C} B \) as follows:
3.1. CATEGORIES

- Objects are the triples \((A, B, f)\) where \(A \in \mathcal{A}, B \in \mathcal{B}\) and \(f : F(A) \rightarrow G(B)\) is an isomorphism in \(\mathcal{C}\).

- Morphisms from \((A, B, f)\) to \((A', B', f')\) are pairs \((a, b)\) where \(a : A \rightarrow A', b : B \rightarrow B'\) s.t. the diagram

\[
\begin{array}{ccc}
F(A) & \xrightarrow{f} & G(B) \\
\downarrow^{F(a)} & & \downarrow^{G(b)} \\
F(A') & \xrightarrow{f'} & G(B')
\end{array}
\]

is commutative.

\(\mathcal{A} \times_{\mathcal{C}} \mathcal{B}\) is a category both over \(\mathcal{A}\) and over \(\mathcal{B}\), and it fits into a 2-fiber products diagram

\[
\begin{array}{ccc}
\mathcal{A} \times_{\mathcal{C}} \mathcal{B} & \rightarrow & \mathcal{B} \\
\downarrow & & \downarrow \\
\mathcal{A} & \rightarrow & \mathcal{C}
\end{array}
\]

where the invertible 2-morphism is given by \(\psi_{(A,B,f)} = f : F(A) \rightarrow G(B)\).

The verification that this defines a final object in the 2-category of 2-commutative diagrams is in [Sta]02X9.

\(\square\)

Cor. (3.1.7.3). The 2-fibered product \(\mathcal{A} \times_{\mathcal{C}} \mathcal{B}\) is a groupoid iff \(\mathcal{A}, \mathcal{B}\) are all groupoids.

Prop. (3.1.7.4). Let \(\mathcal{A} \rightarrow \mathcal{C}, \mathcal{B} \rightarrow \mathcal{C}, \mathcal{C} \rightarrow \mathcal{D}\) be functors between categories, then there is a 2-fiber product diagram

\[
\begin{array}{ccc}
\mathcal{A} \times_{\mathcal{C}} \mathcal{B} & \rightarrow & \mathcal{A} \times_{\mathcal{D}} \mathcal{B} \\
\downarrow & & \downarrow \\
\mathcal{C} & \xrightarrow{\Delta_{\mathcal{C}/\mathcal{D}}} & \mathcal{C} \times_{\mathcal{D}} \mathcal{C}
\end{array}
\]

Proof: \(\square\)

Prop. (3.1.7.5) [2-Fibered Products of Categories]. The \((2,1)\)-category of categories over \(\mathcal{C}\) has 2-fiber products (3.1.3.5). More explicitly, suppose \(\mathcal{F} : \mathcal{X} \rightarrow \mathcal{S}, \mathcal{Y} \rightarrow \mathcal{S}\) be morphisms of categories over \(\mathcal{C}\), \(\mathcal{X} \times_{\mathcal{C}} \mathcal{Y}\) is given as follows:

- Objects of \(\mathcal{X} \times_{\mathcal{C}} \mathcal{Y}\) are quadruples \((U, x, y, f)\), where \(U \in \mathcal{C}, x \in \mathcal{X}_U, y \in \mathcal{Y}_U,\) and \(f : F(x) \rightarrow G(y)\) is an isomorphism in \(\mathcal{S}_U\).

- A morphism \((U, x, y, f) \rightarrow (U', x', y', f')\) is given by a pair \((a, b)\), where \(a : x \rightarrow x'\) is a morphism in \(\mathcal{X}\) and \(y \rightarrow y'\) is a morphism in \(\mathcal{Y}\) that
  - \(a, b\) induce the same morphism \(U \rightarrow U'\).
  - the diagram

\[
\begin{array}{ccc}
F(x) & \xrightarrow{f} & G(y) \\
\downarrow^{F(a)} & & \downarrow^{G(b)} \\
F(x') & \xrightarrow{f'} & G(y')
\end{array}
\]

is an isomorphism.
\(\mathcal{X} \times_S \mathcal{Y}\) is endowed with morphisms to \(\mathcal{X}\) and \(\mathcal{Y}\) over \(\mathcal{C}\) that the invertible 2-morphism giving the 2-commutativity is \(\psi_{(U,x,y,f)} : F(x) \to G(y)\).

The verification of the universal properties are similar to that of (3.1.7.2).

Cor. (3.1.7.6). There is an equivalence of fibre categories:

\[ (\mathcal{X} \times_S \mathcal{Y})_U \cong \mathcal{X}_U \times_{\mathcal{S}_U} \mathcal{Y}_U. \]

Fibered Categories

Def. (3.1.7.7) [(Co)Cartesian Arrows]. Let \(p : \mathcal{F} \to \mathcal{C}\) be a morphism, then a **Cartesian arrow** is an arrow \(\phi : C' \to C\) in \(\mathcal{F}\) that for any object \(C'' \in \mathcal{F}\) the map

\[ \text{Hom}(C'', C') \to \text{Hom}(C'', C) \times_{\text{Hom}(p(C''), p(C))} \text{Hom}(p(C''), p(C')) \]

is a bijection. A **coCartesian arrow** is an arrow that corresponds to a Cartesian diagram in \(\mathcal{F}^{\text{op}} \to \mathcal{C}^{\text{op}}\).

Prop. (3.1.7.8).

- If \(f\) is Cartesian, then \(f \circ g\) is Cartesian iff \(g\) is Cartesian.
- An arrow in \(\mathcal{F}\) whose image is an isomorphism is Cartesian iff it is itself an isomorphism.

Proof: Easy.

Def. (3.1.7.9) [Quasi-Fibration]. A functor \(F : \mathcal{C} \to \mathcal{D}\) is called a **quasi-fibration** if for any \(X \in \mathcal{C}\) and an isomorphism \(f : F(X) \cong Y\), there is an isomorphism \(\overline{f} : X \to Y\) mapping to \(f\).

Def. (3.1.7.10) [2-Category of Fibered Categories]. A **fibered category** over \(\mathcal{C}\) is a category over \(\mathcal{C}\) \(p : \mathcal{F} \to \mathcal{C}\) that for any \(\eta \in \mathcal{F}\) and an arrow \(f : U \to p(\eta)\), there is a Cartesian arrow \(\xi \to \eta\) in \(\mathcal{F}\) lifting \(f\). A **cofibered category** over \(\mathcal{C}\) is a category \(p : \mathcal{F} \to \mathcal{C}\) that the dual category \(p^{\text{op}} : \mathcal{F}^{\text{op}} \to \mathcal{C}^{\text{op}}\) is a fibered category.

A morphism of fibered categories over \(\mathcal{C}\) is a morphism of categories over \(\mathcal{C}\) that maps Cartesian morphisms to Cartesian morphisms. A 2-morphism of fibered categories is the same as a 2-morphism of categories over categories.

Def. (3.1.7.11) [Split Fibered Categories]. A **split fibered category** is a fibered category \(\mathcal{F} \to \mathcal{C}\) that comes from a functor \(\mathcal{C}^{\text{op}} \to \text{Cat}\).

Def. (3.1.7.12) [Cleavage]. A **cleavage** of a fibered category \(\pi : \mathcal{F} \to \mathcal{C}\) is a choice of Cartesian arrow \(f^*\) lifting \(f\) for any \(f \in \text{Arr}(\mathcal{C})\).

Lemma (3.1.7.13). Let \(F : \mathcal{F} \to \mathcal{G}\) be a morphism of fibered categories over \(\mathcal{C}\) that \(\mathcal{F}(U) \to \mathcal{G}(U)\) are fully faithful for any \(U \in \mathcal{C}\), then \(F\) is fully faithful.

Proof: To show \(F\) is fully faithful, it suffices to show for objects \(X, Y\) lying over \(U, V\), \(F\) induces a bijection of morphisms from \(x\) to \(y\) lying over a fixed \(f : U \to V\). Choose a Cartesian morphism \(f^*y \to y\) in \(\mathcal{S}_1\) lying over \(f\), then this induces a bijection between morphisms from \(x\) to \(y\) lying over \(f\) and \(\text{Hom}_{\mathcal{S}_1,U}(x, f^*y)\). Similarly, because \(F\) preserves Cartesian morphisms, we get a bijection between morphisms \(F(x) \to F(y)\) lying over \(f\) and \(\text{Hom}_{\mathcal{S}_2,U}(F(x), F(f^*y))\). Then the desired bijection follows from the hypothesis.
Prop. (3.1.7.14) [Equivalence of Fibered Categories]. Let \( F : \mathcal{F} \to \mathcal{G} \) be a morphism of fibered categories. Then \( F \) is an equivalence iff the restriction \( F_U : \mathcal{F}(U) \to \mathcal{G}(U) \) is an equivalence of categories for any object \( U \) of \( \mathcal{C} \).

Proof: One direction is trivial, for the other, the proof is similar to the fact essentially surjective+fully faithful implies equivalence.

Because \( F(U) \) are equivalences, for any object \( \xi \) of \( \mathcal{G} \) over \( U \), pick an object \( G\xi \) in \( \mathcal{F}(U) \) together with an isomorphism \( \alpha_\xi : \xi \cong F(G\xi) \). And for any morphism \( \xi \to \eta \), by (3.1.7.13), there is a unique arrow \( G\varphi : G\xi \to G\eta \) that \( F(G\varphi) = \alpha_\eta \circ \varphi \circ \alpha_\xi^{-1} \).

Thus clearly there is a 2-isomorphism \( \text{id}_\mathcal{G} \cong F \circ G \). It remains to construct an 2-isomorphism \( \text{id}_\mathcal{F} \cong G \circ F \): For any object \( \xi' \) over \( U \), since \( F(U) \) is fully faithful, there is a unique isomorphism \( \beta_{\xi'} : \xi' \cong G \circ F(\xi) \) in \( \mathcal{F}(U) \) that \( F\beta_{\xi'} = \alpha_{F\xi'} \). Then this is easily checked to be an 2-isomorphism \( \beta : \text{id}_\mathcal{F} \cong F \circ G \).

Prop. (3.1.7.15) [2-Fiber Products of Fibered Categories]. 2-fiber products exists in the category of fibered categories, and it coincides with that defined in (3.1.7.5).

Proof: it suffices to show for fibered categories \( \mathcal{X}, \mathcal{Y} \) over \( \mathcal{C} \), \( \mathcal{X} \times_\mathcal{C} \mathcal{Y} \) is also fibered over \( \mathcal{C} \). Let \((x,y,\varphi)\) be an object of \( \mathcal{X} \times_\mathcal{C} \mathcal{Y} \) mapping to \( U \in \mathcal{C} \) and \( f : V \to U \) is a morphism in \( \mathcal{C} \), choose Cartesian morphisms \( a : f^*x \to x \), \( b : f^*y \to y \) lying over \( f \), then \( F(a) \) and \( G(b) \) are Cartesian. Since \( \varphi : F(x) \to G(y) \) is an isomorphism, by the property of Cartesian morphisms, there exists a unique isomorphism \( f^*\varphi : F(f^*x) \to G(f^*y) \in \mathcal{S}_V \) that \( G(b) \circ f^*\varphi = \varphi \circ F(a) \). In other words, \( (F(a),F(b)) : (V,f^*x,f^*y,f^*\varphi) \to (U,x,y,\varphi) \) is a morphism in \( \mathcal{X} \times_\mathcal{S} \mathcal{Y} \).

The verification that this morphism is Cartesian is omitted.

Lemma (3.1.7.16). Let \( \mathcal{S} \to \mathcal{C} \) be a fibered category that factors through \( \mathcal{C}/U \) where \( U \in \mathcal{C} \), then \( \mathcal{S} \to \mathcal{C}/U \) is also a fibered category.

Proof: Cf.[[Sta]02XR].

Def. (3.1.7.17) [G-Equivariant Object]. Let \( G : \mathcal{C}^{op} \to (\text{Grp}) \) be a group functor and \( p_\mathcal{F} : \mathcal{F} \to \mathcal{C} \) a fibered category, and \( X \) an object of \( \mathcal{C} \) with an action of \( G \). A G-equivalent object of \( \mathcal{F}(X) \) is an object \( \rho \) of \( \mathcal{F}(X) \) that there is an action of \( G \circ p_\mathcal{F} \) on \( \rho \) and for any object \( U \) and \( \xi \in \mathcal{F}(U) \), the function \( p_\mathcal{F} : \text{Hom}_\mathcal{F}(\xi,\rho) \to \text{Hom}_\mathcal{C}(U,\rho) \) is \( G(U) \)-equivariant.

The category \( \mathcal{F}^G(X) \) of \( G \)-equivariant objects of \( \mathcal{F}(X) \) consisting of \( G \circ p_\mathcal{F} \)-equivariant morphism of \( G \)-equivariant objects.

Prop. (3.1.7.18). Let \( \pi_2 \) is the projection \( G \otimes X \to X \), \( \rho \) be an object of \( \mathcal{F}(X) \), then a \( G \)-equivariant structure on \( \rho \) is the same as a Cartesian arrow \( \beta : \pi_2^*\rho \to \rho \) that \( p_\mathcal{F}\beta = \alpha \), and satisfies the desired commutative diagram corresponding to \( (gh)x = g(h(x)) \). And a morphism of \( G \)-equivariant objects just corresponds to a morphism of pairs \( (\rho,\beta) \).

Proof: Cf.[Vistoli, P68].

Def. (3.1.7.19) [Presheaf of Arrows]. Let \( \mathcal{F} \) be a fibered category over \( \mathcal{C} \), and \( \xi,\eta \in \mathcal{F}(S) \), then we can define a quasi-functor \( \text{Hom}_S(\xi,\eta) \to (\mathcal{C}/S) \), where

\[
\text{Hom}_S(\xi,\eta)(U/S) = \{(\xi_1 \to \xi, \eta_1 \to \eta, \varphi)\}
\]
where $\xi_1 \to \xi, \eta_1 \to \eta$ are Cartesian arrows over $U \to S$, and $\varphi : \xi_1 \to \eta_1 \in \mathcal{F}(U)$. The arrows in $\text{Hom}_S(\xi, \eta)$ are uniquely defined by the property of Cartesian arrows. Then it is a quasi-functor, by (3.1.7.30).

Then it is equivalence to a presheaf $\text{Hom}_S(\xi, \eta)$, by (3.1.7.31). Equivalently, this presheaf can be defined by designating a choice of Cartesian arrows.

**Prop. (3.1.7.20)** [Splitting a Fibered Category]. Let $\mathcal{F} \to \mathcal{C}$ be a fibered category, then there exists a canonically defined split fibered category $\tilde{\mathcal{F}} \to \mathcal{C}$ with a canonical equivalence of fibered categories $\tilde{\mathcal{F}} \to \mathcal{F}$ over $\mathcal{C}$.

**Proof:** There is a functor $\mathcal{C}^{\text{op}} \to \text{Cat} : U \mapsto \text{Hom}(h_U, \mathcal{F})$, with corresponds to a split fibered category $\tilde{\mathcal{F}}$. There is an obvious morphism $\tilde{\mathcal{F}} \to \mathcal{F}$, sending an object $\varphi : h_U \to \mathcal{F}$ to $\varphi(\text{id}_U) \in \mathcal{F}(U)$. And for any $f : U \to V \in \mathcal{C}$ and a $\varphi : h_U \to \mathcal{F}$, we send $f^*\varphi \to \varphi \in \tilde{\mathcal{F}}$ to $\varphi(f : V/U \to U/U) \in \mathcal{F}$, Then we get a canonical map of fibered categories $\tilde{\mathcal{F}} \to \mathcal{F}$ over $\mathcal{C}$. It is an equivalence of categories by (3.1.7.14) and (3.1.7.33). □

**Categories Fibered in Groupoids, Sets and Equivalence Relations**

**Def. (3.1.7.21)** [Category Fibered in Groupoids]. A category (co)fibered in groupoids/setoids/equivalence relations over $\mathcal{C}$ is a category $\mathcal{F}$ (co)fibered over $\mathcal{C}$ that $\mathcal{F}(U)$ is a groupoid/setoids/equivalence relations for any $U \in \mathcal{C}$. Also we call a category fibered in equivalence relations over $\mathcal{C}$ a quasi-functor.

**Prop. (3.1.7.22)** [Characterization of Category Fibered in Groupoids]. Let $\mathcal{F}$ be a category over $\mathcal{C}$, then $\mathcal{F}$ is fibered over groupoids over $\mathcal{C}$ iff

- Every morphism in $\mathcal{F}$ is Cartesian.

- Given any $\eta \in \mathcal{F}, U \in \mathcal{C}$ and a morphism $f : U \to p_{\mathcal{F}}(\eta)$, there is an arrow $\varphi : \xi \to \eta \in \mathcal{F}$ mapping to $f$.

And dually for cofibered categories.

**Proof:** If these two holds, then $\mathcal{F}$ is clearly fibered over $\mathcal{C}$, and for any arrow $f : \xi \to \eta$ in $\mathcal{F}(U)$, there is a morphism $g : \eta \to \xi$ that is right inverse to $f$, then clearly it is the inverse.

Conversely, if $\mathcal{F}$ is fibered over $\mathcal{C}$, it suffices to check1: for any arrow $f$, the image in $\mathcal{C}$ can be lifted to a Cartesian diagram in $\mathcal{F}$, and differs $f$ by an isomorphism, thus $f$ is also Cartesian by (3.1.7.8). □

**Cor. (3.1.7.23).** if $\mathcal{A}$ is a category fibered in groupoids over $\mathcal{B}$ and $\mathcal{B}$ is a category fibered in groupoids over $\mathcal{C}$, then $\mathcal{A}$ is a category fibered in groupoids over $\mathcal{C}$.

**Prop. (3.1.7.24)** [Associated Category Fibered in Groupoids]. Let $\mathcal{F} \to \mathcal{C}$ be a fibered category, then the associated category fibered in groupoids $\mathcal{F}_{\text{cart}}$ is the category obtained by deleting all the non-Cartesian arrows. Then $\mathcal{F}_{\text{cart}}$ is a category fibered in groupoids over $\mathcal{C}$.

**Proof:** Firstly $\mathcal{F}_{\text{cart}}$ is a category by (3.1.7.8), and it is a category fibered in groupoids by (3.1.7.22). □

**Def. (3.1.7.25)** [Rigid Fibered Categories]. A rigid fibered category is a fibered category whose associated category fibered groupoids is fibered in setoids. Equivalently, there are no isomorphisms above any id$_U$. 

Prop. (3.1.7.26) [2-Fibered Products of Categories Fibered in Groupoids]. The 2-fibered products of categories fibered in groupoids over $\mathcal{C}$ is a category fibered in groupoids over $\mathcal{C}$.

Proof: The 2-fibered products exist by (3.1.7.15), and using (3.1.7.6), it is fibered in groupoids because the 2-fibered products of groupoids is a groupoid by (3.1.7.3). □

Prop. (3.1.7.27) [Characterization of Categories Fibered in Setoids]. Let $\mathcal{F}$ be a category over $\mathcal{C}$, then $\mathcal{F}$ is fibered in setoids over $\mathcal{C}$ iff for any object $\eta$ of $\mathcal{F}$ and an arrow $f : U \rightarrow p\mathcal{F}\eta \in \mathcal{C}$, there is a unique arrow $\xi \rightarrow \eta$ mapping to $f$.

Proof: Let $\mathcal{F}$ be a category fibered in sets, then pick a Cartesian arrow $\tilde{f}$ over $f$, then any other lifting factors through this lifting by the property of Cartesian, then it is identity, because $\mathcal{F}(U)$ is a setoid.

Conversely, if the hypothesis holds, then clearly $\mathcal{F}(U)$ is a setoid, and the fibered category condition holds, because of the uniqueness. □

Cor. (3.1.7.28) [Presheaves and Categories Fibered in Setoids]. Let $\mathcal{C}$ be a category, then categories fibered in setoids over $\mathcal{C}$ are exactly those equivalent to a presheaf over $\mathcal{C}$.

Cor. (3.1.7.29). In particular, for any object $X \in \mathcal{C}$, the presheaf $h_X$ determines a category fibered in sets, which is just the comma category $\mathcal{C}/X \rightarrow \mathcal{C}$.

Prop. (3.1.7.30) [Characterization of Quasi-Functors]. A category $\mathcal{F}$ over $\mathcal{C}$ is a quasi-functor iff:

- Given any object $\eta \in \mathcal{F}$ and an arrow $f : U \rightarrow p\mathcal{F}\eta$, there is a lifting $\xi \rightarrow \eta$ mapping to $f$. And given any two such extensions, there is a morphism $\xi' \rightarrow \xi$ commuting them.

- Given any two objects $\xi, \eta \in \mathcal{F}$ and an arrow $f : p\mathcal{F}\xi \rightarrow p\mathcal{F}\eta$, there is at most one arrow $\tilde{f} : \xi \rightarrow \eta$ lifting $f$.

Proof: □

Prop. (3.1.7.31). A fibered category over $\mathcal{C}$ is a quasi-functor iff it is equivalent to a presheaf.

Proof: If it is equivalent to a functor, then $\mathcal{F}(U)$ is equivalent to a setoid, thus it is an equivalent relation, by (3.1.1.15). Conversely, if $\mathcal{F}$ is a quasi-functor, then it is fibered in groupoids, thus by (3.1.7.22) every morphism is Cartesian, and if we denote $\Phi(U)$ the equivalence classes of $\mathcal{F}(U)$, then a morphism $U \rightarrow V$ will induce a morphism $\Phi(V) \rightarrow \Phi(V)$ by the property of Cartesian arrows. Then clearly this defines a presheaf that is equivalent to $\mathcal{F}$. □

Representability

Def. (3.1.7.32) [Representable Fibered Category]. A fibered category is called representable if it is equivalent to the fibered category $\mathcal{C}/X$ defined in (3.1.7.29) for some $X \in \mathcal{C}$.

Prop. (3.1.7.33) [2-Categorical Yoneda Lemma]. Let $\mathcal{F}$ be a fibered category over $\mathcal{C}$ and $X \in \mathcal{C}$, there is an equivalence of categories:

\[
\text{Hom}_{\mathcal{C}}((\mathcal{C}/X), \mathcal{F}) \cong \mathcal{F}(X) : \varphi \mapsto \varphi(\text{id}_X)
\]
Proof: To show this functor is essentially surjective, choose a choice of pullbacks of $\mathcal{F}$, for any $\xi \in \mathcal{F}(X)$, we define a $F : \mathcal{C}/X \rightarrow \mathcal{F}$ that maps a $\varphi : U \rightarrow X$ to $\varphi^*\xi$, and to any morphism in $\mathcal{C}/X$ an arrow in $\mathcal{F}$ induced by Cartesian property.

To show it is fully faithful, notice a natural transformation of $\varphi, \psi \in \text{Hom}_\mathcal{C}((\mathcal{C}/X), \mathcal{F})$ is determined by their value on $\text{id}_X$, and any map $\varphi(\text{id}_X) \rightarrow \psi(\text{id}_X)$ induces a natural transformation, by Cartesian properties. □

Cor.(3.1.7.34) [Characterization of Representability]. Translating the 2-Yoneda lemma and (3.1.7.14), we see that a fibered category $\mathcal{F}$ is representable by $X \in \mathcal{C}$ iff $\mathcal{F}$ is fibered in groupoids, and there is an object $\xi \in \mathcal{F}(X)$ that for any object $\rho \in \mathcal{F}$, there is a unique arrow $\rho \rightarrow \xi$.

Cor.(3.1.7.35). If $\mathcal{X}, \mathcal{Y}$ are fibered categories over $\mathcal{C}$ representable by $U, V$ resp., then there is an isomorphism of sets

$$\text{Hom}_\mathcal{C}(\mathcal{X}, \mathcal{Y})/2 \sim \text{Hom}_\mathcal{C}(U, V)$$

Proof: By Yoneda lemma there is an equivalence $\text{Hom}_\mathcal{C}(\mathcal{X}, \mathcal{Y}) \cong \text{Hom}_\mathcal{C}(U, V)$, and then $\text{Hom}_\mathcal{C}(\mathcal{X}, \mathcal{Y})$ is an equivalence relation by (3.1.1.15), so the isomorphism is clear. □

Def.(3.1.7.36) [Representable 1-Morphisms]. Let $\mathcal{C}$ be a category and $F : \mathcal{X} \rightarrow \mathcal{Y}$ be a morphism of categories fibered over $\mathcal{C}$, then $F$ is called representable if for any $U \in \mathcal{C}$ and a morphism $\mathcal{C}/U \rightarrow \mathcal{Y}$, the fibered category $(\mathcal{C}/U) \times_\mathcal{Y} \mathcal{X} \rightarrow \mathcal{C}/U$ is representable (3.1.7.32)(Notice it is a fibered category by (3.1.7.15) and (3.1.7.16)).

Prop.(3.1.7.37) [Diagonal and Representability]. Let $\mathcal{S}$ be a category fibered in groupoids over $\mathcal{C}$. Assume $\mathcal{C}$ has fibered product, then the following are equivalent:

- $\Delta_S : \mathcal{S} \rightarrow \mathcal{S} \times_\mathcal{C} \mathcal{S}$ is representable.

- For every $U \in \mathcal{C}$, any $G : \mathcal{C}/U \rightarrow \mathcal{S}$ is representable.

Proof: Cf.[[Sta]02YA].

The key to this proposition is the fibered product diagram (3.1.7.15)(3.1.1.48)

$$
\begin{array}{c}
X \times F Y \rightarrow \mathcal{F} \\
\downarrow \\
X \times S Y \rightarrow \mathcal{F} \times_\mathcal{S} \mathcal{F}
\end{array}
$$

which still holds in the 2-commutative sense.

So if $\Delta_\mathcal{F}$ is schematic, then $X \times F Y$ is a scheme, so $X \rightarrow \mathcal{F}$ is schematic, for any scheme $X$.

Conversely, consider the fibered products

$$
\begin{array}{c}
\mathcal{F} \times F \times S \mathcal{F} \rightarrow \mathcal{F} \\
\downarrow \\
X \rightarrow \mathcal{F} \times S \mathcal{F}
\end{array}
$$

induced by $h = f \times g : X \rightarrow \mathcal{F} \times S \mathcal{F}$. So in order to prove $\Delta_\mathcal{F}$ is schematic, it suffices to prove $\mathcal{F} \times F \times S \mathcal{F} X$ is a scheme, and for this, it suffices to prove $X \times F X$ is a scheme. But $X \times F X \rightarrow X$ is a pullback of $X \rightarrow F$, so it is a scheme. □
3.2 Categorical Logic

Main references are [Categorical Logic Notes, Jacob Lurie], [Coend Calculus, Fosco Loregian], [Harder-Narasimhan Filtrations, Huayi Chen], [Harder-Narasimhan Theory, Jonathan Pottharst], [Coend Calculus].

1 Monads and Categories

Def. (3.2.1.1)[Monad]. Let \( C \) be a category, a monad on \( C \) is an endofunctor \( C \to C \) together with two natural morphisms:

- (multiplication) \( \mu : T \circ T \to T \).
- (unit) \( \text{id}_C \to T \).

that satisfies associativity and unit diagrams.

Def. (3.2.1.2)[Algebras over Monads]. An algebra over a monad \( T \) is an object \( X \) together with a morphism \( \alpha : TX \to X \) that satisfies the diagrams for an algebra.

2 Group Formation

The goal of this subsection is to give a formation that encompass both the group theory and algebraic group theory.

Def. (3.2.2.1)[Group Formations]. A group formation is a small category \( C \) with a class of arrows \( S \in C \) consisting of monomorphisms, satisfying the following axioms:

- \( G \) is complete and cocomplete.
- \( G \) has a zero object \( e \).
- \( S \) is stable under pullbacks.
- If \( N \to H \to G \in S \) and \( H \to G \) is a monomorphism, then \( N \to H \in S \).
- Let \( N \to G \in S \), then \( N \) is called a normal subobject of \( G \), and \( N = \ker(G \to \text{Coker}(N \to G)) \).
- For \( G \in C \), coproducts exist in \( C/G \), and if \( N \to G, H \to G \in S \), then the coproduct is also in \( S \), denoted by \( NH \to G \).
- Let \( N \to G \in S \) and \( H \to G \) a monomorphism, then
  - there is a natural isomorphism: \( H/N \cap H \cong HN/N \).
  - If \( N \to G \in S \), then there is a natural isomorphism \( G/NH \cong (G/N)/(H/H \cap N) \).

Prop. (3.2.2.2).

3 Filtrations of a Category

Def. (3.2.3.1)[Filtrations in a Category]. Let \( C \) be a category with an initial object, a filtration of an object \( X \) in \( C \) is a family \( \mathcal{F} = (X_t)_{t \in \mathbb{R}} \) of subobjects of \( X \) indexed by \( \mathbb{R} \) that satisfies:

- (decreasing property) if \( s \leq t \), then \( X_s \to X \) factors through \( X_t \).
- (separation property) for sufficiently small \( t \), \( X_t \) is the initial object.
• (exhaustiveness) for sufficiently large $s$, $X_s = X$.

• (right locally constant property) for any $t \in \mathbb{R}$, there exists $\delta > 0$ that for any $s \in [t, t + \delta)$, the morphism $X_t \to X$ are isomorphisms.

• (finite jump) the jump set of $\mathcal{F}$ is finite.

Naturally, we define morphisms of filtrations.

Def.(3.2.3.2)[Pullback and Pushforward Filtrations]. Suppose fibered products exist in $\mathcal{C}$, for any morphism $f : X \to Y$ and a filtration $\mathcal{G} = (Y_t) \to Y$, then the family $f^* \mathcal{G} = (Y_t \otimes_Y X) \to X$ is a filtration on $X$, called the pullback filtration.

If $f : X \to Y$ and $\mathcal{F} : (X_t) \to X$ is a filtration on $X$, then if there is a filtration $f_* \mathcal{F}$ on $Y$ and a morphism of filtrations $\mathcal{F} \to f_* \mathcal{F}$ compatible with $f$, then $f_* \mathcal{F}$ is called the pushforward filtrations.

4 Harder-Narasimhan Formalism

Main references are[Jon20].

Def.(3.2.4.1)[Harder-Narasimhan Formalism]. A Harder-Narasimhan formalism consists of

• An exact category $\mathcal{C}$ (3.3.1.17).

• A function $\text{deg} : \text{Ob}(\mathcal{C}) \to \mathbb{Z}$ that is additive w.r.t. short exact sequences.

• An exact faithful generic fiber functor to an Abelian category $F : \mathcal{C} \to \mathcal{A}$ that induces for each object $F : \mathcal{E} \in \mathcal{C}$ a bijection

\[
\{\text{strict objects of } \mathcal{E}\} \cong \{\text{subobjects of } F(\mathcal{E})\}
\]

where a strict subobject is an object that can be prolonged to an exact sequence.

• An additive function rank: $\mathcal{A} \to \mathbb{N}$ on $\mathcal{A}$ that $\text{rank}(\mathcal{L}) = 0 \iff \mathcal{L} = 0$, and its composition with $F$ is also called rank.

• If $u : \mathcal{E} \to \mathcal{E}'$ is a morphism in $\mathcal{C}$ that $F(u)$ is an isomorphism, then $\text{deg}(\mathcal{E}) \leq \text{deg}(\mathcal{E}')$ with equality iff $u$ is an isomorphism.

Cor.(3.2.4.2).

• We are free to choose the "kernel" for $u$ that $F(u)$ is surjection.

• The subobjects of subobjects are subobjects, by axiom3.

Def.(3.2.4.3)[Saturation]. Let $X'$ be a subobject of $X$, then we let $\tilde{X}'$ denote the strict subobject of $X$ corresponding to the subobject $F(X')$ of $F(X)$, called the saturation of $X'$. The saturation satisfies:

• 

• 

•

Prop.(3.2.4.4). Every morphism $f : X \to Y$ has a kernel and a image in $\mathcal{C}$, and $0 \to \ker f \to X \to \text{Im } f \to 0$ is an exact sequence.
Prop. (3.2.4.5) [HN-Formalism on the Category of Filtered Vector Spaces]. If \( L/K \) is a field extension, there is a category \( \text{VectFil}_{L/K} \) consisting of \( (V, \text{Fil}) \) where \( V \) is a \( K \)-vector space and \( \text{Fil} \) is a finite filtration on \( V \otimes_K L \). It is an exact category by declaring exact sequences be those induce exact sequences on the graded.

The generic fiber functor is \( \text{VectFil}_{L/K} \to \text{Vect}_K \): \((V, \text{Fil}) \mapsto V\), and rank is as usual, the **Hodge-Tate degree** is defined to be \( t_H((V, \text{Fil})) = \sum i \dim_K gr^i(V \otimes_K L) \). This is a HN-filtration.

**Proof:** The axioms can be directly checked, notice a filtration \( W_n \) of a filtration \( V_n \) is a strict object iff \( W_k = W_n \cap V_k \).

\[ \square \]

Def. (3.2.4.6) [Slope]. In a HN-formalism, the **slope** is defined to be \( \text{slope}(E) = \frac{\deg(E)}{\text{rank}(E)} \).

\( E \) is called **semistable of slope** \( \lambda \) iff \( \text{slope}(E) = \lambda \), and \( \text{slope}(E') \leq \lambda \) for any nonzero strict subobject \( E' \subset E \).

Prop. (3.2.4.7). If \( 0 \to E' \to E \to E'' \to 0 \) be a short exact sequence in \( \mathcal{C} \), then:

- If two of them have the same slope, then so does the third.
- If two of them have different slope, then we know the ordering of these slopes.

**Proof:** Just notice that the degree and rank are all additive functions.

\[ \square \]

Prop. (3.2.4.8). If \( E \) is semistable of slope \( \lambda \), then for any morphism \( u: E \to E'' \) that \( F(u) \) is surjective, \( \mu(E'') \geq \lambda \).

**Proof:** Take the kernel of \( F(u) \) in \( \mathcal{A} \), which corresponds to a strict object \( E' \) of \( E \), and \( 0 \to E' \to E \to E'' \to 0 \) is exact, so we can use (3.2.4.19).

\[ \square \]

Cor. (3.2.4.9). If \( E, F \) are semistable of slopes \( \lambda > \mu \), then \( \text{Hom}_\mathcal{C}(E, F) = 0 \).

**Proof:** Notice \( F \) is faithful.

\[ \square \]

Prop. (3.2.4.10) [Semistable Objects]. If \( f: E \to F \) be a map of vector bundles of the same slope \( \lambda \), then \( \ker(f) \) and \( \text{Coker}(f) \) are all semistable vector bundles of slope \( \lambda \), and if \( 0 \to E' \to E \to E'' \to 0 \) is exact and \( E', E'' \) are semistable of slope \( \lambda \), then so does \( E \).

**Proof:** Use \( F(f) \) to find the "coimage" \( A \) and the "image" \( B \) of \( f \), then there is a map from \( F(A) \) to \( F(B) \) which is an isomorphism, but they have the same degree and rank, thus \( A \cong B \) by the last axiom. And the image must has slope \( \lambda \). Then \( \ker(f), \text{Coker}(f) \) all can be defined, and they have the same slope \( \lambda \) by (3.2.4.19).

\( \ker(f) \) is semistable because strict subobjects of \( \ker(f) \) are also strict subobjects of \( E \) (3.2.4.2).

And for \( \text{Coker}(f) \), if it is not semistable, choose \( F' \subset \text{Coker}(f) \) that has slope \( \lambda \), let \( F'' \) be the inverse image, then \( 0 \to \text{Im}(f) \to F' \to F'' \to 0 \), then by (3.2.4.19) slope \( F'' \) > \( \lambda \), contradicting the semi-stability of \( F \).

For the extension, \( \text{slope}(E) = \lambda \) by (3.2.4.19), and for a strict subobject \( F \) of \( E \), then we can find \( F', F'' \) be strict objects of \( E', E'' \) respectively that there is an exact sequence \( 0 \to F' \to F \to F'' \to 0 ? \), which shows \( \text{slope}(F) \leq \lambda \), so \( E \) is semistable.

\[ \square \]

**Harder-Narasimhan Filtration**

**Lemma (3.2.4.11)** [Final Subobjects of Maximal Slope]. Let \( X \) be an object of \( \mathcal{C} \) and \( X', X'' \) its subobjects of maximal slope, then \( X' + X'' \) and \( X' \cap X'' \) are also of maximal slope.

**Proof:** Cf. [Jon20] P8. \( \square \)

**Def. (3.2.4.12).** Given an object \( X \) of \( \mathcal{C} \), consider the following condition on a nonzero subobject \( X' \) of \( X \):

For all subobjects \( X'' \) of \( X \) properly containing \( X' \), \( \mu(X'') < \mu(X') \).

**Def. (3.2.4.13)** [SCSS]. Let \( X' \) be a subobject of \( X \), then the following conditions are equivalent:

- \( X' \) satisfies condition (3.2.4.12) and is semistable.
- \( X' \) satisfies condition (3.2.4.12) and is of maximal slope.
- \( X' \) is the final object of \( X \) of maximal slope.

If \( X' \) satisfies these equivalent conditions and \( X' \neq X \), then \( X \) is called a **strongly contradicting semi-stability** or SCSS of \( X \).

**Proof:** Cf. [Jon20] P8. \( \square \)

**Prop. (3.2.4.14).** Every object \( X \) of \( \mathcal{C} \) admits a SCSS.

**Def. (3.2.4.15)** [Harder-Narasimhan Filtration]. Let \( \mathcal{E} \in \mathcal{C} \), a chain of strict objects \( 0 \subset \mathcal{E}_0 \subsetneq \mathcal{E}_1 \subsetneq \ldots \subsetneq \mathcal{E}_m = \mathcal{E} \) is called a **Harder-Narasimhan filtration** iff each quotient \( \mathcal{E}_i/\mathcal{E}_{i-1} \) is semistable of slope \( \lambda_i \) and \( \lambda_1 > \lambda_2 > \ldots > \lambda_m \).

**Prop. (3.2.4.16).** Every object \( \mathcal{E} \in \mathcal{C} \) has a unique functorial Harder-Narasimhan filtration.

**Proof:** For uniqueness: if there are two filtrations, it suffices to show that \( \mathcal{E}'_1 = \mathcal{E}_1 \), because notice by (3.2.4.2) \( \mathcal{E}_i \) is a strict subobjects of \( \mathcal{E}_j \) for any \( i < j \), so we finish by induction on the length of the filtration and considering \( \mathcal{E}/\mathcal{E}_1 \).

For this, firstly \( \lambda_1 = \lambda'_1 \), suppose the contrary and \( \lambda_1 > \lambda'_1 \), then \( \lambda_1 > \lambda'_i \) for each \( i \), so \( \text{Hom}(\mathcal{E}_1, \mathcal{E}_i/\mathcal{E}_{i-1}) = 0 \) for each \( i \) by (3.2.4.32), so by induction \( \text{Hom}(\mathcal{E}_1, \mathcal{E}) = 0 \), contradiction.

Next by the same reason as in the proof above, \( \mathcal{E}_1 \hookrightarrow \mathcal{E} \) has image in \( \mathcal{E}_1' \), and the reverse is true for \( \mathcal{E}_1' \), so \( \mathcal{E}_1 \cong \mathcal{E}_1' \) in \( \mathcal{E} \).

For existence: Use induction on \( \text{rank}(\mathcal{E}) \). If \( \mathcal{E} \) is semistable, then we finish. Otherwise, there is a strict subobject \( \mathcal{F} \) and \( 0 \to \mathcal{F} \to \mathcal{E} \to \mathcal{G} \to 0 \) that \( \text{slope}(\mathcal{F}) > \text{slope}(\mathcal{E}) \), so \( \text{rank}(\mathcal{F}) < \text{rank}(\mathcal{E}) \). Now by induction \( \mathcal{F} \) and \( \mathcal{G} \) has HN-filtration, thus by argument as above, we see that \( \mathcal{E} \) cannot have strict subobject with slope bigger than slopes appearing in the HN-filtration of \( \mathcal{F}, \mathcal{G} \). So if we choose a strict subobject of \( \mathcal{E}_1 \) of maximal rank among the strict subobjects of maximal slope, we claim the subobjects of \( \mathcal{E}/\mathcal{E}_1 \) all have slopes smaller than \( \text{slope}(\mathcal{E}_1) \): if some \( \text{slope}(\mathcal{G}) \geq \text{slope}(\mathcal{E}_1) \), consider its inverse image \( \mathcal{G}' \), then \( 0 \to \mathcal{E}_1 \to \mathcal{G}' \to \mathcal{G} \to 0 \), thus \( \text{slope}(\mathcal{G}') \geq \text{slope}(\mathcal{E}_1) \) and has bigger rank, contradiction. So we can use induction on \( \mathcal{E}/\mathcal{E}_1 \). \( \square \)

**HN-Polygons**

**Harder-Narasimhan Categories**

This subsection is unnecessary. Main references are [Harder-Narasimhan Categories]
Def. (3.2.4.17) [Harder-Narasimhan Categories]. A **Harder-Narasimhan category** consists of a geometric exact category $\mathcal{C}$ that is additive w.r.t short exact sequences in $\mathcal{E}_A$.

1. A function $\deg : \text{Ob}(\mathcal{C}) \to \mathbb{R}$ that is additive w.r.t short exact sequences in $\mathcal{E}_A$.
2. A function $\text{rank} : \text{Ob}(\mathcal{C}) \to \mathbb{N}$ on $\mathcal{A}$ that is additive w.r.t short exact sequences in $\mathcal{E}$, $\text{rank}(X) = 0 \iff X = 0$.

The **slope** of a nonzero object $X$ is defined to be $\mu(X) = \deg(X)/\text{rank} X$. And $X$ is called **semistable** if $\mu(X) = \lambda$, and $\mu(X') \leq \lambda$ for any nonzero geometric subobject $X' \subset X$.

And the category satisfies the following axiom:

- **NH**: For any nonzero geometric object $X$, there exists a geometric subobject $X_{\text{des}} \subset X$ that
  \[
  \mu(X_{\text{des}}) = \sup\{\mu(Y) | Y \text{ is a non-zero geometric subobject of } X\}
  \]

  and moreover, any nonzero geometric subobject $Z$ of $X$ that $\mu(Z) = \mu(X_{\text{des}})$ is a geometric subobject of $X_{\text{des}}$.

Notice that $X_{\text{des}}$ is semistable and unique up to isomorphisms, called the **destablization** of $X$.

Cor. (3.2.4.18). A geometric object of rank 1 is semistable.

**Proof**: For any nonzero geometric subobject $X' \subset X$, rank $X' = \text{rank} X = 1$, so rank $X/X' = 0$ hence $X/X' = 0$ and $X' \cong X$. Then clearly $\mu(X') = \mu(X)$ and $X$ is semistable. \hfill $\square$

Cor. (3.2.4.19). If $0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0$ be a short exact sequence in $\mathcal{E}_A$, then:

- If two of them have the same slope, then so does the third.
- If two of them have different slope, then we know the ordering of these slopes.

**Proof**: Just notice that the degree and rank are all additive functions. \hfill $\square$

Prop. (3.2.4.20) [Abelian Categories as Harder-Narasimhan Categories]. Let $(\mathcal{C}, \mathcal{E}, \mathcal{A})$ be a geometric exact category with functions $\deg$ and $\text{rank}$, and $\mathcal{C}$ is an Abelian category, $\mathcal{E}$ is the set of short exact sequences, then $(\mathcal{C}, \mathcal{E}, \mathcal{A}, \deg, \text{rank})$ is a Harder-Narasimhan category.

**Proof**: We need to check HN: induct on rank $X$: The condition is clear when $X$ is semistable, in particular when rank $X = 1$ (3.2.4.18), and when $X$ is not semistable, let $Y$ be a geometric subobject of $X$ that $\mu(X') > \mu(X)$ and rank $X'$ is maximal, then by induction hypothesis, there is a destablization $Y_{\text{des}}$, and we want to show $X'_{\text{des}}$ is just $X_{\text{des}}$: Let $Y$ be a nonzero geometric subobject of $X$. If $Y$ is a geometric subobject of $X'$, then $\mu(Y) \leq \mu(X'_{\text{des}})$. If $Y$ is not a geometric subobject of $X'$, then $Y + X'$ is greater than $X'$, and rank$(Y + X') >$ rank $X'$, so by maximality, $\mu(Y + X') \leq \mu(X) < \mu(X')$. Moreover, there is an exact sequence

\[
0 \to Y \cap X' \to Y \oplus X' \to Y + X' \to 0
\]

so

\[
\deg Y = \deg(Y \cap X') + \deg(Y + X') - \deg(X')
\]

\[
< \mu(X'_{\text{des}}) \text{rank}(Y \cap X') + \mu(X')(\text{rank}(Y + X') - \text{rank}(X'))
\]

\[
\leq \mu(X'_{\text{des}})(\text{rank}(Y \cap X') + \text{rank}(Y + X') - \text{rank}(X'))
\]

\[
= \mu(X'_{\text{des}})\text{rank}(Y).
\]

In particular, if $\mu(Y) = \mu(X'_{\text{des}})$, then $Y$ must be a geometric subobject of $X'$ hence a geometric subobject of $X'_{\text{des}}$, so HN holds for $X$. \hfill $\square$
**Prop. (3.2.4.21) [Harder-Narasimhan Filtration].** Let \( X \) be a nonzero geometric object, a chain of admissible monomorphisms \( 0 = X_0 \to X_1 \to \ldots \to X_m = X \) is called a **Harder-Narasimhan filtration** of \( X \) iff each quotient \( \mathcal{E}_i/\mathcal{E}_{i-1} \) are all semistable of slope \( \lambda_i \) and \( \lambda_1 > \lambda_2 > \ldots > \lambda_m \), called the slopes associated to \( X \).

**Prop. (3.2.4.22) [Harder-Narasimhan Filtrations Exist].** Let \( (\mathcal{C}, \mathcal{E}, A, \text{deg}, \text{rank}) \) be a Harder-Narasimhan category, then the Harder-Narasimhan filtration exists for any nonzero geometric object \( X \).

**Proof:** We induct on the rank of \( X \): if \( X \) is semistable, this is clear, so we are done in the case \( \text{rank} X = 1 \) by (3.2.4.18). We choose \( X_1 = X_{\text{des}} \), then \( X_{\text{des}} \) is semistable and \( X' = X/X_{\text{des}} \neq 0 \). Now \( \text{rank} X' < \text{rank} X \), we can apply induction hypothesis to obtain a HN-filtration \( 0 = X'_1 \xrightarrow{f'_1} X'_2 \to \ldots \to X'_{n-1} \xrightarrow{f'_{n-1}} X'_{n} = X' \). Now let \( X_i = X \times_X X'_i \) (exists by Ex6 (3.3.1.17)), then \( X_1 = X_{\text{des}} \).

Since \( X \to X' \) is an admissible epimorphism, \( X_i \to X'_i \) are also admissible epimorphisms, and there are Cartesian diagrams

\[
\begin{array}{ccc}
X_i & \xrightarrow{f_i} & X_{i+1} \\
\downarrow{\pi_i} & & \downarrow{\pi_{i+1}} \\
X'_i & \xrightarrow{f'_i} & X'_{i+1}
\end{array}
\]

and \( f_i \) are monomorphisms, so \( f_i \) is the kernel of \( X_{i+1} \to X'_{i+1}/X'_i \), which is an admissible epimorphism, so \( f_i \) is admissible. There are natural isomorphisms \( \varphi_i : X_{i+1}/X_i \to X'_{i+1}/X'_i \). (Cf.[Harder-Narasimhan Filtrations]), and axiom A6 (3.3.1.20) shows \( \varphi \) is compatible with the geometric structure, so \( X_{i+1}/X_i \) are all semistable, and notice

\[
\mu(X_2/X_1) = \frac{\text{rank}(X_2)\mu(X_2) - \text{rank}(X_1)\mu(X_1)}{\text{rank}(X_2) - \text{rank}(X_1)} < \mu(X_1)
\]

so \( 0 \to X_1 \to X_2 \to \ldots \to X_m = X \) is a HN-filtration for \( X \). \( \square \)

**Prop. (3.2.4.23) [HN-Formalism for Filtrations in an Abelian Category].** Let \( \mathcal{C} \) be an Abelian category and \( \mathcal{E} \) the set of all short exact sequences in \( \mathcal{C} \), \( A(X) \) is the set of isomorphism classes of filtrations on \( X \), then \( (\mathcal{C}, \mathcal{E}, A) \) is a geometric exact category, by (3.3.1.24), given any additive rank function on \( \mathcal{C} \), and define a degree function for any filtration \( \mathcal{F} = (X_\lambda) \) as

\[
\text{deg}(\mathcal{F}) = \int_{\mathbb{R}} \lambda(d \text{ rank } X_{\lambda}),
\]

then \( \text{deg} \) is additive w.r.t short exact sequences of filtrations, and \( (\mathcal{C}, \mathcal{E}, A, \text{deg}, \text{rank}) \) is a Harder-Narasimhan filtration.

Then a filtration is semistable iff it has only one jump. Then the HN-filtration of a filtration is just the jump set ordered decreasingly.

**Prop. (3.2.4.24) [HN Formalism for Vector Spaces with Two Norms].** The vector spaces with two norms is a Harder-Narasimhan category, Cf.[Harder-Narasimhan Filtrations, P9].

**Prop. (3.2.4.25) [HN-Formalism for Torsion-Free Sheaves].** The category of torsion-free sheaves on a geometrically normal projective variety of dimension \( d \geq 1 \) over a field \( K \) is a Harder-Narasimhan category. Cf.[Harder-Narasimhan Filtrations, P10].
3.2. CATEGORICAL LOGIC

Prop. (3.2.4.26) [HH-Formalism for Hermitian Adelic Bundle]. Let $K$ be a number field, then the category of Hermitian adelic bundle over $K$ is a Harder-Narasimhan category. Cf. [Harder-Narasimhan Filtrations, P10].

Prop. (3.2.4.27) [HN Formalism for Filtered Vector Spaces Field]. If $L/K$ is a field extension, there is a category $VectFil_{L/K}$ consisting of $(V,Fil)$ where $V$ is a $K$-vector space and $Fil$ is a (finite) filtration of vector spaces over $L$ on $V \otimes_K L$ (3.2.3.1). It is a geometric exact category by (3.3.1.24) and a Harder-Narasimhan category by (3.2.4.20).

The rank is as usual, and the degree is defined to be

$$\deg((V,Fil)) = \int_R \lambda(d \text{rank } V)(3.2.4.23)$$

Slope Inequalities and Functoriality

Def. (3.2.4.28) [Additional Conditions]. In this subsubsection, we assume the Harder-Narasimhan filtration satisfies the following axiom that is

Def. (3.2.4.29) [Slope Inequality Axioms]. To show the functoriality of the Harder-Narasimhan filtration, we need the following axiom:

- (SI): If $X_1, X_2$ are two semistable geometric objects that $\mu(X_1) > \mu(X_2)$, then there are no non-zero morphism from $X_1$ to $X_2$ compatible with the geometric structures (3.3.1.21).

Prop. (3.2.4.30). If SI holds, then

Prop. (3.2.4.31). If $E$ is semistable of slope $\lambda$, then for any morphism $u : E \to E''$ that $F(u)$ is an isomorphism, slope($E''$) $\geq \lambda$.

Proof: Take the kernel of $F(u)$ in $A$, which corresponds to a strict object $E'$ of $E$, and $0 \to E' \to E \to E'' \to 0$ is exact, so we can use (3.2.4.19). □

Cor. (3.2.4.32). If $E, F$ are semistable of slopes $\lambda > \mu$, then $\text{Hom}_C(E, F) = 0$.

Prop. (3.2.4.33) [Semistable Vector Bundles Form a Weak Serre Subcategory]. If $f : E \to F$ be a map of vector bundles of the same slope $\lambda$, then $\ker(f)$ and $\operatorname{Coker}(f)$ are all semistable vector bundles of slope $\lambda$, and if $0 \to E' \to E \to E'' \to 0$ is exact and $E', E''$ are semistable of slope $\lambda$, then so does $E$.

Proof: Use $F(f)$ to find the "coimage" $A$ and the "image" $B$ of $f$, then there is a map from $F(A)$ to $F(B)$ which is an isomorphism, but they have the same degree and rank, thus $A \cong B$ by the last axiom. And the image must has slope $\lambda$. Then $\ker(f)$, $\operatorname{Coker}(f)$ all can be defined, and they have the same slope $\lambda$ by (3.2.4.19).

$\ker(f)$ is semistable because strict subobjects of $\ker(f)$ are also strict subobjects of $E$ (3.2.4.2). And for $\operatorname{Coker}(f)$, if it is not semistable, choose $F' \subset \operatorname{Coker}(f)$ that has slope $\lambda$, let $F''$ be the inverse image, then $0 \to \operatorname{Im}(f) \to F' \to F'' \to 0$, then by (3.2.4.19) slope($F'$) $> \lambda$, contradicting the semi-stability of $F$.

For the extension, slope($E$) $= \lambda$ by (3.2.4.19), and for a strict subobject $F$ of $E$, then we can find $F', F''$ be strict objects of $E'$, $E''$ respectively that there is an exact sequence $0 \to F' \to F \to F'' \to 0 ?$, which shows slope($F$) $\leq \lambda$, so $E$ is semistable. □
5 Tannakian Categories

Let $k$ be a field.

**Def.(3.2.5.1) [Fiber Functor].** Let $C$ be a $k$-linear Abelian tensor category, then a fiber functor on $C$ with values in a $k$-algebra $R$ is a $k$-linear exact faithful tensor functor $\eta : C \to \text{Mod}_R$ that takes values in the subcategory $\text{Proj}_R$.

**Def.(3.2.5.2) [Tannakian Category].** A Tannakian category is a rigid tensor category $C$ that $\text{End}(1) = k$ together with a fiber functor (3.2.5.1) with values in some $k$-algebra $R$.

**Def.(3.2.5.3) [Neutral Tannakian Categories].** A neutral Tannakian category is a Tannakian category that the fiber functor has values in $k$. By (15.3.2.9), such a category is equivalent to $\text{Rep}_k(G)$ for some affine group scheme $G$.

In particular, a Tannakian category can be thought of as an abstract version of the category of representations of an affine group scheme that has no distinguished “forgetful” functor, just as a vector space is an abstract version of $k^n$ that has no distinguished basis.
3.3 Homological Algebra

Main references are [Sta]Chap12 and ??.

1 Additive Category

Def. (3.3.1.1) [Preadditive Categories]. A category \( \mathcal{A} \) is called **preadditive** iff
- A1: \( \mathcal{A} \) is enriched over the Cartesian category of Abelian groups.

Def. (3.3.1.2) [Zero Element]. Let \( \mathcal{A} \) be a preadditive category and \( x \in \mathcal{A} \), then the following are equivalent:
- \( x \) is initial.
- \( x \) is final.
- \( \text{id}_x = 0 \in \text{Mor}(x, x) \).

Such an element is called a **zero element** in \( \mathcal{A} \), denoted by 0. If 0 exists, then a morphism \( \alpha : x \to y \) factors through 0 iff \( \alpha = 0 \).

Proof: Cf.[Sta]00ZZ.

Cor. (3.3.1.3). An additive functor transforms a zero object to a zero object.

Prop. (3.3.1.4) [Finite Direct Sums]. If \( \mathcal{A} \) is a preadditive category and \( x, y \in \mathcal{A} \). If one of \( x \times y \) and \( x \bigsqcup y \) exists, then so does the other, and they are isomorphic, called the **direct sum** of \( x, y \).

Proof: Cf.[Sta]0101.

Def. (3.3.1.5) [Additive Functors]. A functor between preadditive categories \( F : \mathcal{C} \to \mathcal{D} \) is called **additive** if it is a morphism of \( \text{Ab} \)-enriched categories.

Def. (3.3.1.6) [Kernels, Cokernels, Images and Coimages]. Let \( \mathcal{A} \) be a preadditive category and \( f : X \to Y \) is a map, then

- the **kernel** of \( f \) is the fiber product

\[
\begin{array}{c}
X \\
\downarrow f \\
0 \\
\rightarrow Y
\end{array}
\]

- the **cokernel** of \( f \) is the fiber pushforward

\[
\begin{array}{c}
X \\
\rightarrow f \\
\downarrow \\
0 \\
\rightarrow Y
\end{array}
\]

- the **image** of \( f \) is the cokernel of the kernel.
- the **coimage** of \( f \) is the kernel of the cokernel.

Cor. (3.3.1.7). If they exist, then kernel and coimage are monomorphisms, and cokernel and image are epimorphisms, by general non-sense.

Prop. (3.3.1.8). If the image and coimage of \( f \) exist, then there is a natural decomposition \( f : X \to \text{Im}(f) \to \text{Coim}(f) \to Y \), by the universal property.

Def. (3.3.1.9) [Exact Sequence]. A diagram \( X \overset{f}{\to} Y \overset{g}{\to} Z \) is an **exact sequence** if \( f \) is the kernel of \( g \) and \( g \) is the cokernel of \( f \).
Additive Categories

Def. (3.3.1.10) [Additive Categories]. A preadditive category $\mathcal{A}$ is called an additive category iff moreover it satisfies

- A2: There exists an element that is both initial and final, called the zero element.
- A3: There exists a canonical finite sums and finite products and they are equal, and the sum induce the Abelian structure of $\text{Hom}(X,Y)$.

Prop. (3.3.1.11) [Characterizing Direct Sum Decompositions]. If $\mathcal{A}$ is a preadditive category with zero object, $x, y, z \in \mathcal{A}$, then $z$ is the product and sum of $x, y$ in $\mathcal{A}$ iff there are four morphism that satisfies some identities.

Proof: Cf. [Sta]0102.

Cor. (3.3.1.12). An additive functor between additive categories transforms finite direct sums to direct sums.

Def. (3.3.1.13) [Kernel of an Additive Functor]. The kernel of an additive functor between additive categories is is the full subcategory of objects that are mapped to 0.

Def. (3.3.1.14) [Compact Object]. Let $\mathcal{D}$ be an additive category with arbitrary direct sums, then a compact object $K \in \mathcal{D}$ is an object that

$$\bigoplus_i \text{Hom}(K, E_i) \to \text{Hom}(K, \bigoplus_i E_i)$$

is bijective for any set $I$ and objects $E_i \in \mathcal{D}$.

Karoubian Categories

Def. (3.3.1.15) [Karoubian Categories]. A Karoubian category is an additive category $\mathcal{C}$ that satisfies the following equivalent conditions:

- Every idempotented endomorphism of an object of $\mathcal{C}$ has a kernel.
- Every idempotented endomorphism of an object of $\mathcal{C}$ has a cokernel.
- Every idempotented endomorphism $p : z \to z$ induces a direct sum decomposition $z = x \oplus y$(exists by A3) that $p$ corresponds to the projection $z \to x$.

Proof: 1 $\to$ 3: Let $p : z \to z$ be an idempotent, let $x = \ker(p), y = \ker(1-p)$, then there are maps $x \to z, y \to z$. Then $p : z \to z$ factors through $z \to y \to z$. Similarly $(1-p) : z \to z$ factors through $z \to x \to z$. Then it can be verified that $z = x \oplus y$ is a direct sum decomposition (3.3.1.11).

2 $\to$ 3 is dual.

3 $\to$ 1, 3 $\to$ 2 are easy by (3.3.1.11).

Prop. (3.3.1.16). Let $\mathcal{D}$ be a preadditive category,

- if $\mathcal{D}$ has countable products and kernels of morphisms that have a right inverse, then $\mathcal{D}$ is Karoubian.

- Dually, if $\mathcal{D}$ has countable coproducts and cokernels of morphisms that have a left inverse, then $\mathcal{D}$ is Karoubian.
Proof: Given any idempotented morphism \( e : X \to X \), \( e \) has a kernel iff \( W \mapsto \ker(\text{Mor}(M, X) \xrightarrow{e} \text{Mor}(M, X)) \) is representable. Notice that for any Abelian group \( A \),

\[
\ker(e : A \to A) = \ker(\Phi : \prod_Z A \to \prod_Z A)
\]

where

\[
\Phi(a_1, a_2, \ldots) = (ea_1 + (1 - e)a_2, ea_2 + (1 - e)a_3, \ldots)
\]

and it has a right inverse

\[
\Psi(a_1, a_2, \ldots) = (a_1, (1 - e)a_1 + ea_2, (1 - e)a_2 + ea_3, \ldots)
\]

thus the kernel exists. \( \square \)

### Exact Categories

**Def. (3.3.1.17) [Exact Categories].** Let \( \mathcal{C} \) be an small additive category and \( \mathcal{E} \) be a set of short sequences

\[
0 \to X \to Y \to Z \to 0
\]

in \( \mathcal{C} \). If \( 0 \to X \xrightarrow{\varphi} Y \xrightarrow{\psi} Z \to 0 \) is in \( \mathcal{E} \), then we call \( \varphi \) an admissible monomorphism and \( \psi \) an admissible epimorphism. then \( (\mathcal{C}, \mathcal{E}) \) is called an exact category if it satisfies:

- **Ex1:** For any complex \( 0 \to X \xrightarrow{\varphi} Y \xrightarrow{\psi} Z \to 0 \), \( \varphi \) is the kernel of \( \psi \) and \( \psi \) is the cokernel of \( \varphi \).
- **Ex2:** For any \( X, Y \in \mathcal{C} \), \( 0 \to X \to X \times Y \to Y \to 0 \) is in \( \mathcal{E} \).
- **Ex3:** \( \mathcal{E} \) is saturated in the category of short sequences.
- **Ex4:** if \( f, g \) are admissible monomorphisms, then so is \( gf \).
- **Ex5:** If \( f \) is an admissible monomorphism, then any pushout of \( f \) exists and is an admissible monomorphism.
- **Ex6:** If \( g \) is an admissible epimorphism, then any pullback of \( g \) exists and is an admissible epimorphism.

**Cor. (3.3.1.18).** If \( \mathcal{C} \) is an Abelian category and \( \mathcal{E} \) the set of all exact sequences in \( \mathcal{C} \), then \( (\mathcal{C}, \mathcal{E}) \) is an exact category.

**Cor. (3.3.1.19).** If \( (\mathcal{C}, \mathcal{E}) \) is an exact category, then

- **Ex7:** if \( f : X \to Y \in \mathcal{C} \) is a morphism having a kernel and there is a morphism \( g : Z \to X \) that \( fg \) is an admissible monomorphism, then so is \( f \). Dual argument holds for admissible epimorphisms.

**Proof:** Cf.[Bernhard Keller, Chain complexes and stable categories, P28]. \( \square \)

**Def. (3.3.1.20)[Geometric Exact Categories].** A geometric exact category consists of an exact category \( (\mathcal{C}, \mathcal{E}) \) and a mapping \( A \) from \( \text{Ob}(\mathcal{C}) \) to \( \text{Sets} \) together with morphisms

- a morphism \( f^* : A(X) \to A(Y) \) for any admissible monomorphism \( f : X \to Y \).
- a morphism \( g_* : A(X) \to A(Z) \) for any admissible epimorphism \( g : X \to Z \).

that satisfies the following axioms:
• A1: $A(0) = \text{pt}$.
• A2: If $i, j$ are admissible monomorphisms, then $(ji)^* = i^*j^*$.
• A3: If $p, q$ are admissible epimorphisms, then $(qp)_* = q_*p_*$.
• A4: $\text{id}_X^* = (\text{id}_X)_* = \text{id}_{A(X)}$.
• A5: If $f : X \to Y$ is an isomorphism, then $f^*f_* = f_*f^* = \text{id}$.
• A6: For any Cartesian and Cocartesian diagram $\xymatrix{X \ar[r]^u \ar[d]^p & Y \ar[d]^q \ar[r]^v & Z \ar[r]^w & W}$, if $u$ is admissible monomorphism or $q$ is admissible epimorphism, then $v^*q_* = p_*u^*$.
• A7: If $X \xrightarrow{u} Y \xrightarrow{v} Z$ is a diagram in $\mathcal{C}$ that $u$ is an admissible epimorphism and $v$ is an admissible monomorphism, and if $h_X \in A(X), h_Z \in A(Z)$ satisfy $u_*(h_X) = v^*(h_Z)$, then there exists $h \in A(X \oplus Z)$ that $(\text{id}, vu)^*(h) = h_X$ and $\pi_2(h) = h_Z$. (Notice $(\text{id}, vu)$ is an admissible monomorphism because it is composition of $X \to X \oplus Z$ with the isomorphism $(\pi_1, vu\pi_1 + \pi_2) : X \oplus Z \to X \oplus Z$.
For any $X \in \mathcal{C}$, an element of $A(X)$ is called a geometric structure on $X$.

Exact categories can be viewed as geometric exact categories by asserting $A(X) = \text{pt}$ for all $X \in \mathcal{C}$.

**Def. (3.3.1.21)** [Morphisms compatible with the Geometric Structure]. Let $(\mathcal{C}, \mathcal{E}, A)$ be a geometric exact category, if $(X', h'), (X'', h'')$ are two geometric objects, then a morphism $f : X' \to X''$ is said to be a morphism compatible with the geometric structure if there exists a geometric object $(X, h)$ and an admissible monomorphisms $u : X' \to X$ and an admissible epimorphism $v : X \to X''$ that $h' = u^*(h)$ and $h'' = v_*(h)$ and $f = vu$.

The composition of two morphisms compatible with the geometric structure is also a morphism compatible with the geometric structure.

We denote $\mathcal{C}_A$ the category of geometric objects of $\mathcal{C}$, and $\mathcal{E}_A$ the set of diagrams of geometric objects $0 \to X' \xrightarrow{\phi} X \xrightarrow{\pi_1} X'' \to 0$ that the underlying diagram is in $\mathcal{E}$ and $u, v$ are compatible with the geometric structures.

**Prop. (3.3.1.22)** [Hermitian Spaces]. The f.d. Hermitian spaces over $\mathbb{C}$ or f.d. normed vector spaces over $\mathbb{R}$ form a geometric exact category.

**Proof:** Cf. [Harder-Narasimhan Categories, P4].

**Prop. (3.3.1.23)** [F.D. Ultranormed Banach Spaces]. Let $K$ be a complete valued field, then the category of f.d. ultranormed Banach spaces over $K(12.1.2.4)$ is a geometric exact category.

**Proof:** It suffices to check axiom A7, but $vu$ has norm $\leq 1$, and for any $\varphi : E \to F$ of norm $\leq 1$, we can endow $E \oplus F$ with the maximum norm, then in the decomposition $E \xrightarrow{(\text{id}, \varphi)} E \oplus F \xrightarrow{\pi_2} F$, we have $(\text{id}, \varphi)^*(h) = h_E$ and $(\pi_2)_*(h) = h_F$.

**Prop. (3.3.1.24)** [Filtrations in an Abelian Category]. The filtrations (3.2.3.1) in an Abelian category form a geometric exact category.

**Proof:** Cf. [Harder-Narasimhan Categories, P5].
Def. (3.3.1.25) [K₀ Group]. Let \( \mathcal{A} \) be an exact category, then the \( K₀ \)-group \( K₀(\mathcal{A}) \) is defined to be the quotient Abelian group
\[
\bigoplus_{[0 \to A \to B \to C \to 0] \in \mathcal{E}} \mathbb{Z} \to \bigoplus_{A \in \mathcal{C}} \mathbb{Z} \to K₀(\mathcal{A}) \to 0,
\]
where \( e_{0 \to A \to B \to C \to 0} \) is mapped to \( e_B - e_A - e_C \).

2 Abelian Categories

Def. (3.3.2.1) [Abelian Categories]. An Abelian category \( \mathcal{A} \) is an additive category that satisfies the following axiom:
- A4: The kernels and cokernels exist for any \( f \), and the natural map \( \text{Im}(f) \to \text{Coim}(f) \) are isomorphisms.

Remark (3.3.2.2). WARNING: An additive category that epimorphism+monomorphism is isomorphism need not be an Abelian category. Cf. [https://mathoverflow.net/questions/41722/is-every-balanced-pre-abelian-category-abelian] for a counter-example.

Prop. (3.3.2.3). In an Abelian category, the functor \( X \mapsto \text{Hom}(X,Y) \) and \( X \mapsto \text{Hom}(Y,X) \) is both left exact. (Note that left and right is seen on the image).

Def. (3.3.2.4) [Injectives and Surjectives]. A morphism \( f \) is an Abelian category \( \mathcal{A} \) is called an injection if \( \ker f = 0 \). It is called a surjection if \( \text{Coker} f = 0 \). \( f \) is an injection iff it is a monomorphism, it is a surjection iff it is an epimorphism.

Prop. (3.3.2.5). Axiom A3 asserts the good existence of product and sum of objects as we wanted, and it can be used to prove that monomorphism and epimorphism are stable under pushout and pullback.

But this uses A4 strongly, Cf. [MacLane Categories for working mathematicians P203]. (For epimorphism, first prove \( 0 \to X \times_Y Y \to X \times Y \to U \to 0 \) is exact when \( X \to U \) is epi).

Prop. (3.3.2.6). equalizer and finite product derives finite limit, thus finite limits and finite colimits exists in Abelian categories.

Prop. (3.3.2.7) [Mitchell’s embedding theorem]. If \( \mathcal{A} \) is a small Abelian category, then there exists a unital ring \( R \), not necessary commutative and a fully faithful and exact functor \( \mathcal{A} \to R - \text{Mod} \) that preserves kernel and cokernel. WARNING: it may not preserve sum and product, let alone limits and colimits.

Proof: □

Prop. (3.3.2.8). If \( \mathcal{C}, \mathcal{A} \) are categories and \( \mathcal{A} \) is Abelian, then \( \text{Hom}(\mathcal{C}, \mathcal{A}) \) is an Abelian category. In particular, \( \text{Ch}(\mathcal{A}) \) is Abelian.

Localization

Prop. (3.3.2.9) [Localization Category]. If \( \mathcal{C} \) is a preadditive category and \( S \) is a left or right localizing system of \( \mathcal{C} \), then there exists a natural additive structure on \( S^{-1}\mathcal{C} \) and a localizing functor \( \mathcal{C} \to S^{-1}\mathcal{C} \) that is additive.

Proof: Cf. [Sta]05QD. □
Lemma (3.3.2.10). If \( \mathcal{C} \) is additive and \( S \) is localizing, let \( X \) be an element of \( \mathcal{C} \), then: \( Q(X) = 0 \) iff there is a morphism \( 0 : X \to Y \) that is an element of \( S \) iff there is a morphism \( 0 : Z \to X \) that is an element of \( S \) iff there is a morphism \( 0 : Z \to X \) that is an element of \( S \).

Proof: If such \( 0 : X \to Y \in S \), then it maps to isomorphisms in \( S^{-1}(\mathcal{C}) \) by (3.1.1.57), so \( Q(X) = 0 \). If \( Q(X) = 0 \), then the morphism \( 0 \to X \) is mapped to an isomorphism, so by (3.1.1.59), there are \( g, h \) that \( fg = hf = 0 \), so \( Z \to 0 \to X \in S \). Dually for the other direction. \( \square \)

Prop. (3.3.2.11) [Localized Abelian Categories]. If \( \mathcal{A} \) is Abelian and \( S \) is localizing, then \( S^{-1} \mathcal{A} \) is an Abelian category and \( \mathcal{A} \to S^{-1} \mathcal{A} \) is exact.

Proof: By (3.1.1.57) and its dual, \( \mathcal{A} \to S^{-1} \mathcal{A} \) preserves finite limits and colimits. \( \square \)

Serre Subcategory

Def. (3.3.2.12) [Serre Subcategories]. A Serre subcategory of an Abelian category is a non-empty full subcategory \( \mathcal{C} \) that if

\[
A \to B \to C
\]

is exact and \( A, C \in \text{Ob}(\mathcal{C}) \), then \( B \in \text{Ob}(C) \).

A weak Serre subcategory of an Abelian category is a non-empty full subcategory \( \mathcal{C} \) that if

\[
A \to B \to C \to D \to E
\]

is exact and \( A, B, D, E \in \mathcal{C} \), then \( C \in \mathcal{C} \).

Prop. (3.3.2.13).

- A Serre category is equivalent to a full subcategory \( \mathcal{A} \) that contains 0, all the subobjects and quotient objects of \( \mathcal{A} \), and extensions of objects of \( \mathcal{A} \) are in \( \mathcal{A} \).
- A weak Serre category is equivalent to a full subcategory \( \mathcal{A} \) that contains 0, and all the kernels, cokernels of objects in \( \mathcal{A} \), and all the extensions of objects in \( \mathcal{A} \).

In these cases, \( \mathcal{A} \) is an Abelian category and the functor \( i : \mathcal{A} \to \mathcal{C} \) is exact.

Proof: One direction of these two are trivial, it suffices to prove the converse. For the first, \( 0 \to \text{Im}(A) \to B \to \text{Im}(B) \to 0 \), so \( B \in \mathcal{C} \). For the second, \( 0 \to \text{Coker}(A \to B) \to C \to \text{ker}(D \to E) \to 0 \), so \( C \in \mathcal{C} \). \( \square \)

Prop. (3.3.2.14) [Quotients by Serre Subcategory]. For an exact functor \( F \) between Abelian categories, the kernel of \( F \) is a Serre subcategory. Any Serre subcategory is the kernel of an essentially surjective exact functor \( Q : \mathcal{A} \to \mathcal{A}/\mathcal{C} \), and this functor satisfies the universal property that any exact functor between Abelian categories \( F : \mathcal{A} \to \mathcal{C} \) that \( \mathcal{C} \subset \text{ker}(F) \) factors uniquely through \( \mathcal{A}/\mathcal{C} \).

Proof: The full subcategory of \( \text{ker}(F) \) is clearly a Serre subcategory by checking the definition. Conversely, consider \( S = \)all the morphisms that has kernel and cokernel in \( \mathcal{C} \), first we prove it is a localizing system (3.1.1.54).

The long exact sequence (3.3.4.4) shows that if \( f, g \in S \), then \( gf \in S \). For other verifications, Cf. [Sta] 02MS?

Next we construct \( \mathcal{C}/\mathcal{A} \) as \( S^{-1} \mathcal{C} \). Consider which objects are mapped to 0 in \( \mathcal{C}/\mathcal{A} \), use (3.3.2.10) and consider the kernel and cokernel, it is easy to see that \( \text{ker}(Q) = \mathcal{C} \). If another category \( \mathcal{D} \) and \( F : \mathcal{C} \to \mathcal{D} \) satisfies \( \mathcal{C} \) is mapped to 0, then it is clear that elements in \( S \) is mapped to isomorphism, so it factors through \( \mathcal{C}/\mathcal{A} \) by universal property (3.1.1.57). \( \square \)
Prop. (3.3.2.15)[K₀ Group of Serre Subcategory]. Let $\mathcal{A}$ be an Abelian category and $\mathcal{C}$ a Serre subcategory, with $\mathcal{A}/\mathcal{C} = \mathcal{B}$. Then

- The exact functors $\mathcal{C} \to \mathcal{A} \to \mathcal{B}$ induces an exact sequence

$$K_0(\mathcal{C}) \to K_0(\mathcal{A}) \to K_0(\mathcal{B}) \to 0,$$

- The kernel of $K_0(\mathcal{C}) \to K_0(\mathcal{A})$ is generated by elements of the form

$$\ker(\psi) \left/ \text{Im}(\varphi) \right. - \ker(\varphi) \left/ \text{Im}(\psi) \right.$$  

where $\varphi, \psi : M \to M$ are pairs of maps that $\varphi \circ \psi = \psi \circ \varphi = 0$.

Proof: Cf.[Sta]02MX. □

Artinian Abelian Categories

Def. (3.3.2.16)[Artinian Abelian Categories]. An Artinian Abelian category is an Abelian category that

- $\text{Hom}(A, B)$ are all f.d. vector spaces over $k$.
- Then length of any filtrations $0 = X_0 \subset X_1 \subset \ldots \subset X_l = X$ for any object $X$ is bounded. The maximal length is called the length of $X$.

Prop. (3.3.2.17)[Jordan-Holder]. Let $\mathcal{C}$ be an Artinian category, then any maximal length filtration of an element $X$ has the same length, and the set of quotients $X_{k+1}/X_k$ is the same, up to order.

Proof: □

Others

Def. (3.3.2.18)[Essential Morphism]. In an Abelian category, an injection $A \to B$ is called essential iff every non-zero subobject of $B$ intersects $A$. A surjection is called essential iff every proper subobject of $A$ is not mapped to $B$.

Def. (3.3.2.19)[Noetherian Abelian Category]. In a Grothendieck Abelian category $\mathcal{A}$, an object $M$ is called finitely generated if for every ascending chain

$$M_1 \subset M_2 \subset \ldots \subset M$$

with $\bigcup_i M_i = M$, we have $M_i = M$ for some $i$.

$\mathcal{A}$ is called Noetherian iff a subobject of a f.g. object is f.g.. $\mathcal{A}$ is called Artinian iff every f.g. object has finite length.

Def. (3.3.2.20)[Compact Objects]. An object $M$ in an additive category $\mathcal{C}$ with arbitrary direct sum is called compact if Hom($M, -$) commutes with arbitrary direct sums.
Grothendieck Abelian Category

Def. (3.3.2.21) [Grothendieck Abelian Category]. A Grothendieck Abelian category is an Abelian category \( \mathcal{A} \) satisfying the following axioms:

**AB3**: It is an Abelian category and arbitrary direct sums exists. (Thus colimits over small categories exists.)

**AB5**: Filtered colimits over small categories are exact. This is equivalent to \{ for any family of subobjects \( \{ A_i \} \) of \( A \) to \( B \) indexed by inclusion can induce a morphism \( \sum A_i \to B \) (internal sum) \}?.

**GEN**: It has a generator, which is an object \( U \in \mathcal{A} \) s.t. for any proper subobject \( N \subseteq M \), there is a map \( U \to M \) that doesn’t factor through \( N \).

Def. (3.3.2.22) [Further Grothendieck Axioms]. For a Grothendieck Abelian category \( \mathcal{A} \), we can also formulate the following axioms:

**AB4**: Arbitrary direct sums are exact.

**AB6**: For any index set \( J \) and filtered categories \( I_j, j \in J \) and diagrams indexed over \( I_j \), the natural map

\[
\lim_{i_j \in I_j} \prod_{j \in J} M_{ij} \to \prod_{j \in J} \lim_{i_j \in I_j} M_{ij}
\]

is an isomorphism.

**Dual Axioms**: Axioms with an * meaning that the dual category satisfies something.

Prop. (3.3.2.23). The presheaf category \( \mathcal{A}^C \) is a Grothendieck Abelian category if \( \mathcal{A} \) is Grothendieck Abelian.

**Proof**: For the presheaf, the only problem is the existence of generator, for that, just construct a family of presheaves and sum them. Take \( Z_X = i_f(U) \), where \( U \) is the generator of \( \mathcal{A} \) and \( f = pt \to A^C : pt \to U \). Then \( F(X) = \text{Hom}(Z_X, F) \) by adjointness (5.1.2.9). So they are a family of generators. \( \square \)

Prop. (3.3.2.24). Any Grothendieck Abelian category has a functorial injective embedding.

**Proof**: Cf. [Sta]079H. \( \square \)

Prop. (3.3.2.25) [Representability on Grothendieck Category]. A contravariant functor from a Grothendieck category to \( \text{Sets} \) is representable iff it takes colimits to limits.

**Proof**: \( M \oplus M \to M \) with induce a map \( F(M) \times F(M) \to F(M) \) thus \( F(M) \) is a semigroup, and the inverse of \( \text{id}_M \) in \( \text{Hom}(M, M) \) maps to a \( F(M) \to F(M) \) which is the inverse, Thus in fact \( F \) is a left adjoint functor to \( A_b \).

Let \( U \) be a generator, \( A = \sum_{s \in F(U)} U \), let \( s_{\text{univ}} = (s) \in F(A) = \prod_{s \in F(U)} F(U) \). Let \( A' \) be the largest objects that \( s_{\text{univ}} \) restrics to 0 in \( A' \), let \( \sigma_{\text{univ}} \) be in \( F(A/A') \) that maps to \( s_{\text{univ}} \) in \( F(A) \) (because \( F \) is left exact). Then we claim \( (A/A', \sigma_{\text{univ}}) \) represents \( F \). Cf. [Sta]07D7. \( \square \)

Cor. (3.3.2.26). Grothendieck Category satisfies \( AB3^* \). (because \( F = \prod_i \text{Hom}(-, M_i) \) commutes with colimits).
Examples of Grothendieck Category

**Prop. (3.3.2.27)[Modules].** For $R \in \text{Alg}$, $\text{Mod}_R$ is a Grothendieck Abelian category. More generally, for $R, S \in \text{Alg}$, $\text{Mod}_{R-S} = \text{Mod}_{R \otimes S^{op}}$ is a Grothendieck Abelian category.

**Proof:** This is clear, by (4.1.1.24).

**Prop. (3.3.2.28)[Sheaf of Modules].** $\text{Sh}(\mathcal{O})$ for a ringed site $(\mathcal{C}, \mathcal{O})$ is a Grothendieck Abelian category.

**Proof:** It is obviously an Abelian category and have filtered colimits as presheaves, which are exact because colimits in the category of Abelian groups are exact, and for a family of generators, take $j_U\mathcal{O}_U$ as the representative for $\Gamma(U, -)$, which is the sheaf associated to the sheaf $Z_U$ in the proof of (3.3.2.23).

**Cor. (3.3.2.29).** Let $\mathcal{C}$ be a site, the categories $\text{PSh}(\mathcal{C})$ and $\text{Sh}(\mathcal{C})$ are Grothendieck Abelian categories.

**Proof:** For the presheaf, Cf.(3.3.2.23). For the sheaf, it follows from (3.3.2.28).

**Remark (3.3.2.30).** The category of Abelian sheaves doesn’t satisfy AB4*, i.e. not every limit of epimorphisms is epimorphism.

**Proof:** Consider the constant sheaf $\prod_{\xi \in [0, 1]} B(\frac{\xi}{2}, \frac{1}{4})$ on $[0, 1]$.

**Prop. (3.3.2.31)[Quasi-Coherent Sheaves].** For $X \in \text{Sch}$, $\text{QCoh}(X)$ is Grothendieck category, and there is a coherentor left adjoint to the forgetful functor.

**Proof:** Firstly by (5.5.1.3), $\text{QCoh}(X)$ is an Abelian category, and on affine open set, the colimit is an Qco sheaf, thus the colimit exists in Qco and equals the colimit in the category of sheaves, thus filtered colimits is exact because $\text{Mod}(\mathcal{O}_X)$ is Grothendieck (3.3.2.28). The generator exists, Cf.[Sta]077P.

The coherentor exists by the fact that $h_F$ commutes with colimits and by the property of Grothendieck category (3.3.2.25).

3 Chain Complexes

**Def. (3.3.3.1)[Chain Complex].** A chain complex over an additive category $A$ is $\cdots \rightarrow C_{n+1} \rightarrow C_n \rightarrow C_{n-1} \rightarrow \cdots$. The category of complexes over $A$ is denoted by $\text{Comp}(A)$.

**Prop. (3.3.3.2).** For any Abelian category $A$, $\text{Comp}(A)$ is an Abelian category.

**Prop. (3.3.3.3).** The natural inclusion $A \subset \text{Comp}(A)$ embeds $A$ as a full subcategory of $D(A)$, and $H^0$ is just the left adjoint.

An object $K \in D(A)$ is called discrete if it is in the essential image of this embedding.

**Def. (3.3.3.4)[Shifting of Complexes].** Remember the translation operator $K[n]$ makes the complex lower $n$ dimensions.

**Def. (3.3.3.5) [Truncation of Complexes].** Let $A$ be an Abelian category and $A^*$ be a complex, there are several ways to truncate $A^*$:

- The stupid truncation $\sigma_{\leq n} A = \cdots \rightarrow A_{n-1} \rightarrow A_n \rightarrow 0 \rightarrow \cdots$. There is a morphism $A \rightarrow \sigma_{\leq n} A$. 
• The stupid truncation $\sigma_{\geq n}A = \ldots \to 0 \to A_n \to A_{n+1} \to \ldots$. There is a morphism $\sigma_{\geq n}A \to A$.

• The canonical truncation $\tau_{\leq n}A = \ldots \to A_{n-1} \to \ker(d_n) \to 0 \to \ldots$. There is a natural morphism $\tau_{\leq n}A \to A$ that induces isomorphism on cohomology groups on degree $\leq n$.

• The canonical truncation $\tau_{\geq n}A = \ldots \to 0 \to \coker(d_{n-1}) \to A_{n+1} \to \ldots$. There is a natural morphism $A \to \tau_{\geq n}A$ that induces isomorphism on cohomology groups on degree $\geq n$.

Cor. (3.3.3.6). There are exact sequences of complexes

$$0 \to \tau_{\leq n}A^\bullet \to A^\bullet \to \tau_{\geq n+1}A^\bullet \to 0$$

$$0 \to \sigma_{\geq n+1}A^\bullet \to A^\bullet \to \sigma_{\leq n}A^\bullet \to 0$$

Def. (3.3.3.7) [Cone & Cylinder]. The mapping cone of $f : K^\bullet \to L^\bullet$ is the complex $C(f)^\bullet$ that:

$$C(f) = K[1]^\bullet \oplus L^\bullet, \quad d(k^{i+1}, l^i) = (-d_K k^{i+1}, f(k^{i+1}) + d L l^i)$$

The mapping cylinder of $f : K^\bullet \to L^\bullet$ is the complex $\text{Cyl}(f)$ that:

$$\text{Cyl}(f) = K^\bullet \oplus K[1]^\bullet \oplus L^\bullet, \quad d(k^i, k^{i+1}, l^i) = (d_K k^i - k^{i+1}, -d_K k^{i+1}, f(k^{i+1}) + d L l^i)$$

It is a shame I haven’t see clearly the similarity of this with the topological cone and cylinder, should study it further.

Def. (3.3.3.8) [Double Complexes]. A double complex over an Abelian category is a complex over $\text{Comp}(\text{A})$.

Def. (3.3.3.9) [Totalization]. Given a double complex $K^{\bullet \bullet}$ over an Abelian category $\text{A}$, the associated total complexes is defined to be

$$(\text{Tot}^\Pi(K))^n = \prod_{n=p+q} K^{p,q}, \quad d^n = \prod_{n=p+q} (d^{p,q} + (-1)^p d_2^{p,q})$$

$$(\text{Tot}^\oplus(K))^n = \bigoplus_{n=p+q} K^{p,q}, \quad d^n = \sum_{n=p+q} (d^{p,q} + (-1)^p d_2^{p,q})$$

Def. (3.3.3.10) [Hom Complexes]. Let $\text{A}$ be an Abelian category and $P^\bullet, Q^\bullet \in K(\text{A})$, we define Hom complex $\text{Hom}^n(P^\bullet, Q^\bullet)$ to be

$$\text{Hom}^n(P^\bullet, Q^\bullet) = \prod \text{Hom}_i(P^i, Q^{n+i}),$$

with the differential giving by $d(\{f_k\})_i = \{df_i - (-1)^i f_{i+1}d\}$ and suitable signatures.

It is clear that $H^n(\text{Hom}^n(P^\bullet, Q^\bullet)) = \text{Hom}_{K(\text{A})}(P^\bullet, Q^\bullet[n])$.

Homotopy Category $K(\text{A})$

Def. (3.3.3.11) [Homotopies of Complexes].

Def. (3.3.3.12) [$K(\text{A})$]. Let $\text{A}$ be an additive category, the homotopy category of complexes $K(\text{A})$ is the category whose objects are complexes in $\text{A}$ and whose morphisms are homotopy classes of morphism between complexes.
Prop. (3.3.3.13) [Distinguished Triangle of $K^*(A)$]. For any morphism $K^* \to L^*$, there exists a termwise-splitting exact sequence of Complexes commuting in $K(A)$.

\[
\begin{array}{ccccccccc}
K^* & \longrightarrow & L^* \\
\| & \downarrow \alpha & \downarrow & \\
0 & \longrightarrow & K^* & \longrightarrow & \text{Cyl}(f) & \longrightarrow & C(f) & \longrightarrow & 0 \\
\downarrow \beta & & & & \downarrow & & & & \\
0 & \longrightarrow & L^* & \longrightarrow & C(f) & \longrightarrow & K^*[1] & \longrightarrow & 0
\end{array}
\]

where $\beta \alpha = \text{id}$ and $\alpha \beta \sim \text{id}$. And $K^* \to L^* \to C(f) \to K^*[1]$ is called a distinguished triangle. Any exact triple of complexes in $\text{Kom}(A)$ is quasi-isomorphic to a distinguished triangle. In fact, we can define the distinguished triangle in $K(A)$ as that induced by a split exact sequence, Cf.[Sta]014L.

Notice all this can imitate the similar parallel construction in the category of topological spaces.

Proof: Cf.[Gelfand P157] □

Cor. (3.3.3.14) [Long Exact Sequences]. A distinguished triangle will induce a long exact sequence of cohomology groups, for this, just need to verify that the $\delta$-homomorphism and the morphism $C(f) \to K^*[1]$ induce the same map of cohomology groups.

Cor. (3.3.3.15). A morphism of complexes $f : K^* \to L^*$ is quasi-iso iff $C(f)$ is acyclic. It is homotopic to 0 iff $f$ can be extended to a morphism $C(f) \to L$.

Prop. (3.3.3.16) [$K(A)$ is Triangulated]. If $A$ is an additive category, then $K(A)$ is a triangulated category, with shifting functors defined in (3.3.3.4) and distinguished triangles defined in (3.3.3.13).

Proof: Cf.[Sta]014S. □

Prop. (3.3.3.17). An additive functor $F : A \to B$ between additive categories induces an exact functor $K(A) \to K(B)$. Moreover, this functor maps quasi-isomorphisms to quasi-isomorphisms (3.3.4.1).

Proof: Cf.[Sta]014X. □

Def. (3.3.3.18) [Bounded Subcategories].

Prop. (3.3.3.19). Let $A$ be an Abelian category,

- If $A^* \subset K^+(A)$, then $\tau_{\leq n}(A^*) \to A^*$ is a quasi-isomorphism for $n$ sufficiently large.
- If $A^* \subset K^-(A)$, then $A^* \to \tau_{\geq n}A^*$ is a quasi-isomorphism for $n$ sufficiently small.

Unbounded Complexes

Lemma (3.3.3.20) [Left Resolutions of Unbounded Complexes]. Let $A$ be an Abelian category and $\mathcal{P}$ be a subset of objects of $A$. Assume that every object of $A$ is a quotient of an object of $\mathcal{P}$, then for any complex $K^*$, there exists a commutative diagram

\[
\begin{array}{ccc}
P_1^* & \longrightarrow & P_2^* \\
\downarrow & & \downarrow \\
\tau_{\leq 1}K^* & \longrightarrow & \tau_{\leq 2}K^* \\
& & \\
& & \ldots
\end{array}
\]
where the vertical arrows are quasi-isomorphisms, and each $P^n_\bullet$ is a bounded above complex with terms in $\mathcal{P}$, and each $P^n_\bullet \to P^{n+1}_\bullet$ are termwise-split injections and the cokernel is also a complex with terms in $\mathcal{P}$.

Proof: Cf. [Sta]06XX.

4 Cohomology of Complexes

Def. (3.3.4.1)[Quasi-irosmoepwhiss].

Prop. (3.3.4.2)[Five lemma]. In an Abelian category, if there is a diagram

\[
\begin{array}{c}
\ast & \longrightarrow & \ast & \longrightarrow & \ast & \longrightarrow & \ast & \longrightarrow & \ast \\
\downarrow{s} & & \downarrow{g} & & \downarrow{f} & & \downarrow{h} & & \downarrow{i} \\
\ast & \longrightarrow & \ast & \longrightarrow & \ast & \longrightarrow & \ast & \longrightarrow & \ast
\end{array}
\]

Where the rows are exact and $g, h$ are isomorphisms. If $i$ is injective, then $f$ is surjective; if $s$ is surjective, then $f$ is injective.

Proof: Rotate the diagram counterclockwise $90^\circ$. Then use the two different filtration both converge (3.4.7.8).

Prop. (3.3.4.3)[Snake lemma]. In an Abelian category, if there is a diagram

\[
\begin{array}{c}
\ast & \longrightarrow & \ast & \longrightarrow & \ast & \longrightarrow & \ast & \longrightarrow & 0 \\
\downarrow{f} & & \downarrow{g} & & \downarrow{h} & & & & \\
0 & \longrightarrow & \ast & \longrightarrow & \ast & \longrightarrow & \ast & \longrightarrow & \ast
\end{array}
\]

where the rows are exact, then there is a long exact sequence

$$\ker f \to \ker g \to \ker h \to \text{Coker } f \to \text{Coker } g \to \text{Coker } h$$

And if $i$ is injective, then the first one is injective; if $s$ is surjective, then the last one is surjective.

Proof: Rotate the diagram counterclockwise $90^\circ$. Then use the two different filtration both converge (3.4.7.8).

Cor. (3.3.4.4). In an Abelian category, if $f : A \to B, g : B \to C$, then there is a long exact sequence:

$$0 \to \ker f \to \ker gf \to \ker g \to \text{Coker } f \to \text{Coker } gf \to \text{Coker } g \to 0.$$

Proof: Use snake lemma (as modules), there is a diagrams:

\[
\begin{array}{c}
A & \longrightarrow & B & \longrightarrow & \text{Coker } f & \longrightarrow & 0 \\
\downarrow{gf} & & \downarrow{g} & & & & \\
0 & \longrightarrow & C & \longrightarrow & C & \longrightarrow & 0
\end{array}
\]

So by Snake lemma,

$$\ker gf \to \ker g \to \text{Coker } f \to \text{Coker } gf \to \text{Coker } g \to 0.$$

As Abelian category is dual, we can do this dually to get:

$$0 \to \ker f \to \ker gf \to \ker g \to \text{Coker } f \to \text{Coker } gf.$$

They splint together to get the desired long exact sequence.
Prop. (3.3.4.5). For a $3 \times 3$ diagram of complexes, the connection homomorphism satisfies an anti-commutative diagram:

\[
\begin{array}{ccc}
H^{q-1}(Z'') & \xrightarrow{\delta} & H^q(X'') \\
\downarrow{\delta} & & \downarrow{-\delta} \\
H^q(Z) & \xrightarrow{\delta} & H^{q+1}(X)
\end{array}
\]

by (3.4.1.15) as the category $K(A)$ is triangulated.

Prop. (3.3.4.6) [Universal Coefficient Theorem]. Should be somewhere in [Weibel].

Def. (3.3.4.7) [Herbrand Quotient]. For a complex of $R$-modules cyclic of order 2, we define the
additive Herbrand quotient as $\text{length}_R(H^0) - \text{length}_R(H^1)$, when both are definable and the
multiplicative Herbrand quotient as $|H^0|/|H^1|$ when they are both finite.

Prop. (3.3.4.8). For an exact sequence $0 \to M \to N \to K \to 0$ of complexes of cyclic order 2, we have
$h(N) = h(M) + h(K)$ and $h^*(N) = h^*(M)h^*(K)$ in the sense that if two of them are definable, then so is the third. This is an easy consequence of long exact sequence.

Prop. (3.3.4.9). If each term of this complex has finite length, then $h(M) = 0$. If each term is finite, then $h^*(M) = 0$. This is an consequence of isomorphism theorem. So we have, if a morphism of complexes has kernel and cokernel finite, then it induce an isomorphism on $h$ or $h^*$.

Proof: □

5 Injectives & Projectives

Def. (3.3.5.1). An injective object in a Abelian category is a $I$ s.t. $\text{Hom}(-, I)$ is an exact functor, equivalenty, maps to $I$ can be extended along injections.

A projective object in a Abelian category is a $I$ s.t. $\text{Hom}(I, -)$ is an exact functor, equivalently, maps to $I$ can be pulled back along surjections.

Prop. (3.3.5.2). Product of injective elements are injective, sums of projective elements are projective.

Prop. (3.3.5.3). In an Abelian category, the direct summand of a projective object is projective. (The summand has definition in an Abelian category).

Prop. (3.3.5.4). If a functor $f$ between Abelian categories is left adjoint to an exact functor, then it preserves injectives. Dually for projectives.

Prop. (3.3.5.5). If $A$ is an Abelian category, the chain complex category $Ch(A)$ is abelian by (3.3.2.8).

A chain complex $P$ is projective iff it is a split exact complex of projective objects. The same is true by dual argument for injectives.

Proof: If $K$ is projective, use the surjection $C(\text{id}_K) \to K[1]$, there is a homotopy between $\text{id}_K$ and 0. Thus we have $x = dx + hdw$. And if $dx = hy$, then $dhdy = 0$, thus $dy = 0$, so $K = dhK \oplus hdK$ and thus $K[n] = B_n \oplus B_{n+1}$. Thus $K$ is a direct product of $0 \to B \to B \to 0$. And this one is projective if $B$ is projective. □

Prop. (3.3.5.6) [Check Injectives]. In a Grothendieck Abelian category with generator $U$, an object is injective iff it is extendable over subobjects of $U$. (AB5 assures we can extend by Zorn’s lemma. Then use GEN, Cf.[Sta]079G?). If it is a family of objects, it suffice to extend over each one of them.
Injective Resolutions

Prop. (3.3.5.7) [Horseshoe Lemma]. For a exact sequence $0 \to X_1 \to X \to X_2 \to 0$ and a injective resolution of $X_1$ and $X_2$, there is a injective resolution of $X$ commuting with them. (Choose them one-by-one, in fact, $I_n = I_1 \oplus I_2$ using the injectivity of $I_1$. Snake lemma told us that the cokernel is an exact sequence, use that to define the next one.

Prop. (3.3.5.8). For two lifting of morhpisms $X_1 \to Y_1$ and $X_2 \to Y_2$, there is a lifting of the morphism $X \to Y$ compatible with that. Cf.[Weibel P2.4.6].

Prop. (3.3.5.9) [Cartan-Eilenberg Resolution]. For a complex $K \in \mathcal{K}_B^+$, a Cartan-Eilenberg resolution of $K$ consists of a 2-complex $I^{\bullet \bullet}$ and a map of complexes $K \to I^{\bullet,0}$ that the induced complexes:

\[
0 \to K^i \to I^{i,0} \to I^{i,2} \to \ldots
\]
\[
0 \to B^i(K) \to B^i_x(I^{\bullet,0}) \to B^i_x(I^{\bullet,1}) \to \ldots
\]
\[
0 \to Z^i(K) \to Z^i_x(I^{\bullet,0}) \to Z^i_x(I^{\bullet,1}) \to \ldots
\]
\[
0 \to H^i(K) \to B^i_x(I^{\bullet,0}) \to H^i_x(I^{\bullet,1}) \to \ldots
\]

are all injective resolutions, and the exact sequences

\[
0 \to B^i_x(I^{\bullet,j}) \to Z^i_x(I^{\bullet,j}) \to H^i_x(I^{\bullet,j}) \to 0
\]
\[
0 \to Z^i_x(I^{\bullet,j}) \to I^{\bullet,j} \to Z^i_x(I^{\bullet,j}) \to 0
\]

split.

Then if $I_B$ is sufficiently large, for any $K$ in $K(B)$ there is a Cartan-Eilenberg resolution.

Proof: Cf.[Gelfand P210],[Weibel P146].

Cor. (3.3.5.10). For a CE resolution of a complex $K \in K^+(\mathcal{B})$, the spectral sequence can be applied and shows $K \to \text{Tot}(L)$ is a quasi-isomorphism, i.e. $\text{Tot}(L)$ is an injective resolution of $K$.

Cor. (3.3.5.11) [Functoriality of Cartan-Eilenberg Resolution]. If $f : A \to B$ is a chain map and $A \to P, B \to Q$ are Cartan-Eilenberg resolutions, then there is a double complex map $\tilde{f} : P \to Q$ extending $f$. And if $f$ is homotopic to $g$, then $\tilde{f}$ is homotopic to $\tilde{g}$. In other words, we have a functor $K(A) \to K(I^{\bullet \bullet})$

In particular, for any two Cartan-Eilenberg resolutions $P, Q$ of $A$ and an additive functor $F$, the chain complex $\text{Tot}^{\Pi}(F(P))$ and $\text{Tot}^{\Pi}(F(Q))$ are chain homotopy equivalent.

Def. (3.3.5.12) [Injective Amplitude]. Let $\mathcal{A}$ be an Abelian category with sufficiently injectives, then $K \in D(A)$ is said to have finite injective dimension if $K \subset D^b(I_A)$. It is said to have injective amplitude in $[a, b]$ iff $K \subset D^{[a,b]}(I_{\mathcal{A}})$. 

6 Tensor Category Case

In this subsection we consider complexes over a tensor category \( \mathcal{A} \).

Lemma (3.3.6.1) [Koszul Sign Rule]. There is an isomorphism of complexes
\[
\sigma : C \otimes D \to D \times C : \sigma(x \otimes y) = (-1)^{mn}y \otimes x
\]
where \( x \in C^m \) and \( y \in D^n \).

Proof:
\[
\partial(\sigma(x \otimes y)) = \partial((-1)^{mn}y \otimes x) = (-1)^{mn}(\partial y \otimes x) + (-1)^{mn+n}(y \otimes \partial x) = (-1)^n\sigma(x \otimes \partial y) + \sigma(\partial y \otimes x) = \sigma(\partial(x \otimes y))
\]
\[\square\]

Prop. (3.3.6.2) [Monoidal Structure on \( \text{Comp}^*(\mathcal{A}) \)]. The functor
\[
\text{Comp}^*(\mathcal{A}) \times \text{Comp}^*(\mathcal{A}) \to \text{Comp}^*(\mathcal{A}) : (C, D) \mapsto \text{Tot}^\oplus(C \otimes D)
\]
deeds \( \text{Comp}(\mathcal{A}) \) with a (non-strict) commutative monoidal structure.

Proof: Commutativity follows from (3.3.6.1). Associality follows from the definition of totaliza-
tion (3.3.3.9).
\[\square\]

Prop. (3.3.6.3) [Commutative Monoidal Structure on \( K^*(\mathcal{A}) \)]. This monoidal functor descends
to a strict monoidal structure on \( K^*(\mathcal{A}) \).

Proof: 

Prop. (3.3.6.4) [Tensoring is Exact]. Let \( L^* \in K(\mathcal{A}) \), then tensoring functor \( \text{Tot}^\oplus(\cdot \oplus L^*) \) is an
exact functor between triangulated categories.

Proof: 

Prop. (3.3.6.5). An \( R \)-module \( I \) is injective iff for any injective homomorphism from \( I \) to any \( R\)-
module splits.

Proof: The critical point is that we can always embed \( I \) to an injective hull \( J \) by (3.3.2.24), then
\( J = I \oplus J' \), so \( I \) is clearly injective.
\[\square\]

Prop. (3.3.6.6) [K-Injective under Change of Rings]. If \( R \to S \) is a ring map, then
1. If \( R \to S \) is flat and \( I^* \) is a \( K \)-injective complex of \( S \)-modules, then \( I^* \) is \( K \)-injective as a
complex of \( R \)-modules.
2. If \( R \to S \) is surjective and \( I^* \) is a complex of \( S \)-modules that is \( K \)-injective as a complex of
\( R \)-modules, then it is \( K \)-injective as a complex of \( S \)-modules.
3. If \( I^* \) is a \( K \)-injective complex of \( R \)-modules, then \( \text{Hom}_R(S, I^*) \) is \( K \)-injective as a complex of
\( S \)-modules.

Proof: 1: This is because \( \text{Hom}_{K(R)}(M^*, I^*) = \text{Hom}_{K(S)}(M^* \otimes_R S, I^*) \) and (3.4.3.1), as tensoring
\( S \) is exact.
2: This is because \( \text{Hom}_{K(R)}(N^*, I^*) = \text{Hom}_{K(S)}(N^* \otimes_S I^*) \) for a complex of \( S \)-modules \( N^* \)
and (3.4.3.1).
3: This is because \( \text{Hom}_{K(S)}(N^*, \text{Hom}_R(S, I^*)) = \text{Hom}_{K(R)}(N^*, I^*) \), and (3.4.3.1).
\[\square\]
3.4 Derived Categories

Main references are [G-M03] and [Sta].

1 Triangulated Categories

Def. (3.4.1.1) [Triangulated Categories]. A triangulated category is an additive category \( \mathcal{D} \) with an additive automorphism \( T \) denoted by \( X \mapsto X[1] \) and a set of distinguished triangles \( \text{Tri}(\mathcal{D}) \) that is stable under isomorphism, and satisfying the following axioms:

(TR1): \( X \xrightarrow{\text{id}} \xrightarrow{\text{id}} X \xrightarrow{0} X[1] \in \text{Tri}(\mathcal{D}) \). Any morphism \( X \xrightarrow{u} Y \) can be completed to some \( X \xrightarrow{u} Y \xrightarrow{C(u)} C(1) \xrightarrow{C(1)} X[1] \in \text{Tri}(\mathcal{D}) \).

(TR2): \( X \xrightarrow{\text{id}} \xrightarrow{\text{id}} Y \xrightarrow{\text{id}} Z \xrightarrow{\text{id}} X \xrightarrow{\text{id}} X[1] \in \text{Tri}(\mathcal{D}) \) iff \( Y \xrightarrow{\text{id}} \xrightarrow{\text{id}} Z \xrightarrow{\text{id}} X \xrightarrow{\text{id}} Y[1] \in \text{Tri}(\mathcal{D}) \).

(TR3): Any two consecutive morphisms of two distinguished triangles can be extended to a morphism of distinguished triangles.

(TR4): If \( X \xrightarrow{f} Y \xrightarrow{g} Z \) are morphisms, then there are maps \( C(f) \rightarrow C(gf) \), \( C(gf) \rightarrow C(g) \) by TR3, Then \( C(f) \rightarrow C(gf) \rightarrow C(gf) \rightarrow C(g) \rightarrow C(f)[1] \) is distinguished.

A triangulated subcategory is an additive subcategory \( \mathcal{D}' \) stable under \([1] \) and \([-1]\) together with a subclass of triangles in \( \mathcal{D}' \) that forms a triangulated category.

Def. (3.4.1.2) [Notations]. We use the tuple \((X,Y,Z,f,g,h)\) to represent a distinguished triangle \( X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1] \).

Prop. (3.4.1.3). Given \((X,Y,Z,f,g,h)\), \((X',Y',Z',f',g',h')\), they are both in \( \text{Tri}(\mathcal{D}) \) iff \((X \oplus X',Y \oplus Y',Z \oplus Z',f \oplus f',g \oplus g',h \oplus h')\) is in \( \text{Tri}(\mathcal{D}) \).

Proof: \([\text{Sta}]05QS.\]

Cor. (3.4.1.4). \((X,X \oplus Y,Y,(1,0),(0,1),0)\) is a distinguished triangle.

Prop. (3.4.1.5). There is a natural notation of a product of triangulated categories.

Def. (3.4.1.6) [Exact Functors]. A functor from a triangulated category to an Abelian category is called (co)homological iff it maps a distinguished triangle to a long exact sequence.

Conversely, a \( \delta \)-functor is a functor from an Abelian category to a triangulated category together with a map from the category of exact sequences to the category of distinguished triangles.

A functor \( F \) between two triangulated categories is called exact iff it maps distinguished triangles to distinguished triangles, and there is an isomorphism of functors \( \xi : F \circ [1] \rightarrow [1] \circ F \).

Prop. (3.4.1.7). An exact functor of triangulated categories is additive.

Proof: Cf.\([\text{Sta}]05QY.\]

Def. (3.4.1.8) [Bi-Exact Functors]. Let \( \mathcal{D}, \mathcal{D}', \mathcal{E} \) be triangulated categories, a bi-exact bifunctor \( F : \mathcal{D} \times \mathcal{D}' \rightarrow \mathcal{E} \) is a functor that for any \( X \in \mathcal{D}, F(X, -) : \mathcal{D} \rightarrow \mathcal{E} \) is an exact functor and for any \( Y \in \mathcal{D}', F(-, Y) : \mathcal{D} \rightarrow \mathcal{E} \) is an exact functor. By (3.4.1.7), any bi-exact functor is bi-additive.

Prop. (3.4.1.9). If \((F,G) : \mathcal{D} \Rightarrow \mathcal{D}' \) is an adjunction pair between triangulated categories and \( F \) is exact, then \( G \) is also an exact functor between triangulated categories.
**3.4. DERIVED CATEGORIES**

**Prop. (3.4.1.10).** If \((F, G) : \mathcal{D} \Rightarrow \mathcal{D}'\) is an adjunction pair between triangulated categories and \(F, G\) are exact, \(F\) is fully faithful and \(\ker(G) = 0\), then this is an equivalence of categories.

**Proof:** By (3.1.1.32), \(u : \text{id} \to gf\) is an isomorphism. Now for any \(X \in \mathcal{D}'\), choose a distinguished triangle \((F(G(X)), X \to Y) \in \text{Tri}(\mathcal{D}')\), which corresponds to \((G(F(G(X))), G(X), G(Y)) \in \text{Tri}(\mathcal{D})\), and by (3.1.1.30), \(G(X) \xrightarrow{h} GFG(X) \to G(X) = \text{id}_X\), so we get an isomorphism of triangles \((G(F(G(X))), G(X), G(Y)) \cong (G(X), G(X), 0)\), so \(G(Y) \cong 0\), and \(Y = 0\) by hypothesis. So \(v : FG \to \text{id}\) is also an isomorphism, so \((F, G)\) is an equivalence. \(\Box\)

**Lemma (3.4.1.11).** If \((X, Y, Z, f, g, h)\) is a distinguished triangle, then \(g \circ f = 0\).

**Proof:** By TR1 \((X, X, 0, \text{id}, 0, 0)\) is a distinguished triangle, and by TR3 there is a map of distinguished triangles

\[
\begin{array}{cccccc}
X & \to & X & \to & 0 & \to & X[1] \\
\| & & \| & & \| & & \\
X & \xrightarrow{f} & Y & \xrightarrow{g} & Z & \xrightarrow{h} & X[1]
\end{array}
\]

so \(g \circ f = 0\). \(\Box\)

**Prop. (3.4.1.12).** Let \(\mathcal{D}\) be a triangulated category and \(C \in \mathcal{D}\) be any object, \(\text{Hom}_\mathcal{D}(-, C)\) and \(\text{Hom}_\mathcal{D}(C, -)\) is (co)homological.

**Proof:** By (3.4.1.3), for any distinguished triangle \((X, Y, Z, f, g, h)\), \(\text{Hom}(C, X) \to \text{Hom}(C, Y) \to \text{Hom}(C, Z) = 0\), and if \(a \in \text{Hom}(C, Y)\) is mapped to \(0 \in \text{Hom}(C, Y)\), then the morphism \((a, 0) : (C, 0) \to (Y, Z)\) extends to a morphism of distinguished triangles \((b, a, 0) : (C, C, 0, \text{id}, 0, 0) \to (X, Y, Z, f, g, h)\), thus \(f \circ b = a\).

The converse case is dual. \(\Box\)

**Cor. (3.4.1.13).** If \((a, b, c) : (X, Y, Z, f, g, h) \to (X', Y', Z', f', g', h')\) is a morphism of distinguished triangles that two of \(a, b, c\) are isomorphisms, then this is an isomorphism of triangles.

In particular, the completion in TR1 is unique (may up to non-unique isomorphism) by TR3.

**Proof:** By 5-lemma, \(\text{Hom}(C, X) \to \text{Hom}(C, X')\) is an isomorphism, then \(X \to X'\) is an isomorphism by Yoneda lemma. \(\Box\)

**Prop. (3.4.1.14).** Let \(\mathcal{D}\) be a triangulated category, then \(f : X \to Y \in \mathcal{D}\) is an isomorphism iff \(C(f) = 0\).

**Proof:** There is a morphism \((\text{id}_X, f, 0) : (X, X, 0, \text{id}, 0, 0) \to (X, Y, C(f), f, g, h)\) by (TR1) and (TR3). By (3.4.1.13), \(f\) is an isomorphism iff \(0 \to C(f)\) is an isomorphism, which is equivalent to \(Z = 0\). \(\Box\)
Prop. (3.4.1.15). In a triangulated category $\mathcal{D}$, any commutative diagram
\[
\begin{array}{ccc}
X & \longrightarrow & Y \\
\downarrow & & \downarrow \\
X' & \longrightarrow & Y'
\end{array}
\]
can be extended to a diagram
\[
\begin{array}{cccccc}
X & \longrightarrow & Y & \longrightarrow & Z & \longrightarrow & X[1] \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
X' & \longrightarrow & Y' & \longrightarrow & Z' & \longrightarrow & X'[1] \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
X'' & \longrightarrow & Y'' & \longrightarrow & Z'' & \longrightarrow & X''[1] \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\end{array}
\]
where the lower right is anti-commutative.

\textbf{Proof:} Let $(X, Y, Z), (X', Y', Z'), (X, X', X''), (Y, Y', Y''), (X, Y, A)$ be distinguished triangles, then we can find maps $a : Z \to A, b : A \to Y', a' : X'' \to A, b' : A \to Z$ by TR3(3.4.1.1). Then TR4 says $(Z \to A, Y''), (X'' \to Z \to Z')$ is distinguished.

Now let $(X'', Y'', Z'')$ be distinguished, then we use TR4 again to $(X'', A, Y'')$, then $(Z', Z'', Z[1])$ is distinguished, thus so does $(Z \to Z' \to Z'')$.

Now it is left to verify the anti-commutativity of the righthdown square, for this, Cf.[Sta]05R0.

\[\square\]

Prop. (3.4.1.16) [Kernels are Saturated Triangulated Subcategories]. Let $\mathcal{D}, \mathcal{D}'$ be triangulated categories and $\mathcal{A}$ an Abelian category.

- Let $F : \mathcal{D} \to \mathcal{D}'$ be an exact functor, then the full subcategory of $\mathcal{D}$ consisting of objects $X$ that $F(X) = 0$ is a strictly full saturated triangulated subcategory of $\mathcal{D}$, called the \textbf{kernel} of $F$.

- Let $H : \mathcal{D} \to \mathcal{A}$ be a (co)homological functor, then the full subcategory of $\mathcal{D}$ consisting of objects $X$ that $F(X[n]) = 0$ for all $n$ is a strictly full saturated triangulated subcategory of $\mathcal{D}$, called the \textbf{kernel} of $H$.

\textbf{Proof:} Cf.[Sta]05RC, 05RD. \[\square\]

Prop. (3.4.1.17) [$K^*(\mathcal{A})$ is Triangulated]. For Abelian category $\mathcal{A}$, the categories $K^*(\mathcal{A})$ with distinguished triangles (3.3.3.14) is triangulated, and they are all subcategories of $K(\mathcal{A})$. This is hard to verify, but it solves every problem. Cf[Gelfand P246][[Sta]014S]. And an additive functor will induce exact functor between $K^*$ because distinguished is split.

\textbf{Localizations of Triangulated Category}

Def. (3.4.1.18) [Compatible Localizing Systems]. Let $\mathcal{D}$ be a triangulated category, a localizing system (3.1.1.54) $S$ is said to be \textbf{compatible} with the triangulated structure if it satisfies the following axioms:
(LS4): For $s \in S, s[n] \in S$ for any $n \in \mathbb{Z}$.

(LS5): Any two consecutive morphisms of two distinguished triangle can be extended to a morphism of distinguished triangles by morphisms in $S$.

Cor. (3.4.1.19). Let $\mathcal{D}$ be a triangulated category. If a class of morphisms $S$ satisfy (LS1), (LS5) and (LS6), then (LS2) holds as well.

Proof: Let $f : X \to Y \in \mathcal{D}$ and $s : X \to X' \in S$, we can use (TR1) and (TR2) to extend these to a morphism of distinguished triangles

$$
\begin{align*}
X \xrightarrow{f} Y \xrightarrow{s} Z \xrightarrow{\cdot} X[1] \\
\downarrow^s \quad \downarrow^{s'} \quad \downarrow^{s[1]} \\
X' \xrightarrow{s'} Y' \xrightarrow{s} Z' \xrightarrow{\cdot} X'[1]
\end{align*}
$$

The right extension is dual. □

Prop. (3.4.1.20) [Exact Functors and Saturated Localizing Systems]. Let $\mathcal{D}, \mathcal{D}'$ be triangulated categories and $\mathcal{A}$ an Abelian category.

- If $F : \mathcal{D} \to \mathcal{D}'$ is an exact functor and

$$
S = \{ f \in \mathcal{D}|F(f) \text{ is an isomorphism}\},
$$

then $S$ is a saturated localizing system compatible with the triangulated structure (3.4.1.18).

- If $H : \mathcal{D} \to \mathcal{A}$ is a (co)homological functor and

$$
S = \{ f \in \mathcal{D}|H^i(f) \text{ is an isomorphism}\},
$$

then $S$ is a saturated localizing system compatible with the triangulated structure (3.4.1.18).

Proof: Cf. [Sta]05R4, 05R6. □

Prop. (3.4.1.21) [Localed Triangulated Categories]. Let $\mathcal{D}$ be a triangulated category and $S$ is a localizing system compatible with the triangulated structure, then there is a unique triangulated category structure on $S^{-1}\mathcal{D}$ that the localization functor $Q : \mathcal{D} \to S^{-1}\mathcal{D}$ (3.1.1.53) is exact.

Moreover, $S^{-1}\mathcal{D}$ satisfies the following universal properties:

- If $\mathcal{A}$ is an Abelian category and $H : \mathcal{D} \to \mathcal{A}$ is a cohomological functor that $H(s)$ are isomorphisms for all $s \in S$, then the unique factorization $H' : S^{-1}\mathcal{D} \to \mathcal{A}$ s.t. $H' \circ Q = H(3.1.1.57)$ is also a cohomological functor.

- If $\mathcal{D}'$ is a triangulated category and $F : \mathcal{D} \to \mathcal{D}'$ is an exact functor that $F(s)$ are isomorphisms for all $s \in S$, then the unique factorization $F' : S^{-1}\mathcal{D} \to \mathcal{A}$ s.t. $F' \circ Q = F(3.1.1.57)$ is also an exact functor.

Cor. (3.4.1.22) [Kernel of Localizing Functor]. An object $Z \in \mathcal{D}$ is in the kernel of the localizing functor $Q : \mathcal{D} \to S^{-1}\mathcal{D}$ iff it satisfies the following equivalent conditions:

- There exists $Z'$ s.t. $0 : Z \to Z' \in S$.

- There exists $Z'$ s.t. $0 : Z \to Z' \in S$. 

• There exists $Z'$ and a distinguished triangle $(X, Y, Z \oplus Z', f, g, h)$ that $f \in S$.

Proof: Cf. [Sta]05RH.

Prop. (3.4.1.23) [Triangulated Subcategories of Localized Triangulated Categories]. Let $\mathcal{D}$ be a triangulated category and $S$ is a localizing system compatible with the triangulated structure. Let $\mathcal{D}'$ be a full triangulated subcategory of $\mathcal{D}$ and $S'$ is a localizing system of $\mathcal{D}'$. If either of the following holds:

• For any $s : X \to Y \in S$ and $X \in \mathcal{D}'$, there is a morphism $t : Y \to Z$ that $Z \in \mathcal{D}'$ and $t \circ s \in S'$.

• The same as in item 1 but with arrows reversed.

Then the natural functor $(S')^{-1}\mathcal{D}' \to S^{-1}\mathcal{D}$ is fully faithful.

Proof: This is immediate from (3.1.1.60).

Quotients of Triangulated Categories

Def. (3.4.1.24) [Saturated Triangulated Subcategories]. Let $\mathcal{D}$ be a triangulated category, then a full triangulated subcategory $\mathcal{D}'$ is called a saturated triangulated subcategory if whenever $X \oplus Y$ is isomorphic to an object of $\mathcal{D}'$, $X, Y$ are all isomorphic to an object of $\mathcal{D}'$.

Prop. (3.4.1.25) [Full Triangulated Subcategories and Localizing Systems]. Let $\mathcal{D}$ be a triangulated category.

• If $\mathcal{D}'$ is a full triangulated subcategory, then

$$S = \{ f : X \to Y \in \mathcal{D}' | \text{there exists a distinguished triangle } (X, Y, Z, f, g, h), Z \in \mathcal{D}' \}$$

is a localizing system compatible with the triangulated structure of $\mathcal{D}$. And $S$ is saturated iff $\mathcal{D}'$ is saturated.

• If $S$ is a localizing system of $\mathcal{D}$, then $\mathcal{D}' = \ker(\mathcal{D} \to S^{-1}\mathcal{D})$ (3.4.1.21) (3.4.1.16) is a saturated full triangulated subcategory of $\mathcal{D}$.

Proof: 1: Cf. [Sta]05RH.

Def. (3.4.1.26) [Quotient Triangulated Categories]. Let $\mathcal{D}$ be a triangulated subcategory and $\mathcal{B}$ a full triangulated subcategory, define the quotient triangulated category $\mathcal{D}/\mathcal{B}$ as the localized triangulated category $S^{-1}\mathcal{D}$, where $S$ is the localizing system associated to $\mathcal{B}$ (3.4.1.25).

Moreover, $\mathcal{D}/\mathcal{B}$ satisfies the following universal properties:

• If $\mathcal{A}$ is an Abelian category and $H : \mathcal{D} \to \mathcal{A}$ is a cohomological functor that $\mathcal{B} \subset \ker(H)$, then $H$ factors uniquely through $\mathcal{D}/\mathcal{B}$ by a functor $H'$, and $H'$ is also a cohomological functor.

• If $\mathcal{D}'$ is a triangulated category and $F : \mathcal{D} \to \mathcal{D}'$ is a cohomological functor that $\mathcal{B} \subset \ker(F)$, then $F$ factors uniquely through $\mathcal{D}/\mathcal{B}$ by a functor $F'$, and $F'$ is also an exact functor.

Proof: The universal properties follow from the universal properties of localized triangulated categories (3.4.1.21) and the definition of $S$ (3.4.1.25), using the long exact sequence or (3.4.1.14).

Prop. (3.4.1.27) [Saturation]. Let $\mathcal{D}$ be a triangulated category and $\mathcal{D}'$ be a full triangulated subcategory, then the kernel of the quotient map $\mathcal{D} \to \mathcal{D}/\mathcal{D'}$ (3.4.1.26) is a strictly full saturated subcategory consisting of objects $Z \in \mathcal{D}$ that $Z \oplus Z'$ is an object of $\mathcal{D'}$ for some object $Z' \in \mathcal{D}$. In particular, it is the smallest saturated triangulated subcategory containing $\mathcal{D}'$, called the saturation of $\mathcal{D}'$. 
Proof: the kernel is a strictly full saturated subcategory by (3.4.1.16). The description of the objects of kernel follows from the definition (3.4.1.26)(3.4.1.25) and (3.4.1.22). □

Prop. (3.4.1.28) [Kernel of Cohomological Functor is Saturated]. Let $D$ be a triangulated category and $H : D \to A$ is a cohomological functor, then $\ker(H)$ is a saturated full triangulated subcategory (3.4.1.16) whose corresponding saturated localizing system (3.4.1.20) is the set

$$S = \{ f | H^i(f) \text{ is an isomorphism in } A \},$$

and $H$ factors through the quotient $D \to D/\ker(H)$.

Proof: The description of $S$ is clear from the definitions (3.4.1.16)(3.4.1.25) and a use of long exact sequences. The factorization follows from (3.4.1.26). □

K-Groups

Def. (3.4.1.29) [K-Groups of Triangulated Categories]. Let $D$ be a triangulated categories, then the K-group of $D$ is defined to be the quotient

$$\bigoplus_{X \to Y \to Z \text{ distinguished}} 1 \to \bigoplus_{X \in D} K_0(D) \to 0$$

where $e_{X \to Y \to Z}$ is mapped to $e_Y - e_X - e_Z$.

Prop. (3.4.1.30) [Naturality].

- An exact functor between triangulated categories induce a map of their corresponding K-groups,
- A bi-exact bifunctor $F : D \times D' \to E$ (3.4.1.8) induces a bilinear map $K_0(D) \times K_0(D') \to K_0(E)$ sending $([X], [X'])$ to $F(X, X')$.
- A $\delta$-functor from an Abelian category to a triangulated category induces a map of their corresponding K-groups (Notice these two K-groups are defined differently).
- A functor from an exact category to a triangulated category that sends exact sequences to distinguished triangles induces a map of their corresponding K-groups.

Brown Representability

Def. (3.4.1.31) [Generators]. Let $D$ be a triangulated category, a generator of $D$ is an object of $D$ s.t. for any object $K$ of $D$, there exists some integer $n$ and a non-zero map $E[n] \to K$.

Prop. (3.4.1.32). Let $D$ be a triangulated category, then the compact objects of $D$ form a Karoubian, saturated, strictly full triangulated category of $D$.

Proof: Cf. [Sta]09QH. □

Def. (3.4.1.33) [Compactly Generated]. Let $D$ be a triangulated category with arbitrary direct sums, then $D$ is said to be a compactly generated triangulated category if there exists a set of compact objects $\{ E_i \}$ that $\oplus E_i$ is a generator of $D$ (3.4.1.31).

Prop. (3.4.1.34) [Brown Representability]. Let $D$ be a triangulated category with direct sums that is compactly generated. Let $H$ be a contravariant cohomological functor that transforms direct sums into products, then $H$ is representable.
Proof: Cf.[Sta]018F.

Cor. (3.4.1.35) [Adjointness Lemma]. Let \( \mathcal{D} \) be a triangulated category with direct sums that is compactly generated and \( F : \mathcal{D} \to \mathcal{D}' \) an exact functor of triangulated categories that transforms direct limits to direct limits, then \( F \) has an exact right adjoint.

Proof: By Brown representability, for any \( Y \in \mathcal{D}' \), there is an object \( G(Y) \in \mathcal{D} \) that represents the contravariant cohomological functor \( \mathcal{D} \to \text{Ab} : X \mapsto \text{Hom}_{\mathcal{D}'}(F(X), Y) \). Then \( G \) is a functor by Yoneda lemma. It is exact by (3.4.1.9).

2 Derived Category

Def. (3.4.2.1) [Derived Category]. Let \( \mathcal{A} \) be an Abelian category. The full subcategory \( \text{Ac}(\mathcal{A}) \) of \( K(\mathcal{A}) \) consisting of acyclic complexes is a strictly full saturated triangulated subcategory, and its associated saturated localizing system is the class \( \text{QIso}(\mathcal{A}) \) of quasi-isomorphisms.

Thus the kernel of the localizing functor \( Q_{\mathcal{A}} : K(\mathcal{A}) \to \text{QIso}(\mathcal{A})^{-1}K(\mathcal{A}) \) is \( \text{Ac}(\mathcal{A}) \), and \( H^0 \) factors through \( Q_{\mathcal{A}} \). Then the quotient triangulated category (3.4.1.26)

\[
D(\mathcal{A}) = K(\mathcal{A})/\text{Ac}(\mathcal{A}) = \text{QIso}(\mathcal{A})^{-1}K(\mathcal{A})
\]

is called the derived category of \( \mathcal{A} \).

Proof: As \( H^0 \) is a cohomological functor (3.3.3.14), these follows from (3.4.1.28) and (3.4.1.27).

Cor. (3.4.2.2) [Universal Properties of Derived Categories]. Let \( \mathcal{A} \) be an Abelian category,

- By (3.4.1.21), the derived category \( D(\mathcal{A}) \) of an Abelian category \( \mathcal{A} \) has the universal property that any exact functor between Distinguished categories \( F : K(\mathcal{A}) \to \mathcal{D} \) s.t. quasi-isomorphisms is mapped to isomorphisms uniquely factors through \( D(\mathcal{A}) \).

- Let \( F : \mathcal{A} \to \mathcal{B} \) be an exact functor between Abelian categories, then \( F \) induces an exact functor \( F : K(\mathcal{A}) \to K(\mathcal{B}) \) of triangulated categories (3.3.3.17), and it maps quasi-isomorphisms to quasi-isomorphisms, so by item1 induces a morphism of categories \( D(\mathcal{A}) \to D(\mathcal{B}) \).

Prop. (3.4.2.3) [Universal \( \delta \)-Functors]. The functor \( \text{Comp}(\mathcal{A}) \to D(\mathcal{A}) \) is a \( \delta \)-functor.

Proof: Cf.[Sta]014Z.

Prop. (3.4.2.4) [Truncation Triangles]. Let \( \mathcal{A} \) be an Abelian category and \( K^\bullet \in K(\mathcal{A}) \), then for any \( a \in \mathbb{Z} \), the truncation is a distinguished triangle

\[
\tau_{\leq a}K^\bullet \to K^\bullet \to \tau_{\geq a+1}K^\bullet \to \tau_{\leq a}K^\bullet[1].
\]

Proof: This exact sequence comes from the exact sequence \( 0 \to \tau_{\leq a}K^\bullet \to K^\bullet \to K^\bullet/\tau_{\leq a}K^\bullet \) via the \( \delta \)-functor (3.4.2.3) and the fact \( K^\bullet/\tau_{\leq a} \to K^\bullet \to \tau_{\geq a+1}K^\bullet \) is a quasi-isomorphism thus an isomorphism in \( D(\mathcal{A}) \).

Triangulated Subcategories of \( D(\mathcal{A}) \)

Prop. (3.4.2.5). Let \( \mathcal{A} \) be an Abelian category and \( \mathcal{L} \) a full triangulated subcategory of \( K(\mathcal{A}) \), let \( S = \mathcal{L} \cap \text{QIso}(\mathcal{A}) \), then \( S \) is the saturated localizing system compatible with the triangulated structure associated to the cohomological functor \( H^0 \) restricted to \( L(3.4.1.20) \), the we can form the localizing triangulated category \( S^{-1}\mathcal{L}(3.4.1.21) \) and there is a natural exact functor of triangulated categories \( S^{-1}\mathcal{L} \to D(\mathcal{A}) \) by the universal property (3.4.1.21).
Prop. (3.4.2.6) [Full Subcategories of \( D(\mathcal{A}) \)]. Let \( \mathcal{L} \subset \tilde{\mathcal{L}} \) be full triangulated subcategories of \( K(\mathcal{A}) \), and \( S = \mathcal{L} \cap \text{QIs}(\mathcal{A}), \ S = \tilde{\mathcal{L}} \cap \text{QIs}(\mathcal{A}) \). If either of the following holds:

- For any \( s : L_1 \to \tilde{L}_1 \in \tilde{S} \) and \( L_1 \in \mathcal{L} \), there is a morphism \( t : \tilde{L}_1 \to L_2 \) that \( L_2 \in \mathcal{L} \) and \( t \circ s \in \tilde{S} \).
- The same as in item 1 but with arrows reversed.

then the natural functor \( S^{-1} \mathcal{L} \subset \tilde{S}^{-1} \tilde{\mathcal{L}} \) is fully faithful.

\[ \text{Proof: } \] This follows immediately from (3.4.2.5) and (3.4.1.23). \qed

Cor. (3.4.2.7) [Bounded Derived Categories]. For \( * = -, +, b \), the triangulated categories \( D^*(\mathcal{A}) \) are the localized category of \( K^*(\mathcal{A}) \) at the classes of isomorphism in \( K^*(\mathcal{A}) \) (3.4.2.5). Then they are naturally full subcategories of \( D(\mathcal{A}) \), by (3.4.2.6), as the condition is satisfied by (3.3.3.19).

Def. (3.4.2.8) [Derived Category of Serre Subcategories]. If \( \mathcal{B} \) is a Serre subcategory of an Abelian category \( \mathcal{A} \), let \( D_B^*(\mathcal{A}) \) be the full subcategory of \( D^*(\mathcal{A}) \) consisting of objects \( X \) that \( H^n(X) \in \mathcal{B} \) for all \( n \), then \( D_B^*(\mathcal{A}) \) is a strictly full saturated triangulated subcategory of \( D^*(\mathcal{A}) \), as it is just the kernel of the cohomological functor \( H^0 : D^*(\mathcal{A}) \to \mathcal{A} \to \mathcal{A}/\mathcal{B} \) (3.3.2.14)(3.4.1.16).

Also there are natural exact functors \( D^*(\mathcal{B}) \to D_B^*(\mathcal{A}) \), and \( D^*(\mathcal{A})/D_B^*(\mathcal{A}) \to D^*(\mathcal{A}/\mathcal{B}) \) (3.4.1.26).

Prop. (3.4.2.9). The map \( D^*(\mathcal{A}) \to D^*(\mathcal{A}/\mathcal{B}) \) is essentially surjective.

\[ \text{Proof: } \] Cf.[Sta]06XL. \qed

Prop. (3.4.2.10). Let \( \mathcal{B} \subset \mathcal{A} \) be a Serre subcategory and suppose that for any surjection \( X \to Y \in \mathcal{A} \) with \( Y \in \mathcal{B} \), there is a subobject \( X' \subset X \) that \( X' \to Y \) is surjective, then the exact functor \( D^*(\mathcal{B}) \to D_B^*(\mathcal{A}) \) is an equivalence for \( * = - \) or \( b \).

\[ \text{Proof: } \] Cf.[Sta]0FCL. \qed

Prop. (3.4.2.11). If \( (\mathcal{C}, \mathcal{O}) \) is a ringed site and \( \mathcal{A} \subset \text{Mod}_\mathcal{O} \) is the Serre subcategory of torsion modules, then the functor \( D(\mathcal{A}) \to D_A(\mathcal{O}) \) is an equivalence.

\[ \text{Proof: } \] Cf.[Sta]0DD7. \qed

Prop. (3.4.2.12) [Embedding of \( \mathcal{A} \) in \( D(\mathcal{A}) \)]. The natural inclusion \( i : \mathcal{A} \subset D(\mathcal{A}) \) induces an equivalence of \( \mathcal{A} \) with the subcategory of \( D(\mathcal{A}) \) consisting of complexes with cohomology concentrated at degree 0.

An object \( K \in D(\mathcal{A}) \) is called discrete if it is in the essential image of this inclusion.

\[ \text{Proof: } \] The natural map \( H^0 : D(\mathcal{A}) \to \mathcal{A} \) is inverse to \( i \), so \( i \) is faithful. To show it is full, let \((L, f, s^{-1})\) be a morphism from \( i(M) \) to \( i(N) \), then we get a morphism \((H^0(L), H^0(f), H^0(s)^{-1})\), and these two morphisms are both dominated by the morphisms \((\sigma_{\geq n}L, \sigma_{\leq n} \circ f, (\sigma_{\leq n} \circ s)^{-1})\), so they are equal morphisms in \( D(\mathcal{A}) \). But \((H^0(L), H^0(f), H^0(s)^{-1}) = i(s^{-1}f) \) is in the image of \( i \), so \( i \) is full.

The assertion that any complex with cohomology groups concentrated at degree 0 is true by using truncation functors (3.3.3.19).

\[ \text{Proof: } \] \qed

Prop. (3.4.2.13) [K-Groups]. Let \( \mathcal{A} \) be an Abelian category, then the embedding (3.4.2.12) induces an isomorphism of K-groups \( K_0(\mathcal{A}) \cong K_0(D^b(\mathcal{A})) \) (3.4.1.29).
Proof: The map $A \to D^b(A)$ is a $\delta$-functor by (3.4.2.3), thus by (3.4.1.30) induces a map $K_0(A) \cong K_0(D^b(A))$. There is a reverse map $K_0(D^b(A)) \to K_0(A) : X \mapsto \sum_i (-1)^i H^i(X)$, which is inverse the the map above: one direction is clear, for the other, use induction and the truncation triangles (3.4.2.4).

**Def. (3.4.2.14) [Perfect Complex].** Let $\mathcal{A}$ be an Abelian category, a perfect complex in $D(A)$ is a complex that is equivalent to a bounded complex.

**Operations on the Derived Category**

**Lemma (3.4.2.15) [Direct Sum].** If $\mathcal{A}$ is an Abelian category that has exact countable direct sums, then $D(\mathcal{A})$ has countable direct sums given by term-wise direct sums.

**Proof:** A system of morphisms $K_i^* \to L^*$ is a system of quasiisos $M_i^* \to K_i^*$ and $M_i \to L^*$. Then by hypothesis $\oplus M_i^* \to \oplus K_i^*$ is a quasi-iso, thus defines a morphism $\oplus K_i^* \to L^*$. It can be verified that this morphism is unique.

**Lemma (3.4.2.16) [Termwise Colimit as Hocolim].** Let $\mathcal{A}$ be an Abelian category, $L_n^*$ be a system of complexes of $\mathcal{A}$. Assume colimits over $\mathbb{N}$ exists and are exact over $\mathcal{A}$, then the termwise colimit $L^*$ is a derived colimit in $D(\mathcal{A})$.

**Proof:** We have an exact sequence

$$0 \to \oplus L_n^* \to \oplus L_n^* \to L^* \to 0$$

and the termwise direct sum is the direct sum in $D(\mathcal{A})$ by (3.4.2.15), and then $L^*$ is a derived colimit, by (3.3.3.13).

**Bounded (Co)Homological Dimensions**

**Def. (3.4.2.17) [Bounded Cohomological Dimensions].** An exact functor between two derived categories $F : D(\mathcal{A}) \to D(\mathcal{B})$ is called has cohomological dimension bounded by $N$ if $F(D^{\leq m}(\mathcal{A})) \subset D^{\leq m+N}(\mathcal{B})$. Dually, it has homological dimension bounded by $N$ if $F(D^{\geq m}(\mathcal{A})) \subset D^{\geq m-N}(\mathcal{B})$.

**Prop. (3.4.2.18).** If $(F,G) : D(\mathcal{A}) \to D(\mathcal{B})$ is an adjunction pair of exact functors, then $F$ has cohomological dimension bounded by $N$ iff $G$ has homological dimension bounded by $N$.

**Proof:** If $F$ has cohomological dimension bounded by $N$, let $K \in D^{\geq m}(\mathcal{B})$, then

$$\text{Hom}_{D(\mathcal{A})}(\tau_{\leq m-N-1}GK, GK) = \text{Hom}_{D(\mathcal{B})}(F\tau_{\leq m-N-1}GK, K) = 0.$$ 

The dual case is similar.

**3 K-injectives and K-Adapted Classes**

**Prop. (3.4.3.1) [K-injectives].** For an Abelian category $\mathcal{A}$, a complex $I^*$ in $K(\mathcal{A})$ is called a K-injective object iff it satisfies the following equivalent conditions:

- $\text{Hom}_{K(\mathcal{A})}(S^*, I^*) = 0$ for any acyclic $S^*$ in $K(\mathcal{A})$.
- $\text{Hom}_{K(\mathcal{A})}(N^*, I^*) \cong \text{Hom}_{K(\mathcal{A})}(M^*, I^*)$ for quasi-iso $M^* \to N^*$. 

The dual case is similar.
• $\text{Hom}_{K(A)}(X^\bullet, I^\bullet) \cong \text{Hom}_{D(A)}(X^\bullet, I^\bullet)$ for every $X^\bullet$. In particular, a quasi-iso between two $K$-injective objects is an isomorphism in $K(A)$.

Dually, we can define **$K$-projective** objects.

**Proof:** $1 \to 2$ is by (3.3.3.14); $2 \to 3$ use (3.4.2.7), for $3 \to 1$, notice any acyclic complex is quasi-iso to 0.

**Corollary (3.4.3.2).** $K$-Injectives form a full triangulated subcategory of $K(A)$.

**Corollary (3.4.3.3).** If $I^\bullet$ is $K$-injective and quasi-isomorphic to an object in $K^+(A)$, then $I^\bullet \in K^+(A)$.

**Corollary (3.4.3.4) [K-Injective Resolutions are Unique].** by item 3 of the definition (3.4.3.1), $K$-injective resolutions are unique in $K(A)$.

**Proposition (3.4.3.5) [Injectives and $K$-Injective].** Objects $K^+(I_A)$ are all $K$-injectives. Thus the injective resolution is unique in $K^+$. Dually $K^-(P)$ are all $K$-projectives.

**Proof:** Use the first definition of $K$-injectives (3.4.3.1), we prove any morphism $f : S^\bullet \to I^\bullet$ from an acyclic complex to a $K$-injective $I^\bullet$ is homotopic to $0$ by a homotopy $h$. Let $I_k = 0$ for $k < n$, choose $h_k = 0$ for $k \leq n$, then $f_k = dh_k + h_{k+1}d$ for $k < n$. We use induction on $n$ to find $h_k$, $k \leq n$ that $f_k = dh_k + h_{k+1}d$ for $k < n$. Suppose $h_k$ are constructed for $k \leq n$, for $n + 1$, $(f_n - dh_n)d = f_n d - df_{n-1} = 0$, thus $f_n - dh_n = h_{n+1}d$ for some $h_{n+1}$ as $I_n$ is injective. Then we are done.

**Proposition (3.4.3.6).** If a functor $f$ between Abelian categories is left adjoint to an exact functor, then it preserves $K$-injectives (use definition 1).

**Proposition (3.4.3.7) [Products of $K$-Injectives].** Let $A$ be an Abelian category, $I_t$ be $K$-injective complexes. If the termwise product of $I_t$ exists, then it is also $K$-injective, and is the products of $I_t$ in $D(A)$.

**Proof:** It is clearly $K$-injective by (3.4.3.1) item 1 as it is the product in the category $K(A)$. Thus we can easily use the (3.4.3.1) item 3 to see that $I^\bullet$ is also the product in the category $D(A)$.

**Lemma (3.4.3.8).** [Sta] 070M

**Proposition (3.4.3.9) [Functorial $K$-Injective Resolution].** If $A$ is an Abelian category having enough injectives and exact countable products, then every complex is quasi-isomorphic to a $K$-injective complex that each term is injective.

Moreover, if $A$ is a Grothendieck category, then the $K$-injective resolution can be chosen to be functorial.

**Remark (3.4.3.10).** Maybe this can be extended to any large enough class of elements, at least for $K^+(A)$.

**Proof:** By (3.4.3.8), it suffices to show that $K \to R\lim_{\geq -n}K$ is a quasi-isomorphism for all complex $K$. But this is clear from the distinguished triangle

$$R\lim_{\geq -n}K \to \prod_{\geq -n}K \to \prod_{\geq -n}K \to R\lim_{\geq -n}K[1]$$

and the fact $H^p(\prod_{\geq -n}K) = \prod_{p\geq -n}H^p(K)$.

For the second assertion, Cf. [Sta] 079P.
K-Adapted Classes

**Def. (3.4.3.11) [K-Adapted Classes].** Let \( \mathcal{A} \) be an Abelian category, \( \mathcal{D} \) a triangulated category and \( F : K(\mathcal{A}) \to \mathcal{D} \) a triangulated functor, a **K-adapted class** for \( F \) is a full triangulated subcategory \( \mathcal{R} \subset K(\mathcal{A}) \) that

- If \( I \to I' \) is a quasi-isomorphism in \( \mathcal{R} \), then \( F(I) \to F(I') \) is an isomorphism in \( \mathcal{D} \).
- Every \( A^\bullet \in K(\mathcal{A}) \) admits some quasi-isomorphism \( A^\bullet \to I^\bullet \) where \( I^\bullet \in \mathcal{R} \).

**Cor. (3.4.3.12) [K-Injective is K-Adapted].** If \( \mathcal{A} \) has sufficiently many K-injectives, then the class of K-injectives is K-adapted to any left exact functor \( F \), by (3.4.3.2) and (3.4.3.1).

4 Derived Functors

**Def. (3.4.4.1) [Right Derived Functors].** Let \( \mathcal{A} \) be an Abelian category, \( E \) a triangulated category and \( F : K(\mathcal{A}) \to E \) an exact functor between triangulated categories. Then a **right derived functor** of \( F \) is an exact functor \( RF : D(\mathcal{A}) \to \mathcal{D} \) together with a natural transformation \( \eta : F \to RF \circ Q_A \) that satisfies the following universal property: For any exact functor \( G : D(\mathcal{A}) \to \mathcal{D} \) and a natural transformation \( \eta' : F \to G \circ Q_A \), there is a natural transformation \( \theta : RF \to G \) that

\[
\eta' = (\theta \circ Q_A) \circ \eta.
\]

In particular, if \( RF \) exists, then it is unique up to unique isomorphism of exact functors.

**Prop. (3.4.4.2) [Derived Functors via K-Adapted Classes].** Let \( \mathcal{A} \) be an Abelian category, \( \mathcal{D} \) a triangulated category and \( F : K(\mathcal{A}) \to E \) an exact functor, if there exists a K-adapted class \( \mathcal{R} \) for \( F \), then \( RF \) exists. Moreover, for \( I \in \mathcal{R} \), the morphism \( \eta_I : F(I) \to RF \circ Q_A(I) \) is an isomorphism in \( \mathcal{D} \).

**Proof:** Let \( S = \mathcal{R} \cap \text{QIso}(\mathcal{A}) \), then \( \mathcal{R}, K(\mathcal{A}) \) and the localizing systems \( S, \text{QIso}(\mathcal{A}) \) satisfy the conditions in (3.4.2.6), so \( \iota : S^{-1} \mathcal{R} \subset D(\mathcal{A}) \) is a full triangulated subcategory, and it is also essentially surjective, thus it is an equivalence of categories. Let \( I \) be a right adjoint of the inclusion, then \( I \) is also an exact functor (3.4.1.9), and there is a natural isomorphism \( \zeta : \text{id}_{D(\mathcal{A})} \cong \iota \circ I \).

By the universal property, there is an exact functor \( F_{\mathcal{R}} : S^{-1} \mathcal{R} \to \mathcal{D} \) extending \( F|_{\mathcal{R}} \). Define

\[
RF = F_{\mathcal{R}} \circ I : D(\mathcal{A}) \to \mathcal{D}.
\]

To construct \( \eta : F \to RF \circ Q_A \), for any \( X \in \text{Ob}(K(\mathcal{A})) = \text{Ob}(D(\mathcal{A})) \), the isomorphism \( \zeta \) gives an isomorphism \( X \cong \iota(I(X)) \), which is represented by a roof \( (R, f, s^{-1}, f, s) \in \text{QIso}(\mathcal{A}) \), and we can assume \( R \in \text{Ob}(\iota(S^{-1} \mathcal{R})) = \text{Ob}(\mathcal{R}) \) by hypothesis, thus \( s \in S \), and \( F(s) \) is an isomorphism in \( E \) by hypothesis. Thus we get a morphism \( \eta_X : F(s)^{-1} \circ F(f) : F(X) \to F(\iota(I(X))) = RF(Q_A(X)) \).

This \( \eta_X \) is independent of the representation given, because if there is another dominant roof \( (R', t \circ f, (t \circ s)^{-1}) \), where \( t : R \to R' \in S \), then \( F(t \circ s)^{-1} \circ F(t \circ f) = F(s)^{-1} \circ F(f) \in E \).

And for a morphism \( f : X \to Y \in K(\mathcal{A}) \), \( \zeta \) gives a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\xi_X} & \iota(I(X)) \\
\downarrow f & & \downarrow \iota(I(f)) \\
Y & \xrightarrow{\xi_Y} & \iota(I(Y))
\end{array}
\]

in \( D(\mathcal{A}) \) where \( \xi_X, \xi_Y \) are represented by \( (R_X, f_X, s_X^{-1}), (R_Y, f_Y, s_Y^{-1}) \), and \( I(f) \) is represented \( (R_0, f_0, s_0^{-1}) \), then we can construct roof to realize this commutative diagram in \( K(\mathcal{A}) \) and show
there is a commutative diagram

\[
\begin{array}{ccc}
F(X) & \xrightarrow{F(s_X)\circ F(f_X)} & RF(Q_A(X)) \\
\downarrow{F(f)} & & \downarrow{F(s_0)\circ F(f_0)=RF\circ Q_A(f)} \\
F(Y) & \xrightarrow{F(s_Y)\circ F(f_Y)} & RF(Q_A(Y))
\end{array}
\]

in \( E \), which means \( \eta : F \rightarrow RF \circ Q_A \) is a natural isomorphism.

Notice that \( \eta_I \) is an isomorphism for \( I \in \mathcal{R} \), because in this case \( F(f_I), F(s_I) \) are both isomorphisms.

It remains to show the universal properties of \( \eta \): Given any exact functor \( G : D(A) \rightarrow E \) and a natural transformation \( \eta' : F \rightarrow G \circ Q_A \), for any \( X \in \text{Ob}(K(A)) = \text{Ob}(D(A)) \), we get a morphism \( \eta'_X : F(X) \rightarrow G(X) \) in \( E \). Notation as before, because \( \eta' \) is a natural transformation, we get a commutative diagram in \( K(A) \)

\[
\begin{array}{ccc}
F(X) & \xrightarrow{\eta'_X} & G(X) \\
\downarrow{F(f)} & & \downarrow{G(Q_A(f))} \\
F(R_X) & \xrightarrow{\eta'_R_X} & G(R_X) \\
\downarrow{F(s)} & & \downarrow{G(Q_A(s))} \\
F(\iota(I(X))) & \xrightarrow{\eta'_\iota(I(X))} & G(\iota(I(X)))
\end{array}
\]

In \( E \). As \( \zeta_X = (R_X, f, s^{-1}) \) is an isomorphism between \( X \) and \( \iota(I(X)) \), \( f, s \) are both quasi-isomorphisms, thus the vertical arrows are both isomorphisms, and we get a commutative diagram

\[
\begin{array}{ccc}
F(X) & \xrightarrow{\eta_X} & G(X) \\
\downarrow{\eta'_X} & & \downarrow{G(\zeta_X)} \\
RF(Q_A(X)) & \xrightarrow{\eta'_\iota(I(X))} & G(\iota(I(X)))
\end{array}
\]

So we can define

\[
\theta_X = (G(\zeta_X))^{-1} \circ \eta'_\iota(I(X)) : RF(Q_A(X)) \rightarrow G(X),
\]

then it is is functorial in \( X \) as both \( \eta'_\iota(I(X)) \) and \( G(\zeta_X) \) are functorial in \( X \), so defines a natural transformation \( RF \circ Q_A \rightarrow G \) that \( (\theta \star Q_A) \circ \eta = \eta' \).

For the uniqueness of \( \eta \): For any \( X \in \text{Ob}(S^{-1}\mathcal{R}) = \text{Ob}(\mathcal{R}) \), \( \eta_X \) is an isomorphism, thus \( \eta_X \) is determined, but \( \iota : S^{-1}\mathcal{R} \rightarrow D(A) \) is essentially surjective, so \( \eta_X \) is determined for any \( X \in D(A) \).

\[
\square
\]

\textbf{Cor. (3.4.4.3) [Derived Functors via K-Injective Classes].} Let \( A \) be an Abelian category, \( E \) a triangularized category and \( F : K^+(A) \rightarrow E \) an exact functor, if \( K^+(A) \) has enough K-injectives, then the class of K-injectives is K-adapted to \( F(3.4.3.12) \), so \( RF : D^+(A) \rightarrow E \) exists. Moreover, for any K-injective \( I^* \), the morphism \( \eta_{I^*} : F(I^*) \rightarrow RF \circ Q_A(I^*) \) is an isomorphism in \( E \).
Cor. (3.4.4.4) [Derived Functors via Injectives]. Let \( \mathcal{A}, \mathcal{B} \) be Abelian categories s.t. \( \mathcal{A} \) has enough injective and countable products, and \( F : \mathcal{A} \to \mathcal{B} \) an additive functor, then \( K^*(F) : K^*(\mathcal{A}) \to D^*(\mathcal{A}) \) is an exact functor by (3.4.1.17), and \( K^*(\mathcal{A}) \) has enough K-injectives by (3.4.3.9).

However, this is useless unless \( F \) is left exact in which case we see \( R^0 F(A) = F(A) \) for any \( A \in \mathcal{A} \) by (3.4.4.3).

Cor. (3.4.4.5) [Naturality]. If \( \eta : F \to F' \) is a natural transformation of left-exact functors, then by universal property (3.4.4.1), there is a natural transformation \( R\eta : RF \to RF' \) inducing a long exact sequence about cohomology groups extending \( \eta \).

Prop. (3.4.4.6) [Composition of Derived Functors]. \( \mathcal{A}, \mathcal{B} \) be Abelian categories and \( \mathcal{D} \) a triangulated category. If \( F : K^*(\mathcal{A}) \to K^*(\mathcal{B}), G : K^*(\mathcal{B}) \to \mathcal{D} \) are exact functors between triangulated categories, and \( R_{\mathcal{A}} \) is K-adapted to \( F \) and \( G \circ F \), \( R_{\mathcal{B}} \) is K-adapted to \( G \), then the natural transformation \( R(G \circ F) \to RG \circ RF \) is an isomorphism.

**Proof:** \( RF \) is isomorphic to \( F \) on \( R_{\mathcal{A}}, \) so for any \( A^* \in K^*(\mathcal{A}) \), choose some quasi-isomorphism \( A^* \to R \), where \( R \in R_{\mathcal{A}}, \) then there is a commutative diagram
\[
\begin{array}{ccc}
R(G \circ F)(A^*) & \xrightarrow{\cong} & R(G \circ F)(R) \\
\downarrow & & \downarrow \\
RG \circ RF(A^*) & \xrightarrow{\cong} & RG \circ RF(R)
\end{array}
\]
\[
R(G \circ F)(R) \xrightarrow{\cong} G \circ F(R),
\]
and we are done. \( \square \)

Def. (3.4.4.7) [Universal \( \delta \)-Functor]. A universal \( \delta \)-functor between Abelian categories is one that any natural transformation from \( T^0 \) to another \( \delta \)-functor will generate a \( \delta \)-map. A effaceable \( \delta \)-functor is one that for any \( n > 0 \) and any object \( A \), there is an injection \( A \to B \) that \( T^n(A) \to T^n(B) = 0 \).

Prop. (3.4.4.8) [Grothendieck]. A \( \delta \)-functor is universal if it is effaceable.

**Proof:** We construct by induction on \( n \). choose a \( 0 \to A \to B \to C \to 0 \) such that \( T^{n+1}(A) \to T^{n+1}(B) = 0 \) then there is an isomorphism \( T^{n+1}(A) \cong \text{Coker}(T^n(B) \to T^n(C)), \) and so we can construct the map on \( T^{n+1} \) induces by
\[
\text{Coker}(T^n(B) \to T^n(C)) \to \text{Coker}(G^n(B) \to G^n(C)) \to G^{n+1}(A).
\]
This can be verified to be a \( \delta \) map. \( \square \)

Prop. (3.4.4.9). The derived functors form a universal \( \delta \)-functor (when it exists).

**Proof:** It is a \( \delta \) functor by (3.4.2.1), it is universal by (3.4.4.8). \( \square \)

Prop. (3.4.4.10). Derived functor commutes with filtered colimits on a Grothendieck Abelian category, this is by AB5.
Prop. (3.4.4.11) [Hypercohomology]. Given an Abelian category $\mathcal{A}$ with enough injectives, $\mathcal{B}$ a complete Abelian category, $F : \mathcal{A} \rightarrow \mathcal{B}$ a left exact functor, and $K \in K(\mathcal{A})$, we can define the right hyper-derived functor of $F$ at $K$ as $RF(K) = \text{Tot}^n F(P) \in K(\mathcal{B})$ where $K \rightarrow P$ is a Cartan-Eilenberg resolution of $K$. and the hypercohomologies of $F$ at $K$ as $R^n F(K) = H^n(\text{Tot}^n F(P))$. Dually we can define the left hyper-derived functor and hyperhomologies.

For complexes in $K^+(\mathcal{A})$, there is no restriction and the right derived-hyper functor descends to a functor from $D^+(\mathcal{A}) \rightarrow D^+(\mathcal{B})$.

When the Abelian category $\mathcal{A}$ satisfies AB3* and AB4*, i.e. the direct product is exact, then $\text{Tot}^n$ of the Cartan-Eilenberg resolution of any complex is a quasi-isomorphism to it by the dual of??. (Take horizontal filtration, AB4* assures it collapse).

Derived Bifunctors

Def. (3.4.4.12) [Right Derived Functors of Bi-Exact Bi-Functors]. Let $\mathcal{A}, \mathcal{B}$ be Abelian categories and $F : K(\mathcal{A}) \times K(\mathcal{B}) \rightarrow \mathcal{D}$ be bi-exact bifunctor between triangulated categories, a right derived functor of $F$ is a bi-exact bifunctor $RF : D(\mathcal{A}) \times D(\mathcal{B}) \rightarrow \mathcal{D}$ together with a natural transformation $\eta : F \rightarrow RF \circ (Q_\mathcal{A} \times Q_\mathcal{B})$ that satisfies the following universal property: For any bi-exact bifunctor $G : D(\mathcal{A}) \times D(\mathcal{B}) \rightarrow \mathcal{D}$ and a natural transformation $\eta' : F \rightarrow G \circ (Q_\mathcal{A} \times Q_\mathcal{B})$, there is a natural transformation $\theta : RF \rightarrow G$ that $\eta' = (\theta \circ (Q_\mathcal{A} \times Q_\mathcal{B})) \circ \eta$.

In particular, if $RF$ exists, then it is unique up to unique isomorphisms of bi-exact bi-functors.

Prop. (3.4.4.13) [Deriving Bi-Exact Functors]. Let $\mathcal{A}_1, \mathcal{A}_2$ be Abelian categories and $F : K(\mathcal{A}_1) \times K(\mathcal{A}_2) \rightarrow \mathcal{D}$ be bi-exact bifunctor between triangulated categories, if $\mathcal{R}_i$ are full subcategories of $\mathcal{A}_i$ s.t.

- If $R_i \rightarrow R_i'$ are quasi-isomorphisms in $\mathcal{R}_i$, the induced map $F(R_1, R_2) \rightarrow F(R_1', R_2')$ is an isomorphism in $\mathcal{D}$.
- Any $A_i^\bullet \in K(\mathcal{A}_i)$ admits some quasi-isomorphism $A_i^\bullet \rightarrow I_i^\bullet$ where $I_i^\bullet \in \mathcal{R}_i$.

Then the right derived functor (3.4.4.12) $RF$ exists. Moreover, for any $R_i \in \mathcal{R}_i$, $\eta_{R_1, R_2} : F(R_1, R_2) \rightarrow RF \circ (Q_{A_1} \times Q_{A_2})(R_1, R_2)$ is an isomorphism.

Proof: Let $S_i = \mathcal{R}_i \cap \text{QIso}(\mathcal{A}_i)$, then $\mathcal{R}_i, K(\mathcal{A}_i)$ and the localizing systems $\mathcal{S}_i, \text{QIso}(\mathcal{A}_i)$ satisfy the conditions in (3.4.2.6), so $\iota : S_i^{-1} \mathcal{R}_i \subset D(\mathcal{A}_i)$ is a full triangulated subcategory, and it is also essentially surjective, thus it is an equivalence of categories. Let $I_i$ be a right adjoint of the inclusion, then $I_i$ is also an exact functor (3.4.1.9), and there is a natural isomorphism $\zeta_i : \text{id}_{D(\mathcal{A}_i)} \cong \iota_i \circ I_i$.

By hypothesis of universal properties, the functor $F$ extends to an exact functor $F_\mathcal{R} : \prod_i S_i^{-1} \mathcal{R}_i \rightarrow \mathcal{D}$. Define

$$RF = F_\mathcal{R} \circ \prod_i I_i : \prod_i D(\mathcal{A}_i) \rightarrow \mathcal{D}.$$  

The rest of the proof is verbatim as that of (3.4.4.2).

Remark (3.4.4.14). This proposition can be naturally extended to any multi-exact multi-functors. In fact, I suppose this can be deduced from the usual derived functors by considering the tensor product category $\mathcal{A} \otimes \mathcal{B}$, Cf. [Basic Concepts of Enriched Category Theory, Kelly].

Prop. (3.4.4.15) [Derived Functors of Adjunctions]. Let $\mathcal{A}_1, \mathcal{A}_2$ be Abelian categories and $(F, G)$ be an adjunction between $K(\mathcal{A}_1)$ and $K(\mathcal{A}_2)$, and $\mathcal{R}_i$ are full subcategories of $\mathcal{A}_i$ s.t.

- If $R_i \rightarrow R_i'$ are quasi-isomorphisms in $\mathcal{R}_i$, the induced map $F(R_1', R_2) \rightarrow \text{Hom}_B(R_1, R_2')$ is an isomorphism in $D(\mathcal{A}_B)$.  

Any $A_1^\bullet \in K(A_1)$ admits some quasi-isomorphism $A_1^\bullet \to I_1^\bullet$ where $I_1^\bullet \in \mathcal{R}_1$.

Any $A_2^\bullet \in K(A_2)$ admits some quasi-isomorphism $I_2^\bullet \to A_2^\bullet$ where $I_2^\bullet \in \mathcal{R}_2$.

then there is a functorial isomorphism

$$R\text{Hom}(LF(A^\bullet), B^\bullet) \cong R\text{Hom}(A^\bullet, RG(B^\bullet)) \in D(\text{Ab})$$

for $A^\bullet \in K(A), B^\bullet \in K(B)$. In particular,

$$\text{Hom}(LF(A^\bullet), B^\bullet) \cong \text{Hom}(A^\bullet, RG(B^\bullet)) \in \text{Ab}$$

Proof: Regard both side as a right derived functor of the isomorphic bi-exact bi-functors

$$K(A)^{op} \times K(B) \to D(\text{Ab}) : (A^\bullet, B^\bullet) \mapsto \text{Hom}_B^\ast(F(A^\bullet), B^\bullet) \cong \text{Hom}_A^\ast(A^\bullet, G(B^\bullet)) \in D(\text{Ab}).$$

Then the functorial isomorphism follows from universal properties. □

Prop. (3.4.4.16). Situation as in (3.4.4.15), for any $K^\bullet \in K(A_2)$, there is a commutative diagram of adjunction maps

$$\begin{array}{ccc}
LF \circ G(K^\bullet) & \longrightarrow & F \circ G(K^\bullet) \\
\downarrow & & \downarrow \\
LF \circ RG(K^\bullet) & \longrightarrow & K^\bullet
\end{array}$$

Proof: Cf. [Sta] 0FPI. □

Internal Hom

Def. (3.4.4.17) [Internal Hom]. If $\mathcal{A}$ is an Abelian category and $K(\mathcal{A})$ has enough K-injectives or enough K-projectives, thus by (3.4.4.13), we can define the internal Hom

$$R\text{Hom} : D(\mathcal{A})^{op} \times D(\mathcal{A}) \to D(\mathcal{A})$$

as the right derived functor of the bi-exact bifunctor $\text{Hom}^\ast : K(\mathcal{A})^{op} \times K(\mathcal{A}) \to D(\text{Ab})$.

Prop. (3.4.4.18) [Ext Groups]. For $X, Y \in D(\mathcal{A})$, define the ext groups

$$\text{Ext}^i_{\mathcal{A}}(X, Y) = H^i(R\text{Hom}(X, Y)) = \text{Hom}_{D(\mathcal{A})}(X[0], Y[i]).$$

Proof: To show $H^i(R\text{Hom}(X, Y)) = \text{Hom}_{D(\mathcal{A})}(X[0], Y[i])$, choose a K-injective resolution $Y \to I^\bullet$ of $Y$, then

$$H^i(R\text{Hom}(X, Y)) = H^i(\text{Hom}_{\mathcal{A}}(X, I^\bullet)) = \text{Hom}_{K(\mathcal{A})}(X, I^\bullet[n]) = \text{Hom}_{D(\mathcal{A})}(X, I^\bullet[n]) = \text{Hom}_{D(\mathcal{A})}(X, Y[n]),$$

by (3.3.3.10) and the definition (3.4.3.1). □

Prop. (3.4.4.19). If $P^\bullet \to X^\bullet$ is a projective resolution, then $\text{Ext}^i(X^\bullet, Y^\bullet) = \text{Hom}_{K(\mathcal{A})}(P^\bullet[-i], Y^\bullet)$. If $Y^\bullet \to I^\bullet$ is an injective resolution, then $\text{Ext}^i(X^\bullet, Y^\bullet) = \text{Hom}_{K(\mathcal{A})}(X^\bullet, I^\bullet)$.

Prop. (3.4.4.20). If $X \in D^{\leq a}(\mathcal{A})$ and $Y \in D^{\geq b}(\mathcal{A})$, then for $i < b - a$, $\text{Ext}^i(X, Y) = 0$, and $\text{Ext}^{b-a}(X, Y) = \text{Hom}(H^a(X), H^b(Y))$.

In particular, for $A, B \in \mathcal{A}$, $\text{Ext}^i(A, B) = 0$ for $i < 0$ and $\text{Ext}^0(A, B) = \text{Hom}(A, B)$. 
Proof: This is because $X$ can be represented by $K\leq a(P)$ or $Y$ can be represented by $K\geq b(I)$. □

**Prop. (3.4.4.21) [Long Exact Sequences]**. Let $0 \to A_1 \to A_2 \to A_3 \to 0$ be an exact sequence in $\mathcal{A}$, then it is distinguished in $D(\mathcal{A})$, so by (3.4.1.12), for any $B \in \mathcal{A}$, there is a long exact sequence

$$0 \to \text{Hom}(B, A_1) \to \text{Hom}(B, A_2) \to \text{Hom}(B, A_3) \to \text{Ext}^1(B, A_1) \to \text{Ext}^1(B, A_2) \to \ldots,$$

and similarly a long exact sequence

$$0 \to \text{Hom}(A_3, B) \to \text{Hom}(A_2, B) \to \text{Hom}(A_1, B) \to \text{Ext}^1(A_3, B) \to \text{Ext}^1(A_2, B) \to \ldots.$$

**Def. (3.4.4.22) [Yoneda Extensions]**. Let $\mathcal{A}$ be an Abelian category and $A, B \in \mathcal{A}$, a **Yoneda extension** of $B$ by $A$ of degree $d$ is an exact sequence

$$0 \to A \to Z_{d-1} \to \ldots \to Z_0 \to B \to 0.$$

One Yoneda extension is said to **dominate** another if there is a map of extensions s.t. restricts to $\text{id}_A$ and $\text{id}_B$. Two Yoneda extensions of degree $d$ is called **equivalent** if they are dominated by a common Yoneda extension. (Notice this is an equivalence relation by (3.4.4.23).

**Prop. (3.4.4.23) [Ext and Yoneda Extensions]**. There is a map from the equivalence classes of Yoneda extensions of degree $d$ of $B$ over $A$ to $\text{Ext}^d(B, A)$, which maps the exact sequence $0 \to A \to Z_{d-1} \to \ldots \to Z_0 \to B \to 0$ to $fs^{-1} \in \text{Hom}_{D(\mathcal{A})}(B[0], A[d])$, where $f : (A \to Z_{d-1} \to \ldots \to Z_0) \to A[d]$, and $s : (A \to Z_{d-1} \to \ldots \to Z_0) \to B[0]$.

and corresponds to the set of $i$-term extensions of $Y$ by $X$. There is a natural map

$$\text{Ext}^i_A(X, Y) \times \text{Ext}^j_A(Y, Z) \to \text{Ext}^{i+j}_A(X, Z)$$

by composition or equivalently the conjunction of extensions.

Proof: Cf.[Sta]06XU. □

**Prop. (3.4.4.24) [Explicit Addition as Extensions]**. In an Abelian category with enough injectives, the extension $\text{Ext}^1(N, M)$ is equivalent with the Abelian group of extensions with Baer sum as addition.

Proof: We choose a projective resolution $0 \to K \to P \to N \to 0$, so $\text{Hom}(K, M) \to \text{Ext}^1(N, M)$ is surjective, so choose a lifting and the pushout $0 \to M \to L \to N \to 0$ with be the corresponding extension, Now the Baer sum is easy to define and verify. □

**Prop. (3.4.4.25)**. If $\mathcal{A}$ is an Abelian category and $p \geq 0$ s.t. $\text{Ext}^p(A, B) = 0$ for any $A, B \in \mathcal{A}$, then $\text{Ext}^i(A, B) = 0$ for any $i \geq p$ and $A, B \in \mathcal{A}$.

Proof: Any Yoneda extension of degree $i$ is a conjunction of extensions of degree $p$ and degree $i-p$. □

**Cor. (3.4.4.26)**. If $\mathcal{A}$ is an Abelian category s.t. $\text{Ext}^2(A, B) = 0$ for any $A, B \in \mathcal{A}$, then each object of $D^b(\mathcal{A})$ is isomorphic to a direct sum of cohomologies.

Proof: Let $K$ be represented by $K^\bullet \in D^{[a,b]}(\mathcal{A})$. We use induction on $b-a$. If $b-a > 0$, then there is a distinguished triangle $\tau_{b-1}K \to K^\bullet \to H^b(K)[-b] \to \tau_{b-1}K^\bullet[1]$. (3.4.2.4). If we can prove $H^b(K)[-b] \to \tau_{b-1}K^\bullet[1]$ is 0, then we finish by (3.4.1.4). But by induction and the hypothesis,

$$\text{Hom}_{D(\mathcal{A})}(H^b(K)[-b], \tau_{b-1}(K^\bullet)[1]) = \bigoplus_{b \leq i \leq b} \text{Ext}^{b-i+1}_A(H^b(K), H^i(K)),$$

which vanishes by hypothesis. □
Acyclic Objects

Prop. (3.4.4.27) [F-Acyclic Objects]. For a left exact functor $F$, an object $X$ is (right)$F$-acyclic if $RF$ is defined for $X$, and the natural map $F(X) \to RF(X)$ is an isomorphism, or equivalently $R^iF(X) = 0$ for all $i > 0$.

Then there is an adapted class of $F$ iff the class of $F$-acyclic objects $Acy(F)$ is sufficiently large, and in this case adapted classes of $F$ are exactly sufficiently large subclasses of $Acy(F)$, and $Acy(F)$ contains all injectives. (But the class of injectives may not be sufficiently large!)

Proof: Cf.[Gelfand P195]. □

Prop. (3.4.4.28) [Leray’s Acyclicity Lemma]. Let $F : A \to B$ be an additive functor and $RF$ is everywhere defined, then for a complex $A^\bullet$ in $K^+(A)$ consisting of $F$-acyclic objects, the natural map $F(A^\bullet) \to RF(A^\bullet)$ is an isomorphism.

Proof: Cf.[Sta]015E. This may be equivalent to (3.4.4.27). □

Prop. (3.4.4.29) [Acyclic Criterion]. Let $F$ be a left exact functor from an Abelian category $C$ of enough injectives to another Abelian category, $T$ is a class of objects of $C$ that satisfies:

- $T$ is sufficiently large.
- Cokernel of maps between elements of $T$ is in $T$ and $0 \to F(A) \to F(A') \to F(\text{Coker}) \to 0$ is exact. (To use induction).

Then every object of $T$ is $F$-acyclic.

Proof: Cf.[Sta]05T8. □

Prop. (3.4.4.30) [Injectives are adapted]. By (3.4.3.5), if $A$ contains sufficiently many injectives, then injective objects are adapted to any left exact functor $F$. (Because id on acyclic injective complexes is homotopic to 0 by the lemma).

5 (Co)Homological Dimension

Prop. (3.4.5.1). If $A$ has enough projectives, then the projective dimension of an object $X$ is the length of projective resolutions. (Use resolution and long sequence).

Prop. (3.4.5.2) [Hilbert Theorem]. For an Abelian category $A$, the category $A[T]$ is an Abelian category. If $A$ has enough projectives and have infinite direct sum, then $\text{dhp}_{A[T]}(X, t) \leq \text{dhp}_A(X) + 1$ and equality with $t = 0$.

Cor. (3.4.5.3). The Categories $\text{Ab}$ and $K[X]$-mod have homological dimension 1. $K[X_1, \ldots, X_k]$ has homological dimension $k$.

Def. (3.4.5.4) [Injective Amplitude]. Let $A$ be an Abelian category with enough injectives, $K \in D(A)$ is said to have finite injective dimension if $K \in D^b(I)$. It is said to have injective amplitude in $[a, b]$ if $K \in D[a, b](I)$.

Prop. (3.4.5.5). Let $A$ be an Abelian category and $K \in D(A)$,

- If $K \in D^b(A)$ and $H^i(K)$ all have finite injective dimensions, then $K$ also has finite injective dimension.
- If $K$ is represented by $K^\bullet \in K^b(A)$, and $K^i$ all have finite injective dimensions, then $K$ also has finite injective dimension.
3.4. DERIVED CATEGORIES

Proof: 1 follows from the Grothendieck spectral sequence applied to the functor $\text{Hom}(N, -)$ for any $N \in \mathcal{A}$ and the CE resolution of $K$ (3.3.5.9).

2 follows from 1 as we can use induction to show all $H^i(K)$ has finite injective dimensions. □

6 Derived Limits and Colimits

Def. (3.4.6.1) [Derived (Co)Limits]. Let $\mathcal{D}$ be a triangulated category, and $(K_n, f_n)$ is an inverse system of objects in $\mathcal{D}$, then an object $K$ is called the derived colimit of it iff there exists and there is a distinguished triangle

$$\oplus K_n \rightarrow K \rightarrow \oplus K_n[1]$$

where the first map is given by $(1 - f_n)$. By TR1, the derived colimit exists as long as $\oplus K_n$ exists, and by TR3 (3.4.1.12), the colimit is unique if it exists. And by TR3 again a morphism of systems induces a morphism of colimits.

The definition of derived limit is dual.

Prop. (3.4.6.2) [Cofinality of Hocolim]. Let $\mathcal{D}$ be a triangulated category and $(K_n, f_n)$ be a system, if $0 \leq n_{i_0} < n_{i_1} < \ldots$ be a sequence of integers, then there is an isomorphism $\text{hocolim} K_{n_i} \rightarrow hocolim K_n$.

Proof: Cf. [Sta]0CRJ. □

Lemma (3.4.6.3). Let $\mathcal{A}$ be an Abelian category with countable products and enough injectives, then the derived limit $R\lim$ for any inverse system in $D^+(\mathcal{A})$ exists.

Proof: It suffices to show $\prod K^\bullet_n$ exists in $D(\mathcal{A})$. But every $K^\bullet_n$ has a $K$-injective resolution $I^\bullet_n$, by (3.3.5.9)(3.4.3.5). And then $\prod K^\bullet_n$ is represented by $\prod I^\bullet_n$, by (3.4.3.7). □

Def. (3.4.6.4) [Rlim]. $R\lim$ on an Abelian category $\mathcal{A}$ with countable products and enough injectives is defined to be the right derived functor of $\lim : \mathcal{A}^\mathbb{N} \rightarrow \mathcal{A}$. Equivalently, it is just the derived limit (3.4.6.1)(3.4.6.3) in $D(\mathcal{A})$ restricted to the case where each $K_n$ is discrete.

Prop. (3.4.6.5). Let $R\lim A$ exists on $\mathcal{A}$, if $K_n, f_n$ is a system of objects in $D^+(\mathcal{A})$, then there are exact sequences

$$0 \rightarrow R^1 \lim (H^m(K_n), f_n) \rightarrow R^{m+1} \lim (K_n, f_n) \rightarrow \lim (H^m(K_n), f_n) \rightarrow 0.$$

Immediately from the definition (3.4.6.1).

7 Spectral Sequence

Reference for this section is [Weibel Ch5]. All the definition below is dual for homology and cohomology, just rotate the diagram 180 degree.

We work in an Abelian category.

Def. (3.4.7.1). A convergent Spectral Sequence is a three-dimensional arrange of entries $E^{p,q}_r$ that:

1. $d_r : E^{p,q}_r \rightarrow E^{p+r,q-r+1}_r$ that $d_r d_r = 0$.

2. $H^p,q(E^{p,q}_r) \cong E^{p,q}_{r+1}$. And $E^{p,q}_r$ has a direct limit $E^{p,q}_\infty$.  

3. There is a complex $E^\bullet$ and a decreasing bounded filtration $F^pE^n$ on each $E^n$ and $E^{p,q}_\infty \cong F^pE^{p+q}/F^{p+1}E^{p+q}$.

**Def. (3.4.7.2)** [Notations For Cohomological Spectral Sequence].
- The cohomology filtration is called **bounded below** $F^{n_s}E^n = 0$ for some $n_s$, it is called **bounded above** $F^{n_s}E_n = E^n$ for some $n^s$.
- The cohomology filtration is called **exhaustive** if $\cup F^iE^n = E^n$.
- The spectral sequence is called **regular** if $d_{pq}^r = 0$ for sufficiently large $r$.
- A spectral sequence is said to **weakly converges** to $E^\bullet$ if there is a filtration $$\ldots \subset F^dH^n \subset F^{d-1}H^n \subset \ldots \subset F^sH^n \subset \ldots \subset H^n$$ that $E^{pq}_\infty \cong F^pH^{p+q}/F^{p+1}H^{p+q}$.
- A spectral sequence **approaches** $E^\bullet$ if it weakly converges to $E^\bullet$.
- A spectral sequence **converges** to $E^\bullet$ if it approaches $E^\bullet$, it is regular, and $E^n = \lim(E^n/F^pE^n)$.
- If a first quadrant spectral sequence converges to $E^\bullet$, then the morphisms $E^{n,0}_0 \to E^{n,0}_\infty \subset E^n$ and $E^n \to E^{0,n}_\infty \to E^{0,n}_0$ are called the **edge morphisms**.

**Prop. (3.4.7.3)** [Notation for Filtrations on Homological Complexes]. Let $C_\bullet$ be a complex and $\ldots \subset F_{p-1}C \subset F_pC \subset \ldots \subset C$ be filtrations of complexes. Then it is called **exhaustive** if $C = \lim F_pC$. It is called **Hausdorff** if $\cap F_pC = 0$. It is called **complete** if $C = \lim C/F_pC$.

**Def. (3.4.7.4)** [Spectral Sequence of a Filtered Complex]. For a complex $K^\bullet$ and a filtration $F^pK^n$ on $K^n$, we have a natural spectral sequence $$E^{pq}_1 = H^{p+q}(F^pE^{p+q}/F^{p+1}E^{p+q}), \quad E^n = H^n(K^\bullet), \quad F^pE^n = H^n(F^pK^\bullet).$$

For a morphism of filtered complexes that are isomorphism for some $r$, induction on the exact sequence $0 \to F^pE^n \to F^{p+1}E^n \to E^{p,n-p}_\infty$ and use five-lemma shows it induces isomorphism on $H^SE$.

**Prop. (3.4.7.5)** [Comparison Theorem]. For a morphism $F$ between two convergent spectral sequences, if it is an isomorphism for some $r$, then it induce isomorphism on the infinite homologies.

**Proof:** Clearly $F$ induces isomorphisms on $E^{p,q}_\infty$. Because there are exact sequence $$0 \to F^{p+1}H^n \to F^pH^n \to E^{p,n-p}_\infty \to 0$$ we can use five lemma and induction to show that $F$ induces isomorphisms on $F^pH^n/F^sH^n$. Then because $H^n = \cup F^pH^n$, we can take colimit to show $F$ induces isomorphisms on $H^n/F^sH^n$, then take inverse limits, we are done.

**Prop. (3.4.7.6)** [Classical Convergence]. If the filtration on a complex $C_\bullet$ is bounded below and exhaustive for all $C_n$, then there is a spectral sequence that is also bounded below and converges to $H_\bullet(C_\bullet)$.

**Proof:** Cf[Gelfand P203] for cohomological case and [Weibel P135] for homological case.
Prop. (3.4.7.7) [Complete convergence]. If the filtration is complete, exhaustive and the spectral sequence is regular, then the spectral sequence weakly converges to $H_\bullet(C_\bullet)$. And if it is also bounded above, then it converges to $H_\bullet(C_\bullet)$.

Proof: Cf. [Weibel, P139].

There are two examples, the stupid filtration and the canonical filtration, the canonical filtration is natural and factors through $D(A)$.

Prop. (3.4.7.8) [Spectral Sequence of a Double Complex]. A double complex has two natural filtrations of the total complex, they define two spectral sequences, one has

$$E^{p,q}_{2,x} = H^p_x(H^q_y(L_\bullet))$$

and the other has

$$E^{p,q}_{2,y} = H^p_y(H^q_x(L_\bullet)).$$

Cf. [Gelfand P209]. In fact under reflection, there is only one spectral sequence. For the horizontal filtration, the differential goes vertical first, for the vertical filtration, the differential goes horizontal first. The differential goes one way, the convergence goes reversely.

If both the filtration is finite and bounded, in particular if $E$ is in the first quadrant, then they both converge to $H^n(E)$, this will generate important consequences.

Cor. (3.4.7.9). If a double complex in the first quadrant has its all column acyclic (3rd-quadrant pointing), then the total complex is acyclic. Thus a morphism of double complex inducing quasi-isomorphism on each column induces a quasi-isomorphism on the total complex.

If a double complex has $H_p(C_{\bullet,q}) = 0, \forall p > 0, q$, then

$$H_n(\text{Tot}C_{\bullet,*}) = H_n(\text{Coker}(C_{1,*} \to C_{0,*})$$

Prop. (3.4.7.10) [Horizontal Filtration]. For a second-quadrant-free homology double complex, the filtration is bounded below and exhaustive for $\text{Tot}^\oplus$, so the classical convergence (3.4.7.6) applies and there is a convergence

$$E^{p,q}_{2} = H^p_x(H^q_y(C)) \Rightarrow H_{p+q}(\text{Tot}^\oplus C).$$

For a fourth-quadrant free homology double complex, the filtration is complete and exhaustive for $\text{Tot}^\Pi$, so the complete convergence (3.4.7.7) applies and there is a weak convergence

$$E^{p,q}_{2} = H^p_x(H^q_y(C)) \Rightarrow H_{p+q}(\text{Tot}^\Pi C).$$

Cor. (3.4.7.11) [Grothendieck Spectral Sequence]. If $\mathcal{A}, \mathcal{B}, \mathcal{C}$ be Abelian categories, $\mathcal{B}$ have enough injectives and $F: K^+(\mathcal{A}) \to K^+(\mathcal{B}), G: K^+(\mathcal{B}) \to K^+(\mathcal{C})$ are exact functors between triangulated categories. If $R_\mathcal{A}$ is adapted to $F, G \circ F$, then for any $X^\bullet \in K^+(\mathcal{A})$, there is a spectral sequence convergence (to upper left)

$$E^{p,q}_{2} = R^pG(R^qF(X)) \Rightarrow E^n = R^n(G \circ F)(X).$$

And if $R_\mathcal{A} = I_\mathcal{A}$, this spectral sequence is functorial in $X^\bullet$.

In particular, this applies to the case that $F$ is right adjoint to an exact functor and both $\mathcal{A}, \mathcal{B}$ have enough injectives.
Proof: Choose a functorial injective resolution \( X \mapsto \mathcal{I}_X^\bullet(3.4.3.9) \), let \( K^\bullet = F(I_X^\bullet) = RF(X) \), and choose a functorial CE resolution of \( K^\bullet(3.3.5.9) \), because the resolutions for \( B^i \to Z^i \to H^i \) and \( Z^i \to K^i \to B^{i+1} \) split and \( G \) is additive, we have

\[
H^q_x(G(L^{**})) = G(H^q_x(L^{**})) = RG(H^q(K))
\]

So

\[
E^{p,q}_{2,y} = H^p_y(H^q_x(L^{**})) = R^pG(H^q(K)) = R^pG(R^qF(X))
\]

and

\[
E^\bullet = RG(Tot(L)) = G(Tot(L)) = RG(K) = RG \circ RF(X) \cong R(G \circ F)(X)(3.4.4.6).
\]

\( \square \)

**Cor. (3.4.7.12).** The low degree parts read:

\[
0 \to R^1G(F(A)) \to R^1(G \circ F)(A) \to G(R^1F(A)) \to R^2(G \circ F)(A).
\]

(Check definition). More generally, if \( R^pG(R^qF(A)) = 0, 0 < q < n \), then

\[
R^mG(F(A)) \cong R^m(G \circ F)(A) \quad m < n
\]

And

\[
0 \to R^nG(F(A)) \to R^n(G \circ F)(A) \to G(R^nF(A)) \to R^{n+1}(G \circ F)(A).
\]

**Remark (3.4.7.13).** The Grothendieck spectral sequence is tremendously important.

**Cor. (3.4.7.14) [Spectral Sequence for Hypercohomologies].** For chain complex \( K \) in \( K^+(A) \) and a left exact functor \( F \), the CE resolution will generate two spectral sequences by(3.4.7.10):

\[
E^{p,q}_{2,x} = H^p_x(R^qF(A)) \Rightarrow R^{p+q}(A), \text{when } A \text{ is bounded below}
\]

\[
E^{p,q}_{2,y} = (R^pF)(H^q(A)) \Rightarrow R^{p+q}(A) \text{, weakly convergent}
\]

where the RHS is the hypercohomologies(3.4.4.11).

8 T-Structures

**Examples**
3.5 Differential Graded Algebras

Main references are [Ker] and [Sta].

Def. (3.5.0.1) [Differential Graded Algebras]. A differential graded algebra or DGA is a chain complex $A^\bullet$ of $R$-modules with $R$-linear maps $A^m \times A^n \to A^{m+n}$ that

$$d(ab) = d(a)b + (-1)^n ad(b),$$

that makes $\oplus A^n$ into an associative and unital $R$-algebra.

Notice the first condition is equivalent to giving a map $\text{Tor}(A^\bullet \times_R A^\bullet) \to A$.

For a differential algebra $A^\bullet$, a right differential module is defined naturally. The tensor operation gives a closed symmetric monoidal structure $M_A$.

Notice a usual $R$-algebra $A$ can be seen as a differential graded algebra as $A^0 = A$ and $A^n = 0$ for $n > 0$.

And as in the case of chain complexes, the category of differential modules over $A$ can be given a derived category.

Def. (3.5.0.2). A differential graded algebra $A^\bullet$ is called commutative if $ab = (-1)^{\deg(a)\deg(b)}ba$. It is called strictly commutative if moreover $a^2 = 0$ for $\deg(a)$ odd.

Def. (3.5.0.3). For two differential graded algebras $A, B$, the tensor graded algebra $A^\bullet \otimes B^\bullet$ is given by the $\text{Tor}(A^\bullet \otimes_R B^\bullet)$.

1 dg-Categories

Def. (3.5.1.1) [dg-Categories]. Given a DGA $A$, a dg-category over $A$ is a category enriched over the monoidal category $M_A(3.5.0.1)$. Let $\text{dgCat}_A$ denote the category of small dg-categories over $A$ where morphisms are given by monoidal functors.

Def. (3.5.1.2) [Homotopy Categories]. Because $H^0$ and $Z^0$ are right-lax monoidal functors from $\text{Ch}(R)$ to $\text{Mod}(R)$, given a dg-category $C$, by transferring, we can get categories $H^0(C)$ and $Z^0(C)$ enriched over $\text{Mod}_{A^0}$.

Def. (3.5.1.3) [Equivalences]. A morphism between dg-categories are called an equivalence if induces quasi-isomorphisms on all hom-complexes.

Prop. (3.5.1.4) [Model Category of dg-Categories]. There is a cofibrantly generated model category on $\text{dgCat}_A$, where weak equivalences are quasi-equivalences and the fibrations are morphisms $F : A \to B$ that:

- induces component-wise surjections on hom-complexes.

- given an isomorphism $g : F(X) \to Y \in H^0(B)$, there is an isomorphism in $H^0(A)$ lifting $g$.

This monoidal structure is induced from that of the case $A = R$ and the right-lax monoidal functor $\text{Ch}(R) \to M(A)$ given by $M^\bullet \mapsto A \otimes M$.

2 Sheaves of DGAs
3.6 Topology I

Main references are [Mun00], [Mor19], [H-J99].

1 Basics

Def. (3.6.1.1) [Topologies].

Def. (3.6.1.2) [Continuous Functions].

Def. (3.6.1.3) [Semicontinuous Functions]. A function from $X \to [-\infty, \infty]$ is called upper semi-continuous iff $f^{-1}((-\infty, a))$ are all open. It is called lower semicontinuous iff $f^{-1}((a, \infty])$ are all open.

Def. (3.6.1.4). A topological space is called separable if it has a countable dense subset.

Def. (3.6.1.5) [Product Topology]. Arbitrary product exists in the category of topological spaces. It is constructed as follows: for a family of topology spaces $X_i$ indexed over an index set $I$, the product $\prod_I X_i$ is the set-theoretic product endowed with the topology generated by the basis $\pi_i^{-1}(U)$ for $U_i$ open in $X_i$.

Prop. (3.6.1.6) [Limits and Colimits]. Arbitrary limits and colimits exist in the category of topological spaces. The limits is given as a subspace of the product topology, and the colimits $X = \text{colim} X_i$ is given a topology that $U \subset X$ is open iff $U \cap X_i$ is open for each $i$.

Prop. (3.6.1.7) [Pullback Space]. Let $E \to X$ and $f : X' \to X$ be maps of spaces, then there is a pullback map $f^*E = E \times_X X' \to X'$, called the pullback space.

Def. (3.6.1.8) [Quotient Topology]. Let $f : X \to Y$ be a surjective map of spaces, and $X$ has a topology, then we can define a quotient topology on $Y$ that $U \subset Y$ is open iff $f^{-1}(U)$ is open in $X$. It has the universal property that any continuous map $X \to Z$ that factors through $f$ set-theoretically factors through $f$ as a continuous map.

Such a map is called a quotient map.

Prop. (3.6.1.9). A surjective open map $\pi$ is a quotient map.

Proof: It is clearly that a subset $U$ is open iff $\pi^{-1}(U)$ is open. \qed

Def. (3.6.1.10) [Glueing Space]. Let $A \subset X$ and $f : A \to Y$, then we have the glueing space $Y \coprod_f X$.

Def. (3.6.1.11) [Mapping Cylinder]. Let $f : X \to Y$ be a map, then we define the mapping cylinder $M(f) = Y \coprod_f X \times I$, where $X \times \{0\} \subset X \times I$ mapsto $Y$ by $f$.

Def. (3.6.1.12) [Cone]. For $X \in \text{Top}$, define the cone over $X$ to be the space $C(X) = (X \times \mathbb{I})/(X \times \{1\})$. Notice that $C(\emptyset) = \text{pt}$.

Def. (3.6.1.13) [Mapping Cone]. Let $f : X \to Y$ be a map, then we define the mapping cone $C(f) = M(f)/X \times \{1\}$.

Lemma (3.6.1.14). If $f : X \to Y$ is a surjective continuous map that $f(E) \neq Y$ for any proper closed subspace of $X$, then for any $U \subset X$ open, $f(U) \subset Y \setminus f(X \setminus U)$. 

3.6. TOPOLOGY I

Proof: Take $y \in f(U)$ and a nbhd $V$ of $y$ in $Y$, we show that $V$ intersect $Y \setminus f(X \setminus U)$: $W = U \cap f^{-1}(V)$ is nonempty, thus $f(X \setminus W) \neq Y$, take $y' \in Y \setminus f(X \setminus W)$, then it is clear $y' \in Y \setminus f(X \setminus U)$, and $y' \in V$. □

Def. (3.6.1.15) [Locally Closed Subset]. A subset $Z$ of $X$ is called locally closed if for any $z \in Z$, there is a nbhd $U$ of $z$ in $X$ that $U \cap Z$ is closed in $Z$. Equivalently, a locally closed subset is the intersection of an open subset with a closed subset.

Proof: An intersection of an open subset and a closed subset is clearly locally closed. Conversely, if $Z$ is locally closed, we choose for each $z \in Z$ a nbhd $U_z$ that $U_z \cap Z$ is closed in $U$, then we can show $Z = \overline{Z} \cap \bigcup_z U_z$. This is because if $x \in \overline{Z} \cap \bigcup_z U_z$, then $x \in U_z$ for some $z$, and also $x \in Z$, thus $x$ is in $Z$. □

Filter Langrange

Def. (3.6.1.16) [Convergence and Filter]. For a filter $F$ on a topological space, $F$ converges to a point $y$ iff any open set containing $y$ is in $F$.

If $X$ is a set and $Y$ is a topological space and $X \to Y$ is a function, then $y \in Y$ is a $F$-limit of $f$ if $f_* F$ converges to $y$.

Prop. (3.6.1.17) [Ultrafilter Convergence Theorem]. Let $X, Y$ be a topological space, then:

1. $Y$ is compact iff any ultrafilter on $Y$ has a limit point.

2. $Y$ is Hausdorff iff any ultrafilter on $Y$ has at most one limit point.

3. A function $f : X \to Y$ is continuous iff for any filter on $X$ converging to $x$, the filter $f_* F$ converges to $y$.

Proof:

1. If $Y$ is compact but every point is not a limit point, then for any $x$, there is an open set $U_x$ that $U_x \notin F$, but then $F$ of them covers $Y$, which is in $F$, so one of them must be in $F$ by (1.1.8.7), contradiction.

Conversely, if $\cup_i U_i = X$ but no finite union of them cover $X$, then $X - U_i$ satisfies the finite intersection property, so there is an ultrafilter containing $X - U_i$ by (1.1.8.4) and (1.1.8.5). Then clearly any point $x$ is not a limit point of $F$.

2. If $Y$ is Hausdorff and $x, y$ are both limit point of a filter $F$, then there are two non-intersecting nbhd of them in $F$, so its intersection $\emptyset \notin F$, contradiction.

Conversely, if $x, y$ are two point that their nbhds both intersect, then their nbhds together satisfies the finite intersection property, so there is an ultrafilter containing all of them, by (1.1.8.4) and (1.1.8.5), thus converging to both $x$ and $y$.

3. This is an easy consequence considering the filter of all the nbhd containing $x$. □

Connected Components

Def. (3.6.1.18) [Connectedness]. A space $X$ is called connected if it satisfies: for any open subset $U, V$ of $X$ that $U \cup V = X$ and $U \cap V = \emptyset$, either $U = \emptyset$ or $V = \emptyset$.

$X$ is called locally connected if there is a basis of $X$ consisting of connected open subsets of $X$.
Def. (3.6.1.19) [Path-Connectedness]. A space $X$ is called path-connected if any two points of $X$ can be connected by an arc.

$X$ is called locally path-connected if there is a basis of $X$ consisting of path-connected open subsets of $X$.

Prop. (3.6.1.20). If $X$ is an ordered set with the least upper bound property and satisfies: for any $x < y \in X$, there exists $z \in X$ s.t. $x < z < y$. Then $X$ is connected, so are intervals and rays in $X$.

Proof: Let $Y$ be an interval or ray in $X$. Suppose for contradiction $Y = A \mathbin{\cup} B$, where $A, B$ are open and non-empty in $Y$. Choose $a \in A, b \in B$, then $[a, b] \subseteq Y$. Let $A_0 = A \cap [a, b]$ and $B_0 = B \cap [a, b]$, and $c = \sup A_0 \in [a, b]$.

Then $c \notin B_0$: If $c \in B_0$, then $c \neq a$, and because $B_0$ is open, there exists some $a \leq d < c$ s.t. $(d, c] \subseteq B_0$. So $d$ is a smaller upper bound for $A_0$, contradiction.

And also $c \notin A_0$: If $c \in A_0$, then $c \neq b$, and because $A_0$ is open, there exists some $c < e \leq b$ s.t. $[c, e) \subseteq A_0$. Then by hypothesis, there exists $z \in (c, e) \subseteq A_0$, contradicting the fact $c$ is an upper bound for $A_0$.

Then we derived a contradiction that $c \notin Y$, which proves $Y$ is connected. \hfill \Box

Def. (3.6.1.21) [Connected Components]. In a topological space $X$, if $x \in X$, the connected component of $x$ is the maximal connected subspace of $X$ containing $x$. The path-connected component of $x$ is the maximal path-connected subspace of $X$ containing $x$.

Prop. (3.6.1.22).

- Any connected component of $X$ is closed.
- If $X$ is locally connected, then any connected component of $X$ is clopen.
- If $X$ is locally path-connected, then any path-connected component of $X$ is open, and any connected component is also open.

Prop. (3.6.1.23) [Clopen Subsets and Connected Components]. Let $X$ be a normal topological space and $x \in X$, then the connected component of $X$ containing $x$ is the intersection of clopen subsets containing $x$, denoted by $A$.

Proof: Assume $A$ splits into two components $B, D$. Since $A$ is closed, $B$ and $D$ are both closed, because $X$ is normal there are disjoint open neighborhoods $U$ and $V$ around $B$ and $D$, respectively. The open sets $U$ and $V$ cover the intersection of all clopen neighborhoods of $A$, so cause $X$ is compact, there must exist a finite number of clopen sets around $A$, say $A_1, \ldots, A_n$ such that $U \cup V$ covers $K = \bigcap_{i=1}^n A_i$.

Note that $K$ is clopen. We can assume that $x \in U$. It is not difficult to see that $K \cap U$ is clopen and does not contain all of $A$, contradicting the definition of $A$. \hfill \Box

Cor. (3.6.1.24). For a compact Hausdorff topological space $X$ and a point $x \in X$, the connected component of $X$ containing $x$ is the intersection of all compact open neighborhoods of $x$, because $X$ is normal (3.6.7.6).

Def. (3.6.1.25) [Totally Disconnected Space]. A space is called totally disconnected iff any connected subset of $X$ contains only one point.

Prop. (3.6.1.26). A subspace of a totally disconnected space is totally disconnected, because totally disconnected is equivalent to the only connected subsets are pt sets.
Extremally Disconnected Space

**Def. (3.6.1.27) [Extremally Disconnected Space].** A topological space $S$ is called **extremally disconnected** if the closure of any open subset of $X$ is open.

**Prop. (3.6.1.28).** Let $X$ be an extremally disconnected space, if $U, V$ are disjoint open subsets of $X$, then $U, V$

*Proof:* Because $V \cap U = \emptyset$, thus similarly $V \cap U = \emptyset$. □

**Lemma (3.6.1.29).** Let $f : X \to Y$ be a continuous surjective map of compact Hausdorff spaces that $Y$ is extremally disconnected and $f(Z) \neq Y$ for any proper closed subspace of $X$, then $f$ is a homeomorphism.

*Proof:* By (3.6.2.11) it suffices to show that $f$ is injective. Suppose $f(x) = f(x') = y$, then choose disjoint nbhd $U, U'$ of $x, x'$, and $T = f(X \setminus U), T' = f(X \setminus U')$ closed in $Y$, then $Y = T \cup T'$ and $y$ is contained in the closure of $Y \setminus T$ and $Y \setminus T'$ by (3.6.1.14), but this contradicts (3.6.1.28). □

**Prop. (3.6.1.30) [Projective Spaces].** Compact Hausdorff extremally disconnected spaces are exactly the projective objects in the category of compact Hausdorff spaces.

*Proof:* Assume $X$ is projective, let $U \subseteq X$ be open, and the complement by $Z$, then consider the surjection $U \coprod Z \to X$, and let $\sigma$ be the projection, then $\sigma(U) \subseteq \mathcal{U}$, thus $\sigma^{-1}(U) = \mathcal{U}$, and it is open.

Conversely, if $X$ is extremally disconnected, then by (3.6.2.13), there is a compact subset $E \subseteq Y$ that $f(E) = X$ and $f(E') \neq X$ for all closed subspace $E' \subseteq E$. Then (3.6.1.29) says $f|_E$ is a homeomorphism, and the inverse of it gives a desired section. □

**Prop. (3.6.1.31) [Gleason].** In an extremally disconnected space $X$, a convergent sequence is eventually constant. In particular, $\mathbb{Z}_p$ is a profinite group that is not extremally disconnected.

*Proof:* Cf.[Projective Topological Spaces] □

## 2 Compactness

**Def. (3.6.2.1) [Quasi-Compact Space].** A topological space is called **compact** or **quasi-compact** iff any open covering of it has a finite sub-covering. A subspace of a topological space is called **precompact** if its closure is compact.

**Def. (3.6.2.2) [Quasi-Compact Morphism].** A map of topological spaces is called a **quasi-compact morphism** if the inverse image of any quasi-compact open subset is quasi-compact open.

**Prop. (3.6.2.3) [Alexander Subbase Theorem].** A topological space is compact iff the closed subsets has the finite intersection property(1.1.8.3). In fact, it suffices to show that the family of complements of a subbasis of open sets has the finite intersection property.

*Proof:* Cf.[Sta]08ZP. □

**Prop. (3.6.2.4).** Let $X$ be a totally ordered set with the least upper bound property, then each closed interval of $X$ is compact in the order topology. In particular, this applies to a complete totally ordered set $X(1.1.3.19)$. 
Proof: Let \( a < b \) and \( \mathcal{U} \) a covering of \([a, b]\). We first show that for any \( x \in [a, b] \), there exists some \( x < y \leq b \) that \([x, y]\) can be covered by at most two elements of \( \mathcal{U} \): If \( x \) has an immediate successor, then take \( y \) to be it. If \( x \) has no immediate successor, choose an element \( U \) of \( \mathcal{U} \) containing \( x \), then \( U \) contains some \([x, c]\). Choose \( y \in [x, c] \), then \([x, y]\) is covered by a single element of \( \mathcal{U} \).

Now let \( C \) be the set of points \( y \in [a, b] \) that \([a, y]\) can be covered by f.m. elements of \( \mathcal{U} \). We showed before this set is non-empty. Let \( c \) be the least upper bound of \( C \), then \( a < c \leq b \).

Next, we show \( c \in C \): take an element \( U \) of \( \mathcal{U} \) containing \( c \), then \( U \) contains some \((d, c]\). There must be some element of \( C \) lying in the interval \((d, c]\), otherwise \( d \) is an upper bound of \( C \). Then \([a, y]\) is covered by f.m. elements of \( \mathcal{U} \), so \( c \in C \).

Finally, we show \( c = b \), but this is because otherwise we can find \( c < y \leq b \) that \([c, y]\) is covered by 2 elements, thus \( y \in C \), so \( y \leq c \), contradiction. \( \square \)

Prop. (3.6.2.5) [Tychonoff]. An arbitrary direct product of compact topological groups is compact.

Proof: We prove the finite intersection property. If \( A \) is a family of subsets that any finite intersection of closure of them is nonempty, then consider a maximal family \( \mathcal{D} \) of subsets containing \( A \) that any finite intersection of closures of them is nonempty, it exists by Zorn’s lemma. Consider the projection of \( \mathcal{D} \) onto a coordinate, then by Hypothesis, it has an intersection \( x_\alpha \). Now we want to show \( x = (x_\alpha) \) belongs to each \( D \in \mathcal{D} \).

If \( U_\beta \) is any subbasis element containing \( x \), then \( U_\beta \) intersect each \( \mathcal{D} \) because \( x_\beta \in \pi_\beta(D) \), so it is in \( \mathcal{D} \), by maximality of \( \mathcal{D} \). So the finite intersections are also in \( \mathcal{D} \), so all local basis of \( x \) are in \( \mathcal{D} \). This means that local basis intersect each element of \( \mathcal{D} \), that is, all closure of elements in \( \mathcal{D} \) contains \( x \).

Def. (3.6.2.6) [Sequentially Compact]. A subset \( A \) in a space \( X \) is called sequentially compact iff any sequence of points in \( A \) has a convergent subsequence in \( X \). It is called self sequentially compact if it is sequentially compact in itself.

Prop. (3.6.2.7). \( f : X \to Y \), \( X \) is compact and \( Y \) is Hausdorff, then for a descending chain \( Y_i \) of closed subsets of \( X \),

\[ f(\bigcap_n Y_n) = \bigcap_n f(Y_n). \]

Proof: The left side is compact, so if \( x \notin f(\bigcap_n Y_n) \), there is a closed subsets \( x \in T \) that \( T \cap f(\bigcap_n Y_n) = 0 \), so \( f^{-1}(T) \bigcap_n Y_n = 0 \), so \( f^{-1}(T) \bigcap_n Y_n = 0 \) for some \( n \), hence \( x \notin f(Y_n) \). \( \square \)

Prop. (3.6.2.8) [Fixed Point Theorem]. If \( X \) is a compact metric space \( M \), \( T \) is a continuous map \( X \to X \) that \( d(x, y) < d(Tx, Ty) \), then \( T \) has a unique fixed point in \( X \).

Proof: The uniqueness is obvious, for the existence, first notice \( T \) is obviously continuous, so consider \( d(x, Tx) \), this is a continuous function on \( M \), so it contains a minimum value, if it not 0, then \( d(Tx, Tx^2) < d(x, Tx) \), which is a contradiction. \( \square \)

Def. (3.6.2.9) [Proper Map]. A proper map is a continuous map s.t. the inverse image of compact subsets are compact.

Prop. (3.6.2.10). If \( X \) is compact and \( Y \) is Hausdorff, then a continuous map \( f : X \to Y \) is proper.

Cor. (3.6.2.11). A continuous bijective map from a compact space to a Hausdorff space is a homeomorphism.
Prop. (3.6.2.12) [Proper Continuous Maps Closed]. Let $f : X \to Y$ be a proper continuous map with $Y$ locally compact Hausdorff, then $f$ is a closed map.

Proof: Let $K \subset X$ closed, and $y \in \overline{f(K)}$. Choose precompact open nbhd $U$ of $y$, then $f^{-1}(U)$ is compact in $X$, so $f(K \cap f^{-1}(U)) = f(K) \cap U$ is compact and thus closed in $Y$. Then $y \in f(K)$, and $f(K)$ is closed.

Lemma (3.6.2.13). Let $f : X \to Y$ be a continuous map of compact Hausdorff spaces, then there exists a smallest closed subset $E$ of $X$ that $f(E) = Y$.

Proof: Use Zorn’s lemma, noticing that the intersection of a chain of possible $E_i$s also maps to $Y$, by the intersection property (3.6.2.3).

Stone-Čech Compactification

Def. (3.6.2.14) [Stone-Čech Compactification]. The Stone-Čech Compactification $\beta$ is defined to be a functor from the category of sets to the category of compact Hausdorff space that is left adjoint to the forgetful functor.

The construction of $\beta(X)$ is as follows: $\beta X =$the set of all ultrafilters on $X$, and the topology is generate by $U_A = \{ F | A \in F \}$ as a basis of clopen subsets. For a map $f : X \to Y$, the map $\beta X \to \beta Y$ is given by $f_*$.

Proof: First $\beta X$ is a compact Hausdorff space: it is compact because if there are sets $A_i$ that any ultrafilter contains at least one of them, then f.m. of them must cover $X$, otherwise $X - A_i$ satisfies the finite intersection property thus is contained in some ultrafilter, by (1.1.8.4) and (1.1.8.5), contradiction. Then by (1.1.8.7) shows that any ultrafilter contains one of them. It is Hausdorff because for any two different ultrafilter, there must be an $A$ that $A \in F_1$ and $X - A \in F_2$. $f_*$ is continuous because $f^{-1}(U_A) = U_{f^{-1}(A)}$.

Now for any map $f : X \to Y$ where $Y$ is a topological space, map an ultrafilter $F$ to the unique limit point of $f_*F$ in $Y$ (existence and uniqueness by (3.6.1.17)). This map is continuous from $\beta X$ to $Y$ because for any open set $V \subset Y$, $U_{f^{-1}(V)}$ is mapped into $V$. And for any $\beta X \to Y$ continuous, consider $X \to Y$ which maps $x$ to the image of the principle ultrafilter $F_x$ in $Y$.

This two map are mutually converses to each other, first for a $f : X \to Y$, $X \to \beta X \to Y$ is $f$ itself, because the pushout of the principle ultrafilter clearly converges to $f(x)$. And for a $\beta X \to Y$, if $F$ doesn’t map to $\lim f_*F$ but mapped to some $t$, then by definition, there is a nbhd $U$ of $t$ that $f^{-1}(U) \not\in F$, but by continuity, there is a $F \in U_B$ mapped into $U$. But then $B \in f^{-1}(U)$, otherwise if $x \in B - f^{-1}(U)$, then $F_x$ is mapped to $U$, contradiction, so $f^{-1}(U)$ containing $B$ is also in $F$, contradiction.

Lemma (3.6.2.15). In fact, the spaces in the image of the Stone-Čech compactification are all profinite spaces.

Proof: As shown before, for any two different ultrafilter, there must be an $A$ that $A \in F_1$ and $X - A \in F_2$, $U_A$ is open and closed.

Prop. (3.6.2.16) [Stone Representation Theorem]. The Stone-Čech compactification $\beta$ gives an equivalent of categories from the category of Boolean algebras to the category of profinite spaces.

Proof: $\beta B$ is a profinite space by lemma (3.6.2.15), and $B$ can be recovered from $\beta B$ as the Boolean algebra of all clopen subsets of $\beta B$, because $\beta B$ is compact. This is an inverse isomorphism because ?.
Prop. (3.6.2.17). The Stone-Čech compactification of a set \( \beta S_0 \) is extremally disconnected.

Proof: We check condition (3.6.1.30): For any surjection \( S' \to \beta S_0 \), we may take a lift \( S_0 \to S \) arbitrarily, then by definition there is a morphism \( \beta S_0 \to S' \) extending this morphism. It is a section by the universal property. \( \square \)

Locally Compact Space

Def. (3.6.2.18) [Locally Compact Space]. A Hausdorff space is called **locally compact** if for any point \( x \), there is a compact subset containing a nbhd of \( x \).

Prop. (3.6.2.19). If \( X \) is Hausdorff, then \( X \) is locally compact iff for any \( x \in X \) and \( x \in U \) open, there exists a precompact nbhd \( V \) that \( x \in V \subset \overline{V} \subset U \).

Proof: One direction is trivial. For the other, for any \( x \in X \) and a nbhd \( U \) of \( x \), let \( U_0 \) be a precompact nbhd of \( x \), then \( U_0 \setminus U \) is closed thus compact and disjoint from \( x \). Because \( X \) is Hausdorff, we can find a nbhd \( V' \) of \( x \) that \( \overline{V'} \) is disjoint from \( U_0 \setminus U \). Now let \( V = V' \cap U_0 \), then \( \overline{V} \subset U_0 \) is closed thus compact, and \( \overline{V} \subset \overline{V'} \cap U_0 \subset U \). \( \square \)

Cor. (3.6.2.20). Open subsets and closed subsets of a locally compact Hausdorff space \( X \) is locally compact Hausdorff.

Proof: If \( A \subset X \) is closed and \( x \in A \), then there exists a precompact nbhd \( U \) of \( x \), then \( A \cap \overline{U} \) is closed in \( U \) thus compact, and contains the nbhd \( U \cap A \) of \( x \), so \( A \) is locally compact.

If \( A \subset X \) is open, \( x \in A \), let \( x \in U \subset A \), and \( U \) open in \( X \), then we can apply (3.6.2.19) to find a precompact nbhd \( V \) that \( x \in V \subset \overline{V} \subset U \), so \( A \) is locally compact. \( \square \)

Prop. (3.6.2.21) [One-Point Compactification]. Let \( X \) be a space, then \( X \) is locally compact Hausdorff iff there exists a compact Hausdorff space \( Y \) containing \( X \) s.t. \( Y \setminus X \) is a single point. Moreover, in this case, \( Y \) is unique up to homeomorphisms, called the **one-point compactification** of \( X \).

Proof: Cf. [Mun00]P183. \( \square \)

Cor. (3.6.2.22). A space \( X \) is homeomorphic to an open subset of a compact open subspace iff it is locally compact Hausdorff, by (3.6.2.21) and (3.6.2.20).

Prop. (3.6.2.23). A locally compact second countable Hausdorff space \( X \) has a countable basis consisting of precompact open subsets. In particular, \( X \) is \( \sigma \)-compact.

Proof: Choose a countable basis \( \{ U_n \} \) of \( X \). For any \( x \in X \) and any nbhd \( U \) of \( x \), there exists a precompact \( U_x \subset U \) containing \( x \) by (3.6.2.19). Then for some \( n(x) \), \( U_{n(x)} \subset U_x \) containing \( x \), so \( U_{n(x)} \) is precompact. Thus the set of \( U_n \) that is precompact forms a countable basis of \( X \). \( \square \)

Prop. (3.6.2.24). If \( f : X \to Y \) is a quotient map and \( Z \) is locally compact, then \( X \times Z \to Y \times Z \) is also a quotient map.

Proof: Consider \( W \) as \( Y \times Z \) in the quotient map topology, then \( X \times Z \to W \) is continuous, which means \( X \to \text{Map}(Z,W) \) is continuous. But then \( Y \to \text{Map}(Z,W) \) is continuous because \( Y \) is a quotient map. Applying (3.6.3.7), we see \( Y \times Z \to W \) is continuous. \( W \to Y \times Z \) is continuous by quotient map hypothesis, so \( Y \times Z \cong W \). \( \square \)
Compactly Generated Spaces

**Def. (3.6.2.25)** [Compactly Generated Spaces]. A **compactly generated space** is a space that is the colimit of its compact Hausdorff subspaces. The category of compactly generated spaces is denoted by \( \mathcal{CG} \).

**Prop. (3.6.2.26).** For \( X \in \mathcal{CG} \) and \( Y \in \text{Top} \), a set-theoretical map \( f : X \to Y \) is continuous iff for any \( K \in \text{Top} \) compact Hausdorff and a map \( i : K \to X \), the composite map \( K \to Y \) is continuous.

**Prop. (3.6.2.27)** [Compact Generating Functor]. There is a compact generating functor \( (-)_c : \text{Top} \to \mathcal{CG} \) right adjoint to the inclusion functor.

**Proof:** \( k \) is constructed by \( X \mapsto \lim_{\longrightarrow K \subset X, K \text{ compact}} K \). Notice \( X_c = X \) set-theoretically. It is easy to verify that if \( Y \in \mathcal{CG} \) and \( Y \to X \) is continuous, then the set-theoretical map \( Y \to X_c \) is also continuous. So \( (-)_c \) is right adjoint to the inclusion functor. \( \square \)

**Cor. (3.6.2.28).** \( \mathcal{CG} \) is both complete and cocomplete, and the colimits coincide with colimits in \( \text{Top} \).

**Cor. (3.6.2.29).** \( \mathcal{CG} \) is Cartesian closed (3.1.4.7).

**Cor. (3.6.2.30).** The right adjoint to the Cartesian product is the compactification of the mapping space functor (3.6.3.1), by (3.6.3.6) and (3.6.2.27).

**Prop. (3.6.2.31).** Locally compact Hausdorff topological spaces are compactly generated.

**Proof:** For \( X \in \text{Top} \), if \( Z \subset X \) satisfies \( Z \cap K \) is closed for any compact Hausdorff subset \( K \subset X \), for any \( x \in X \), there exists a precompact nbhd \( U \) of \( x \) in \( X \), so \( Z \cap U \) is closed, and \( Z \cap U \) is closed in \( U \). Thus \( Z \) is closed in \( X \). \( \square \)

**Prop. (3.6.2.32).** Quotients and closed subspaces of a compactly generated space are compactly generated. Colimits of compactly generated spaces are compactly generated.

**Proof:** These follow from (3.6.2.25). \( \square \)

**Prop. (3.6.2.33).** If \( X \in \mathcal{CG} \) and \( Y \) is locally compact Hausdorff, then \( X \times Y \in \mathcal{CG} \).

**Proof:** Notice by (3.6.3.7), a map \( X \times Y \to Z \) is continuous iff \( C \times Y \to Z \) is continuous for any compact Hausdorff subset \( C \subset X \). The assertion is equivalent to \( X \times Y \to (X \times Y)_c \) is continuous, which is then equivalent to \( C \times Y \to (X \times Y)_c \) continuous for any compact subset \( C \subset X \). But \( Y \) is compactly generated, and \( C \) is locally compact, thus it suffices to show \( C \times C' \to (X \times Y)_c \) is continuous for any compact subset \( C' \subset Y \). Then this is true because \( C \times C' \) is compact. \( \square \)

### 3 Mapping Spaces

**Compact-Open Topology on Mapping Spaces**

**Def. (3.6.3.1)** [Compact-Open Topology]. The **compact-open topology** on a function space \( \text{Map}(X,Y) \) is a topology generated by the sets \( (K,U) = \{ f : f(K) \subset U \} \), where \( K \) is compact in \( X \) and \( U \) is open in \( Y \).

**Prop. (3.6.3.2).** For \( X' \to X, Y \to Y' \in \text{Top} \), the induced map \( \text{Map}(X,Y) \to \text{Map}(X',Y') \) is continuous. In particular, if \( X \cong X' \) and \( Y \cong Y' \), then \( \text{Map}(X,Y) \cong \text{Map}(X',Y') \).
Prop. (3.6.3.3). If \( Y \) is compact and \( X \) a metric space, this the compact open topology on \( \text{Map}(Y, X) \) coincides with the uniform topology on functions.

Proof: If \( f \in (K, U) \), then \( f(K) \subset U \), then there is a \( \varepsilon > 0 \) that \( B(K, \varepsilon) \subset U \), thus \( B(f, \varepsilon) \subset (K, U) \).

For any \( f \in \text{Map}(Y, X) \), \( f(Y) \) is compact thus there are f.m. open balls \( B(f(y_i), \frac{\varepsilon}{2}) \) that covers \( f(Y) \). Now if \( K_i = f^{-1}(B(f(y_i), \frac{\varepsilon}{2})) \), then \( \bigcup K_i = Y \), and \( f \in \cap_i(K_i, B(f(y_i), \frac{\varepsilon}{2})) \). Also \( \cap_i(K_i, B(f(y_i), \frac{\varepsilon}{2})) \subset B(f, \varepsilon) \), because for any \( g \in \cap_i(K_i, B(f(y_i), \frac{\varepsilon}{2})) \) and \( y \in K_i \), \( |f(y) - g(y)| \leq |f(y) - f(y_i)| + |f(y_i) - g(y_i)| < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon \). \( \square \)

Def. (3.6.3.4) [Relative Maps]. Let \( A \subset X \) and \( B \subset Y \), we denote by \( \text{Map}((X, A), (Y, B)) \) the subspace of \( \text{Map}(X, Y) \) consisting of continuous functions \( f : X \to Y \) that map \( A \) into \( B \).

Prop. (3.6.3.5) [Composition is Continuous]. If \( Y \) is locally compact Hausdorff, then the composition map

\[
\text{Map}(Y, Z) \times \text{Map}(X, Y) \to \text{Map}(X, Z)
\]

is continuous.

Proof: For any compact \( K \subset X \), open \( U \subset Y \) and \( g \circ f \in (K, U) \), \( f(K) \subset g^{-1}(U) \subset Y \). Because \( Y \) is locally compact, there is an precompact open subset \( V \) that \( f(K) \subset V \subset \overline{V} \subset g^{-1}(U) \), then \( (\overline{V}, U) \times (K, V) \) maps into \( (K, U) \). \( \square \)

Lemma (3.6.3.6) [Subbasis]. Let \( X \) be Hausdorff, \( W_\alpha \) be a subbasis of \( Y \), then \( (K, W_\alpha) \) where \( K \subset X \) compact is a subbasis of \( \text{Map}(X, Y) \).

Proof: If \( f \in (K, U) \subset \text{Map}(X, Y) \), let \( U = \bigcup_\beta U_\beta \), where \( U_\beta = \bigcap_{j=1}^{k(\beta)} W_{\beta,j} \). Now \( K \subset \bigcup_\beta f^{-1}(U_\beta) \), because \( K \) is compact Hausdorff thus the partition of unity(3.6.7.9) gives us f.m. compact subsets \( K_1, \ldots, K_n \) of \( K \) that \( K_i \subset f^{-1}(\overline{U_\beta}) \) for some \( \beta \). Then

\[
f \in \bigcap_{i=1}^n \bigcap_{j=1}^{k(\beta)} (K_i, W_{\beta,i,j}) = \bigcap_{i=1}^n (K_i, U_{\beta,i}) \subset (K, \bigcup_{i=1}^n U_{\beta,i}) \subset (K, U).
\]

\( \square \)

Prop. (3.6.3.7) [Adjoints of Mapping Space]. Let \( Y \) be a locally compact Hausdorff space, then

\[
\text{Map}(X \times Y, Z) \cong \text{Map}(X, \text{Map}(Y, Z))
\]

as sets. And if moreover \( X \) is Hausdorff, then it is a homeomorphism.

Proof: Let \( \varphi \in \text{Map}(X \times Y, Z) \), for any \( x \in X \), take \( \varphi(x) : Y \to Z : \varphi(x)(y) = \varphi(x, y) \), then \( \varphi(x) \) is continuous, and \( \varphi : X \mapsto \text{Map}(Y, Z) : x \mapsto \varphi(x) \) is continuous: for any compact \( K \subset Y \) and open \( U \subset Z \), \( \varphi^{-1}(K, U) = \{ x \in X | \varphi(x, K) \subset U \} \), which is open.

Conversely, for any \( \psi : X \to \text{Map}(Y, Z) \), let \( \tilde{\psi} : X \times Y \to Z \) be given by \( \tilde{\psi}(x, y) = \psi(x)(y) \). Then \( \tilde{\psi} \) is continuous: For any open \( U \subset Z \), if \( (x, y) \in \tilde{\psi}^{-1}(U) \), then \( \psi(x)y \subset U \). Because \( \psi(x) \) is continuous, there is a nbhd \( W \) of \( y \in Y \) that \( \varphi(x)(W) \subset U \). Then because \( Y \) is locally compact Hausdorff, there is a precompact nbhd \( V \) of \( y \in Y \) that \( y \in V \subset \overline{V} \subset W \). Then \( \psi^{-1}((\overline{V}, U)) \) is a nbhd of \( x \in X \), and \( (x, y) \in (\psi^{-1}((\overline{V}, U)), V) \subset \tilde{\psi}^{-1}(U) \), thus \( \tilde{\psi}^{-1}(U) \) is open, and \( \tilde{\psi} \) is continuous.
Now let $F : \varphi \mapsto \bar{\varphi}$ and $G : \psi \mapsto \bar{\psi}$, then we show $F,G$ are both continuous: By (3.6.3.6), $(K,(L,U))$ is a subbasis of $\text{Map}(X,\text{Map}(Y,Z))$. $F$ is continuous because $F((K \times L,U)) = (K,(L,U))$. $G$ is continuous because $X \times Y$ is Hausdorff and for any $J$ compact in $X \times Y$, $J \times J \xrightarrow{(pr_1,pr_2)} X \times Y$ is continuous, so for any $U \subset Z$ open, there exists $J_1 \subset X, J_2 \subset Y$ compact s.t. $G((J_1,(J_2,U))) \subset (J,U)$. \hfill $\square$

**Cor. (3.6.3.8).** If $Y$ is locally compact and Hausdorff, $A \subset X, B \subset Y, C \subset Z$, then

$$\text{Map}((X \times Y, X \times B \cup A \times Y),(Z,C)) \equiv \text{Map}((X,A),\text{Map}((Y,B),(Z,C)))$$

as sets, and if moreover $X$ is Hausdorff, then it is a homeomorphism.

**Def. (3.6.3.9)[Admissible Topology].** For $X,Y \in \text{Top}$, an admissible topology on $\text{Map}(X,Y)$ is a topology that makes the evaluation map $e : \text{Map}(X,Y) \times X \to Y$ continuous.

**Prop. (3.6.3.10).** The compact-open topology on $\text{Map}(X,Y)$ is coarser than admissible topology on it (3.6.3.9). And if $X$ is locally compact Hausdorff, then it is admissible.

**Proof:** It suffices to show any $(K,U)$ is open in $\text{Map}(X,Y)$. Let $f \in (K,U)$, then for any $x \in K$, $e(f,x) \in U$, thus there is a nbhd $U_x$ of $f$ and a nbhd $W_x$ of $x$ that $e(U_x \times W_x) \subset U$. Now because $K$ is compact, we can choose a nbhd $V$ of $f$ that $e(V \times K) \subset U$. Thus $f \in V \subset (K,U)$, and $(K,U)$ is open in $\text{Map}(X,Y)$. If $Y$ is locally compact Hausdorff, then $\text{Map}(Y,Z) \times X \to Z$ continuous by applying (3.6.3.5) with $X = \text{pt}$. \hfill $\square$

**Mapping Spaces in $\mathcal{C}^G$**

**Def. (3.6.3.11)[Mapping Spaces].** For $X,Y \in \mathcal{C}^G$, the mapping space $\text{Map}_c(X,Y)$ is the compact generation (3.6.2.27) of the space of continuous functions from $X$ to $Y$ with the topology generated by the sets $(K,U) = \{ f : f(i(K)) \subset U \}$, where $K$ is a compact Hausdorff space, $i : K \to X$ and $U$ is open in $Y$.

**Prop. (3.6.3.12).** For $X' \to X, Y \to Y' \in \mathcal{C}^G$, the induced map $\text{Map}_c(X,Y) \to \text{Map}_c(X',Y')$ is continuous. In particular, if $X \cong X'$ and $Y \cong Y'$, then $\text{Map}_c(X,Y) \cong \text{Map}_c(X',Y')$.

**Lemma (3.6.3.13)[Evaluations are Continuous].** For $X,Y \in \mathcal{C}^G$, the composition map

$$\text{Map}_c(Y,X) \times_c Y \to X$$

is continuous.

**Proof:** It suffices to prove that for any compact Hausdorff space $K, F$ mapping into $\text{Map}(Y,X), Y, K \times F \to X$ is continuous: For $(f_0,y) \in \text{Map}_c(Y,X) \times_c Y$ and $f_0(y) \in U$, as $f_0$ is continuous, there exists a nbhd $N$ of $y \in Y$ s.t. $f_0(N \cap F) \subset U$, and then $(f_0,y) \in (K \cap (N \cap F), N \cap F)$ is mapped into $U$. \hfill $\square$

**Prop. (3.6.3.14)[Adjointness of Mapping Space].** For $X,Y,Z \in \mathcal{C}^G$, there is a natural homeomorphism

$$\text{Map}_c(X \times_c Y,Z) \cong \text{Map}_c(X,\text{Map}_c(Y,Z))$$
Proof: Let \( \varphi \in \text{Map}_c(X \times_c Y, Z) \), for any \( x \in X \), take \( \varphi(x) : Y \to Z : \varphi(x)(y) = \varphi(x, y) \), then \( \varphi(x) \) is continuous, and \( \tilde{\varphi} : X \to \text{Map}(Y, Z) : x \mapsto \varphi(x) \) is continuous: if \( \varphi(x) \in (K, U) \), \( \tilde{\varphi}^{-1}(K, U) = \{ x \in X | \varphi(x \times i(K)) \subset U \} \), which is open.

To prove this construction is continuous, notice we have already seen that if \( f : X \times_c Y \to Z \) is continuous then \( f : Y \to \text{Map}_c(Y, Z) \) is continuous. Apply this to

\[
\text{Map}_c(Y \times_c X, Z) \times_c Y \times_c X \to Z
\]

we see that

\[
X \times_c \text{Map}_c(Y \times_c X, Z) \to \text{Map}_c(Y, Z)
\]

is continuous, and

\[
\text{Map}_c(Y \times_c X, Z) \to \text{Map}_c(X, \text{Map}_c(Y, Z))
\]

is continuous. Similarly, as

\[
\text{Map}_c(X, \text{Map}_c(X, Z)) \times_c Y \times_c X \to Z
\]

is continuous, we get

\[
\text{Map}_c(X, \text{Map}_c(Y, Z)) \to \text{Map}_c(X \times_c Y, Z)
\]

is continuous, and it is clearly the inverse to the construction above. \( \square \)

Cor. (3.6.3.15). For \( X, Y, Z \in \mathcal{C} \), \( A \subset X, B \subset Y, C \subset Z \), then there is a natural homeomorphism

\[
\text{Map}((X \times Y, X \times B \cup A \times Y), (Z, C)) \cong \text{Map}((X, A), \text{Map}((Y, B), (Z, C)))
\]

Cor. (3.6.3.16). Products in \( \mathcal{C} \) commute with colimits.

Cor. (3.6.3.17)[Compositions are Continuous]. For \( X, Y, Z \in \mathcal{C} \), the composition map

\[
\text{Map}_c(Y, Z) \times_c \text{Map}_c(X, Y) \to \text{Map}_c(X, Z)
\]

is continuous.

Proof: It suffices to show that

\[
\text{Map}_c(Y, Z) \times_c \text{Map}_c(X, Y) \times_c X \to Z
\]

is continuous, and this follows from (3.6.3.13). \( \square \)

Construction of Spaces

Def. (3.6.3.18)[Path Spaces]. For \( f : A \to B \in \text{Top} \), let \( E_f \) be the subspace of \( A \times \text{Map}(I, B) \) consisting of pairs \( (a, \gamma) \) that \( \gamma(0) = a \).

The fibers of \( E_f \to B \) are called homotopy fibers of \( f \).

Def. (3.6.3.19)[n-Loop Space]. The \( n \)-loop space of \( X \) is defined to be \( \Omega^n(X, x_0) = M(I^n, \partial I^n; X, x_0) \). Then by (3.6.3.8) we have

\[
\Omega(\Omega^n(X, x_0), \bar{x}_0) \cong \Omega^{n+1}(X, x_0).
\]

Prop. (3.6.3.20)[Loop spaces are Homotopy Fibers]. Let \( f : x_0 \to B \) be a point, then \( E_f \) is the path space \( PB \) of all paths starting from \( x_0 \), and the homotopy fiber over \( x_0 \) is just the loop space \( \Omega(X, x_0) \). \( PB \) is contractible, with the contraction given by \( H : PB \times I \to PB : \gamma_t(x) = \gamma(tx) \).
4 Profinite Space

Def. (3.6.4.1) [Profinite Space]. A space is called a **profinite space** if it is a cofiltered limit of discrete topological spaces. The category of profinite spaces is denoted by $\mathcal{P}rof$.

A profinite space is the same thing as a totally disconnected, compact Hausdorff topological space. Thus a closed subspace of a profinite space is profinite.

Proof: The profinite spaces are clearly totally disconnected, compact Hausdorff (by Tychonoff).

Conversely, if it is totally disconnected and compact Hausdorff, let $I$ be the set of clopen decompositions $X = \bigsqcup_i U_i$ of $X$, then for each $I \subset I$, there is a map $X \to I$, and there is a partial order on the decompositions of $X$. We show that the map $X \to \varinjlim_{I \subset I} I$ is a homeomorphism. It is injective by (3.6.1.25)(3.6.1.23)(3.6.7.6). It is surjective by compactness of $X$, and it is clearly open, thus homeomorphism by (3.6.2.11).

Cor. (3.6.4.2). A cofiltered limit of profinite spaces is profinite.

Prop. (3.6.4.3). Any open covering of a profinite space has a clopen disjoint subcover.

Proof: By (3.6.4.1), we may assume that $X = \varinjlim_{i \in I} X_i$, where $X_i$ is finite. Let $f_i$ be the projection, as the limit is filtered, a fundamental family of nbhds of a point $(x_i) f_i^{-1}(x_i)$, Then for each covering, we may assume it is finite $X = \bigcup_i f_i^{-1}(x_i)$, choose a $j > i$ for each $i$, as $I$ is cofiltered, then $X = \bigsqcup_{x \in X_j} f_j^{-1}(x)$ satisfies the desired property.

Prop. (3.6.4.4). If $X$ is quasi-compact and any connected component of $X$ is the intersection of clopen sets containing it (e.g. $X$ is normal (3.6.1.23)), then $\pi_0(X)$ is a profinite space.

Proof: $\pi_0(X)$ is an image of $X$, so it is quasi-compact, also it is clearly totally disconnected. To show it is Hausdorff, let $C, D$ be disjoint connected components of $X$, then $C = \cap U_\alpha$, where $U_\alpha$ are clopen. Since $C \cap D = \emptyset$, $U_\alpha \cap D = \emptyset$ for some $\alpha$. and then the image of $U_\alpha$ separates $C$ and $D$ in $\pi_0(X)$.

Locally Profinite Space

Def. (3.6.4.5) [Locally Profinite Space]. A space is called **locally profinite** iff it is a totally disconnected, locally compact Hausdorff topological space.

Prop. (3.6.4.6). A locally closed subsets of a locally profinite space is locally profinite. And compact subsets are profinite.

Proof: Closed subsets are clearly locally profinite, for the open subsets, it is also locally compact.

Cor. (3.6.4.7). Any open covering of a compact subsets of a locally profinite space has an clopen disjoint subcover, by (3.6.4.3).

Prop. (3.6.4.8). The set of all compact open subsets form a basis of the topology of $G$.

Prop. (3.6.4.9). If $X$ is locally profinite and $K$ is a compact subspace of $X$. Let $K \subset \cup U_\alpha$ be an open covering, then there exist f.m. disjoint open compact subsets $V_i \subset X$ that each $V_i \cap K \subset U_\alpha$ for some $\alpha$, and $K \subset \cup V_i$.

Proof: Because $K$ is profinite (3.6.4.6), (3.6.4.3) shows there is a finite disjoint compact open subcover $W_i$ of $U_\alpha$, then $W_i = V_i \cap K$ for $V_i$ compact, and using compactness of $W_i$, we can assume $V_i$ is compact. Finally to make $V_i$ disjoint, we can let $V_i = V_i \setminus (\cup_{k=1}^{i-1} V_k)$.  \(\square\)
5 Real Numbers

References are [H-J99]Chap10 and [Mun00].

Topology

Prop. (3.6.5.1) [\( \mathbb{R} \) is Connected]. \( \mathbb{R} \) is connected, and so are intervals and rays in \( \mathbb{R} \).

Proof: This follows from (3.6.1.20), as the hypothesis is satisfied by \( \forall \)nd the fact for any \( a < b \in \mathbb{R}, a < \frac{a+b}{2} < b \).

Prop. (3.6.5.2). \( \mathbb{R}^n \) satisfies the Heine-Borel property (10.6.1.7), i.e. bounded closed sets are compact.

Proof: It suffices to consider the square metric. If \( A \) is bounded, then \( A \) is in \( [-N, N]^n \) for some number \( N \). \([-N, N]^n \) is compact by (3.6.2.4) and (3.6.2.5).

Borel Set

Def. (3.6.5.3). Let \( U \) be an ultrafilter on a set \( I \) and \( \{a_I\} \) be a bounded sequence of real numbers. Then a number \( a \) is called the \( U \)-limit of \( \{a_I\} \) is for every \( \varepsilon > 0, \{i \in I| |a_i - a| < \varepsilon \} \in U \).

There is at most one limit, because \( \{i \in I| |a_i - a| < \varepsilon \}, \{i \in I| |a_i - b| < \varepsilon \} \) will be disjoint hence cannot both be in \( U \).

Prop. (3.6.5.4) [Generalized Limit]. Let \( U \) be an ultrafilter on \( \mathbb{N} \), then for any bounded sequence of real numbers \( \{a_n\} \), \( \lim_U a_n \) exists. i.e. There is a functional from \( l^\infty \) to \( \mathbb{R} \).

And if \( \{a_n\} \) has a limit pt \( a \) in the usual sense, then \( \lim_U a_n = a \) for any non-principal ultrafilter \( U \), because any \( \{i \in I| |a_i - a| < \varepsilon \} \) is cofinite hence in \( U \) (1.1.8.9).

Proof: Let \( A_x = \{n|a_n < x\} \). Then \( A_x \) is monotone, then we can choose \( c = \sup\{x|A_x \notin U\}\) (1.1.3.19). And it is easily verified that \( c = \lim_U a_n \). □

Cor. (3.6.5.5) [Density Measure]. There exists a measure \( m \) on \( \mathbb{N} \) that \( m(A) = d(A) \) for each set \( A \subset \mathbb{N} \) that has a density \( d(A) \).

Proof: Let \( U \) be a non-principal ultrafilter on \( \mathbb{N} \), let \( m(A) = \lim_U \frac{A(n)}{n} \). It is clearly additive and monotone. And it equals the density by (3.6.5.4) □

6 Separation Axioms

Prop. (3.6.6.1). Any Quasi-compact \( T_0 \) space \( X \) contains a closed point.

Proof: Consider the family of non-empty closed subsets of \( X \), there is a minimal element by quasi-compactness. Choose a minimal element \( T \), and let \( x \in T \), then \( \{x\} = T \). Then \( x \) is closed, otherwise there is some \( x' \neq x \in \{x\} \), and \( \{x'\} \neq \{x\} \) because \( X \) is \( T_0 \). □

Hausdorff

Hausdorffization

Cf. [the Hausdorff Quotient].
Regular

Completely Regular

Normal (T4)

Prop. (3.6.6.2) [Urysohn lemma]. Let $X$ be normal, $A$ and $B$ two closed subset of $X$, then there exists a continuous map from $X$ to $[0, 1]$ that maps $A$ to 0 and $B$ to 1.

Proof: Use the countability of rational numbers to construct a family of $U_q$ s.t. $p < q \Rightarrow \overline{U}_p \subset U_q$. Then choose $f(x) = \inf\{p \in \mathbb{Q} | x \in U_p\}$, then this $f$ meets the requirement. \hfill \Box

Cor. (3.6.6.3) [Tietze extension]. If $X$ is normal and $Y$ is a closed subspace, then any continuous function $f$ on $Y$ can be extended to a continuous function on $X$.

Proof: \hfill \Box

7 Paracompactness

Def. (3.6.7.1) [Paracompactness]. A space $X$ is called paracompact if any open covering $U$ has a locally finite open refinement covering.

Prop. (3.6.7.2) [Characterization of Paracompactness]. If $X$ is regular, then TFAE:

1. Each open cover of $X$ has an open locally finite refinement.
2. Each open cover of $X$ has a locally finite refinement.
3. Each open cover of $X$ has a closed locally finite refinement.
4. Each open cover of $X$ is even. i.e. for any cover, there is an open nbhd $V$ of diagonal of $X \times X$ such that $\forall x, V[x] = \{y | (x, y) \in V\}$ refines the cover.
5. Each open cover of $X$ has an open $\sigma$-discrete refinement.

If this is satisfied, then $X$ is called paracompact.

Proof: $6 \rightarrow 2$: Just minus every open set the part of open sets that appeared in families that ordered before it. $2 + 4 \rightarrow 1$: Use the lemma below, we can transform the cover $A$ into $V[A] \cap U_A$ which is an open locally finite cover. Cf. [General Topology Kelley] and [Mun00]P254. \hfill \Box

Lemma (3.6.7.3). If $X$ satisfies 4, let $U$ be a nbhd of diagonal of $X \times X$, then their exists a symmetric nbhd of diagonal s.t. $V \circ V \subset U$, where $U \circ V = \{(x, z) | (x, y) \in U, (y, z) \in V, \exists y\}$.

Proof: $\forall x$ in $X$, there is a nbhd s.t. $W[x] \times W[x] \subset U$, this is an open cover, so there is a nbhd $R$ of diagonal s.t. $R[x]$ refines it. Hense $R[x] \times R[x] \subset U$. Let $V = R \cap R^{-1}$, $V \circ V$ is the union of sets $V[x] \times V[x]$, so $V \circ V \subset U$. \hfill \Box

Lemma (3.6.7.4). In the preceding proposition, if $X$ satisfies 4, Let $A$ be a locally finite(resp. discrete i.e. intersect only one) family of subsets of $X$, then use the last lemma, there is a nbhd $V$ of diagonal of $X \times X$ such that $V[A] = \{y | (x, y) \in V, \exists x \in A\}$ is locally finite(resp. discrete).
Prop. (3.6.7.5). A locally compact second countable Hausdorff space $X$ is paracompact.

Proof: Let $U$ be a covering of $X$, because $X$ is second countable and locally compact, by (3.6.2.23), we may assume $U$ is a countable covering and consisting of precompact subsets. Moreover, we can change $U_n$ to $U'_n = \bigcup_{i=1}^n U_i$, because if \{$B_\alpha$\} is a locally finite refinement of \{${\cup}_{i=1}^n U_i$\}, then \{$B_\alpha \cap U_n$\} is a locally finite refinement of \{${U}_i$\}. So $U_n \subset U_{n+1}$, and because $U_n$ is compact, we may assume $U_n \subset U_{n+1}$.

Now let $K_n = U_{n+1} \setminus U_n$ (where $U_0 = \emptyset$), then $K_n$ are all compact, and $W_n = U_{n+1} \setminus U_{n-2}$ is an open subset containing $K_n$. So there are f.m. open subsets of $W_n$ that cover $K_n$. There open subsets is then a refinement covering of $U$, and they are locally finite, because any $x \in X$ is contained in $U_n$ for some $n$.

Prop. (3.6.7.6) [Paracompact Spaces are Normal]. A Hausdorff paracompact space $X$ is normal. In particular, a compact Hausdorff space is normal.

Proof: Firstly $X$ is regular: Let $x \in X$ and $B$ a closed subset disjoint from $x$, then because $X$ is Hausdorff, there is a covering of $B$ by open subsets $V_\alpha$ that $x \not\in V_\alpha$. Now consider the open covering \{$X \setminus B, V_\alpha$\} of $X$, then there is a locally finite refinement \{\{$B_\beta$\}\}. Those $B_\beta$ that intersect $B$ is then a locally finite cover of $B$. Let $U$ be the union of these open subsets, then $B \subset U$ and $x \not\in U$, because of the locally finiteness.

To prove $X$ is normal, we do the same but $x$ replaced by a closed subset disjoint from $B$ and use regularity.

Prop. (3.6.7.7) [Paracompactness for Manifolds]. For a connected Hausdorff locally Euclidian space, the condition of paracompact, second countable and a compact exhaustion is equivalent.

Proof: Cf. [Paracompactness and second countable].

Lemma (3.6.7.8) [Shrinking Lemma]. Let $X$ be a paracompact Hausdorff space and \{$U_\alpha$\}$_{\alpha \in I}$ an open covering of $X$, then there is an open covering \{$V_\alpha$\} of $X$ that $V_\alpha \subset U_\alpha$ for any $\alpha$.

Proof: Let $A$ be the family of open subsets $A$ of $X$ that $\overline{A} \subset U_\alpha$ for some $\alpha$, then because $X$ is normal (3.6.7.6), $A$ is a covering of $X$. Then we find a locally finite open covering $\mathcal{B}$ of $A$, and let the covering map be $B_\beta \subset U_{f(\beta)}$, then we can get a covering $V$ of $X$ indexed by $I$ that $V_\alpha = \bigcup_{f(\beta) = \alpha} B_\beta$. This is also locally finite, and $V_\alpha \subset U_\alpha$ by the locally finiteness of $B$.

Prop. (3.6.7.9) [Partition of unity]. In a paracompact Hausdorff space, given any open cover \{$U_\alpha$\}, there exists a partition of unity \{$\rho_\alpha$\} that $\text{supp} \rho_\alpha \subset U_\alpha$, and \{$\text{Supp}(\rho_\alpha)$\} is locally finite. Moreover, if $X$ is locally compact, we can assume

Proof: Using shrinking lemma (3.6.7.8) twice, we can find locally finite open coverings \{$W_\alpha$\}, \{$V_\alpha$\} that $W_\alpha \subset V_\alpha$, $V_\alpha \subset U_\alpha$. Because $X$ is normal, we can find functions $\psi_\alpha$ on $X$ that $\psi(W_\alpha) = 1$, $\psi_\alpha(x) \leq 0$. Then $\text{Supp}(\psi) \subset V_\alpha \subset U_\alpha$, so \{$\text{Supp}(\psi_\alpha)$\} is locally finite. So we can define $\Phi(x) = \sum_\alpha \psi_\alpha(x)$. $\Phi(x) > 0$ for any $x$ because \{$W_\alpha$\} is a covering of $X$. Finally, we define $\rho_\alpha = \psi_\alpha / \Phi$, then this is a partition of unity dominated by \{$U_\alpha$\}. 

$\Box$
8 Metric Space

Def.(3.6.8.1)[Metric Balls]. Let $X$ be a metric space and $x \in X, \delta \in \mathbb{R}_+$, define the metric balls

$$U(x, \delta) = \{y \in X : d(x, y) < \delta\}, \quad D(x, \delta) = \{y \in X : d(x, y) \leq \delta\}.$$

Prop.(3.6.8.2)[Metric Spaces are Paracompact]. Any metric space is paracompact.

Proof: Cf.[Mun00]P257.

Complete Metric Space

Def.(3.6.8.3). A set $E$ in a metric space is called **totally bounded** iff for every $\varepsilon > 0$, there exists a finite set $F$ that $E \subset B(F, \varepsilon)$. This definition is compatible with that in the case of a topological vector space when it is metrizable.

Prop.(3.6.8.4). The closure of a totally bounded set in a metric space is totally bounded.

Proof: For each $\varepsilon > 0$, choose a finite set $F$ that $E \subset B(F, \varepsilon/2)$, then $\overline{E} \subset B(F, \varepsilon)$.

Prop.(3.6.8.5). A totally bounded metric space $X$ is separable.

Proof: $\bigcup N_n$ is dense and countable in $X$, where $N_n$ is a finite $1/n$-net of $X$.

Prop.(3.6.8.6)[Hausdorff]. Let $X$ be a metric space, then:

1. A sequentially compact subset $M$ is totally bounded and the converse is true if $X$ is complete.
2. A subset $M$ is compact iff it is self-sequentially compact iff it is closed and sequentially compact.
3. $M$ is precompact iff it is sequentially compact.

Proof:

1. If $M$ is not totally bounded, then for some $\varepsilon > 0$, we can choose consecutively a sequence of points $x_i$ that $d(x_i, x_j) \geq \varepsilon$, this cannot has a convergent subsequence in $X$.

Conversely, if $M$ is totally bounded, choose a $1/k$-net for each $k$, then for any sequence in $M$, there is a $y_i$ that some infinite subsequence $\{x^{(1)}_n\} \subset B(y_1, 1)$, and consecutively find infinite subsequences $\{x^{(m)}_n\} \subset B(y_k, 1/k)$, then finally choose the diagonal, then it is a Cauchy sequence.

2. If it is compact, given a sequence, if no point is a convergent point, then each point has a nbhd that contains at most one point of the sequence. Then by compactness, there are at most f.m. points, contradiction. A compact set must has the convergent point in itself because it is closed as $M$ is Hausdorff.

Conversely, if it is self-sequentially compact, then it is totally bounded by 1. so if $M$ is not compact, then for each $n$ it has $1/n$-net $N_n$, then there is at least one $x_n$ that $B(x_n, 1/n)$ cannot by covered by f.m. of the covering, The sequence $\{x_n\}$ has a subsequence $\{x_{n_k}\}$ that is convergent to $x$. But $x \in M$ is in some open cover, so $B(x_{n_k}, 1/n_k)$ is contained in some open cover, contradiction.

That closed and sequentially compact is equivalent to self sequentially compact is obvious.
3. If it is precompact, then it is sequentially compact by 2, conversely, if \( x_i \) is a sequence in \( M \), then choose \( |y_n - x_n| \leq 1/n \), so some sequence \( y_{n_k} \) is convergent to \( y_0 \in M \), so \( x_{n_k} \) also converges to \( y_0 \). So \( M \) is self-sequentially compact, so it is compact by 2.

\[ \square \]

**Cor. (3.6.8.7) [Arzela-Ascoli].** For \( M \) compact Hausdorff, \( F \subset C(M) \) is a sequentially compact (precompact, by (3.6.8.6)) subset iff it is uniformly bounded and equicontinuous.

**Proof:** As \( C(M) \) is complete metric space, sequentially compact is equivalent to totally bounded. If it is totally bounded, then it is clearly uniformly bounded, and for every \( \varepsilon > 0 \), find a \( \varepsilon/3 \)-net for \( F \), which means f.m. functions in \( F \) that any other function is \( \varepsilon/3 \)-close to one of them. So they are equicontinuous.

Conversely, if it is uniformly bounded and equicontinuous, for every \( \varepsilon > 0 \), find a finite covering of \( M \) that for any two points \( x, y \) in one cover of them, \( |f(x) - f(y)| < \varepsilon/3 \) for all \( f \in F \). Then choose for each covering a point \( x_i \), consider \( f : F \to \mathbb{C}^n : \varphi \mapsto (\varphi(x_1), \ldots, \varphi(x_n)) \), then the image is bounded, hence precompact by (3.6.5.2), so it is totally bounded by (3.6.8.6). So we can choose an \( \varepsilon/3 \)-net \( \varphi_k \) for \( x_i \) simultaneously, and it is by \( \varepsilon/3 \) argument that these \( \varphi_k \) is a \( \varepsilon \)-net for \( F \). \( \square \)

**Prop. (3.6.8.8) [Fixed point theorem].** If \( X \) is a complete metric space and \( f : X \to X \) satisfies \( d(f(x), f(y)) \leq \lambda d(x, y) \) for some \( 0 \leq \lambda < 1 \), then \( f \) has a unique fixed point in \( X \). If \( X \) is moreover compact, then and \( f \) that \( d(f(x), f(y)) < d(x, y) \) will have a unique fixed point.

**Proof:** \( x + f(x) + f^2(x) + \cdots \) is the fixed point. And uniqueness is easy. For compact case, notice the image \( \text{Im } f^n \) is a descending chain, it must stable to some \( T \). If \( x, y \in Y \) attains the diameter of \( Y \), and let \( x = f(X), y = f(Y) \), where \( X, Y \in T \), then \( d(x, y) < d(X, Y) \leq d(x, y) \), contradiction. \( \square \)

**Prop. (3.6.8.9) [Dilation Closed].** If \( X, Y \) are metric spaces that \( X \) is complete metric space, then if \( f : X \to Y \) is continuous function that is a dilation, i.e. \( d(f(x_1), f(x_2)) \geq d(x_1, x_2) \), then \( f(X) \) is closed.

So a continuous dilation map on a complete metric space is a closed map.

**Proof:** If \( y \in f(X) \), then because \( Y \) is metric, there are \( x_n \) that \( y = \lim f(x_n) \). Thus \( \{f(x_n)\} \) is Cauchy in \( Y \), and \( \{x_n\} \) is Cauchy too. So there is a \( x = \lim x_n \), and clearly \( f(x) = y \). \( \square \)

**Compact Metric Space**

**Lemma (3.6.8.10) [Lebesgue Number Lemma].** For any open covering \( U_i \) of a compact metric space \( X \), there exists a \( \delta > 0 \) that any subset \( X \) of diameter smaller than \( \delta \) is contained in some \( U_i \).

**Proof:** If \( X \) is in the covering \( U_i \), then there is nothing to prove, otherwise, it suffices to assume the covering is a finite covering, let \( C_i = X - U_i \), and let \( f(x) = \frac{1}{n} \sum d(x, C_i) \). Notice \( f(x) > 0 \), because \( x \notin C_i \) for some \( C_i \). Now it is also continuous, so it has a minimal value \( > \delta > 0 \).

Now if \( B \) has diameter smaller than \( \delta \), then if \( x_0 \in B, \delta < f(x_0) < d(x, C_{i_0}) \), where \( d(x, C_{i_0}) \) is the maximal among \( d(x, C_k) \), and \( B \in B(x, \delta) \), thus \( B \in U_{i_0} \). \( \square \)

**Prop. (3.6.8.11) [Uniform Continuity Theorem].** If \( f : X \to Y \) is a continuous map between two metric spaces that \( X \) is compact, then \( f \) is uniformly continuous.
3.6. TOPOLOGY I

Proof: Take an open covering of \( Y \) with balls \( B(y_i, \varepsilon/2) \) of diameter \( \varepsilon/2 \), and consider their inverse image, then choose the lebesgue number \( \delta \) for this covering.(3.6.8.10), we see that for any \( d(x, y) < \delta \), \( d(f(x), f(y)) < \varepsilon \).

Prop.(3.6.8.12). If \( f \) is an isometry of a compact metric space \( X \), then it is a bijection thus an homeomorphism.

Proof: It is clearly injective. If it is not surjective, then choose a \( x \notin \text{Im}(f) \), because \( \text{Im}(f) \) is compact hence closed in \( X \), \( d(x, \text{Im}(f)) = \varepsilon > 0 \). Now consider the minimal \( N \) that we can cover \( X \) with open subsets of diameter smaller than \( \varepsilon \), this \( N \) exists because \( X \) is compact. Now if \( U_i \) covers \( X \), then the one that contains \( x \) cannot intersect with \( \text{Im}(f) \). But \( f^{-1}(U_i) \) is an open cover of \( X \) with smaller numbers of open subsets, contradiction.

9 Baire Space

Def.(3.6.9.1)[Baire Spaces]. A subset of a topological space \( X \) is called of first category if it is contained in some countable union of closed subsets of \( X \) having no interior point. It is called of second category if it is not of first category.

A Baire space is a topological space that any nonempty open subsets of \( X \) is of second category.

Prop.(3.6.9.2)[Baire Category Theorem]. Every complete metric space & locally compact Hausdorff space is a Baire space.

Proof: Choose consecutively (precompact)open subsets that doesn’t intersect \( \overline{E_n} \) to find a limit point.

10 Uniform Space

Def.(3.6.10.1)[Uniform Spaces].

Def.(3.6.10.2)[Cauchy Filter in the Topological Group Case]. A Cauchy filter is a topological Abelian group is a filter \( \mathcal{F} \) that for any nbhd \( U \) of 0, there exists \( E \in \mathcal{F} \) that \( x - y \in U \) if \( x, y \in E \).

Def.(3.6.10.3)[Complete Uniform Spaces]. A topological Abelian group is called complete uniform space iff it is Hausdorff, and any Cauchy filter has a limit.

11 Manifolds

Def.(3.6.11.1)[Manifolds]. A (topological) manifold of dimension \( n \) is a topological space that is Hausdorff, second countable and locally Euclidean. By(3.6.7.7), the last condition is equivalent to say it is paracompact.

The category of topological manifolds is denoted by \( \text{Mani} \).

Thm.(3.6.11.2) [Annulus Theorem, Rado-Moise-Quinn-Kirby]. For any map \( h : \mathbb{R}^n \to \mathbb{R}^n \) that maps \( D^n \) into its interior, there is a homeomorphism \( D^n \setminus h(D^n) \cong S^{n-1} \times I \) that identifies \( \partial D^n \) and \( h(\partial D^n) \) with \( S^{n-1} \times \{0\}, S^{n-1} \times \{1\} \) resp.

Proof:
Triangularizations

Def. (3.6.11.3) [Triangularizations]. A triangularizable space is a space that is homeomorphic to the geometrization of a simplicial set (3.12.3.7).

Thm. (3.6.11.4) [Triangularization of Surfaces]. All compact connected surface is triangularizable.

Proof: □

Surfaces

Def. (3.6.11.5) [Topological Surfaces]. A topological surface (with boundaries) is a topological manifold of dimension 2 (with boundaries).

Def. (3.6.11.6) [Planer Glueing Diagram]. A planer glueing diagram is a polygon with some glueing of its edges with orientations clockwise such that no three edges are glued together. We can label the edges by symbols and their inverses. Different symbols are considered not glued together. For example, $aba^{-1}b^{-1}, abab$.

A compact planer glueing diagram is a planer glueing diagram that every symbol appear exactly twice in the edges of the polygon.

Prop. (3.6.11.7). The space correspond to a planer glueing diagram is a compact topological surface with boundaries.

The space correspond to a compact planer glueing diagram is a compact topological surface.

Proof: It is compact as a quotient of a compact space. It can verified that it is locally Euclidean at each space. And it is clearly Hausdorff. □

Lemma (3.6.11.8). $T^2 \# \mathbb{RP}^2 \cong \mathbb{RP}^2 \# \mathbb{RP}^2 \# \mathbb{RP}^2$.

Proof: By ??, it suffices to show that $aabcb^{-1}c^{-1}$ is homeomorphic to $eefgg$. For this, use cut-and-paste.? □

Thm. (3.6.11.9) [Classification of Surfaces]. Any compact topological surface is homeomorphic to exactly one of the following: $S^2, \#^n T^2$ or $\#^n \mathbb{RP}^2$, $n \in \mathbb{Z}_+$. The corresponding planer diagram is $aa^{-1}, a_1b_1a_1^{-1}b_1^{-1} \ldots a_nb_n a_n^{-1}b_n^{-1}, e_1e_1e_2e_2 \ldots e_ne_n$.

Proof: By triangularization theorem (3.6.11.4), it is easy to see that any compact surface is the space corresponding to a compact planer diagram. Then it suffices to show any compact planer diagram is isomorphic to either $aa^{-1}, a_1b_1a_1^{-1}b_1^{-1} \ldots a_nb_n a_n^{-1}b_n^{-1}, e_1e_1e_2e_2 \ldots e_ne_n$.

Firstly we can reduce to the case where all vertices are glued together: Take a vertex $P$, then we can spot all the vertices that are glued to $P$. If these are not all the vertices, we can find an edge $e = PQ$, and let $RPQ$ be a triangle, then we can cut this triangle out to paste along the edge pairing $e$. Then we can reduce the number of vertices glued to $P$. Eventually, we can eliminate $P$.

Secondly we can collect all edges with the same orientation (i.e. $\ldots a \ldots a \ldots$) to be adjacent: (i.e. $\ldots aa \ldots$). To do this, suppose $a = P_1Q_1 = P_2Q_2$, we simply cut along the line $P_1P_2$ and glue $a$ together.

Now if all edges glued together are of the same orientations, then it is clearly isomorphic to $\#^n \mathbb{RP}^2$. Otherwise there are edges $a, a^{-1}$ glued together with the opposite orientation. Then
there must be another pair $b, b^{-1}$ s.t. these four pairs are ordered by $a, b, a^{-1}, b^{-1}$. This is because otherwise there will be two vertices. Then by some cut-and-paste, we can move these edges together as $\ldots aba^{-1}b^{-1}\ldots$. By induction, we can make all edges with the opposite orientations together and in pairs.

Thus our diagram is a connected sum of $T^2$ and $\mathbb{RP}^2$. Then we can reduce the diagram to one of the three kinds by (3.6.11.8).

Finally, it suffices to show these three kinds are different: Their Euler characteristics are

$$
\chi(S^2) = 2, \quad \chi(\#^n T^2) = 2 - 2n, \quad \chi(\#^n \mathbb{RP}^2) = 2 - n.
$$

So the only case their Euler characters equal are $\chi(\#^n T^2) = \chi(\#^2 \mathbb{RP}^2)$. But in this case, they are still not homeomorphic, as $H_2(\#^n T^2) = \mathbb{Z}$ and $H_2(\#^2 \mathbb{RP}^2) = 0$. □

12 Common Spaces

Def. (3.6.12.1) [Torus]. The $(n$-dimensional) torus $T^n$ is defined to be $T^n = (S^1)^n$.

Def. (3.6.12.2) [RP $^n$]. The real projective space $\mathbb{RP}^n$ is the $\mathbb{R}$-points of $\mathbb{RP}_\mathbb{R}$ with the canonical topology.

Def. (3.6.12.3) [Möbius Band]. The Möbius band is the space defined to be the planer glueing diagram $abac$.

Def. (3.6.12.4) [Klein Bottle]. The Klein bottle $K^2$ is the space defined by the planer glueing diagram $aba^{-1}b$. 
3.7 Model Categories

Main references are [Model Category and Simplicial Methods, Goerss], [Model Categories, Kan-
tor], [Homotopy Theories and Model Categories, Dwyer/Spalinski], [Higher Topos Theory, Lurie].

Prop.(3.7.0.1). If \(C\) is a class of morphisms in a category, we denote \(l(C)\) the set of morphisms that
has left lifting property w.r.t. all morphisms in \(C\), and \(r(C)\) the set of morphisms that have right
lifting property w.r.t. all morphisms in \(C\). Then \(l(C)\) is stable under pushout and \(r(C)\) is stable
under base change.

Def.(3.7.0.2) [Model Structure]. A model structure on a category \(C\) is three classes of mor-
phisms: fibrations, cofibrations and weak equivalences that satisfy the following axioms: (Den-
ote a A trivial (co)fibration is a (co)fibration that is also a weak equivalence.)
M1 \(C\) has finite limits and colimits.
M2 (two out of three)If two of \(f, g, fg\) is weak equivalence, then so is the third.
M3 (retracts) Fibrations, cofibrations and weak equivalences are closed under retract.
M4 (lifting property) We have a lifting property with a cofibration \(i\) and fibration \(p\) when either
of them is a weak equivalence.
M5 (factorization) Any map \(f\) can be factored as \(pi\) where \(i\) is trivial cofibration and \(p\) is a fibration,
and also as \(pi\) where \(i\) is a cofibration and \(p\) is a trivial fibration.

Remark(3.7.0.3). Notice the axioms are symmetric in fibrations and cofibrations, thus the opposite
category \(\mathcal{C}^{op}\) has a natural model structure. So whenever we write a theorem, we should always
remember its dual counterpart.

Lemma(3.7.0.4)[Closedness]. A model category satisfies retraction axiom iff:
- fibration= \(r(\text{trivial cofibrations})\),
- cofibration= \(l(\text{trivial fibrations})\),
- weak equivalence= \(uv\), where \(v\) is in \(l(\text{fibrations})\) and \(u\) in \(r(\text{cofibrations})\).

Proof: If these are satisfied, retraction axiom is easy: A retract satisfies the same lifting properties.
Hence retraction of a (co)fibration is a (co)fibration. For retracts weak equivalences, Cf.[Quillen,
Homotopical Algebra, Chap5.2].

Conversely, using(3.1.6.7), we first factorize a \(p = f \circ i\), where \(i\) is a trivial cofibration, then
because \(p\) is in \(r(i)\), \(p\) is a retraction of \(f\) hence a fibration. And similarly for cofibrations and weak
equivalences. \(\square\)

Cor.(3.7.0.5). In a model category,
- trivial fibrations= \(r(\text{cofibrations})\),
- trivial cofibrations= \(l(\text{fibrations})\).

Proof: The proof is the same as that of(3.7.0.4). \(\square\)

Cor.(3.7.0.6). In a model category, the class of (trivial)fibrations is stable under base change and
the class of (trivial)cofibrations is stable under cobase change.

Prop.(3.7.0.7). Let \(p\) be a fibration in \(C_{\text{cf}}\), then \(p \in r(\text{Cof})\) iff \(\gamma(p)\) is an isomorphism, Cf.[Quillen
5.2]. So if conditions of(3.7.0.4) are satisfied (i.e. \(C\) is a closed model category), \(\gamma(f)\) is an isomor-
phism iff \(f\) is a weak equivalence by the characterization of weak-equivalence of(3.7.0.4).
**Def. (3.7.0.8) [Proper].** A model category is called **left proper** if weak equivalences are stable under cobase change by cofibrations. Dually it is called **right proper** if weak equivalences are stable under base change by fibrations.

**Lemma (3.7.0.9) [Cofibration is Left Proper].** For a pushout diagram

\[
\begin{array}{ccc}
  A & \xrightarrow{i} & B \\
   \downarrow{j} & & \downarrow{j'} \\
  A' & \xrightarrow{i'} & B'
\end{array}
\]

in a model category \( \mathcal{C} \), if \( i \) is cofibration and \( A, A' \) are cofibrant, and \( j \) is weak equivalence, then \( j' \) is also weak equivalence.

**Proof:** It suffices to show \( j' \) is an isomorphism in \( \text{Ho}(\mathcal{C})(3.7.1.15) \). For this, by Yoneda lemma, it suffices to show \( \text{Hom}_{\text{Ho}(\mathcal{C})}(B', Z) \cong \text{Hom}_{\text{Ho}(\mathcal{C})}(B, Z) \) for any fibrant object \( Z \).

For surjectivity, by (3.7.1.18), it suffices to show \( \pi(B', Z) \cong \pi(B, Z) \). Given a map \( f : B \to Z \), because \( j \) is weak equivalence, there is a map \( g : A' \to Z \) that \( g \circ j \sim f \circ i \). Then by (3.7.1.10), there is a \( f' \sim f \) that \( f' \circ i = g \circ j \), which determines a morphism \( B' \to Z \).

For injectivity, If \( P \) is a path object that \( H : B \to P \) induces a homotopy between maps \( s \circ j', s' \circ j' \), then we need to extend this homotopy to \( \tilde{H} : B' \to P \), and the method is the argument is the same as above. \( \square \)

### 1 Homotopies

**Def. (3.7.1.1) [Cylinder Objects].** A **cylinder object** for an object \( X \) is an object \( X \wedge I \) which gives a factorization of the natural map \( X \coprod X \to X \) as \( X \coprod X \xrightarrow{j} X \wedge I \xrightarrow{i} X \), where \( j \in W \). It is called a **good cylinder object** if \( i \) is a cofibration, and **very good cylinder object** if \( j \) is trivial fibration. By factorization axiom, every object has a very good cylinder object.

There are two natural morphisms \( X \Rightarrow X \wedge I \), denoted by \( \partial_0 \) and \( \partial_1 \).

Dually we can define **path object** \( Y^I \) for \( Y \), and every object has a very good path object.

**Prop. (3.7.1.2).** If \( A \) is cofibrant and \( A \wedge I \) is a cylinder object for \( A \), then \( \partial_i : A \to A \times I \) are trivial cofibrations.

**Proof:** Because it’s pushout of \( \emptyset \to A \) and \( \sigma \circ \partial_i = \text{id}_A \). \( \square \)

**Cor. (3.7.1.3).** if \( f \sim^l g \), then \( f \) is a weak equivalence iff \( g \) is a weak equivalence.

**Proof:** This is because \( f = H \circ \partial_0, g = H \circ \partial_1 \), and we can use (3.7.1.2). \( \square \)

**Def. (3.7.1.4) [Homotopies].** Two morphisms \( f, g : X \to Y \) are called **(good/very good) left homotopic**, denoted by \( f \sim^l g \) iff there is a (good/very good) cylinder object \( X \coprod X \to X \wedge I \) with \( X \wedge I \to Y \) that induce \( (f, g) : X \coprod X \to Y \). Dually for right homotopies. And we denote by \( \pi^l(A, B)/\pi^r(A, B) \) the equivalence classes of \( \text{Hom}(A, B) \) under the equivalence relation generated by left/right homotopies.

If \( f, g \in \text{Hom}(X, Y) \) and \( \varphi \in \text{Hom}(Y, Z) \) that \( \varphi \circ f = \varphi \circ g \), then \( f, g \) is called **left homotopic over** \( Z \) if there is a homotopy \( H \) of \( f \sim^l g \) that \( \varphi H \) is the trivial homotopy. Dually for **right homotopic under** \( X \).
Lemma (3.7.1.5) [Very Good Homotopies]. For \( f, g \in \text{Hom}(X, Y) \), if \( f \sim_l g \), then \( f, g \) are good left homotopic. And if \( Y \) if fibrant, then \( f, g \) are moreover very good left homotopic.

Proof: The first assertion is each, just choose a factorization of the cylinder object \( X \coprod X \xrightarrow{j} X \times I \) that \( i \) is cofibrant. If \( Y \) is fibrant, then we further factorize \( X \times I \xrightarrow{i} X \times I'' \xrightarrow{j} X \), where \( i \) is cofibrant and \( j \) is trivial fibration, then by two out of three, \( i \) is also trivial cofibration, and it suffices to extend the homotopy \( X \times I' \to Y \) to \( X \times I'' \to Y \), and this is because \( Y \) is fibrant. \( \square \)

Prop. (3.7.1.6) [Homotopy is Equivalence Relation]. If \( A \) is cofibrant, then the left homotopy is an equivalence relation on \( \text{Hom}(A, B) \).

Proof: Reflexivity and symmetry is trivial, the only problem is transitivity, so we construct a glueing \( A \times I'' \) as the pushout of \( \partial_1 : A \to A \times I \) and \( \partial_0 : A \to A \times I' \). \( A \times I'' \to A \) is a weak equivalence by the universal property and (3.7.0.4), so this is a cylinder object. The rest is easy. \( \square \)

Prop. (3.7.1.7) [Properties of Left Homotopies]. If \( A \) is cofibrant and \( f, g \in \text{Hom}(A, B) \), then
1. If \( f, g \) are right homotopic, then \( s \to B^I \) can be chosen to be trivial Cof.
2. If \( f, g \) are right homotopic, then so does \( uf \sim ug \) or \( fv \sim gv \). Thus if \( A \) is cofibrant, there is a composition map: \( \pi^r(A, B) \times \pi^r(B, C) \to \pi^r(A, C) \).
3. For any trivial fibration \( X \to Y \), \( \pi_l(A, X) \to \pi^l(A, Y) \) is a bijection.
And dual arguments hold for fibrant objects.

Proof:
1. factorize \( B \to B^I \) to \( B \to B'' \to B^I \) where \( B \to B'' \in \text{TCof} \) and \( B'' \to B^I \in \text{W} \), so \( B'' \) is also a cylinder object and the homotopy \( A \to B^I \) can be lifted to \( A \to B'' \).

\[
\begin{array}{ccc}
B & \xrightarrow{su} & C^I \\
\downarrow s & & \downarrow (d_0, d_1) \\
B^I & \xrightarrow{(d_0 u, d_1 u)} & C \times C
\end{array}
\]

will give the desired homotopy.

3. the map is well-defined, it is surjective because of lifting property, and it is injective because \( A \coprod A \to A \times I \in \text{Cof} \) so the homotopy can be lifted to \( X \).
Cf. [Homotopy Theories and Model Categories, P20, 21]. \( \square \)

Lemma (3.7.1.8) [Left and Right Homotopies]. If \( X \) is cofibrant, then for \( f, g \in \text{Hom}(X, Y) \), if \( f \sim_l g \), then \( f \sim_r g \). And the dual conclusion holds for \( Y \) fibrant.

In particular, for morphisms between bifibrant objects, left and right homotopic are equivalent.

Proof: Consider a cylinder object \( j : X \times I \to X \) for \( X \) and a path object for \( Y \). Suppose \( f, g \) are left homotopic via a map \( H : X \times I \to Y \), then we consider the diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y & \xrightarrow{Y^I} \\
\downarrow \partial_1 & & \downarrow & \\
X \times I & \xrightarrow{(j \times H \times)} & Y \times Y
\end{array}
\]
Then it can be solved by some \( \tilde{H} \) because \( \partial_1 \) is trivial cofibration (3.7.1.2), and then it can be checked \( H \circ \partial_1 \) gives the desired right homotopy.

\[ \square \]

**Prop.** (3.7.1.9) **[Whitehead’s Theorem].** Let \( X, Y \in \mathcal{C} \) be bifibrant, then a map \( f : X \to Y \) is an equivalence iff there is a \( g : X \to Y \) that \( fg \) and \( gf \) are homotopic to id.

**Proof:** Cf. [Homotopy Theories and Model Categories, P23].

\[ \square \]

**Prop.** (3.7.1.10) **[Lifting Criterion].** Let \( \mathcal{C} \) be a model category and \( i : A \to B \) be a cofibration between cofibrant objects, and \( X \) is fibrant, \( g : B \to X \), \( f : A \to X \) satisfies \( g \circ i \sim f \), then there is a \( g' \sim g \) that \( g' \circ i = f \).

**Proof:** Choose a good cylinder object \( C(A) \) for \( A \) and factorize
\[
C(A) \coprod_{A \coprod A} (B \coprod B) \to C(B) \to B
\]
where the first map is cofibration and the second is trivial fibration, then \( C(B) \) is a good cylinder object for \( B \).

The homotopy is given by a map \( C(A) \coprod_A B \to X \), and we check \( (A) \coprod_A B \to C(B) \) is a trivial cofibration (check \( C(A) \coprod_A B \to C(B) \) is a weak equivalence using (3.7.0.6) and check \( C(A) \coprod_A B \to C(A) \coprod_B (B \coprod B) \) is a cofibration as a cobase change of \( A \to B \) and \( C(A) \coprod_A (B \coprod B) \to C(B) \) is a cofibration by definition), so the homotopy extends to a homotopy \( C(B) \to X \), which is a homotopy between \( g \) and some \( g' \) and \( g' \circ i = f \).

\[ \square \]

**Def.** (3.7.1.11). Let \( C_c, C_f, C_{cf} \) denote the full subcategory of cofibrant, fibrant and cofibrant-fibrant objects. And we define \( \pi C_c \) as the category module right homotopy equivalence between morphisms, dually for \( \pi C_f \).

Notice (3.7.1.7) assures \( \pi C_c, \pi C_f \) are truly categories.

Notice for \( C_{cf} \), left homotopy is equivalent to right homotopy by (3.7.1.8), so \( \pi C_{cf} \) is full subcategory for both \( \pi C_c \) and \( \pi C_f \).

**Lemma** (3.7.1.12) **[Fibrant and Cofibrant Replacement].** For an object \( X \) in a model category \( \mathcal{C} \), the axioms show there is a cofibrant object \( QX \) and a trivial fibration \( QX \to X \). Also there is a fibrant object \( RX \) and a trivial cofibration \( X \to RX \). We fix choices of \( Q, R \) that is identity on bifibrant objects, and consider it a mapping from \( \mathcal{C} \) to \( \mathcal{C} \).

Then given any morphism \( f : X \to Y \), there is a morphism \( \tilde{f} : QX \to QY \) lifting \( f \), and \( \tilde{f} \) depends up to left and right homotopy only on \( f \). And if \( Y \) is fibrant, then it depends up to left and right homotopy only on the left homotopy classes of \( f \).

Dually assertions also holds, so we have functors: \( Q : \mathcal{C} \to \pi \mathcal{C}_c \) and \( R : \mathcal{C} \to \pi \mathcal{C}_f \).

**Proof:** The existence of the lifting follows from the fact \( QX \) is fibrant and \( QY \to Y \) is trivial fibration. The uniqueness of left homotopy follows from (3.7.1.7), and also right homotopy, because \( QX \) is cofibrant and use (3.7.1.8). For the last assertion, notice when \( Y \) is fibrant, (3.7.1.7) shows the left homotopy class of \( QX \to Y \) is determined, and use (3.7.1.7) again, the class of \( \tilde{f} \) is also determined.

\[ \square \]

**Cor.** (3.7.1.13). The restrictions define functors \( Q' : \pi \mathcal{C}_c \to \pi \mathcal{C}_{cf} \) and \( R' : \pi \mathcal{C}_f \to \pi \mathcal{C}_{cf} \).
Def. (3.7.1.14) [Homotopy Category]. For any model category $\mathcal{C}$, we construct a homotopy category $\text{Ho}(\mathcal{C})$ whose objects are the same as $\mathcal{C}$, but $\text{Hom}_{\text{Ho}(\mathcal{C})}(X, Y) = \pi\text{c}_{\mathcal{C}}(RQX, RQY)$.

There is a functor $\gamma : \mathcal{C} \to \text{Ho}(\mathcal{C})$ by sending $X$ to $RQX$, by (3.7.1.12).

Prop. (3.7.1.15) [Weak Equivalence and Isomorphisms]. A morphism in $\mathcal{C}$ maps to an isomorphism in $\text{Ho}(\mathcal{C})$ iff it is a weak equivalence. The morphisms in $\text{Ho}(\mathcal{C})$ are generated by the image of morphisms in $\mathcal{C}$ and the inverse of images of weak equivalences in $\mathcal{C}$.

Proof: If $f \in \mathcal{C}$ is a weak equivalence, then $f' = RQ(f)$ is also a weak equivalence, by two out of three lemma. Then Whitehead theorem (3.7.1.9) shows $f'$ is an isomorphism in $\pi\text{c}_{\mathcal{C}}$ hence in $\text{Ho}(\mathcal{C})$. Conversely, if $f'$ has an inverse in $\text{Ho}(\mathcal{C})$, then $f'$ is a weak equivalence by Whitehead (3.7.1.9) again, and so is $f$.

For the last assertion, just notice $\text{Hom}(RQX, RQY) \to \text{Hom}_{\text{Ho}(\mathcal{C})}(X, Y)$ is a surjection, and $X \to RQX, Y \to RQY$ are weak equivalence hence are isomorphisms in $\text{Ho}(\mathcal{C})$. □

Cor. (3.7.1.16). If $F, G : \text{Ho}(\mathcal{C}) \to \mathcal{D}$ are two functors and $t : F \circ \gamma \to G \circ \gamma$ is a natural transformation, then $t$ also gives a natural transformation $F \to G$.

Proof: This is because the objects of $\text{Ho}(\mathcal{C})$ are the same as that of $\mathcal{C}$, and the morphisms are generated by $\gamma(f)$ and $\gamma(g)^{-1}$ where $g$ is a weak equivalence. Then the desired transformation commutative diagrams commute. □

Lemma (3.7.1.17). Let $\mathcal{C}$ be a model category and $F : \mathcal{C} \to \mathcal{D}$ be a functor taking weak equivalences to isomorphisms, then if $f \sim^l g$ or $f \sim^r g$, $F(f) = F(g)$.

Proof: We only prove for left homotopy and the right homotopy is dual: given the cylinder object $A \wedge I$, just need to prove that $F(\partial_0) = F(\partial_1)$. □

Prop. (3.7.1.18). Suppose $A$ is cofibrant and $X$ is fibrant, then the map $\gamma : \text{Hom}(A, X) \to \text{Hom}_{\text{Ho}(\mathcal{C})}(A, X)$ is surjective, and induces a bijection $\pi(A, X) \cong \text{Hom}_{\text{Ho}(\mathcal{C})}(A, X)$.

Proof: (3.7.1.17) shows $\gamma$ identifies homotopic maps. Consider the following commutative diagram:

\[
\begin{array}{ccc}
\pi(RA, QX) & \longrightarrow & \pi(A, X) \\
\downarrow \gamma & & \downarrow \gamma \\
\text{Hom}_{\text{Ho}(\mathcal{C})}(RA, QX) & \longrightarrow & \text{Hom}_{\text{Ho}(\mathcal{C})}(A, X)
\end{array}
\]

The second vertical arrow is isomorphism by (3.7.1.15), the first arrow is isomorphism by (3.7.1.7). The left vertical arrow is identity by construction, so the right vertical arrow is also isomorphism. □

Prop. (3.7.1.19) [Homotopy Category as Localizing Category]. Let $\mathcal{C}$ be a model category and $W$ the class of weak equivalences, then the functor $\gamma : \mathcal{C} \to \text{Ho}(\mathcal{C})$ is the localizing category of $\mathcal{C}$ w.r.t $S$.

Proof: Cf. [Homotopy Theories and Model Categories, P29]. □
2 Quillen Functors and Derived Functors

Def. (3.7.2.1) [Quillen Adjunctions]. An adjoint pair of functors \((F, G)\) between model categories is called a Quillen adjunction if \(F\) preserves cofibrations and \(G\) preserves fibrations. By adjointness and (3.7.0.4), in fact \(F\) preserves also trivial cofibrations and \(G\) preserves trivial fibrations.

It is called a Quillen equivalence if for any cofibrant object \(C\) and fibrant object \(D\), a map \(C \to G(D)\) is a weak equivalence iff the adjoint map \(F(C) \to D\) is a weak equivalence.

Def. (3.7.2.2) [Derived Functors]. Let \(\mathcal{C}\) be a model category and \(F: \mathcal{C} \to \mathcal{D}\) a functor, then a left derived functor of \(F\) is a left Kan extension of \(F\) along \(\gamma: \mathcal{C} \to \text{Ho}(\mathcal{C})\).

Dually we can define right derived functors.

Prop. (3.7.2.3) [Existence of Derived Functors]. In the situation of (3.7.2.2), if \(F\) maps weak equivalences between cofibrant objects to isomorphisms in \(\mathcal{D}\), then the left derived functor \((LF, t)\) exists, and for each cofibrant object \(X\), the morphism \(t_X: LF(X) \to F(X)\) is an isomorphism.

Dually for the right derived functor case.

Proof: Cf. [Homotopy Theories and Model Categories, P42].

Lemma (3.7.2.4). Let \(\mathcal{C}\) be a model category and \(F: \mathcal{C}_c \to \mathcal{D}\) be a functor that maps trivial cofibrations in \(\mathcal{C}_c\) to isomorphisms, then \(F\) maps right-homotopic morphisms to the same morphism.

Proof: Let \(H: A \to B^I\) be a right homotopy between \(f\) and \(g\), where \(B^I\) is a very good path object (3.7.1.5), then \(B \to B^I\) is a trivial cofibration, and thus mapped by \(F\) to an isomorphism. Then we can show \(F(\partial_0) = F(\partial_1)\), and then \(F(f) = F(g)\).

Def. (3.7.2.5) [Total Left Derived Functors]. Let \(F: \mathcal{C} \to \mathcal{D}\) be a morphism of model categories, then a total derived functor

\[ LF: \text{Ho}(\mathcal{C}) \to \text{Ho}(\mathcal{D}) \]

is defined to be a left derived functor of the morphism \(\mathcal{C} \to \mathcal{D} \to \text{Ho}(\mathcal{D})\).

Lemma (3.7.2.6) [Brown]. Let \(F\) be a morphism of model categories that maps trivial cofibration between cofibrant objects to weak equivalences, then it preserves weak equivalences between cofibrant objects.

Proof: If \(f: A \to B\) is a weak equivalence between cofibrant objects, then we can factor the morphism \((f, \text{id}): A \coprod B \to B\) as \(A \coprod B \xrightarrow{q} C \xrightarrow{p} B\) that \(q\) is cofibration and \(p\) is trivial fibration. It can be shown that \(q \circ \partial_i: B \to C\) are trivial fibrations and \(C\) is cofibrant, thus \(F(q \circ \partial_i)\) are weak equivalences, and hence also \(F(p)\) is weak equivalence and so does \(F(f)\).

Prop. (3.7.2.7) [Total Derived Functors and Quillen Equivalence]. If \((F, G)\) is a pair of Quillen functors between two model categories \(\mathcal{C}, \mathcal{D}\), then total derived functors

\[ LF: \text{Ho}(\mathcal{C}) \rightleftharpoons \text{Ho}(\mathcal{D}) : RG \]

exists and form an adjoint pair. And if \((F, G)\) is a Quillen equivalence, then \((LF, RG)\) defines an equivalence of homotopy categories.
Proof: By (3.7.2.3) and its dual and (3.7.2.6), the total derived functors \( LF, RG \) exist.

Next for \( A \) cofibrant in \( \mathcal{C} \) and \( X \) fibrant in \( \mathcal{D} \), we can show the adjunction map \( \text{Hom}(A, G(X)) \cong \text{Hom}(F(A), X) \) preserves homotopy equivalence relations (3.7.1.8) and induces an isomorphism \( \pi(A, G(X)) \cong \pi(F(A), X) \): If \( H : A \land I \to X \) is a good homotopy between \( f, g \), then \( A \land I \) is cofibrant, and because \( F \) preserves colimits and because of (3.7.2.6), \( F(A \land I) \) is cylinder object for \( F(A) \), thus \( f^\flat \sim g^\flat \). A dual argument shows the converse.

Now for any \( A \in \mathcal{C} \) and \( X \in \mathcal{D} \), there is a bijection
\[
\text{Hom}_{\text{Ho}(\mathcal{C})}(A, RG(X)) \cong \pi(QA, G(SX)) \cong \pi(F(QA), SX) \cong \text{Hom}_{\text{Ho}(\mathcal{D})}(LF(A), X)
\]
where the first isomorphism is due to the fact \( QA \to RQA \) is trivial cofibration and \( G(SX) \) is fibrant, thus we can use (3.7.1.7), dually for the last isomorphism.

Finally if \((F, G)\) is a Quillen equivalence, then consider the unit map:
\[
A \to RG(LF(A)).
\]
If \( A \) is cofibrant, then this is \( A \to G(SF(A)) \) which is a weak equivalence because \( F(A) \to SF(A) \) does, so it is an isomorphism in \( \text{Ho}(\mathcal{C}) \). Now any object in \( \text{Ho}(\mathcal{C}) \) is isomorphic to a cofibrant object, we know the unit map is an isomorphism. Dually the counit map is an isomorphism, thus \( LF, GF \) are a pair of equivalences.

3 Combinatorial Model Structure

Cf.[HTT, A.2.6]

Def.(3.7.3.1)[Combinatorial Model Category]. A cofibrantly generated model category is a model category \( \mathcal{C} \) that
- there is a set \( I \) of generating cofibrations that generates the class of cofibrations as the minimal weakly saturated class containing \( I \).
- there is a set \( J \) of generating trivial cofibrations that generates the class of trivial cofibrations as the minimal weakly saturated class containing \( J \).
A combinatorial model category is a cofibrantly generated and presentable model category.

4 Generating new Model Categories

Prop.(3.7.4.1). If \( \mathcal{C} \) is a model category and \( A \) is an object, then the undercategory \( \mathcal{C}_{/A} \) and the overcategory \( \mathcal{C}_{A\setminus} \) have natural model structures.

Prop.(3.7.4.2)[Transfer Model Structures via Left Adjoint]. Let
\[
F : \mathcal{C} \rightleftarrows \mathcal{D} : G
\]
be an adjoint pair of categories and
- \( \mathcal{C}, \mathcal{D} \) are complete and cocomplete,
- \( \mathcal{C} \) is a cofibrantly generated model category,
- \( \mathcal{C}, \mathcal{D} \) are presentable categories and \( G \) is an accessible functor.
- If we define a morphism \( f \) in \( \mathcal{B} \) a fibration/weak equivalent iff \( G(f) \) is a fibration/weak equivalence, and a cofibration iff it has left lifting property w.r.t. trivial fibrations, then \( \mathcal{B} \) has a path object factorization and a fibrant replacement operator.
Then this defines a cofibrantly generated model category on \( \mathcal{B} \), and makes \((F,G)\) a Quillen adjunction.

**Proof:** It suffices to show that the factorization property holds: In fact, it suffices to show if \( I, J \) are generating classes of cofibrations and trivial cofibrations, then \( F(I), F(J) \) are generating classes of cofibrations and trivial cofibrations. But this suffices to show \( F(J) \) is are weak equivalence. For this, show that any morphism in \( \mathcal{B} \) that has left lifting properties w.r.t. all fibrations is a weak equivalence using hypothesis item 4.

\[ \square \]

## 5 Diagram Categories and Homotopy (Co)Limits

Cf. [HTT, A.3.3, A.3.5].

**Def. (3.7.5.1).** Let \( \mathcal{C} \) be a small \( \mathcal{S} \)-enriched category and \( \mathcal{A} \) a combinatorial \( \mathcal{S} \)-enriched model category, then a natural transformation \( \alpha : F \to G \) in \( \mathcal{A}^{\mathcal{C}} \) is called

- an **injective cofibration** if \( F(C) \to G(C) \) is a cofibration in \( \mathcal{A} \) for each \( C \).
- a **projective fibration** if \( F(C) \to G(C) \) is a fibration in \( \mathcal{A} \) for each \( C \).
- a **weak equivalence** if \( F(C) \to G(C) \) is a weak equivalence in \( \mathcal{A} \) for each \( C \).

**Prop. (3.7.5.2).** Let \( \mathcal{S} \) be an excellent model category and \( \mathcal{A} \) a combinatorial \( \mathcal{S} \)-enriched model category, \( \mathcal{C} \) a small \( \mathcal{S} \)-enriched category, then there are two model structures on \( \mathcal{A}^{\mathcal{C}} \):

- The **projective model category** determined by the projective cofibrations and weak equivalences,
- The **injective model category** determined by the injective cofibrations and weak equivalences.

**Proof:** Cf. [HTT, P868].

**Prop. (3.7.5.3).** Let \( \mathcal{C} \) be a model category and let

\[
\begin{array}{ccc}
A & \xrightarrow{j} & A_1 \\
\downarrow{i} & & \downarrow{} \\
A_0 & \longrightarrow & A_0 \amalg_A A_1
\end{array}
\]

be a pushout diagram, then it is a homotopy pushout diagram if either of the following is satisfied:

- \( j \) is a cofibration and \( A, A_0 \) are cofibrant.
- \( j \) is a cofibration and \( \mathcal{C} \) is left proper.

**Proof:**

\[ \square \]

## 6 Enriched and Monoidal Model Categories

**Def. (3.7.6.1)[Left Quillen Bifunctor].** Let \( \mathcal{A}, \mathcal{B}, \mathcal{C} \) be model categories, then a functor \( \mathcal{A} \times \mathcal{B} \to \mathcal{C} \) is called a **left Quillen bifunctor** if
• For any cofibrations \( i : A \rightarrow A' \in A, B \rightarrow B' \in B \), the induced map

\[
i \land j : F(A', B) \coprod_{F(A, B)} F(A, B') \rightarrow F(A', B')
\]

is a cofibration in \( 
\).

• \( F \) preserves small colimits separably in each variables.

**Def. (3.7.6.2) [Monoidal Model Category].** A monoidal model category is a monoidal category \( S \) equipped with a model structure that:

- The tensor product \( \otimes : S \times S \rightarrow S \) is a left Quillen bifunctor.
- The unit objects \( 1 \in S \) is cofibrant.
- The monoidal structure is closed.

**Def. (3.7.6.3) [Enriched Model Category].** Given a monoidal model category \( S \), an \( S \)-enriched model category is an \( S \)-enriched category \( A \) with a model structure satisfying:

- \( A \) is tensored and cotensored over \( S \).
- the tensor product \( A \times S \rightarrow S \) is a left Quillen bifunctor.

**Prop. (3.7.6.4).** The second condition in (3.7.6.3) is equivalent to the following: For a cofibration \( i : U \rightarrow V \) and a fibration \( p : X \rightarrow Y \), the induced map

\[
\text{Map}(V, X) \xrightarrow{(i^*, p_*)} \text{Map}(U, X) \times_{\text{Map}(U, Y)} \text{Map}(V, Y)
\]

is a fibration in \( S \), and trivial fibration if any of \( i, p \) is weak equivalence.

**Proof:** Use the adjunction relations to write it out.

**Def. (3.7.6.5) [Fibrant Enriched Categories].** Let \( A \) be a \( S \)-enriched category, the we denote \( A^\circ \) the subcategory of bifibrant objects of \( A \), which is also a \( S \)-enriched category.

**Prop. (3.7.6.6).** Let \( \mathcal{C}, \mathcal{D} \) be \( S \)-enriched model categories and

\[
F : \mathcal{C} \rightleftharpoons \mathcal{D} : G
\]

is a Quillen adjunction of underlying model categories. Assume every objects of \( \mathcal{C} \) is cofibrant and the maps \( \beta_{X, S} : S \otimes F(X) \rightarrow F(S \otimes X) \) is a weak equivalence for \( X \in \mathcal{C}, S \in S \) cofibrant, then the following are equivalent:

- \((F, G)\) is a Quillen equivalence.
- \( G \) determines a weak equivalence of the underlying \( S \)-enriched categories \( \mathcal{D}^\circ \rightarrow \mathcal{C}^\circ \).

**Proof:** Cf.[HTT, P853].

**Lemma (3.7.6.7).** Let \( S = \text{Set}_\Delta \), then the map \( \beta_{X, S} \) is a weak equivalence for every cofibrant object \( X \in \mathcal{C} \).

**Proof:** Cf.[HTT, P853].
Prop. (3.7.6.8). Let $\mathcal{C}, \mathcal{D}$ be simplicial model categories and $$ F : \mathcal{C} \rightleftarrows \mathcal{D} : G $$ is a Quillen equivalence, and every element of $\mathcal{C}$ is cofibrant, then $G$ induces an equivalence of $\infty$-categories $N(\mathcal{D}^\circ) \cong N(\mathcal{C}^\circ)$.  

Proof: This is because $G : \mathcal{D}^\circ \to \mathcal{C}^\circ$ is an equivalence of simplicial categories, by (3.7.6.6) and (3.7.6.7), and then (3.12.4.14) shows $N(G) : N(\mathcal{D}^\circ) \to N(\mathcal{C}^\circ)$ is an equivalence of $\infty$-categories. □

7 $S$-enriched Categories

Def. (3.7.7.1) [Homotopy Category]. Let $S$ be a monoidal model category, then there is a natural monoidal structure on the homotopy category $hS$ (3.7.1.14), and the functor $S \mapsto hS$ is monoidal, thus we can transfer from a category $\mathcal{C}$ enriched over $S$ to an $hS$-enriched category, called the homotopy category of $\mathcal{C}$.

Def. (3.7.7.2) [Weak Equivalences]. Let $S$ be a monoidal model category and $\mathcal{C}$ be the category of categories enriched over $S$, then a morphism in $\mathcal{C}$ is called a weak equivalence if it induced an isomorphism of their homotopy categories.

Def. (3.7.7.3) [Generating Cofibrations in $\mathcal{C}_S$]. Let $S$ be a monoidal model category, $A$ is an object of $S$, then we can denote $[1]_A$ the $S$-enriched category consists of objects $\{X, Y\}$ and that $\text{Hom}(X, X) = \text{Hom}(Y, Y) = 1_S, \text{Hom}(X, Y) = A, \text{Hom}(Y, X) = \emptyset$. And if $1_S$ is the initial object of $S$, then we denote $[1]_1$ by $[1]_S$. Also we denote $[0]_S$ the $S$-enriched category consisting of one element and the morphism space is $1_S$.

Let $[1]_S$ be the category consisting of two objects $\{X, Y\}$ that $\text{Hom}(Z_1, Z_2) = 1_S$ for any $Z_1, Z_2 \in S$.

Let $C_0$ be the class of morphisms in $\mathcal{C}_S$ consisting of

- $\emptyset \to [0]_S$.
- The induced map $[1]_S \to [1]_{S'}$ where $S \to S'$ ranges over a generating class of cofibrations of $S$.

Prop. (3.7.7.4) [Model Category on $\mathcal{C}_S$]. Let $S$ be a combinatorial monoidal model category that every object of $S$ is cofibrant and the collection of weak equivalences of $S$ is stable under filtered colimits, then there exists a left proper combinatorial model structure on $\mathcal{C}_S$ that

- The class of cofibrations in $\mathcal{C}_S$ is the smallest weakly saturated class generated by $C_0$ defined in (3.7.7.3),
- The weak equivalences are as defined in (3.7.7.2).

Proof: Cf. [HTT, P856]. □

Cor. (3.7.7.5). Let $$ f : S \rightleftarrows S' : g $$

be a Quillen adjunction between monoidal model categories satisfying conditions in (3.7.7.4), then they induces a Quillen adjunction $$ F : \mathcal{C}_S \rightleftarrows \mathcal{C}_{S'} : G $$

and this is a Quillen equivalence if $(f, g)$ is.
**Proof:**

**Def. (3.7.7.6) [Local Fibrations].** Let $\mathcal{C}$ be an $S$-enriched category where $S$ is a monoidal model category, then a morphism $f \in \mathcal{C}$ is called an **equivalence** if it maps to an isomorphism in $h\mathcal{C}$.

$\mathcal{C}$ is called **locally fibrant** if for any $X, Y \in \mathcal{C}$, the mapping space $\text{Map}(X, Y)$ is fibrant in $S$.

An $S$-enriched functor $F : \mathcal{C} \to \mathcal{C}'$ is called a **local fibration** if the following conditions are satisfied:

- for any $X, Y \in \mathcal{C}$, the induced map $\text{Map}(X, Y) \to \text{Map}(FX, FY)$ is a fibration in $S$.
- the induced map $h\mathcal{C} \to h\mathcal{C}'$ is a quasi-fibration of categories.

**Def. (3.7.7.7) [Invertibility Hypothesis].** We say a monoidal model category $S$ satisfies the **invertibility hypothesis** if: For any cofibrant morphism $[1]_S \to \mathcal{C}(3.7.7.3)$ of $S$-enriched categories, and maps to a morphism $f$ which is invertible in the homotopy category $h\mathcal{C}$, take the pushout:

$$
\begin{array}{ccc}
[1]_S & \xrightarrow{i} & \mathcal{C} \\
\downarrow & & \downarrow j \\
[1]_S \tilde{\gamma} & \to \mathcal{C}(f^{-1})
\end{array}
$$

then $j$ is a weak equivalence of $S$-enriched categories.(3.7.7.2).

**Def. (3.7.7.8) [Excellent Model Category].** An **excellent model category** is a monoidal model category $S$ that The monoidal structure is symmetric.

- $S$ is combinatorial,
- Every monomorphism in $S$ is a cofibration, and the collection of cofibrations is stable under products,
- The class of weak equivalences in $S$ is stable under filtered colimits,
- $S$ satisfies the invertibility condition(3.7.7.7)

**Lemma (3.7.7.9).** Let $T : S \to S'$ be a monoidal functor between monoidal model categories satisfies axioms besides invertibility hypothesis, that is also a left Quillen functor, then if $S'$ satisfies invertibility hypothesis, so does $S$.

**Proof:** Cf.[HTT, P862].

**Prop. (3.7.7.10) [Dwyer, Kan].** The category of simplicial sets is an excellent model category with the Kan model structure and the Cartesian monoidal structures.

**Proof:**

**Prop. (3.7.7.11) [Fibration and Local Fibration].** If $S$ is an excellent model category, then

- An $S$-enriched category $\mathcal{C}$ is a fibrant object in $\text{Cat}_S$ iff it is locally fibrant.(3.7.7.6).
- Let $F : \mathcal{C} \to \mathcal{D}$ be an $S$-enriched functor and $\mathcal{D}$ is fibrant in $\text{Cat}_S$, then $F$ is fibrant in $\text{Cat}_S$ iff it is a local fibration.

**Proof:** Cf.[HTT, P863].
8 Examples

Prop. (3.7.8.1) [Kan Model Structure]. The category of Simplicial sets $\text{Set}_{\Delta}$ is a combinatorial left and right proper model category with
- Weak homotopy equivalences as weak equivalences.
- Inclusions as cofibrations,
- Kan fibrations as fibrations,

Proof: Cf. [Jardine P62].

Prop. (3.7.8.2). $\text{Set}_{\Delta}$ is a monoidal model category w.r.t the Cartesian product and the Kan model structure.

Proof: □

Prop. (3.7.8.3) [$q$-Model Structure]. For a unital ring $R$, then the category $\text{Comp}_{n \geq 0} R$ has the structure of a model category with a morphism $f : M \rightarrow N$ being
- a weak equivalence if $H_n(f)$ is isomorphism for any $n$.
- a fibration if $M_n \rightarrow N_n$ is surjective for any $n \geq 1$.
- a cofibration if $M_n \rightarrow N_n$ is injective with projective cokernel for any $n \geq 0$.

Proof: [Model category and simplicial methods, P5] or [Homotopy Theories and Model Categories].

Prop. (3.7.8.4) [Serre-Quillen]. The category $\text{Top}$ can be given a Serre-Quillen model structure with
- Weak equivalences: weak homotopy equivalence,
- Fibrations: Serre fibrations,
- Cofibrations: Retracts of morphisms $X \rightarrow Y$ where $Y$ is obtained from $X$ by attaching cells. And this restricts to a model category on the category $\text{CGH}$ of compactly generated weak Hausdorff spaces.

Proof: See (3.9.6.28).

Prop. (3.7.8.5) [Hurewicz-Strøm]. The category $\text{Top}$ can be given a Hurewicz-Strøm model structure with
- Weak equivalences: homotopy equivalences.
- Cofibrations: closed Hurewicz cofibrations.
- Fibrations: Hurewitz fibrations.

Proof: See (3.9.6.31).

Prop. (3.7.8.6) [Derived Category Model]. If $\mathcal{A}$ is an Abelian category with enough injectives, then $K^+(\mathcal{A})$ is a model category with
- Weak equivalence: quasi-isomorphisms,
- Fibration: epimorphisms with ker in $K^+(\mathcal{I})$,
- Cofibration: monomorphisms.
Proof: □

Prop. (3.7.8.7) [Joyal]. The

Prop. (3.7.8.8) [Reedy Model Structures]. Cf. [HTT, A.2.9].
3.8 Topology II

1 Topological Groups

Def. (3.8.1.1). A topological group is a group object in the category of groups (3.1.1.61).

Prop. (3.8.1.2). If $U$ is a nbhd of 1 in a topological group, then there is a nbhd $V$ of 1 that $VV \subset U$.

Proof: Consider the map $G \times G \to G$ continuous, and it maps $(1, 1)$ to $1 \in U$, so the preimage of $U$ contains a nbhd of $(1, 1)$, thus some $V_1 \times V_2$, then choose $V = V_1 \cap V_2$. □

Prop. (3.8.1.3). Let $G$ be a connected topological group, then for any nbhd $U$ of $e$, $G = \bigcup_{n=1}^{\infty} (U \cup U^{-1})^n$. In particular, any open subgroup of $G$ equals $G$.

Proof: This is because the RHS is an open subgroup of $G$, so all its cosets in $G$ are also open, so it equals $G$ as $G$ is connected. □

Prop. (3.8.1.4) [Separating Axioms]. For a topological group $G$, the following are equivalent:

- $e$ is a closed pt.
- $G$ is $T_1$.
- $G$ is Hausdorff($T_2$).
- $G$ is regular.
- $G$ is completely regular

Proof:

Prop. (3.8.1.5). Hausdorff topological group is completely regular.

Proof: Use a sequence of neighbourhood of identity to construct a uniform metric on $G$. Then set $\phi(x) = \min\{1, 2\sigma(a, x)\}$. Cf. [Abstract Harmonic Analysis Ross §8.4] □

Prop. (3.8.1.6). For a compact subset $K$ and a nbhd $U$ of $e$ in a topological group, there exists a nbhd $V$ of $e$ that $xVx^{-1} \subset U$ for any $x \in K$.

Proof: For any $x$, there exists a nbhd $W_x$ of $x$ and a nbhd $V_x$ of $e$ that $txt^{-1} \in U$ for any $t \in W_x$ and $y \in V_x$. Let f.m. $W_{x_i}$ cover $K$, then $V = \cap V_{x_i}$ satisfies the condition. □

Prop. (3.8.1.7). A compact open nbhd of $e$ in a Hausdorff topological group contains an open subgroup of $G$.

Proof: Cf. [Etale Cohomology Fulei P147] □

Prop. (3.8.1.8) [Homogenous Space]. Let $G$ be a topological group and $H$ a closed subgroup. $G/H$ is the quotient space in the quotient topology (3.6.1.8), then it is Hausdorff.

Proof: If $x \neq y$, then consider a preimage $xy^{-1} \in G\setminus H$, then we can find some open subset $V$ that $VV \subset G\setminus H$ by (3.8.1.2), thus $x + \overline{V} \cap \overline{y} + \overline{V} = \emptyset$. Hence $G/H$ is Hausdorff. □
Group Actions

Prop. (3.8.1.9) [Quotient by Group Action is Open]. Let \( G \times X \to X \) be a group action, then the quotient map \( \pi : X \to X/G \) is open.

Proof: This is because the \( \pi^{-1}(\pi(U)) = \bigcup_{g \in G} gU \).

Def. (3.8.1.10) [Regular Action]. An regular action is an action \( \gamma : G \times X \to X \) that satisfies the following equivalent conditions:
- the graph of \( \gamma \) in \( X \times X \) is closed.
- The diagonal \( \Delta \subset X \times X \) is closed.
- \( X/G \) is Hausdorff.

Proof: \( 2 \iff 3 \) is clear, for \( 1 \), notice \( X/G \times X/G \simeq (X \times X)/(G \times G) \), and the inverse image of \( \Delta \) in \( X \times X \) is just the graph of \( \gamma \).

Def. (3.8.1.11) [Proper Action]. A proper action is an action \( \gamma : G \times X \to X \) that the graph map \( \Gamma : G \times X \to X \times X \) is a proper map.

Prop. (3.8.1.12) [Proper Action is Regular]. A proper action of a group \( G \) on a locally compact Hausdorff space \( X \) is a regular action.

Proof: This follows from (3.6.2.12).

Def. (3.8.1.13) [Proper Discontinuous Actions]. A group action is called proper discontinuous iff any elements \( x, y \in H \) there are nbhds \( U_x, U_y \) that \( \{ g \in G | g(U_x) \cap U_y \neq \emptyset \} \) is finite.

Def. (3.8.1.14) [Covering Space Action]. A covering space action is action of a topological group \( G \) on a topological space \( Y \) is called if for any \( y \in Y \), there is a nbhd \( U \) that \( g(U) \cap U = \emptyset \) if \( g \neq 1 \).

Prop. (3.8.1.15) [Characterization of Proper Actions]. Let \( \gamma : G \times X \to X \) be a group action that \( X \) is Hausdorff, then \( \gamma \) is a proper action iff any \( K \subset X \) compact, the set \( G_K = \{ g \in G | g(K) \cap K \neq \emptyset \} \) is compact.

Proof: Let \( \Gamma : G \times X \to X \times X \) be the graph.

1 \to 2: \( G_K = \pi_1(\Gamma^{-1}(K \times K)) \), thus it is compact.

2 \to 1: Let \( L \subset M \times M \) be compact, then \( L \subset \pi_1(L) \times \pi_2(L) \), and \( L \) is closed. Let \( K = \pi_1(L) \cup \pi_2(L) \), then \( \Gamma^{-1}(L) \subset \Gamma^{-1}(\pi_1(L) \times \pi_2(L)) \subset G_K \times K \), which is a closed subset of a compact set, so \( \Gamma^{-1}(L) \) is compact, and \( \Gamma \) is a proper map.

Prop. (3.8.1.16). If \( G \) is a compact topological group, then any group action \( \gamma : G \times X \to X \) on a Hausdorff space \( X \) is proper.

Prop. (3.8.1.17) [Orbit of Proper Maps]. Let \( \theta \) be a proper action of \( G \) on a Hausdorff space \( X \), then each orbit map \( \theta^{(p)} \) is proper. In particular, if \( X \) is locally compact, then the orbits are all closed (3.6.2.12).

Proof: For any compact subset \( K \subset X \), \( (\theta^{(p)})^{-1}(K) \) is closed by continuity and is contained in \( G_K \cup \{p\} \), thus is compact.
Prop.(3.8.1.18)[Properly Discontinuous Map is Proper]. If $G$ acts properly discontinuously on a topological space $H$, then for any compact subsets $K_1, K_2 \in H$, $\{g \in G | K_2 \cap g(K_1) \neq \emptyset \}$ is finite. In particular, if $H$ is Hausdorff, then it is a proper action.

Proof: Notice for any two points we can find nbhds that f.m. $g$ intersects these two nbhds, so we can use the compactness to find f.m. pair of nbhds to cover $K_2$, and then use these nbhds to cover $K_1$ and finite the proof. □

Prop.(3.8.1.19)[Proper Free Action is a Covering Space Action]. Let $G \times X \to X$ be a proper free action on a locally compact Hausdorff space, then it is a covering space action.

Proof: For any $p \in X$, choose a precompact nbhd $U$ of $x$, then $G_U$ is finite, then shrink $U$. □

Prop.(3.8.1.20)[Continuity]. Let a topological group $G$ acts freely and properly on a space $X$. If $G$ and $X \rtimes G$ are both connected, then $X$ is connected.

Proof: If $U,V$ are open subsets of $X$ that $U \cap V = \emptyset, U \cup V = X$, then $\pi(U), \pi(V)$ are open by (3.8.1.9). Now $\pi(U) \cap \pi(V) = \emptyset$, because otherwise there is a $G$-orbit of $X$ intersecting both $U$ and $V$, contradiction the fact $G$ is connected. Then $\pi(U) = \emptyset$ or $\pi(V) = \emptyset$, thus $U = \emptyset$ or $V = \emptyset$, and $X$ is connected. □

Def.(3.8.1.21)[Constructible Action]. An action of a topological group $G$ on a topological space $X$ is called constructible if its graph is constructible in $X \times X$ (3.8.3.10).

Prop.(3.8.1.22). Let $\gamma : G \times X \to X$ be an action

- $\gamma$ is constructible iff the diagonal $\Delta_{X/G} \subset X/G \times X/G$ is constructible.
- If $\gamma$ is constructible and $X$ is non-empty, then there is a $G$-invariant open subset $U \subset X$ that $G$ acts regularly.
- For a constructible action, each $G$-orbit is locally closed.

Proof: Cf.[Bernstein-Zelevinsky, P54]. □

Totally Disconnectedness

Prop.(3.8.1.23). A compact topological group is totally disconnected iff the intersection of all compact open nbhds of $e$ equals $\{e\}$.

Proof: If it is totally disconnected, then $\{1\}$ is closed, so $G$ is Hausdorff (3.8.1.4), so by (3.6.1.24), the assertion is true. Conversely, if the intersection of all compact open nbhds of $e$ equals $\{e\}$, then $\{1\}$ is closed because $G$ is a group. □

Proof: Cf.[Etale Cohomology Fulei P147]. □
2 Hausdorff Geometry

Def. (3.8.2.1). The **Hausdorff distance** for two subset \( Y_1, Y_2 \in X \) is the
\[
d^H_X(Y_1,Y_2) = \inf \{ \varepsilon | Y_2 \subset B(Y_1,\varepsilon), Y_1 \subset B(Y_2,\varepsilon) \}.
\]
The **Gromov-Hausdorff metric** for two metric space is
\[
d^{GH}(X_1,X_2) = \inf \{ d^H_Z(i_1(X_1),i_2(X_2)) \}
\]
where \( i_1, i_2 \) are isometry of \( X_1, X_2 \) into a metric space \( Z \).

This metric makes the set of all compact metric space into a complete Hausdorff space \( M\mathcal{ET} \).

Def. (3.8.2.2). A map from \( X \) to \( Y \) is called a \( \varepsilon \) **approximation** iff \( B(f(X),\varepsilon) = Y \) and \( |d(x,y) - d(f(x),f(y))| \leq \varepsilon \).

We have: if there is a \( \varepsilon \) approximation, then \( d^{GH}(X,Y) \leq 3\varepsilon \), and if \( d^{GH}(X,Y) \leq \varepsilon \), there is a \( 3\varepsilon \) approximation.

Prop. (3.8.2.3). The set of isometries of

3 Spaces from Algebraic Geometry

Noetherian Space

Def. (3.8.3.1) [Noetherian Spaces]. A **Noetherian space** is a space \( X \in \mathcal{Top} \) that any descending chain of closed subsets stabilizes. A **locally Noetherian space** is a space \( X \in \mathcal{Top} \) that every point has a nbhd \( U \) s.t. \( U \) is a Noetherian space.

Prop. (3.8.3.2). A Noetherian space is quasi-compact and all subsets of it in the induced topology is Noetherian hence quasi-compact.

Proof: Let \( T \subset X \), for a chain of closed subsets \( Z_i \cap T \) of \( T, Z_1, Z_1 \cap Z_2, \ldots \) stabilize in \( X \), hence the chain stabilize in \( T \). \( \square \)

Prop. (3.8.3.3). If \( X \) can be covered by f.m. Noetherian subspaces, then \( X \) is Noetherian.

Proof: \( \square \)

Prop. (3.8.3.4) [Noetherian Space F.M. Irreducible Components]. A Noetherian space has only f.m. irreducible component, hence it has only f.m. connected components.

Proof: Let \( C \) be the family of closed subset that has infinitely many component, then there is a minimal object, but it is not irreducible, one of the component has infinitely many components and be smaller. \( \square \)

Quasi-Separated

Def. (3.8.3.5) [Quasi-Separated]. A space \( X \) is called **quasi-separated** if the diagonal morphism is quasi-compact(3.6.2.2). If \( X \) has a basis consisting of quasi-compact open subsets, then this is equivalent to any intersection of two quasi-compact open subsets is quasi-separated open.
Specialization & Generalization

Def.(3.8.3.6)[Specializations and Generalizations]. Let $X \in \text{Top}$ then $x$ is said to be a specialization of $y$ if $x \in \{y\}$. And in this case $y$ is said to be a generalization of $x$.

And they are called immediate specializations/generalizations if there are no other points $z \in X$ s.t. $y \to z \to x$.

Def.(3.8.3.7)[Going Up and Down]. A map $f$ of spaces is said to satisfy the going-up property iff specialization lifts along $f$. It is said to satisfy the going-down property iff generalization lifts along $f$.

Prop.(3.8.3.8). A closed map satisfies going-up.

Proof: If $y \to y'$, $f(x) = y$, consider $f(\{x\})$, it is closed and contains $y$, so it contains $y'$, thus the result. \qed

Constructible Set

Def.(3.8.3.9)[Retrocompact Subset]. A subset of $X$ is called retrocompact if the inclusion map is quasi-compact (3.6.2.2).

Def.(3.8.3.10)[Constructible Subset]. A subset of $X$ is called constructible if it is a finite union of sets of the form $U \cap V^c$ where $U,V$ are open and retrocompact in $X$. In the case when $X$ is Noetherian, by (3.8.3.2), all subsets are retrocompact hence constructible sets are just union of locally closed subsets of $X$.

A set of $X$ is called locally constructible if locally it is constructible. If $X$ is quasi-compact, then a locally constructible set is just a constructible set.

Prop.(3.8.3.11). Constructible subsets of $X$ forms a Boolean algebra.

Proof: Cf.[Sta]005H. \qed

Prop.(3.8.3.12)[Constructible and Subsets].

- If $U$ is open in $X$, then for any $E$ constructible in $X$, $E \cap U$ is constructible in $U$.
- If $U$ is retrocompact open and $E$ is constructible in $U$, then $E$ is constructible in $X$.

Proof: Easy. \qed

Prop.(3.8.3.13). Any constructible subsets of $X$ is retrocompact.

Proof: It suffices to prove $U_i \cap V_i^c \cap W$ is quasi-compact for $W$ quasi-compact, but this is because it is a closed subspace of the quasi-compact subspace $U_i \cap W$. \qed

Cor.(3.8.3.14). An open subset of $X$ is constructible iff it is retrocompact, a closed subset of $X$ is constructible iff its complement is retrocompact.((3.8.3.11) used).

Def.(3.8.3.15)[Constructible topology]. The constructible topology $X_{cons}$ on a quasi-compact space $X$ is generated by the open subsets $U, U^c$, where $U$ is a quasi-compact open.

Notice that the space is quasi-compact, so the constructible topology is the coarsest topology that every constructible subset of $X$ is both open and closed.
Prop. (3.8.3.16). Let $X$ be quasi-compact and quasi-separated, then any constructible subset of $X$ is quasi-compact. In particular, if $Y$ is closed in $X$, then $Y$ is constructible iff it is quasi-compact.

Proof: For $Y = \bigcup_{i=1}^{n} (U_i - V_i)$, with $U_i, V_j$ quasi-compact open in $X$, then $U_i - V_i$ is closed in $U_i$ thus quasi-compact, and then $Y$ is quasi-compact. \hfill \Box

Prop. (3.8.3.17). Let $E$ be a constructible subset of a space $X$, if $E$ is dense in then $E$ contains some open dense subset of its closure.

Proof: Let $Y = \bigcup_{i=1}^{k} Y_i$ where $Y_i$ are locally closed. Denote $Z_i = Y_i \setminus Y_i$, $Z = \bigcup Z_i$, $W = Y \setminus Z$. Then $W \subset Y$, and we show that $W$ is open dense in $Y$: As $Y_i$ are locally closed, $Y_i$ is open in $\overline{Y_i}$, thus $Z_i$ is closed, and $Z$ is closed, so $W$ is open in $Y$. To show $W$ is dense in $Y$: If some open subset $U$ of $Y$ satisfies $U \cup Z_i$, then $U$ cannot be contained in any $Z_i$, so we can inductively show $U \setminus Z_1, U \setminus (Z_1 \cup Z_2), \ldots$ are non-empty, which is a contradiction. \hfill \Box

Irreducible

Def. (3.8.3.18) [Irreducible Space]. A space is called irreducible iff there are no two nonempty nonintersecting open subsets. Thus an open subset of an irreducible set is dense and irreducible.

Prop. (3.8.3.19). If $Y$ is irreducible in $X$, then $\overline{Y}$ is also irreducible.

Proof: Any two nonempty open sets of $\overline{Y}$ must intersect $Y$ thus must intersect. \hfill \Box

Prop. (3.8.3.20). If $X \in \mathcal{Top}$ and $U \subset X$ is open, then $Y \mapsto \overline{Y}$ is a order preserving bijection between irreducible closed subspaces of $U$ and irreducible closed subspaces of $X$ meeting $U$.

Jacobson Space

Def. (3.8.3.21). Let $X$ be a space and $X_0$ the set of closed pts of $X$, then $X$ is called Jacobson iff $Z \cap X_0 = Z$ for every closed subset $Z$ of $X$. This is equivalent to every non-empty locally closed subset of $X$ contains a closed pt.

Thus there is a correspondence between closed subsets of $X_0$ and closed subsets of $X$, so they have the same Krull dimension.

Prop. (3.8.3.22). Being Jacobson is local. And for an open covering $U_i$ of $X$, $X_0 = \bigcup U_i$.

Proof: Firstly, if $X = \bigcup U_i$ where $U_i$ are Jacobson, $X_0 \cap U_i = U_i$. One direction is trivial, for the other, let $x$ be closed in $U_i$, then consider $\{x\} \cap U_j$. If $x \notin U_j$, then $x$ is closed in $U_j$, consider $T = \{x\} \cup (U_j - U_i \cap U_j)$, then $T$ is closed in $U_j$, so by hypothesis, closed pts of $U_j$ are dense in $T$, so $x$ must be closed in $U_j$, so $x$ is closed in $X$. Now clearly $X$ is Jacobson.

Conversely, if $X$ is Jacobson, for a closed subset $Z$ of $U_i$, $X_0 \cap Z$ is dense in $Z$, so $X_0 \cap Z$ is dense in $Z$, then clearly $U_i$ is Jacobson. \hfill \Box

Cor. (3.8.3.23). If $X$ is Jacobson, then any locally constructible sets of $X$ is Jacobson. And its closed pts are closed in $X$.

Proof: By the proposition, we only have to prove for constructible sets. For $T = \bigcup T_i$ where $T_i$ is locally closed, then a locally closed set in $T$ has a non-empty intersection $T \cap T_i$ which is also locally closed for some $i$.

Hence is has a closed pt in $X$ hence in $T$, so $T$ is Jacobson. The second assertion is implicit in the proof. \hfill \Box
**Prop. (3.8.3.24).** If $X$ is Jacobson, then an open set $U$ of $X$ is compact iff $U \cap X_0$ is compact, hence an open set $U$ is retrocompact iff $U \cap X_0$ is retrocompact.

Hence the constructible sets of $X$ correspond to the constructible sets of $X_0$. And irreducible closed subsets correspond to irreducible subsets of $X_0$.

**Krull Dimension**

**Def. (3.8.3.25).** The Krull dimension of a topological space is the length of the longest chain of closed irreducible subsets.

The local dimension $\dim_x(X) = \min\{\dim U | x \in U \subset X \text{ open in } X\}$.

**Prop. (3.8.3.26).** If $Y \subset X$, then $\dim Y \leq \dim X$, because the closure of any chain of $Y$ is a chain of $X$ by (3.8.3.19).

For an open covering $\{U_i\}$ of $X$, $\dim X = \sup \dim U_i$, because for any chain of closed irreducible subsets, if $U_i$ intersects the minimal one, then $\dim U_i = \text{length of this chain}$.

**Prop. (3.8.3.27).** $\dim X = \sup \dim_x(X)$.

**Proof:** The right is smaller than the left by (3.8.3.26), and for any chain $Z_0 \subset Z_1 \subset \ldots \subset Z_n$ of irreducible closed subset of $X$, if I choose a point $x \in Z_0$, then $\dim_x(X) \geq n$. □

**Prop. (3.8.3.28).** In case $X = \text{Spec } A$ for a Noetherian ring $A$, $\dim X = \sup \dim A_p$, because $A$ is of finite ?

**Def. (3.8.3.29) [Codimensions].** Let $X \in \text{Top}$ and $Y \subset X$ be an irreducible closed subspace, then the codimension of $Y$ in $X$ is defined to be the supremum of lengths $e$ of chains $Y = Y_0 \subset Y_1 \subset \ldots \subset Y_e = X$, denoted by $\text{codim}(Y, X)$.

**Sober Spaces**

**Def. (3.8.3.30) [Sober Spaces].** A space $X$ is called sober if every irreducible closed subset has a unique generic point.

**Prop. (3.8.3.31).** A sober space is $T_1$. Conversely, a finite $T_0$ space is sober.

**Proof:** The first assertion is because if $x \in \{y\}$ and $y \in \{x\}$, then $\{x\} = \{y\}$, and this irreducible closed subset has two generic point, contradiction.

If the space is finite, then for a closed irreducible subset $T = \{x_1, \ldots, x_n\}$, $T = \cup \{x_i\}$, as it is irreducible, $T = \{x_i\}$ for some $x_i$, and $i$ is unique as it is $T_1$, so $X$ is sober. □

**Prop. (3.8.3.32) [Soberization].** There is a left adjoint $t$ to the forgetful functor from the Sober spaces. $t(X)$ consists of irreducible closed subsets of $X$, and use $t(Y)$ for $Y$ closed as closed subsets. For a map $f : X \to Z$ to a sober space $Z$, the extension maps the generic point of an irreducible $Y$ to the generic point of the closure of $f(Y)$.

**Def. (3.8.3.33) [Zariski Space].** A Noetherian Sober space is called a Zariski space.
Catenary spaces and Dimension Functions

**Def. (3.8.3.34) [Catenary Space].** A space $X$ is called **catenary** iff for any inclusion of irreducible closed subsets of $X$, their codimension is finite and every maximal chain of irreducible closed subsets has the same dimension. This is equivalent to $\text{codim}(X,Y) + \text{codim}(Y,Z) = \text{codim}(X,Z)$.

**Prop. (3.8.3.35).** Catenary is a local property, by (3.8.3.20).

**Def. (3.8.3.36) [Dimension Function].** For $X \in \mathcal{T}_\text{op}$, consider the specialization relation (3.8.3.6), a **dimension function** is a function $\delta : |X| \to \mathbb{Z}$ that

- if $y$ is a specialization of $x$ in $X$, then $\delta(y) < \delta(x)$.
- if it is a direct specialization, then $\delta(y) = \delta(x) - 1$.

The dimension function is usually considered only when the space is sober.

**Prop. (3.8.3.37).** Let $X \in \mathcal{T}_\text{op}$ be sober and catenary with a catenary function, then $X$ is catenary, and if $x$ is a specialization of $x$ in $X$, then

$$\delta(x) - \delta(y) = \text{codim} \left( \overline{\{y\}}, \overline{\{x\}} \right).$$

**Proof:** This is clear from the definitions (3.8.3.29).

**Prop. (3.8.3.38).** If $X \in \mathcal{T}_\text{op}$ be locally Noetherian and sober, and $\delta, \delta'$ are two dimension functions on $X$, then $\delta - \delta'$ is locally constant on $X$.

**Proof:** We may assume $X$ is Noetherian, so it has only f.m. irreducible components by (3.8.3.4), then $\delta - \delta'$ is locally constant on the $X$ minus the irreducible components not passing through $x$ by (3.8.3.37).

**Prop. (3.8.3.39) [Catenary and Sober].** Let $X \in \mathcal{T}_\text{op}$ be locally Noetherian, sober, then $X$ is catenary iff any point $x \in X$ has a nbhd $U$ which has a dimension function.

**Proof:** Cf. [Sta]02IC. The other direction follows from (3.8.3.37) and (3.8.3.35).

Sober Spaces

**Def. (3.8.3.40) [Sober Spaces].** A space $X$ is called **sober** if every irreducible closed subset has a unique generic point.

**Prop. (3.8.3.41).** A sober space is $T_1$. Conversely, a finite $T_0$ space is sober.

**Proof:** The first assertion is because if $x \in \overline{\{y\}}$ and $y \in \overline{\{x\}}$, then $\overline{\{x\}} = \overline{\{y\}}$, and this irreducible closed subset has two generic point, contradiction.

**Prop. (3.8.3.42) [Catenary and Sober].** Let $X \in \mathcal{T}_\text{op}$ be locally Noetherian, sober and catenary, then any point $x \in X$ has a nbhd $U$ which has a dimension function.

**Proof:** Cf. [Sta]02IC.
4 Spectral Spaces

References are [Sta]5.23 and [Adic Spaces].

**Def. (3.8.4.1) [Spectral Space]**. A space is called spectral iff it is quasi-compact, quasi-separated(3.8.3.5), sober and the quasi-compact opens form a basis for the topology.

A space is called locally spectral iff it has an open covering by spectral spaces.

A morphism \( f : X \to Y \) between locally spectral spaces is called spectral if for any open spectral spaces \( U \subset f^{-1}(V) \), \( f : U \to V \) is quasi-compact.

**Prop. (3.8.4.2) [Connected Components]**. Let \( X \) be a spectral space, then any connected subset of \( X \) is an intersection of clopen subsets.

**Proof**: Let \( x \in X \) and \( S \) be the intersection of all clopen subsets of \( X \) containing \( x \), then it suffices to show \( S \) is connected. Suppose \( S = B \amalg C \) with \( B, C \) closed, then \( B, C \) are compact, thus there exist quasi-compact opens \( U, V \subset X \) that \( B = U \cap S, C = V \cap S \). Then \( U \cap V \cap S = \emptyset \). Now \( U \cap V \) is quasi-compact also, so there exists some clopen \( Z_\alpha \) containing \( x \) that \( Z_\alpha \cap U \cap V = \emptyset \).

Similarly, there exists some clopen \( Z_\beta \) containing \( x \) that \( Z_\beta \subset U \cup V \). Then \( Z_\gamma = Z_\alpha \cap Z_\beta \) is clopen and contained in \( U \Delta V \). Then both \( Z_\gamma \cap U \) and \( Z_\gamma \cap V \) is clopen, so \( U = \emptyset \) or \( V = \emptyset \).

**Cor. (3.8.4.3)**. Let \( X \) be a spectral space, then for a subset \( T \) of \( X \), \( T \) is an intersection of clopen subsets of \( X \) iff \( T \) is closed in \( X \) and is a union of connected components of \( X \).

**Proof**: If \( T \) is an intersection of clopen subsets, then \( T \) is clearly a union of connected components of \( X \). Conversely, if \( T \) is a union of connected components of \( X \), if \( x \notin T \), let \( C \) be a connected components containing \( x \). Then \( C \) is an intersection of clopen subsets, by (3.8.4.2). These subsets are closed under finite intersections, so by the compactness of \( T \), there is a clopen subset containing \( T \) but not \( x \), so we are done.

**Constructible Topology**

**Lemma (3.8.4.4)**. If \( X \) is a finite \( T_0 \) space, then it is spectral and every subset of \( X \) is constructible.

**Proof**: Cf.[Adic Space Morel, P26].

**Prop. (3.8.4.5)**. If \( X \) is a spectral space, then the constructible topology(3.8.3.15) is Hausdorff, totally disconnected and quasi-compact.

**Proof**: The space is sober hence \( T_0(3.8.3.41) \), and then the constructible topology is Hausdorff and totally disconnected.

To show quasi-compactness, it suffices to show that the family \( C \) of quasi-compact open and complement quasi-compact open subsets has the finite intersection property(3.6.2.3). Notice elements in \( C \) are all quasi-compact. Now if there is a family that has the finite intersection property by has intersection 0, by Zorn’s lemma, there is a maximal one of them, \( B \). Let \( Z \) be the intersection of all the closed subsets in \( B \), then it is non-empty as \( X \) is quasi-compact. And we claim \( Z \) is irreducible: otherwise \( Z = Z_1 \cup Z_2 \), thus there are quasi-compact open sets \( U_1, U_2 \) that \( U_1 \cap Z_1 \neq \emptyset, U_1 \cap Z_2 = \emptyset, U_2 \cap Z_2 \neq \emptyset, U_2 \cap Z_1 = \emptyset \). then let \( B_i = X - U_i \), then \( B_1, B_2 \) cannot by added to \( B \) by maximality, so there is a finite intersection \( T_1, T_2 \) that \( B_1 \cap T_1 = 0 \). But then \( Z \cap T_1 \cap T_2 = 0 \), but \( Z \) is an intersection of closed subsets, thus some finite intersection of closed subsets in \( B \) will \( \cap T_1 \cap T_2 = 0 \), contradiction.

So now \( Z \) is irreducible, but then for every element \( B \in B \), \( Z \cap B \) contains the generic point of \( Z \), thus the intersection of \( B \) is not empty, contradiction.
Cor. (3.8.4.6). Let $X$ be a spectral space, then
- The constructible topology is finer than the original topology.
- A subset $X$ is constructible iff it is clopen in the constructible topology of $X$.
- If $U$ is open in $X$, then the constructible topology induces the constructible topology on $U$.

Proof:
1: Every open subset of $X$ is a union of its quasi-compact open subsets, so it is open in the constructible topology.
2: Clearly constructible subset is clopen in the constructible topology. Conversely, if $Y$ is clopen, then $Y$ is a union of constructible subsets, but also it is quasi-compact, so it is a finite union of constructible subsets, thus constructible.

Prop. (3.8.4.7). If $E \subset X$ is closed in the constructible topology, then it is a spectral space with the induced topology, and the inclusion map is spectral.

Proof:  Cf. [Mor19] P34.

Prop. (3.8.4.8). For a set $E$ closed in the constructible topology in a spectral space,
- every point of $\overline{E}$ is a specialization of elements in $E$. Thus if $E$ is stable under specialization, then it is closed.
- If $E$ is open in the constructible topology and stable under generalization, then it is open.

Proof:  Cf. [Sta]0903.

Prop. (3.8.4.9). For a map between spectral spaces $f : X \to Y$, the following are equivalent:
- $f$ is spectral.
- $f$ is quasi-compact.
- $f : X_{cons} \to Y_{cons}$ is continuous.

And if this is true, then $f : X_{cons} \to Y_{cons}$ is proper.

Proof:  $1 \to 2 \to 3$ is trivial, an open subset of $X$ is quasi-compact iff it is clopen in the constructible topology (3.8.4.6), so $3 \to 2$. For $2 \to 1$, notice that if $U \subset f^{-1}(V)$ are open spectrals, and $W \subset U$ is quasi-compact open, then $f^{-1}W \cap U$ is quasi-compact open, because $X$ is quasi-separated.

Finally, $f$ is proper because $X_{cons}, Y_{cons}$ is compact Hausdorff (3.8.4.5), then use (3.6.2.10).

Criterion of Spectralness

Lemma (3.8.4.10). Let $X$ be a quasi-compact $T_0$ space that is has a subbasis consisting of quasi-compact open subsets that is stable under finite intersections. Let $X'$ be the topology generated by the quasi-compact open subsets and their complements, then the following are equivalent:
- $X$ is spectral.
- $X'$ is compact Hausdorff, and its topology has a basis consisting of open and closed subsets.
- $X'$ is quasi-compact.

Proof:  Cf. [Adic Space Morel P30].
Prop.(3.8.4.11) [Hochster’s Criterion of Spectrality]. Let $X' = (X_0, T')$ be a quasi-compact topological space, and let $\mathcal{U}$ be the family of clopen subsets of $T'$, let $T$ be the topology generated by $\mathcal{U}$, let $X = (X_0, T)$.

Then if $X$ is $T_0$, then it is spectral, and every element of $\mathcal{U}$ is quasi-compact open in $X$, and $X' = X_{cons}$.

Proof: Cf.[Adic Space Morel, P29]. □

Prop.(3.8.4.12) [Spectral and Inverse Limit]. A space is spectral iff it is a direct limit of finite sober($T_{1}(3.8.3.41)$) spaces.

Proof: Cf.[Sta]09XX. □

Prop.(3.8.4.13) [Spec and Spectral Space]. A spectral space is exactly the underlying space of spectrum of some ring.

Proof: The spectrum of a ring is qc: if $\cup D(f_i) = \text{Spec} A$, then $(f_i) = (1)$, so f.m. of them generate (1). And similarly it is quasi-separable and $D(f) = \text{Spec} A_f$ is quasi-compact. For the other direction, Cf.[M. Hochster. Prime ideal structure in commutative rings, Thm6]?.

Cor.(3.8.4.14). Every quasi-compact irreducible scheme is homeomorphic to an affine scheme.

Cor.(3.8.4.15) [Characterization of Spectral Spaces]. The following are equivalent for a topological space $T$:

1. $T \cong \text{Spec} R$ for some ring $R$.
2. $T \cong \varprojlim T_i$ where $\{T_i\}$ is an inverse system of finite $T_0$ spaces.
3. $T$ is spectral.

Proof: This follows from (3.8.4.13) and (3.8.4.12). □

w-localness

Def.(3.8.4.16) [pro-Zariski Localization]. A map of spectral spaces $f : W \to V$ is called a Zariski localization if $W = \coprod U_i$ where $U_i \to V$ is a quasi-compact open immersion. A pro-Zariski localization is a cofiltered limit of Zariski localizations of $V$.

Def.(3.8.4.17) [w-Local]. A spectral space is called w-local if the set of closed pts of $X$ is closed and any point of $X$ specializes to a unique closed pt. A morphism of w-local spaces are called w-local if it is spectral and maps closed pts to closed pts.

Prop.(3.8.4.18). If $X$ is w-local and $Y \subset X$ is a closed subset, then $Y$ is also w-local.

Proof: $Y$ is spectral by (3.8.4.7). $Y_0$ is closed because $Y_0 = Y \cap X_0$. And the second assertion is also trivial. □

Prop.(3.8.4.19). Let $X$ be a spectral space and $T$ profinite, then $Y = X \times_{\pi_0(X)} T$ is also spectral and $T = \pi_0(Y)$. If moreover $X$ is w-local, then $Y$ is also w-local and $Y \to X$ is w-local.

Proof: Cf.[Sta]096C. □
Def. (3.8.4.20) [Localization Along a Closed Set]. Given a closed set \( Z \) of a spectral set \( X \), the pro-open subset of \( X \) consisting of all points that specializes to a point of \( Z \) is called the localization of \( X \) along \( Z \). And \( X \) is called local along \( Z \) if \( X_0 \subset Z \).

Prop. (3.8.4.21). A spectral space that is local along a closed w-local subset \( Z \subset X \) with \( \pi_0(Z) \cong \pi_0(X) \), is also w-local.

Proof: \( X_0 = Z_0 \) is clearly closed, and if a pt \( x \) of \( X \) specializes to two closed pts of \( Z \), then the \( \pi_0 \) map is not injective, contradiction. \( \square \)
3.9 Algebraic Topology I: Homotopies

Main references are [Hat02], [AGP02], [同调论, 姜伯驹], [May99], [https://ncatlab.org/nlab/show/Introduction+to+Homotopy+Theory#HomotopyGroupsOftopologicalSpaces].

Notations (3.9.0.1).
- Use notations defined in Topology I.
- All spaces are assumed to be compactly generated, and products and mapping spaces are assumed to be compact generated versions.

1 Homotopy Types

Def. (3.9.1.1) [Retraction]. A retraction of a space $X$ to a subspace $A$ is a map $r : X \to A$ that $r|_A = \text{id}_A$.

Def. (3.9.1.2) [Homotopy]. A homotopy $f_t : X \to Y$ is a family of maps $f_t$ for every $t \in I$ that $f : X \times I \to Y$ is continuous. For two homotopies $F : X \times I \to Y$ and $F' : X \times I \to Y$ s.t. $F_1 = F'_0$, we can define the composite homotopy $F' \cdot F : X \times I \to Y$.

Two maps $f_0, f_1 : X \to Y$ are called homotopic if there is a homotopy $f_t : X \to Y$ connecting them. Homotopy relations are denoted by $f_0 \simeq f_1$.

Let $A$ be a subspace of $X$, then a homotopy relative to $A$ is a homotopy $f_t : X \to Y$ whose restriction to $A$ is fixed.

Let $E_1, E_2$ be spaces over $B$, then maps $f_0, f_1 : E_1 \to E_2$ over $B$ are called fiber homotopic if there is a homotopy $f_t : E_1 \to Y$ connecting them such that each $f_t$ are maps over $B$. Homotopy relations over $B$ are denoted by $f_0 \simeq_B f_1$.

Def. (3.9.1.3) [Homotopy Equivalences]. A map $f : X \to Y$ is called a homotopy equivalence if there is a map $g : Y \to X$ that $f \circ g \simeq \text{id}$ and $g \circ f \simeq \text{id}$.

A space having the homotopy type of a point is called contractible.

A map $f : X \to Y$ over $B$ is called a fiber homotopy equivalence if there is a map $g : Y \to X$ over $B$ that $f \circ g \simeq_B \text{id}$ and $g \circ f \simeq_B \text{id}$.

Def. (3.9.1.4) [Deformation Retraction]. A deformation retraction of a space $X$ onto a subspace $A$ is a homotopy $f_t : X \to X, t \in I$ that $f_0 = \text{id}, f_1(X) = A$ and $f_t|_A = \text{id}_A$ for all $t$.

Prop. (3.9.1.5). A map $X \to Y$ is a homotopy equivalence iff the mapping cylinder deformation retracts onto $X$.

Proof: ?

Def. (3.9.1.6) [Excisive Triads]. A triad of spaces is a triple $(X; A, B)$ s.t. $A \subset X, B \subset X$. An excisive triad is a triad $(X; A, B)$ s.t. $A^o \cup B^o = X$.

Relative Spaces

Def. (3.9.1.7) [Relative Spaces]. The category $\mathcal{G}_\text{rel}$ is the category of pairs $(X, A)$ where $A \subset X \in \mathcal{G}$, and morphisms in $\mathcal{G}_\text{rel}$ are equivariant maps.

Def. (3.9.1.8) [Smash Products]. smash products in $\mathcal{G}_\text{rel}$ are defined to be $(X, A) \land (Y, B) = (X \times Y, (X, A) \vee (Y, B))$, where $(X, A) \cup (Y, B) = X \times B \cup A \times Y \subset X \times Y$. 

Show/Introduction+to+Homotopy+Theory#HomotopyGroupsOftopologicalSpaces
Def. (3.9.1.9) [Cones and Suspensions]. For \((X, A) \in \mathcal{Top}^{\text{rel}}\), the cone over \((X, A)\) is defined to be \(C(X, A) = (X, A) \wedge (I, \{1\})\). The suspension of \((X, A)\) is defined to be \(\Sigma(X, A) = (X, A) \wedge S^1\).

Prop. (3.9.1.10) [\(\mathcal{CG}^{\text{rel}}\) is Closed]. For \((X, A), (Y, B), (Z, C) \in \mathcal{CG}^{\text{rel}}\), by (3.6.3.15) there is a homeomorphism
\[
\text{Map}((X, A) \wedge (Y, B), (Z, C)) \cong \text{Map}((X, A), \text{Map}(Y, B), (Z, C)).
\]
In particular, \(\mathcal{CG}^{\text{rel}}\) is a closed symmetric monoidal category.

Def. (3.9.1.11) [Pointed Spaces]. The category \(\mathcal{CG}^{\text{pt}}\) is the subcategory of \(\mathcal{CG}^{\text{rel}}\) consisting of pairs \((X, A)\) s.t. \(A \cong \text{pt}\). It is stable under finite products.

We can define similarly homotopies of maps between pointed spaces, and denote \((X, Y)\) the homotopy classes of maps from \(X\) to \(Y\).

Def. (3.9.1.12) [Smash Products]. For \(X, Y \in \mathcal{CG}^{\text{pt}}\), the smash product \(X \wedge Y\) is defined to be \(X \wedge Y = X \times Y / X \wedge Y\), where \(X \vee Y = X \coprod Y\), called the wedge sum of \(X\) and \(Y\). Similar to (3.9.1.9), we can define cones and suspensions of pointed spaces.

Then the smash product and wedge sums are commutative and associative, and they satisfy
\[
(X \vee Y) \wedge Z = X \wedge Z \vee Z \wedge Z.
\]
Because of (3.9.1.14), the smash product and wedge sums are also denoted by \(X \otimes Y\) and \(X \oplus Y\).

Proof: For the identities, use the fact product commutes with colimits (3.6.3.16).

Prop. (3.9.1.13) [Smash Products, and Homotopy]. Suspensions preserves homotopy, as \(\Sigma(X \wedge I) = X \wedge I \wedge S^1 \cong (X \wedge S^1) \wedge I\).

Prop. (3.9.1.14) [\(\mathcal{CG}^{\text{pt}}\) is Closed]. For \(X, Y, Z \in \mathcal{CG}^{\text{pt}}\), by (3.9.1.10), there is a bijection
\[
\text{Map}(X \wedge Y, Z) \cong \text{Map}(X, \text{Map}(Y, Z)).
\]
In particular, \(\mathcal{CG}^{\text{pt}}\) is a closed symmetric monoidal category.

Def. (3.9.1.15) [Well-Pointed Spaces]. A pointed space \((X, *) \in \mathcal{CG}^{\text{pt}}\) is called a well-pointed space if \(* \to X\) is a cofibration. The category of well-pointed spaces is denoted by \(\mathcal{CG}^{\text{well-pt}}\).

Def. (3.9.1.16) [Augmentation]. There is a functor \(\mathcal{CG} \to \mathcal{CG}^{\text{well-pt}} : X \mapsto X_+ = (X \coprod \text{pt}, \text{pt})\).

Prop. (3.9.1.17). The cone construction
\[
\mathcal{Top}^{\text{rel}} \to \mathcal{Top} : (X, A) \mapsto C(A \to X)
\]
preserves homotopy equivalence.

Prop. (3.9.1.18) [Path Spaces and Loop Spaces]. For \(X \in \mathcal{CG}^{\text{pt}}\), define the path space \(P(X) = \text{Map}((I, \{0\}), X)\), and define the loop space \(\Omega(X) = \text{Map}(S^1, X)\).

Then by (3.9.1.14), there are homeomorphism of spaces
\[
\text{Map}(\Sigma(X), Y) \cong \text{Map}(X, \Omega(Y)).
\]
Thus also
\[
\langle \Sigma(X), Y \rangle \cong \langle X, \Omega(Y) \rangle.
\]

Def. (3.9.1.19) [Weak Products]. For \(\{X_\alpha\}_\Sigma \in \mathcal{CG}^{\text{pt}}\), define the weak product \(\prod' X_\alpha\) as
\[
\prod' X_\alpha = \lim_{S \subset \Sigma, \#S < \infty} \bigvee_{i \in S} X_i
\]
with base point \(\prod *\).
2 Isotopies

Prop.(3.9.2.1)[Alexander’s Trick]. If \( f, g : \mathbb{D}^n \to \mathbb{D}^n \) be two self-homeomorphisms that there is an isotopy \( F : \mathbb{D}^n \times I \to \mathbb{D}^n \) between \( f|_{\partial \mathbb{D}^n} \) and \( g|_{\partial \mathbb{D}^n} \), then there exists an isotopy between \( f \) and \( g \) extending \( F \).

Proof: Firstly, if \( g = \text{id}_{\mathbb{D}^n} \) and \( f \) fixes every points on the boundary, then an isotopy connecting \( f \) to the identity is given by

\[
J(x, t) = \begin{cases} 
  tf(x/t), & 0 \leq ||x|| < t \\
  x, & t \leq ||x|| \leq 1
\end{cases}
\]

In general, isotopy \( g^{-1}F : \mathbb{D}^n \times I \to \mathbb{D}^n \) between \( g^{-1}f|_{\partial \mathbb{D}^n} \) and \( \text{id}_{\mathbb{D}^n} \) can be extended to an isotopy from \( F' : \text{Cone}(g^{-1}f|_{\partial \mathbb{D}^n}) \) to \( \text{id}_{\mathbb{D}^n} \). Then \( \text{Cone}(g^{-1}f|_{\partial \mathbb{D}^n}) \) and \( g^{-1}f \) are identical on \( \partial \mathbb{D}^n \), so by the argument above, they are isotopic. Then \( g^{-1}f \cong \text{id}_{\mathbb{D}^n} \), which gives an isotopy between \( f \) and \( g \). □

Prop.(3.9.2.2). Any orientation-preserving self-homeomorphism \( f \) of \( S^d \) is isotopic to \( \text{id}_{S^d} \).

Proof: By the decomposition of \( S^d \) into two hemispheres and using the annulus theorem (3.6.11.2), we see we can isotopy \( f \) to a map that fixes the equator. Then we can use Alexander’s trick (3.9.2.1). □

3 CW Complexes

Def.(3.9.3.1)[CW Complexes]. A CW complex is a space \( X \) that \( \varnothing \to X \) is cofibrantly generated by \( S^n \to \mathbb{D}^n \).

For a CW complex \( X \), a representation of \( X \) is given as follows:

- \( \text{sk}_0 X \) is a discrete set, whose elements are regarded as 0-cells.
- Inductively, form the \( n \)-skeleton \( \text{sk}_n X \) from \( \text{sk}_{n-1} X \) by adding \( n \)-cells \( e^n_\alpha \) via maps \( \varphi_\alpha : S^{n-1} \to \text{sk}_{n-1} X \).
- Let \( X = \bigcup \text{sk}_n X \) be given the quotient topology from \( \coprod \text{sk}_n X \).

We will also call the image of \( e^n_\alpha \) as an \( n \)-cell. The category of CW complexes is denoted by \( \mathcal{CW} \). Any CW complex is compactly generated, by definition.

Def.(3.9.3.2)[Sub-CW Complexes]. For a CW complex \( X \), a subcomplex \( Y \subseteq X \) is a subspace \( Y \subseteq X \) s.t. the cells with images in \( Y \) makes \( Y \) a CW complex.

Def.(3.9.3.3)[Finite CW Complexes].

- A CW complex of finite dimension is a CW complex \( X \) s.t. \( X = \text{sk}_n X \) for some \( n \in \mathbb{N} \).
- A CW complex of finite type is a CW complex \( X \) that has only finitely many \( n \)-cells for each \( n \).
- A finite CW complex is a CW complex that is both of finite dimensional and of finite type.
- A locally finite CW complex is a CW complex that each cell intersect only f.m. other cells.

Prop.(3.9.3.4)[Dimension of CW Complexes]. Given a representation of a CW complex of finite dimension \( X \), \( \text{dim} X \) is defined to be the minimal \( n \) s.t. \( X = \text{sk}_n X \). Then this dimension is independent of the presentation given.
Proof:

Prop. (3.9.3.5). Any compact subspace $K$ of a CW complex $X$ is contained in a finite subcomplex. In particular, a CW complex is compact iff it is finite.

Proof: Firstly $K$ intersects with only f.m. interiors of cells of $X$ (where we assume the interior of a point in $sk_0 X$ is the point itself): otherwise take $S = \{x_1, x_2, \ldots\}$ be an infinite sequence of points lying in different cells, then $S \cap e_\alpha$ is closed for any cell $e_\alpha$ of $X$, so $S$ is closed. But the same argument show any single point of $S$ is also closed, so $S$ is discrete, so $S$ is finite, contradiction.

Then it suffices to show that any cell meets only f.m. cells: for this we can use induction on dim $X$, and notice that for any cell $e_\alpha$, the image of its attaching map is compact.

Prop. (3.9.3.6) [Miyazaki]. Any CW complex is paracompact Hausdorff, thus also normal by (3.6.7.6).

Proof: To show it is Hausdorff, for any two points $x, y$, it is not hard to find disjoint precompact nbhds of $x, y$ by induction on cells.

To show it is paracompact, Cf. [Rudolph Fritsch and Renzo Piccinini, Cellular Structures in Topology] Thm1.3.5.

Prop. (3.9.3.7). A CW complex is locally compact iff it is locally finite. A connected CW complex is metrizable iff it is locally finite.

Prop. (3.9.3.8) [Product of CW Complexes]. For $X, Y \in CW$, then the compactly generated product space $X \times_c Y$ admits a CW complex structure with

$$sk_n X = \bigcup_{i+j=n} sk_i X \times sk_j Y.$$ 

And if either $X$ or $Y$ is locally compact or both $X, Y$ have countably many cells, then $X \times_c Y = X \times Y$.

Proof: Given presentations of CW complexes of $X, Y$, we can define the CW complex structure on $X \times Y$ by choosing homeomorphisms of pairs

$$(D^n, S^n) \cong (D^p \times D^q, D^p \times S^{q-1} \cup S^{p-1} \times D^q),$$

where $p + q = n$. Then it is a CW structure on $X \times_c Y$ by (3.6.3.16).

For the last assertion, the case $X$ is locally compact follows from (3.6.2.33). The case that $X, Y$ both have countably many cells follow from [Hatcher, P524].

Prop. (3.9.3.9) [Cellular Maps]. Given $X, Y \in CW$, a cellular map $f : X \to Y \in CW$ is a map s.t. $f(sk_n X) \subset sk_n Y$ for any $n \in \mathbb{N}$. And a cellular homotopy between two cellular maps $f, g : X \to Y$ is a homotopy $F : X \times I \to Y$ between $f$ and $g$ s.t. $F$ is a cellular map.

Prop. (3.9.3.10) [CW Structure on Compact Manifolds]. $\text{Mani}_{\text{cpt}} \in CW^{\text{fin}}$.

Proof:
Prop. (3.9.3.12) [Pathspace is CW Complex]. The homotopy fibers (3.6.3.18) of any map \( f: A \to B \) between CW complexes are homotopic to a CW complex.

Proof: [Milnor, 1959]. or [Rudolph Fritsch and Renzo Piccinini, Cellular Structures in Topology]. □

Cor. (3.9.3.13) [Loop Space]. For \( X \in CW^pt \), the loop space (3.6.3.19) \( \Omega X \) is homotopic to a pointed CW complex. In particular, if \( X \) is of f.t., then so does \( \Omega X \).

Proof: This is a special case of (3.9.3.12) applied to \( A = \{*\} \), by (3.6.3.20). □

Common CW complexes

Def. (3.9.3.14) [Infinite Vector Spaces]. Let \( K = \mathbb{R}, \mathbb{C} \) or \( \mathbb{H} \), then the **infinite vector space** \( K^\infty \) is the CW complex \( \lim_n^\infty K^n \).

There can be given a norm map on \( K^\infty \), as the canonical embedding is norm preserving.

Prop. (3.9.3.15) [Grassmannian]. Let \( K = \mathbb{R}, \mathbb{C} \) or \( \mathbb{H} \), then the **Grassmannian** \( \text{Gra}(k, K^n) \) admits a CW complex structure.

Proof: Cf. [Algebraic Topology Miller, P46] or [Characteristic Classes, Milnor]. □

Def. (3.9.3.16) [Infinite Grassmannian]. Let \( K = \mathbb{R}, \mathbb{C} \) or \( \mathbb{H} \), then the **infinite Grassmannian** \( \text{Gra}(k, K^\infty) \) is the CW complex \( \lim_n^\infty \text{Gra}(k, K^n) \) (11.6.2.12).

In particular, \( \text{Gra}(1, K^\infty) \cong \lim_n^\infty K P^n \) is defined to be the **infinite projective space** \( K P^\infty \).

Def. (3.9.3.17) [Infinite Stiefel Manifold]. Let \( K = \mathbb{R}, \mathbb{C} \) or \( \mathbb{H} \), then the **infinite Stiefel Manifold** \( V_k(K^\infty) \) is the CW complex \( \lim_n^\infty V_k(K^n) \) where \( V_k(K^n) \) is the set of orthonormal \( k \)-frames (11.6.2.12).

\( V_1(K^\infty) = \lim_n^\infty S^n \) is called the **infinite sphere**. It is isomorphic to

\[
S^\infty = \lim_n^\infty S^{2k+1} = \lim_k^\infty C^{2k+1}\backslash \{0\}/\mathbb{R}^+ = (C^\infty\backslash \{0\})/\mathbb{R}^+.
\]

Prop. (3.9.3.18). \( V_k(K^\infty) \) is contractible.

Proof: We prove for \( S^\infty \), the proof for \( V_k(K^\infty) \) is verbatim, using Smith orthogonalization.

There is a map \( H: S^\infty \times I \to S^\infty \) defined by

\[
H((x_1, x_2, \ldots), t) = ((1 - t)x_1, tx_2 + (1 - t)x_1, tx_3 + (1 - t)x_2, \ldots)/N
\]

where \( N \) is the norm of the non-zero element \( ((1 - t)x_1, tx_2 + (1 - t)x_1, tx_3 + (1 - t)x_2, \ldots) \). The image of \( H_1 \) is in the subspace \( S^\infty_0 \) of elements \( (x_1, x_2, \ldots) \) with \( x_1 = 0 \). Notice there is another map \( H': S^\infty_1 \times I \to S^\infty \) defined by

\[
H'((0, x_2, \ldots), t) = (t, (1 - t)x_2, (1 - t)x_3, \ldots)/N'
\]

where \( N' \) is the norm of the non-zero element \( (t, (1 - t)x_2, (1 - t)x_3, \ldots) \). Then the composition homotopy \( (H' \circ H_1) \cdot H \) gives the desired homotopy from \( \text{id}_{S^\infty} \) to a constant map. □
Prop. (3.9.3.19). $\mathbb{R}P^\infty = S^\infty/\{\pm 1\} = (\mathbb{C}^\infty \backslash \{0\})/\mathbb{R}^\times$.

Def. (3.9.3.20) [James Reduced Product]. Let $X$ be a space with a basepoint $e$, let the James reduced product space $J(X)$ be the quotient of $\prod_n X^n$ under the identification $(x_1, \ldots, x_j, \ldots, x_n) \sim (x_1, \ldots, \hat{x}_j, \ldots, x_n)$ if $x_j = e$.

$J(X)$ is a union of subspaces $J_m(X)$, where $J_m(X)$ is the quotient space of $X^m$ under the identification $(x_1, \ldots, x_j, \ldots, x_n) \sim (x_1, \ldots, e, x_j, \ldots, x_n)$. If $(X, e)$ is a CW-pair, then $J_m$ is obtained from $X^m$ by gluing together its $m$ subcomplexes where one of the coordinates is $e$. It is then clear $J$ is a CW complex.

Def. (3.9.3.21) [Infinite Symmetric Product]. Let $X$ be a space with a basepoint $e$, define the infinite symmetric product as the quotient of $J(X)$ by permutations. If $X$ is a simplicial complex, then $SP(X)$ is a CW-complex.

Proof: Cf.[Hat02]P482.

4 Homotopy Groups

Def. (3.9.4.1) [Homotopy Groups]. For $(X, *) \subset \mathcal{Top}^pt$ and $n \in \mathbb{N}$, define the homotopy groups $\pi_n(X) = \pi_n(X, *) = \langle S^n, X \rangle$, which is a pointed set.

And $\pi_1(X)$ is a group as $S^1$ has a cogroup structure: $S^1 \to S^1 \wedge S^1$. Similarly, $\pi_n(X) = \pi_1(\Omega^{n-1} X)$ are also groups, and the group structure are given by the cogroup structure $S^n \to S^n \wedge S^n$.

Prop. (3.9.4.2) [Loop Spaces and Homotopy Groups]. $\pi_{i+1}(M) \cong \pi_i(\Omega(M))$.

Proof: This follows from the fact $S^n = \Sigma^n(S^0)$ and (3.9.1.18).

Prop. (3.9.4.3) [Homotopy Groups are Abelian]. For $X \in \mathcal{CG}^pt$, the homotopy group $\pi_n(X)$ is an Abelian group for $n \geq 2$.

Proof: By (3.9.4.2), it suffices to show for $n = 2$, and $\pi_2(X) = \pi_1(\Omega X)$ is Abelian by (3.10.2.30) and (3.10.2.24).

Cor. (3.9.4.4). For any $X \in \mathcal{CG}$, $\langle \Sigma(X), Y \rangle$ is a group and $\langle \Sigma^2(X), Y \rangle$ is an Abelian group.

Prop. (3.9.4.5) [Homotopy Groups and Change of Basepoints]. Let $X \in \mathcal{CG}$ and $\gamma : I \to X$ be a path from $a$ to $b$, then for any $n \in \mathbb{Z}_+$, we can define a map $\gamma_\# : \pi_n(X, a) \to \pi_n(X, b)$ as follows: For any $f : (I^n, \partial I^n) \to (X, a)$, identity $I^n$ with the subspace of $\mathbb{R}^n$ consisting of vectors $x$ s.t. $d(x) \leq \frac{1}{2}$, where $d((x_1, \ldots, x_n)) = \min(|x_i|)$, and

$$\gamma_\#(f) : (I^n, \partial I^n) \to X : x \mapsto \begin{cases} f(2x), & ||x|| \leq \frac{1}{4} \\ \gamma(4||x|| - 1), & \frac{1}{4} \leq ||x|| \leq 1 \end{cases}$$

Then for any $x_0 \in X$, this defines an actions of $\pi_1(X, x_0)$ on $\pi_n(X, x_0)$ by group homomorphisms for any $n \in \mathbb{Z}_+$. And for $n = 1$, this is just the conjugation action.

Proof: It is a well-defined action because any homotopy between two maps $f_1, f_2 : (I^n, \partial I^n) \to (X, a)$ can generate a homotopy between $\gamma_\#(f_1)$ and $\gamma_\#(f_2)$, and it is an action by group homomorphism because there is a homotopy between $\gamma_\#(f) \cdot \gamma_\#(g)$ and $\gamma_\#(f \cdot g)$, which is easy to write out.
Def.(3.9.4.6)[Simple Spaces]. A space $X \in \mathcal{S}$ is called a simple topological space if for any $x_0 \in X$, the action of $\pi_1(X, x_0)$ defined in (3.9.4.5) is trivial.

Def.(3.9.4.7)[Weak Homotopy Equivalences]. $f : X \rightarrow Y \in \mathcal{S}$ is called a weak homotopy equivalence if it induces isomorphism $\pi_n((X, x_0)) \cong \pi_n(Y, f(x_0))$ for any $n \in \mathbb{N}$ and $x_0 \in X$.

Prop.(3.9.4.8). Let $f_0, f_1 : X \rightarrow Y \in \mathcal{S}$ be maps and $h : I \times X \rightarrow Y$ be a homotopy $x_0 \in X$, then if $\gamma : I \rightarrow Y : t \mapsto h(t, x_0)$, then

$$\gamma_\# \circ \gamma_\#(f_0)_* = (f_1)_*.$$

Proof: For $f : f : (I^n, \partial I^n) \rightarrow (X, x_0)$ is easy to write out a homotopy between $\gamma_\#(f_0)_*(f)$ and $(f_1)_*(f)$. \qed

Cor.(3.9.4.9). Any homotopy equivalence is a weak homotopy equivalence.

Def.(3.9.4.10)[Relative Homotopy Groups]. For an inclusion $i : (A, *) \subset (X, *) \in \mathcal{Top}_{pt}$, $n \in \mathbb{Z}_+$, define the relative homotopy groups $\pi_n(X, A) = \pi_n(X, A, *) = \pi_{n-1}(P(X; *, A))$, where $P(X; *, A)$ is the homotopy fiber of $i$. Equivalently, if we denote $J^n = \partial I^n \times I \cup I^{n-1} \times \{0\} \subset I^n$ for $n \geq 2$ and $J^1 = \{0\} \subset I^1$, then

$$\pi_n(X, A) = [(I^n, \partial I^n, J^n), (X, A, *)].$$

This is a pointed set for $n = 1$, a group for $n = 2$, and an Abelian group for $n \geq 3$.

Prop.(3.9.4.11)[Long Exact Sequence of Relative Homotopy Groups].

Proof: \qed

Cor.(3.9.4.12)[Covering Spaces and Homotopy Groups]. If $E \rightarrow B$ is a covering space, then $\pi_n(E) \rightarrow \pi_n(B)$ is an isomorphism for $n \geq 2$.

Prop.(3.9.4.13). If $X \in \mathcal{S}_{pt}$ is contractible, then $\pi_n(X) = 0$ for any $n \geq 0$.

Prop.(3.9.4.14)[Products and Homotopy Groups]. For $X, Y \in \mathcal{S}_{pt}$, $\pi_n(X \times Y) = \pi_n(X) \times \pi_n(Y)$ for any $n \in \mathbb{N}$.

Prop.(3.9.4.15)[Colimits and Homotopy Groups]. If $X = \lim\nolimits_i X_i \in \mathcal{S}_{pt}$ is a filtered colimits, there are natural isomorphisms

$$\lim\nolimits_i \pi_n(X_i) \cong \pi_n(X)$$

for each $n \in \mathbb{N}$.

Proof: This follows from the fact any compact subset of $X$ is contained in some $X_i$. \qed

Def.(3.9.4.16)[n-Connectedness]. For $n \in \mathbb{N}$, $(X, A) \in \mathcal{S}_{rel, pt}$ is called $n$-connected if $\pi_i(X, A) = *$ for any $i \leq n$. $X \in \mathcal{Top}_{pt}$ is called $n$-connected if $\pi_i(X) = *$ for any $i \leq n$.

Def.(3.9.4.17) [$n$-Equivalences]. For $n \in \mathbb{Z}_+$, $f : (X, A) \rightarrow (Y, B) \in \mathcal{Top}_{rel}$ is called an $n$-equivalence if $f_* : \pi_p(X, A) \rightarrow \pi_p(Y, B)$ are isomorphisms for $p < n$, and surjective for $p = n$.

Thm.(3.9.4.18)[Excision for Homotopy Groups]. If $m, n \geq 0$, $(X; A, B)$ is an excise triad s.t. $(A, A \cap B)$ is $m$-connected and $(B, A \cap B)$ is $n$-connected, then $(A, A \cap B) \rightarrow (A \cup B, A)$ is an $m + n$-equivalence.
Proof: Cf.[Hatcher P360].

**Cor. (3.9.4.19).** For \( n > 1 \), \( \pi_n(\bigvee S^n) \) is free Abelian with \( \pi_n(S^n) \) as generators. This is because \( (\prod S^n, \bigvee S^n) \) is \((2n - 1)\)-connected thus use excision, because \( \pi_n(\prod S^n) \) is easy to calculate.

**Prop. (3.9.4.20).** If \( f : X \to Y \) is an \( n \)-equivalence between \((n - 1)\)-connected spaces, then the quotient map \( pr : (M(f),X) \to (C(f),*) \) is an \( 2n \)-equivalence. And if \( X,Y \) are both \( n \)-connected, then \( pr \) is an \( 2n + 1 \)-equivalence.

**Proof:**

**Cor. (3.9.4.21) [Quotients and Homotopy Groups].** For \( n \in \mathbb{Z}_+ \), if \( i : A \to X \) is a cofibration that is a \( (n - 1) \)-equivalence of \((n - 1)\)-connected space, then the map \( (X,A) \to (X/A,*) \) is an \( 2n \)-equivalence. And if \( A, X \) are \( n \)-connected, then this is a \( 2n + 1 \)-equivalence.

**Proof:** This follows from the commutative diagram

\[
\begin{align*}
(M(i), A) & \longrightarrow (C(i), *) \\
\downarrow & \\
(X, A) & \longrightarrow (X/A, *)
\end{align*}
\]

where the vertical maps are homotopy equivalences, by (3.9.6.7).

**Prop. (3.9.4.22) [Suspension and Homotopy Groups, Freudenthal].** For \( X \in \mathcal{G}^{\text{well-pt}} \), there are maps

\[
\Sigma_* : \pi_p(X) \to \pi_{p+1}(\Sigma(X)) : f \in \langle S^p, X \rangle \mapsto \Sigma(f) \in \langle S^{p+1} \cong \Sigma(S^p), \Sigma(X) \rangle
\]

Then if \( n \in \mathbb{N}, X \in \mathcal{G}^{\text{well-pt}} \) and \( X \) is \( n \)-connected, then \( \Sigma_* \) is bijective for \( p \leq 2n \) and surjective for \( p = 2n + 1 \).

In particular, \( \Sigma^n(X) \) is \((n - 1)\)-connected.

**Proof:** Cf.[May, P85].

**Def. (3.9.4.23) [Stable Homotopy].** For \( X \in \mathcal{G}^{\text{well-pt}} \), using the suspension (3.9.4.22), we can form the colimit

\[
\pi^*_p(X) = \lim_{n \in \mathbb{N}} \pi_{p+n}(\Sigma^n(X)).
\]

Then by (3.9.4.22),

\[
\pi^*_p(X) = \pi_{p+n}(\Sigma^n(X)), \quad n \geq p + 2.
\]

**Prop. (3.9.4.24).** The homotopic direct limit of a family of homotopy equivalence is a homotopy equivalence. Cf.[Morse Theory Milnor].

**Fundamental Groups**

**Def. (3.9.4.25) [Simply Connected].** A space is called **simply connected** if it is connected and \( \pi_1(X, x) = 0 \) for some point \( x \in X \).

**Def. (3.9.4.26) [Semilocally Simply Connected].** A space is called **semilocally simply connected** if for any point \( x \in X \), there is a nbhd \( U \) of \( x \) that the image of the inclusion-induced map \( \pi_1(U, x) \to \pi_1(X, x) \) is trivial.
Prop. (3.9.4.27) [Van Kampen]. If $X$ is a union of path-connected subsets $A_{\alpha}$ all containing $x_{0}$ that $A_{\alpha} \cap A_{\beta}$ and $A_{\alpha} \cap A_{\gamma}$ are all path-connected, then $\ast \pi_{1}(A_{\alpha})/\sim$ where $\sim$ is generated by $i_{\ast}(\pi_{1}(A_{\alpha} \cap A_{\beta})) \in \pi_{1}(A_{\alpha}) \sim i_{\ast}(\pi_{1}(A_{\alpha} \cap A_{\beta})) \in A_{\beta}$ for every $\alpha, \beta$.

Proof: Cf. [Hatcher P52].

Prop. (3.9.4.28) [Wedge Sums]. If $X_{i} \in \mathcal{C}^{\text{well-pt}}$ and $X = \bigvee X_{i}$, then $\pi_{1}(X) = \ast_{i} \pi_{1}(X_{i})$.

5 CW Approximations

Prop. (3.9.5.1) [CW Complex has Homotopy Extension Property]. For $(X, A) \in \mathcal{C}^{\text{rel}}$, $X \times \{0\} \cup A \times I$ is a deformation retract of $X \times I$, thus $(X, A)$ has the homotopy extension property (3.9.6.1).

Proof: Cf. [Hat02]P15.

Lemma (3.9.5.2) [Compression and Homotopies]. For $n \in \mathbb{Z}_{+}$, $f : B \to Y \in \mathcal{C}$, the following are equivalent:

- $f_{\ast}$ induces an injection on $\pi_{n}$ and a surjection on $\pi_{n+1}$.
- Any map $(D^{n}, S^{n}) \to (Y, B) \in \mathcal{Top}^{\text{rel}}$ is homotopic rel $S^{n}$ to a map $D^{n} \to B$.

Proof: Cf. [May, P70].

Thm. (3.9.5.3) [Compression Theorem]. If $n \in \mathbb{Z}_{+}$, $(X, A) \in \mathcal{C}^{\text{rel}}$ has relative dimension $\leq n$ and $f : B \to Y$ an $n$-equivalence, then any map $(X, A) \to (Y, B) \in \mathcal{C}^{\text{rel}}$ is homotopic rel $A$ to a map $X \to B$.

In particular, (relative) homotopy doesn’t depend on (2-degree) higher dimensional cells, (but might on lower one).

Proof: Use (3.9.5.2) on each cells.

Thm. (3.9.5.4) [Whitehead]. If $f : Y \to Z \in \mathcal{C}$ is an $n$-equivalence, then $[X, Y] \to [X, Z]$ is bijective for $X \in \mathcal{C}^{\text{pt}}$ of dimension $\leq n - 1$, and surjective for $\dim X = n$.

Proof: The surjectivity follows from the compression theorem for the pair $(\emptyset, X) \in \mathcal{C}^{\text{rel}}$, and the injectivity follows from the compression theorem applied to $(X \times I, X \times \partial I) \in \mathcal{C}^{\text{rel}}$.

Cor. (3.9.5.5). If $Y \to Z \in \mathcal{Top}^{\text{pt}}$ is a weak-equivalence, then $(X, Y) \to (X, Z)$ is an equivalence for any $X \in \mathcal{C}^{\text{pt}}$.

Cor. (3.9.5.6) [Whitehead]. For $n \in \mathbb{Z}_{+}$, an $n$-equivalence of CW complexes of dimension $\leq n - 1$ is a homotopy equivalence.

A weak equivalence of CW complexes is a homotopy equivalence.

Proof: Let $e : Y \to Z \in \mathcal{C}$ satisfies the hypothesis, then because $e_{\ast} : [Z, Y] \to [Z, Z]$ is a bijection by compression theorem (3.9.5.3), there exists $f : Z \to Y$ s.t. $e \circ f \cong \text{id}$. Thus $e \circ f \circ e \cong e$. Then since $e_{\ast} : [Y, Y] \to [Y, Z]$ is also a bijection by compression theorem, $f \circ e \cong \text{id}$.

Cor. (3.9.5.7). If $X \in \mathcal{C}^{\text{pt}}$ and $\pi_{n}(X) = 0$ for all $n$, then $X$ is contractible.
Cor. (3.9.5.8) [Whitehead Combinatorial Homotopy Theorem I]. If $M$ and $K$ is dominated by CW complexes, then any weak homotopy equivalence is an homotopy equivalence. If the map is an inclusion, then it is a deformation retract. In particular, if $M$ is manifold, then it is dominated by its tubular nbhd, so this theorem is applied.

Proof: For inclusion, use compression, and in general use mapping cylinder and cellular approximation.

Cellular and CW Approximations

Lemma (3.9.5.9). For $n \in \mathbb{Z}_+$, $f (X, A) \in \mathcal{CW}^{rel}$ has no $m$-cells for $m \leq n$, then $(X, A)$ is $n$-connected. In particular, $(X, X^n)$ is $n$-connected.

Proof: It suffices to show that any map $f : (\mathbb{D}^n, \partial \mathbb{D}^n, \mathbb{S}^n) \to (X, A, \ast)$ is homotopic to a map $(\mathbb{D}^n, \mathbb{S}^n) \to (A, \ast)$ rel $\mathbb{S}^n$ (3.9.1.1). For this, notice that the image is compact, thus we can assume that $(X, A)$ is finite. Thus by doing one cell by one cell, it suffices to show for $X = A \coprod_{f \mathbb{S}^n} \mathbb{D}^n$. In this case, notice that by simplicial approximation, we can find a homotopic map $f \simeq f'$ that $f'$ avoids some point in $(\mathbb{D}^n)^\circ$. Then we can use projection to construct a homotopy.

Thm. (3.9.5.10) [Cellular Approximationss]. Any map $f : (X, A) \to (Y, B) \in \mathcal{CW}^{rel}$ is homotopic rel $A$ to a cellular map.

In particular, any $f : X \to Y \in \mathcal{CW}$ is homotopic to a cellular map.

Proof: This follows from (3.9.5.9).

Remark (3.9.5.11). The cellular approximation makes the computation of homotopy theoretically easier, but the difficulty comes from the complexity of the homotopy group of the sphere.

Remark (3.9.5.12). In fact, all the rest of this subsubsection can be rewritten by the geometric realization functor $\Gamma(X) \to X$ (3.12.3.7). It is functorial in the level of spaces.

Prop. (3.9.5.13) [n-Connected CW Models]. For a pair $(A, X)$, if $A$ is CW complex, then there is a n-connected (3.9.4.16) CW pairs $(Z, A) \to (X, A)$ that is identity on $A$, and $\pi_i(Z) \to \pi_i(X)$ is isomorphism for $i > n$ and injection for $i = n$.

Such a pair $(Z, A)$ is called a n-connected CW model of $(X, A)$, and moreover it can be constructed from $A$ by attaching cells of dimension greater than $n$.

Proof: Cf. [Hatcher P353].

Cor. (3.9.5.14). For an $n$-connected CW pair $(X, A)$, there exist a homotopic $(Z, A) \cong (X, A)$ rel $A$ that $Z \setminus A$ has only cells of dimension greater than $n$.

Proof: Choose the $n$-connected approximation as above. The map induce and isomorphism on $\pi_{>n}$ by definition and on $\pi_{<n}$ because $\pi_i(A) \to \pi_i(Z)$ and $\pi_i(A) \to \pi_i(X)$ are isomorphisms. And on $\pi_n$, it is injective by definition and surjective because $\pi_n(A) \to \pi_n(Z) \to \pi_n(X)$ is isomorphism.

Hence we know that the collapsed mapping cylinder at is weak-homotopy equivalent to $Z$, thus it deforms into $Z$ by (3.9.5.8), thus $Z \to X$ rel $A$ by (3.9.1.5).
**Cor. (3.9.5.15)** [Functorial CW Approximations]. A CW approximation of a space $X$ is a CW complex $Z$ and a weak homotopy equivalence $Z \to X$. A CW approximation of a pair $(X, A)$ is pair of CW complexes $(Z, Z_0)$ and a morphism $(Z, Z_0) \to (X, A)$ that induces isomorphisms on both relative and absolute homotopy groups.

Thus there exists a CW approximation for any space $A$, and also there exists a CW approximation for any pair $(X, X_0)$.

*Proof:* Just choose $A$ to be a set containing a point for each connected component of $X$, then $\pi_0(Z) \to \pi_0(X)$ is surjective hence injective.

For pairs, first approximate $X_0$ and use the mapping cylinder to get a embedding. 

**Prop. (3.9.5.16)** [Functoriality of CW Models]. Given $n$-connected CW model $f : (Z, A) \to (X, A)$ and $f' : (Z', A') \to (X', A')$, then any map of pairs $g : (X, A) \to (X', A')$ can be extended to a map of pairs $h : (Z, A) \to (Z', A')$ that $gf \cong f'h$ rel $A$. And such a map $h$ is unique up to homotopy rel $A$.

*Proof:* Cf.[Hatcher, P355].

**Cor. (3.9.5.17)** [Uniqueness of CW approximation]. The CW approximation is unique up to homotopy.

**Cor. (3.9.5.18)** [Localizing Category]. Together with Whitehead combinatorial homotopy theorem (3.9.5.8) the homotopy category of spaces defined in (3.12.2.3) is the category of spaces $\mathcal{CG}$ localized by the class of weak homotopy equivalence classes.

**Prop. (3.9.5.19)** [CW Approximation of Excisive Triads]. Cf.[May, 79].

### 6 Fibrations and Cofibrations

**Cofibrations**

**Def. (3.9.6.1)** [Homotopy Extension Property]. $(X, A) \in \text{Top}^{\text{rel}}$ is said to satisfy the **homotopy extension property** if every map $X \times \{0\} \sqcup A \times I \to Y$ can be extended to a map $X \times I \to Y$.

**Def. (3.9.6.2)** [Cofibrations]. A **cofibration** is a map $j : A \to X$ that for every map $X \times \{0\} \sqcup A \times I \to Y$ can be extended to a map $X \times I \to Y$.

This implies $X \times \{0\} \cup A \times I \to X \times I$ has a left inverse. And the converse is clearly true.

Then a cofibration is just a topological embedding with closed image that $(X, A)$ has the homotopy extension property (3.9.6.1).

Cofibrations is stable under cobase change and coproducts.

*Proof:* 

**Def. (3.9.6.3)** [NDR-Pairs]. An neighborhood deformation retraction pair, or an **NDR-pair** is a pair $(X, A) \in \text{Top}^{\text{rel}}$ s.t. there is a map $u : X \to I$ s.t. $u^{-1}(0) = A$, and a homotopy $f_t : X \to X$ rel $A$ s.t. $f_0 = \text{id}_X$, and $f_1(u^{-1}([0, 1])) \subset A$.

**Prop. (3.9.6.4)** [NDR Pairs and Cofibrations]. If $A \subset X$ is closed, then $(X, A)$ is a NDR-pair (3.9.6.3) iff $A \to X$ is a cofibration.

*Proof:* Cf.[May, P45].

Prop. (3.9.6.5) [CW-Pairs are Cofibrations]. By compression theorem (3.9.5.3), for any CW-pair \((A, X)\), \(A \to X\) is a cofibration.

Def. (3.9.6.6) [Hurewitz Cofibration]. A closed Hurewicz cofibration \(i : A \subset B\) is a closed inclusion of spaces that \(B \times \{0\} \amalg A \times I \to B \times I\) has left extension property w.r.t any map \(Y \to \text{pt}\).

Prop. (3.9.6.7) [Quotient a Contractible Cofibration]. If \(A \to X\) is a cofibration and \(A\) is contractible, then the quotient map \(X \to X/A\) is a homotopy equivalence. In particular, this applies to \((X, A) \in \text{CW}^\text{rel}\), by (3.9.5.1).

Proof: Let \(f_t : X \to Y\) be a homotopy extending a contraction of \(A\) to a point, with \(f_0 = \text{id}\). Since \(f_t(A) \subset A\), they descend to a homotopy \(\overline{f}_t : X/A \to X/A\). Because \(f_1(A)\) is a point, there is a map \(g\) in the following diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f_1} & X \\
\downarrow{\pi} & & \downarrow{\pi} \\
X/A & \xrightarrow{\overline{f}_1} & X/A
\end{array}
\]

So \(g\) and \(\pi\) are inverse homotopy equivalences, because \(f_1 \cong f_0 = \text{id}\) and \(\overline{f}_1 \cong \overline{f}_0 = \text{id}\). \(\square\)

Prop. (3.9.6.8). Let \(X\) be a normal space, then an inclusion \(j : A \hookrightarrow X\) is a cofibration iff \(A \hookrightarrow V\) is a cofibration for some open nbhd \(V\) of \(j(A) \subset X\).

Proof: Cf. [AGP02] P92. \(\square\)

Prop. (3.9.6.9) [Homotopic Glueing Functions]. Let \(A \to X_1\) be a cofibration with \(X\) Hausdorff, and we have attaching maps \(f, g : A \to X_0\) that is homotopic, then \(X \amalg_f X_1 \cong X \amalg_g X_1\) rel \(X_0\).

Proof: Now choose a homotopy \(H : A \times I \to X_0\) connecting \(f\) and \(g\), then \(H\) induces a quotient space \(Z = X_0 \amalg_H (X_1 \times I)\). Let \(X = X_0 \amalg_f X_1, Y = X_0 \amalg_g X_1\), then there are natural inclusion maps \(i : X_1 \to Z, j : Y \to Z\), and there are also deformation retractions \(Z \to X, Z \to Y\) constructed as follows:

Choose a deformation retraction \(r\) of \(X_1 \times I\) onto \(X_1 \times \{0\}\) \(\amalg A \times I\) (3.9.6.1), and \(H\) induces a map \(\overline{H} : D^n \times \{0\} \amalg S^n \times I \to S^n \amalg_f D^n\), making the following diagram commutative

\[
\begin{array}{ccc}
A \times I & \xrightarrow{r} & X_1 \times I \\
\downarrow{H} & & \downarrow{\overline{H}} \\
X_0 & \xrightarrow{id} & X_0 \amalg_f X_1
\end{array}
\]

which by definition defines a deformation retraction \(r_1 : X_0 \amalg_H (X_1 \times I) \to X_0 \amalg_f X_1\). Similarly we have deformation retraction \(r_2 : Z \to Y\). So \(r_2 \circ i\) and \(r_1 \circ j\) induce an homotopy equivalence between \(X\) and \(Y\). \(\square\)

Prop. (3.9.6.10). If \(A \to X, A \to Y\) are cofibrations, and \(f : X \to Y\) is a homotopy equivalence that \(f|_A = \text{id}_A\), then \(f\) is a homotopy equivalence rel \(A\).

Proof: Cf. [Hatcher] P16. \(\square\)

Cor. (3.9.6.11). If \(j : A \to X\) is a cofibration which is also a homotopy equivalence, and \(X\) is Hausdorff, then \(A\) is a deformation retraction of \(X\).
Serre Fibrations

Def. (3.9.6.12) [Serre Fibration]. A Serre fibration is the right lifting class of $D^n \times \{0\} \to D^n \times I$ for every $n$. This is equivalent to: for any homotopy of $\partial D^n$ and a image $D^n$, there is a homotopy of $D^n$.

In particular, Serre fibrations are stable under base change, by (3.7.0.1).

Prop. (3.9.6.13). Being a Serre fibration is local on the target.

Proof: Cf. [Homotopical Point of View] P127. □

Prop. (3.9.6.14) [Long Exact Sequence of Serre Fibration]. Let $\pi : E \to X$ be a Serre fibration, let $b_0 \in B$ and $x_0 \in F = \pi^{-1}(b_0)$, then the map $\pi_* : \pi_n(E, F, x_0) \to \pi_n(B, b_0)$ is an isomorphism for all $n \geq 1$. In particular, there is a long exact sequence

$$\cdots \to \pi_n(F, x_0) \to \pi_n(E, x_0) \to \pi_n(B, b_0) \to \pi_{n-1}(F, x_0) \to \cdots \to \pi_0(B, b_0) \to 0.$$ 

by (3.9.4.11).

Proof: Cf. [Hat02] P376. [nLab]. □

Hurewicz Fibrations

Def. (3.9.6.15) [Hurewicz Fibrations]. A Hurewicz fibration is a map $p : X \to Y \in \mathcal{G}$ that has right lifting property w.r.t maps $A \times \{0\} \to A \times [0, 1]$ for any $A \in \mathcal{G}$. In particular, a Hurewicz fibration is a Serre fibration (3.9.6.12).

Hurewicz fibrations are stable under base change.

Prop. (3.9.6.16) [Comparing Fibers of a Hurewicz Fibration]. If $\pi : E \to B$ is a Hurewicz fibration, then for any arc $\gamma$ in $B$ with $\gamma(0) = a, \gamma(1) = b$, there is a homotopy equivalence $f_\gamma : \pi^{-1}(a) \cong \pi^{-1}B$, and the homotopy class of $f_\gamma$ only depends on the homotopy class of $\gamma$.

In other words, a Hurewicz fibration over $B$ determines a contravariant functor $\Pi_1(B) \to \text{Ho}(\mathcal{G})$.

Proof: This follows from the homotopy lifting property. □

Cor. (3.9.6.17). For a Hurewicz fibration $E \to B$, if $B$ is contractible, then it is fiber homotopy equivalent to a trivial fiber bundle.

Prop. (3.9.6.18). Let $\pi : E \to B, \pi' : E' \to B$ be Hurewicz fibrations and $f : E \to E'$ be a map over $B$ that is also a homotopy equivalence, then $f$ is a fiber homotopy equivalence.

Proof: Cf. [Miller, P141] ?

Prop. (3.9.6.19) [Homotopy Invariance of Pullbacks]. Let $\pi : E \to X$ be a Hurewicz fibration and $f_0, f_1 : Y \to X \in \mathcal{G}$ are two maps that are homotopic, then the two Hurewicz fibrations $f_0^*E/Y, f_1^*E/Y$ are fiber homotopy equivalent.

Proof: Cf. [Miller, P140] ?

Prop. (3.9.6.20) [Homotopy Fiber of Contractible Fibration]. Let $f : E \to B$ be a Hurewicz fibration with $E$ contractible, then the homotopy fibers (3.6.3.18) $F$ over $b_0$ is weak homotopy equivalent to $\Omega(B, b_0)$. 
Proof: Let \( x_0 \in \pi^{-1}(b_0) \). If we compose the contraction of \( E \) to \( x_0 \) with \( \pi \), then we get for each \( x \in E \) a path \( \gamma_x \) from \( \pi(x) \) to \( b_0 \). Then these give a map \( E \to PB : x \mapsto \pi \gamma_x^{-1} \), which is a lift of \( \pi \).

Then this map gives a commutative diagram

\[
\begin{array}{ccc}
F & \to & E \\
\downarrow & & \downarrow \\
\Omega(B, b_0) & \to & PB \\
\end{array}
\]

corresponding long exact sequences (3.9.6.14). Thus \( F \to \Omega(B, b_0) \) is a weak homotopy equivalence because \( E, PB \) are both contractible (3.6.3.20).

Prop. (3.9.6.21) [Pathspaces are Hurewicz Fibrations]. For any map \( f : A \to B \), the map \( \pi : E_f \to B : (a, \gamma) \mapsto \gamma(1) \) from the pathspace (3.6.3.18) is a Hurewicz fibration.

In particular, take \( A = \{x_0\} \), then the path space \( PB \to B \) is a Hurewicz fibration.

Proof: Firstly this map is continuous by (3.6.3.5). To verify the homotopy lifting property, let \( g : X \to B \) be a homotopy and \( \tilde{g}_0 : X \to E_f \) be a lifting, let \( \tilde{g}_0(x) = (h(x), \gamma_x) \). Define a lift \( \tilde{g}_t : X \to E_f \) by \( \tilde{g}_t(x) = (h(x), \gamma_x \cdot g_{0,t}(x)) \). The second term is concatenation, which can be defined because \( g_0(x) = \pi \tilde{g}_0(x) = \gamma_x(1) \).

To check this is a continuous homotopy, by (3.6.3.7), it suffices to show \( A \times I \times I \to B : (x, s, t) \mapsto \gamma_x \cdot g_{0,s}(x)(t) = \begin{cases} \gamma(x, (1 + t)s) & s \leq \frac{1}{1 + t} \\ g_{(1+t)s-1}(x) & s \geq \frac{1}{1 + t} \end{cases} \) is continuous.

Cor. (3.9.6.22) [Homotopy Fibers]. We can embed \( A \) into \( E_f \) by mapping \( x \) to \( (x, \gamma_x) \), where \( \gamma_x \) is the trivial loop at \( x \). Then \( A \) is a deformation contraction of \( E_f \), by restricting to shorter and shorter initial segments: \( H_t : E_f \to E_f : (a, \gamma) \mapsto (a, \gamma_t) \), where \( \gamma_t(x) = \gamma(t x) \).

Then we factored \( f \) as a homotopy equivalence followed by a fibration: \( A \to E_f \to B \).

If \( x_0 \in X \) and \( F_f \) is the fiber of \( E_f \) over \( x_0 \), then a map \( (I^{i+1}, \partial I^{i+1}, J^i) \to (A, B, x_0) \) is the same as a map \( (I^i, \partial I^i) \to (F_f, \gamma_0) \), where \( \gamma_0 \) is the trivial loop at \( x_0 \). Thus \( \pi_{i+1}(A, B, x_0) = \pi_i(F_f, \gamma_0) \).

Prop. (3.9.6.23) [Pathspace of a Hurewicz Fibration]. If \( \pi : E \to B \) is a fibration, then the inclusion \( E \to E_\pi \) (3.6.22) is a fiber homotopy equivalence. In particular, the homotopy fibers of \( \pi \) are homotopy equivalent to the actual fibers.

Proof: \( \square \)

Prop. (3.9.6.24) [Fibration Sequence]. Given a fibration \( \pi : E \to B \) with \( F = \pi^{-1}(b_0), x_0 \in F \), there is a sequence

\[
\ldots \to \Omega^2(B, b_0) \to \Omega(F, x_0) \to \Omega(E, x_0) \to \Omega(B, b_0) \to F \to E \to B \to 0
\]

where any two consecutive maps form a fibration, up to homotopy.

Proof: By (3.9.6.23), the inclusion \( i \) of \( F \) to the homotopy fiber \( F_\pi \) over \( \pi \) over \( p \) is a homotopy equivalence, and it extends to a map \( i : F_p \to E : (x, \gamma) \mapsto x \), which is also a Hurewicz fibration, because it is the pullback of the fibration \( PB \to B \) (3.9.6.21).

Thus we can take the homotopy fiber \( F_i \) of \( i : F_p \to E \) over \( x_0 \), and similarly there is a fibration \( j : F_i \to F \), and \( F \) is naturally homotopic to the actual fiber of \( i \), which is just \( \Omega(B, b_0) \). \( \square \)
Model Category Structure

**Lemma (3.9.6.25) [Cofibrant Replacement]**. Any map \( f : X \to Y \) is a composition \( X \to M_f \to Y \). Notice \( M_f \to Y \) is a homotopy equivalence and \( X \to M_f \) is cofibrant by (3.9.6.4).

**Cor. (3.9.6.26) [Homotopy equivalence and mapping cylinder]**. A map \( f : X \to Y \) is a homotopy equivalence iff \( X \) is a deformation retraction of the mapping cylinder \( M_f \). In particular, two spaces are homotopically equivalent iff there is a third space containing both of them as deformation retracts.

*Proof:* Cf.[Hatcher] P16.

**Lemma (3.9.6.27) [Fibrant Replacement]**. Any map \( f : X \to Y \) is a composition \( X \to N(f) \to Y \), where \( N(f) = X \times_Y Y^I \), where \( Y^I \to Y \) is evaluation at \( \{0\} \), and \( X \to N(f) \) is given by \( x \mapsto (x, c_f(x)) \), where \( c_f(x) \in Y^I \) is the constant map \( f(x) \).

It is true that \( N(f) \to Y \) is a fibration, Cf.[May, 50].

*Proof:* \( X \to N(f) \) is homotopy inverse to the projection map: We can use the homotopy \( N(f) \times I \to N(f) : (x, a) \mapsto \chi : t \mapsto \chi(at) \).

To show that \( N(f) \to Y \) is a fibration, Cf.[May, 50].

**Prop. (3.9.6.28) [Serre-Quillen]**. The category \( CG \) can be given a Serre-Quillen model structure with
- Weak equivalences: weak homotopy equivalence,
- Fibrations: Serre fibrations,
- Cofibrations: Retracts of morphisms \( X \to Y \) where \( Y \) is obtained from \( X \) by attaching cells.

*Proof:* Cf.[Homotopy Theories and Model Categories, Chap8].

**Prop. (3.9.6.29)**. The homotopy category \( Ho(\mathcal{Top}) \) of the Serre-Quillen model structure is equivalent to the homotopy category of spaces \( \mathcal{H} \).

*Proof:* □

**Lemma (3.9.6.30)**. Every map can be decomposed as a homotopy equivalence followed by a fibration, by the construction of homotopy fibers.

*Proof:* □

**Prop. (3.9.6.31) [Hurewicz-Ström]**. The category \( CG \) can be given a Hurewicz-Ström model structure with
- Weak equivalences: homotopy equivalences.
- Cofibrations: closed Hurewicz cofibrations.
- Fibrations: Hurewitz fibrations.

*Proof:* Cf.[strum paper].

**Prop. (3.9.6.32)**. The homotopy category of the Hurewicz-Ström model structure is equivalent to the usual category of homotopy types.
7 Calculations of Homotopy Groups

**Prop.(3.9.7.1).** For $0 < k < n \in \mathbb{Z}$, $\pi_k(S^n) = 0$. And for $0 < n$, $\pi_0(S^n) = \ast$.

**Proof:** This follows from cellular approximation (3.9.5.10) and the canonical CW structure on $S^n$. □

**Prop.(3.9.7.2).** For $i \geq 2$, $\pi_1(\mathbb{RP}^i) \cong \mathbb{Z}/(2)$, and $\pi_n(\mathbb{RP}^i) \cong \pi_n(S^i)$ for $n \neq 1$.

**Proof:** This follows from the fiber sequence $\mathbb{Z}/(2) \to S^n \to \mathbb{RP}^n$ and (3.9.4.12). □

**Lemma(3.9.7.3).** There is a covering space $\mathbb{R} \to S^1$ with fiber $\mathbb{Z}$, thus $\pi_1(S^1) \cong \mathbb{Z}$.

**Prop.(3.9.7.4)[Hopf Fibration].** By (3.11.1.12) and (3.9.6.14), there is a long exact sequence

$$\ldots \to \pi_i(S^1) \to \pi_i(S^3) \to \pi_i(S^2) \to \pi_{i-1}(S^1) \to \ldots \to \pi_0(S^2) \to 1.$$

Thus $\pi_i(S^3) \cong \pi_i(S^2)$ for $i \geq 3$, and $\pi_2(S^2) \cong \pi_1(S^1) \cong \mathbb{Z}(3.9.7.3)$.

**Prop.(3.9.7.5)[Finiteness of Sphere Homotopy].** For $p > n > 1$, $\pi_p(S^n)$ are all finite except for $\pi_{4n-1}(S^{2n})$.

**Proof:**

**Prop.(3.9.7.6)[Basic Sphere Homotopy].** For $n \in \mathbb{Z}_+$, there are maps $\pi_i(S^n) \to \pi_{i+1}(S^{n+1})$ that is an isomorphism for $i < 2n - 1$ and surjective for $i = 2n - 1$.

In particular, $\pi_n(S^n) \cong \pi_2(S^2) \cong \mathbb{Z}$ for any $n \geq 2$.

**Proof:** This follows from Freudenthal suspension theorem (3.9.4.22). The last assertion follows from (3.9.7.3). □

**Prop.(3.9.7.7).** $\pi_4(S^3) \cong \pi_4(S^2) \cong \mathbb{Z}/(2)$.

**Proof:** □

**Prop.(3.9.7.8).** For $i \leq 2m$, $\pi_i G_m(\mathbb{C}^{2m}) \cong \pi_{i-1} U(m)$, and

$$\pi_{i-1} U(m) \cong \pi_{i-1} U(m + 1) \cong \ldots .$$

and for $j \neq 1$, $\pi_j U(m) \cong \pi_j SU(m)$.

Similarly, $\pi_i \Omega(2m) \cong \pi_{i+1} \Omega(2m)$ for $i \leq n - 4.(11.3.1.12)$, Cf[Morse Theory Milnor Prop23.4].

**Cor.(3.9.7.9)[Bott Periodicity theorem for Unitary Groups].** The stable homotopy group $\pi U$ has period 2. $\pi_{2k+1} U \cong 0$ and $\pi_{2k} U \cong \mathbb{Z}$.

**Proof:** Use the last proposition and long exact sequence to show that for $1 \leq i \leq 2m$,

$$\pi_{i-1} U = \pi_{i-1} U(m) \cong \pi_i G_m(\mathbb{C}^{2m}) \cong \pi_{i+1} SU(2m) \cong \pi_{i+1} U.$$ Notice that $U(m) \to U(2m)/U(m) \to G_m(\mathbb{C}^{2m})$ □

**Prop.(3.9.7.10) [Bott Periodicity for $O$].** For the infinite dimensional orthogonal space $O$, $\Omega_8(16r) \cong O(r)$, $\Omega_4(8r) \cong Sp(2r)$. So $\Omega_8 \cong O$ and $\Omega_4 O \cong Sp$. Thus by (3.9.4.2),

$$\pi_i(O) = \mathbb{Z}/(2), \mathbb{Z}/(2), 0, \mathbb{Z}, 0, 0, 0, \mathbb{Z}\ldots , \quad \pi_i(Sp) = 0, 0, 0, \mathbb{Z}, \mathbb{Z}/(2), \mathbb{Z}/(2), 0, \mathbb{Z}\ldots$$

respectively. (Use (11.3.1.13)) Cf.[Morse Theory Prop24.7].

**Prop.(3.9.7.11).** If a simply-connected finite complex $X$ is not contractible, then infinitely many of its homotopy groups are non-zero.

**Proof:** Cf.[Jean-Pierre Serre, Cohomologie modulo 2 des complexes d'Eilenberg-Maclane] □
3.10 Algebraic Topology II: Homologies and Cohomologies

Notations (3.10.0.1).
- Use notations defined in Algebraic Topology I: Homotopies.

1 Homologies

Axiomatic Homologies

Def. (3.10.1.1) [Eilenberg-Steenrod Homology Theories]. A Eilenberg-Steenrod homology theory is given by the following data:
- A functor $E_p(\_): \text{Ho}(\text{Top}^{\text{rel}}) \rightarrow \text{Ab}$ for any $p \in \mathbb{Z}$. For $X \in \text{Top}$, denote $H_p(X, \emptyset)$ by $E_p(X)$.
- For any $p \in \mathbb{Z}$, an equivariant boundary map $\partial: E_p(X, A) \rightarrow E_{p-1}(A)$ for any $(X, A) \in \text{Ho}(\text{Top}^{\text{rel}})$.

that satisfies

Exact Sequence: For $(X, A) \in \text{Top}^{\text{rel}}$, there is a natural long exact sequence
\[
\cdots \rightarrow E_p(A) \rightarrow E_p(X) \rightarrow E_p(X, A) \xrightarrow{\partial} E_{p-1}(A) \rightarrow \cdots.
\]

Excision: For any excisive triad $(X; A, B) (3.9.1.6)$, the inclusion $(A, A \cap B) \rightarrow (X, B)$ induces an isomorphism
\[
E_p(A, A \cap B) \cong E_p(X, B).
\]

Additivity: If $(X, A) = \coprod_{\alpha} (X_{\alpha}, A_{\alpha})$, then there are natural isomorphisms
\[
\bigoplus_{\alpha} E_p(X_{\alpha}, A_{\alpha}) \cong E_p(X, A).
\]

By functorial CW approximations on relative spaces (3.9.5.15), CW approximation of excisive triads (3.9.5.19) and Whitehead theorem (3.9.5.6), such a theory is equivalent to a theory restricted to all CW complexes with cellular maps as morphisms.

Prop. (3.10.1.2) [Cofibrations]. Given an Eilenberg-Steenrod homology theory $E_*$, for any cofibration $i: A \rightarrow X \in \text{Top}$, there is a natural isomorphism
\[
E_*(X, A) \cong E_*(X/A, \text{*)}.
\]

Proof: As $i$ is a cofibration, $C(A) \rightarrow C(i) = X \coprod_{A \times \{0\}} C(A)$ is also a cofibration. Consider the commutative diagram
\[
\begin{array}{ccc}
E_*(X \coprod_{A \times \{0\}} (A \times [0, 2/3]), A \times [1/3, 2/3]) & \rightarrow & E_*(C(i), (A \times [1/3, 1])/(A \times \{1\})) \\
\downarrow & & \downarrow \\
E_*(X, A) & \rightarrow & E_*(X/A, \text{*)}
\end{array}
\]

Then the upper horizontal map is an isomorphism by excision, and the vertical maps are isomorphisms by homotopy invariance. The right vertical map is
\[
(C(i), (A \times [1/3, 1])/(A \times \{1\})) \cong (C(i), C(A)) \cong (X/A, \text{*)}
\]
by (3.9.6.7). Then the lower horizontal map is also an isomorphism. \qed
**Def. (3.10.1.3) [Reduced Homology Theories]**. A reduced Eilenberg-Steenrod homology theory is given by the following data: A functor $\tilde{E}_*(\;): \text{Ho}(\mathcal{C}^\text{well-pt}) \to \text{Ab}$ for any $p \in \mathbb{Z}$ that satisfies

**Exactness**: For any cofibration $i : A \to X \in \mathcal{C}^\text{well-pt}$, the sequences

$$\tilde{E}_p(A) \to \tilde{E}_p(X) \to \tilde{E}_p(X/A)$$

are exact.

**Suspension**: For any $X \in \mathcal{C}^\text{well-pt}$, there are natural isomorphisms

$$\Sigma_* : \tilde{E}_p(X) \cong \tilde{E}_{p+1}(\Sigma X).$$

**Additivity**: If $X = \bigvee_{\alpha} X_{\alpha}$, then there are natural isomorphisms

$$\bigoplus_{\alpha} \tilde{E}_p(X_{\alpha}) \cong \tilde{E}_p(X).$$

By functorial CW approximations on pointed spaces (3.9.5.15), such a theory is equivalent to a theory restricted to all CW complexes with cellular maps as morphisms.

**Prop. (3.10.1.4) [Reduction to Reduced Homology Theories]**. Giving an Eilenberg-Steenrod homology theory is equivalent to giving a reduced Eilenberg-Steenrod homology theory. Thus from now on we will not distinguish from a reduced ES-homology theory and an ES-homology theory.

**Proof**: Given an ES homology theory $E_*$, for $X \in \text{Top}^\text{pt}$, define $\tilde{E}_*(X) = E_*(X, \ast)$, then the maps $\ast \to X \to \ast$ induce a natural splitting $E_*(X) \cong \tilde{E}_*(X) \oplus E_*(\ast)$. Then it is easy to show $\tilde{E}_*$ is a reduced ES homology theory by (3.10.1.2): For suspension, because $C(X)$ is contractible and $X \to C(X)$ is a cofibration, the long exact sequence for $C(X)/X \cong \Sigma(X)$ and (3.10.1.2) implies the isomorphism

$$\Sigma^{-1} : \tilde{E}_{p+1}(\Sigma(X)) \cong \tilde{E}_{p+1}(C(X)/X) \cong E_{p+1}(C(X), X) \xrightarrow{\partial} \tilde{E}_p(X).$$

Conversely, if $\tilde{E}_*$ is a reduced ES homology theory, define $E_*(X, A) = \tilde{E}_*(C(A \to X))$ where $C(A \to X)$ is pointed over the cone point. In particular, $E_*(X) = \tilde{E}_*(X_+)$ (3.9.1.16). We also define the boundary map as

$$\partial : E_*(X, A) \cong \tilde{E}_*(C(i_+)) \xrightarrow{\partial} \tilde{E}_*(\Sigma(A_+)) \xrightarrow{\Sigma^{-1}} E_{*-1}(A_+),$$

where $\partial$ comes from $\Sigma(A_+) \cong C(i_+)/X_+$.

To show $E_*$ is a ES homology theory: additivity is clear. The homotopy invariance follows from (3.9.1.17). To show exactness?. To show excision?. Cf. [May, P110].

To show that these two constructions are inverse to each other, it suffices to show that the $\partial$ and $\Sigma$ defined are inverse to each other?.

**Lemma (3.10.1.5)**. Let $E$ be an ES-homology theory and $B \subset A \subset X$, then there is a functorial long exact sequence

$$\cdots \to E_p(A, B) \to E_p(X, B) \to E_p(X, A) \xrightarrow{\partial} E_{p-1}(A, B) \to \cdots,$$

where $\partial : E_p(X, A) \to E_{p-1}(A) \to E_{p-1}(A, B)$. 

Proof: This follows from diagram chase or using the functorial CW approximations (3.9.5.15).

**Lemma (3.10.1.6).** If $E$ be an ES-homology theory and $(X; A, B)$ is an excisive triad, then the natural map
\[ E_*(A, A \cap B) \oplus E_*(B, A \cap B) \to E_*(X, A \cap B) \]
is an isomorphism.

Proof: This is done by using the CW approximations for excisive triads (3.9.5.19).

**Prop. (3.10.1.7) [Mayer-Vietoris Sequences].** Let $E$ be an ES-homology theory and $(X; A, B)$ be an excisive triad, then there is a long exact sequence
\[
\cdots \to E_p(A \cap B) \xrightarrow{((i_1)_*,(i_2)_*)} E_p(A) \oplus E_p(B) \xrightarrow{(j_1)_*-(j_2)_*} E_p(X) \xrightarrow{\Delta} E_{p-1}(A \cap B) \to \cdots ,
\]
where $\Delta$ is the composite
\[ E_p(X) \to E_p(X, B) \cong E_p(A, A \cap B) \xrightarrow{\partial} E_{p-1}(A \cap B). \]

Proof: Cf. [May, P112].

**Prop. (3.10.1.8) [Relative Mayer-Vietoris Sequences].** The relative MV-sequence is related to the MV-sequence (3.10.1.7) by
\[
\cdots \to E_p(Y, A \cap B) \xrightarrow{\partial} E_p(Y, A) \oplus E_p(Y, B) \xrightarrow{\partial \oplus \partial} E_p(Y, X) \xrightarrow{\partial} E_{p-1}(Y, A \cap B) \to \cdots 
\]

**Prop. (3.10.1.9) [Colimits].** If $X = \lim_{i \in \mathbb{N}} X_i$, then there is a natural isomorphism
\[ \lim_{i \in \mathbb{N}} E_*(X_i) \cong E_*(X). \]

Proof: Cf. [May, P115].

**Cor. (3.10.1.10).** For a reduced ES-homology theory $\tilde{E}_*$ and $(X_i)_{i \in \mathbb{N}} \in \text{Top}^{pt}$, there are natural isomorphisms
\[ \lim_{i \in \mathbb{N}} \tilde{E}_*(X_i) \cong \tilde{E}_*(\coprod_i X_i) (3.9.1.19). \]

The Ordinary Homology Theory

**Def. (3.10.1.11) [Ordinary Homology Theories].** For $\Lambda \in \text{Ab}$, an ordinary homology theory with coefficients in $\Lambda$ is a generalized homology theory (3.10.2.1) that satisfies the additional axiom

**Dimension:**
\[ E_p(pt) = \begin{cases} \Lambda, & p = 0 \\ 0, & p \neq 0 \end{cases}. \]

**Def. (3.10.1.12) [Ordinary Reduced Homology Theories].** For $\Lambda \in \text{Ab}$, an ordinary reduced homology theory with coefficients in $\Lambda$ is a reduced homology theory (3.10.1.3) that satisfies the additional axiom
Dimension: \( \tilde{E}_p(S^0) = \begin{cases} \Lambda & , p = 0 \\ 0 & , p \neq 0 \end{cases} \).

Def. (3.10.1.13) [Hurewicz Homomorphism]. For an ordinary homology theory \( H_* \), if we denote the generator of \( \tilde{H}_0(S^0) \) by \( a_0 \), and \( a_n = \Sigma^n(a) \in \tilde{H}_n(S^n) \), then for any \( X \in \mathcal{C}^{\text{pt}} \), define the Hurewicz homomorphism

\[ \text{Hur}_X : \pi_n(X) \to \tilde{H}_n(X) : f \mapsto f_*(a_n). \]

Prop. (3.10.1.14). For \( n \in \mathbb{Z}_+ \), \( X \in \text{Top}^{\text{pt}} \), \( \text{Hur}_X \) is a homomorphism of groups.

Proof: Cf. [May, P117]. \( \square \)

Prop. (3.10.1.15) [Generalized Hurewicz theorem]. If \( n \geq 2 \) and \( (X, A) \) is a \((n - 1)\)-connected pair of spaces, then the Hurewicz map induces an isomorphism

\[ \pi_n(X, A) / \sim \pi_1(A) \cong H_n(X, A), \]

and \( H_k(X, A) = 0 \), \( k < n \). Moreover, the Hurewicz map \( \pi_{n+1}(X, A) \to H_{n+1}(X, A) \) is surjective.

Proof: Cf. [Hatcher P371 and 390Ex23]. \( \square \)

Cor. (3.10.1.16) [Converse Whitehead]. If \( f : X \to Y \) is a map of simple pointed spaces that induces isomorphisms on all homology groups, then \( f \) is a weak homotopy equivalence.

Proof: We may change \( Y \) to the mapping cylinder of \( f \), then notice all the relative homology groups \( H_n(Y, X) \) vanishes by long exact sequence, and then by the generalized Hurewicz theorem, \( \pi_n(Y, X) = 0 \), and then \( f \) is a weak homotopy equivalence, by (3.9.4.11). \( \square \)

Thm. (3.10.1.17) [Hurewicz]. For \( n \in \mathbb{Z}_+ \), if \( X \in \mathcal{C}^{\text{pt}} \) is \((n - 1)\)-connected, then \( \text{Hur}_X : \pi_n(X) \to \tilde{H}_n(X) \) induces an isomorphism \( \pi_n(X)^{\text{ab}} \cong \tilde{H}_n(X) \). In particular, if \( n > 1 \), \( \pi_n(X) \cong \tilde{H}_n(X)(3.9.4.1) \).

Proof: Cf. [May, P118]. \( \square \)

The Cellular and Singular Realizations

Def. (3.10.1.18) [Degree of Maps]. For any \( f : S^n \to S^n \in \text{Top} \), we can choose a base point and use cellular approximation to make it homotopic to a cellular map \((S^n, \star) \to (S^n, \star)\), and define the degree of \( f \) to be the multiplying factor of \( f_* : \pi_n(S^n) \cong \mathbb{Z} \to \pi_n(S^n) \cong \mathbb{Z}(3.9.7.6) \).

Then this degree is independent of the base point chosen simply by rotation.

Prop. (3.10.1.19). The antipodal map \( S^n \to S^n \) has degree \((-1)^{n-1}\).

Proof: This is because the antipodal map is a composition of \( n+1 \) reflections, and each reflection is an \( n \)-suspension of a reflection on \( S^1 \to S^1 \), which clearly has degree \(-1\). Thus we finish by (3.9.7.6). \( \square \)
Def. (3.10.1.20) [Cellular Complex on $\mathbb{C}W$]. Given $X \in \mathbb{C}W$ with presentation $X = \bigcup_i X^i$, we can define the cellular homology groups as follows: Let $C_\bullet(X)$ be the complex with $C_p(X)$ the free Abelian group generated by the $p$-cells of $X$, and the map $C_p(X) \to C_{p-1}(X)$ is given by $e_\alpha \mapsto a_{\alpha \beta} e_\beta$, where for any $n$-cell $\alpha$ and $n-1$-cell $\beta$, $a_{\alpha \beta}$ is the degree (3.10.1.18) of the map

$$S^{p-1} \stackrel{\alpha}{\to} X^{p-1} \to X^{p-1} / X^{p-2} \xrightarrow{\beta^{-1}} S^{p-1}.$$ 

Then $C_\bullet(X)$ is truly a complex. More generally, for any $\Lambda \in \text{Ab}$, we can define $C_\bullet(X; \Lambda) = C_\bullet(X) \otimes \Lambda$.

Proof: Cf. [May, P99]. □

Def. (3.10.1.21) [Cellular Homology Groups]. For $X \in \mathbb{C}W$ and a subcomplex $A \subset X$, there is an inclusion $C_\bullet(A) \to C_\bullet(X)$. If we define $C_\bullet(X, A) = C_\bullet(X) / C_\bullet(A)$. Define the homology groups

$$H_p(X) = H_p(C_\bullet(X)), H_p(X, A) = H_p(C_\bullet(X, A)).$$

Then the long exact sequence associated to the exact sequence $0 \to C_\bullet(A) \to C_\bullet(X) \to C_\bullet(X, A) \to 0$ gives a boundary map $\partial : H_p(X, A) \to H_{p-1}(A)$.

More generally, for any $\Lambda \in \text{Ab}$, we can define $C_\bullet(X, A; \Lambda)$ and also $H_p(X; \Lambda), H_p(X, A; \Lambda)$.

Def. (3.10.1.22) [Cellular Complex of Products]. For $X, Y \in \mathbb{C}W$, with the CW structure on $X \times Y$ given in (3.9.3.8), then

$$C_\bullet(X) \otimes C_\bullet(Y) \cong C_\bullet(X \times Y).$$

Proof: The map $C_\bullet(X) \otimes C_\bullet(Y) \cong C_\bullet(X \times Y)$ is given by $e_\alpha \otimes e_\beta \mapsto (-1)^{|\alpha||\beta|} e_{\alpha \beta}$.

It is clear that this is an isomorphism up to sign. For the sign problem, see [May, P101]. □

Prop. (3.10.1.23). The cellular homology groups in (3.10.1.21) defines a ES-homology theory (3.10.1.21).

Proof: For homotopy invariance, notice a homotopy $X \times I \to Y$ between $f, g : X \to Y$ will induce a map

$$C_\bullet(X) \otimes C_\bullet(I) \to C_\bullet(Y)$$

by (3.10.1.22), and with the canonical CW structure, $C_\bullet(I)$ is just $0 \to \mathbb{Z} \xrightarrow{(1,-1)} \mathbb{Z} \oplus \mathbb{Z} \to 0$. By writing it out, this gives exactly a homotopy between the two maps $f_*, g_*$. Additivity, excision and exactness is clear. □

Def. (3.10.1.24) [Singular Homologies]. For $X \in \text{Top}$, $\Lambda \in \text{Ab}$, the singular cohomology groups with coefficients in $R$ is defined to be $H_{\text{sing}*}(X; \Lambda) = H_*(\Gamma(X); R)$ (3.12.3.7). This is the just the homology on $\text{Top}^{\text{red}}$ corresponding to the cellular homology on CW-pairs.

Thm. (3.10.1.25) [Uniqueness of Ordinary Homology Theories]. There exists a unique ordinary homology theory, i.e. the one defined in (3.10.1.21).

Proof: Cf. [May, P119]. □
2 Cohomologies

Remark (3.10.2.1)[Eilenberg-Steenrod Cohomology Theories]. The whole basic theory of cohomologies is dual to that of homologies, so it is omitted here. We only focus on new features appearing.

Def. (3.10.2.2)[Cohomological Operators]. Given reduced ES-cohomology theories \( \tilde{E}^* \), \( \tilde{F}^* \), \( p, n \in \mathbb{Z} \), a cohomological operator of type \( p \) and degree \( n \) is a natural homomorphism \( \tilde{E}^p \to \tilde{F}^{p+n} \).

A stable cohomological operator of degree \( n \) is a sequence of cohomological operators \( \Phi^p_n \) of type \( p \) and degree \( n \) that commutes with the suspension isomorphism.

Ordinary Cohomology Theories

Thm. (3.10.2.3)[Uniqueness of Ordinary Homology Theories]. There exists a unique ordinary cohomology theory, i.e. the one given by cellular cohomology groups.

Proof: The proof is the same as that of (3.10.1.25).

Prop. (3.10.2.4)[Universal Coefficient Theorem]. See (3.3.4.6).

Cor. (3.10.2.5). A map between topological spaces that induce isomorphism on arbitrary homology group induce isomorphisms on cohomology groups.

Def. (3.10.2.6)[Cup Product]. For \( X, Y \in \mathcal{CW} \), as \( C_\bullet(X) \otimes C_\bullet(Y) \cong C_\bullet(X \times Y) \) (3.10.1.22), for any \( R \in \mathcal{CAlg} \), there is a chain homomorphism

\[
\text{Hom}^\bullet(C_\bullet(X), R) \otimes \text{Hom}^\bullet(C_\bullet(Y), R) \to \text{Hom}^\bullet(C_\bullet(X \times Y), R),
\]

which induces a natural cross product map

\[
H^*(X; R) \otimes H^*(Y; R) \to H^*(X \times Y; R).
\]

And composing with the diagonal map \( \Delta_X : X \to X \times X \) gives a cup product map

\[
H^*(X; R) \times H^*(X; R) \to H^*(X \times Y; R)
\]

that makes \( H^*(X; R) \) into a unital commutative graded \( R \)-algebra.

Proof: Cf. [May, P139].

Def. (3.10.2.7)[Bockstein Homomorphism].

Prop. (3.10.2.8). The square of the Bockstein homomorphism \( H^n(X, \mathbb{F}_p) \to H^{n+2}(X, \mathbb{F}_p) \) is trivial.

Proof: There is a commutative diagram of commutative rings

\[
\begin{array}{cccccc}
0 & \to & \mathbb{Z} & \xrightarrow{x^m} & \mathbb{Z} & \to & \mathbb{Z}/(m) & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \to & \mathbb{Z}/(m) & \xrightarrow{x^m} & \mathbb{Z}/(m^2) & \to & \mathbb{Z}/(m) & \to & 0
\end{array}
\]
which induces commutative diagrams

\[
\begin{array}{ccc}
H^n(X, \mathbb{Z}/(m)) & \xrightarrow{\bar{\beta}} & H^{n+1}(X, \mathbb{Z}) \\
\downarrow & & \downarrow \rho \\
H^n(X, \mathbb{Z}/(m)) & \xrightarrow{\beta} & H^n(X, \mathbb{Z}/(m))
\end{array}
\]

so \( \beta = \rho \bar{\beta} \), and \( \beta^2 = \rho \beta \rho \bar{\beta} = 0 \), as \( \bar{\beta} \rho = 0 \) by long exact sequence.

\( \square \)

**Prop. (3.10.2.9)** [Lefschetz Fixed Point Theorem].

**Prop. (3.10.2.10)** [Wedge Sums]. For \( M, N \in \text{Top} \), \( \tilde{H}^i(M \vee N) = \tilde{H}^i(M) \otimes \tilde{H}^i(N) \).

**Proof:** As \( M \# N/S^{d-1} = M \vee N \), there is a long exact sequence

\[ \ldots \rightarrow \tilde{H}^i(M \vee N) \rightarrow \tilde{H}^i(M \# N) \rightarrow \tilde{H}^i(S^{d-1}) \rightarrow \tilde{H}^{i+1}(M \# N) \rightarrow \ldots \]

Thus by (3.10.2.10), \( \tilde{H}^i(M \# N) = \tilde{H}^i(M) \oplus \tilde{H}^i(N) \) for \( i \neq d-1, d \). And there is an exact sequence

\[ 0 \rightarrow \tilde{H}^{d-1}(M \vee N) \rightarrow \tilde{H}^{d-1}(M \# N) \rightarrow \mathbb{Z} \rightarrow \tilde{H}^d(M \vee N) \rightarrow \tilde{H}^d(M \# N) \rightarrow 0. \]

If \( M, N \) are both orientable, then so does \( M \# N \), and the sequence looks like

\[ 0 \rightarrow \tilde{H}^{d-1}(M \vee N) \rightarrow \tilde{H}^{d-1}(M \# N) \rightarrow \mathbb{Z} \rightarrow \tilde{H}^d(M \vee N) \rightarrow 0. \]

and \( \tilde{H}^{d-1}(M \# N) \cong \tilde{H}^{d-1}(M \# N) \).

If only one of \( M, N \) is orientable, then similarly, \( \tilde{H}^{d-1}(M \vee N) \cong \tilde{H}^{d-1}(M \# N) \).

If neither \( M, N \) are orientable, then nor does \( M \# N \), and the sequence looks like

\[ 0 \rightarrow \tilde{H}^{d-1}(M \vee N) \rightarrow \tilde{H}^{d-1}(M \# N) \rightarrow \mathbb{Z} \rightarrow 0 \otimes 0 \rightarrow 0 \rightarrow 0. \]

which splits \( \square \), so \( \tilde{H}^{d-1}(M \# N) \cong \tilde{H}^{d-1}(M \vee N) \oplus \mathbb{Z} \).

**Cup and Cap Products**

Main references are [Hat02]Chap3.2.

**Prop. (3.10.2.12).** The cup product will restrict to a relative version:

\[ H^*(X, A) \times H^*(X, B) \rightarrow H^*(X, A \cup B), \]

This implies that if \( X \) is a union of \( n \) contractible open set, then the cup product of \( n \)-elements vanish. In particular, the cup product in a suspension vanishes.

**Prop. (3.10.2.13)** [Künneth Formula]. The cross product \( H^*(X, R) \otimes_R H^*(Y, R) \rightarrow H^*(X \times Y, R) \) is an isomorphisms of rings if \( X, Y \) are CW complexes and \( H^*(Y, R) \) are a finite free \( R \)-modules for any \( k \).

**Proof:** Cf. [Hat02]P219.

**Def. (3.10.2.14)** [Cap Products].
Cohomology of Fiber Bundles

Prop. (3.10.2.15) [Leray-Hirsch]. For a fiber bundle $F \to E \to B$ and a ring $R$ s.t. $H^n(F, R)$ is f.g free for all $n$, and there exist classes $c_j$ of $H^*(E)$ that constitute a basis for each fiber $F$, then

$$H^*(B, R) \otimes H^*(F, R) \to H^*(E, R)$$

is an isomorphism of $H^*(B, R)$-modules.

Proof:

□

Cor. (3.10.2.16).

• $H^*(U(n); \mathbb{Z}) = \Lambda_{\mathbb{Z}}[x_1, x_3, \ldots, x_{2n-1}]$.

• $H^*(SU(n, \mathbb{R}); \mathbb{Z}) = \Lambda_{\mathbb{Z}}[x_3, \ldots, x_{2n-1}]$.

• $H^*(Sp(n); \mathbb{Z}) = \Lambda_{\mathbb{Z}}[x_3, x_7, \ldots, x_{4n-1}]$.

Prop. (3.10.2.17). $H^*(G(n, K^{\infty}); \mathbb{Z})$ where $K = \mathbb{R}, \mathbb{C}, \mathbb{H}$ is generated by the symmetric polynomials, where for $\mathbb{R}$ the coefficient is $\mathbb{Z}_2$.

Proof: Use the flag variety and first calculate for $\infty$. Then use Poincare duality to show it is mapped onto the symmetric polynomials. Cf. [Hatcher P435]. □

Prop. (3.10.2.18) [Leray-Serre]. For a Serre fibration, e.g. fiber bundle, $F \to E \to B$, that $B$ is simply connected, then there is a spectral sequence

$$E_2^{pq} = H_p(B, H_q(F)) \Rightarrow H_{p+q}(E)$$

$$E_2^{pq} = H^p(B, H^q(F)) \Rightarrow H^{p+q}(E)$$

Cor. (3.10.2.19) [Wang Sequence]. When $B = S^n$, there is a long exact sequence:

$$\cdots \to H_q(F) \to H_q(E) \to H_{q-n}(F) \to H_{q-1}(F) \to H_{q-1}(E) \to \cdots$$

Cor. (3.10.2.20) [Gysin Sequence]. When $F = S^n$, there is a long exact sequence:

$$\cdots \to H_{p-n}(B) \to H_p(E) \to H_p(B) \to H_{p-n-1}(B) \to H_{p-1}(E) \to \cdots$$

H-Spaces

Def. (3.10.2.21) [H-Spaces]. An **H-space** is a unital magma object in $\text{Ho}(\mathcal{G}^{pt})$. Equivalently, an H-space is a pointed space $X \in \mathcal{G}^{pt}$ with a map $\mu : X \times X \to X \in \text{Ho}(\mathcal{G}^{pt})$ s.t. $X \to \{\ast\} \times X \to X$ and $X \to X \times \{\ast\} \to X$ is homotopic to $\text{id}_X$.

An **associative H-space** is an H-space s.t. $\mu_X$ is associative in $\text{Top}^{pt} / \sim$. Similarly, we can define group-H-spaces and commutative H-spaces.

An H-space is called strictly associative (or a monoid space) if it comes from a unital associative object in the category of spaces.

Remark (3.10.2.22). The definition of a H-space structure can be modified when $X$ is a CW complex. In fact, when $(X, e)$ is a CW-pair, if there exists a map $\mu : X \times X \to X$ and a point $e \in X$ that $X \to \{e\} \times X \to X$ and $X \to X \times \{e\} \to X$ is homotopic to $\text{id}_X$, then $\mu$ can be homotoped that $e$ is a strict identity.
3.10. ALGEBRAIC TOPOLOGY II: HOMOLOGIES AND COHOMOLOGIES 303

Proof:  

Prop. (3.10.2.23). If $H$ is an H-space, then for any $X \in \text{Top}^\text{pt}$, $(X, H)$ is a magma. Moreover, if $H$ is a commutative associative group H-space, then $(X, H) \in \text{Ab}$. 

Prop. (3.10.2.24)[Loop Spaces are H-Spaces]. For any $X \in \text{Top}^\text{pt}$, $\Omega(X)$ is an associative group-H-space, and $\Omega^2(X)$ is a associative commutative group-H-space.

Proof: The multiplication is given by concatenation of loops. It is continuous by adjunction arguments. 

Prop. (3.10.2.25). $CP^\infty$ can be given a commutative strictly associative H-space structure. More generally, $B(Z/n) \cong (C^\infty \setminus \{0\})/(R^\times \mu_n)$(3.11.3.13) can be given a commutative strictly associative H-space structure. In particular this applies to $RP^\infty$. 

Proof: We can regard $C^\infty$ as the space of polynomials with complex coefficients, then the polynomial multiplication gives a map $(C^\infty \setminus \{0\}) \times (C^\infty \setminus \{0\}) \to C^\infty \setminus \{0\}$ that descends to a map $B(Z/n) \times B(Z/n) \to B(Z/n)$. And $e = (1, 0, \ldots, 0, \ldots)$ is the unit. 

Prop. (3.10.2.26). The James reduced product $J(X)$ is a strictly associative H-space with multiplication given by $(x_1, \ldots, x_n) (y_1, \ldots, y_m) = (x_1, \ldots, x_n, y_1, \ldots, y_m)$, and the identity $e$. This H-space structure also descends to a H-space structure on $SP(X)$(3.9.3.21). 

Prop. (3.10.2.27). The universal cover of a H-space is a H-space.

Proof: Take an arbitrary lift that maps $(\tilde{e}, \tilde{e})$ to $\tilde{e}$. Notice the homotopy can also be lifted. 

Prop. (3.10.2.28)[Cohomology Ring]. The cohomology ring of a H-space is a topologists’ Hopf algebra, by Kunneth formula and naturality. 

Cor. (3.10.2.29). $CP^n$ is not a H-space.

Proof: This is because $H^*(CP^n, Z) = Z[\alpha]/\alpha^n, |\alpha| = 2$, which is not a topologist’s Hopf algebra, by(2.9.1.14). 

Prop. (3.10.2.30). The fundamental group of an H-space is Abelian. 

Proof: This is because $\pi_1$ preserves products, so takes unital magma space to unital magma objects(3.1.1.66). And the unital magma objects in the category of groups is the Abelian groups(3.1.1.65). 

Prop. (3.10.2.31)[Adam]. $S^0, S^1, S^3, S^7$ are the only spheres that have H-structures. 

Proof: Firstly $S^1 \subset C, S^3 \subset H, S^7 \subset O$ are submonoids, so they have H-structures. 

Cor. (3.10.2.32). $RP^n$ has a H-structure iff $n = 1, 3, 7$. 

Proof: This is because the universal cover of a H-space is a H-space(3.10.2.27). Also $S^1, S^2, S^3, S^7$ are monoid spaces, and $-1$ are in their center, so the quotients are also monoid spaces.
Examples of Calculations

Cor. (3.10.2.33).

\[ H^*(\mathbb{R}P^n, F_2) = \mathbb{Z}/(2)[a]/a^{n+1}, |a| = 1, \quad H^*(\mathbb{C}P^n, \mathbb{Z}) = \mathbb{Z}[\alpha]/\alpha^{n+1}, |\alpha| = 2 \]

Proof: We prove for \( \mathbb{R}P^n \), the \( \mathbb{C}P^n \) case is similar. Use induction. For \( n = 1 \), this is clear. For \( n > 1 \), notice \( \mathbb{R}P^n \) is the \( n-1 \)-skeleton of \( \mathbb{R}P^n \), thus the map of rings \( H^*(\mathbb{R}P^n, F_2) \to H^*(\mathbb{R}P^{n-1}, F_2) \) maps the generator of \( H^2(\mathbb{R}P^n, F_2) \) to the generator \( a \) of \( H^2(\mathbb{R}P^{n-1}, F_2) \). Then by hypothesis \( a^{n-1} \neq 0 \). The \( H^{n-1}(\mathbb{R}P^n, F_2) \cong H_1(\mathbb{R}P^n, F_2) \cong \mathbb{Z}/(2) \) is generated by \( a^{n-1} \). Then the Poincaré duality shows that \( \alpha \cup a^{n-1} \neq 0 \), so we are done.

Cor. (3.10.2.34). For \( n > 1 \), the natural homomorphism \( H^n(\mathbb{R}P^n, \mathbb{Z}/2\mathbb{Z}) \to H^n(S^n, \mathbb{Z}/2\mathbb{Z}) \) is 0.

Proof: Because the cohomology ring map maps \( a \in H^1(\mathbb{R}P^n, \mathbb{Z}/2\mathbb{Z}) \) to 0 in \( H^1(S^n, \mathbb{Z}/2\mathbb{Z}) = 0 \).

Prop. (3.10.2.35) \([H^*(K, \mathbb{Z}/(2))]\). The cohomology ring of the Klein bottle \( K \) is \( H^*(K, \mathbb{Z}/(2)) = F_2[x, y]/(xy, x^2 - y^2, x^3, y^3) \).

Proof: Let \( \varphi \in C^0(K, \mathbb{Z}/(2)) \) be the dual of \( v \), \( \alpha, \beta, \gamma \in C^1(K, \mathbb{Z}/(2)) \) be the dual of \( a, b, c \), and \( \mu, \lambda \in C^2(K, \mathbb{Z}/(2)) \) be the dual of \( A, B \), then

\[ \partial(\varphi)(a) = \partial(\varphi)(b) = \partial(\varphi)(c) = 0 \]
\[ \delta(\alpha)(A) = \alpha(\partial(A)) = \alpha(a + b - c) = 1, \quad \delta(\alpha)(B) = \alpha(\partial B) = \alpha(b + c - a) = -1 \]
\[ \delta(\beta)(A) = \beta(\partial(A)) = \beta(a + b - c) = 1, \quad \delta(\beta)(B) = \beta(\partial B) = \beta(b + c - a) = 1 \]
\[ \delta(\gamma)(A) = \gamma(\partial(A)) = \gamma(a + b - c) = -1, \quad \delta(\gamma)(B) = \gamma(\partial B) = \gamma(b + c - a) = 1 \]

So

\[ H^0(K, \mathbb{Z}/(2)) = \mathbb{Z}/(2)\varphi, \quad H^1(K, F_2) = F_2(\alpha + \beta) \oplus F_2(\alpha + \gamma), \quad H^2(K, F_2) = (F_2 \mu \oplus F_2 \lambda)/(\mu + \lambda). \]

Now we calculate the cup product:

\[ (\alpha + \beta) \cup (\alpha + \beta)(A) = (\alpha + \beta)(a) \cdot (\alpha + \beta)(b) = 1 \]
\[ (\alpha + \beta) \cup (\alpha + \gamma)(A) = (\alpha + \beta)(a) \cdot (\alpha + \gamma)(b) = 0 \]
\[ (\alpha + \gamma) \cup (\alpha + \gamma)(A) = (\alpha + \gamma)(a) \cdot (\alpha + \gamma)(b) = 0 \]
\[ (\alpha + \beta) \cup (\alpha + \beta)(B) = (\alpha + \beta)(b) \cdot (\alpha + \beta)(c) = 0 \]
\[ (\alpha + \beta) \cup (\alpha + \gamma)(B) = (\alpha + \beta)(b) \cdot (\alpha + \gamma)(c) = 1 \]
\[ (\alpha + \gamma) \cup (\alpha + \gamma)(B) = (\alpha + \gamma)(b) \cdot (\alpha + \gamma)(c) = 0 \]

Then \( (\alpha + \beta) \cup (\alpha + \beta) = (\alpha + \beta) \cup (\alpha + \gamma) = \mu \in H^2(K, \mathbb{Z}/(2)) \). Now if we set \( \alpha + \beta = x, \beta + \gamma = y \), then the cohomology ring

\[ H^*(K, \mathbb{Z}/(2)) = \mathbb{Z}/(2)[x, y]/(xy, x^2 - y^2, x^3, y^3). \]

Prop. (3.10.2.36) \([H^*(L, \mathbb{Z}/(m))]\). Let \( L \) be the Lens space, then the cohomology ring is calculated at [?]P304.

Proof:
3 Manifolds

Orientations

Prop. (3.10.3.1). Let $d \in \mathbb{Z}_+, R \in \mathcal{C}\text{Alg}, M \in \text{Mani}^d, X \subset M$, then for any $x \in M$, choose a nbhd $U$ of $x \in M$ s.t. $U \cong \mathbb{R}^n$, then by excision and exactness,

$$H_d(M,M\setminus x) \cong H_d(U, U\setminus x) \cong \tilde{H}_{d-1}(U\setminus \{x\}) \cong \tilde{H}_{d-1}(S^{d-1}) \cong R.$$  

Prop. (3.10.3.2) [Vanishing]. For $M \in \text{Mani}_{\text{cpt, cntd, } \partial}^d, \Lambda \in \mathcal{A}b$, $H_i(M; \Lambda) = 0$ for $i > d$, and $\tilde{H}_d(M; \Lambda) = 0$ unless $M$ is compact without boundary.

Proof:

Def. (3.10.3.3)[$R$-Fundamental Class]. Let $R \in \mathcal{C}\text{Alg}, M \in \text{Mani}^d_{\text{cntd}}, X \subset M$, an $R$-fundamental class of $M$ at $X$ is an element $z \in H_d(M,M\setminus X)$ s.t. for any $x \in X$, the map

$$H_d(M,M\setminus X) \rightarrow H_d(M,M\setminus \{x\})$$

maps $z$ to a generator of $H_d(M,M\setminus \{x\}) \cong R(3.10.3.1)$.

Def. (3.10.3.4)[$R$-Orientation]. Let $R \in \mathcal{C}\text{Alg}, M \in \text{Mani}^d_{\text{cntd}}, X \subset M$, an $R$-orientation of $M$ is an open cover \{$U_i$\} of $M$ and $R$-fundamental classes $z_i$ of $M$ at $U_i$ s.t. $z_i, z_j$ restricts to the same element in $H_d(M,M\setminus (U_i \cup U_j))$.

For $M \in \text{Mani}^d_{\text{cntd, } \partial}$, an $R$-orientation is an $R$-orientation of $M^u$.

Prop. (3.10.3.5)[$R$-Fundamental Classes and $R$-Orientations]. For $R \in \mathcal{C}\text{Alg}, M \in \text{Mani}^d$ and $K \subset M$ compact, then

- $H_i(M,M\setminus K, R) = 0$ for $i > d$.
- Any $R$-orientation of $M$ defines an $R$-fundamental class of $M$ at $K$ that is compatible for $x \in K$.

In particular, if $M$ is compact, then an $R$-orientation is equivalent to an $R$-fundamental class.

Proof: Firstly, if $K \subset U$ and $U \cong \mathbb{R}^n$ is a coordinate chart on which the $R$-orientation is defined, then by excision and exactness,

$$H_i(M,M\setminus K, R) \cong H_i(U, U\setminus K, R) \cong H_{i-1}(U\setminus K, R)$$

which vanishes for $i > n$ by vanishing theorem(3.10.3.2). And the $R$-orientation restricts to $K$.

In general, $K$ can be written as a sum of compact subsets each contained in a coordinate chart on which the $R$-orientation is defined. Then using induction, it suffices to show that if the results hold for $K, L, K \cap L$, then it holds for $K \cup L$: item1 follows from the MV-sequence

$$H_{i+1}(M,M\setminus (K \cup L)) \rightarrow H_i(M,M\setminus (K \cup L)) \rightarrow H_i(M,M\setminus K) \oplus H_i(M,M\setminus L) \rightarrow H_i(M,M\setminus (K \cap L)).$$

For item2, the same MV-sequence with $R$-coefficients and $i = d$ together with the definition of $R$-orientation classes(3.10.3.4) shows there exists a fundamental class at $K \cap L$ that restricts to the fundamental classes at $K$ and $L$. 

Prop. (3.10.3.6) [Orientation Dichotomy]. For $d \in \mathbb{Z}_+, M \in \text{Mani}^d_{\text{cntd, cpt}}$, there are only two cases:
• $M$ is non-orientable, and $H_d(M) = 0$.

• $M$ is orientable, and the map $H_d(M) \to H_d(M, M\backslash\{x\}) \cong \mathbb{Z}(3.10.3.1)$ is an isomorphism for any $x \in M$.

Proof: For any $R \in \mathbb{C}\text{Alg}$, as $M\backslash\{x\}$ is connected and non-compact, $H_d(M\backslash\{x\}; R) = 0$ by(3.10.3.2), thus

$$H_d(M, R) \to H_d(M, M\backslash\{x\}; R) \cong R$$

is injective. Thus $H_d(M) \cong 0$ or $\mathbb{Z}$. In particular, by universal coefficients theorem,

$$H_d(M) \otimes \mathbb{F}_p \to H_d(M, M\backslash\{x\}) \otimes \mathbb{F}_p$$

is injective for any $p \in \mathbb{P}$. Then it is clear to see that $H_d(M) \to H_d(M, M\backslash\{x\})$ is an isomorphism for any $x \in M$.

\[\square\]

Prop.(3.10.3.7) [Fundamental Classes on Manifolds with Boundaries]. For $M \in \text{Mani}^d_\partial$, $\partial M \neq 0$, an $R$-orientation on $M$ determines an $R$-orientation of $\partial M$. Moreover, the fundamental class $[\partial M]_R$ defined by(3.10.3.5) comes from the partial of a unique element $[M]_R \in H_d(M, \partial M; R)$, called the $R$-fundamental class determined the orientation.

\[\begin{proof}\]

By collar nbhd theorem, $M \cong M^\circ$, and by vanishing theorem, $H_d(M) \cong H_d(M^\circ) = 0$, thus $H_d(M, \partial M; R) \to H_{d-1}(\partial M; R)$ is injective. Let $N$ be an open collar of $\partial M$, then $H_d(M^\circ, M^\circ \cap N; R) \cong H_n(M, \partial M; R)$. Also, $M \backslash N$ is compact, so the orientation on $M^\circ$ defines a fundamental class in $H_d(M, M^\circ \cap N; R) \cong H_n(M, \partial M; R)$. Then this class determined the orientation on every point of $M^\circ$, and determines the orientation on $\partial M$, Cf.[May, P170].

\[\square\]

Prop.(3.10.3.8) [Orientation Coverings].

\[\begin{proof}\]

\[\square\]

Cor.(3.10.3.9). If $M \in \text{Mani}^d_\text{cntd}$, then if $M$ is orientable, it has exactly two orientations. And if $M$ is simply connected or $\pi_1(M)$ has no subgroup of index 2, then $M$ is orientable.

Def.(3.10.3.10) [Connected Sums]. For $M, N \in \text{Mani}^d_\text{cntd, cplt}$, define the connected sum $M \# N$ as follows: Take a subset $D \subset M, D' \subset N$ that are contained in coordinate charts(orientable coordinates charts if $M, N$ are oriented). $\varphi : U \cong \mathbb{R}^d, \varphi' : U' \cong \mathbb{R}^d$ s.t. $\varphi(D) \cong D(0) \cong \varphi(D' \setminus D')$. Then define

$$M \# N = (M \backslash D) \bigsqcup_{\partial D \cong \partial D'} (N \backslash D')$$

where $\partial D \cong \partial D'$ is an orientation-reversing homeomorphism when $M, N$ are both orientable. This is independent of $D, D'$ and the homeomorphism $\partial D \cong \partial D'$ chosen.

\[\begin{proof}\]

Firstly we show that $M \backslash D$ is independent of $D$ chosen: As $M$ is locally path connected and connected, it is path connected, Then we can consider a chain of charts isomorphic to $\mathbb{R}^d$ that connects any two such subsets $D, D'$. Then reducing to affine charts, it suffices to show for the case $M \cong \mathbb{R}^d$. In this case, we can use isotopy of $M$ to make $D \subset D'$, and then use the coordinate charts and annulus theorems(3.6.11.2) to show that $D' \backslash D$ is isomorphic to $S^{d-1} \times I$. Then the homeomorphism $M \backslash D \cong M' \backslash D'$ can be easily given.

Now we show the connected sum is independent of the homeomorphism chosen: $\partial D$ and $\partial D'$ are given orientations by the coordinate charts, and in the non-orientable case, use the argument above
on the orientation covering of $M(3.10.3.8)$, we know there exists a self-homeomorphism of $M$ that is isotopic to $\text{id}_M$ that reverses the orientation on $\partial D$. Thus in both cases, we can assume $\partial D \cong \partial D'$ is orientation-preserving. Now (3.9.2.2) shows any such homeomorphism is isotopic, and using the coordinate charts, we can extend the isotopy to a nbhd of nbhd of $\partial D$. Thus the connected sum is well-defined.

\textbf{Remark (3.10.3.11).} WARNING: The connected sum may be different in the orientable case if we change one of the orientations: $\mathbb{C}P^2 \# \mathbb{C}P^2$ is not homeomorphic to $\mathbb{C}P^2 \# \overline{\mathbb{C}P^2}$.

\textit{Proof:}

\textbf{Poincaré Duality}

\textbf{Lemma (3.10.3.12) [Poincaré Duality].} For $R \in \mathcal{C}\text{Alg}$, if $M \in \text{Mani}^d_{\text{cndt, cpct}}$ is $R$-oriented, then for any $p \in \mathbb{Z}$, there is an isomorphism

$$D = - \cap [M]_R : H^p(M; R) \cong H_{n-p}(M; R).$$

In particular, $H^n(X, \mathbb{F}_2) \cong \mathbb{Z}/(2)$, and the non-trivial element is called the \textbf{fundamental homology class mod 2}, denoted by $[M]_2$.

\textit{Proof:} which follows immediately from (5.8.6.30) and (5.3.5.9). (Should also attain the compact cohomology case if we know the relation of compact sheaf cohomology better).

\textbf{Prop. (3.10.3.13) [Relative Poincaré Duality].} Let $R \in \mathcal{C}\text{Alg}$, $M \in \text{Mani}^d_{\text{cpct, cntd}}$ be $R$-orientable with fundamental class $[M]_R \in H_d(M, \partial M; R)$, then for any $\Lambda \in \text{Mod}_R$, capping with $[M]_R$ defines isomorphisms

$$H^p(M, \partial M; \Lambda) \cong H_{d-p}(M), \quad H^p(M; \Lambda) \cong H_{d-p}(M, \partial M; \Lambda).$$

\textit{Proof:} Cf. [May, P170].

\textbf{Cor. (3.10.3.14).} For $M \in \text{Mani}^d_{\text{cndt, cpct, orntd}}$, for any $p \in \mathbb{Z}$, there is a perfect pairing

$$H^p(M)_{\text{if}} \times H^{n-p}(M)_{\text{if}} \to \mathbb{Z} : (\alpha, \beta) \mapsto \langle \alpha \cup \beta, [M] \rangle.$$

\textit{Proof:} By universal coefficient theorem?, $H^p(M)_{\text{if}} \cong \text{Hom}(H_p(M), \mathbb{Z})$. So if $\alpha \in H^p(M)$ is non-zero in $H^p(M)_{\text{if}}$, there exists $a \in H_p(M)$ s.t. $\langle a, \alpha \rangle = 1$. Then by Poincaré duality (3.10.3.12), there exists $\beta \in H^{d-p}(M)$ s.t. $\beta \cap [M] = a$. Thus $\langle \alpha \cup \beta, [M] \rangle = \langle \alpha, \beta \cap [M] \rangle = 1$.

\textbf{Def. (3.10.3.15) [Intersection Pairing].} Let $k \in \mathbb{N}, M \in \text{Mani}^{2k}_{\text{cpct, orntd, cntd}}$. The Poincaré duality (3.10.3.14) shows the cup product pairing

$$H^k(M; \mathbb{Q}) \times H^k(N; \mathbb{Q}) \to \mathbb{Q} : (\alpha, \beta) \mapsto \langle \alpha \cup \beta, [M] \rangle$$

is non-degenerate, called the \textbf{intersection pairing} of $M$. Notice if $k$ is odd, it is skew-symmetric, and if $k$ is even, it is symmetric.

\textbf{Def. (3.10.3.16) [Index].} For $M \in \text{Mani}^d_{\text{cpct, orntd, cntd}}$, define the \textbf{index of $M$} as the index of the symmetric intersection pairing of $M$ if $d = 4k$, and 0 otherwise. The index of $M$ is denoted by $I(M)$.
Prop. (3.10.3.17). For $M, N \in \text{Mani}_{\text{cpt,orntd,cntd}}$, $I(M \times N) = I(M)I(N)$.

Proof: Cf.[May, P167]. □

Prop. (3.10.3.18). For $k \in \mathbb{N}, k \in \text{Field}, M \in \text{Mani}_{\text{cpt,\&}}^{2k+1}$, then

$$\dim_k H_k(\partial M; k) = 2 \dim \ker(H_k(\partial M; k) \xrightarrow{i_\ast} H_k(M; k)) = 2 \dim \text{Im}(H_k(\partial M; k) \xrightarrow{i_\ast} H^k(M; k)).$$

Proof: There is a commutative diagram

$$
\begin{array}{ccc}
H^k(\partial M; k) & \xrightarrow{i_\ast} & H^k(M; k) \\
\downarrow D & & \downarrow D \\
H_{k+1}(M, \partial M; k) & \xrightarrow{\partial} & H_k(M; k) \xrightarrow{i_\ast} H_k(\partial M; k)
\end{array}
$$

where the vertical arrows are isomorphisms and $i_\ast$ is the vector dual of $i^\ast$ by universal coefficient theorem. Thus the theorem follows. □

Prop. (3.10.3.19) [Gysin Sequence]. Cf.[姜伯驹同调论].

Euler Characteristic

Def. (3.10.3.20) [Euler Characteristic]. For any $X \in \text{Top}$ with finite $\mathbb{Z}$-homologies, define the Euler character of $X$ to be

$$\chi(X) = \sum_i (-1)^i H_i(X; \mathbb{Z}).$$

Then by universal coefficients theorem (3.10.2.4),

$$\chi(X) = \sum_i (-1)^i H_i(X; k)$$

for any $k \in \text{Field}$. The condition holds for $X \in \mathbb{C}W_{\text{fin}}$, in particular any $X \in \text{Mani}_{\text{cpt}}$ (3.9.3.10).

Prop. (3.10.3.21). For any $i \in \mathbb{N}, X \in \text{Mani}_{\text{cpt,orntd}}^{2i+1}$, $\chi(X) = 0$.

Proof: This follows from Poincaré duality for $\mathbb{F}_2$-coefficients. □

Prop. (3.10.3.22) [Euler Characteristic and Boundary]. For $i \in \mathbb{N}, M \in \text{Mani}_{\text{cpt,\&}}^{2i+1}$, then

$$\chi(\partial M) = 2\chi(M).$$

Proof: Consider the “double” $\widetilde{M}$ of $M$ along $\partial M$, then $\widetilde{M} \in \text{Mani}_{\text{cpt,\&}}^{2i+1}$. It is clear by excision and collar neighborhood theorem that $\chi(\widetilde{M}) + \chi(\partial M) = 2\chi(M)$. Then we use (3.10.3.21). □

Cor. (3.10.3.23). If $N \in \text{Mani}_{\text{cpt}}$ is a boundary of some other $M \in \text{Mani}_{\text{cpt,\&}}$, then $\chi(N) = 0$.

Proof: If dim $N$ is odd, this is (3.10.3.21). If dim $N$ is even, this is (3.10.3.22). □

Prop. (3.10.3.24). For any $i \in \mathbb{N}, M \in \text{Mani}_{\text{cpt,orntd}}^{4i+2}$, $\chi(M)$ is even.

Proof: The parity of $\chi(M)$ is the same as $H^{2i+1}(M, \mathbb{Q})$, which is odd by (3.10.3.15) and (2.3.8.7). □
Prop. (3.10.3.25) [Morse Inequality]. For any $X \in \mathcal{CW}$,
$$\chi(X) \leq \sum (-1)^i c_i(X),$$
where $c_i(X)$ is the number of $I$-dimensional cells. (Use the dimension counting of the long exact sequence).

**Prop. (3.10.3.26).** For $M \in \text{Mani}_{\text{cpt,orntd}}^d$, $I(M) \equiv \chi(M) (\mod 2)$.

**Proof:** If $d$ is odd, $I(M) = 0 = \chi(M)$ is even by (3.10.3.21). If $d = 4k + 2$, then $I(M) = 0$ and $\chi(M)$ is even by (3.10.3.24). If $d = 4k$, then $I(M) \equiv \chi(M) \equiv \dim H^{2k}(M, \mathbb{Q})$.

**deRham Cohomology**

**Prop. (3.10.3.27) [de Rham Comparison].** For $X \in \text{Mani}_{\text{sm}}$, $G \in \mathcal{Ab}$, by (5.3.5.11).
$$H^*_\text{dr}(X, G) \cong H^*(X, G).$$

**Prop. (3.10.3.28) [Homotopy Axiom for deRham Cohomology].** For two homotopic map between two smooth manifold, they induce the same map on deRham Cohomology.

**Proof:** We only have to prove the case of $M \times \mathbb{R} \to M$, where any constant section map induces an isomorphism $H^*_\text{dr}(M \times I) \cong H^*_\text{dr}(M)$. Because any homotopy is a morphism $M \times I \to N$ where $f$ and $g$ are the sections 0 and 1.

For the zero section, we define $K : a + bdt \mapsto \int_0^t b$. This is the desired homotopy, Cf.[Differential Forms in Algebraic Topology Bott Tu].

4 Applications

**Prop. (3.10.4.1) [No Contraction to the Boundary].** For $M \in \text{Mani}_{\text{cpt,fr}}^d$, there are no retraction from $M$ onto $\partial M$.

**Proof:** We may assume $\partial M$ is connected and non-empty, otherwise clearly there are no retraction. If it has a retraction, $H_{d-1}(\partial M, \mathbb{F}_2) \to H_{d-1}(M, \mathbb{F}_2)$ has a left inverse. Thus it suffices to show that $H_{d-1}(\partial M, \mathbb{Z}/(2)) \to H_{d-1}(M, \mathbb{Z}/(2))$ is 0. So it suffices to show that $H_d(M, \partial M, \mathbb{Z}/(2)) \to H_{d-1}(\partial M, \mathbb{Z}/(2))$ is surjective. And this follows from (3.10.3.7) and (3.10.3.6) as the image of $[M]_2$ is $[\partial M]_2$, which generates $H_{d-1}(\partial M, \mathbb{F}_2)$.

**Prop. (3.10.4.2) [Brouwer Fixed Point Theorem].** For any $f : \mathbb{D}^n \to \mathbb{D}^n \in \mathcal{Top}$, $\text{Fix}(f) \neq \emptyset$.

**Proof:** If $\text{Fix}(f) = \emptyset$, consider the intersection of the ray $f(x)x$ with $S^{n-1}$, then it depends continuously on $x$, and this defines a function from $D^n$ to $S^n$ that is identity on $S^n$, but then this is a retraction from $\mathbb{D}^n \to \mathbb{S}^n$, which is impossible by (3.10.4.1).

**Prop. (3.10.4.3).** If $M \in \text{Mani}_{\text{cntd,fr}}^d$, then if $M$ is contractible and $\partial M \neq \emptyset$, $\partial M$ is a homotopy sphere.

**Proof:** As $M^n \sim M$ is contractible, it is orientable by (3.10.3.9). Then by relative Poincaré duality (3.10.3.13) and the long exact sequence,
$$H_p(\partial M) \cong H_{p+1}(M, \partial M) \cong H^{d-p-1}(M) = 0.$$
Lemma (3.10.4.4). If $m > n \in \mathbb{Z}^+$, any map $f : \mathbb{R}P^m \to \mathbb{R}P^n$ induces $f_* = 0 : \pi_1(\mathbb{R}P^m) \to \pi_1(\mathbb{R}P^n)$.

Proof: As $\pi_1(\mathbb{R}P^m) = \begin{cases} \mathbb{Z}/(2), & m > 1 \\ \mathbb{Z}, & m = 1 \end{cases}$. The assertion is clearly true for $n = 1$. And if $n \in \mathbb{Z}^+, f_* \neq 0$, then by the naturality of Hurewicz homomorphism (3.10.1.17), $f_* \neq 0 : H_1(\mathbb{R}P^m) \to H_1(\mathbb{R}P^n)$. Then by universal coefficient theorem, so is $f^* \neq 0 : H^1(\mathbb{R}P^n, \mathbb{F}_2) \to H^1(\mathbb{R}P^m, \mathbb{F}_2)$. But $f^*$ is a ring homomorphism and $H^*(\mathbb{R}P^m)$ is generated by $a = f^*(a') \in H^1(\mathbb{R}P^m)(3.10.2.33)$, so $a^{n+1} = f^*((a')^{n+1}) = 0$, contradiction. \square

Lemma (3.10.4.5). If $m > n \geq 1$, there are no antipodal maps: $f : S^m \to S^n$, i.e. $f(x) = -f(-x)$.

Proof: Any such map induces a map $\mathbb{R}P^m \to \mathbb{R}P^n$, which induces 0 on $\pi_1$, so by covering space theory, there exists a lifting $\mathbb{R}P^m \to S^n$. The composition $S^m \to \mathbb{R}P^m \to S^n$ is the original map, by the theory of covering spaces, as $S^n$ is connected and they agree at least on one point. But then $f$ takes antipodal maps to the same point, contradiction. \square

Thm. (3.10.4.6) [Borsuk-Ulam]. For ant map $f : S^n \to \mathbb{R}^n$, there exists $x \in S^n$ s.t. $f(x) = f(-x)$.

Proof: If $f(x) \neq f(-x)$ for any $x \in S^n$, then we can define a map $S^n \to S^{n-1}$ that maps $x$ to the intersection of the ray $0, f(x) - f(-x)$ with $S^n$. Then this map is antipodal, which contradicts (3.10.4.5). \square

5 Obstruction Theory & General Cohomology Theory

Towers

Prop. (3.10.5.1) [Towers]. There are Whitehead Towers and Postnikov Towers for a CW complex $X$.

$$\cdots \to Z_2 \to Z_1 \to Z_0 \to X \to \cdots \to X_2 \to X_1 \to X_0$$

$Z_n$ annihilate $\pi_{\leq n}(X)$, $X_n$ remains only $\pi_{\leq n}(X)$. The towers can be chosen to be fibrations, with fibers $K(\pi_nX, n)$ by (3.9.6.30).

Prop. (3.10.5.2). There is a Postnikov towers of:

$$B\text{String}(n) \to B\text{Spin}(n) \to B\text{SO}(n) \to BO(n)$$

with corresponding obstructions $w_1(X), w_2(X)$ and $p_1(X)/2$.

Prop. (3.10.5.3) [Obstructions]. If a connected abelian CW complex $X$ ($\pi_1(X)$ abelian and action on higher homotopy trivial) and $(W, A)$ satisfies $H^{n+1}(W, A; \pi_nX) = 0$ for all $n$, then $A \to X$ can extend to a map $M \to X$.

Proof: Cf. [Hatcher P417]. \square

Cor. (3.10.5.4). A map between Abelian CW complexes that induce isomorphisms on homology is a homotopy equivalence.

Proof: Notice that $\pi_1(X)$ acts trivially on $\pi_1(Y, X)$ and use Hurewicz. \square
6 Brown Representability

Prop.(3.10.6.1). For any $Z \in \mathcal{Top}^{pt}$, the functor

$$\langle - , Z \rangle : \mathcal{CW}^{pt} \to \mathcal{Set}^{pt}$$

satisfies:

**Exactness:** If $A \subset X$ is a subcomplex, then there is an exact sequence

$$\langle X/A, Z \rangle \to \langle X, Z \rangle \to \langle A, Z \rangle.$$

**Additivity:** If $X = \bigvee_i X_i \in \mathcal{CW}^{pt}$, then

$$\langle X, Z \rangle \cong \prod_i \langle X_i, Z \rangle.$$

*Proof:* 1 follows from the fact that $A \to X$ is a cofibration(3.9.6.5). 2 is trivial. □

**Spectrum**

Def.(3.10.6.2)[Prespectrums]. A prespectrum is a sequence of pointed spaces $(T_n)_{n \in \mathbb{Z}}$ together with maps $\sigma_n \in \langle \Sigma T_n \to T_{n+1} \rangle \cong \langle T_n, \Omega T_{n+1} \rangle$.

An $\Omega$-Spectrum is an prespectrum $(T_n)_{m \in \mathbb{Z}}$ s.t. $\sigma_n$ are all weak-homotopy equivalences.

Def.(3.10.6.3)[Suspension Prespectrums]. For $X \in \mathcal{Top}^{pt}$, the sequence of pointed spaces $(\Sigma^n(X))_{n \in \mathbb{Z}}$ (where we define $\Sigma^{-1} = \Omega$) is a prespectrum, called the suspension prespectrum of $X$. If $X = S^0$, this is called the sphere spectrum.

Prop.(3.10.6.4)[Prespectrum and Homotopy Theories]. Let $(T_n)_{n \in \mathbb{N}}$ be a prespectrum consisting of pointed CW complexes s.t. $T_n$ is $(n-1)$-connected for any $n \in \mathbb{N}$, then

$$\tilde{E}_p(X) = \lim_{n} \pi_{p+n}(X \wedge T_n)$$

is a reduced homology theory on $\mathcal{CW}^{pt}$.

*Proof:* Cf.[May, P176]. □

Prop.(3.10.6.5)[$\Omega$-Prespectrum and ES-Cohomology theories]. If $K_n$ is an $\Omega$-spectrum, i.e. $K_n \cong \Omega K_{n+1}$ weak equivalence, then the functors $X \mapsto \langle X, K_n \rangle$ define a reduces ES-cohomology theory on $\mathcal{CW}^{pt}$

*Proof:* By(3.10.6.1), these functors satisfy the additivity and exactness. The natural suspension isomorphism is given by

$$\Sigma : \langle X, T_n \rangle \to \langle \Sigma(X), \Sigma T_n \rangle \cong \langle \Sigma(X), \Sigma T_n \rangle,$$

which is an isomorphism by(3.9.5.5). □

Thm.(3.10.6.6)[Brown Representability]. Any reduced ES-cohomology theory on $\mathcal{CW}^{pt}$ is represented by a $\Omega$-prespectrum.

*Proof:* ? □
Eilenberg-Maclane Spaces

Def. (3.10.6.7) [Eilenberg-Maclane Spaces]. For $\Lambda \in Ab$, an Eilenberg-Maclane space is defined to be a pointed CW complex $K(\Lambda, n) \in \mathcal{CW}^pt$ s.t. $\pi_k(K(\Lambda, n)) = \begin{cases} \Lambda, & k = n \\ 0, & \text{otherwise.} \end{cases}$

Prop. (3.10.6.8) [Eilenberg-Maclane Spaces and Homologies]. For $X \in \mathcal{CW}^pt, \Lambda \in Ab$, there are isomorphisms

$$\tilde{H}_p(X; \Lambda) \cong \lim_{\longrightarrow} \pi_{p+n}(X \wedge K(\Lambda, n)).$$

Proof: Cf. [May, P176]. □

Prop. (3.10.6.9) [Eilenberg-Maclane Spaces and Cohomologies]. For $\Lambda \in Ab, X \in \mathcal{CW}^pt, n \in \mathbb{N}, K(\Lambda, n)$ are unique up to weak homotopy, and there are natural isomorphisms

$$\tilde{H}^n(X; \Lambda) \cong \langle X, K(\Lambda, n) \rangle.$$

Proof: Given a $K(\Lambda, n)$, if we define $K(\Lambda, m) = \Sigma^{m-n}(K(\Lambda, n))$, then these are all CW complexes by (3.9.3.13), and it defines an ordinary cohomology theory: The dimension axiom follows from the definition of $K(\Lambda, n)$, and it is a reduced ES-cohomology theory by (3.9.5.5) and (3.10.6.10). Thus the asserted isomorphism follows from (3.10.2.3).

This shows in particular that $K(\Lambda, n)$ are unique up to homotopy by Yoneda lemma. □

Cor. (3.10.6.10) [Uniqueness of Eilenberg-Maclane Spaces]. $K(\Lambda, n)$ is unique up to homotopy, and $\Omega(K(\Lambda, n)) \sim K(\Lambda, n - 1) \in \mathcal{CW}^pt$.

Prop. (3.10.6.11) [Eilenberg-Maclane Spaces Exist]. Take $K(\Lambda, n) = \Gamma(B(\Lambda, n))(3.11.3.7)$, where $\Lambda$ is regarded as a discrete subgroup.

Note $K(G, 1)$ is constructed the same as by (3.12.7.30).

Proof: □

Prop. (3.10.6.12) [Cohomology Operators]. Cohomological operators $\tilde{H}^p(-; \Lambda) \rightarrow \tilde{H}^{p+n}(-; \Lambda)$ are in bijection with elements in $\tilde{H}^{p+n}(K(\Lambda, p); \Lambda')$, by (3.10.6.9) and Yoneda lemma.

Prop. (3.10.6.13) [Examples].

- $K(\mathbb{Z}, 1) = S^1 = U(1)$.
- $K(\mathbb{Z}, 2) = \mathbb{C}P^\infty$.
- $K(\mathbb{Z}/(2), 1) = \mathbb{R}P^\infty$.

Proof: 1 is clear.

2: This is because by (3.11.1.17), $S^\infty \rightarrow \mathbb{C}P^\infty$ is a locally trivial bundle with fiber $S^1$, and $S^\infty$ is contractible by (3.9.3.18) thus by (3.9.6.14), $\pi_2(\mathbb{C}P^\infty) = \mathbb{Z}$ and $\pi_n(\mathbb{C}P^\infty) = 0$ for $n \neq 2$.

3: This is because by (3.11.1.17), $S^\infty \rightarrow \mathbb{C}P^\infty$ is a locally trivial bundle with fiber $\{\pm 1\}$, and $S^\infty$ is contractible by (3.9.3.18) thus by (3.9.6.14), $\pi_2(\mathbb{C}P^\infty) = \mathbb{Z}/2\mathbb{Z}$ and $\pi_n(\mathbb{C}P^\infty) = 0$ for $n \neq 2$. □
Steenrod Powers

Prop.(3.10.6.14)[Steenrod Powers]. There are stable cohomology operators

\[ Sq : H^*(X, F_2) \to H^*(X, F_2) : x \in H^k(X, F_2) \mapsto \sum_{i \in \mathbb{N}} Sq^i(x), \quad Sq^i(x) \in H^{k+i}(X, F_2) \]

called Steenrod Powers that satisfies

- \( Sq(\alpha \cup \beta) = Sq(\alpha) \cup Sq(\beta). \)
- \( Sq^i(\alpha) = \alpha^2 \) if \( i = |\alpha|, \) and 0 if \( i > |\alpha|. \)

For \( p \in P, \) the total Steenrod powers \( P \) is a similar map from \( H^n(X, F_p) \to H^{n+i}(X, F_p) \) that
\[ P^i(\alpha) = \alpha^p \] if \( 2i = |\alpha| \) and 0 if \( 2i > |\alpha|. \)

Proof: Cf.[Hatcher P497]. □

Prop.(3.10.6.15)[Adam Relations]. For \( 0 < i < 2j \in \mathbb{Z}, \)

\[ Sq^i Sq^j = \sum_{0 \leq k \leq \lfloor \frac{j}{2} \rfloor} \binom{j-k-1}{i-2k} Sq^{i+j-k} Sq^k \in \text{End}(H^*(-, F_2)) \]

There are Adam relation calculators in terms of Serre-Cartan basis at https://math.berkeley.edu/~kruckman/adem/.

Proof: □

Cor.(3.10.6.16). The subalgebra of \( \text{End}(H^*(-, F_2)) \) generated by \( \{ Sq^Z \} \) is generated respectively by elements \( Sq^{2k}. \)

and for \( p \in P \) The subalgebra of \( \text{End}(H^*(-, F_p)) \) generated by \( \{ P^Z \} \) is generated by elements \( P^p, \) and \( \beta. \)

Proof: □

Prop.(3.10.6.17)[\( H^*(K(F_2, p), F_2) \). \( H^*(K(F_2, p), F_2) \)] can be calculated, Cf.[May, P185].

Proof: □

7 Stable Homotopy Theory
3.11 Fiber Bundles & K-Theory

Main references are [Ati64], [AGP02] and [M-S74].

Remark (3.11.0.1). Any base space $B$ in this section is assumed to be paracompact. Instead, we may require in the definition of locally trivial bundles s.t. there exists a trivialization that is dominated by a partition of unity on $B$.

1 Fiber Bundles

Def. (3.11.1.1) [Fiber Bundles]. $\pi : E \to X \in \mathcal{CG}$ is called a fiber bundle with fiber $F$ if every fiber $\pi^{-1}(x)$ is homeomorphic to $F$. If any $x \in X$ has a nbhd $U$ together with a homeomorphism $\pi^{-1}(U) \cong U \times F$ over $U$, then it is called a locally trivial bundle. And a numerical locally trivial bundle is a locally trivial bundle $\pi : E \to X$ s.t. there is a numerical covering $\{U_i \to X\}$ s.t. there are homeomorphisms $\pi^{-1}(U_i) \cong U_i \times F$ over $U_i$ for each $i$.

Prop. (3.11.1.2) [Dold]. If $\pi : E \to X \in \mathcal{CG}$ and there is a numerical covering $\{U_i \to X\}$ s.t. $\pi^{-1}(U_i) \to U_i$ are Hurewicz fibrations, then $\pi$ is a Hurewicz fibration.

Proof: Cf. [Tammo tom Dieck, Algebraic Topology] Chap13. \qed

Cor. (3.11.1.3) [Fiber Bundles are Hurewicz Fibrations]. Every numerical locally trivial bundle is a Hurewicz fibration.

Prop. (3.11.1.4) [Pullback Bundle]. Let $\pi : E \to X$ be a fiber bundle with fiber $F$ and $f : Y \to X$ a map, then the pullback space $f^*E \to Y$ (3.6.1.7) is also a fiber bundle over $Y$ with fiber $F$, called the pullback bundle.

Prop. (3.11.1.5). If $E \to B, E' \to B'$ are fiber bundles both with compact Hausdorff fibers/or both with discrete fibers/, and $f : E/B \to E'/B'$ is a bundle map that induces isomorphisms on the fibers, then $E \cong f^*E'$ over $B$.

Proof: \qed

Lemma (3.11.1.6). Suppose $\pi : E \to B \times I$ is a fiber bundle whose restriction to $B \times [0,a]$ and $B \times [a,1]$ are all trivial for some $a \in I$, then $E \to B \times I$ is a trivial bundle.

Proof: Choose trivializations $\varphi_1 : B \times [0,a] \times B \times F \to \pi^{-1}(B \times [0,a])$, and $\varphi_2 : B \times [a,1] \times B \times F \to \pi^{-1}(B \times [a,1])$, then these induces a map

$$ B \times \{a\} \times F \xrightarrow{\varphi_1|} \pi^{-1}(B \times \{a\}) \xrightarrow{\varphi_2^{-1}} B \times \{a\} \times F, $$

of the form $(b,a,v) \mapsto (b,a,g(b)v)$, where $g : B \to \text{Homeo}(F)$ is continuous. Then we get a trivialization

$$ B \times I \times F \to E : \varphi(b,t,v) = \begin{cases} \varphi_1(b,t,v) & t \leq a \\ \varphi_2(b,t,g(b)v) & t \geq a \end{cases}. $$

\qed

Lemma (3.11.1.7). Let $E \to B \times I$ be a fiber bundle, then there exists a covering $\{U_i\}$ of $B$ that $E$ is trivial on each $U_i \times I$.
Prop. (3.11.1.13) [Ehresmann].

Lemma (3.11.1.8). Let \( \pi : E \to B \times I \) be a fiber bundle, where \( B \) is a paracompact space, and \( r : B \times I \to B \times I \) defined by \( r(b,x) = (b,1) \), then there exists a bundle morphism \( f \) over \( r \) that induces an isomorphism \( r^*E \cong E \) over \( B \times I \).

Proof: By (3.11.1.7), we can choose a covering \( \{U_\alpha\} \) of \( B \) that is \( E \) is trivial over each \( U_\alpha \times I \), and let \( \psi_\alpha \) be a partition of unity \( 1 = \sum \psi_i \) that \( \text{Supp}(\psi_i) \subset U_i \) and \( \{\text{Supp}(\psi_i)\} \) is locally finite. We also define \( \mu_\alpha(x) = \frac{\psi_\alpha(x)}{\max(\psi_\beta(x))} \), then \( \mu_\alpha \) are all continuous and subordinate to \( \{U_\alpha\} \), and for each \( x \in B, \max\{\mu_\alpha(x)\} = 1 \).

Let \( \varphi_\alpha : U_i \times I \times F \to \pi^{-1}(U_i \times I) \) be the local trivializations. We define a bundle map \( f_\alpha : E/B \times I \to E/B \times I \) by identity outside \( \pi^{-1}(U_i \times I) \) and \( f_\alpha(\varphi_\alpha(b,t,v)) = \varphi_\alpha(b,\max(\mu_\alpha(x),t),v) \), then \( f_\alpha \) is continuous and induces an isomorphism \( f_\alpha^*E \cong E \) over \( B \times I \). Now choose a well-ordering on \( \alpha \), by local finiteness, for each \( v \in E \), there is a nhhd \( W_v \times I \) of \( \pi(v) \in B \times I \) that \( W_v \cap U_\alpha \neq \emptyset \) for only \( \alpha \) in a finite set \( \{\alpha_1, \ldots, \alpha_m\} \) with \( \alpha_1 < \alpha_2 < \cdots < \alpha_m \). Then we define a bundle map \( f : E \to E \) that \( f|_{\pi^{-1}(W_v \times I)} = f_{\alpha_m} \circ \cdots \circ f_{\alpha_1} \). Then this is well-defined, and it is a bundle over \( r \) that induces an isomorphism \( r^*E \cong E \).

Prop. (3.11.1.9) [Homotopy Invariance of Fiber Bundles]. Let \( E' \to B' \) be fiber bundles. If \( f,g : B \to B' \) are two homotopic maps with \( B \) paracompact, then there is a bundle isomorphism \( f^*E' \cong g^*E' \).

Proof: Let \( F : B \times I \to B' \) be a homotopy from \( f \) to \( g \), and let \( i_v : B \to B \times I : i_v(b,x) = (b,v) \) for \( v = 0,1 \). Let \( r : B \times I \to B \times I \) be the retraction defined by \( r(b,x) = (b,1) \), then by (3.11.1.8), there is an isomorphism of fiber bundles

\[
f^*E' \cong (F \circ i_0)^*E' \cong i_0^*F^*E' \cong i_0^*\circ r^*F^*E' \cong i_1^*F^*E' \cong g^*E'.
\]

Prop. (3.11.1.10) [Cone Bundles]. Let \( E/X \) be a fiber bundle with fiber \( F \), then we can construct a new fiber bundle \( \text{Cone}(E)/X \) with bundle \( C(F) \).

Cor. (3.11.1.11). This is because we can use the transformation characterization to extend maps \( U_i \cap U_j \to \text{Aut}(F) \) to maps \( U_i \cap U_j \to \text{Aut}(C(F)) \).

Prop. (3.11.1.12) [Hopf Fibration]. There is a locally trivial fiber bundle \( S^3 \to S^2 \) with fiber \( S^1 \), called the Hopf fibration.

Proof: Cf. [AGP02] P129.

Prop. (3.11.1.13) [Ehresmann]. Let \( f : E \to B \in \text{Man}_{\text{sm}} \) be a proper submersion, then it is a locally trivial bundle.

Proof: Cf. [Björn Dundas, A Short Course in Differential Topology].

Cor. (3.11.1.14). There is a locally trivial bundle \( S^{2n-1} \to \mathbb{C}P^n \) with fiber \( S^1 \).

Proof:
Cor. (3.11.1.15). There is a locally trivial bundle $\mathbb{R}P^{2n-1} \to \mathbb{C}P^n$ with fiber $S^1$.

Proof: □

Prop. (3.11.1.16) [Classifying Space Bundles]. There is a locally trivial bundle $U(n,K) \to V_n(K^\infty) \to \text{Gra}(n,K^\infty)$ for $K = \mathbb{R}, \mathbb{C}$ or $\mathbb{H}$.

Proof: □

Cor. (3.11.1.17). There is a locally trivial bundle $S^\infty \to \mathbb{C}P^\infty$ with fiber $S^1$.

Prop. (3.11.1.18). There is a locally trivial bundle $S^n \to \mathbb{R}P^n$ with fiber $\{\pm 1\}$.

Proof: □

Prop. (3.11.1.19). There is a locally trivial fiber bundle $S^\infty \to \mathbb{R}P^\infty$ with fiber $\{\pm 1\}$.

Proof: Cf. [AGP02] P335.

Covering Space

Def. (3.11.1.20) [Covering Space]. A covering space is a fiber bundle $E \to X$ with discrete fibers.

Prop. (3.11.1.21). If $X$ and $Y$ are Hausdorff spaces, $f : X \to Y$ is a local homeomorphism, $X$ is compact, and $Y$ is connected, then $f$ a covering map.

Proof: First, $f$ is surjective (using the connectedness), and that for each $y \in Y$, $f^{-1}(y)$ is finite. Because $X$ is compact, there exists a finite open cover of $X$ by $\{U_i\}$ such that $f(U_i)$ is open and $f|_{U_i} : U_i \to f(U_i)$ is a homeomorphism. For $y \in Y$, let $\{x_1, \ldots, x_n\} = f^{-1}(y)$ (the $x_i$ all being different points). Choose pairwise disjoint neighborhoods $U_1, \ldots, U_n$ of $x_1, \ldots, x_n$, respectively (using the Hausdorff property).

By shrinking the $U_i$ further, we may assume that each one is mapped homeomorphically onto some neighborhood $V_i$ of $y$.

Now let $C = X \setminus (U_1 \cup \cdots \cup U_n)$ and set
\[ V = (V_1 \cap \cdots \cap V_n) \setminus f(C) \]

$V$ should be an evenly covered nbhd of $y$. □

Prop. (3.11.1.22). If $\pi : \tilde{B} \to B$ is a local onto homeomorphism with the property of lifting arcs. Let $\tilde{B}$ be arcwise connected and $B$ simply connected, then $\pi$ is a homomorphism.

Proof: only need to prove injective. If $p_1$ and $p_2$ map to the same point, then they can be connected, and the image is a loop thus contractable, contradiction. □

Cor. (3.11.1.23). If $\tilde{B}$ is locally arcwise connected and $B$ is locally simply connected, then $\pi$ is a covering map.

Proof: Choose the connected components of a simply connected nbhd of a point $p$ and use (3.11.1.22). □
Prop. (3.11.1.24) [Homotopy Lifting Property]. Given a covering space \( \pi : \tilde{X} \to X \), and a homotopy \( f_t : Y \to X \), and a map \( f_0 : Y \to \tilde{X} \) lifting \( X \), then there is a unique homotopy \( \tilde{f}_t : Y \to \tilde{X} \) of \( f_0 \) lifting \( f_t \).

**Proof:** Let \( U_\alpha \) be a covering of \( X \) that the We first construct a lift \( \tilde{F} : N \times I \to \tilde{X} \) for \( N \) a nbhd near some point \( y_0 \in Y \). Because \( f \) is continuous, there is a nbhd \( N \) of \( y_0 \) and a partition \( 0 = t_0 < t_1 < \ldots < t_m = 1 \) of \( I \) that each \( N \times [t_i, t_{i+1}] \) is mapped into some \( U_\alpha \). Then we can construct a lifting \( \tilde{F} : N \times I \to \tilde{X} \) by induction using the local homeomorphism property of covering space.

Next we show the uniqueness in the special case that \( Y \) is a point. This can also be done using a partition of \( I \) and induction.

Finally we can construct lifting near every point \( y \in Y \), and also they coincide on the overlap because of the uniqueness we just proved. So these liftings glue together to give a lifting \( \tilde{f}_t : Y \to \tilde{X} \).

□

Cor. (3.11.1.25). The map \( \pi_* : \pi_1(\tilde{X}, \tilde{x}_0) \to \pi_1(X, x_0) \) induced by the covering map is injective. And the image of this map consists of homotopy types of loops that based at \( x_0 \) whose lift starting at \( \tilde{x}_0 \) are also loops.

**Proof:** This is because a homotopy of a the image of a loop to trivial loop in \( \tilde{X} \) can be lifted to a homotopy of the loop itself to trivial loop. And this homotopy also fixes the endpoint, because the lifting of a trivial loop must be a trivial loop.

For the second assertion, one direction is easy, for the other, if a loop is a homotopic to the image of a loop of \( \tilde{X} \), then it is itself the image of a loop of \( \tilde{X} \).

□

Prop. (3.11.1.26) [Degree of a Covering]. Let \( \pi : \tilde{X} \to X \) be a covering map, then the cardinality of \( \pi^{-1}(x) \) is a a locally constant function of \( x \). Thus if \( X \) is constant, this cardinality is fixed for any \( x \in X \), and it is called the degree of the covering.

The number of sheets of a covering with \( \tilde{X} \) path-connected equals the index of \( \pi_*(\pi_1(\tilde{X}, \tilde{x}_0)) \) in \( \pi_1(X, x_0) \).

**Proof:** For a loop \( g \) in \( X \) based at \( x_0 \), let \( \tilde{g} \) be its lift to \( \tilde{X} \) starting at \( \tilde{x}_0 \). Now if \( h \in \pi_*(\pi_1(\tilde{X}, \tilde{x}_0)) \), then the loop \( h \cdot \tilde{g} \) has lift that has the same ending as \( \tilde{g} \). So we get a map from the quotient set \( \pi_1(X, x_0)/\pi_*(\pi_1(\tilde{X}, \tilde{x}_0)) \) to \( p^{-1}(x_0) \) mapping \( \pi_*(\pi_1(\tilde{X}, \tilde{x}_0)) \) to \( \tilde{g}(1) \). This map is injective, and it is surjective because \( \tilde{X} \) is path-connected. Then we are done.

□

Prop. (3.11.1.27) [Unique Lifting Property]. Let \( \pi : (\tilde{X}, \tilde{x}_0) \to (X, x_0) \) be a covering space and \( f : (Y, y_0) \to (X, x_0) \) be a map with \( Y \) path-connected and locally path-connected, then a lift \( \tilde{f} : (Y, y_0) \to (\tilde{X}, \tilde{x}_0) \) exists iff \( f_* (\pi_1(Y, y_0)) \subset \pi_* (\pi_1(\tilde{X}, \tilde{x}_0)) \). And when \( Y \) is connected, this lifting is unique.

In particular, a covering space has unique path lifting property.

**Proof:** One direction is clear, for the other, to construct a lifting, choose a path \( \gamma \) from \( y_0 \) to \( y \), the path \( f \gamma \) has a unique lifting \( \tilde{f} \gamma \) starting from \( \tilde{x}_0 \). Define \( \tilde{f}(y) = \tilde{f} \gamma \). This is a well-defined map: if \( \gamma' \) is another path from \( y_0 \) to \( y \), then \( f \gamma^{-1} f \gamma' \) is a loop that is homotopic to the image of a loop at \( \tilde{x}_0 \). Now we can lift this homotopy, and then \( f \gamma^{-1} f \gamma' \) is also the image of a loop at \( \tilde{x}_0 \), which must be \( \tilde{f} \gamma^{-1} \gamma' \) by uniqueness. So \( \tilde{f} \) is well-defined.

It can be verified that \( \tilde{f} \) is continuous.

The uniqueness is clear, because if there are two lifts, the points that they are equal and the points that they are not are both open in \( Y \).

□
Prop. (3.11.1.28) [Galois Theory of Covers]. Let $X$ be a path-connected and locally path-connected and semilocally simply-connected space (3.9.4.26), then
- there is a connected and simply-connected covering space $\tilde{X}$ of $X$, called a **universal cover** of $X$.
- The fundamental group acts continuously and properly on $\tilde{X}/X$.
- For any subgroup $H$ of $\pi_1(X,x_0)$, there is a connected covering space $\pi : X_H \to X$ that $\pi_* (\pi_1(X_H, \tilde{x}_0)) = H$ for a suitably chosen base point $\tilde{x}_0$. And this covering space is unique up to isomorphism over $(X, x_0)$. Thus by (3.11.1.27), there is an inclusion-preserving bijection between isomorphism classes of covering spaces over $X$ and the the set of conjugacy classes of subgroups of $\pi_1(X, x_0)$.

*Proof:* Cf. [Hat02] P64, P67. \square

Def. (3.11.1.29) [Normal Covering Spaces]. A **normal covering space** is a covering space $\pi : \tilde{X} \to X$ that for any $x \in X$ and two elements $\tilde{x}, \tilde{x}' \in \pi^{-1}(x)$, there is a covering isomorphism of $\tilde{X}/X$ taking $\tilde{x}$ to $\tilde{x}'$.

Prop. (3.11.1.30). Let $\pi : (\tilde{X}, \tilde{x}_0) \to (X, x_0)$ be a path-connected covering space of a path-connected, locally path-connected space $X$, and let $H$ be the subgroup $\pi_*(\pi_1(\tilde{X}, \tilde{x}_0)) \subset \pi_1(X, x_0)$, then
- The covering space is normal iff $H$ is normal in $\pi_1(X, x_0)$.
- The group $G(\tilde{X})$ of covering transformations of $\tilde{X}$ is isomorphic to $N(H)/H$.

*Proof:* 1: Let $\tilde{x}_1, \tilde{x}_2 \in \pi^{-1}(x_0)$ and $\gamma$ a path from $\tilde{x}_1$ to $\tilde{x}_2$ corresponding to an element of $\pi_1(X, x_0)$, then $H$ is normal is equivalent to $\pi_*(\pi_1(\tilde{X}, \tilde{x}_1)) = \pi_*(\pi_1(\tilde{X}, \tilde{x}_2))$. Then the lifting criterion shows there is a covering transformation taking $\tilde{x}_1$ to $\tilde{x}_2$. The converse is also true.

2: From the above argument, we can define a map $N(H) \to G(\tilde{x})$ by mapping a $\gamma \in N(H)$ to a covering transformation mapping $\tilde{x}_0$ to $\tilde{x}_1$. And the kernel of this map is exactly those $\gamma$ lifting to a loop at $\tilde{x}_0$, which are exactly the elements of $H$. \square

Prop. (3.11.1.31) [Covering Space Action]. If $G$ is a discrete group and $G \times Y \to Y$ is a covering space action (3.8.1.14), then the quotient map $Y \to Y/G$ is a normal covering space. And if $Y$ is path-connected, $G$ is the group of covering transformations.

*Proof:* The condition on the action shows it is locally a homeomorphism, thus it is a covering space. And it is a normal covering space because $g_1 g_2^{-1}$ takes any $g_1(x)$ to $g_2(x)$. The group of covering transformations is just $G$, because the covering transformation on a path-connected space is determined by its action on a single point. \square

2 Vector Bundles

Basics

Def. (3.11.2.1) [Vector Bundle]. Let $K = \mathbb{R}$ or $\mathbb{C}$, a **K-vector bundle** of dimension $n$ over a topological space $X$ is a fiber bundle over $X$ with fiber $K^n$ that each trivialization $\varphi_a$ restricts to $K$-linear isomorphisms on the fibers. The category of vector bundles over $X$ is denoted by $\text{Vect}_K(X)$. A **vector bundle homomorphism** $E \to F$ is a map of spaces over $X$ that the maps on the fibered are all $K$-linear.

Then a $K$-vector bundle of dimension $n$ over $X$ is just an associated $\text{GL}(n, K)$-bundle with fiber $K^n$ over $X$. In particular, there is a bijection $\text{Vect}_K^n(X) \cong \mathcal{O}_{\text{GL}(n, K)}(X)$ by (3.11.3.4).
Def. (3.11.2.2) [Trivial Vector Bundles]. For any \( n \in \mathbb{N} \), the trivial vector bundle of rank \( n \) is denoted by \( e^n \).

Prop. (3.11.2.3) [Constructions of Vector Bundles]. Let \( T : (\text{Vect}^f / \mathbb{K})^\otimes_n \rightarrow \text{Vect}^f / \mathbb{K} \) be a functor that is either covariant or contravariant for each of its factors in that \( T : \bigoplus_i \text{Hom}(V_i,W_i) \rightarrow \text{Hom}(T(V_i),T(W_i)) \) is continuous, then we have a functor \( T : \text{Vect}(X)^n \rightarrow \text{Vect}(X) \) that is either covariant or contravariant for each of its factors.

Cor. (3.11.2.4). In this way, given a vector bundles \( E, F \) on \( X \), we can construct
\[
E \oplus F, \quad E \otimes F, \quad \text{Hom}(E,F) \cong E^* \otimes F, \quad E^*, \quad T^n E, \quad \wedge^i E.
\]

Prop. (3.11.2.5) [Existence of Hermitian Metric]. There exists a Hermitian (Riemannian) metric on any bundle \( E \) over a paracompact space \( X \). In this way, \( E^* \cong E(\overline{E}) \).

Proof: Choose a metric on each trivialization open subset and use partition of unity to glue.

Cor. (3.11.2.6). A vector bundle over a paracompact space can have its transform maps \( \in O(n) \) (or \( U(n) \)).

Proof: We can choose the metric on it compatible with the given metric. In this way, the transform map is \( \in O(n) \) (or \( U(n) \)).

Cor. (3.11.2.7) [Semisimplicity of Vect(\( B \))]. Any exact sequence of vector bundles over a paracompact space \( B \) splits.

Proof: Because we can take the orthogonal complement.

Cor. (3.11.2.8). If \( f : X \rightarrow Y \) is a homotopy equivalence, then \( f^* : \text{Vect}(Y) \rightarrow \text{Vect}(X) \) is an isomorphism.

In particular, if \( X \) is contractible, then every bundle over \( X \) is trivial.

Def. (3.11.2.9) [Orientations of Vector Bundles]. Let \( \pi : E \rightarrow X \) be a vector bundle of rank \( n \) over a space \( X \) and \( R \cong \mathbb{Z} \) or \( \mathbb{Z} / 2\mathbb{Z} \), then a orientation of \( E \) with coefficient \( R \) is a functions that assigns a generator \( u_x \) of \( H^n(E_x, 0, R) \cong R \) for any \( x \in X \) s.t. for any \( x \in X \), there is a nbhd \( U \) of \( x \in X \) and an element \( u \in H^n(\pi^{-1}N, \pi^{-1}(N)_0, R) \) s.t. \( u \) pulls back to \( u_x \) via \( (E_x, 0) \subset (\pi^{-1}N, \pi^{-1}(N)_0) \) for any \( x \in U \). In particular, any vector bundle is \( \mathbb{F}_2 \)-orientable.

Prop. (3.11.2.10) [Orientation of Complex Vector Bundles]. For \( E / X \in \text{Vect}_C(X) \), the underlying real bundle has a preferred orientation, which is compatible with direct sums.

In particular, the tangent bundle of a complex manifold gives rise to a unique orientation of the underlying real manifold.

Proof: Let \( a_1, \ldots, a_\ell \) be a complex basis for \( E \), then take the real basis to be \( a_1, ia_1, \ldots, a_\ell, ia_\ell \). This orientation is stable under \( GL(\ell, \mathbb{C}) \) transformation, as \( GL(\ell, \mathbb{C}) \) is connected.

Prop. (3.11.2.11). If \( E \) is a complex vector bundle over \( X \), then \( E \otimes_{\mathbb{R}} \mathbb{C} \cong E \oplus \overline{E} \) as complex vector bundles.

Lemma (3.11.2.12). Suppose \( \pi : E \rightarrow B \times I \) is a fiber bundle whose restriction to \( B \times \{0, a\} \) and \( B \times \{a, 1\} \) are all trivial for some \( a \in I \), then \( E \rightarrow B \times I \) is a trivial bundle.
Proof: The proof is similar to that of (3.11.1.6)

Lemma (3.11.2.13). Let $E \to B \times I$ be a fiber bundle, then there exists a covering $\{U_i\}$ of $B$ that $E$ is trivial on each $U_i \times I$.

Proof: The proof is similar to that of (3.11.1.7)

Lemma (3.11.2.14). Let $\pi : E \to B \times I$ be a fiber bundle, where $B$ is a paracompact space, and $r : B \times I \to B \times I$ defined by $r(b, x) = (b, 1)$, then there exists a bundle morphism $f$ over $r$ that induces an isomorphism $r^*E \cong E$ over $B \times I$.

Proof: The proof is similar to that of (3.11.1.8)

Prop. (3.11.2.15) [Homotopy Invariance of Vector Bundles]. Let $E' \to B'$ be a vector bundle. If $f, g : B \to B'$ are two homotopic maps with $B$ paracompact, then there is a bundle isomorphism $f^*E' \cong g^*E'$.

Proof: The proof is similar to that of (3.11.1.9)

Bundles of Finite Type

Def. (3.11.2.16) [Bundles of Finite Type]. Let $X$ be a paracompact Hausdorff space, then a vector bundle of finite type over $X$ is a vector bundle over $X$ that has a covering by f.m. trivialization maps. The category of $k$-dimensional vector bundles over $X$ of f.t. is denoted by $\text{Vect}_k^f(X)$. Trivially, any vector bundle over a compact space is of f.t..

Prop. (3.11.2.17) [Vector Bundles on the Quotient]. Let $Y$ be a closed subspace of $X$, $E$ a vector bundle over $X$, then a trivialization $\alpha : E|_Y \cong Y \times V$ defines a bundle $E/\alpha$ over $X/Y$. The isomorphism class of $E/\alpha$ only depends on the homotopy type of $\alpha$.

Proof: To show it is a vector bundle, notice the trivialization $\alpha$ extends to a

Prop. (3.11.2.18) [Splitting Principle]. For a vector bundle $E \to X$, there is a space $Y \to X$ that $p^*$ is injective on $H^*(-, \mathbb{Z})$ and $p^*E$ splits as a sum of line bundles. This proposition is useful when proving theorems about characteristic classes.

Proof: It suffice to find a $Y$ that $p^*E$ has a subbundle, then choose its orthogonal part, and use induction. For this, choose $Y = P(E)$, then $Y$ has a tautological bundle, which is a subbundle of $p^*E$, and $Y$ is fibered over $X$ with fiber $\mathbb{P}^n$, and we want to use Leray-Hirsch, so check the fact $H^*(\mathbb{P}^n)$ is free and generated by the first Chern class, by (3.11.4.16) and (5.7.2.1). And Chern class is functorial, so the powers of Chern class of $f^*E$ will generate the cohomology ring of any stalks.

Prop. (3.11.2.19). For any bundle $E$ over a compact Hausdorff space $X$, there is a surjective bundle map $X \otimes \mathbb{R}^n \to E$ for some $m \geq 0$.

Proof: Choose a finite cover of trivialization of $E$, then we can glue these maps together via a partition function.

Cor. (3.11.2.20) [Negation of Bundles]. For any vector bundle $E$ on a compact space $X$, there is a vector bundle $F$ that $E \oplus F$ is a trivial bundle.
Prop. (3.11.2.23) [Constructing Vector Bundles].

Cor. (3.11.2.24). There is a natural isomorphism \( \text{Vect}_n(S(X)) \cong [X, GL(n, \mathbb{C})] \).

Proof: Write \( \Sigma(X) = C^+(X) \coprod C^-(X) \), and \( C^\pm(X) \) are both contractible, thus \( E \) are trivial restricted to them(3.11.2.8). Let \( \alpha^\pm \) be the trivialization isomorphism, then \( \alpha^+ \circ \alpha^- \) is a bundle map of \( X \times \mathbb{R}^n \), which is equivalent to a map \( \alpha : X \to GL(n, \mathbb{C}) \). The homotopy type of \( \alpha \) is determined because \( C^\pm(X) \) are both contractible, and vise versa.

Prop. (3.11.2.25) [Vector Bundles as Modules]. \( \Gamma \) induces an equivalence between the category of vector bundles over \( X \) and the category of finitely projective modules over \( C(X) \).

Proof: Clearly a bundle induces a module over \( C(X) \). And it is a fully faithful functor. Now the image is the subcategory of finite projective modules, because every bundle is a direct summand of a trivial bundle, and a trivial bundle corresponds to a finite free \( C(X) \)-modules.

Thom isomorphism

Prop. (3.11.2.26) [Thom Class]. Let \( R = \mathbb{Z} \) or \( \mathbb{F}_2 \) and an \( R \)-orientable vector bundle \( E \) over base \( B \) of rank \( n \).

Then there exists uniquely **Thom class** \( u_E \in H^n(E, E\backslash B, R) \) that induce the preferred generator \( H^n(E_x, E_x\backslash \{0\}, R)(3.11.2.9) \) on every fiber. Then the relative Leray-Hirsch will give an isomorphism

\[
\varphi_R : H^i(B, R) \cong H^{i+n}(E, E\backslash B, R) : x \mapsto \pi^*(x) \cup u_E.
\]

For \( \mathbb{F}_2 \) coefficient there exists a Thom class, and for orientable bundle there exists a \( \mathbb{Z} \)-Thom class. Notice that fiber bundle over a simply connected base is orientable.

Proof:

Cor. (3.11.2.27) [Naturality].

- Let \( B' \to B \) be a map and \( E/B \) be an \( R \)-orientable vector bundle, which induces a map \( f^* : H^n(E, E_0, R) \to H^n(f^*(E), E'_0, R) \). Then \( f^*u_E \cong u_{f^*(E)} \).
- The Thom class \( u_E \) maps to \( u_{E,2} \) under the change of coefficients \( \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \).

Prop. (3.11.2.28). Similarly, for a orientable fiber bundle \( S^{n-1} \to E \to B \), make it a \( D^n \to E' \to B \) bundle, then \( E' \) is homotopy equivalent to \( B \) so there is a Gysin sequence

\[
\cdots \to H^{i-n}(B) \xrightarrow{\gamma^e} H^i(B) \to H^i(E) \to H^{i-n+1}(B) \to \cdots
\]

Where the Euler class \( e \) is chosen to commute with the Thom isomorphism.
Examples of Vector Bundles

Def. (3.11.2.29) [n-Universal \( k \)-Vector Bundle]. Let \( K = \mathbb{R} \) or \( \mathbb{C} \), endow \( \mathbb{K}^n \) with the canonical Hermitian metric, define \( E_k(\mathbb{K}^n) \) be the subspace of \( \text{Gra}(k, \mathbb{K}^n) \times \mathbb{K}^n \) consisting of pairs \((W, v)\) that \( v \in W \). Then this is a vector bundle over the Grassmannian \( \text{Gra}(k, \mathbb{K}^n) \) (11.6.2.12), called the \( n \)-universal \( k \)-vector bundles, or the tautological bundles.

Proof: We construct localization maps: endow \( \mathbb{K}^n \) with the natural metric. For \( W_0 \in G_k(\mathbb{K}^n) \), then the subspace \( U \) of \( G_k(\mathbb{K}^n) \) consisting of \( W \) that \( W \cap W_0^\perp = \emptyset \) is a nbhd of \( W_0 \), and it is naturally homeomorphic to \( \text{Hom}(W_0, W_0^\perp) \). There is an isomorphism

\[
\pi^{-1}(U) \cong U \times W_0 : (f, (f + id)w_0) \mapsto (f, w_0).
\]

Prop. (3.11.2.30) [Universal Vector Bundle]. Because by (3.11.3.20) \( E_k(\mathbb{K}^\infty) / \text{Gra}(k, \mathbb{K}^\infty) \) is the universal bundle, there is a map \( i_k : \text{Gra}(k, \mathbb{K}^\infty) \to \text{Gra}(k + 1, \mathbb{K}^\infty) \) s.t. \( i_k^*(E_{k+1}(\mathbb{K}^\infty)) \) is the bundle \( E_k(\mathbb{K}^\infty) \oplus \mathbb{K} \). Then it can be shown

\[
BU(\mathbb{K}) = \text{colim}_k (\text{Gra}(k, \mathbb{K}^\infty) \xrightarrow{i_k} \text{Gra}(k+1, \mathbb{K}^\infty))
\]

is a CW complex.

Moreover, there are maps \( w_{k,l} : \text{Gra}(k, \mathbb{K}^\infty) \times \text{Gra}(l, \mathbb{K}^\infty) \to \text{Gra}(k + l, \mathbb{K}^\infty) \) that corresponds to the bundle \( E_k(\mathbb{K}^\infty) \times E_l(\mathbb{K}^\infty) \), and these maps induces an H-space structure on \( BU \).

Proof:

Prop. (3.11.2.31) [Tautological Line Bundles]. For \( \text{Gra}(1, \mathbb{R}^{n+1}) \cong \mathbb{R}P^n \), the line bundle \( E_1(\mathbb{R}^{n+1}) \) is denoted by \( \gamma_n \).

Then the tangent bundle \( \tau_n \) of \( \mathbb{R}P^n \) is isomorphic to \( \text{Hom}(\gamma_n^1, \gamma_n^1) \), where \( \gamma_n^1 \) is the orthogonal complement of \( \gamma_n \) in \( e_{\mathbb{R}P^n}^{n+1} \) (with the canonical norm).

Proof: This is because a tangent vector at \( x \in \mathbb{R}P^n \) is equivalent to a homomorphism \([x] \) to \([x]^\perp \).

How to prove this rigorously.

Cor. (3.11.2.32). \( \tau_n \oplus e^1 \cong (\gamma_n^1)^{n+1} \).

Proof: By (3.11.2.31), \( \tau_n \oplus e^1 \cong \text{Hom}(\gamma_n^1, \gamma_n^1) \oplus \text{Hom}(\gamma_n^1, \gamma_n^1) = \text{Hom}(\gamma_n^1, \mathbb{R}^n) = (\gamma_n^1)^{\ast n} \). Then we are done because \( \gamma_n^{1\ast} \) is self-dual because it has a Euclidean metric (3.11.2.5).

Prop. (3.11.2.33) [Pullback the Universal Bundle]. For \( V \in \text{Vect}/\mathbb{K} \), for any continuous map \( \varphi : X \to \text{Gra}(k, V) \), we get a subspace \( E_\varphi = \{(x, v) \in X \times V | v \in \varphi(x)\} \subset X \times V \). This is a vector bundle over \( X \), and it is a subbundle of the trivial bundle \( X \times V \to X \). In fact, \( E_\varphi \cong f^*E_k(V) \) (3.11.2.29).

Cor. (3.11.2.34). Let \( f : X' \to X \) and \( \varphi : X \to Pr(V) \), then \( f^*(E_\varphi) = E_{\varphi \circ f} \).

Prop. (3.11.2.35) [Infinite Universal \( k \)-Vector Bundle]. The \( n \)-universal \( k \)-vector bundles \( E_k(\mathbb{K}^n) \) (3.11.2.29) for various \( n \) gets together to a bundle \( E_k(\mathbb{K}^\infty) \) on \( \text{Gra}(k, \mathbb{K}^\infty) \) that the pullback of \( E_k(\mathbb{K}^\infty) \) via \( i : \text{Gra}(k, \mathbb{K}^n) \to \text{Gra}(k, \mathbb{K}^\infty) \) is \( E_k(\mathbb{K}^n) \).

Def. (3.11.2.36) [Hopf Bundle]. Define a map \( \varphi : C^\mathbb{P}^n \to G_1(\mathbb{C}^{n+1}) \) that \( \varphi([z]) = [z] \), then this defines a vector bundle on \( C^\mathbb{P}^n \) by (3.11.2.33), called the dual of Hopf bundle. The Hopf bundle is defined to be the dual of the dual of Hopf bundle.
3 Principal Bundles

Main reference is [Principal Bundles and Classifying Space].

Def. (3.11.3.1) [Principal Bundles]. For $G \in \text{TopGrp}$, a principal $G$-bundle is a bundle $P$ with $G$-fibers that the transition function is right $G$-map, i.e. left multiplication by some $g_{\alpha\beta}$. A associated bundle of a representation $G \to \text{End}(V)$ is the total space of $P \times V$ module the equivalence $[gg_0, v] = [g, g_0v]$. The corresponding transition function is just the left action by $g_{\alpha\beta}$.

For $B \in \text{Top}$, denote $\mathcal{P}_G(B)$ the isomorphism classes of vector bundles on $B$.

Prop. (3.11.3.2) [Homogeneous Space]. For $G \in \text{LieGrp}$ and $H \leq G$ is a closed subgroup, then the quotient $H \backslash G$ can be given a structure of a $G$-homogeneous space and $G \to H \backslash G$ is a principal $H$-bundle.

Proof: □

Prop. (3.11.3.3). The projection $S^{2n+1} \to \mathbb{C}P^n$ is a principal $S^1$-bundle.

Proof: □

Prop. (3.11.3.4) [Associated Bundles]. If $G \in \text{TopGrp}$ and $G$ acts freely on $F \in \text{Top}$, then an associated $G$-bundle with fiber $F$ is a locally trivial $F$-bundles with a $G$-action. Then the isomorphism classes of associated $G$-bundles with fiber $F$ over $B$ is in bijection with $\mathcal{P}_G(B)$.

Proof: □

Classifying Space

Def. (3.11.3.5) [Classifying Spaces]. For $G \in \text{TopGrp}$, a classifying space of $G$ is a space $B(G) \in \text{Top}$ together with a principal $G$-bundle $E(G) \to B(G)$ s.t. $E(G)$ is contractible.

Notice $\pi_{n+1}(BG) = \pi_n(G)$ by ??.

Thm. (3.11.3.6) [Classifying Spaces and Principal Bundles]. If $G \in \text{TopGrp}$ and $E(G) \to B(G)$ is a classifying space for $G$, then for any $B \in \text{Top}$ that is paracompact, the pullback induces a bijection

$$[B, B(G)] \cong \mathcal{P}_G(B).$$

In particular, the classifying spaces is uniquely defined ique up to homotopy, if it exists.

Proof: ??

Prop. (3.11.3.7) [Classifying Spaces Exist]. For $G \in \text{TopGrp}$, define

$$E_n(G) \in s\text{Top} : E_n(G) = G^{n+1}$$

$$d_i((g_1, \ldots, g_{n+1})) = \begin{cases} (g_2, \ldots, g_{n+1}), & i = 0 \\ (g_1, g_{i-1}, g_i g_{i+1}, g_i g_{i+2}, \ldots, g_{n+1}), & 1 \leq i \leq n \end{cases}$$

$$s_i((g_1, \ldots, g_n)) = (g_1, \ldots, g_i, e, g_{i+1}, \ldots, g_n), \quad 0 \leq i \leq n$$

And

$$B_n(G) \in s\text{Top} : B_n(G) = G^n$$
Then there is a map
\[ \text{pr} : E_*(G) \to B_*(G) \in s\text{Top} : (g_1, \ldots, g_{n+1}) \in E_n(G) \mapsto (g_1, \ldots, g_n) \in B_n(G). \]
Denote \( E(G) = |E_*(G)|, B(G) = |B_*(G)|, \) then \( \text{pr} \) induces a map \( \text{pr} : E(G) \to B(G) \). \( B(G) \) is called the **classifying space** of \( G \).

**Cor. (3.11.3.8).** Any group \( G \) is a fundamental group of a topological space.

**Prop. (3.11.3.9).** Situation as in (3.11.3.7), there is a right action of \( G \) on \( E_*(G) \) on the last coordinates, which induces an action of \( G \) on \( E(G) \), and \( B(G) \cong E(G)/G \). Then if \((G, e)\) is well-pointed, \( E(G) \to B(G) \) is a locally trivial fiber bundle with fiber \( G \), and \( E(G) \) is contractible. In particular, \( G \cong \Omega(BG) \), by (3.9.6.20).

**Proof:** \( \square \). Cf.[Milnor, Construction of Universal Fiber Bundles, I, II].

**Cor. (3.11.3.10).** For \( G, G' \in \text{Top}_{s}\text{r} \),
\[ E(G \times G') \cong E(G) \times E(G'), \quad B(G \times G') \cong B(G) \times B(G'). \]

**Cor. (3.11.3.11).** If \( G \) is commutative, then \( G \times G \to G \) is a homomorphism that makes \( B(G) \) a commutative topological group. Then we can define for any \( n \in \mathbb{N} \),
\[ B(G, n) = B^0(G). \]

**Prop. (3.11.3.12).** \( [X, BG] \cong G \)-bundles on \( X \). And \( BG \) is Abelian if \( G \) is Abelian. Thus the classifying space \( BG \) is unique up to homotopy equivalence because they all represent the functor from the CW homotopy category to the set of \( G \)-bundles on it.

**Proof:** Cf.[Principal Bundles and Classifying Space P13]. \( \square \)

**Prop. (3.11.3.13)[Examples of Classifying Spaces].**
- \( B(\mathbb{Z}/n\mathbb{Z}) \cong S^\infty / (\mathbb{Z}/n) = (\mathbb{C}^\infty \backslash \{0\}) / (\mathbb{R}^+ \times \mu_n)(3.9.3.17) \). In particular, \( B(\mathbb{Z}/2) \cong \mathbb{R}P^\infty (3.9.3.19) \).
- \( BSU(2, \mathbb{R}) = \mathbb{H}P^\infty \).
- \( B(\mathbb{T}^g) \times \mathbb{T}^1 \) because \( \mathbb{R} \to \mathbb{T}^1 \) is a universal cover, this can be seen observing only \( \mathbb{R} \) has to satisfy the sum of inner angle is \( \pi \).
- \( BO(n), BU(n), BSp(n) \) are respectively the infinite Grassmannians \( \text{Gra}(n, \mathbb{R}^\infty), \text{Gra}(n, \mathbb{C}^\infty), \text{Gra}(n, \mathbb{H}^\infty) \), because there is a locally trivial fiber bundle (3.11.1.16) \( U(n, K) \to V_n(K^\infty) \to \text{Gra}(n, K^\infty) \), and \( V_n(K^\infty) \) is contractible (3.9.3.18). In particular, \( B(\mathbb{Z}/2) = \mathbb{R}P^\infty \) and \( BS^1 = \mathbb{C}P^\infty \).

**Proof:** \( \square \)
Def. (3.11.3.14) [Admissible Subgroups]. A subgroup of a topological group $G$ is called **admissible** if $G \to G/H$ is a principal $H$-bundle. In particular, this is the case for $G \in \text{LieGrp}$ and $H \leq G$ closed, by (3.11.3.2).

Prop. (3.11.3.15). If $H$ is an admissible subgroup of $G$, then there is a homotopy fiber sequence $G/H \to BH \to BG$.

*Proof:* Cf. [Principal Bundles and Classifying Space P22].

Cor. (3.11.3.16). There are homotopy equivalences $\Omega BK \cong K$ and $B\Omega K \cong K$.

Prop. (3.11.3.17). If $H$ is an admissible normal subgroup of $G$, then there is a homotopy fiber sequence $BH \to BG \to B(G/H)$.

*Proof:* 

Cor. (3.11.3.18).
- there are fiber bundles $S^0 \to BSO(n) \to BO(n)$ and similarly for $BSU(n)$ and $BSp(n)$.
- there are fiber bundles $S^n \to BO(n) \to BO(n + 1)$.
- there are fiber bundles $U(n)/T^n \to (\mathbb{C}P^\infty)^n \to BU(n)$, where $U(n)/T^n$ is the variety of complete flags in $\mathbb{C}^n$.
- for a discrete group $H \subset G$, $BH \to BG$ is a covering map.
- there are fiber bundles $BSO(n) \to BO(n) \to \mathbb{RP}^\infty$ and similarly for $\mathbb{C}$ and $\mathbb{H}$.
- there are fiber bundles $\mathbb{RP}^\infty \to B\text{Spin}(n) \to BSO(n)$.

*Proof:* These are all classifying spaces of Lie groups.

Prop. (3.11.3.19) [Classifying Line Bundles]. Note that $K(\mathbb{Z}, 2) = \mathbb{CP}^\infty = B(K(\mathbb{Z}, 1)) = BU(1)$ (3.11.3.13), thus we have a bijection $H^2(X, \mathbb{Z}) \cong [X, K(\mathbb{Z}, 2)] \cong \text{Vect}_\mathbb{C}^1(X)$. Similarly, we have a bijection $H^1(X, \mathbb{Z}/2\mathbb{Z}) \cong \text{Vect}_\mathbb{R}^1(X)$.

**Classifying Spaces**

Prop. (3.11.3.20) [Universal Real Bundle]. Let $X$ be paracompact, then there is a natural bijection

$$ [X, \text{Gra}(k, K^\infty)] \to \text{Vect}_\mathbb{R}^1(X) : f \mapsto f^*E_k(K^\infty).$$

*Proof:* Because $E$ is of f.t., we can find a f.d. vector space $W$ with a metric and a vector bundle epimorphism $\varphi : X \times W \to E$ via partition of unity. Then we can take the map $\varphi : X \to G_k(W) : x \mapsto \ker(\varphi_x)^\perp$. Then $f^*E_k(K^\infty) \cong E$ via restriction of $\varphi$. The last assertion follows from the definition of $E_k(K^\infty)$ (3.11.2.35) and (3.11.2.15). Cf. [AGP02] P284.

Cor. (3.11.3.21). By (3.10.6.13), there are isomorphisms

$$ \text{Vect}_\mathbb{R}^1(X) \cong [X, \text{Gra}(1, K^\infty)] = [X, K(\mathbb{Z}/(2), 1)] = H^1(X, \mathbb{F}_2). $$

$$ \text{Vect}_\mathbb{C}^1(X) \cong [X, \text{Gra}(1, \mathbb{C}^\infty)] = [X, K(\mathbb{Z}, 2)] = H^2(X, \mathbb{Z}). $$
Cohomology of Classifying Spaces

Prop. (3.11.3.22). $H_*(BG, \mathbb{Z}) \cong H_*(\Lambda, \mathbb{Z})$ and $H^*(BG, \mathbb{Z}) \cong H^*(G, \mathbb{Z})$.

Proof: Because $EG$ is weakly contractible, $S_*(EG)$ is a free $\mathbb{Z}[G]$-module resolution of $\mathbb{Z}$ and $S_*(EG)_G$ is identified with $S_*(BG)$. The rest is easy. □

Def. (3.11.3.23) [Whitney Sums].

Prop. (3.11.3.24). The diagonal map $(\mathbb{R}P^\infty)^n \to O(n)$ induces a map

$$\omega : (\mathbb{R}P^\infty)^n \cong (BO(1))^n \to BO(n).$$

The conjugation by permutation matrices preserves $O(1)^n$, thus induces a covariant action on this map. The action on $BO(n)$ is identity?, and the action on $(BO(1))^n$ is by permutation.

Then it induces a map

$$H^*(BO(n)) \to H^*((BO(1))^n)^{\Delta_n} \cong F_2[\sigma_1, \sigma_2, \ldots, \sigma_n]$$

where $\sigma_i$ are the elementary symmetric functions. This is injective and thus surjective when tensoring any field, thus it is a bijection?.

Denote the inverse image of $\sigma_i$ by $w_i$, then

$$H^*(BO(n)) \cong F_2[w_1, \ldots, w_n], \quad |w_i| = i$$

and these elements satisfy

- $c_0 = 1$.
- $i_1^*(c_1)$ is the canonical generator of $H^2(BU(1))$.
- $i_n^*(w_i) = c_i$.
- $p^*(w_i) = \sum_{j=0}^i w_j \otimes w_{i-j}$.

Proof: Cf. [Cohomology of Classifying Space Toda P82]. □

Prop. (3.11.3.25) \[H^*(BSO(n), F_2), \text{pr : } BSO(n) \to BO(n) \text{ is the universal covering with fiber} \]

$$\mathbb{Z}/(2), \text{ and}$$

$$H^*(BSO(n), F_2) \cong F_2[pr^* \omega_2, \ldots, pr^* \omega_n].$$

Proof: □

Prop. (3.11.3.26). The diagonal map $U(1)^n \to U(n)$ induces a map

$$\omega : (\mathbb{C}P^\infty)^n \cong (BU(1))^n \to BU(n).$$

The conjugation by permutation matrices preserves $U(1)^n$, thus induces a covariant action on this map. The action on $BU(n)$ is identity?, and the action on $(BU(1))^n$ is by permutation.

Then it induces a map

$$H^*(BU(n)) \to H^*((BU(1))^n)^{\Delta_n} \cong \mathbb{Z}[\sigma_1, \sigma_2, \ldots, \sigma_n]$$
where $\sigma_i$ are the elementary symmetric functions. This is injective and thus surjective when tensoring any field, thus it is a bijection.

Denote the inverse image of $\sigma_i$ by $c_i$, then

$$H^*(BU(n)) \cong \mathbb{Z}[c_1, \ldots, c_n], \quad |c_i| = 2i$$

and these elements satisfy

- $c_0 = 1$.
- $i_1^*(c_1)$ is the canonical generator of $H^2(BU(1))$.
- $i_n^*(c_i) = c_i$.
- $p^*(c_i) = \sum_{j=0}^i c_j \otimes c_{i-j}$.

**Proof:** Cf. [Cohomology of Classifying Space Toda P81].

**Prop. (3.11.3.27).**

$$H^*(BO(2n), \mathbb{Z}[\frac{1}{2}]) \cong H^*(BO(2n+1), \mathbb{Z}[\frac{1}{2}]) \cong H^*(BSO(2n+1), \mathbb{Z}[\frac{1}{2}]) = \mathbb{Z}[\frac{1}{2}][p_1, p_2, \ldots, p_n], \quad |p_i| = 4i$$

Cf. [Cohomology of Classifying Space Toda P81].

**Prop. (3.11.3.28)[Complexifications].** As $BSO(n)$ is the set of oriented real $n$-planes in $\mathbb{R}^\infty$, $BU(n)$ is the set of complex $n$-planes in $\mathbb{C}^\infty$, regarding a complex $n$-plane as an oriented real $2n$-plane induces a map

$$r : BU(n) \to BSO(2n).$$

And complexification of a real plane induces a map

$$e : BO(n) \to BU(n).$$

Then

$$p_k = (-1)^k e^*(c_{2k}) \in H^{4k}(BO(n)), \quad e^*(c_k) = w_k^2 \in H^{2k}(BO(n), F_2), \quad p_k = w_{2k}^2 \in H^{4k}(BO(n), F_2)$$

$$r^*(w_{2k}) = c_k \in H^{2k}(BU(n), F_2), \quad r^*(e) = c_n \in H^{2n}(BU(n)).$$

Cf. [Cohomology of Classifying Space Toda P81].

4 Characteristic Classes

References are [Cohomology of Classifying Space, Toda], [May99] and [M-S74].

**Def. (3.11.4.1) [Characteristic Classes].** For an ES-cohomology theory $E^*$, $p \in \mathbb{Z}, n \in \mathbb{N}$, a characteristic class functor of degree $p$ for $n$-dimensional K-bundles is a natural assignment $c : \text{Vect}_k^n(X) \to E^p(X)$ for any $X \in \text{Top}$ paracompact that is functorial w.r.t. pullbacks.

By (3.11.3.20), there is a bijection between characteristic class functors of degree $p$ with elements in $E^p(BO(n))$. 
Stiefel-Whitney Classes

**Def. (3.11.4.2) [Stiefel-Whitney Classes].** A Stiefel-Whitney class functor $w$ for real bundles is a total characteristic class functor for real bundles for the ordinary cohomology theory with $F_2$ coefficients $H^*(-, F_2)$ that satisfies:

- $w(E) = 1 + w_1(E) + \ldots + w_n(E) \in H^*(X, F_2)$, $|w_i| = i, n = \text{rank}(E)$.
- $f^*(w(E)) = w(f^*(E))$.
- $w(E \oplus F) = w(E)w(F)$.
- On the tautological bundle $\gamma_1^1$ over $RP^1$, $w(\gamma_1^1) = 1 + w_1(\gamma_1^1)$ and $w_1(\gamma_1^1)$ is the unique non-trivial element in $H^1(RP^1, F_2)$.

**Prop. (3.11.4.3) [Existence and Uniqueness of Stiefel-Whitney Classes].** There exists uniquely a Stiefel-Whitney class functor, and they can be defined using the Thom isomorphism

$$\varphi_E : H^i(B; F_2) \cong H^{i+n}(E, E \backslash B; F_2) \quad (3.11.2.26)$$

as

$$w(E) = \varphi^{-1}_E Sq(\varphi_E(1)) \in H^*(B; F_2) = \varphi^{-1} Sq(u_E).$$

**Proof:** Cf.[May, P191] and [Milnor, P92].

**Prop. (3.11.4.4).** For $B \in \text{Top}$ paracompact, $E, E' \in \text{Vect}_R(B)$, then

- If $E$ is trivial, $w(E) = 1$.
- If $E \oplus E'$ is trivial, then

$$w(E') = w(E)^{-1} = 1 + w_1 + (w_1^2 + w_2) + (w_1^3 + w_3) + (w_1^4 + w_1^2w_2 + w_2^2 + w_4) + \ldots.$$  

- Let $\gamma_1^n$ be the tautological line bundle over $RP^n \quad (3.11.2.31)$, then $w(\gamma_1^n) = 1 + a$.
- Let $\xi, \eta$ be vector bundles on $M, N$, then

$$w(\xi \times \eta) = \pi_1^\ast w(\xi) \cup \pi_2^\ast w(\eta) = w(\xi) \times w(\eta)$$

in $H^*(M \times N, F_2)$.

**Proof:** 1: A trivial bundle is the pullback of a bundle over pt, thus $w(f^*(E)) = w^*(e(E)) = 1$.

2: This is trivial.

3: This is because $E_1(R)/RP^1 \to E_1(R^n)/RP^n$ is a bundle map, thus $w_1(E_1(R^n))$ pulls back to $w_1(E_1(R)) \neq 0$, thus $w_1(E_1(R^n)) = a$.

4: This follows from the definition that $\xi \times \eta = \pi_1^\ast \xi \oplus \pi_2^\ast \eta$ and Kunneth formula(3.10.2.13).

**Cor. (3.11.4.5) [Tangent and Normal Bundles].** Let $M$ be a submanifold of a smooth manifold $N$, let $T_M, T_N$ be the tangent bundles and $\nu$ the normal bundle, then

$$w(N_{M/N}) = w(T_N)w(T_M)^{-1}$$

**Proof:** This follows form the smooth nbhd theorem ?.

\[\square\]
Prop. (3.11.4.6) [Wu Formula]. For $E \in \text{Vect}_B$,

$$\text{Sq}^i(w_j) = \sum_{t=0}^{i} \binom{j+t-i-1}{t} w_{i-t} w_{i+t}$$

Proof: Use splitting principle.

Def. (3.11.4.7) [Characteristic Classes of Smooth Manifolds]. For $M \in \text{Mani}_{\text{sm}}$, denote $w(M) = w(TM)$.

Prop. (3.11.4.8) [Wu Formula]. For $M \in \text{Mani}_{\text{sm, cpt}}$, define the Wu class $\nu(M) = \sum v_i \in H^*(M, \mathbb{F}_2)$ s.t.

$$\langle \nu(M) \cup x, [M]_2 \rangle = \langle \text{Sq}(x), [M]_2 \rangle$$

for any $x \in H^*(M, \mathbb{F}_2)$. In particular, $\nu_k(M)_k \cup x = \text{Sq}^k(x)$ for any $x \in H^{d-k}(M, \mathbb{F}_2)$. Notice such a class exists by Poincaré duality.

Then the Stiefel-Whitney class of $M$ is given by the Wu class:

$$w(M) = \text{Sq}(\nu(M)) \tag{3.10.6.14}$$

Proof: Cf. [Milnor, P132].

Cor. (3.11.4.9) [Homotopy Invariance of Stiefel-Whitney Classes of Manifolds]. The Stiefel-Whitney classes only depends on the homotopy type of $M$, and pullbacks of Stiefel-Whitney classes along smooth maps between smooth manifolds only depends on the homotopy type of the map.

Def. (3.11.4.10) [Stiefel-Whitney Numbers]. Let $M$ be a closed smooth manifold of dimension $n$, then for each tuple $(i_1, \ldots, i_k)$ with $i_1 + \ldots + i_k = n$, define the Stiefel-Whitney number

$$w_{i_1, \ldots, i_k}(M) = (w_{i_1}(TM) \cup \ldots \cup w_{i_k}(TM), [M]) \in \mathbb{Z}/2\mathbb{Z}.$$

Euler Classes

Def. (3.11.4.11) [Euler Classes]. Axioms for Euler classes for orientable real bundles $E/B$:

- $e(e^1) = 0$.
- For any map $f : B' \to B$, $f^*(e(E)) = e(f^*(E))$.
- $e(E \oplus F) = e(E)e(F)$.
- For the opposite orientation $-E$, $e(-E) = -e(E)$.

Prop. (3.11.4.12) [Existence of Euler Classes]. For any oriented $E/B \in \text{Vect}_B$, let $e(E)$ be defined as the image of the Thom class (3.11.2.26) under the maps

$$\varphi_E^{-1} : H^n(E, E_0, \mathbb{Z}) \to H^n(E, \mathbb{Z}) \cong H^n(B, \mathbb{Z}).$$

or equivalently, $e(E) = \varphi^{-1}(u_E \cup u_E)$ where $u_E$ is the Thom class and $\varphi$ is the Thom isomorphism (3.11.2.26). Then it is the desired Euler class.
Proof: ?
1: If $E$ has a non-zero section $s : B \to E_0$, then $B \xrightarrow{s} E_0 \subset E \to B$ is identity, thus

$$H^n(B) \xrightarrow{\pi^*} H^n(E) \to H^n(E_0) \xrightarrow{s^*} H^n(B)$$

is the identity. But $H^n(B) \xrightarrow{\pi^*} H^n(E) \to H^n(E_0)$ equals the restriction of $u_E$ to $E_0$, which is 0.
2: This $e(E)$ is compatible with base change by (3.11.2.27) and the definition.
3: For products, Cf.[Milnor, P100].
4: If the orientation is reversed, then $u_{-E} = -u_E$. \hfill \Box

Cor. (3.11.4.13).
- For a trivial line bundle, $e(E) = 0$.
- For an odd dimensional vector space $E/B$, $2e(E) = 0$.

Proof: 1: A trivial bundle is the pullback of a bundle over pt, thus $e(f^*(E)) = f^*(e(E))$ is trivial.
2: This is because their is an orientation preserving isomorphism $(-1) : E/B \cong (-E)/B$ that is isomorphism on the base, so $e(-E) = e(E)$. \hfill \Box

Cor. (3.11.4.14)[Euler classes and Whitney Classes]. For a vector bundle $E/B$ of rank $n$, the natural map $H^n(B, \mathbb{Z}) \to H^n(B, \mathbb{Z}/2\mathbb{Z})$ maps the Euler class $e(E)$ to the top Whitney class $w_n(E)$.

Proof: $e(E) = \varphi^{-1}(u_E \times u_E)$, which maps to $\varphi_2^{-1}(u_{E,2} \cup u_{E,2}) = \varphi_2^{-1}(Sq^n(u_{E,2})) = w_n(E)$ by (3.11.2.27). \hfill \Box

Prop. (3.11.4.15)[Euler Class and Euler Characteristic]. For $M \in \text{Man}_{\text{cpt}, \text{sm}, \text{orntd}}$, then

$$\langle e(T_M), [M] \rangle = \chi(M).$$

Proof: ? \hfill \Box

Chern Classes

Def. (3.11.4.16)[Chern Classes], Axioms for Chern classes for complex bundles:
- $c(E) = 1 + c_1(E) + \ldots + c_n(E) \in H^*(X, \mathbb{Z})$, \quad $|c_i| = 2i, n = \deg(E)$.
- $f^*(c(E)) = c(f^*(E))$.
- $c(E \oplus F) = c(E)c(F)$.
- For the tautological bundle $\eta$ over $\mathbb{CP}^\infty$, $c_1(\eta)$ corresponds to the element $\text{id} \in [\mathbb{CP}^\infty, \mathbb{CP}^\infty] \cong H^2(\mathbb{CP}^\infty)$.

Prop. (3.11.4.17). There exists uniquely a natural transformation $c : \text{Vect}_C(X) \to H^*(X, \mathbb{Z})$ satisfying these axioms. (For this, it suffice to calculate the cohomology ring of $BGL_n(\mathbb{C})$, Cf.[Cohomology of Classifying Space Toda]).

Cor. (3.11.4.18). For a trivial bundle $E = \mathbb{C}$, $c_i(E) = 0$ for $i > 0$, because $E$ is a pullback from a bundle on pt.

In particular, for any complex vector bundle $E$, $c(E \oplus \mathbb{C}) = c(E)$.
Prop. (3.11.4.19) [First Chern Class Map]. A complex line bundle can be seen as an element of $H^1(X, \mathbb{C}^\ast)$, by (5.3.2.14), by the exact sequence

$$0 \to \mathbb{Z} \to \mathbb{C} \xrightarrow{\exp(2\pi i - )} \mathbb{C}^\ast \to 0$$

($\mathbb{C}$ is sheaf of smooth functions from $X$ to $\mathbb{C}$) which gives a map $H^1(X, \mathbb{C}^\ast) \to H^2(X, \mathbb{Z})$, called the first Chern class map. It is called so because it gives the first Chern class of this complex line bundle. It is also an isomorphism because $\mathbb{C}$ is fine sheaf so acyclic.

Proof: Only have to prove they are equal in $H^2(X, \mathbb{C})$. We choose a totally convex covering $U_i$ of $X$ by (11.2.3.21), then it is a fine cover, so by (5.3.2.15) the Čech cohomology and sheaf cohomology equal.

Use the Chern-Weil map definition of the Chern class, a connection on a line bundle satisfies $\nabla e_\alpha = \omega_\alpha e_\alpha$, and if $e_\beta = e_\alpha g_{\alpha \beta}$, then $\omega_\beta = g_{\alpha \beta}^{-1} \omega_\alpha g_{\alpha \beta} + g_{\alpha \beta}^{-1} \omega_{\alpha \beta} = \omega_\alpha + d(\log g_{\alpha \beta})$. So $\Omega_\alpha = d\omega_\alpha$ locally, and the first Chern class is giving by $\Omega_\alpha$ in $H^2(X, \mathbb{C})$.

Then we need to understand the deRham isomorphism. For the exact sequence $0 \to \mathbb{C} \to \mathcal{A}^0 \to \mathcal{A}^1 \to \ldots$, it has a splitting: $0 \to \mathbb{C} \to \mathcal{K}^1 \to 0$ and $0 \to \mathcal{K}^1 \to 0 \to \mathcal{A}^1 \to \mathcal{K}^2 \to 0$, this gives

$$0 \to H^1(X, \mathcal{K}^1) \xrightarrow{\delta} H^2(X, \mathbb{C}) \to 0, \quad \mathcal{A}^1(X) \to \mathcal{K}^2(X) \xrightarrow{\delta} H^1(X, \mathcal{K}^1) \to 0.$$

because $\mathcal{A}^k$ are fine sheaves. The composite of them is just the de Rham isomorphism (Here we are identifying $H^2(X, \mathbb{C})$ to $H^2(X, \mathbb{C})$ by (5.3.5.9)). Tracking the lifting, we notice $\Omega$ is mapped to the cocycle $\{\log g_{\alpha \beta} + \log g_{\beta \gamma} - \log g_{\alpha \gamma}\}$, which is exactly the image of the first Chern class map. $\square$

Cor. (3.11.4.20). Complex line bundles are characterized by the first Chern class up to smooth isomorphism, because $H^1(X, \mathbb{C}^\ast) \to H^2(X, \mathbb{Z})$ is an isomorphism.

Pontryagin Classes

Def. (3.11.4.21) [Pontryagin Classes]. The Pontryagin classes are defined as $p_k(E) = (-1)^k c_{2k}(E_C) \in H^{4k}(X, \mathbb{Z})$.

Def. (3.11.4.22) [Pontryagin Number]. Let $M$ be a closed manifold of dimension $4n$, then for each tuple $I = (i_1, \ldots, i_k)$ with $i_1 + \ldots + i_k = n$, define the Pontryagin numbers

$$p_I(M) = (p_{i_1}(TM) \cup \ldots \cup p_{i_k}(TM), [M]) \in \mathbb{Z}.$$

Prop. (3.11.4.23) [Pontryagin Number of Product Manifolds]. Let $M, N$ be closed submanifolds of dimension $4m, 4n$ resp., then for any tuple $I = (i_1, \ldots, i_k)$ with $i_1 + \ldots + i_k = m + n$,

$$p_I(M \times N) = \sum_{I_1, I_2 | I_1 + I_2 = I} p_{I_1}(M)p_{I_2}(N)$$

where the summation is over all partitions $I_1, I_2$ of $m, n$ resp..

Proof: Cf. [Milnor, P193]. $\square$

Combinatorial Pontryagin Classes

Calculations and Applications

Prop. (3.11.4.24). \( w(\mathbb{R}P^n) = (1 + a)^{n+1} \). In particular, \( w(\mathbb{R}P^n) = 1 \) iff \( n = 2^k - 1 \) for some \( k \).

Proof: This follows from (3.11.2.32).

\[ \square \]

Cor. (3.11.4.25). Let \( n = 2^k - 1 - r \), where \( r \leq 2^{k-1} - 1 \), then \( \mathbb{R}P^n \) can be immersed into \( \mathbb{R}^{n+d} \) iff \( d \geq r \).

Proof: By (3.11.4.5), the normal bundle \( \nu \) satisfies \( w(\nu) = (1+a)^r \), and \( r < n \), thus \( d = \text{rank}(\nu) \geq r \).

\[ \square \]

Cor. (3.11.4.26). If \( n + 1 = 2^r m \), then there doesn’t exist \( 2^r \)-linearly independent vector fields on \( \mathbb{R}P^n \).

Proof: This is because if their is, then \( w(\mathbb{R}P^n) \) has degree \( \leq n - 2^r = 2^r(m - 1) - 1 \), but in fact it equals \((1 + a^2)^m\) has leading term \( a^{2^r(m-1)} \).

\[ \square \]

Remark (3.11.4.27). By considering irreducibility, we can prove stronger results, like \( \tau_{\mathbb{R}P^4} \) doesn’t contain a subbundle of rank 2.

Prop. (3.11.4.28)[Non-Vanishing Vectors]. \( \mathbb{R}P^n \) admits a non-vanishing vector field iff \( n \) is odd.

Proof: If \( n = 2k + 1 \), consider the non-vanishing vector field on \( S^{2k+1} : (x_1, \ldots, x_{2k+2}) \mapsto (x_2, -x_1, x_4, -x_3, \ldots, x_{2k+2}, -x_{2k+1}) \). Then This descends to a non-vanishing vector field on \( \mathbb{R}P^{2k+1} \). Conversely, if \( n = 2k \), by (3.11.4.26), there doesn’t exist a non-vanishing vector field on \( \mathbb{R}P^{2k} \).

\[ \square \]

5 K-Theory

Def. (3.11.5.1) [Topological K-Groups]. For \( X \in \text{Top}_{\text{cpt}} \), the K-group \( K(X) \) is defined to be \( K_0(\text{Vect}(X))(3.3.1.25) \), which is a ring under sum and tensor. Two vector bundles \( E, F \) are called stably equivalent if \( [E] = [F] \).

There is a degree map \( \deg K(X) \to \mathbb{Z} \), and the kernel is denoted by \( \tilde{K}(X) \). There is a canonical splitting \( K(X) \cong \tilde{K}(X) \oplus \mathbb{Z} \).

Prop. (3.11.5.2). A continuous map \( f : X \to Y \) induces a group morphism \( f^* : K(Y) \to K(X) \).

By (3.11.1.9), this map only depends on \( f \in [X, Y] \).

Prop. (3.11.5.3). By (3.11.2.20), over a compact Hausdorff space, \( E, F \) is stably equivalent iff \( E \oplus \mathbb{R}^n \cong F \oplus \mathbb{R}^n \) for some \( n \).

Thm. (3.11.5.4) [Periodicity Theorem]. Let \( L \) be a line bundle over \( X \), then as a \( K(X) \)-algebra, \( K(P(L \oplus 1)) \) is generated by \([H]\), and is subject to the single relation \( ([H] - [1])([L][H] - [1]) = 0 \).

Proof: Cf.[K theory, Atiyah, P46].

\[ \square \]

Cor. (3.11.5.5). \( K(S^2) \) is generated by \([H]\) as a \( K(\text{pt}) \)-module, and is subject to the single relation \( ([H] - [1])^2 = 0 \).

Cor. (3.11.5.6). There is an isomorphism \( \mu : K(X) \otimes K(S^2) \to K(X \times S^2) \), where \( \mu(a \otimes b) = (\pi_1^*a)/(\pi_2^*b) \).
Def. (3.11.5.7) [Setup for Proof of Periodicity Theorem]. Given a line bundle $E$ over $X$, we can associate a projective bundle $P(E)$ that $P(E)_x = P(E_x)$. Now denote $P^0$ the subspace of $P(E)$ consisting of all vectors of length $\leq 1$ and $P_\infty$ the subspace consisting of all vectors of length $\geq 1$ together with the infinity section. There are projections $\pi_0 : P_0 \to X$ and $\pi_\infty : P_\infty \to X$, which are homotopy equivalences.

Now by (3.11.2.8),

6 Adam Operators

7 Cobordism

Def. (3.11.7.1) [Bordism Groups]. If $X$ is a topological space, define the bordism group $\Omega_n(X)$ to be the set of pairs $(M, f)$ where $M$ is a closed smooth manifold of dimension $n$ and $f : M \to X$ is a continuous map, under the equivalence relation that $(M_0, f_0) \sim (M_1, f_1)$ iff there is an $n + 1$ manifold $N$ and a map $F : N \to X$ that $\partial F = f_1 \amalg f_2$. This is a vector space over $F_2$.

Let $\Omega = \Omega_0(pt)$, then for any $m, n$, there is a map $\Omega_m \times \Omega_n \to \Omega_{m+n} : (M, N) \mapsto M \times N$, so $\Omega_*$ is a graded commutative ring.

Prop. (3.11.7.2) [Thom]. If $N \in \text{Mani}_{s^m,\text{cpt}}^{n+1}$ and $\partial(N) = M$, then all the Stiefel-Whitney numbers of $M$ vanish.

Conversely, if $M \in \text{Mani}_{s^m,\text{cpt}}^{n}$ with all Stiefel-Whitney numbers $0$, then it is the boundary of a compact smooth manifold with boundary.

**Proof:** Let $[N] \in H_{n+1}(N, M)$ be the fundamental homology class of the pair, then $\partial([N]) = [M]$. Let $\tau N, M$ be the tangent bundle of $N, M$, then $\tau N|_M = \tau M \oplus R^1$, because there is an outward pointing normal bundle. Thus the Stiefel-Whitney classes of $M$ comes from restriction of that of $N$. Now the composite $H^n(N) \to H^n(M) \xrightarrow{\delta} H^n(N, M)$ is $0$, so $\delta(w_{i_1}, \ldots, w_k(M)) = 0$. Thus

$$\langle w_{i_1}, \ldots, w_k(M), [M] \rangle = \langle \delta(w_{i_1}, \ldots, w_k(M)), [N] \rangle = 0.$$

Conversely, Cf. [Stong, Notes on Cobordism Theory].

Prop. (3.11.7.3). For $m \in \mathbb{Z}_+$, $RP^{2m-1}$ is a boundary and $RP^{2m}$ is not a boundary.

**Proof:** Consider the fiber bundle $S^1 \to RP^{2n-1} \to CP^n$, its cone bundle is $D^1 \to M^n \to CP^{2n-1}$, which has boundary $RP^{2n-1}$.

$RP^{2m}$ is not a boundary by (3.11.7.2) and the fact its top Stiefel-Whitney class is non-zero.

Thm. (3.11.7.4) [Thom].

$$\Omega_* = F_2[t_2, t_4, t_5, \ldots]$$

is a graded polynomial algebra where there’s one generator $t_n \in \Omega_n$ for each $n \not= 2^k - 1$.

Also $\Omega_*(X) = H_*(X, \Omega_*) \cong H_*(X, F_2) \otimes_{F_2} \Omega_*$. 

**Proof:**

Cor. (3.11.7.5). A map $f : X \to Y$ induces a map $f_* : \Omega_n(X) \to \Omega_n(Y)$. This map only depends on the homotopy type of $f$. 

Oriented Cobordism

Def. (3.11.7.6) [Oriented Bordism Groups]. When $X$ is an orientable manifold, define the oriented bordism group $\Omega_n^s(X)$ to be the set of pairs $(M, f)$ where $M$ is an oriented smooth manifold of dimension $n$ and $f : M \to X$ is a continuous map preserving orientation, under the equivalence relation that $(M_0, f_0) \sim (M_1, f_1)$ iff there is an $n+1$ manifold $N$ and a map $F : N \to X$ that $\partial F = (−f_1) ∪ f_2$.

Let $\Omega_n^s = \Omega_n^s(pt)$, then for any $m, n$, there is a map $\Omega_m^s \times \Omega_n^s \to \Omega_{m+n}^s : (M, N) \mapsto M \times N$, and $M \times N \cong (−1)^{mn}N \times M$, so $\Omega_n^s$ is a graded anti-commutative ring.

Prop. (3.11.7.7). The relation of (oriented) bordism is truly an equivalence class. It suffices to show transitivity, and this is because we can piece together two manifold with boundaries by collar neighborhood theorem (11.1.1.2).

Prop. (3.11.7.8). If $N \in \text{Man}_{n+1}^\text{o, sm,cpt,ornt,∂}$ and $\partial(N) = M$, then all the Pontryagin numbers of $M$ vanish.

Proof: Let $[N] \in H_{n+1}(N, M)$ be the fundamental homology class of the pair, then $\partial([N]) = [M]$. Let $\tau_N, M$ be the tangent bundle of $N, M$, then $\tau_{N|M} = \tau_M \oplus \mathbb{R}^1$, because there is an outward pointing normal bundle. Thus the Stiefel-Whitney classes of $M$ comes from restriction of that of $N$. Now the composite $H^n(N) \to H^n(M) \overset{\delta}{\to} H^n(N, M)$ is 0, so $\delta(w_{i_1, \ldots, i_k}(M)) = 0$. thus

$$\langle w_{i_1, \ldots, i_k}(M), [M]\rangle = \langle \delta(w_{i_1, \ldots, i_k}(M)), [N]\rangle = 0.$$  

□

Prop. (3.11.7.9) [Mayer-Vitores]. Let $X = U \cup V$ where $U, V$ are open subsets of $X$.

Thm. (3.11.7.10) [Thom].

$$\Omega_*^s \otimes \mathbb{Q} \cong \mathbb{Q}[u_1, \ldots, u_n, \ldots],$$

where $u_i \in \Omega_{4i}^s$ and is represented by $[\mathbb{CP}^{2i}]$. Moreover,

- $\Omega_0^s = \mathbb{Z}$.
- $\Omega_1^s = 0$.
- $\Omega_2^s = 0$.
- $\Omega_3^s = 0$.
- $\Omega_4^s = \mathbb{Z}$, generated by $\mathbb{CP}^2$.
- $\Omega_5^s = \mathbb{Z}/2\mathbb{Z}$, generated by $Y^5$.
- $\Omega_6^s = 0$.
- $\Omega_7^s = 0$.
- $\Omega_8^s = \mathbb{Z} \oplus \mathbb{Z}$, generated by $\mathbb{CP}^4$ and $\mathbb{CP}^2 \times \mathbb{CP}^2$.
- $\Omega_9^s = \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$, generated by $Y^9$ and $Y^5 \times \mathbb{CP}^2$.
- $\Omega_{10}^s = \mathbb{Z}/2\mathbb{Z}$, generated by $Y^5 \times Y^5$.
- $\Omega_{11}^s = \mathbb{Z}/2\mathbb{Z}$, generated by $Y^{11}$.
- $\Omega_n^s \neq 0$ for $n \geq 8$. 

Proof: Cf. [Milnor, P203].

By (3.11.7.8), for any partition $I$ of $k$, there is a map $\Omega_{4k} \to \mathbb{Z}: M \mapsto p_I(M)$. These maps can be used to show that the products $\{\mathbb{CP}^{2i_1} \times \mathbb{CP}^{2i_r} | \sum i_r = k\}$ are linearly independent in $\Omega_{4k}$ by (3.11.4.23).

\[ \square \]

Prop. (3.11.7.11) [Index and Oriented Cobordism]. If $k \in \mathbb{N}, W \in \text{Mani}_{cntd,orntd,cpct}^{4k+1}$, then the index $I(M) = 0$.

Proof: This follows from the fact the image of $H^{2k}(W) \overset{i^*}{\rightarrow} H^{2k}(M)$ is a half-dimensional subspace (3.10.3.18) that the intersection product is trivial:
\[
\langle i^*\alpha \cup i^*\beta, \partial[W] \rangle = \langle \alpha \cup \beta, i^*\partial[W] \rangle = 0.
\]

Then it is by linear algebra that the signature of this pairing is 0. \[ \square \]

Def. (3.11.7.12) [Stably Framed Manifold]. A stably framed manifold is a smooth manifold $M$ of dimension $n$ together with an isomorphism $TM \oplus \mathbb{R}^N \cong \mathbb{R}^{N+n}$ for some $N$.

Def. (3.11.7.13) [Framed Bordism Groups]. Because $T(\partial N) \oplus \mathbb{R} \cong TN|_{\partial N}$, we have the notion of a stably framed bordism $\Omega^fr_n(X)$. Denote $\Omega^fr_n = \Omega^fr_n(pt)$.

Prop. (3.11.7.14). $S^3 \cong SU(2)$ is naturally framed, and this generates $\Omega^fr_3 \cong \mathbb{Z}/24$.

Thm. (3.11.7.15) [Pontryagin]. $\Omega^fr_n \cong \pi_{n+N}(S^N)$.

Applications

Prop. (3.11.8.1). A simply connected manifold is orientable. (Use the orientable double cover).
3.12 Simplicial Homotopy Theory

Main references are [Jardine Simplicial Homotopy Theory], [Lur09].

1 Simplicial Objects

Def.(3.12.1.1)[Simplex Category]. The simplex category $\Delta$ consists of simplicial objects $[n]$ for each $n \geq 0$ and there maps are order-preserving maps.

$\Delta$ has a subcategory $\Delta_+$ consisting of the same objects but the morphisms are all surjective order-preserving maps.

For $C \in \text{Top}$, a simplicial object in $C$ is a functor $\Delta^{\text{op}} \to C$. A cosimplicial object in $C$ is a simplicial object in $C^{\text{op}}$. The category of simplicial objects in $C$ is denoted by $sC$.

Def.(3.12.1.2). $\Delta^n$ is the simplicial set $\Delta^n([m]) = \text{Hom}([m],[n])$.

Def.(3.12.1.3)[Augmentation]. If $X$ is a simplicial object in a category, then an augmentation of $X$ is a morphism $d : A \to X$ that $dd_0 = dd_1$. In case $C$ is $\text{Mod}_R$, this is equivalent to a morphism $\pi_0(X) \to A$.

Def.(3.12.1.4)[s-Free Simplicial Objects]. $X \in sC$ is called s-free if the underlying category $\Delta_+^{\text{op}} \to C$ is $\Delta_+^{\text{op}}$-free (3.1.2.16).

Equivalently, an s-free object is a simplicial object $X$ that there are objects $Z_n \in C$ that $X_n = \coprod_{\varphi : [n] \to [k]} \varphi^*Z_k$. Moreover, a simplicial morphism of simplicial objects are called s-free if the underlying diagram $X_+ \to Y_+$ is of the form $X_+ \to X_+ \coprod Y_0$ where $Y_0$ is s-free.

Prop.(3.12.1.5)[sC is a Simplicial Category]. Let $sC$ be the category of simplicial $C$-objects, then it can be made into a simplicial category which is also tensored and cotensored (3.1.5.6) over $\text{Set}_\Delta$.

Proof: We define first a action of $\text{Set}_\Delta$ on $sC$:

$$\otimes : \text{Set}_\Delta \times sC \to sC : (K,X) \mapsto (K \otimes X)_n = \coprod_{K_n} X_n,$$

with the simplicial maps determined by that of $K$ and $X$.

Also there is a action of $\text{Set}_\Delta^{\text{op}}$ on $sC$:

$$(-) : \text{Set}_\Delta^{\text{op}} \times sC \to sC : (K \otimes X)_n = \prod_{K_n} X_n$$

with the simplicial maps determined by that of $K$ and $X$.

Then there is an adjointness

$$\text{Hom}_{sC}(K \otimes X,Y) \cong \text{Hom}_{sC}(X,Y^K)$$

for any simplicial set $K$.

Next we define $\text{Map}_{sC}(X,Y) \subset \text{Set}_\Delta$ as $(\text{Map}_{sC}(X,Y))_n = \text{Hom}_{sC}(X \otimes \Delta^n,Y)$, then there are functorial isomorphisms

$$\text{Map}_{sC}(K \otimes X,Y) \cong \text{Map}_{sC}(X,Y^K) \cong \text{Map}_{\text{Set}_\Delta}(K,\text{Map}_{sC}(X,Y))$$

(easy to check). So we are done.
Remark (3.12.1.6) [Realization Functor]. For $\mathcal{C} \in \text{Cat}$ that has countable colimits, there is a simplicial realization functor

$$| - | : s\mathcal{C} \to \mathcal{C} : X \mapsto \lim_{\Delta_+^\text{op}} X_n.$$ 

2 Topological Categories

Def. (3.12.2.1) [Topological Categories]. A topological category is a category that is enriched over the category $\mathcal{S}$ of compactly generated and Hausdorff spaces. The category of topological categories is denoted by $\text{Cat}_{\text{Top}}$.

Two topological categories is called strongly equivalent if they are equivalent as enriched categories.

Def. (3.12.2.2) [Homotopy Category of Spaces]. Given a topological category $\mathcal{C}$, the homotopy category $h\mathcal{C}$ of $\mathcal{C}$ is defined to be the category transferred from $\mathcal{C}$ (3.1.5.3) by the right-lax monoidal functor $\pi_0$ (3.1.4.13).

Def. (3.12.2.3) [Homotopy Category of Spaces]. Let $\mathcal{C}$ be the category of CW complexes that the morphisms are given the compact-open topology, then its homotopy category $\mathcal{H}$ is called the homotopy category of spaces.

3 Simplicial Sets

Simplicial Set

Remark (3.12.3.1). The fact that any simplicial set $X$ is a colimit of $\Delta^n$ (3.1.2.13) is important in proving properties of constructions of simplicial set.

Def. (3.12.3.2) [Objects, Morphisms and Equivalences]. Given a simplicial set $S$, its objects are just maps $\Delta^0 \to S$, and its morphisms are maps $\Delta^1 \to S$.

Def. (3.12.3.3) [Nerves]. The nerve of a category $\mathcal{C}$ is a simplicial set with $(N(\mathcal{C}))_n = \text{Hom}([n], \mathcal{C})$, i.e. composable arrows of morphisms of length $n$. It is a fully faithful functor from the category of small categories to the category of simplicial sets.

Prop. (3.12.3.4) [Natural Transformation and Homotopy]. A natural transformation will induce homotopic nerve map. thus a pair of adjoint functors will induce a simplicial homotopy between their nerve.

Prop. (3.12.3.5). The nerve construction is a fully faithful functor $\text{Cat} \to s\text{Set}$.

Prop. (3.12.3.6) [Characterization fo Nerves]. For any simplicial set $K$, there is a small category $\mathcal{C}$ that $K \cong N(\mathcal{C})$ iff for each diagram

$$\Delta^n \to K$$

there exists uniquely a dotted arrow.

Proof: [HTT, P9].
Def. (3.12.3.7) [Set $\Delta$ and $\mathcal{C}G$]. There is a functor $v : \Delta \to \mathbb{Top} : [n] \mapsto \Delta^n$?, which induces a map $s \text{Set} \to s \mathbb{Top}$.

The (topological) **geometrization** is the functor

$$s \text{Set} \to \mathbb{Top} : X \mapsto |X| = |v(X)|.$$

The **singular complex functor** maps a topological space $Y$ to a simplicial set

$$(\text{Sing}(Y))_n = \text{Map}(\Delta_n, Y).$$

The geometrization functor is left adjoint to the singular functor as functors between the categories $\mathcal{C}G$ and $\text{Set}_\Delta$ (use colimit definition of $X$). This is just the Kan extension in (3.1.2.14).

Moreover, the geometrization as a functor from $\text{Set}_\Delta \to \mathcal{C}G$ preserves finite limits. Cf. [Jardine P9].

The three kinds of geometrization of a bisimplicial set is the same: geometrization the diagonal simplicial set, the twice geometrization of left(resp. right) simplicial set.

**Proof:**

Def. (3.12.3.8) [Weak Homotopy Equivalence]. A morphism of simplicial sets $S \to T$ is called a **weak homotopy equivalence** if the induced map $|S| \to |T|$ is a weak homotopy equivalence.

Prop. (3.12.3.9) [Quillen]. The geometrization functor and the singular complex functor defines a Quillen equivalence:

$$|−| : \text{Set}_\Delta \rightleftarrows \mathcal{C}G : S(−)$$

where the RHS is Serre-Quillen model category (3.9.6.28).

The functor $|−| \circ S(−)$ is denoted by $\Gamma : \mathcal{C}G \to \mathcal{C}G$.

**Proof:** Cf. [May, P125].

Cor. (3.12.3.10). The localized category of $\mathcal{C}G$ and $\text{Set}_\Delta$ at weak homotopy equivalence classes are the same, and it is just the homotopy category of spaces $\mathcal{H}$, by (3.7.2.7).

**Constructing Simplicial Sets**

Def. (3.12.3.11) [Joins]. Let $S, S'$ be simplicial sets, then the **join** of $S, S'$ is defined to be the simplicial set that for all any finite ordered set $J$,

$$(S \star S')(J) = \bigcup_{J = I \coprod I'} S(I) \times S(I').$$

where $I, I'$ satisfies $i < i'$ for any $i \in I, i' \in I'$. And the glueing is natural. Join clearly commutes with colimits.

Prop. (3.12.3.12) [Monoidal Structure of $\text{Set}_\Delta$]. The join operation makes the category of sets a monoidal category.

Def. (3.12.3.13) [Cones]. For a simplicial set $K$, the **left/right cone** of $K$ are defined to be the join $K^\diamond = \Delta^0 \star K$ and $K^\blacksquare = K \star \Delta^0$.

For a map $f : X \to S$, the **left/right cone** of $f$ are defined to be $S \coprod_X X^\diamond$ and $S \coprod_X X^\blacksquare$. 
Def. (3.12.3.14) [Overcategories]. Let \( p : K \to S \) be a morphism of simplicial sets, then there is a simplicial set \( S_{/p} \) that
\[
\text{Hom}(Y, S_{/p}) \cong \text{Hom}_p(Y \times K, S).
\]
Where \( \text{Hom}_p \) indicates that we only consider morphisms that \( f|_K = p \). And dually we can define the undercategories.

Proof: We just define \((S_{/p})_n = \text{Hom}_p(\Delta^n \times K, S)\), then the condition holds for \( \Delta^n \), and use the fact every simplicial set is a colimit of \( \Delta^n \)s (3.12.3.1), and both sides commutes with colimits. □

Prop. (3.12.3.15) [Generating Simplicial Sets]. Let \( \mathcal{U} \) be a collection of simplicial sets that:
- \( \mathcal{U} \) is stable under isomorphisms,
- \( \mathcal{U} \) is stable under disjoint union,
- \( \Delta^n \subset \mathcal{U} \) for any \( n \),
- If there is a pushout diagram \( X \xrightarrow{f} X' \xleftarrow{g} Y \xrightarrow{h} Y' \) and \( X, X', Y \in \mathcal{U} \) and \( f \) is a monomorphism, then \( Y' \in \mathcal{U} \),
- suppose we are given a sequence of monomorphisms between objects in \( \mathcal{U} \) indexed over \( \mathbb{N} \), then the colimit belongs to \( \mathcal{U} \).

Proof: Use induction on the dimension of \( S \), and notice \( S \) is glued together using their simplexes. □

Fibrations and Anodynes

Def. (3.12.3.16) [Fibrations]. A morphism of simplicial sets is called a
- Kan fibration iff it has right lifting property w.r.t all \( \Lambda^i_k \to \Delta^n \).
- left fibration iff it has right lifting property w.r.t. all inclusions \( \Lambda^i_k \subset \Delta^n, 0 \leq i < n \).
- right fibration iff it has right lifting property w.r.t all inclusions \( \Lambda^i_k \subset \Delta^n, 0 < i \leq n \).
- inner fibration iff it has right lifting property w.r.t all inclusions \( \Lambda^i_k \subset \Delta^n, 0 < i < n \).

A morphism of simplicial set is called a
- anodyne iff it has left lifting property w.r.t. all Kan fibrations.
- left anodyne iff it has left lifting property w.r.t. all left fibrations.
- right anodyne iff it has left lifting property w.r.t. all right fibrations.
- inner anodyne iff it has left lifting property w.r.t all inner fibrations.

So a morphism between topological spaces \( X \to Y \) is a Serre fibration iff \( S(X) \to S(Y) \) is a Kan fibration (3.12.3.7).

Def. (3.12.3.17) [Trivial Fibration]. A morphism \( X \to S \) of simplicial sets that has right lifting property w.r.t. all inclusions \( \partial \Delta^n \to \Delta^n \) is called a trivial fibration.

A cofibration is a morphism that has left lifting property w.r.t all trivial fibrations. By (3.1.6.10) a cofibration of simplicial sets is just an inclusion.
Lemma (3.12.3.18) [Join and Anodynes]. If $f : A_0 \subset A$ and $g : B_0 \subset B$ are inclusions of simplicial sets, then
\[ h : (A_0 \ast B) \coprod_{A_0 \ast B_0} (A \ast B_0) \subset A \ast B \]
is an \( \ast \)-inner anodyne if either $f$ is right anodyne or $g$ is left anodyne, then
• inner anodyne if either $f$ is right anodyne or $g$ is left anodyne.

Proof: 1: By symmetry we assume $f$ is right anodyne. Notice the class of all morphisms $f$ that the conclusion holds is weakly saturated because $\ast$ commutes with colimits, so it suffice to check for $f : \Lambda^n_k \subset \Delta^n$. Then similarly it suffices to check for $g : \partial \Delta^m \subset \Delta^m$, but then the inclusion is just $\Lambda^{m+n+1}_j \subset \Delta^{m+n+1}$, which is left anodyne.

Prop. (3.12.3.19) [Anodynes].
• The saturated class generated by either of the following three classes of monomorphisms are both left anodynes:
  1. $\Lambda^n_k \subset \Delta^n$, $0 \leq k < n$.
  2. $(\Delta^m \times \{0\}) \coprod (\partial \Delta^m \times \Delta^1) \subset \Delta^m \times \Delta^1$.
  3. $(S' \times \{0\}) \coprod (S \times \Delta^1) \subset S' \times \Delta^1$, where $S \subset S'$.

Similar conclusion holds for right anodynes and together implies the similar conclusion for anodynes.

Proof: 2 and 3 are equivalence because any inclusion comes from attaching cells (3.12.3.3).
Now inclusions in 2 are compositions of pushouts of inclusions $\Lambda^{n+1}_k \subset \Delta^{n+1}$, where $0 \leq k \leq n$, thus it is generated by 1. Conversely, $\Lambda^n_k \subset \Delta^n$ is a retract of $(\Delta^n \times \{0\}) \coprod (\Lambda^n_k \times \Delta^1) \subset \Delta^n \times \Delta^1$:
Cf. [HTT, P64].

Cor. (3.12.3.20) [Products and Anodynes]. Let $A \subset A'$ be an inner anodyne and $B \subset B'$, then so does the induced map
\[ (A \times B') \coprod_{A \times B} (A' \times B) \to A' \times B'. \]

Proof: For left anodyne, the proof is similar to that of (3.12.3.18), just check for classes 3 of (3.12.3.19), and use the fact
\[ (S' \times \Delta^1) \times B \coprod (S' \times \{0\}) \coprod (S \times \Delta^1) \times B' \to (S' \times \Delta^1) \times B' \]
is just
\[ (S' \times B \coprod S \times B') \times \Delta^1 \coprod (S' \times B') \times \{0\} \to (S' \times B') \times \Delta^1. \]
which is left(inner) anodyne. And similarly for inner anodynes.
3.12. SIMPLICIAL HOMOTOPY THEORY

**Left Fibration**

**Remark (3.12.3.21)**[Left and Right Fibrations Dual]. The theory of left fibrations is dual to the theory of right fibrations, thus we don’t study right fibrations.

**Prop. (3.12.3.22)**[Left Fibration and CoFibered in Groupoids]. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor, then $\mathcal{C}$ is a category cofibered in groupoids over $\mathcal{D}$, iff the induced functor $N(F) : N(\mathcal{C}) \to N(\mathcal{D})$ is a left fibration of simplicial sets.

**Proof:** By (3.12.3.6), $N(F)$ is an inner fibration, thus it suffices to check for $\Lambda^n_0 \to \Delta^n$. For $n = 1$, this is the definition of cofibered category (3.1.7.10), and $n = 2$ is just the surjectivity of the map defining CoCartesian arrows (3.1.7.7), and $n = 3$ is equivalent to the injectivity of the map defining Cocartesian arrows. And for $n > 3$, then extension is automatic for nerves. □

**Remark (3.12.3.23)**[Right Fibrations and Fibered Categories]. The (left)right fibration is the $\infty$-categorial analogue of (co)fibered categories in usual category theory.

**Remark (3.12.3.24).** Given a left fibration $X \to S$ is more or less similar to given a functor from the homotopy category $hS$ to the $\infty$-category $\mathcal{H}$ of spaces.

**Proof:** Cf.[HTT, P58]. □

**Prop. (3.12.3.25)**[Over(Under)categories and Fibrations]. Given a digram of simplicial sets:

$$A \subset B \xrightarrow{q} X \xrightarrow{p} S.$$  

Let $r = q \circ p$, $p_0 = p|_A$, $r_0 = r|_A$, and $q$ is an inner fibration, then

- the induced map $X_{p/} \to X_{p_0/} \times_{S_{r_0/}} S_{r/}$ is a left fibration. And dual argument holds for overcategories.
- If $q$ is a left fibration or $A \subset B$ is right anodyne, then $X_{p/} \to X_{p_0/} \times_{S_{r_0/}} S_{r/}$ is a trivial fibration.
- If $q$ is moreover a left fibration, then the induced map $X_{r/} \to X_{p_0} \times_{S_{r_0}} S/r$ is a left fibration.

**Proof:** These just follow from (3.12.3.18). □

**Prop. (3.12.3.26)**[Homotopy Extension Lifting Property]. Let $p : X \to S$ be a map of simplicial sets and $i : A \subset B$, consider the map

$$q : X^B \to X^A \times_{S^A} S^B.$$  

- If $p$ is a left fibration, then $q$ is a left fibration.
- If $p$ is a left fibration and $i$ is a left anodyne, then $q$ is a trivial fibration.
- If $i : \{0\} \subset \Delta^1$, then $p$ is a left fibration iff $q$ is a trivial fibration.
- If $p$ is an inner fibration, then $q$ is an inner fibration.
- If $p$ is an inner fibration and $i$ is an inner anodyne, then $q$ is a trivial fibration.

**Proof:** First notice that a right lifting of $q$ w.r.t a map $Z \to Z'$ is equivalent to a right lifting of $p$ w.r.t the map $Z \times B \coprod Z' \times A \to Z' \times B$. Then the conclusions follow from (3.12.3.20) and (3.12.3.19). □
Prop. (3.12.3.27) [Homotopy Section and Left Fibration]. Let $X \to S$ be a map of simplicial sets and $s : S \to X$ be section of $p$, and let $h \in \text{Hom}_S(X \times \Delta^1, X)$ that $h|_{X \times \{0\}} = s \circ p$ and $h|_{X \times \{1\}} = \text{id}$, then $s$ is a left anodyne.

Proof: Cf.[HTT, P65]. □

Prop. (3.12.3.28) [Left Fibration and Functor to Spaces]. Let $X \to S$ be a left fibration, then the fibers are all Kan complexes by (3.13.2.5), and for any edge $f : s \to s' \in S$, we can solve the lifting diagram

\[
\begin{array}{ccc}
\{0\} \times X_s & \to & X \\
\downarrow & & \downarrow \\
\Delta^1 \times X_s & \to & \Delta^1 \xrightarrow{f} S
\end{array}
\]

because the left hand side is left anodyne by (3.12.3.20), thus getting a morphism $f_! : X_s \to X_{s'}$.

Then this determines a functor from $hS$ to $\mathcal{H}$ the homotopy category of spaces.

Proof: First notice $f_!$ is uniquely defined up to homotopy: given to dotted arrow solving the diagram, we can use the lifting property w.r.t. the map

\[
\Delta^1 \times \partial \Delta^1 \times X_s \coprod_{\{0\} \times \partial \Delta^1 \times X_s} \{0\} \times \Delta^1 \times X_s \to \Delta^1 \times \Delta^1 \times X_s
\]

which is a left anodyne by (3.12.3.20), to get a homotopy between them.

Next if $\eta \in \text{Hom}_H(K, X_s), \eta' \in \text{Hom}_H(K, X_{s'})$, then $\eta' = f_! \circ \eta$ iff there is a map $q : K \times \Delta^1 \to X$ that $q \circ p$ is given by the mapping $X_s \times \Delta^1 \to \Delta^1 \xrightarrow{f_!} S$, and $p|_{K \times \{0\}}, p|_{K \times \{1\}}$ have homotopy types $\eta, \eta'$ resp..

Then for any $g \circ f \cong h \in S$, which is depicted by a 2-complex, we can use the left anodyne $X_u \times \{0\} \subset X_u \times \Delta^2$ to get a morphism $p : X_u \times \Delta^2 \to X$, then $p|_{X_u \times \{1\}} \cong f_!, p|_{X_u \times \{2\}} \cong h_!$, and the map $p|_{X_u \times \Delta(1,2)}$ witnesses the fact $g_! \circ f_! \cong h_!$. □

Kan Fibrations

Remark (3.12.3.29) [Kan Complexes and Groupoids]. Kan complexes are $\infty$-categorical analogy of groupoids, by (3.13.2.5).

Lemma (3.12.3.30). If a left fibration $p : S \to T$ is a weak homotopy equivalence of Kan complexes, then it is a surjection on vertices.

Proof: Because it is homotopy equivalence, for any $t \in T$, there is a morphism $p(s) \to t$ for some $s \in S$(Kan complex used), thus it lifts to a morphism in $S$, so surjective on vertices. □

Lemma (3.12.3.31) [Fibrations of Kan Complexes]. If $S \to T$ is a left fibration and $T$ is a Kan complex, then $p$ is a Kan fibration.

Proof: Firstly $S$ is a Kan complex. Let $A \subset B$ be anodyne morphisms, we need to show $p : S^B \to S^A \times_{T^A} T^B$ is surjective on vertices. Since $S, T$ are complexes, $S^B \to S^A$ and $T^B \to T^A$ are trivial fibrations by (3.12.3.26). Cf.[HTT, P66].

Notice this is an immediate consequence of (3.12.3.36), because the homotopy category of a Kan complex is a groupoid, by (3.13.2.5), so $f_!$ must be isomorphisms. □
Prop. (3.12.3.32) [Examples of Kan Complexes].
- The singular complex of topological space is a Kan complex.
- The nerve of a topological space is a Kan complex.
- The nerve of a category is a Kan complex iff the category is a groupoid, by (3.12.3.22).
- Simplicial $R$-module are Kan complexes, by (8.1.1.1).

Prop. (3.12.3.33). The bar resolution $BG$ is a Kan fibration for every group $G$.

Proof: □

Prop. (3.12.3.34). A principal $G$ fibration, i.e. $X \to X/G$ where $X$ is a simplicial object of $G$-sets that $G$ acts freely on $X_n$, is a Kan fibration.

Lemma (3.12.3.35). Let $p : S \to T$ be a left fibration that all the fibers are contractible, then $p$ is a trivial Kan fibration.

Proof: By duality, it suffices to prove for right fibrations. Because fiber is nonempty, it has right lifting property w.r.t $\emptyset \subset \Delta^0$, and for $n > 0$, let $\partial \Delta^n \to S$ be any map, then to show the lifting property, we may take fiber product and assume $T = \Delta^n$, thus $S$ is an $\infty$-category. Cf. [HTT, P66]. □

Prop. (3.12.3.36) [Characterization of Kan Fibrations]. Let $p : S \to T$ be a left fibration of simplicial sets, then $p$ is a Kan extension iff the morphism $f!$ defined in (3.12.3.28) is an isomorphism in $\mathcal{H}$ for any morphism $f \in T$.

Proof: Cf. [HTT, P66]. □

4 Simplicial Categories & Model Categories

Def. (3.12.4.1) [Simplicial Category]. The category $\mathcal{Cat}_\Delta$ of simplicial categories consists of categories enriched over the Cartesian monoidal category $\mathbf{Set}_\Delta$ of simplicial sets.

Def. (3.12.4.2) [Homotopy Category]. There are singular complex functor and geometrization functor that induce isomorphism of $h(\mathbf{Set}_\Delta) \cong h(\mathcal{G})$ by (3.12.3.10), thus the theory of simplicial categories and topological categories are the same.

Simplicial Nerves

Def. (3.12.4.3) [Thickened Finite Ordered Sets]. Let $J$ be a finite ordered set, define a simplicial category $\mathcal{C}[\Delta^J]$ as follows:
- The objects are elements of $J$.
- For $i, j \in J$, $\text{Mor}(i, j) = N(P_{i,j})$, where $P_{i,j}$ is the partially ordered set of subsets $I \subset J$ that $i, j \in I$.
- The morphism is induced by the inclusion of partially ordered sets $P_{i,j} \times P_{j,k} \subset P_{i,k}$.

Prop. (3.12.4.4) [$\mathcal{C}$].
- There is a unique functor $\mathcal{C}[\Delta^n] \to \Delta^n$, and it is an equivalence of simplicial categories, because each morphism space in $\mathcal{C}[\Delta^n]$ is a cube.
• The mapping $J \mapsto \mathcal{C}[\Delta^J]$ is a functor from $\Delta$ to $\mathcal{C}at_\Delta$. In other words, $\mathcal{C}$ defines a cosimplicial object in $\mathcal{C}at_\Delta$.

• $\mathcal{C}$ extends naturally to a colimit-preserving morphism $\mathcal{S}et_\Delta \to \mathcal{C}at_\Delta$, by (3.12.3.1).

**Def. (3.12.4.5) [Simplicial Nerve].** For a simplicial category $\mathcal{C}$, we define the simplicial nerve to be the simplicial set that

$$(N(\mathcal{C}))_n = \text{Hom}_{\mathcal{C}at_\Delta}(\mathcal{C}[\Delta^n], \mathcal{C}).$$

If $\mathcal{C}$ is a topological category, then define the topological nerve to be the simplicial nerve of $\text{Sing}(\mathcal{C})$.

By the definition and the adjointness of (3.12.3.7), the nerve functor $N$ is right adjoint to the functor $[\mathcal{C}[-]]$ or $\mathcal{C}[-].$

**Remark (3.12.4.6).** It should be checked that to give a 2-complex in $N(\mathcal{C})$ is equivalent to giving morphisms $f, g, h \in \mathcal{C}$ and a path from $g \circ f$ to $h$.

**Prop. (3.12.4.7) [Nerve and Simplicial Nerve].** If we forget the enriched structure on $hS$, then the usual nerve $N$ and $h$ determines a adjoint between $\mathcal{S}et_\Delta$ and $\mathcal{C}at_\Delta$.

*Proof:* Notice that the usual nerve is a special case of simplicial nerve by the inclusion $\mathcal{C}at \subset \mathcal{C}at_\Delta$. And also the inclusion $\mathcal{S}et \subset \mathcal{S}et_\Delta$ is left adjoint to the functor $\pi_0$. □

**Prop. (3.12.4.8) [Kan Fibrations Nerve Inner Fibrations].** Let $F : \mathcal{C} \to \mathcal{D}$ be a a map of simplicial categories that for any $C, C' \in \mathcal{C}$, $\text{Map}(C, C') \to \text{Map}(F(C), F(C'))$ is a Kan fibration, then the induced map of simplicial sets $N(\mathcal{C}) \to N(\mathcal{D})$ is an inner fibration.

*Proof:* This is because a lifting of $N(\mathcal{C}) \to N(\mathcal{D})$ w.r.t. $\lambda^p_j \subset \Delta^n$ is equivalent to a lifting of $\mathcal{C} \to \mathcal{D}$ w.r.t. $\mathcal{C}[\Delta^p_j] \subset \mathcal{C}[\Delta^n]$. But this lifting is equivalent to a lifting of $\text{Map}(F(0), F(n)) \to \text{Map}(F'(0), F'(n))$ w.r.t. the anodyne map $\text{Map}_{\mathcal{C}[\Delta^p_j]} \subset \text{Map}_{\mathcal{C}[\Delta^n]}$, which is a cube removing the interior and a face. □

**Cor. (3.12.4.9).** The topological nerve of a topological category $\mathcal{C}$ is an $\infty$-category, as the singular complex of a topological space is always a Kan complex, by (3.12.3.32).

**Def. (3.12.4.10) [Homotopy Category].** For a simplicial set $S$, the homotopy category $hS$ is defined to be the homotopy category (3.12.4.2) of the simplicial category $\mathcal{C}[S]$. A map of simplicial sets is called a categorical equivalence if their homotopy categories are equivalent as $\mathcal{S}$-enriched categories.

**Remark (3.12.4.11).** It is immediate that $S \cong T$ categorically iff $\mathcal{C}[S] \cong \mathcal{C}[T]$ iff $|\mathcal{C}[-]| \cong |\mathcal{T}|$.

**Lemma (3.12.4.12).** Let $\mathcal{C}$ be a topological category, then the counit map $|\mathcal{C}(N(\mathcal{C}))| \cong \mathcal{C}(3.12.4.5)$ is an equivalence of topological categories.

*Proof:* By the Quillen equivalence between $\mathcal{S}et_\Delta$ and $\mathcal{C}at_\Delta(3.12.3.9)$, as by (3.7.7.11) and (3.12.3.32), $\text{Sing}(\mathcal{C})$ is a fibrant simplicial category. □

**Lemma (3.12.4.13).** Let $\mathcal{C}$ be fibrant simplicial category, then the counit map $u : \text{Map}_{\mathcal{C}[N(\mathcal{C})]}(x, y) \to \text{Map}_{\mathcal{C}}(x, y)$ is a weak homotopy equivalence of simplicial sets.

*Proof:* Cf. [HTT, P72]. □
Prop. (3.12.4.14) [Topological Category and \(\infty\)-Category Equivalent]. The adjoints functors \(N\) and \(|\cdot|\) define an equivalence of the category of topological categories and \(\infty\)-categories modulo equivalence.

**Proof:** It suffices to show the units and counits are equivalences:

\[
|\mathcal{C}[N(\mathcal{E})]| \cong \mathcal{E}, \quad S \mapsto N(|\mathcal{C}[S]|).
\]

The first is (3.12.4.12), and the second follows from the first by remark (3.12.4.11). \(\Box\)

Prop. (3.12.4.15). For simplicial sets \(S, S'\), the natural map \(\mathcal{C}[S \times S'] \to \mathcal{C}[S] \times \mathcal{C}[S']\) is an equivalence of simplicial categories.

**Proof:** If \(S, S'\) are nerves of fibrant simplicial categories \(\mathcal{C}, \mathcal{C}'\), then we have a diagram \(\mathcal{C}[S \times S'] \to \mathcal{C}[S] \times \mathcal{C}[S'] \to \mathcal{C} \times \mathcal{C}'\). Then by the two out of three axiom, the assertion follows from the fact that for any fibrant simplicial category \(\mathcal{D}\), \(\mathcal{C}[N(\mathcal{D})] \to \mathcal{D}\) is an equivalence (3.12.4.12).

Now for general \(S, S'\), we can find a categorical equivalences \(\mathcal{C} \to \mathcal{C}[N(\mathcal{C}[S])] = T\), and then \(S \times S' \to T \times T'\) is also categorical equivalence by (3.12.4.15), and we are done, by (3.12.5.16). \(\Box\)

### Simplicial Model Categories

Def. (3.12.4.16) [Simplicial Model Category]. A simplicial model category is a \(\text{Set}_{\Delta}\)-enriched model category (3.7.6.3).

Prop. (3.12.4.17) [Simplicial Model Category Criterion]. Let \(\mathcal{C}\) be a simplicial category that is equipped with a model structure that every object of \(\mathcal{C}\) is cofibrant and the collection of weak equivalences in stable under filtered colimits, then \(\mathcal{C}\) is a simplicial model category iff the following conditions holds:

- \(\mathcal{C}\) is both tensored and cotensored over \(\text{Set}_{\Delta}\).
- Given a cofibration of simplicial sets \(i : K \to L\) and a cofibration \(C \to D \in \mathcal{C}\), the induced map \((C \otimes L) \coprod_{C \otimes K} D \otimes K \to D \otimes L\) is a cofibration in \(\mathcal{C}\).
- The natural map \(C \otimes \Delta^n \to C \otimes \Delta^0 \cong C\) is a weak equivalence in \(\mathcal{C}\).

**Proof:** Cf. [HTT, P850]. \(\Box\)

Prop. (3.12.4.18). Let \(\mathcal{C}\) be a simplicial model category and \(X\) cofibrant and \(Y\) fibrant, then \(K = \text{Map}(X, Y)\) is a Kan complex, and there is a canonical bijection \(\pi_0 K \cong \text{Hom}_{\text{Ho}(\mathcal{C})}(X, Y)\).

**Proof:** Use (3.7.6.4). \(\Box\)

Prop. (3.12.4.19).

5 Covariant Model Structure

Prop. (3.12.5.1) [Covariant Model Structure]. Let \(S\) be a simplicial set, then we call a map \(X \to Y \in (\text{Set}_{\Delta})_S\)

- **covariant cofibration** if it is a monomorphism.
- **covariant equivalence** if the induced map \(X^\circ \coprod_X S \to Y^\circ \coprod_Y S\) is a categorical equivalence (3.12.4.10).
Then these define a left proper combinatorial model structure on \((\mathbf{Set}_\Delta)/S\).

**Proof:** Cf.[HTT, P69]. □

**Lemma (3.12.5.2).** Every left anodyne map in \((\mathbf{Set}_\Delta)/S\) is a covariant equivalence.

**Proof:** Cf.[HTT, P69]. □

**Prop. (3.12.5.3)[Covariant Model Structure].** \((\mathbf{Set}_\Delta)/S\) is a simplicial model category with the contravariant model structure and the simplicial structure where

\[
\text{Map}(X,Y) = Y^X \times_{S^X} \{\varphi\} \in \mathbf{Set}_\Delta
\]

where \(\varphi : X \to S\) is the structure map.

**Proof:** We use (3.12.4.17), it suffices to check that \(X \times \Delta^n \to X \times \Delta^0\) is a covariant equivalence. But it has a section, which is a left anodyne by (3.12.3.20), thus it is a covariant equivalence by (3.12.5.2). □

**Cor. (3.12.5.4)[Contravariant Model Structure].** Let \(S\) be a simplicial set, then the covariant model is usually not self-dual, and we can define a **contravariant model structure** as follows:

- A **contravariant cofibration** is a monomorphism of simplicial sets.
- \(f\) is a **contravariant equivalence** in \((\mathbf{Set})/S\) iff \(f^{op}\) is a covariant equivalence in \((\mathbf{Set})/S^{op}\).
- \(f\) is a **contravariant fibration** in \((\mathbf{Set})/S\) iff \(f^{op}\) is a covariant fibration in \((\mathbf{Set})/S^{op}\).

**Prop. (3.12.5.5)[Base Change].** Let \(S \to S'\) be a map of simplicial sets, then the forgetful functor and base change functor \(j_!, j^*\) defines a Quillen adjunction of covariant models:

\[
j_! : (\mathbf{Set}_\Delta)/S \rightleftarrows (\mathbf{Set}_\Delta)/S' : j^*
\]

**Proof:** it is clearly a pair of adjoints, and \(j_!\) preserves cofibrations. \(j_!\) also preserves covariant equivalences: Cf.[HTT, P71]? Thus it is a Quillen adjunction. □

**Lemma (3.12.5.6).** Let \(S' \subset S\) be simplicial sets, let \(p : X \to S\) be a map and \(q : Y \to S\) be a right fibration. Let \(X' = X \times_S S', Y' = Y \times_S S'\), then the restriction map

\[
\varphi : \text{Map}(\mathbf{Set}_\Delta)/S(X,Y) \to \text{Map}(\mathbf{Set}_\Delta)/S'(X',Y')
\]

is a Kan fibration.

**Proof:** Firstly it is a right fibration because it has right lifting property w.r.t. right anodyne inclusion \(A \to B\): this is because \((A \times X') \sqcup (A \times X) \subset B \times X\) is also a right anodyne (3.12.3.20). Next we apply this to the inclusion \(\emptyset \subset S'\) to see that \(\text{Map}(\mathbf{Set}_\Delta)/S'(X',Y')\) is a Kan complex (3.13.2.5), and then \(\varphi\) is a Kan fibration by (3.12.3.31). □

**Lemma (3.12.5.7).** Let \(p : X \to S\) be an object of \((\mathbf{Set}_\Delta)/S\), then \(p\) is a right fibration iff it is a covariant fibrant object in \((\mathbf{Set}_\Delta)/S\).

**Proof:** Cf.[HTT, P85]. □
Def. (3.12.5.8) [Pointwise Equivalence]. Let \( X \to Y \) be a map in \( RFib(S) \), then \( f \) is called a \textbf{pointwise equivalence} iff the induced map \( X_s \to Y_s \) is a homotopy equivalence of Kan complexes (3.13.2.5) for any \( s \in S \).

Lemma (3.12.5.9). Let \( f : X \to Y \) be a morphism in \( RFib(S) \), then the following are equivalent:

- \( f \) is a pointwise equivalence.
- \( f \) is an equivalence in the simplicial category \((\text{Set})/S\).
- For any \( A \in (\text{Set})/S \), \( f \) induces a homotopy equivalence of Kan complexes:
  \[
  \text{Map}_{(\text{Set}_\Delta)/S}(A,X) \to \text{Map}_{(\text{Set}_\Delta)/S}(A,Y).
  \]

Proof: Cf. [HTT, P82]. \( \square \)

Prop. (3.12.5.10) [Equivalences]. In the situation of (3.12.5.8), \( f \) is a pointwise equivalence iff it is a contravariant equivalence iff it is a categorical equivalence.

Proof: Cf. [HTT, 2.2.3.13, 3.3.1.5]? \( \square \)

Prop. (3.12.5.11) [Cotravariant Fibration as Right Fibration]. Let \( f : X \to Y \) be a map in \( RFib(S) \), then \( f \) is a contravariant fibration in \((\text{Set}_\Delta)/S\) iff it is a right fibration.

Proof: Cf. [HTT, P86]. \( \square \)

### Straightening and Unstraightening

Def. (3.12.5.12) [Straightening and Unstraightening]. Fix a simplicial set \( S \), a simplicial category \( \mathcal{C} \) and a functor \( \mathcal{C}[S] \to \mathcal{C}^{op} \). Given an object \( X \in (\text{Set}_\Delta)/S \), let \( v \) be the cone point of \( X^\circ \). Then the simplicial category \( \mathcal{M} = \mathcal{C}[X^\circ] \coprod \mathcal{C}[X] \mathcal{C}^{op} \) can be viewed as a correspondence between \( \mathcal{C}^{op} \) and \( \Delta^0 \), thus giving a simplicial functor

\[
\text{St}_\varphi : \mathcal{C} \to \text{Set}_\Delta : C \mapsto \text{Map}_\mathcal{M}(C,v).
\]

Then \( \text{St}_\varphi \) is called the \textbf{straightening functor} associated to \( \varphi \). And we denote by \( \text{St}_S \) the functor \( \text{St}_\varphi \) where \( \varphi : \text{id}_{\mathcal{C}[S]} \).

By the adjoint functor theorem (3.1.1.35), \( \text{St}_\varphi \) has a left adjoint called \textbf{unstraightening functor} \( \text{Un}_\varphi \)?.

Prop. (3.12.5.13). Let \( S \) be a simplicial set, \( \mathcal{C} \) a simplicial category and \( \varphi : \mathcal{C}[S] \to \mathcal{C}^{op} \) a simplicial functor, then the straightening and unstraightening functor determines a Quillen adjunction

\[
\text{St}_\varphi : (\text{Set}_\Delta)/S \rightleftarrows \text{Set}_\Delta^{\mathcal{C}} : \text{Un}_\varphi
\]

determines a Quillen adjunction, where the LHS has the contravariant model structure and the RHS has the projective model structure. And if \( \varphi \) is an equivalence of simplicial categories, then \((\text{St}_\varphi, \text{Un}_\varphi)\) is a Quillen equivalence.

Proof: \( \square \)
Unstraightening of Right Fibrations

Prop. (3.12.5.14). For every simplicial set $S$, the unstraightening $Un_S$ induces an equivalence of simplicial categories

$$(\text{Set}^{\mathcal{C}[S]}_{\Delta})^{\circ} \rightarrow \text{RFib}(S).$$

(3.7.6.5), where the RHS is the category of fibrations $X \rightarrow S$.

Proof: Cf.[HTT, P83].

Joyal Model Structure

Lemma (3.12.5.15) [Inner Anodyne is Categorical Equivalence]. Every inner anodyne map $A \rightarrow B$ of simplicial sets is a categorical equivalence.

Proof: The class of morphisms $f$ that $\mathbb{C}(f)$ is a trivial cofibration is weakly saturated (because $\mathbb{C}$ is a left adjoint of $\mathbb{C}(S)$), then it suffices to check for $\Lambda^n_j \subset \Delta^n$. Then $\mathbb{C}[\Lambda^n_j] \subset \mathbb{C}[\Delta^n]$ is a pushout of $[i]_K \subset [1]_{(\Delta^1)^{n-1}}$, where $K$ is obtained form $(\Delta^1)^{n-1}$ by moving a face and the interior. Thus it is a trivial cofibration (3.7.7.4). □

Prop. (3.12.5.16) [Joyal Model Structure]. There is a left proper combinatorial model structure called Joyal model structure on $\text{Set}_{\Delta}$, with:

- Cofibrations: monomorphisms.
- Weak equivalences: categorical equivalences defined in (3.12.4.10).
- Fibrations: categorical fibrations which has the right lifting property w.r.t. trivial cofibrations.

And the adjoint functors $(\mathbb{C}, N)$ determines a Quillen equivalence between $\text{Set}_{\Delta}$ and $\mathbb{C}at_{\Delta}$.

Proof: Cf.[HTT, P89],?

Firstly we show $\mathbb{C}$ preserves cofibrations. It suffices to show that $\mathbb{C}[\partial \Delta^n] \subset \mathbb{C}[\Delta^n]$ is a cofibration (3.7.7.4). But notice this two simplicial category only differ at $\text{Hom}_{\mathbb{C}[\partial \Delta^n]}(0, n)$ is the boundary of the simplicial cube $(\Delta^1)^{n-1} \cong \text{Hom}_{\mathbb{C}[\Delta^n]}(0, n)$, thus the inclusion is a pushout of the inclusion $[1]_{(\Delta^1)^{n-1}} \subset [1]_{(\Delta^1)^{n-1}}$, which is a cofibration by (3.7.7.3).

Left properness is clear (3.7.0.9). $\mathbb{C}$ preserves weak equivalences by (3.12.4.10) and (3.7.7.4), so $(\mathbb{C}, N)$ is a Quillen adjunction. To show it is a Quillen equivalence: It suffices to check for each simplicial set $S$ and fibrant simplicial category $\mathbb{C}$, a map $u : S \rightarrow N(\mathbb{C})$ is a categorical equivalence iff the adjoint map $v : \mathbb{C}[S] \rightarrow \mathbb{C}$ is an equivalence of simplicial categories. But $v$ factors as

$$\mathbb{C}[S] \xrightarrow{[u]} \mathbb{C}[N(\mathbb{C})] \xrightarrow{w} \mathbb{C}$$

and the counit map $w$ is an equivalence by (3.12.4.13). □

Cor. (3.12.5.17). if $f : A \rightarrow B$ is a categorical equivalence of simplicial sets and $K$ is a simplicial set, then $A \times K \rightarrow B \times K$ is also a categorical equivalence.

Proof: Choose a factorization $B \rightarrow Q$, which is an inner anodyne and $Q$ is an $\infty$-category, by small object argument (3.1.6.8), then $B \times K \rightarrow Q \times K$ is also an inner anodyne map (3.12.3.20), hence a categorical equivalence (3.12.5.15), so we can assume $B$ is an $\infty$-category. Similarly we can reduce to the case $A, K$ are also $\infty$-categories.

For the rest, Cf.[HTT, P92]. □
Prop. (3.12.5.18) [∞-Category Fibrant in Joyal Model]. A simplicial set $C$ is fibrant in the Joyal model structure iff it is an $\infty$-category.

Proof: Fibrant objects are $\infty$-categories, by (3.12.5.15). For the converse, fix an $\infty$-category and an inclusion $A \subset B$, given a map $A \to \mathcal{C}$, the inclusion $\mathcal{C} \subset C \coprod_A B$ is also a categorical equivalence because Joyal model structure is left proper (3.12.5.16), thus $\mathcal{C}$ is a retract of $C \coprod_A B$ by (3.12.5.19), which gives an extension $B \to \mathcal{C}$.

Lemma (3.12.5.19). Let $\mathcal{C} \subset \mathcal{D}$ be an inclusion of simplicial sets that is also a categorical equivalence, and $\mathcal{C}$ is also an $\infty$-category, then $\mathcal{C}$ is a retract of $\mathcal{D}$.

Proof: Include $\mathcal{D}$ into an $\infty$-category by small object argument and (3.12.5.15), we may assume $\mathcal{D}$ is also an $\infty$-category, then we finish by applying (3.12.5.20) for $A = \mathcal{C}$ and $B = \mathcal{D}$.

6 Cartesian Fibrations

Remark (3.12.6.1). The theory of Cartesian fibrations is an analogue of the theory of fibered categories.

Def. (3.12.6.2) [p-Cartesian]. Let $p : X \to S$ be an inner fibration and $f$ is an edge of $X$, then $f$ is called a $p$-Cartesian if the induced map

$$X/f \to X/y \times_{s(y)} S_{p(f)}$$

is a trivial Kan fibration.

Remark (3.12.6.3). For an ordinary category $\mathcal{C}$ and a map $p : N(\mathcal{C}) \to \Delta^1$, then a morphism $f \in \mathcal{C}$ is $p$-Cartesian iff it is Cartesian in the usual sense.

Prop. (3.12.6.4) [Characterization of Cartesian Fibrations]. Let $p : \mathcal{C} \to \mathcal{D}$ be an inner fibration of $\infty$-categories, then an edge $f : Y \to Z \in \mathcal{C}$ is $p$-Cartesian iff for every object $X \in \mathcal{C}$, there is a Cartesian diagram

$$\begin{array}{ccc}
\text{Map}(X,Y) & \longrightarrow & \text{Map}(X,Z) \\
\downarrow & & \downarrow \\
\text{Map}(p(X),p(Y)) & \longrightarrow & \text{Map}(p(X),p(Z))
\end{array}$$

Proof: Cf. [HTT, P131].

Cartesian Fibrations

Def. (3.12.6.5) [Cartesian Fibration]. A Cartesian fibration is an inner anodyne map $p : X \to S$ that for any edge $f : x \to y \in S$ and a vertex $\tilde{y}$ mapping to $y$, there is a $p$-Cartesian edge $\tilde{f}$ with $p(\tilde{f}) = f$. The dual of a Cartesian fibration is called a coCartesian fibration.

Prop. (3.12.6.6). The class of Cartesian fibrations is stable under compositions and base change.

Prop. (3.12.6.7) [Cartesian Fibration and Right Fibration]. Let $p : X \to S$ be an inner fibration, then the following are equivalent:

- $p$ is a Cartesian fibration and the every edge of $X$ is $p$-Cartesian.
- $p$ is a right fibration.
- $p$ is a Cartesian fibration and every fiber $X_s$ is a Kan complex.

Proof: Cf.[HTT, P122].

**Def.(3.12.6.8)[Locally Cartesian Fibration].** A map $X \to S$ of simplicial sets is called a **locally Cartesian fibration** if it is an inner fibration and for every edge $\Delta^1 \to S$, the pullback $X \times_S \Delta^1 \to \Delta^1$ is a Cartesian fibration.

**Prop.(3.12.6.9)[Cartesian and Locally Cartesian].** Let $p : X \to S$ be a locally Cartesian fibration, then the following are equivalent:
- $p$ is a Cartesian fibration.
- Given a composition $fg \simeq h$ in the homotopy category, if $f, g$ are both locally $p$-Cartesian, then $h$ is also locally $p$-Cartesian.
- Every locally $p$-Cartesian edge in $X$ is $p$-Cartesian.

Proof: Cf.[HTT, P124].

**Prop.(3.12.6.10).** Given maps of $\infty$-categories: $C \xrightarrow{p} D \xrightarrow{q} E$, if $q, q \circ p$ are both locally Cartesian fibrations and $p$ maps locally $(q \circ p)$-Cartesian maps to locally $q$-Cartesian maps and for any $Z \in E$, $p$ induces a categorial equivalence $C_Z \to D_Z$, then $p$ is a categorical equivalence.

Proof: Cf.[HTT, P132].

**Prop.(3.12.6.11).** Categorical equivalences between $\infty$-categories are stable under base change of Cartesian fibrations of $\infty$-categories.

Proof: Cf.[HTT, P132].

# 7 Cyclic Homology Theory (欧阳恩林)

**Combinatorial Category**

**Def.(3.12.7.1).** The **Segal category** $\text{Fin}_*$ is the category of pointed finite sets. A morphism is called **inert** iff $|f^{-1}([i])| = 1$ for all $i \neq *$. It is called **active** iff $f^{-1}([*]) = \{*\}$.

A morphism can be uniquely factorized as a composition $gh$, where $h$ is inert and $g$ is active.

**Prop.(3.12.7.2).** There is a morphism $\text{Cut} : \Delta^{op} \to \text{Fin}_*$ where we interpret $[n] \in \text{Fin}_*$ as the set of cut in $[n]$, and

$$\text{Cut}(\alpha)(i) = \begin{cases} j & \text{if there are } j \text{ s.t. } \alpha(j - 1) < i \leq \alpha(j) \\ 0 & \text{otherwise} \end{cases}$$

**Prop.(3.12.7.3).** The category of functors from the $E_\infty = \text{Fin}_*$ to $\text{Cat}$ that

$$X([n]) \xrightarrow{\prod_{i=2}^n X(\rho)} \prod_{i=1}^n X([1]) \quad n \geq 0$$

and $X([0])$ is the final object, is equivalent to the category of symmetric unital monoidal categories with base category $(X([1]))$. (Because the commutativity of morphisms encodes the fact that the tensor action is symmetric).
Similarly, the category of functors from the $\Delta^{op}$ to $\text{Cat}$ that

$$X([n]) \xrightarrow{\prod_{i=2}^{n} X([\rho_i])} \prod_{i=1}^{n} X([1]) \quad n \geq 0$$

is equivalent to the category of symmetric unital monoidal categories ($X([1])$). And it is symmetric iff it factors through Cut:$\Delta^{op} \rightarrow \text{Fin}_*$.  

**Def. (3.12.7.4).** The *Connes cyclic category* $\Delta_C$ is a category containing $\Delta$ that $\text{Aut}_{\Delta_C}([n])$ is $C_{n+1}$. And every morphism $[n] \rightarrow [m]$ in $\Delta_C$ can be uniquely written as the form $\varphi g$, where $\varphi \in \text{Hom}_\Delta([n],[m])$ and $g \in \text{Aut}_{\Delta_C}([n])$.

$\Delta^{op}$ is isomorphic to $\Delta_C$ Cf.[杨樱循环同调 P31], thus $\Delta$ and $\Delta^{op}$ are all subcategories of $\Delta_C$.

**Def. (3.12.7.5).** The category $\Delta_S$ is the category that $\text{Aut}_{\Delta_S}([n]) \cong \mathbb{S}^n$ and every morphism $[n] \rightarrow [m]$ in $\Delta_S$ can be uniquely written as the form $\varphi g$, where $\varphi \in \text{Hom}_\Delta([n],[m])$ and $g \in \text{Aut}_{\Delta_S}([n])$.

**Def. (3.12.7.6).** For a category $C$, a *cyclic object* in $C$ is a functor $\Delta^{op}_C \rightarrow C$.

For example, the functor that maps $[n]$ to $C_{n+1}$ and the functor maps to the pull back of the order of the cyclic, is a cyclic object.

**Hochschild Homology (Jeremy Hahn)**

**Def. (3.12.7.7) [Hochschild Homology Group].** Let $R$ be a commutative ring and $A$ a flat $R$-algebra, $A^{\text{env}} = A \otimes_R A^{\text{op}}$. Then an $A^{\text{env}}$-module is equivalent to an $(A,A)$-bimodule.

If $M$ is an $(A,A)$-bimodule, then we define the *Hochschild homology group* $HH_n(A/R,M) = \text{Tor}^{A^{\text{env}}}_n(M,A)$. And also we denote $HH_n(A/R) = HH_n(A/R,M)$.

$H_n(A,M)$ is a $Z(A)$ module by the action of $Z(A)$ on $M$ and $HH_n$ defines a functor $\text{Alg}_R \rightarrow \text{Mod}_R$.

**Def. (3.12.7.8) [Hochschild Complex].** Let $R$ be a commutative ring and $A$ a flat $R$-algebra, we define $A^{\text{env}} == A \otimes^L_R A^{\text{op}}$, and $HH(A/R) = A \otimes^L_{A^{\text{env}}} A \in D(A)$.

**Def. (3.12.7.9) [Flat Case].** For a flat $R$-algebra $A$ and a $(A,A)$-bimodule $M$, there is a simplicial module $C(A,M)$ called the *Hochschild complex* of $A$ with coefficient in $M$, with $M_n = M \otimes A^n$ that

$$d_i(m,a_1,\ldots,a_n) = \begin{cases} (m_0a_1,a_2,\ldots,a_n) & i = 0 \\ (a_n m_0,a_1,\ldots,a_{n-1}) & i = n \\ (m_0,a_1,\ldots,a_ia_{i+1},\ldots,a_n) & \text{otherwise} \end{cases}$$

$$s_j(m,a_1,\ldots,a_n) = (m,a_1,\ldots,a_{j-1},1,a_{j+1},\ldots,a_n)$$

The homology group of the Moore complex associated to the Hochschild complex is just $HH_n(A,M)$. The Moore complex is of the form

$$\ldots \rightarrow M \otimes A \otimes A \otimes A \xrightarrow{\partial_3} M \otimes A \otimes A \xrightarrow{\partial_2} M \otimes A \xrightarrow{\partial_1} M \xrightarrow{\partial_0} 0 \rightarrow 0 \rightarrow \ldots$$

where

$$\partial_1(m \otimes a) = ma - am, \quad \partial_2(m \otimes a_1 \otimes a_2) = ma_1 \otimes a_2 - m \otimes a_1 a - 2 + a_2 m \otimes a_1$$

$$\partial_3(m \otimes a_1 \otimes a_2 \otimes a_3) = ma - 1 \otimes a_2 \otimes a_3 - m \otimes a_1 a_2 \otimes a_3 + m \otimes a_1 \otimes a_2 a_3 - a_3 m \otimes a_1 \otimes a_2.$$
Proof: □

Example (3.12.7.10).

- \( HH_n(R, R) = R \) if \( n = 0 \) and 0 otherwise.
- \( HH_0(A/R, A/R) = A^{ab} \).
- If \( A \) is commutative, \( HH_1(A, A) \cong \Omega^1_{A/R} \) giving by \( a \otimes x \mapsto adx \) by (4.4.3.4).
- For a symmetric \((A, A)\)-module \( M \), thus we have \( H_1(A, M) = M \otimes_A A^{ab} \) and \( H_1(A, M) = M \otimes_A \Omega^1_{A/R} \). And if \( M \) is flat, \( H_n(A, M) = M \otimes_A H_n(A, A) \).
- \( HH_n(R[X]/R) = \begin{cases} R[X] & n = 0 \\ \Omega^1_{R[X]/R} & n = 1 \\ 0 & \text{otherwise} \end{cases} \).

Example (3.12.7.11) \([HH(F_p/\mathbb{Z})]\). Because \( F_p \otimes_{\mathbb{Z}} F_p = (\mathbb{F}_p^0 \to \mathbb{F}_p) \).

\[
HH_*(\mathbb{F}_p, \mathbb{Z}) \cong \mathbb{F}_p[X_1, X_2, \ldots]/(X_iX_j = \binom{i+j}{i}X_{i+j})
\]

where \( \deg(X_i) = 2i, \partial X_i = 0 \).

Prop. (3.12.7.12). Suppose \( A, B \) are \( R \)-algebras, then

\[
HH(A \otimes^L_R B/R) = HH(A/R) \otimes^L_R HH(B/R).
\]

Cor. (3.12.7.13). \( HH(R[X_1, \ldots, X_n]/R) = \Omega^*_R[X_1, \ldots, X_n]/R \).

Prop. (3.12.7.14). If \( A \) is a commutative \( R \)-algebra, then \( HH(A/R) \) is naturally a commutative dga. In particular, \( HH_*(A/R) \) is a graded ring.

Prop. (3.12.7.15) [Spectral Sequence]. For a commutative ring \( A \) and a symmetric \( A \)-bimodule \( M \), there is a spectral sequence

\[
E^2_{pq} = \operatorname{Tor}_p^R(H_p(A, A), M) \Rightarrow H_{p+q}(A, M).
\]

Hochschild Homology

Prop. (3.12.7.16) [Hochschild-Kostant-Rosenberg]. The isomorphism \( \Omega^1_{A/R} \cong HH_1(A) \) extends to a graded ring map

\[
\Psi : \Omega^*_{A/k} \to H_*(A, A)
\]

. If \( A/R \) be smooth algebra and \( R \) Noetherian, then \( \Psi \) is an isomorphism of graded algebra. Cf.[Weibel P322], [阳恩林循环同调 P133].

Def. (3.12.7.17) [Tsigan’s Double Complex]. For a cyclic objec \( M \) in an Abelian category, let \( t^* \) be the cyclic morphism and \( \partial_n = \sum_{i=0}^{n}(-1)^i d_i \), \( \partial'_n = \sum_{i=0}^{n-1}(-1)^i d_i \), \( N_n = \sum_{k=0}^{n}((-1)^n t^n) \), then
there is a double complex $CC(M)$:

\[
\begin{array}{ccc}
\partial & \downarrow & \partial \\
M_1 & \leftarrow & M_1 \\
\downarrow & N \uparrow & \downarrow \\
M_0 & \leftarrow & M_0 \\
\end{array}
\]

That the column are 2-cyclic. Cf. [Weibel P337]. The first column is called the Hochschild complex of $M$: $C^h(M)$, the second column is called acyclic complex of $M (3.12.7.18) C^a(M)$. And we can even augment a cokernel column on the left, which is the complex of $M$ modulo the cyclic action, called the Conne complex $C^\lambda(M)$.

We define the Cyclic Homotopy Group $HC_n(M) = H_n(TotCC(M))$ and when $M$ is the cyclic module $C(A)(3.12.7.9)$, denote $CC(C(A)) = CC(A)$, $HC_n(A) = HC_n(C(A))$.

**Lemma (3.12.7.18).** The second column is exact and $h = t_{n+1}s_n$ is a null-homotopy. Cf. [Weibel P337].

**Lemma (3.12.7.19).** Notice the rows are in fact a group homology $\text{Hom}(\mathbb{Z}/(n + 1)\mathbb{Z}, M_n)$, thus when $Q \in R$, we have the rows are acyclic because the group homology is killed by $|G|??$, thus $HC_s(M) \cong H_s^\lambda(M)$ are isomorphisms by spectral sequence.

**Prop. (3.12.7.20)[Conne SBI Sequence].** For a cyclic module $M$, there is a long exact sequence

\[
\cdots \to HH_n(M) \overset{L}{\to} HC_n(M) \overset{S}{\to} HC_{n-2}(M) \overset{B}{\to} HH_{n-1}(M) \to \cdots
\]

**Proof:** shift the diagram 2 column right, then there is an exact sequence of double complexes and notice the second column is exact (3.12.7.18), thus we have the kernel is quasi-isomorphic to $C^b(M)$.

So the sequence follows. \( \Box \)

**Cor. (3.12.7.21).** $HC_0(A) = HH_0(A) = A^{ab}$.

When $A$ is commutative, $HC_1(A) = \text{Coker}(HC_0(A) \overset{B}{\to} HH_1(A)) = \Omega^1_{A/R}/dA$ as a $R$ module, because we can verify that $B(a) = a \otimes 1 - 1 \otimes A$.

**Cor. (3.12.7.22).** For a morphism of two cyclic objects, $HH_*(M) \cong HH_*(M')$ iff $HC_*(M) \cong HC_*(M')$. (Use five lemma).

**Def. (3.12.7.23).** A mixed complex $(M, b, B)$ is a complex with $b : M_n \to M_{n-1}$ and $B : M_n \to M_{n+1}$ that makes $M$ into a double chain complex. And there is a Conne double complex associated with this mixed complex. And similarly there is a same SBI sequence associated to the following diagram:

\[
\begin{array}{ccc}
\downarrow & \downarrow & \downarrow \\
M_2 & \leftrightarrow & M_1 \\
\downarrow & B \downarrow & \downarrow \\
M_0 & \leftrightarrow & M_0 \\
\downarrow & \downarrow & \downarrow \\
C_1 & \leftrightarrow & C_0 \\
\downarrow & B \downarrow & \downarrow \\
C_0
\end{array}
\]
From a cyclic object $M$, we notice that the $2k$-th column is acyclic (3.12.7.18), thus there is a snake-like connection homomorphism $B$ that makes $M$ into a mixed complex $BM$. Cf.[Weibel P344]. And the Conne double complex will compute the same cyclic homology with previous defined cyclic homology, Cf.[Weibel P345].

Notice for this $B$, $B_n$ on homology is exactly the composition $BI$.

**Prop.(3.12.7.24).** Let $R$ be a unital commutative ring and $A$ is a commutative $R$-algebra and $M$ is a $A$-module, then there is a natural morphism

$$ M \otimes_A \Omega^n_{A/R} \xrightarrow{\varepsilon_n} H_n(A, M) \xrightarrow{\pi_n} M \otimes_A \Omega^n_{A/R}, $$

such that $\pi_n \circ \varepsilon_n = n!$.

We first define a map $\varepsilon_n : M \otimes \wedge^n A \to H_n(A, M)$ that

$$ \varepsilon_n(m, a_1, \ldots, a_n) = \sum \sgn(\sigma)(m, a_{\sigma^{-1}(1)}, \ldots, a_{\sigma^{-1}(n)}) $$

then define $\varepsilon_n(m \otimes xd a_1 \wedge \cdots \wedge da_n) = \varepsilon_n(mx, a_1, \ldots, a_n)$. And we verify that this map is well-defined and maps into $Z_n(C(A, M), \text{Cf.[}}$[Weibel P344]). And the Conne double complex will compute the same cyclic homology with previous defined $A$-module, then there is a natural morphism

$$ (m, a_1, \ldots, a_n) \mapsto \sum_{i=0}^n (-1)^i \big(1, a_i, \ldots, a_n, m, a_1, \ldots, a_{i-1} \big) - \sum_{i=0}^n (-1)^i \big(a_i, 1, a_{i+1}, \ldots, a_n, m, a_1, \ldots, a_{i-1} \big). $$

Cf.[阳恩林循环同调 P128].

**Prop.(3.12.7.25).** When $A$ is a unital $R$-algebra, there is a commutative diagram

$$ \begin{array}{ccc}
\Omega^n_{A/R} & \xrightarrow{(n+1)d} & \Omega^{n+1}_{A/R} \\
\pi_n & \xrightarrow{d} & \pi_{n+1} \\
HH_n(A) & \xrightarrow{\varepsilon_n} & HH_{n+1}(A)
\end{array} $$

**Proof:** We notice $B = (1 - (-1)^n) sN :$

$$(m, a_1, \ldots, a_n) \mapsto \sum_{i=0}^n (-1)^i \big(1, a_i, \ldots, a_n, m, a_1, \ldots, a_{i-1} \big) - \sum_{i=0}^n (-1)^i \big(a_i, 1, a_{i+1}, \ldots, a_n, m, a_1, \ldots, a_{i-1} \big).$$

Cf.[阳恩林循环同调 P128].

**Cor.(3.12.7.26).** For a commutative unital $R$-algebra $A$, there is a functorial $\varepsilon_n : \Omega^n_{A/R}/d\Omega^{n-1}_{A/R} \rightarrow HC_n(A)$ making the following diagram commutative:

$$ \begin{array}{cccccc}
0 & \xrightarrow{\varepsilon_{n-1}} & \Omega^{n-1}_{A/R} & \xrightarrow{d} & \Omega^n_{A/R} & \xrightarrow{\varepsilon_n} & \Omega^n/d\Omega^{n-1} & \xrightarrow{0} & \Omega^{n-2}/d\Omega^{n-3} & \cdots \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
HC_{n-1} & \xrightarrow{B} & HH_n & \xrightarrow{l} & HC_n & \xrightarrow{s} & HC_{n-2} & \xrightarrow{B} & \cdots
\end{array} $$

which is induced by the cokernel. Cf.[阳恩林循环同调 P130]. When $Q \in R$, $\varepsilon_n$ is a split injection.

**Prop.(3.12.7.27).** When $Q \in R$, $\frac{1}{n!} \pi_n$ induces a morphism of mixed complexes $(BA, \partial, B) \rightarrow (\Omega^*_{A/R}, 0, d)$ by (3.12.7.24), thus there is a natural map

$$ HC_n(A) \rightarrow \Omega^n_{A/R}/d\Omega^{n-1}_{A/R} \bigoplus_{i>0} H^{n-2i}_d(A). $$
Prop. (3.12.7.28) [Morita Invariance]. \( Tr : HH_*(M_r(A), M_r(M)) \cong HH_*(A, M) \) by the trace and inclusion functors. Cf. [Morita Invariance]. In particular, there is an isomorphism \( HH_*(M_r(A)) \cong HH_*(A) \), thus also \( HC_*(M_r(A)) \cong HC_*(A) \) by (3.12.7.20).

Prop. (3.12.7.29) [Karoubi]. \( BG \) is a cyclic group, and then the cyclic homology group \( HC_n(G, A) \cong \bigoplus_{k \geq 0} H_{n-2k}(G, A) \). Cf. [Weibel P339].

Simplicial Homotopy

Prop. (3.12.7.30). For a Kan fibration \( X \), there can be defined a homotopy groups \( \pi_n \) that they agree with \( \pi_i(|X|) \) thus also \( \pi_i(S|X|) \), Cf. [Weibel P263]. Thus we see that \(|BG|\) is truly the Eilenberg-MacLane spaces \( BG \).
3.13 Higher Topos Theory

1 Introduction

Remark (3.13.1.1). This subsection is a place that contains all the heuristic ideas leading to $\infty$-category. It should be deleted after the completion of this section.

Axiom (3.13.1.2) [Grothendieck’s Homotopy Hypothesis]. Spaces and $\infty$-groupoids should be the same.

Axiom (3.13.1.3). Kan complexes and $\infty$-groupoids should be the same.

2 $\infty$-Categories

Def. (3.13.2.1) [$\infty$-Category]. An $\infty$-category is a simplicial set that has lifting property w.r.t all $\Lambda^n_i \to \Delta^n$, where $0 < i < n$.

Prop. (3.13.2.2) [Characterization of $\infty$-Categories]. $\mathcal{C}$ is an $\infty$-category iff the restriction map

$$\text{Map}(\Delta^2, \mathcal{C}) \to \text{Map}(\Lambda^2_1, \mathcal{C})$$

is a trivial Kan fibration.

Proof: This follows immediately from (3.12.3.19). □

Def. (3.13.2.3) [Equivalences]. Two morphisms to an $\infty$-category are called homotopic if they define the same morphism in the homotopy category (3.12.4.10). An equivalence is a morphism that defined an isomorphism in the homotopy category.

Def. (3.13.2.4) [$\infty$-Groupoid]. An $\infty$-groupoid is an $\infty$-category that $h\mathcal{C}$ is a groupoid (3.12.4.10).

Prop. (3.13.2.5) [$\infty$-Groupoids and Kan Complex]. Let $\mathcal{C}$ be a simplicial set, then the following are equivalent:

- $\mathcal{C}$ is an $\infty$-groupoid.
- $\mathcal{C} \to \Delta^0$ is a left fibration.
- $\mathcal{C} \to \Delta^0$ is a right fibration.
- $\mathcal{C}$ is a Kan complex.

Proof: 1, 2 are equivalent by (3.13.10), and dually 1, 3 are equivalent, and $4 = 2 + 3$. □

Prop. (3.13.2.6) [Join]. The join of two $\infty$-categories is also an $\infty$-category.

Proof: Given a morphism $p : \Lambda^n_i \to S \star S'$, if the image is in $S$ or $S'$, then it can be extended to $\Delta^n$ by hypothesis. Then we may assume that it maps $\{0, \ldots, j\}$ into $S$ and $\{j + 1, \ldots, n\}$ into $S'$, then we restricts $p$ to get a morphism $\Delta^{[0 \ldots j]} \to S, \Delta^{[j + 1 \ldots n]} \to S'$, which determines a map $\Delta^n \to S \star S'$ extending $p$. □

Prop. (3.13.2.7) [Homotopic Maps]. If $X$ is an $\infty$-category, then so does $X^B$ for any simplicial set $B$, by (3.12.3.26).

And we can call two maps in $\text{Map}(B, X)$ homotopic if they are homotopic as vertices in $X^B$ (3.13.2.3).
Lemma (3.13.2.8). Let $p : C \to D$ be a left fibration of $\infty$-categories and $f : X \to Y$ be a morphism that $p(f)$ is an equivalence in $D$, then $f$ is an equivalence in $D$. Compare with (3.1.7.8).

Proof: Let $\overline{g}$ be a homotopy inverse to $f$, then there is a 2-complex

$$
\begin{array}{ccc}
p(f) & \rightarrow & p(Y) \\
p(X) & \searrow & p(X) \\
\downarrow & & \downarrow \\
\bigcirc & \Downarrow & \bigcirc
\end{array}
$$

and by left fibration property lifts to a 2-complex

$$
\begin{array}{ccc}
f & \rightarrow & Y \\
g & \searrow & \bigcirc \\
\bigcirc & \Downarrow & \bigcirc \\
X & \rightarrow & X
\end{array}
$$

So $f$ admits a left homotopy inverse, and by the same reason, $g$ admits a left homotopy inverse, thus $g$ has a left homotopy inverse, and it can be chosen to be $f$. □

Lemma (3.13.2.9) [Equivalence Lifts via Left Fibrations]. Let $p : C \to D$ be a left fibration of $\infty$-categories, if $Y \in D$ and $x \in C$ and $f : X \to p(Y)$ is an equivalence, then $f$ can be lifted to a morphism in $C$. (Which is also an equivalence by (3.13.2.8)).

Proof: □

Prop. (3.13.2.10) [Equivalence and Left Extension]. Let $C$ be an $\infty$-category and $\varphi$ an edge, then $\varphi$ is an equivalence iff for any $n \geq 2$ and every map $\Lambda^n_0 \to C$ that $f_0|\Delta^{0,1} = \varphi$, there exists an extension of $f_0$ to $\Delta^n$.

Proof: If $\varphi$ is an equivalence, then consider the diagram

$$
\begin{array}{ccc}
\{0\} & \rightarrow & C/\Delta^{n-2} \\
\downarrow & & \downarrow \varphi' \\
\Delta^1 & \rightarrow & C/\partial \Delta^{n-2}
\end{array}
$$

Because $C/\partial \Delta^{n-2} \to C$ is right fibration (3.12.3.25), and by the dual of (3.13.2.8), $\varphi'$ is an equivalence, thus by the dual of (3.13.2.9) the dotted arrow exists.

Conversely, if the condition holds, then we can use a diagram $\Lambda^n_0 \to C$ to find a morphism $\psi$ that $\psi \circ \varphi \cong \text{id}$, and we can also use a diagram $\Lambda^3_0 \to C$ to witness the fact $\varphi \circ \psi \cong \text{id}$, so $\varphi$ is an equivalence. □

Cor. (3.13.2.11). An equivalence in $\text{Map}(K, C)$ is equivalent to a map $K \times \Delta^1 \to C$ that $\{x\} \times \Delta$ are all mapped to equivalences in $C$.

Proof: Cf. [HTT, P106]. □

Def. (3.13.2.12) [Space of Morphisms]. For vertices $x, y$ in a simplicial set $S$, we want to defines a representative for $\text{Map}_h S(x, y)$ other than $\text{Map}_S S(x, y)$. We define the space of right morphisms

$$
\text{Hom}_S^R(x, y) = S/y \times_S \{x\}.
$$
The definition is not symmetric, instead, we define the **space of left morphisms** \( \text{Hom}_L^S(x,y) = \left( \text{Hom}_R^{\text{op}}(x,y) \right)^{op} \).

Also we define \( \text{Hom}_S(x,y) = \{x\} \times_S S^\Delta^1 \times_S \{y\} \), then there are natural inclusions:

\[
\text{Hom}_R^S(x,y) \twoheadrightarrow \text{Hom}_S(x,y) \hookrightarrow \text{Hom}_L^S(x,y).
\]

**Prop. (3.13.2.13).** If \( C \) is an \( \infty \)-category and \( x, y \in C \), then \( \text{Hom}_C^R(x,y) \) is a Kan complex.

**Proof:** This is obvious, because the right lifting diagram w.r.t. \( \Lambda^n_j \subset \Delta^n, 0 < j < n \) is equivalent to an extension \( \Lambda^n_j \times \Delta^0 \subset \Delta^{n+1} \) that satisfies \( \bar{u}|_{\Delta^0} = x \). It can be solved by a two-step extension where the first is by identity extension and then extend using inner fibration property. \( \square \)

**Prop. (3.13.2.14) [Space of Morphisms Homotopic].** When \( S \) is an \( \infty \)-category, the inclusions defined in (3.13.2.12) are homotopy equivalences.

**Proof:** Cf. [HTT, 4.2.1.8]. \( \square \)

**Prop. (3.13.2.15).** Let \( p : C \to D \) be an inner fibration of \( \infty \)-categories, then the the induced maps on the spaces of right morphisms are Kan fibrations.

**Proof:** Since \( p \) is an inner fibration, the induced map \( \tilde{\varphi} : C/Y \to D/p(Y) \times_D C \) is a right fibration by (3.12.3.25), and the morphism on \( \text{Hom}_C^R(X,Y) \) is obtained from \( \tilde{\varphi} \) by restricting to fiber over \( X \), thus also a right fibration. And by (3.13.2.13) and (3.12.3.31). \( \square \)

**Prop. (3.13.2.16) [Mapping Space].** Let \( C, D \) be \( \infty \)-categories and \( K, K' \) simplicial sets, then

- \( \text{Map}(K,C) \) is also an \( \infty \)-category.
- If \( f : C \to D \) is a categorical equivalence, then the induced map \( \text{Map}(K,C) \to \text{Map}(K,D) \) is also a categorical equivalence.
- If \( g : K \to K' \) is a categorical equivalence, then the induced map \( \text{Map}(K',C) \to \text{Map}(K,C) \) is also a categorical equivalence.

**Proof:** 1 follows from (3.12.3.20). 2, 3 follows from [HTT, P94]. \( \square \)

**Prop. (3.13.2.17).** Let \( C \) be an \( \infty \)-category and \( p : K \to C \) be an morphism, then the projection \( C_{p/} \to C \) is a left fibration. In particular, \( C_{p/} \) is itself an \( \infty \)-category.

**Proof:** We use the proposition (3.12.3.25) in case \( S = \Delta^0, A = \emptyset, X = C \). \( \square \)

**Lemma (3.13.2.18).** Let \( C \to D \) be a fully faithful map of \( \infty \)-categories and a diagram \( K \to C \), the map of Kan complexes (3.12.2.17)

\[
C_{p/} \times_C \{x\} \to D_{pj/} \times_D \{p(x)\}
\]

is a homotopy equivalence.

**Proof:** Cf. [HTT, P134]. \( \square \)

**Prop. (3.13.2.19) [Invariance of Undercategories].** Let \( p : C \to D \) be a weak equivalence of \( \infty \)-categories and let \( j : K \to C \) be a map, then the induced map \( C_{j/} \to D_{pj/} \) is a categorical equivalence.
Proof: There is a factorization \( C_j/ \xrightarrow{f} \mathcal{D}_{pj}/ \times \mathcal{C} \xrightarrow{g} \mathcal{D}_{pj}/. \) (3.13.2.18)(3.13.2.17) shows \( C_j/ \) and \( \mathcal{D}_{pj}/ \times \mathcal{C} \) are fiberwise equivalent left fibrations over \( \mathcal{C} \), thus by (3.12.6.7) and (3.12.6.10), \( f \) is a categorical equivalence. Also, \( g \) is a categorical equivalence by (3.12.6.11). So we are done. \( \square \)

**Prop. (3.13.2.20)** [Lifting of Homotopies]. Let \( p : \mathcal{C} \rightarrow \mathcal{D} \) be a categorical equivalence of \( \infty \)-categories and \( A \subset B \) be an inclusion of simplicial sets. Let \( f_0 : A \rightarrow \mathcal{C}, g : B \rightarrow \mathcal{D} \) be any maps that \( h_0 : A \times \Delta^1 \rightarrow \mathcal{D} \) be an equivalence between \( g|_A \) and \( p \circ f_0 \), then there exists a map \( B \rightarrow \mathcal{C} \) and an equivalence \( h : B \times \Delta^1 \rightarrow \mathcal{D} \) between \( g \) and \( p \circ f \) that \( h_0 = h|_{A \times \Delta^1} \).

**Proof:** Working with simplexes, it suffices to prove for \( A = \partial \Delta^n \subset B = \Delta^n \). The case \( n = 0 \) is true because categorical equivalence is essentially surjective. For \( n > 0 \), we need to construct \( h \) from \( h|_{\Delta^n \times \{0\}} \prod \partial \Delta^n \times \Delta^1 \), and this is a composition of pushout of \( \Lambda_{n+1}^k \subset \Delta^{n+1} \). For \( k \neq 0 \), the extension is clear because \( \mathcal{D} \) is \( \infty \)-category, and for \( k = 0 \), we need to use [HTT, P136]. \( \square \)

**Def. (3.13.2.21)** [Correspondence]. Let \( \mathcal{C}, \mathcal{D} \) be \( \infty \)-categories, an correspondence between \( \mathcal{C}, \mathcal{D} \) is defined to be an \( \infty \)-category \( \mathcal{M} \) and a map \( \mathcal{M} \rightarrow \Delta^1 \mathcal{C} \cong \mathcal{M}_0 \) and \( \mathcal{D} \cong \mathcal{M}_1 \).

**Prop. (3.13.2.22)** [Equivalent Definition of Adjoint]. Cf.[HTT, P5.2.2.8].

**Prop. (3.13.2.23).** Left adjoints preserves all colimits and right adjoints preserves all limits.

**Def. (3.13.2.24)** [Localization Category]. A full subcategory \( \mathcal{C}_0 \) of \( \mathcal{C} \) is called a localization of \( \mathcal{C} \) if the inclusion has a left adjoint.

**\( n \)-Categories**

**Def. (3.13.2.25)** [\( n \)-Categories]. Let \( \mathcal{C} \) be a simplicial set and \( n \geq -1 \), then \( \mathcal{C} \) is called an \( n \)-category if it is an \( \infty \)-category and:

- Given any maps \( f, f' : \Delta^n \rightarrow \mathcal{C} \) that are homotopic (3.13.2.7) relative to \( \partial \Delta^n \), then \( f = f' \).
- For any \( m > n \) and maps \( f, f' : \Delta^m \rightarrow \mathcal{C} \) that coincide on \( \partial \Delta^n \), then \( f = f' \).

Also \( \mathcal{C} \) is called an \((-2)\)-category iff it is isomorphic to \( \Delta^0 \).

The definition of an \( n \)-category is equivalent to the following: if \( f, f' : K \rightarrow \mathcal{C} \) satisfies \( f|_{sk^nK} \) is homotopic to \( f'|_{sk^nK} \) relative to \( sk^{n-1}K \), then \( f = f' \).

**Prop. (3.13.2.26).** A \((-1)\)-category is seen to be isomorphic to \( \emptyset \) or \( \Delta^0 \). A 0-category is equivalent to the nerve of a partially ordered set.

**Prop. (3.13.2.27).** If \( \mathcal{C} \) is an \( n \)-category and \( m > n + 1 \), then the restriction map \( \text{Hom}(\Delta^m, \mathcal{C}) \rightarrow \text{Hom}(\partial \Delta^m, \mathcal{C}) \) is bijective. (use \( \infty \)-category property to extend).

**Prop. (3.13.2.28)** [Usual Category as 1-Category]. For a simplicial set \( S \), the following are equivalent:

- \( u : S \rightarrow N(hS)(3.12.4.7) \) is an isomorphism of simplicial sets.
- There is a small category \( \mathcal{C} \) that \( S \cong N(\mathcal{C}) \).
- \( S \) is a 1-category.
Proof: It suffices to show $3 \to 1$: we induct on the dimension: $n = 0$ is trivial and $n = 1$ follows from the definition of 1-category (3.13.2.25). For $n > 1$, the injectivity of $u$ follows from induction hypothesis and (3.13.2.25), and for surjectivity, for a map $\Delta^n \to N(hS)$, choose $0 < i < n$ and let lift $\Lambda^i_n$ to $S$, then use the fact $S$ is an $\infty$-category to lift to $\Delta^n$, and now it coincide on $N(hS)$ because it is a nerve of a category.

Prop. (3.13.2.29). If $\mathcal{C}$ is an $n$-category, then for any simplicial set $X$, $\mathcal{C}^X$ is also an $n$-category.

Proof: This is because $sk^p(K \times X) \subset sk^p(K) \times X$ for any simplicial set $K$ and integer $p$, and use (3.13.2.25).

Prop. (3.13.2.30). Let $n \geq 1$ and $\mathcal{C}$ an $\infty$-category, then $\mathcal{C}$ is an $n$-category iff it satisfies the unique lifting property w.r.t. the inclusion $\Lambda_i^m \subset \Delta^m$, where $0 < i < m$.

Proof: Cf. [HTT, P109].

Def. (3.13.2.31) $[n$-Truncated Kan Complex]. Let $X$ be a Kan complex and $k \geq -1$, then a Kan complex is called $k$-truncated if for every $i > k$ and every point $x \in X$, we have $\pi_i(X, x) \cong *$. And it is called $(\sim 2)$-truncated if it is contractible.

Prop. (3.13.2.32). A $(-1)$-truncated Kan complex is either empty or contractible. A 0-contractible Kan complex is a Kan complex that $X \to \pi_0(X)$ is a homotopy equivalence.

Proof: ?

Prop. (3.13.2.33) $[Equivalent to an n$-Category]. Let $\mathcal{C}$ be an $\infty$-category and $n \geq -1$, then the following conditions are equivalent:

- There is a minimal model $\mathcal{C}' \subset \mathcal{C}$ that is $n$-truncated.
- $\mathcal{C}$ is categorically equivalent to an $n$-truncated category.
- For any $X, Y \in \mathcal{C}$, the mapping space $\text{Map}(X, Y)$ is $(n-1)$-truncated.

Proof: Cf. [HTT, P112].

Cor. (3.13.2.34). A Kan complex is categorically equivalent to an $n$-category iff it is $n$-truncated.

Proof: Cf. [HTT, P113].

Cor. (3.13.2.35). Let $\mathcal{C}$ be an $\infty$-category and $K$ a simplicial set, if $\text{Map}(C, D)$ is $n$-truncated for any objects $C, D \in \mathcal{C}$, then the $\infty$-category $\mathcal{C}^K$ has the same property.

Proof: Cf. [HTT, P114].

3 $\infty$-Category of $\infty$-Categories

4 Limits and Colimits

5 Presentable and Accessible $\infty$-Categories

Def. (3.13.5.1) $[Presentable \ infty$-Category]. An $\infty$-category is called presentable if it is accessible and admits small limits.

Prop. (3.13.5.2). A presentable $\infty$-category also admits all small limits, Cf. [HTT, P5.5.2.4].
Prop. (3.13.5.3). An $\infty$-category is presentable iff it is an accessible localization of an $\infty$-category of presheaves, Cf.[HTT, P5.5.1.1].

Prop. (3.13.5.4) [Adjoint Functor Theorem]. Let $F : C \to D$ be a functor between presentable $\infty$-categories, then

- $F$ admits a right adjoint iff it preserves small colimits.
- $F$ admits a left adjoint iff it preserves small limits and $\kappa$-filtered colimits for some regular cardinal $\kappa$.

Proof: [HTT. 5.5.2.9].

6 $\infty$-Algebras

7 Topological Cyclic Homology(Scholze)
3.14 Stable $\infty$-Categories

1 Stable $\infty$-Categories

Main References are [HTT, Chap8].

Def. (3.14.1.1) [Stable $\infty$-Category]. Stable $\infty$-category is a "linearized $\infty$-category" for doing geometry. A Stable $\infty$-category is an $\infty$-category that
- There exists a zero element.
- Every morphism $g$ in $\mathcal{C}$ admits a fiber and cofiber over the zero object.
- A triangle in $\mathcal{C}$ is a fiber sequence iff it is a cofiber sequence.

Def. (3.14.1.2) [Suspensions and Loops].

Prop. (3.14.1.3). The suspension and loop are functors from $\mathcal{C} \to \mathcal{C}$ that are mutually inverse equivalences.

Proof: Cf.[HTT, 4.3.1.5]. □

Prop. (3.14.1.4) [Stable $\infty$-Categories and Triangulated Categories]. The distinguished triangles in $h\mathcal{C}$ endow $h\mathcal{C}$ with the classical structure of triangulated category.

Prop. (3.14.1.5) [HA.1.1.3.4]. A stable $\infty$-category admits all finite limits and colimits. And pullback squares and pushout squares coincide.

Prop. (3.14.1.6). Let $\mathcal{C}$ be a pointed $\infty$-category, then the following are equivalent:
- $\mathcal{C}$ is stable.
- $\mathcal{C}$ admits finite colimits, and the suspension functor $\Sigma : \mathcal{C} \to \mathcal{C}$ is an equivalence.

Proof: Cf.[HA, 1.4.2.27]. □

Def. (3.14.1.7) [Exact Functors]. A functor $F : \mathcal{C} \to \mathcal{D}$ between stable $\infty$-categories is called exact if the following equivalent definitions hold:
- $F$ preserves fiber sequences.
- $F$ is left exact.
- $F$ is right exact.

Prop. (3.14.1.8). Let $\mathcal{C}at^\mathbb{E}_{\infty} \subset \mathcal{C}at_{\infty}$ be the subcategory of all stable $\infty$-categories and exact functors, then it admits all small limits and small filtered colimits, and they are preserved by the inclusion.

Proof: Cf.[HA1.1.4.4., 1.1.4.6.] □

Def. (3.14.1.9) [T-Structure]. A $T$-structure on a stable $\infty$-category $\mathcal{C}$ is a pair of full subcategories $\mathcal{C}_{\geq 0}, \mathcal{C}_{\leq 0}$ that

Prop. (3.14.1.10). For any $n \in \mathbb{Z}$, $\mathcal{C}_{\leq n} \subset \mathcal{C}$ is a localization, thus admits a left adjoint $\tau_{\leq n}$, called the truncation functor. Dually for $\tau_{\geq n}$.

Proof: Cf.[HA, P1.2.1.5]. □

Def. (3.14.1.11) [Heart]. The heart $\mathcal{C}^{\flat} \subset \mathcal{C}$ is defined to be the full subcategory of $\mathcal{C}_{\leq 0} \cap \mathcal{C}_{\geq 0} \subset \mathcal{C}$.

2 Monoidal $\infty$-Categories
4 | Commutative Algebras

4.1 Commutative Algebra I

Main References are [A-M69], [Mat80], [Sta]Chap10, [Commutative Algebra with a View Towards Algebraic Geometry] and [Wei94]Chap4.

Commutative rings are studied in this subsection.

Notations(4.1.0.1).

• All rings and algebras in this section is assumed to be commutative.

1 Basics

Def.(4.1.1.1) [Ideals]. For \( R \in \mathbb{C}\text{Ring} \), an ideal of \( R \) is a subgroup \( I \leq R \) that is a left ideal. The category of ideals of \( R \) is denoted by \( \text{Ideal}(R) \).

Prop.(4.1.1.2) [Quotients]. For \( R \in \mathbb{C}\text{Ring}, I \in \text{Ideal}(R) \), there is a quotient ring \( R/I \in \mathbb{C}\text{Ring}_R \) with the universal property: any \( f : R \to R' \in \mathbb{C}\text{Ring} \) that vanishes on \( I \) factors through \( R/I \).

Proof:

Prop.(4.1.1.3). The quotient map induces an order-preserving bijection of ideals of \( A/I \) and ideals of \( A \) containing \( I \).

Prop.(4.1.1.4) [Prime Avoidance]. Let \( R \in \mathbb{C}\text{Ring}, I \in \text{Ideal}(R) \), and \( p_i \) are f.m. prime ideals that \( I \not\subseteq p_i \) for any \( i \), then \( I \not\subseteq \cup p_i \).

Proof: Use induction on the number of primes \( n \). For \( n = 1 \) this is trivial. For \( n > 2 \), let \( z_i \in I \setminus \cup_{j \neq i} P_j \). Now consider \( z = z_1 \cdot z_{n-1} + z_n \). If \( z \in P_i \) for some \( i \leq n \), then \( z_{n-1} \in P_i \), contradiction. If \( z \in P_n \), then some \( z_i, i < n \) is in \( P_n \) because \( P_n \) is a prime ideal, contradiction. □

Prop.(4.1.1.5) [Existence of a Maximal Ideal]. Any non-zero commutative ring has a maximal ideal.

Proof: Use Zorn’s lemma, the union of a chain of ideals is an ideal. □

Cor.(4.1.1.6). Any non-trivial ideal is contained in a maximal ideal.

Proof: If \( I \subset A \) is a non-trivial ideal, then \( A/I \) is a non-zero ring, thus \( A/I \) has a maximal ideal, which corresponds to a maximal ideal of \( A \) containing \( I \).

Prop.(4.1.1.7). If \( r(I) \) and \( r(J) \) are coprime, then \( I, J \) are coprime.
Proof: As \( a + b = 1 \), and \( a^m \in I, b^n \in J, 1 = (a + b)^{m+n} \in I + J \). \( \square \)

**Def. (4.1.1.8)** [Local Ring]. A local ring is a commutative ring \( R \) that has only one maximal ideal. Equivalently, there is a prime ideal \( \mathfrak{m} \) that any element in \( R \setminus \mathfrak{m} \) is invertible.

**Proof:** If \( \mathfrak{m} \) is the maximal ideal, then for any \( x \in R \), if \( (x) \) is not all of \( R \), then \( x \) is contained in a maximal ideal by (4.1.1.5), which can only be \( \mathfrak{m} \). Conversely, if there is a prime ideal \( \mathfrak{m} \) that any element in \( R \setminus \mathfrak{m} \) is invertible, then clearly every non-trivial ideal is included in \( \mathfrak{m} \). \( \square \)

**Prop. (4.1.1.9).** Any quotient of a local ring is also a local ring.

**Def. (4.1.1.10)** [Local Ring Map]. A map between two local rings are called local ring map if it maps non-invertible elements to non-invertible elements, equivalently, \( f^{-1}(\mathfrak{m}_S) = \mathfrak{m}_R \).

**Def. (4.1.1.11)** [Ideal of Definition]. In a Noetherian local ring \( (R, \mathfrak{m}) \), an ideal \( I \subset R \) is called an ideal of definition if \( \sqrt{I} = \mathfrak{m} \).

**Prop. (4.1.1.12)** [Ideals of Products and Filters]. If \( F_i, i \in I \) is a collection of fields, then the prime ideals in the ring \( \prod F_i \) is in bijection with the ultrafilters on \( I \), where the ultrafilter \( \mathcal{F} \) corresponds to the ideal \( p_{\mathcal{F}} = \{ (a_i) \mid \text{the set of coordinates that } a_i = 0 \text{ is in } \mathcal{F} \} \). And in the same way, ideals of \( \prod F_i \) corresponds to the filters on \( I \).

**Proof:** Clearly \( p_{\mathcal{F}} \) is an ideal, and if \( \mathcal{F} \) is an ultrafilter, let \( Z(a) \) be the coordinates that \( a \) is zero on, and notice \( Z(ab) = Z(a) \cup Z(b) \), then \( \mathfrak{ab} \in \mathcal{P} \) iff \( a \in \mathfrak{p} \) or \( b \in \mathfrak{p} \), by (1.1.8.7), so it is a prime ideal. Conversely, notice that any two \( a, b \) with \( Z(a) = Z(b) \) differs by a unit, so \( \mathcal{F}_p = \{ Z(a) \mid z \in p \} \) is easily checked to be a filter. And if \( p \) is a prime, then for any \( A \subset I \), let \( a, b \in \prod F_i \) be that \( Z(a) = A, Z(b) = I - A \), then \( \mathfrak{ab} = 0 \in p \), so \( a \in \mathfrak{p} \) or \( b \in \mathfrak{p} \). \( \square \)

**Def. (4.1.1.13)** [Torsion-Free Modules]. Let \( S \subset A \) be a set in a commutative ring, then an \( A \)-module \( M \) is called \( S \)-torsion-free if for any \( \{ x \in M | Sx = 0 \} = 0 \).

**Prop. (4.1.1.14)** [Maximal Torsion-Free Quotient]. Let \( S \subset A \) be a set, the functor from the category of torsion-free \( A \)-modules to the category of \( A \)-modules has a left adjoint, called the maximal \( S \)-torsion-free quotient.

**Proof:** A quotient of \( M \) is determined by the kernel. It suffices to prove if \( M/N_1, M/N_2 \) are both \( S \)-torsion-free, then \( M/N_1 \cap N_2 \) is also \( S \)-torsion-free: This is easy. \( \square \)

**Prop. (4.1.1.15).** Let \( A \) be a ring and \( B \) a finite \( A \)-algebra. if \( A \to B \) is epimorphism in the category of rings, then \( A \to B \) is surjective.

**Proof:** Notice that \( h^B \to h^A \) is injective iff \( h^B \times_{h^A} h^B \cong h^B \), or equivalently, \( B \times_A B \to B \) is an isomorphism. Now we can localize \( A \) at maximal ideals, thus we can assume \( A \) is local, with maximal ideal \( \mathfrak{m} \) and residue field \( k \). And then use Nakayama lemma, it suffices to show that \( k \to B/\mathfrak{m} = C \) is surjective. But \( C \times_k C \cong C \), so \( \dim_k C = 1 \) or 0, which means \( k \to C \) is surjective. \( \square \)

**Def. (4.1.1.16)** [Locally Nilpotent]. A locally nilpotent ideal is an ideal consisting of nilpotent elements.

**Prop. (4.1.1.17).** If \( I \) is a locally nilpotent ideal of \( A \), then \( 1 + I \to 1 + I : x \mapsto x^n \) is an isomorphism.

**Proof:** The converse is given by \( x \mapsto (1 + x)^{1/n} = 1 + (\frac{1}{1^n})x + (\frac{1}{2^n})x^2 + \ldots \). \( \square \)

**Cor. (4.1.1.18).** If \( I \) is a locally nilpotent ideal of \( A \), then a unit in \( A \) is an \( n \)-th power if it is an \( n \)-th power in \( A/I \).

**Proof:** If \( a \equiv b^n \mod I \), then \( b \) is also a unit, and \( ab^{-n} = c^n \) for some \( n \) by (4.1.1.17), thus \( a \) is a \( n \)-th power. \( \square \)
Tensor Product, Limits and Colimits

Remark (4.1.1.19) [Tensor Product]. Tensor product is defined in (2.2.4.13). Notice that in case the rings are all commutative, there are no need to distinguish between left and right modules.

Def. (4.1.1.20) [Tensor Algebras]. For a module $M$ over a commutative ring $R$, we define the

- **tensor algebra** operator from $\text{Mod}_R$ to graded algebras over $R$ that is left adjoint to the forgetful functor. It can be defined as follows:
  $$T(M) = \bigoplus_{n \geq 0} \otimes^n M$$
  as the module, and the algebra structure determined by the canonical map $\otimes^m M \times \otimes^n M \to \otimes^{m+n} M$.

- **exterior product** $\wedge^k M$ as the module with the universal property that $\text{Hom}_B(\wedge^k M, N)$ is the set of all morphisms $M^n \to N$ that vanishes on all elements that have two equal coordinates.

- **exterior algebra** operator $\wedge$ from $\text{Mod}_R$ to the category of strict graded commutative algebras over $R$ that is left adjoint to the forgetful functor. It can be defined as follows:
  $$\wedge(M) = T(M)/(x \otimes x),$$
  where $x \in M$, or equivalently $\wedge(M) = \bigoplus_{k \geq 0} \wedge^k(M)$.

- **symmetric algebra** operator $S$ from $\text{Mod}_R$ to $\text{C} \text{Ring}_R$ that is left adjoint to the forgetful functor. It can be defined as follows: $\wedge(M) = T(M)/(x \otimes y - y \otimes x)$ where $x, y \in M$.

Cor. (4.1.1.21). The construction of $T(M), \wedge M$ and $\text{Sym}(M)$ commutes with all colimits, because they are all left adjoints.

Prop. (4.1.1.22) [Tensor Product and Quotient]. Let $R$ be a commutative ring and $I, J$ be ideals of $R$, then $R\llcorner I \otimes_R R\llcorner J \cong R\llcorner (I + J)$.

Proof: This follows from the universal property of quotient and tensoring.

Prop. (4.1.1.23). There is a pullback square

$$
\begin{array}{ccc}
R/I \cap J & \longrightarrow & R/I \\
\downarrow & & \downarrow \\
R/J & \longrightarrow & R/(I + J)
\end{array}
$$

Proof: The pullback is just the elements in $R/I \times R/J$ that map to the same element in $R/(I + J)$. If $(x + I, y + J)$ maps to the same element $z + I + J$, then $x = y + i + j$, so $x - i = y + j$, and the pullback lies in the image of $\Delta : R \hookrightarrow R/I \times R/J$. Now the kernel is just $I \cap J$.

Prop. (4.1.1.24) [Filtered Colimits of Modules are Exact]. Let $\mathcal{I}$ be an index category that each connected components of $\mathcal{I}$ is filtered, then taking colimits over $\mathcal{I}$ is exact in the category $\text{Mod}_R$ of modules over a ring $R$.

Proof: It is clearly right exact. To check left exactness, Cf. [Sta]04B0.?

Cor. (4.1.1.25) [Filtered Colimits of Abelian Groups are Exact]. Filtered colimits are exact in $\text{Ab}$.

Prop. (4.1.1.26). Let $k$ be a field and $A, B$ be $k$-algebras and let $b \subset A \otimes_k B$ be an ideal. Then among the ideals $a \subset A$ that $b \subset a \otimes_k B$, there exists a smallest one.

Proof: Choose a $k$-basis of $B$, then the smallest ideal $a$ is just the ideal generated by all the $A$-coefficients of elements of $b$. 

□
**Localization**

**Def. (4.1.1.27) [Localization as Filtered Colimit].** Let \( A \) be a commutative ring and \( S \) be a multiplicatively closed subset of \( A \) containing 1 and not containing 0, the localization \( S^{-1}A \) is defined to be a ring over \( A \) that any ring map \( A \to B \) that maps elements of \( S \) to units factors through \( S^{-1}A \).

\( S^{-1}A \) can be constructed as

\[
\lim_{s \in S} A
\]

where the ordering is defined to be \( s < t \) if \( t = sr \) for some \( r \in S \), and if \( t = sr \), there is a map from \( A_s \) to \( A_t \) defined by multiplying by \( r \). This is easily seen to be a filtered colimit. There is easily seen to be the localization.

**Prop. (4.1.1.28) [Localization is exact].** \( S^{-1} \) is an exact functor from \( \text{Mod}_R \) to \( \text{Mod}_R \). Because it is a filtered colimit (3.3.2.27)(4.1.1.24).

**Cor. (4.1.1.29).** \((R/I)_P \cong R_P/I_RP\), in particular, \( k(R/P) \cong R_P/P_RP\).

**Def. (4.1.1.30) [Total Ring of Fractions].** For any ring \( R \), the set of non-zerodivisors in \( R \) is a multiplicatively closed set \( S \), and the localization \( \text{Frac}(R) = S^{-1}R \) is called the **total ring of fractions** of \( R \).

**Prop. (4.1.1.31) [Localization Along an Ideal].** Let \( I \) be an ideal of \( A \), then the localization of \( A \) along \( I \) is the ring \( \tilde{A} \) that \( \text{Spec} \tilde{A} \) is the localization of \( \text{Spec} A \) along \( V(I) \) as defined in(3.8.4.20)(because \( \text{Spec} A \) is spectral, by(3.8.4.13)).

Equivalently, it can be defined as \( \tilde{A} = S^{-1}A \), where \( S = A \setminus (\cup_{p \in V(I)} p) \). (It can be checked that \( S \) is multiplicatively closed).

Notice then \( I \subset \text{rad} \tilde{A} \).

For \( f \in A \), we call the localization of \( A \) along \( f \) the **\( f \)-localization** of \( A \). In fact, it is the universal \( A \)-algebra that \( f \in \text{rad} \tilde{A} \).

**Prop. (4.1.1.32).** Let \( R \) be a commutative ring, \( f_1, \ldots, f_n \in R \), and \( M \) an \( R \)-module, then \( M \to \bigoplus_i M_{f_i} \) is injective iff \( M \to \bigoplus_i M : m \mapsto (mf_1, \ldots, mf_n) \) is injective.

**Proof:** Cf.[Sta]0565. \(\square\)

**Prop. (4.1.1.33).** For any ring \( A \), \( A \to \prod A_m \) is injective, where \( m \) are maximal ideals of \( A \).

For a domain \( A \), \( A = \bigcap A_m \) inside the fraction field of \( A \), where \( m \) are maximal ideals of \( A \).

**Proof:** if \( g \in \text{Frac}(A) \) is in the RHS, then \( I = \{ x \in A | xg \in A \} \) is an ideal of \( A \) not contained in any maximal ideal, thus \( I = 1(4.1.1.6) \), and thus \( g \in A \). \(\square\)

**Lemma (4.1.1.34).** Let \( R \) be a ring and \( \mathfrak{p} \) be a prime, then there exists an \( f \in R, f \notin \mathfrak{p} \) that \( R_f \subset R_{\mathfrak{p}} \), if any of the following holds:

- \( R \) is a domain.
- \( R \) is Noetherian.
- \( R \) is reduced and has f.m. irreducible components.

**Proof:** Cf.[Sta]0BX1. \(\square\)
Def. (4.1.1.35) [Identifying Local Rings]. A ring map \( A \to B \) is said to identify local rings if for every prime \( q \subset B \), the map \( A_{\varphi^{-1}(q)} \to B_q \) is an isomorphism.

Prop. (4.1.1.36). The property of identifying local rings is stable under base change and composition. (This is immediate from (4.1.1.37)).

Prop. (4.1.1.37) [Tensor Product and Localization]. For a ring map \( R \to S \), let \( q \subset \text{Spec} \, S \), \( p = q \cap R \), then \( (M \otimes_R S)_q = M_p \otimes_{R_p} S_q \) for any \( R \)-module \( M \).

Proof: \( (M \otimes_R S)_q = M \otimes_R S_q = M \otimes_R R_p \otimes_{R_p} S_q = M_p \otimes_{R_p} S_q \). □

Noetherian

Def. (4.1.1.38) [Noetherian Module]. Let \( R \) be a commutative ring and \( M \) an \( R \)-module, then \( M \) is called Noetherian iff every ascending chain of submodules stabilizes.

\( R \) is called a Noetherian ring iff \( R \) is Noetherian over itself.

Prop. (4.1.1.39). Let \( R \in \mathcal{C} \text{Ring} \) and \( 0 \to M_1 \to M \to M_2 \) be an exact sequence in \( \text{Mod}_R \), then \( M \) is Noetherian iff \( M_1, M_2 \) are both Noetherian.

Prop. (4.1.1.40). Let \( A \) be a Noetherian ring, then quotient ring, f.g. module, f.g. algebra, localization and power series of \( A \) are Noetherian. Hence graded algebra of a Noetherian ring \( A \) by an ideal \( I \) is Noetherian. Products of Noetherian rings are Noetherian.

Proof: Only need to prove \( A[X] \) and \( A[[X]] \), localization and others are quotients of these. For an ascending chain of ideal \( I_j \) of \( A[X] \), we consider the coefficients ideal \( I_{i,j} \) of \( X^i \) of \( I_j \), then there are only f.m. different \( I_{i,j} \), so we have \( I_j \) stabilize as well.

Similarly for \( A[[X]] \), we prove any ideal \( I \) is f.g. Consider the lowest terms coefficient ideal at degree \( i \), then it is ascending and stabilize, then a set of generators as a whole generate \( I \). □

Remark (4.1.1.41). The subring of a Noetherian ring is NOT necessarily Noetherian, by the example of \( k[X_1, \ldots, X_n, \ldots] \subset k(X_1, \ldots, X_n, \ldots) \).

Prop. (4.1.1.42). When \( A \) is Noetherian and is quipped with \( I \)-adic topology, then \( I \) is f.g., and there is a surjective ring map \( A[[X]] \to A^\wedge \), mapping to the generators of \( I \), hence the completion is Noetherian. (It is surjective can be seen by the Cauchy sequence construction of completion).

Prop. (4.1.1.43). If \( R \to R' \) is ring map of f.t., then if \( S \in \mathcal{C} \text{Ring} / R \) and \( S \) is Noetherian, then \( S \otimes_R R' \) is Noetherian, because \( S \times_R R' \) is of f.t. over \( S \), and use (4.1.1.40).

Cor. (4.1.1.44). For \( k \in \text{Field}, S \in \mathcal{C} \text{Ring} / k \), then for any f.g. field extension \( K/k \), \( S \otimes_k K \) is Noetherian. (Because there is a f.g. algebra \( B \) over \( k \) that \( K \) is the localization of \( B \), and use (4.1.1.40)).

Prop. (4.1.1.45). If \( R \) is Noetherian and \( M \) is a f.g. \( R \)-module, then there is a filtration \( \{M_i\} \) of \( M \) that the quotients are all isomorphic to \( R/p_i \) where \( p_i \) are primes.

Proof: \( M \) is generated by \( x_i \), so \( (x_i) \cong R/I_i \), and so we modulo \( x_i \), then the result follows by induction. So we may assume \( M = R/I \). We use Noetherian condition to choose a maximal element \( J \) that is a counterexample, then \( J \) is not a prime, so there are \( a, b \notin J \) that \( ab \in J \). Then we have a filtration \( 0 \subset aR/(J \cap aR) \subset R/J \). Notice \( R/(J + bR) \to aR/(J \cap aR) \to 0 \), and the second quotient is \( R/(J + aR) \), so they all can be factorized. □
**Prop.(4.1.1.46).** A Noetherian ring has only f.m. minimal prime ideals.

*Proof:* This is a consequence of (5.4.1.20)(5.4.1.21) and (3.8.3.4). □

**Prop.(4.1.1.47)[Cohen].** If $R \in \mathbb{CRing}$ and every prime ideal is f.g., then $R$ is Noetherian.

*Proof:* Suppose $P$ is not Noetherian. Firstly the set of non-finitely generated ideals has the chain property: if $I_i$ is a chain of non-f.g. ideals of $R$, then $I = \cup_{i \in \Phi} I_i$ is non-f.g., otherwise there are $(f_i) = I$, but $\{f_i\} \in I_h$ for some $h$, thus $I_h$ is f.g.. Then we use the Zorn’s lemma to find a maximal non-f.g. ideal $I$. We show that $I$ is a prime ideal:

$I \neq R$ because $R = (1)$. So if $a, b \in R \setminus I$ that $ab \in I$, then $I + (a)$ and $I + (b)$ is f.g. by $p_i + r_i a$, by maximality, and let $K = (P : a)$, then $I \subset I + (b) \subset K$, thus $K$ is f.g., so does $aK$.

Now I claim $I = (p_1) + \ldots + (p_n) + aK$: one direction is clear, and if $r \in I \subset I + (a)$, then $r = \sum c_i(p_i + r_i a)$, thus $(\sum c_i r_i)a = r - \sum c_i p_i \in I$, thus $\sum c_i r_i \in K$, thus $r = \sum c_i p_i + (\sum c_i r_i)a \in (p_1) + \ldots + (p_n) + aK$.

So now $I$ is f.g., contradiction, which shows $I$ is a prime, but this contradicts the hypothesis. □

**Prop.(4.1.1.48)[Modules over Noetherian Ring are Noetherian].** Let $R$ be a Noetherian ring, then any submodule of a finite module $M$ over $R$ is finite. Thus any module over $R$ is a Noetherian module (4.1.1.38). In particular, any module over $R$ is of f.p.

*Proof:* it suffices to prove the first assertion: we use induction on the minimal number of generators of $M$: if it is generated by 1 element, then $M \cong R/I$ for some ideal $I$, thus $N \subset M$ is isomorphic to some $J/I$, so it is finite because $J$ is finite. If the minimal number of generators of $M$ is greater than 1, then there exists an exact sequence

$$0 \to M' \to M \to M'' \to 0$$

where $M', M''$ has fewer number of generators. Now there is also an exact sequence

$$0 \to N \cap M' \to N \to N' \to 0,$$

and the minimal number of generators of $N$ is smaller than the sum of that of $M'$ and $M''$, thus it is also finite. □

**Prop.(4.1.1.49)[Artin-Tate].** Let $R$ be a Noetherian ring and $S$ a f.g. $R$-algebra. If $T \subset S$ is an $R$-subalgebra that $S$ is a finite module over $T$, then $T$ is f.g. over $R$.

*Proof:* Cf.[Sta]00IS. □

**Prop.(4.1.1.50)[Krull-Akizuki].** If $R$ is a Noetherian domain of dimension 1 with fraction field $K$, $L/K$ a finite extension of fields, then for any ring $A$ s.t. $R \subset A \subset L$, $A$ is Noetherian.

*Proof:* Cf.[Sta]00PG. □

### 2 Lengths

**Def.(4.1.2.1) [Lengths].** The *length* of a $R$-module $M$ is the supremum of lengths of chains of submodules of $M$, denoted by $\text{length}_R(M)$.

**Prop.(4.1.2.2).** Length is an additive function on $\text{Mod}_R$. □
Prop. (4.1.2.3). If $\text{length}_R(M) < \infty$, then any maximal chain of submodules has the same length.

Proof: Let $l(M)$ be the minimal length of a maximal chain, then if $M \subseteq N$, then firstly $l(M) < l(N)$, because a maximal chain of $M$ restricts to a maximal chain of $N$, and if the length is the same, then each term is in $M$, so $N \subset N$, contradiction. Now any chain has length $l(M)$, because if there is a chain $M_i$, then $l(M_0) < l(M_1) < \ldots < l(M)$.

Prop. (4.1.2.4). Let $R \in \mathcal{C}$Ring and $S$ a multiplicative set of $R$, then $\text{length}_R(M) \geq \text{length}_{S^{-1}R}(S^{-1}M)$.

Proof: This is because any $S^{-1}R$-submodule of $S^{-1}M$ is of the form $S^{-1}N$ where $N$ is a $R$-submodule of $M$.

Prop. (4.1.2.5). If $R$ is a ring with a maximal ideal $\mathfrak{m}$, $M$ is an $R$-module that $\mathfrak{m}M = 0$, then $\text{length}_R(M) = \dim_{k(\mathfrak{m})}(M)$.

Prop. (4.1.2.6)[Length over a Local Ring]. Let $(R, \mathfrak{m})$ be a local ring, and $M \in \text{Mod}_R$ is of finite length, then $\mathfrak{m}^nM = 0$ for some $n \in \mathbb{N}$.

Conversely, if $\mathfrak{m}$ is f.g. and $M$ is a finite $R$-module, and $\mathfrak{m}^nM = 0$ for some $n \in \mathbb{N}$, then $\text{length}_R(M) < \infty$.

Proof: $M$ is clearly a finite module over $R$. Take $n = \text{length}_R(M)$. If $f_1, \ldots, f_n \in \mathfrak{m}$ and $x \in M$ s.t. $f_1 \ldots f_n x \neq 0$, then by Nakayama the submodules

$$0 \subset (f_1 \ldots f_n)x \subset (f_2 \ldots f_n)x \subset (f_n)x \subset M$$

are all different, so $\text{length}_R(M) \geq n$, contradiction.

For the converse, use additivity on the filtration $0 = \mathfrak{m}^nM \subset \mathfrak{m}^{n-1}M \subset \ldots \subset M$, where each quotient is finite over $R$ and annihilated by $\mathfrak{m}$, so we conclude by (4.1.2.5).

Prop. (4.1.2.7). If $(A, \mathfrak{m})$ is a local ring and $B$ is a ring over $A$ with f.m. maximal ideals $\mathfrak{m}_i$ s.t. each $\mathfrak{m}_i$ is over $\mathfrak{m}$ and $k(\mathfrak{m}_i)/k(\mathfrak{m})$ is finite, then there for any $M \in \text{Mod}_B$ with $\text{length}_B M < \infty$,

$$\text{length}_A M = \sum_i [k(\mathfrak{m}_i) : k(\mathfrak{m})] \text{length}_{B \mathfrak{m}_i} M_{\mathfrak{m}_i}.$$  

Prop. (4.1.2.8). Let $A \to B$ be a flat local maps of local rings, then for any $M \in \text{Mod}_A$,

$$\text{length}_A(M) \text{length}_B(B/\mathfrak{m}_A B) = \text{length}_B(M \otimes_A B).$$

Proof: Cf.[Sta]02M1.

Cor. (4.1.2.9). Let $A \to B \to C$ be local maps of local rings, $C/B$ is flat, and $\mathfrak{m}_A$ the maximal ring of $A$, then

$$\text{length}_B(B/\mathfrak{m}_A B) \text{length}_C(C/\mathfrak{m}_B C) = \text{length}_C(C/\mathfrak{m}_B C).$$

Prop. (4.1.2.10)[Order of Vanishing]. If $R$ is a semi-local Noetherian domain of dimension 1 and $a, b$ are not zero-divisors, then $f(a) = \text{length}(R/(a))$ satisfies $f(a) + f(b) = f(ab) < \infty$.

So this $R \subset K$ and has fraction field $K$, then $f$ extends to an additive function on $K^*$, denoted by $\text{ord}_R(f)$.

Proof: It is finite by [Sta]00PF. It is additive because length is additive (4.1.2.1) and $0 \to R/(a) \to R(ab) \to R(b) \to 0$. 

□
3 Artinian Ring

Def. (4.1.3.1) [Artinian Rings]. A ring $A$ is called Artinian if any descending chain of ideals of $A$ stabilizes.

For example, a f.g. $k$-algebra that is a finite $k$-module is an Artinian ring.

Lemma (4.1.3.2). Let $A$ be an Artinian ring, then $A$ has f.m. maximal ideals.

Proof: Consider $m_1 \supset m_1 \cap m_2 \supset \ldots$, then it is a descending chain, by Chinese remainder theorem. So it has f.m. maximal ideals. \qed

Lemma (4.1.3.3). If $A$ is an Artinian ring, then the Jacobson radical is nilpotent.

Proof: Consider the Jacobson radical $I$, $I^n = I^{n+1}$ for some $n$, let $J = \text{Ann}(I^n)$, it suffices to show $J = A$. If not, choose a minimal $J'$ that contains $J$ but not $J$ (exists by Artinian property), then $J' = J + Ax$, and $IJ' \subseteq J$ by Nakayama, so $xI^{n+1} \subseteq JI^n = 0$, so $x \in J$, contradiction. \qed

Prop. (4.1.3.4) [Characterization of Artinian Rings]. The following are equivalent:

1. $A$ is Artinian.
2. $A$ is Noetherian of dimension 0.
3. $\text{length}_A A < \infty$.
4. $A$ is a finite product of local Artinian rings.
5. $A$ is Noetherian, Jacobson (4.2.6.4), and has f.m. maximal ideals.

Proof: 1 $\iff$ 3: if $\text{length}_A A < \infty$, then $A$ is clearly Artinian. Conversely, if $A$ is Artinian, then by (4.1.3.2) (4.1.3.3) (4.2.6.7) $A$ a finite product of its localization of maximal ideals, so we may assume $A$ is local with maximal ideal $m$. Then $m^n = 0$ for some $n$ by (4.1.3.3), and $m^i/m^{i+1}$ has length the same as their dimension as a $A/m$ vector space, by (4.1.2.5), which is finite because $A$ is Artinian, so $\text{length}_A A < \infty$.

1 + 3 $\rightarrow$ 5: $A$ has f.m. maximal ideals by (4.1.3.2). It is Jacobson by (4.1.3.3). $\text{length}_A A < \infty$ clearly implies $A$ is Noetherian.

5 $\rightarrow$ 2: By (4.2.6.7).

2 $\rightarrow$ 5: all prime ideals are maximal, so $\text{Spec} A$ is discrete, so $A$ has f.m. maximal ideals, and it is clearly Jacobson.

5 $\rightarrow$ 3: By (4.2.6.7), $R$ is a product of its local rings, and the local rings are all Noetherian and Jacobson (4.2.6.6), so by Nakayama, they have finite lengths. So also $R$ has finite length.

5 $\rightarrow$ 4: By lemma (4.2.6.7) below, $A$ is a product of its localization, and its localizations also satisfies 5, and by 5 $\rightarrow$ 3 $\rightarrow$ 1, they both have descending conditions.

4 $\rightarrow$ 5: An Artinian ring is Noetherian and Jacobson by 1 + 3 $\rightarrow$ 5, then so does their product. \qed

Cor. (4.1.3.5) [Reduced Artinian Ring]. A reduced local Artinian ring is a field. In particular, $A$ reduced Artinian ring is a product of fields.

Proof: An Artinian local ring $A$ is Jacobson (4.1.3.4) so the maximal ideal $m = 0$ as $A$ is reduced. \qed

Prop. (4.1.3.6). For an Artinian local ring $A$, the following are equivalent:

1. $A$ is a PID.
2. the maximal ideal \( \mathfrak{m} \) is principal.
3. \( \dim_k(\mathfrak{m}/\mathfrak{m}^2) \leq 1 \).

*Proof:* It suffices to prove \( 3 \implies 1 \): If \( \mathfrak{m} = \mathfrak{m}^2 \), then \( \mathfrak{m} = 0 \) by Nakayama, so \( A \) is a field. If \( \dim_k(\mathfrak{m}/\mathfrak{m}^2) = 1 \), then \( \mathfrak{m} \) is principle by Nakayama. And \( \mathfrak{m} \) is nilpotent by (4.1.3.4), so for any ideal \( a \) there is a minimal \( n \) that \( a \subset \mathfrak{m}^n \). Now choose \( y \in a - \mathfrak{m}^{n+1} \), then \( y = ux^r \), and \( u \notin (x) \), so \( u \) is a unit, thus \( x^r \in a \), meaning \( a = \mathfrak{m}^n \) hence principal. \( \square \)

### 4 Local Properties

**Def.** (4.1.4.1) *Local properties.* A property \( P \) of rings or modules over a ring is called **local property** iff \( X \) has \( P \) iff \( X_f \) all has \( P \) for a covering \((f_1, \ldots, f_n) = 1\).

A property of morphisms of rings is called **local on the target** iff \( R \to S \) has \( P \) iff \( R_{f_i} \to S_{f_i} \) has \( P \) for a covering \((f_1, \ldots, f_n) = 1 \) in \( R \).

**Prop.** (4.1.4.2) *Stalkwise Properties.* For a commutative ring \( R \), a property \( P \) is called stalkwise if \( A \) satisfies \( P \) iff all \( A_{\mathfrak{m}} \) satisfies \( P \) where \( \mathfrak{m} \) are maximal ideals, and iff all \( A_{\mathfrak{p}} \) satisfies \( P \) where \( \mathfrak{p} \) are prime ideals of \( A \).

1. Trivial is stalkwise for modules over \( R \). Hence so does injectivity and surjectivity because localization is exact.
2. Torsion-free is stalkwise for modules over \( R \) if \( R \) is integral.
3. Flatness for modules over \( R \).
4. Flatness for rings over \( R \) on the source.
5. Formal unramifiedness for rings over \( R \), both on the target and source.
6. (universally)catenary is stalkwise.
7. reducedness is stalkwise.
8. Integral+integrally closed is stalkwise.
9. normal is stalkwise.
10. regular is stalkwise.

*Proof:*

1. It suffice to prove an element is trivial on every localization then it is 0. For this, consider the annihilator \( \text{Ann}(x) \), it is not contained in any maximal ideal so it contains 1.
2. if \( xf = 0 \) but \( f \neq 0 \), then \( x \in \text{Ann}(f) \neq (1) \), so \( \text{Ann}(f) \subset \mathfrak{m} \) maximal, so \( f \) is torsion in \( M_{\mathfrak{m}} \) over \( R_{\mathfrak{m}} \). Conversely, if \( f \) is torsion in \( R_{\mathfrak{m}} \), then it is clearly torsion over \( R \).
3. We use the definition (4.4.1.2). Notice \( (IM)_{\mathfrak{p}} = I_{\mathfrak{p}} M_{\mathfrak{q}} \) and every ideal of \( R_{\mathfrak{p}} \) is of the form \( I_{\mathfrak{p}} \). Then use the fact injective is stalkwise (4.1.4.2).
4. We use the definition (4.4.1.2). Notice \( (I \otimes_R S)_{\mathfrak{q}} = I_{\mathfrak{p}} \otimes_{R_{\mathfrak{p}}} S_{\mathfrak{q}} \) for all primes \( \mathfrak{q} \) of \( S \) and \( \mathfrak{p} = \mathfrak{q} \cap R \). And every ideal of \( R_{\mathfrak{p}} \) is of the form \( I_{\mathfrak{p}} \). Then use the fact injective is stalkwise (4.1.4.2).
5. Because formally unramified is equivalent to \( \Omega_{R/S} = 0 \) (4.4.6.1), so we get the result by functorial properties of \( \Omega_{S/R} \) (4.4.3.6) and triviality is stalkwise (4.1.4.2).
6. For any two prime ideals \( \mathfrak{p} \subset \mathfrak{q} \), we can choose a maximal ideal containing them.
7. use (4.1.1.33).

8. If $A$ is integrally closed, then clearly any localization of $A$ is integrally closed. Conversely, if $r \in K(A)$ is integral over $A$ but $r \notin A$, let $I = \{ s \in A \mid rs \in A \}$, then $I \neq A$, so $I \subset \mathfrak{m}$ for some maximal ideal $\mathfrak{m}$, then $r \notin A_{\mathfrak{m}}$, so $A_{\mathfrak{m}}$ is not integrally closed, contradiction.

9. By definition.

10. By definition.

Remark (4.1.4.3). Our main technique of proving local properties are using affine communication theorem (5.4.1.2).

Prop. (4.1.4.4) [Local Properties]. For a fixed ring $R$,

1. Every property that is stalkwise is a local property. (4.1.4.2) The properties listed below should be not stalkwise.

2. Every property that satisfies faithfully flat descent is a local property. The properties listed below should not satisfy faithfully flat descent.

3. Noetherian.

4. F.t. ring maps on the source.

5. F.p. ring maps on the source.

7. Nagata for rings.

Proof:

1.

2.

3. If $A$ is Noetherian, then $A_{f_i}$ are Noetherian by (4.1.1.40). Conversely, if $A_{f_i}$ are all Noetherian and $I_1 \subset I_2 \subset \ldots$ is an ascending chain of ideals of $A$, consider $A \to \prod A_{f_i}$ faithfully flat, thus $I_1 \otimes_A (\prod A_{f_i}) \subset I_2 \otimes_A (\prod A_{f_i}) \subset \ldots$ is an ascending chain of $\prod A_{f_i}$. Now $\prod A_{f_i}$ are Noetherian by (4.1.1.40), so this chain stabilizes. But this ring map is faithfully flat, so the original chain must also stabilizes.

4. Let $(g_1, \ldots, g_n) = 1$, choose $\sum h_i g_i = 1$, and let $x_{ij} = y_{ij}/g_i^{n_{ij}}$ generates $S_{g_i}$. Now let $S'$ be the sub-$R$-algebra of $S$ generated by $y_{ij}, g_i, h_i$. Then $(S')_{f_i} \to S_{f_i}$ is surjective for any $i$, so $S' \to S$ is also surjective, by (4.1.4.2). Then $S' = S$, and $S$ is f.g. over $R$.

5. Cf. [Sta]00EP.

6. If $A$ is N-1, then $A_{f_i}$ are N-1 because taking integral closure commutes with localization. The same for N-2. Conversely, if all $A_{f_i}$ are N-1 or N-2, so is $A$ because finiteness is local (4.1.4.4). The universal Japanese case follows from the N-2 case.

7. This follows from the localness of Noetherian and N-2 (4.1.4.4).
5 Miscellaneous

Fitting Ideals

Def. (4.1.5.1) [Fitting Ideals]. Let \( R \in \mathfrak{C} \mathfrak{R} \)ing and \( M \) be a finite \( R \)-module, then for any presentation
\[
\oplus_{j \in J} R \rightarrow R^{\oplus n} \rightarrow M \rightarrow 0
\]
given by a \( n \times J \) matrix \( A \), the ideal generated by the \( (n-k) \times (n-k) \) matrices of \( A \) is independent of the presentation chosen, called the \( k \)-th Fitting ideal of \( A \), denoted by \( \text{Fit}_k(M) \).

6 Rings and Categories

Quotient by Equivalence Relations

Prop. (4.1.6.1) [Quotients by Equivalence Relations]. Let \( u_0, u_1 : A_0 \rightarrow A_1 \) be an equivalence in the dual category of \( \mathfrak{C} \mathfrak{R} \)ing\(_R_{\mathfrak{R}0}(3.1.1.24)\). If \( u_0 \) is locally free of constant rank \( r \), then a quotient \( u : A \rightarrow A_0 \) exists, and \( u \) is locally free of constant rank \( r \).

Proof: Cf. [Mil17b]P592. \( \square \)

Morita Equivalence

Basic References are [Morita Equivalence] and [Fuller Rings and Categories of Modules].

Def. (4.1.6.2). Two ring \( R, S \) are called Morita equivalent if the category of mod-\( R \) is equivalent to the category of mod-\( S \).

Prop. (4.1.6.3). For an Abelian category \( \mathcal{A} \) satisfying AB3 (i.e. arbitrary sum exists), An object \( P \) of \( \mathcal{A} \) is a progenerator if the functor \( h' : X \mapsto \text{Hom}_\mathcal{A}(P, X) \) is exact and and strict: \( h'(X) = 0 \) implies \( X = 0 \). Then \( h' \) determines an equivalence from \( \mathcal{A} \) to mod-\( R \), where \( R = \text{Hom}_\mathcal{A}(P, P) \).

Similarly, if \( \mathcal{A} \) is an Abelian Noetherian category and \( P \) is a progenerator, then \( R \) is Noetherian and \( \mathcal{A} \) is equivalent to the category of finitely generated \( R \)-categories.

Proof: Essentially surjective: construct using direct limit and cokernel.

Notice that \( h'(X) \cong h'(X') \rightarrow X \cong X' \) by strictness and A4 axiom. So let \( X = \text{Coker}(P^{\oplus I}, P^{\oplus J}) \),
\[
\text{Hom}(h'(X), h'(Y)) = \text{Hom}(\text{Coker}(h'(P^{\oplus I}), h'(P^{\oplus I})), h'(Y)) = \ker(\text{Hom}(h'(P^{\oplus I}), h'(Y)) \rightarrow \text{Hom}(h'(P^{\oplus I}), h'(Y)))) = \ker(h'(Y^{\Pi}) \rightarrow h'(Y^{\Pi})) = \text{Hom}(X, Y)
\]
\( \square \)

Prop. (4.1.6.4). In the case when \( \mathcal{A} \) is the category mod-\( R \), \( P \) is a generator \( \iff \ h' : X \mapsto \text{Hom}_R(P, X) \) is faithful \( \iff \) every \( M \) is a quotient of direct sums of \( P \). And a progenerator is a f.g. projective generator.
Prop. (4.1.6.5). Let $P$ be a $(A,B)$-bimodule, iff $P$ is a progenerator as a right $B$ module, then it is a progenerator as a left $A$ module.

Prop. (4.1.6.6). Let $P$ be a progenerator as a

Prop. (4.1.6.7) [Morita]. The following are equivalent:
- categories $A$-mod and $B$-mod are equivalent.
- categories mod-$A$ and mod-$B$ are equivalent.
- There exist a finitely generated progenerator $P$ of mod-$A$ that $B \cong \text{End}_A P$.

Proof: $2 \rightarrow 3$: $A$ is a progenerator in mod-$A$, thus when $A \sim B$, $F : \text{mod-}A \rightarrow \text{mod-}B$, $A \cong \text{End}_A A = \text{End}_B F(A)$, and $F(A)$ is a left $A$ module as well as a progenerator of $B$. Thus there is a $(A,B)$-bimodule $P$ that $A \cong \text{End}_B P$, and a $(B,A)$-bimodule $Q$ that $B \cong \text{End}_A Q$. \hfill $\square$

Prop. (4.1.6.8). There can be defined another Morita invariance that $R \sim S$ iff there are $(R,S)$-bimodule $P$ and $(S,R)$-bimodule $Q$ that $P \otimes_S Q \cong R$ as a $(R,R)$-bimodule and $Q \otimes_R P \cong S$ as a $(S,S)$-bimodule. This will immediately generate equivalence between $R$-mod and $S$-mod as well as equivalence between mod-$R$ and mod-$S$ by tensoring. And $P$ and $Q$ are projective modules respectively, because equivalence is a kind of adjoint.

Prop. (4.1.6.9). Let $D$ be a division ring over $k$ of finite degree and $A = M_n(D)$. Let $S = D^r$ with $A$ acting by left multiplication and $D$ acting by right multiplication, then there $S$ is a simple $A$-module, and every $A$-module is a direct sum of copies of $S$. This means that $S \otimes_D -$ induces an equivalence from $\text{Mod}_D$ to $\text{Mod}_A$.

Prop. (4.1.6.10) [Properties Preserved under Morita Invariance]. Cf. [Rings and Categories of Modules P54].

7 Spectra

Lemma (4.1.7.1). In Spec $A$, a subset $U$ is retrocompact iff it is quasi-compact iff it is a finite union of standard opens $D(f_i)$. In particular, any constructible subset of Spec $A$ is a finite union of morphisms of the form $D(f_i) \cap V(g_1, \ldots, g_m)$.

Proof: Retrocompact is quasi-compact because Spec $A$ is quasi-compact. A quasi-compact subset is equivalent to a finite union of $D(f_i)$. Now for any quasi-compact subset $V = \bigcup_i D(g_j)$, $U \cap V = \bigcup_{ij} D(f_ig_j)$ is also quasi-compact, so $\bigcup D(f_i)$ is retrocompact. \hfill $\square$

Lemma (4.1.7.2). Let $R$ be a ring, then
- the image of any standard open subsets of Spec $R[X]$ is qc open in Spec $R$.
- for $g, f \in R[X]$ with $g$ monic, the image of $D(f) \cap V(g)$ is qc open in Spec $R$.

Proof: 1: For any prime $\mathfrak{p}$ of $R$, the primes mapping to $\mathfrak{p}$ has a minimal one, $\mathfrak{p}[X]$, so $\mathfrak{p}$ is in the image of Spec $R[X] \rightarrow$ Spec $R$ iff $f \in \mathfrak{p}[X]$, which means the image is $D(a_0,a_1,\ldots,a_n)$, where $f = a_0 + a_1X + \ldots + a_nX^n$.

2: $R[X]/g$ is finite free over $R$, let $P(T) = T^d + r_{d-1}T^{d-1} + \ldots + r_0$ be the characteristic polynomial of $f$ acting on $R[X]/g$ by left multiplication, then $\mathfrak{p} \in V(r_0,\ldots,r_{d-1})$ iff $f$ acts nilpotently on $R[X]/g \otimes_R k(\mathfrak{p})$, which is equivalent to $\mathfrak{p}$ being in the image of $D(f) \cap V(g)$ (by base change to $k(\mathfrak{p})$ argument). \hfill $\square$
Lemma (4.1.7.3) [Affine Chevalley]. The Spec map of a f.p. ring map maps constructible sets to constructible sets.

Proof: Suppose \( S = R[X_1, \ldots, X_n](f_1, \ldots, f_m) \), then it suffices to show for the case \( S = R/(f_1, \ldots, f_m) \) and \( S = R[X] \).

If \( S = R/(f_1, \ldots, f_m) = R/I \), it suffices to show the image of \( D(\overline{g}) \cap V(\overline{h_1}, \ldots, \overline{h_m}) \) is retrocompact in \( \text{Spec } R \); in fact its image is just \( D(g) \cap V(h_1, \ldots, h_m) \cap V(I) \), where \( g, h_i \) are any inverse images in \( R \).

For the second case, we first prove some localizing result: If \( S = R_f \), then the compact open subsets of \( \text{Spec } S \) are compact open subsets of \( \text{Spec } R \), so \( \text{Spec } S \to \text{Spec } R \) maps constructible sets to constructible sets. Now for any \( c \in R \), \( \text{Spec } R = \text{Spec } R/c \coprod \text{Spec } R_c \), so to prove the proposition for \( R \), it suffices to prove for \( R_c \) and \( R/c \).

Let \( D(f) \cap V(g_1, \ldots, g_n) \subset \text{Spec } R[X] \), where \( f, g_i \) are polynomials. We can use induction on the degree series \( \deg(g_1) \leq \deg(g_2) \leq \cdots \leq \deg(g_n) \). If the leading coefficient of \( g_1 \) is invertible, then we can use reduction to \( R/c \) and \( R_c \) to either reduces the degree of \( g_1 \) or reduce to the case it is invertible. If it is invertible, then we can use Euclidean division. Eventually, it can be reduced to the case \( D(f) \cap V(g) \) where \( g \) is monic, or \( D(f) \). This is proved in the above lemma (4.1.7.2). □

Lemma (4.1.7.4). For a Noetherian local ring \((A, m)\), \( \text{Spec } A - m \) is affine iff \( \dim A \leq 1 \).

Proof: If \( \dim A = 0 \), this is true, if \( \dim A = 1 \), let \( f \in m \) not in any other minimal primes of \( A \), then \( \text{Spec } A - m = \text{Spec } A_f \).

Conversely, Cf. [[Sta]0BCR]. □

Idempotents

Prop. (4.1.7.5) [Clopen Subsets]. The clopen subsets of \( \text{Spec } A \) corresponds to idempotents in \( A \).

Proof: This is all equivalent to the fact that there exists \( e + f = 1, ef = 0 \):

If \( A = U \coprod V \), then both \( U, V \) are closed hence qc, so \( \text{Spec } A = U \cup V(\overline{f}_i) \coprod U \cup V(\overline{g}_j) \), then \( f_i g_j \) is nilpotent by (4.2.6.2). Denote \( I = (\overline{f}_i), J = (\overline{g}_j) \), then \( (IJ)^N = 0 \) and \( I + J = A \), there are \( 1 = x + y, x \in I^N, y \in J^N \).

For uniqueness, if \( e_1 \neq e_2 \), then \( 0 \neq e_1 - e_2 = e_1(e_2 + f_2) - e_2(e_1 + f_1) = e_1 f_2 - e_2 f_1 \), so may assume \( e_1 f_2 \neq 0 \), and it is not nilpotent, so there is a \( e_1 f_2 \subset p \), which is a contradiction. □

Cor. (4.1.7.6). A local ring has no non-trivial idempotents, and then an idempotent is defined by the maximal ideals that it vanishes.

Cor. (4.1.7.7). If \( I \) is an ideal of \( R \) that \( I = I^2 \), and \( I \) is f.g., then \( V(I) \) is open and closed in \( \text{Spec } R \), and \( V(I) = R_e \) for some idempotent \( e \).

Proof: By Nakayama, there is a \( a \) \( f = 1 - e \) with \( e \in I \) that \( f I = 0 \). So \( e - e^2 = 0 \) and \( f^2 = f \).

\( V(I) = D(f) = D(e) \). □

Lemma (4.1.7.8). If \( I \) is a locally nilpotent ideal, then \( R \to R/I \) induces a bijection on idempotents.

Proof: Because \( R \to R/I \) induces a homeomorphism on the spectra, and clopen subsets of the spectrum corresponds to the idempotents (4.1.7.5). □

Lemma (4.1.7.9). Let \( R \) be a ring and \( T \subset \text{Spec } R \) is a set. Then the following are equivalent:
\begin{itemize}
\item $T$ is closed and is a union of connected components of $\text{Spec } R$.
\item $T$ is an intersection of clopen subsets.
\item $T = V(I)$ where $I$ is generated by idempotents.
\end{itemize}

**Proof:** 1 and 2 are equivalent by (3.8.4.3), and $2 \rightarrow 3 \rightarrow 1$ are easy.

**Prop. (4.1.7.10).** Let $R$ be a ring, then any connected component of $\text{Spec } R$ is of the form $V(I)$, where $I$ is an ideal generated by idempotents that any idempotent of $R$ maps to either $0$ or $1$ in $R/I$.

**Proof:** By (3.8.4.2) and (3.8.4.13), a connected component of $\text{Spec } R$ is an intersection of clopen subsets, so it is of the form $V(I)$ where $I$ is generated by idempotents. The last assertion is equivalent to $V(I)$ being connected.

**Going-up and down**

**Def. (4.1.7.11) [Going-up and Going Down].** Going-up and down for topological spaces is defined in (3.8.3.7). A ring map $R \to S$ is said to satisfy the going-up property iff its $\text{Spec}$ map does, equivalently, for any prime ideal $q \subsetneq S$ and prime ideal $p \subsetneq q \cap R$, there exists a prime ideal $q' \subset neq q$ that $q' \cap R = p$.

It is said to satisfy the going-down property iff its $\text{Spec}$ map does, equivalently, for any prime ideal $q \subsetneq S$ and prime ideal $q \cap R \subsetneq p$, there exists a prime ideal $q' \subsetneq q$ that $q' \cap R = p$.

**Prop. (4.1.7.12).** Going-up and Going-down are stable under composition, trivially.

**Prop. (4.1.7.13) [Integral Map satisfies Going-Up].** Integral ring map satisfies going-up (4.2.1.5).

Flat ring map satisfies going-down (4.4.1.19).

**Lemma (4.1.7.14).** If the image of the $\text{Spec}$ map of a ring map is closed under specialization, then this image is closed.

**Proof:** Let it be $R \to S$, let $I$ be the kernel, then the image is contained in $V(I)$, so we may replace $R$ be $R/I$, then $R \subsetneq S$. Now we show the image contains all the minimal primes of $R$: for a minimal prime $p$, $A_p \subsetneq B_p$, thus $B_p$ is not-empty, and thus has a maximal ideal, whose intersection with $A_p$ can only be $p$ by hypothesis, thus $p$ is in the image of Spec. Then the image is all of Spec $R$ by hypothesis, thus closed.

**Cor. (4.1.7.15) [Going-up and Spec Closed].** Going-up is equivalent to Spec map closed.

**Proof:** If going-up holds, then Spec map is closed by (4.1.7.14). Conversely, a closed map satisfies going-up, by (3.8.3.8).

**Prop. (4.1.7.16).** If $R \to S$ is a ring map that satisfies going-up, and $P \subset S$ is a maximal ideal, then $P \cap R$ is also a maximal ideal.

**Prop. (4.1.7.17) [Krull].** If $A \subset B$ is an integral extension of integral domains, and $A$ is normal, then going-down holds.
Prop. (4.1.7.22) [Zerodivisors in a Reduced Ring]. Let \( R \) be a reduced ring, then 
\[
\mathfrak{p} = \mathfrak{p}^2 \quad \text{implies} \quad \mathfrak{p} = 0.
\]

Proof: For \( \mathfrak{p} \) is minimal, \( \mathfrak{p}^2 = 0 \Rightarrow \mathfrak{p} = 0 \).

Prop. (4.1.7.23) [Irreducible Components of Spectrum]. Let \( R \) be a ring, then 
\[
\text{Spec}(R) = \bigcup_{\mathfrak{p} \in \text{Min}(R)} \{ \mathfrak{p} \}.
\]

Proof: By (4.2.6.1), \( \mathfrak{p} \subseteq \mathfrak{p}^2 \Rightarrow \mathfrak{p} = 0 \).

Lemma (4.1.7.20). If \( \mathfrak{p} \) is a minimal prime of \( R \), then \( \mathfrak{p} \mathfrak{R}_\mathfrak{p} \) is locally nilpotent by (4.2.6.1). In particular, if \( R \) is reduced, then \( \mathfrak{R}_\mathfrak{p} \) is a field.

Prop. (4.1.7.21) [Zerodivisors in a Reduced Ring]. Let \( R \) be a reduced ring, then

- \( R \to \prod_{\mathfrak{p}} \mathfrak{R}_\mathfrak{p} \) is an embedding into a product of fields.
- \( \bigcup_{\mathfrak{p}} \mathfrak{R}_\mathfrak{p} \) is the set of zerodivisors of \( R \).

Proof: 1. By (4.1.7.20), \( \mathfrak{R}_\mathfrak{p} \) are fields. In particular, the kernel of \( R \to \mathfrak{R}_\mathfrak{p} \) is \( \mathfrak{p} \). Then the kernel of the map \( R \to \prod_{\mathfrak{p}} \mathfrak{R}_\mathfrak{p} \) is \( \bigcap_{\mathfrak{p}} \mathfrak{R}_\mathfrak{p} = 0 \) by (4.2.6.1).

2. If \( xy = 0 \) and \( x \neq 0 \), then \( x \notin \mathfrak{p} \) for some minimal prime \( \mathfrak{p} \) by (4.2.6.1), thus \( y \in \mathfrak{p} \). Conversely, if \( y \in \mathfrak{p} \) for some minimal prime \( \mathfrak{p} \), then \( y \) is mapped to \( 0 \in \mathfrak{R}_\mathfrak{p} \), which means there are some \( x \notin \mathfrak{p} \) that \( xy = 0 \).

Prop. (4.1.7.22). If \( R \) is a ring with f.m. minimal primes \( \mathfrak{q}_i \) and \( \bigcup_i \mathfrak{q}_i \) is the set of zerodivisors of \( R \), then the ring of fractions of \( R \) is equal to \( \prod_i \mathfrak{R}_{\mathfrak{q}_i} \).

Proof: Cf. [Sta] 02LX.

Prop. (4.1.7.23) [Irreducible Components of Spectrum]. The irreducible closed subsets of \( \text{Spec}(R) \) are exactly the sets of the form \( V(\mathfrak{p}) \) for some prime \( \mathfrak{p} \subseteq R \). The irreducible components of \( \text{Spec}(R) \) are exactly the sets of the form \( V(\mathfrak{p}_i) \) for some minimal prime \( \mathfrak{p}_i \).

Prop. (4.1.7.24) If \( R \) is a ring and \( \mathfrak{p} \) a minimal prime of \( R \). If \( W \subseteq \text{Spec}(R) \) is a quasi-compact open subset of \( \text{Spec}(R) \) not containing \( \mathfrak{p} \), then there exists some \( f \in R \) that \( \mathfrak{p} \subseteq D(f) \) and \( D(f) \cap W = \emptyset \).

Proof: 
\[
W = \bigcup_{i=1}^n D(f_i) \quad \text{and} \quad f_1 \notin D(f_i), f_i \in \mathfrak{p} \quad \text{for each} \quad i.
\]

Then (4.1.7.20) says \( f_i \) are nilpotent in \( \mathfrak{R}_\mathfrak{p} \), so there is some \( g \in R \) that \( gf_i \) are nilpotent in \( R \) for any \( i \), which means \( g \) satisfies the requirement.

Prop. (4.1.7.25). For \( R \subseteq S \), all the minimal primes of \( R \) are in the image of the Spec map of a minimal prime of \( S \).

Proof: 
Localize w.r.t. to the minimal prime \( \mathfrak{p} \), then it is a local ring with only one prime. And \( S_\mathfrak{p} \) is nonzero because localization is exact, so it has a maximal ideal \( \mathfrak{q} \). Now we choose a minimal prime of \( S \) contained in \( \mathfrak{q} \), then it is also mapped to \( \mathfrak{p} \).
Universal Homeomorphism

Cf. [Sta]10.45 and [Sta]28.44.

Prop. (4.1.7.26). If \( \varphi : R \to S \) is a ring map and \( p \) is a prime number that satisfies:
- \( S \) is generated over \( R \) by elements \( x \) that there is \( n \) that \( x^{p^n} \in \varphi(R) \) and \( p^n x \in \varphi(x) \).
- \( \ker(\varphi) \) is locally nilpotent.

then \( \text{Spec} \, S \to \text{Spec} \, R \) is a homeomorphism, and any base change of \( \varphi \) satisfies the above conditions, so it is a universal homeomorphism.

In particular, this applies to any base change of a field extension \( k'/k \) that is purely inseparable, because it is f.f. hence injective.

Proof: Cf. [Sta]0BRA. \( \square \)
4.2 Commutative Algebra II

Main references are [Sta].

1 Integral Extensions

Def. (4.2.1.1) [Totally Integrally Closed]. For two rings \( A \to B \), \( f \in B \) is called **almost integral** (or totally integral when almost mathematics is performed:) over \( A \) if \( f^n \) lies in a f.g. \( A \)-module of \( B \). It is clear that the elements of totally integral elements of \( B \) is a subring. And \( A \) is called **totally integrally closed** in \( B \) iff any \( f \in B \) totally integral over \( A \) is in \( A \).

Prop. (4.2.1.2). For a ring map \( \varphi : A \to B \), an element \( x \) is integral over \( A \) iff \( x \) is contained in a finite \( A \)-module in \( B \). In particular, the elements of \( B \) that are integral over \( A \) is a ring containing \( \varphi(A) \).

Proof: If \( x \) is integral, then \( \varphi(A)[x] \) is finite. If \( \varphi(A)[x] \) is finite, then there is a set of generators of polynomials in \( x \). Then for \( m \) large, \( x^m = \sum a_i f_i(x) \), so \( x \) is integral over \( A \).

Prop. (4.2.1.3) [Integral Extension of Field]. For \( A \subseteq B \), if \( B \) is integral over \( A \), then \( A \) is a field iff \( B \) is a field.

Proof: If \( A \) is a field, \( y^{-1} = -a_n^{-1}(y^{n-1} + \ldots + a_{n-1}) \in B \). If \( B \) is a field, \( x^{-1} = -(b_1 + b_2 x + \ldots + b_m x^{m-1}) \in A \).

Cor. (4.2.1.4). If \( B \) is integral over \( A \), then a prime \( p \subset B \) is maximal iff \( p \cap A \) is maximal.

Proof: Look at the integral extension \( A/(p \cap A) \to B/p \).

Prop. (4.2.1.5) [Going-Up]. Let \( A \to B \) integral. Then:

1. There is no inclusion relation between prime ideals of \( B \) lying over a fixed prime ideal of \( A \).
2. if \( A \subseteq B \), then the Spec map is surjective. In particular, for any \( p \subseteq A \), \( pB \cap A = p \).
3. The going-up holds. In particular, the Spec map of an integral ring map is closed, by (4.1.7.15).

Proof:

1. If \( p \cap A = p' \cap A = q \), localize at \( q \), then \( p, p' \) are both maximal ideals of \( B_q \) by (4.2.1.4), they cannot contain each other.
2. For any prime \( p \) of \( A \), since \( A_p \subseteq B_p \), \( B_p \neq 0 \), so it has a maximal ideal (4.1.1.5), and use (4.2.1.4).
3. for any prime ideal \( q \) of \( B \) and \( p = q \cap A \), replace \( A \to B \) by \( A/p \subseteq B/q \), then we can use 2.

2 Graded Rings

Cf. [Matsumura Ch11].

Def. (4.2.2.1) [Graded Rings]. A **graded ring** is a ring \( A = \bigoplus A_n \) that \( A_mA_n \subseteq A_{m+n} \). A **graded module** over a graded ring \( A \) is a module \( M = \bigoplus M_n \) that \( A_mA_n \subseteq M_{m+n} \).

Notice that often we mean \( \mathbb{Z}_{\geq 0} \)-graded rings when we say graded rings. For a \( \mathbb{Z}_{\geq 0} \)-graded ring \( A \), the subset \( A_+ = \bigoplus_{n=1}^\infty A_n \) is an ideal of \( A \), called the **irrelevant ideal**.
Def. (4.2.2.2) [Twisted Modules]. Let $A$ be a graded ring and $M$ a graded $A$-module, denote $M(n)$ the graded $A$-module s.t. $M(n)_m = M_{m+n}$.

Lemma (4.2.2.3). Let $A = \bigoplus_{n=0}^{\infty} A_n$ be a graded ring, then a set of homogenous elements $f_i \in A_+$ generate $A$ as an algebra over $A_0$ if and only if they generate $A_+$ as an ideal of $A$.

Proof: If $f_i$ generate $A$ as an algebra over $A_0$, then every element of $A_+$ is a polynomial in $f_i$ with constant coefficients in $A_0$, thus $f_i$ generates $A_+$ as an ideal. Conversely, if $f_i$ generate $A_+$ as an ideal, then for any homogenous element $f$ we can use induction on the degree of $f$ to show that $f$ is a polynomial in $f_i$. □

Prop. (4.2.2.4) [Noetherian Graded Rings]. A graded ring $A = \bigoplus_{n=0}^{\infty} A_n$ is Noetherian if and only if $A_0$ is Noetherian and $A_+$ is f.g. as an ideal of $A$.

Proof: If $A$ is Noetherian, then clearly $A_+$ is f.g. and $A_0 = A/A_+$ is Noetherian. Now if $A_+$ is f.g. as an ideal of $A$, then it is generated by f.m. homogenous elements $f_i$, so we see $f_i$ generates $A$ as an algebra over $A_0$, which means $A$ is a quotient of a polynomial ring over $A_0$, thus Noetherian by (4.1.1.40). □

Def. (4.2.2.5) [Homogenous Ideals]. Let $A_\bullet$ be a graded ring, then a homogenous ideal $I_\bullet$ of $A_\bullet$ is a ring that is generated by homogenous elements.

Prop. (4.2.2.6) [Equivalent definition of Homogenous Ideals]. Let $S_\bullet$ be a graded ring, then

- an ideal $I$ of $S_\bullet$ is homogenous iff it contains the degree $n$ part of each of its element for any $n$.
- The set of homogenous ideals of $S_\bullet$ is stable under sum, product, intersection and radical.
- A non-trivial homogenous ideal $I$ of $S_\bullet$ is a prime ideal iff for any homogenous elements $a, b$, if $ab \in I$, then $a \in I$ or $b \in I$.

Proof: 1: If $I$ contains the degree $n$ part of each of its element for any $n$, then clearly it is generated by homogenous elements. Conversely, if it is generated by homogenous elements, then any element $f = \sum a_i f_i$, where $f_i$ is homogenous. Then we can see $[f]_n = \sum [a_i]_{n-\deg f_i} f_i$ is also in $I$.

2: Use 1 and the definition. For radicals, we show $\sqrt{I}$ contains all its homogenous parts: if $f \in \sqrt{I}$, then $f^n \in I$ for some $n$, then we see that the minimal degree part $[f]_m$ of $f$ also satisfies $[f]_m^n \in I$, because $I$ contains the homogenous parts of each of its elements. Then we can use induction to show that all the homogenous parts of $f$ is in $\sqrt{I}$.

3: One direction is trivial, for the other, if $a = \sum a_i, b = \sum b_i$ satisfies $ab \in I$, and $a \notin I, b \notin I$, and $a_i, b_j$ homogenous. Let $i_0, j_0$ be the minimal numbers that $a_{i_0} \notin I, b_{j_0} \notin I$, then $a_{i_0} b_{j_0}$ is not in $I$, contradicting the fact $I$ is homogenous. □

Prop. (4.2.2.7). Let $R \to S$ be a homomorphism of graded rings, then the integral closure of $R$ in $S$ is a homogenous ideal of $S$.

Proof: Consider the base change $\varphi : R \otimes_{R_0} R_0[t, t^{-1}] \to S \otimes_{S_0} S_0[t, t^{-1}]$, where $\deg(t) = 0$, and the integral closure is denoted by $A$. Then there is an automorphism of $\varphi$: $s \mapsto t^{\deg s} \cdot s$. This automorphism thus preserves the integral closure. If $s = s_n + s_{n+1} + \ldots + s_m \in S$ is integral over $R$, to show each $s_i$ are integral over $S$. We may assume $n > 0$ because $s_0$ is clearly integral over $R_0$. 

Now we use induction on $m$. If $m > n$, consider $t^n s_n + \cdots + t^m s_m$ is also in $A$, we see $(t^m - t^i)s_i \in A$ by induction hypothesis.

Notice $S \subseteq S[t, t^{-1}]/(t^m - t^i - 1) = S[t]/(t^m - t^i - 1)$ is injective, and the image of $(t^m - t^i)s_i$ is $s_i$, which is integral over $R[t]/(t^m - t^i - 1)$, and this ring is finite over $R$, so $s_i$ is also integral over $R$. \hfill $\square$

**Proposition 4.2.2.8.** Let $A$ be a graded ring that is f.g. over $A_0$ and $M$ be a f.g. graded $A$-module, then each $M_n$ is a finite $S_0$-module.

**Definition 4.2.2.9 [Reductions of Graded Rings].** Let $S$ be a graded ring and $d \geq 1$, define $S^{(d)}$ the graded ring $\oplus_{n \geq 0} S_{nd}$. And for a graded $S$-module $M$, define $M^{(d)} = \oplus_{n \in \mathbb{Z}} M_{nd}$.

**Proposition 4.2.2.10.** If $S$ is a graded ring that is f.g. over $S_0$, then for $d$ sufficiently divisible, $S^{(d)}$ is generated by the degree 1 part over $S_0$.

**Proof:** Let $S$ be generated by homogeneous elements $f_1, \ldots, f_r$. Let $M = \text{lcm}(\deg(f_1), \ldots, \deg(f_r))$, then for any $f \in S_{Nm}$ and $N \geq r$, by pigeonhole principle, there are some $i$ s.t. $f_i^{M/\deg(f_i)} | f$. Thus any monomials of degree $nrM$ is a product of polynomials of degree $rM$. So $d = rM$ satisfies the hypothesis. \hfill $\square$

**Topology Defined by Ideals**

**Definition 4.2.2.11 [Filtrations on Graded Modules].** Let $A$ be a ring, $M$ a graded $A$-module, and $a$ be an ideal of $A$, an $a$-filtration of $M$ is a descending sequence of submodules $M = M_0 \supseteq M_1 \supseteq \cdots$ that $aM_n \subseteq M_{n+1}$. It is called a stable filtration iff there is an $N$ that $aM_n = M_{n+1}$ for $n \geq N$.

For an ideal $a \subseteq A$, there can be associated a graded ring $A^* = \oplus a^n$, and an $a$-filtration $M$ can be associated a graded module over $A^* : M^* = \oplus M_n$. When $A$ is Noetherian, then so is $A^*$, because it is a quotient of a polynomial ring over $A(4.1.1.40)$.

**Lemma 4.2.2.12.** If $A$ is a Noetherian ring and $M$ is a f.g. $A$-module that has a $a$-filtration $M_n$, then $M^*$ is f.g. over $A^*$ iff $M_n$ is a stable filtration.

**Proof:** As every $M_n$ is finite over $A$, if it is stable, then $M^*$ is generated over $A^*$ by all the generator of $M_n, n \leq N$, so it is f.g.. Conversely, if it is f.g., then it is clear that $M_n$ is a stable filtration. \hfill $\square$

**Proposition 4.2.2.13 [Artin-Rees].** For $A$ Noetherian and $I$ an ideal, let $N \subseteq M$ be finite $A$-modules, then if $M_n$ is a stable filtration of $M$, then $M_n \cap N$ is a stable filtration of $N$.

In particular, let $M_0 = I^n M$, then $I^n M \cap N = I^{n-r}(I^r M \cap N)$, hence the $I$-adic topology on $M$ induce the $I$-adic topology on $N$.

**Proof:** This is immediate from the lemma above, as $N^*$ is an $A^*$-submodule of $M^*$, and $A^*$ is Noetherian(4.2.2.11). \hfill $\square$

**Corollary 4.2.2.14 [Krull’s Intersection Theorem].** Notation as in(4.2.2.13), let $N = \bigcap I^n M$, then the $I$-adic topology on $N$ is trivial, by Artin-Rees, thus $IN = N$. So Nakayama tells us there is an element $a \in 1 + I$ that $aN = 0$. Thus if $I \subseteq \text{rad}(A)$ or $A$ is an integral domain, $N = 0$. This can be used to use induction to prove some theorem.

In particular, for any prime ideal $p$ containing $I$, use the above on $R_p$ shows $N_p = 0$. But also $N$ is f.g., so there exists an element $g \not\in p$ that $N_p = 0$. \hfill $\square$
Cor. (4.2.2.15) [Krull]. For a Noetherian, if \( I \subset \text{rad}(A) \) or \( A \) is a domain, then \( \bigcap_{n=1}^{\infty} I^n = 0 \).

Prop. (4.2.2.16). Notice for any ring \( A \) and a non-zero-divisor \( f \), if \( I = \bigcap_n f^n A \), then \( fI = I \), needless of the Noetherian property.

Proof: If \( x \in I \), \( x = fy \), because \( x \in f^n A \), \( fy = f^n t \) for some \( t \), so \( y = f^{n-1} t \), so \( f \in I \). Thus \( I = fI \).

Def. (4.2.2.17) [Hilbert-Serre]. Let \( A \) be a Noetherian graded ring with \( A_0 \) Artinian that \( A_+ \) is generated by \( A_1 \). For a f.g. graded \( A \)-module \( M = \bigoplus M_n \), we have \( l(M_n) \) is a numerical polynomial of \( n \) sufficiently large, called the Hilbert Polynomial. Its degree is the dimension of \( \text{Supp} M \subset \text{Proj}(A) \).

Proof: We prove by induction on the minimal number of generators of \( A_1 \) (it is finite by (4.2.2.4)). If it is 0, then \( M_n = 0 \) for \( n \) large and the result holds. Now choose \( x \in S_1 \) as one of the minimal set of generators, then the induction hypothesis applies to \( S/(x) \).

Firstly, if \( x \) acts nilpotently on \( M \), then we do induction on the minimal number \( r \) that \( x^r M = 0 \). If \( r = 1 \), then \( M \) is a module over \( S/(x) \) and the assertion holds. If \( r > 1 \), then we can find an exact sequence \( 0 \to M' \to M \to M'' \to 0 \) that \( M', M'' \) has smaller \( r \), then we have the desired result, because \( l \) is additive.

Next, if \( x \) doesn’t act nilpotently on \( M \), let \( M' \subset M \) is the largest submodule that \( x \) acts nilpotently, then there is an exact sequence \( 0 \to M' \to M \to M/M' \to 0 \). So we can assume multiplication by \( x \) is injective on \( M \).

Let \( \overline{M} = M/xM \), then for any \( d \), there are exact sequences
\[
0 \to M_d \xrightarrow{x} M_{d+1} \to \overline{M}_{d+1}.
\]
so \( l(M_{d+1}) - l(M_d) = l(\overline{M}_{d+1}) \). Then we finish by (20.1.2.15).

Cor. (4.2.2.18). Let \( k \) be a field, \( I \subset k[X_1, \ldots, X_n] \) be a non-zero graded ideal, and \( M = k[X_1, \ldots, X_n]/I \), then the numerical polynomial \( n \mapsto \dim_k(M_n) \) has degree \( < d - 1 \).

Proof: The numerical polynomial associated to \( k[X_1, \ldots, X_n] \) is \( n \mapsto \binom{n-1+d}{d} \), and for any non-zero homogenous element \( f \in I \) of degree \( e \), \( f \cdot k[X_1, \ldots, X_n]_{d-e} \subset I_d \); thus \( \dim_k(M_n) < \binom{n-1+d}{d} - \binom{n-e-1+d}{d-1} \), which means the numerical polynomial has degree \( < d - 1 \).

Prop. (4.2.2.19) [Hilbert Polynomial and Dimension]. For a Noetherian local ring \( A \), the Hilbert polynomial of a f.g. module \( M \) w.r.t \( m \) has degree \( \dim M \). And \( \dim M \) is the smallest integer \( r \) s.t. there exists \( x_1, \ldots, x_r \) that \( l(M/x_1 M + \ldots, x_r M) < \infty \).

Proof: Cf. [Mat P76].

3 Completions

This subsubsection should be combined with the derived completion.

Prop. (4.2.3.1). Let the topology on a \( A \)-module be defined by countable filtration of submodules, then iff \( M \) is complete, then \( M/N \) is complete in the quotient topology.

Proof: Write \( x_{i+1} - x_i = y_i + z_i \) with \( y_i \in M_n \) and \( z_i \in N \), then the image of the limit of \( \sum y_i \) is the limit of \( x_i \).
Def. (4.2.3.2) [Completeness]. Let \( I \) be an ideal of \( R \), the \( I \)-adic completion of a \( R \)-module is a functor \( \varphi : M \mapsto \hat{M} = \lim M/I^nM. \) An \( R \)-module is called \( I \)-adically complete if the natural map \( M \mapsto \hat{M} \) is an isomorphism.

This is compatible with the general notion of completion of a topological Abelian groups (10.3.1.5).

Prop. (4.2.3.3). Let \( R \) be a ring and \( I \subset R \) be an ideal, \( \varphi : M \rightarrow N \) be a map of \( R \)-modules. Then
- If \( M/I^2M \rightarrow N/I^2N \) is surjective, then \( \hat{M} \rightarrow \hat{N} \) is surjective. In particular, this holds for \( M \rightarrow N \) surjective.
- If \( 0 \rightarrow K \rightarrow M \rightarrow N \rightarrow 0 \) is exact and \( N \) is flat, then \( 0 \rightarrow \hat{K} \rightarrow \hat{M} \rightarrow \hat{N} \rightarrow 0 \) is exact.
- \( M \otimes_R \hat{R} \rightarrow \hat{M} \) is surjective for any finite \( R \)-module \( M \).

Proof: Cf. [Sta] 0315. \( \square \)

Prop. (4.2.3.4). Let \( I \) be a f.g. ideal of \( A \) and \( M \) an \( A \)-algebra, then \( \hat{M} \) is \( I \)-adically complete and \( \hat{I}^n\hat{M} = \ker(\hat{M} \rightarrow M/I^nM) = (I^nM)^\wedge \).

Proof: Because \( I \) is f.g., so does \( I^n \). If \( I^n = (f_1, \ldots, f_r) \). Applying (4.2.3.3) to \((f_1, \ldots, f_r) : M^r \rightarrow I^nM\) shows
\[
\hat{M}^r \rightarrow (I^nM)^\wedge = \lim_{n \geq n} I^nM/I^nM = \ker(\hat{M} \rightarrow M/I^nM)
\]
but the image is clearly \( I^n\hat{M} \), so \( \hat{M}/I^n\hat{M} \cong M/I^nM \). Taking inverse limit yields \((M^\wedge)^\wedge = M^\wedge \). \( \square \)

Cor. (4.2.3.5) [Completion is Complete]. Let \( I \) be a f.g. ideal of \( A \) and \( (M_n) \) an inverse system of \( A \)-modules that \( I^nM_n = 0 \), then \( M = \lim M_n \) is \( I \)-adically complete.

Proof: We have maps \( M \rightarrow M/I^n \rightarrow M_n \), taking limit, we get \( M \rightarrow \hat{M} \rightarrow M \), so \( M \) is a direct summand of \( \hat{M} \). Since \( \hat{M} \) is \( I \)-adically complete by (4.2.3.4), so does \( M \). \( \square \)

Prop. (4.2.3.6). If \( I \) is a f.g. ideal of \( A \) and \( (M_n) \) is an inverse system of \( A \)-modules that \( M_n = M_{n+1}/I^nM_{n+1} \), then \( M = \lim M_n \) is \( I \)-adically complete and \( M/I^nM = M_n \).

Proof: \( \hat{M} \) is \( I \)-adically complete by (4.2.3.5), and \( M \rightarrow M_n \) are all surjective because the transition maps are surjective. Consider the inverse system \( N_n = \ker(M \rightarrow M_n) \). Since \( M_n = M_{n+1}/I^nM_{n+1} \), the map \( N_{n+1} + I^nM \rightarrow N_n \) is surjective, and thus \( N_{n+1}/(N_{n+1} \cap I^{n+1}M) \rightarrow N_n/(N_n \cap I^nM) \) is surjective.

Taking the inverse limit of the exact sequences
\[
0 \rightarrow N_n/(N_n \cap I^nM) \rightarrow M/I^nM \rightarrow M_n \rightarrow 0,
\]
we get an exact sequence
\[
0 \rightarrow \lim N_n/(N_n \cap I^nM) \rightarrow \hat{M} \rightarrow M.
\]
As \( M \) is \( I \)-adically complete, \( \hat{M} = M \), thus \( \lim N_n/(N_n \cap I^nM) = 0 \), thus \( N_n/(N_n \cap I^nM) = 0 \) for any \( n \) as \( n \) the transition maps are surjective. Then \( M/I^nM = M_n \), as desired. \( \square \)

Cor. (4.2.3.7) [Spectrum Map of Completions]. \( \text{Spec } R^\wedge \rightarrow \text{Spec } R \) has image \( \text{Spec } R/I \subset \text{Spec } R \). This follows from (4.2.3.18) and \( R/I \cong R^\wedge/I \).
\textbf{Prop.(4.2.3.8).} If $I$ is an ideal of $R$ and $0 \to M \to N \to Q \to 0$ is an exact sequence that $Q$ is annihilated by a power of $I$, then completion produces an exact sequence

$$0 \to \widehat{M} \to \widehat{N} \to Q \to 0$$

\textit{Proof:} If $I^n Q = 0$, then $Q/I^n Q = Q$ cor $n \geq c$, and $I^n M \subset M \cap I^n N \subset I^{n-c} M$ because of this. Then $\widehat{M} = \varprojlim M/(M \cap I^n N)$ by (3.1.1.41), and we apply (4.3.3.2) to the inverse system of exact sequences

$$0 \to M/(M \cap I^n N) \to N/I^n N \to Q \to 0$$

to conclude. \hfill $\Box$

\textbf{Cor.(4.2.3.9).} If $A$ is a ring with a nonzero-divisor $t$ and there is an exact sequence $0 \to M \to N \to Q \to 0$ of $A$-modules that $IQ = 0$, then $M$ is $t$-adically complete iff $N$ is $t$-adically complete.

\textit{Proof:} Use snake lemma. \hfill $\Box$

\textbf{Cor.(4.2.3.10).} Take $I = (f)$ and $M = N = R$, then we see that if $t$ is a nonzero-divisor in $R$ then $t$ is a nonzero-divisor in $R$.

\textbf{Prop.(4.2.3.11).} \textit{The completion of a submodule $N \subset M$ is the closure of} $\varphi(N)$ \textit{(By direct construction). The completion of} $M/N$ \textit{is} $M^*/N^*$ \textit{because it is right exact.}

\textbf{Cor.(4.2.3.12).} If $N$ is open in $M$ then $M/N \cong M^*/N^*$ because $M/N$ is discrete hence complete.

\textbf{Prop.(4.2.3.13).} If $A$ is Noetherian and $M$ is finite $A$-module, then the natural map $M \otimes_A A^* \to M^*$ is an isomorphism (use $M$ is finite presentation and tensor & completion is right exact), and five lemma.

\textbf{Cor.(4.2.3.14).} If $A$ is Noetherian, $A \to A^\wedge$ is flat (because flatness is check for finite module).

And when $A$ is complete Hausdorff, any finite module $M$ is complete Hausdorff and hence any its submodule is complete thus closed in it. Hence the the completion of a submodule $N \subset M$ is $\varphi(N)A^*$ in $M^*/MA^*$. In fact this implies complete Hausdorff adic-ring is Zariski.

\textbf{Remark(4.2.3.15).} WARNING: If $A$ is not Noetherian, in general $A \to A^\wedge$ is not flat, Cf.[Sta]0AL8.

\textbf{Lemma(4.2.3.16).} Let $A$ be a ring and $I = (f_1, \ldots, f_r)$ be a f. g. ideal. If $M \to \varprojlim M/f_i^n M$ is surjective for each $i$, then $M \to \varprojlim M/I^n M$ is also surjective.

\textit{Proof:} Note that $\varprojlim M/I^n M = \varprojlim M/(f_1^n, \ldots, f_r^n)M$, as $I^n \subset (f_1^n, \ldots, f_r^n) \subset I^n$, and elements in $\varprojlim M/(f_1^n, \ldots, f_r^n)M$ can be written as an infinite sum $\xi = \sum_n \sum_i f_i^n x_{n,i}$. There is an element $x_i$ mapping to $\sum_n f_i^n x_{n,i}$ for any $i$, thus $\sum x_i$ maps to $\xi$. \hfill $\Box$

\textbf{Lemma(4.2.3.17).} Let $A$ be a ring and $I \subset J$ be ideals, if $M$ is $J$-adically complete and $I$ is f.g., then $M$ is $I$-adically complete.

\textit{Proof:} It is clearly $I$-adically Hausdorff, and for completeness, by (4.2.3.16) it suffices to show for $I = (f)$: Let $x_n \in M$ with $x_n - x_{n+1} \in f^n M$, then $\{x_n\}$ is $J$-adically Cauchy, thus there is an element $x$ that $x - x_n \in J^n$, and we can replace $x_n$ by $x_n - x$ to assume $x_n \in J^n$. Now we prove $x_n \in (f^n)$: Assume $x_n - x_{n+1} = f^n z_n$, then

$$x_n = f^n (z_n + f \sum_{i=1}^{n+1} z_i)$$

This equation is true because it is $J$-adically Cauchy. \hfill $\Box$
**Properties of Complete Rings**

**Prop. (4.2.3.18).** If $A$ is $I$-adically complete, then $I \subset \text{rad} A$.

**Prop. (4.2.3.19).** Let $A$ be a ring with a non-zero-divisor $t$, then any limit of $t$-adically complete algebras is $t$-adically complete.

**Proof:** Check the definition directly. \qed

**Prop. (4.2.3.20) [Zariski Rings].** A Noetherian $I$-adic ring is called **Zariski ring** if it satisfies the following equivalent conditions:

- Every finite module is Hausdorff in the $I$-adic topology.
- Every submodule in a finite module is closed in the $I$-adic topology.
- Every ideal is closed.
- $I \subset \text{rad} A$.
- $A^\wedge \triangleleft A$ is f.f.

Hence every complete Hausdorff ring is Zariski.

**Proof:**

1 $\rightarrow$ 2: Apply it to the submodule $M/N$.

3 $\rightarrow$ 4: If $I \not\subseteq m$, then $I^n + m = A$, thus $\overline{M} = A$, contradiction.

4 $\rightarrow$ 1: by intersection theorem (4.2.2.14).

4 $\rightarrow$ 5: for any maximal ideal $m$, $I \subset m$ so it is open, thus $A^*/mA^* = A/m \neq 0$ by (4.2.3.12) thus f.f. by (4.4.1.5).

5 $\rightarrow$ 1: by (4.4.1.21), for any $m$ maximal, there is a maximal ideal $m'$ lying over $m$, so $IA^* \subset m^*$ by (4.2.3.14), thus $I \subset m$, hence $I \subset \text{rad} A$. \qed

**Cor. (4.2.3.21).** In a Zariski ring $A$, maximal ideals are open, thus $A/m \cong A^*/mA^*$ by (4.2.3.12), thus Spec $A^* \rightarrow$ Spec $A$ is bijection on closed pt.

**Prop. (4.2.3.22) [Cohen Structure Theorem].** If $A$ is a complete local ring containing a field $k$ that the residue field is separably generated over $k$, then there is a field $K$ containing $k$ that is a Cohen ring, i.e. complete local ring with a prime number as a uniformizer, that has the same residue field as $A$.

**Proof:** \qed

**Lemma (4.2.3.23) [Complete Interchanging Lemma].** If $R$ is a commutative ring, $x, y \in R$, if $x$ is not a zero-divisor in $R$ and $R$ is $x$-adically complete, and $y$ is not a zero-divisor in $R/x$ and $R/x$ is $y$-adically complete, then the same is true with $x, y$ interchanged.

**Proof:** \qed

4 Dimension

**Def. (4.2.4.1) [Dimensions and Heights].** For a $A$-module $M$, $\text{dim}(M)$ is defined as $\text{dim}(A/\text{Ann}(M))$.

The **height** of an ideal $I$ in $A$ is defined as the infimum of heights of the prime ideals over $I$.

The **dimension** of a ring $R$ is defined to be the supremum of heights of prime ideals of $R$.

**Prop. (4.2.4.2).** For any ring $A$ $\text{dim} A = \sup \text{dim} A_p$. 

Def. (4.2.4.3) [Catenary Rings]. \( A \in \mathcal{C}	ext{Alg} \) is called **catenary** if for any pair of primes \( p \subset q \subset A \), any maximal chain of primes \( p = p_0 \subset p_1 \subset \ldots \subset p_e = q \) has the same length. A Noetherian ring is called **uniformly catenary** if all f.g. algebras over it are catenary.

Prop. (4.2.4.4). \( A \in \mathcal{C}	ext{Alg} \) is catenary iff \( \text{Spec} \ A \) is a catenary space (3.8.3.34).

Prop. (4.2.4.5). Any quotient ring and localization of a (uniformly)catenary ring is catenary. Any quotient of a Noetherian uniformly catenary ring is uniformly catenary. Catenary and uniformly catenary are stalkwise properties (4.1.4.2).

Prop. (4.2.4.6). If \( (A, m) \) is a Noetherian local ring, then \( A \) is catenary iff \( p \to \dim(A/p) \) is a dimension function on \( \text{Spec} \ A \).

Proof: This follows from (3.8.4.13)(3.8.3.39) and (3.8.3.37).

Example (4.2.4.7) [Uniformly Catenary Rings]. The following are same examples of uniformly catenary Rings:

- A f.g. algebra over a uniformly catenary ring.
- A Noetherian C.M. rings.
- 1-dimensional Noetherian domains,
- Fields.

Proof: Cf. [Sta]00NM.?

Def. (4.2.4.8) [Hilbert Polynomials]. Let \( (A, m) \) be a Noetherian local ring, \( I \) an ideal of definition, then

**Dimension of Noetherian Local Rings**

Prop. (4.2.4.9). For a Noetherian local ring \( R \), the following three numbers are equal:

- \( \dim R \).
- \( d(R) \).
- the minimal number of elements needed to generate an ideal of definition of \( R \) (4.1.1.11).

A **system of parameters** is \( d \) elements \( g_1, \ldots, g_d \) that generate an ideal of definition of \( R \), where \( d = \dim R \).

Proof: Cf. [Sta]00KQ.?

Cor. (4.2.4.10). The dimension of a Noetherian local ring is finite, by item 3. Thus the codimension of a subscheme in a Noetherian scheme is finite.

Cor. (4.2.4.11). If \( A \) is a Noetherian local ring with maximal ideal \( \mathfrak{m} \), then \( \dim A \leq \dim_k \mathfrak{m}/\mathfrak{m}^2 \).

Proof: By Nakayama, if \( x_1, \ldots, x_d \in \mathfrak{m} \) generate \( \mathfrak{m}/\mathfrak{m}^2 \), then \( (x_1, \ldots, x_d) = \mathfrak{m} \).
4.2. COMMUTATIVE ALGEBRA II 387

Dimension and Ring Extensions

Prop. (4.2.4.12) [Dimension and Going-Up(Down)]. If \( A \to B \) is a ring map that Spec map is surjective and \( A \to B \) satisfies either going-up or going-down, then \( \text{dim } B \geq \text{dim } A \).

**Proof:** The hypothesis implies any chain of primes in \( A \) can lifted to a chain of primes in \( B \). \( \square \)

Prop. (4.2.4.13) [Dimensions and Noetherian Ring Extensions]. Let \( A \to B \) be a map between Noetherian rings, \( P \) a prime ideal of \( B \), \( p = P \cap A \), then:
- \( \text{ht}(P) \leq \text{ht}(p) + \text{ht}(P/pB) \), in other words \( \text{dim}(B_P) \leq \text{dim}(A_p) + \text{dim}(B_P/pB_P) \).
- equality holds if going-down holds. For example, if it is flat (4.1.7.13).

**Proof:**
1: Localize at \( p \) and \( P \), we may assume \( A, B \) are local rings with maximal ideals \( p \) and \( P \), then use the characterization (4.2.4.9) of dimension, if \( x_1, \ldots, x_d \) generate an ideal of definition of \( A_p \) and \( y_1, \ldots, y_e \) generate an ideal of definition of \( B_P/pB_P \), then \( x_1, \ldots, x_d, y_1, \ldots, y_e \) generate an ideal of definition of \( B_P \).
2: If going down holds, for any chain of primes in \( B_P \) containing \( pB_P \), we can lift the chain of primes in \( A_p \) to a chain of primes in \( B_P \) to get a longer chain, thus we get the other direction of inequality. \( \square \)

Prop. (4.2.4.14) [Dimension of Integral Extensions]. Let \( A \to B \) be an integral ring map, then:
1. Spec maps closed points to closed points, and \( \text{dim } (A) \geq \text{dim } (B) \), which equality if \( A \subset B \).
2. If \( A, B \) is Noetherian, \( \text{ht}(P) \leq \text{ht}(P \cap A) \)
3. If \( A, B \) is Noetherian and going down holds, then \( \text{ht}(J) = \text{ht}(J \cap A) \) for any ideal \( J \subset B \).

**Proof:**
1: By (4.2.4.5), there is no inclusion relation between prime over a fixed prime, so \( \text{dim } (B) \leq \text{dim } (A) \). On the other hand, if \( A \subset B \), then Spec map is surjective going-up holds (4.2.4.12), so \( \text{dim } (B) \geq \text{dim } (A) (4.2.4.12) \).
2: Follows from (4.2.4.13)(1) since \( \text{ht}(P/(P \cap A)B) = 0 \) by (4.2.4.15).
3: In this case, \( \text{ht}(P) = \text{ht}(P \cap A) \) holds by (4.2.4.13)(2), then use the surjectiveness of Spec for the integral extension \( A/J \cap A \subset B/J (4.2.4.15) \). \( \square \)

Cor. (4.2.4.15). If \( A \to B \) is integral and faithfully flat, then \( \text{dim } A = \text{dim } B \).

**Proof:** This follows from (4.2.4.14) and (4.4.1.28). \( \square \)

Prop. (4.2.4.16) [Dimension and Completion]. For a local ring \( A \), \( \text{dim } \hat{A} = \text{dim } A \).

**Proof:**

Noetherian Normalization

Prop. (4.2.4.17). For a Noetherian ring \( A \), \( \text{dim } A[X] = \text{dim } A + 1 \).

**Proof:** Let \( \mathfrak{p} \) be a prime ideal of \( A \) and let \( \mathfrak{q} \) be a prime ideal of \( A[X] \) maximal among primes lying over \( \mathfrak{p} \), then \( \text{ht}(\mathfrak{q}/\mathfrak{p}A[X]) = 1 \). In fact, by localizing, we can assume \( \mathfrak{p} \) is a maximal ideal, then \( A[x]/\mathfrak{p}A[x] \) is a polynomial ring over a field thus a PID and \( \text{ht}(\mathfrak{q}/\mathfrak{p}A[X]) = 1 \). Thus \( \text{ht}(\mathfrak{q}) = \text{ht}(\mathfrak{p}) + 1 \) by (4.2.4.13). Now we are done, because \( \text{Spec } A[X] \to \text{Spec } A \) is surjective. \( \square \)
Prop. (4.2.4.18) [Krull’s Height Theorem]. In a Noetherian domain \( R \), the height of an ideal generated by \( n \) elements is at most \( n \).

\textit{Proof:} Let \( p \) be a minimal ideal containing \( (f_1, \ldots, f_n) \), then it suffices to show \( \dim(R_p) \leq n \). In this case, \( (f_1, \ldots, f_n) \) is an ideal of definition of \( R_p \), thus we can use (4.2.4.9). \( \square \)

Prop. (4.2.4.19) [Number of Generators]. To show an ideal \( I \subset A \) cannot be generated by smaller than \( n \) element, choose a maximal ideal \( m \), then show that \( \dim_{A/m} I/mI \geq n \).

Cor. (4.2.4.20).
- \((x, z)\) is not principal in \( k[x, y, z] \).
- \((wz - xy)\) is not principal in \( k[x, y, z] \).
- \((xy, yz, xz)\) is not generated by two elements in \( k[x, y, z] \).

Lemma (4.2.4.21). Let \( A = k[X_1, \ldots, X_n] \) be a polynomial ring over a field \( k \), and \( I \) is an ideal of \( A \) of height \( r \), then we can choose \( Y_1, \ldots, Y_n \in A \) that \( A \) is integral over \( k[Y_1, \ldots, Y_n] \) and \( I \cap k[Y_1, \ldots, Y_n] = (Y_1, \ldots, Y_r) \).

\textit{Proof:} We use induction on \( r \). \( r = 0 \) is easy. For \( r = 1 \), let \( f(X) \) be any non-zero polynomial in \( I \), then we can assign suitable integral weights \( d_1, d_2, \ldots, d_n \) to \( X_i \) such that monomials of \( f \) have different weights. Put \( Y_i = X_i - X_1^{d_i} \) for \( i \geq 2 \), and

\[ Y_1 = f(X) = f(X_1, Y_2 + X_1^{d_2}, \ldots, Y_n + X_1^{d_n}) = a_1X_1^N + g(X_1, Y_2, \ldots, Y_n) \]

where \( g \) has degree in \( X_1 \) lower that \( N \). Then \( X_1 \) is integral over \( k[Y_1, \ldots, Y_n] \), and hence \( X_1 = Y_1 + X_1^{d_1} \) is also integral over \( k[Y] \).

Now \((Y_1)\) is a prime ideal in \( k[Y] \) of height 1 and \( (Y_1) \in I \cap k[Y] \). Also notice \( I \cap k[Y] \) has height 1 by (4.2.4.14) (Because going-down holds by (4.1.7.17)), so \( (Y_1) = I \cap k[Y] \).

For \( r \geq 2 \), let \( J \subset I \) be an ideal with height \( r - 1 \), let \( J \) be an ideal of \( k[X] \) contained in \( I \) that \( \text{ht}(J) = r - 1 \). (This is possible by choosing \( f_i \) out of all minimal primes containing \((f_1, \ldots, f_{r-1})\) and use Krull’s Height Theorem). By induction hypothesis, there exists \( Z_1, \ldots, Z_n \) that \( k[X] \) is integral over \( k[Z] \), and \( J \cap k[Z] = (Z_1, \ldots, Z_{r-1}) \). Now \( \text{ht}(I \cap k[Z]) = r \) by the same argument above, thus there exist \( f \in I \cap k[Z] \setminus (Z_1, \ldots, Z_{r-1}) \), and do the same for \( r = 1 \) again, we can find the desired \( Y_i \) that \( Y_k = Z_k \) for \( k \leq r - 1 \). \( \square \)

Prop. (4.2.4.22) [Noetherian Normalization Theorem]. If \( A \) is a f.g. algebra over a field, then there are \( r \) alg. independent elements \( y_i \) that \( A \) is integral over \( k[y_i] \).

\textit{Proof:} Let \( A = k[X_1, \ldots, X_n]/I \) and \( \text{height}(I) = n - r \), then by the lemma we can choose \( Y_1, \ldots, Y_n \) that \( k[X_1, \ldots, X_n] \) is integral over \( k[Y_1, \ldots, Y_n] \) (so \( Y_1, \ldots, Y_n \) are algebraically independent) and \( I \cap k[Y_1, \ldots, Y_n] = (Y_{r+1}, \ldots, Y_n) \). Now we can just choose \( y_i = Y_i \) for \( i \leq r \). \( \square \)

Cor. (4.2.4.23) [Dimension and Transcendental Degree]. If \( A \) is a f.g. integral ring over a field \( k \), then \( \dim A = \text{tr.deg}_k A \).

\textit{Proof:} This is because integral extensions of integral Noetherian rings have the same dimensions (4.2.4.14) and their fraction fields have the same transcendental degrees. \( \square \)

Cor. (4.2.4.24). Let \( A, B \) be f.g. algebras over a field \( k \), then \( \dim(A \otimes_k B) = \dim A + \dim B \).
Cor. (4.2.4.25) [Dimension and Field Base Change]. Let $K/k$ be a field extension and $S$ a f.g. algebra over $k$, then $\dim S = \dim S \otimes_k K$.

Proof: By Noetherian normalization, there exists a finite injective map $k[d_1, \ldots, d_n] \to S$ where $n = \dim S$. Then there exists a finite injective map $K[d_1, \ldots, d_n] \to S_K$, so $\dim S \otimes_k K = n$, by (4.2.4.14) and (4.2.4.17).

Prop. (4.2.4.26) [Codimensions and Field Base Change]. Let $K/k$ be a field extension and $S$ a f.g. $k$-algebra. Let $\mathfrak{a}$ be a prime of $S$ and $q_K$ be a prime of $S_K$ lying over $\mathfrak{a}$, then

$$\dim(S_K \otimes_S k(q))_{q_K} = \dim(S_K)_{q_K} - \dim S_{\mathfrak{a}} = \deg k(q) - \deg k(q_K).$$

Moreover, for any $\mathfrak{a}$, we can choose $q_K$ so that this number is 0.

Proof: Cf.[Sta]0CWE.

Local Dimension over Fields

Prop. (4.2.4.27) [Local Dimension]. Let $S$ be an algebra f.g. over a field $k$, $X = \Spec S$ and $x \in X$, then the following three numbers are equal:

- the local dimension (3.8.3.25) $\dim_x(X)$.
- $\max \dim (Z)$ where $Z$ runs through irreducible components of $X$ passing through $x$.
- $\min \dim(S_m)$, where $m$ are maximal ideals containing $\mathfrak{p}_x$.

Proof: Cf.[Sta]00OT.

Lemma (4.2.4.28). Let $k$ be a field and $S$ a f.g. $k$-algebra, $X = \Spec S$, $x \in X$, then

$$\dim_x(X) = \dim S_{\mathfrak{p}} + \deg k(\mathfrak{p}).$$

Proof: Cf.[Sta]00P1.

Cor. (4.2.4.29). Let $S' \to S$ be a surjection of f.g. algebras over a field $k$, $\mathfrak{p}$ a prime ideal of $S$ and $\mathfrak{p}'$ its inverse image in $S'$, corresponding to $x, x'$ in $X = \Spec S, X' = \Spec S'$ resp., then

$$\dim_{x'}(X') - \dim_x(X) = \ht(\mathfrak{p}') - \ht(\mathfrak{p}).$$

Def. (4.2.4.30) [Relative Dimension]. Let $R \to S$ be a ring map of f.t., and $\mathfrak{a} \subseteq S$ be a prime over $\mathfrak{p} \subseteq R$, then we define the relative dimension of $S/R$ at $\mathfrak{a}$ to be $\dim_{\mathfrak{a}}(\Spec S)_{\mathfrak{p}}$. The supremum of all these numbers over $\mathfrak{a} \subseteq \Spec S$ is called the relative dimension of $S/R$, denoted by $\dim(S/R)$.

Lemma (4.2.4.31) [Local Dimension and Field Extension]. Let $K/k$ be a field extension, $S$ be a f.g. $k$-algebra, and $X = \Spec S$. Now if $\mathfrak{p}_K$ is an element of $S_K$ lying over $\mathfrak{p} \subseteq S$, then $\dim S_{\mathfrak{p}} = \dim_{\mathfrak{p}_K}(S_K)$.

Proof: The proof is by reduction to polynomial ring. Let $S = k[X_1, \ldots, X_n]/I$, let $\mathfrak{p}_K', \mathfrak{p}'$ be primes of $k[X_1, \ldots, X_n]$ and $K[X_1, \ldots, X_n]$ that is the image of $x$ and $x_K$, then there is a commutative diagram

$$
\begin{array}{ccc}
K[X_1, \ldots, X_n]_{\mathfrak{a}_K} & \longrightarrow & (S_K)_{q_K} \\
\downarrow & & \downarrow \\
k[X_1, \ldots, X_n]_{\mathfrak{a}_K} & \longrightarrow & S_{\mathfrak{a}}
\end{array}
$$
The vertical arrows are flat because they are local morphisms of flat maps, and their fibers are the same, so by (5.6.3.17), \( \text{ht}(q_K') - \text{ht}(q_K) = \text{ht}(q) - \text{ht}(q) \). Also use (4.2.4.29) on the horizontal maps, then we get the desired assertion. □

Prop. (4.2.4.32) [Semicontinuity of Dimensions]. Let \( f : R \to S \) be a ring map of f.t., then the map \( q \mapsto \dim_S(S\langle R) \) is a upper-semicontinuous function on \( \text{Spec}(S) \).

Moreover, if \( f \) is of f.p., then the set \( \{ q | \dim_S(S\langle R) \leq n \} \) is quasi-compact open in \( \text{Spec}(S) \).

Proof: Cf. [Sta]00QH, 00QJ. □

5 Support and Associated Primes

Def. (4.2.5.1) [Support of a Module]. The support \( \text{Supp}(M) \) of a module \( M \) is the set of all \( p \) that \( M_p \neq 0 \). When \( M \) is f.g., \( \text{Supp}(M) = V(\text{Ann}(M)) \).

Prop. (4.2.5.2) [Support is Non-Empty]. The support of a nonzero module is not empty, because triviality is stalkwise by (4.1.4.2).

Prop. (4.2.5.3). If \( 0 \to N \to M \to Q \to 0 \), then we have \( \text{Supp}(M) = \text{Supp}(N) \cup \text{Supp}(Q) \), this is because localization is exact.

Cor. (4.2.5.4).

Prop. (4.2.5.5). Let \( (R, m) \) be a Noetherian local ring and \( M \) a finite \( R \)-module, \( f \in m \), then
\[
\dim \text{Supp}(M) - 1 \leq \dim(\text{Supp}(M/fM)) \leq \dim(\text{Supp}(M))
\]

Proof: Cf. [Sta]0B52. □

Prop. (4.2.5.6). Let \( 0 = M_0 \subset M_1 \subset \ldots \subset M_n = M \) be a filtration of \( M \) that \( M_i/M_{i-1} \cong R/p_i \) where \( p_i \) are primes, by (4.1.1.45), then \( \text{Supp}(M) = \cup_i V(p_i) \).

In particular, the minimal primes in \( \{ p_i \} \) are the same as the minimal primes of \( \text{Supp}(M) \). Moreover, the multiplicity of a prime \( p_i \) equals \( \text{length}_{R/p_i} M_p \).

Proof: Cf. [Sta]00L7. □

Prop. (4.2.5.7). Let \( (R, m) \) be a Noetherian local ring and \( M \) a non-zero finite \( R \)-module, then \( \text{Supp}(M) = V(m) \) iff \( \text{length}_R(M) < \infty \).

Proof: Cf. [Sta]00L5. □

Prop. (4.2.5.8). Let \( A \) be Noetherian and \( I \) be an ideal, then \( I^n M = 0 \) for some \( n \) iff \( \text{Supp}(M) \subset V(I) \).

Proof: If \( I^n M = 0 \), then if \( I \nsubseteq P \), then \( M_P = 0 \). Conversely, we have a filtration of \( M \), and by (4.2.5.3) we have all the \( P_i \) include \( I \), so \( I^n \) annihilate \( M \). □

Prop. (4.2.5.9). If \( R \) is a ring and \( M \) is a f.p. \( R \)-module, then \( \text{Supp}(M) \) is a closed subset of \( \text{Spec} R \) whose complement is quasi-compact.

Proof: Let \( R^m \to R^n \to M \to 0 \), then the support of \( M \) is just the the locus that some minor of the linear map from \( R^m \to R^n \) doesn’t vanish. Then its complement is quasi-compact. □
Prop. (4.2.5.10). Let \((R, \mathfrak{m})\) be a Noetherian local ring and \(M\) is a finite \(R\)-module, then \(d(M) = \dim(\text{Supp}(M))\).

Proof: Cf.[Sta]00L8.

Prop. (4.2.5.11). Let \(R\) be a Noetherian ring and \(0 \to M' \to M \to M'' \to 0\) be an exact sequence of finite \(R\)-modules, then \(\dim \text{Supp}(M) = \max(\dim \text{Supp}(M'), \dim \text{Supp}(M''))\).

Proof: Cf.[Sta]0B51.

Associated Primes of a Module

Def. (4.2.5.12) [Associated Primes of a Module]. The weakly associated primes \(\text{Ass}(M)\) of an \(A\)-module \(M\) is the set of minimal primes of \(A/\text{Ann}(m)\) for some \(m \in M\).

The associated primes \(\text{Ass}(M)\) is the set of primes \(\{p = \text{Ann}(m)\}\) where \(m \in M\).

Prop. (4.2.5.13). \(\text{Ass}_R(M) \subset \text{WeakAss}_R(M)\), and if \(R\) is Noetherian, the converse is also true.

Proof: Cf.[Sta]058A.

Prop. (4.2.5.14) [Associated Primes and Exact Sequence]. For an exact sequence \(0 \to M_1 \to M \to M_2 \to 0\), \(\text{WeakAsso}(M) \subset \text{WeakAsso}(M_1) \cup \text{WeakAsso}(M_2)\) and \(\text{WeakAsso}(M_1) \subset \text{WeakAsso}(M)\).

Proof: Cf.[Sta]0548?

Cor. (4.2.5.15) [F.M. Associated Primes]. For a finite module \(M\) over a Noetherian ring \(A\), \(\text{Ass}_A(M)\) is finite by (4.1.1.45).

Prop. (4.2.5.16) [Associated Primes and Support]. \(\text{WeakAsso}(M) \subset \text{Supp} M\), and their minimal elements are the same.

If \(M \neq 0\), \(\text{WeakAsso}(M) \neq \emptyset\) by (4.2.5.2), and \(\text{WeakAsso}(A/I)\) contains all the minimal primes over \(I\).

Proof: If \(p = \text{Ann}(m)\), then \(m\) is nonzero in \(M_p\), so \(M_p\) is nonzero, i.e. \(p \in \text{Supp}(M)\).

For the second assertion, we first prove for \(M\) finite, and then write any module as sum of finite submodules, and use the fact \(\text{Supp}\) and \(\text{ass}\) are all unions of those of the submodules. Cf.[Sta]05C4 0588?

Prop. (4.2.5.17) [Weakly Associated Primes and Zero-divisors]. Let \(M\) a \(R\)-module, then the union of the weakly associated primes of \(M\) is the set of zero-divisors in \(M\).

Proof: Elements in associated points are zero-divisors obviously, and conversely, if \(xm = 0\), then \(x \in \text{Ann}(m)\) and \(\text{Ann}(m)\) has an associated point \(q\) by (4.2.5.16). Now \(x\) must be in \(q\) and \(q\) is also an associated point of \(M\) by (4.2.5.16). Cf.[Sta]05C3?

Cor. (4.2.5.18). Use the prime avoidance (4.1.1.4), we can prove if \(R\) is Noetherian and \(M\) is a finite \(R\)-module, then \(I \subset p\) for some \(p \in \text{WeakAss}(M)\) iff \(I\) consists of zero-divisors.
Prop. (4.2.5.19) [Associated Primes and Maps]. For a ring map \( \varphi : R \to S \) and a \( S \)-module \( M \), then
\[
\text{Spec}(\varphi)(\text{Ass}_S(M)) \subset \text{Ass}_R(M) \subset \text{WeakAss}_R(M) \subset \text{Spec}(\varphi)(\text{WeakAss}_S(M)).
\]
Equalities hold if \( S \) is Noetherian. Also \( \text{WeakAss}_R(M) = \text{Spec}(\varphi)(\text{WeakAss}_S(M)) \) if \( \varphi \) is a finite ring map.

Proof: Cf. [Sta] 05C7, 05E1.

We prove it is equal. If \( p = \text{Ann}_R(m) \), then we let \( I = \text{Ann}_S(m) \), then \( R/p \subset S/I \subset M \), so by (4.1.7.25), there is a minimal prime of \( S \) over \( I \) that are mapped to \( p \), now this prime is in \( \text{Ass}(S/I) \) by (4.2.5.16) and also in \( \text{Ass}_S(M) \) by (4.2.5.14).

Prop. (4.2.5.20) [Associated Primes and Localization]. Let \( \varphi : \text{Spec} S^{-1}A \to \text{Spec} A \) and \( M \) an \( A \)-module, then

\[
\text{Ass}_A(S^{-1}M) = \text{Spec}(\varphi)(\text{WeakAss}_{S^{-1}A}(S^{-1}M)) = \text{WeakAss}_A(M) \cap \varphi(\text{Spec}(S^{-1}R)).
\]

Proof: Cf. [Sta] 05C9?.

The first equality is by (4.2.5.19). For the second, if \( \text{Ann}_A(x) = p \) and \( p \cap S = \emptyset \), then \( \text{Ann}_{S^{-1}A}(x/1) = S^{-1}(p) \). Conversely, if \( \text{Ann}_{S^{-1}A}(x/s) = S^{-1}p \), then \( p \cap S = \emptyset \), and \( \text{Ann}_A(x) \subset S^{-1}p \cap A = p \).

Cor. (4.2.5.21) [Associated Primes are Stalkwise]. Let \( R \) be a ring and \( M \) an \( R \)-module, \( p \subset R \), then the following are equivalent:

- \( p \subset \text{WeakAss}(M) \).
- \( pR_p \subset \text{WeakAss}(M_p) \).
- \( M_p \) contains some element \( m \) that \( \sqrt{\text{Ann}(m)} = pR_p \).

Proof: 1 \( \to \) 2: \( p \) is a minimal prime of \( I = \text{Ann}(m) \) for some \( m \in M \), so \( I_p \) is the minimal prime of \( \text{Ann}(m) \subset R_p \).

2 \( \to \) 3: As \( pR_p \) is the maximal prime, it is the only prime over \( \text{Ann}(m) \), so \( pR_p = \sqrt{\text{Ann}(m)} \).

3 \( \to \) 1: This means there are some \( m \in M \) that \( \sqrt{I_p} = pR_p \), which means that \( p \) is a minimal prime over \( \text{Ann}(m) \).

Prop. (4.2.5.22). If \( M \) is an \( R \)-module, then \( M \to \prod_{p \subset \text{WeakAss}(M)} M_p \) is injective.

Proof: Cf. [Sta] 05CB.

If \( m \neq 0 \in M \), there is an associated prime \( p \) of \( Rm(4.2.5.16) \), then it is an associated prime of \( M \), and then \( (x)_p \subset M_p \) is not zero.

Def. (4.2.5.23) [Embedded Primes]. A non-minimal prime in \( \text{Ass}_R(M) \) is called a embedded prime. Equivalently, it is an associated point that is not a generic point of \( \text{Supp}(M) \).

Prop. (4.2.5.24). For a reduced ring \( R \), \( \text{WeakAss}_R(R) \) is just the set of minimal primes of \( R \).

Proof: Cf. [Sta] 0EMA.

Cor. (4.2.5.25) [Reduced Ring No Embedded Primes]. A reduced ring has no embedded primes, because it has no nilpotent elements. Hence all its associated primes are just the minimal primes.

Def. (4.2.5.26) [Unmixed Ideals]. \( I \) is called unmixed if primes in \( \text{Ass}(A/I) \) all have the same height. In particular, they don’t contain each other.
Primary Decomposition

**Def.** (4.2.5.27). For $R$ Noetherian, a $R$-module $M$ is called **coprimary** iff it has only one associated primes. A submodule $N$ of $M$ is called **$p$-primary** iff $\text{Ass}(M/N) = \{p\}$. A ring is called **$p$-primary** iff $(0)$ is $p$-primary.

Notice coprimary is equivalent to the following: if $a \in A$ is a zero divisor for $M$, then for each $x \in M$, there is a $n$ that $a^n x = 0$, i.e. **locally nilpotent**. And for ideals in a Noetherian ring, this is equivalent to $r(I)$ is a prime.

**Proof:** If $M$ is $p$-primary, if $x \in M$ is nonzero, then $\text{Ass}(Rx) = \{p\}$, so $p$ is the unique minimal element of $\text{Supp}(Rx) = V(\text{Ann}(x))$ by (4.2.5.16). So $p$ is the radical of $\text{Ann}(x)$, i.e. $a^n x = 0$ for some $n$ (4.2.6.2).

Conversely, we know the ideal $p$ of locally nilpotent elements equals the union of the associated primes (4.2.5.17), so if $q \in \text{Ass}M = \text{Ann}(x)$, then by definition, $p \subseteq q$. So $p = q$, and thus $\text{Ass}M = \{p\}$.

**Lemma** (4.2.5.28). A primary ring has no nontrivial idempotent element, because $e$ and $1 - e$ will all belong to the same minimal ideal $p$.

**Lemma** (4.2.5.29). The intersection of $p$-primary submodules are $p$-primary. (Because there is a injection $M/Q_1 \cap Q_2 \to M/Q_1 \oplus M/Q_2$).

**Lemma** (4.2.5.30) [Associated Prime and Primary Decomposition]. If $N = \cap Q_i$ is an irredundant primary decomposition and if $Q_i$ belongs to $p_i$, then we have $\text{Ass}(M/N) = \{p_1, \ldots, p_r\}$.

**Proof:** There is a injection $M/N \to M/Q_1 \oplus \ldots M/Q_r$ which shows $\text{Ass}(M/N) \subseteq \{p_1, \ldots, p_r\}$. And for the inverse, notice $Q_2 \cap \ldots \cap Q_r/N$ is a submodule of $M/Q_1$, which shows $\text{Ass}(Q_2 \cap \ldots \cap Q_r/N) = \{p_1\}$ by (4.2.5.16).

**Prop.** (4.2.5.31). If $N$ is a $p$-primary submodule of a $R$-module $M$, and $p'$ is a prime ideal, then

- $N_{p'} = M_{p'}$ if $p \not\subseteq p'$.
- $N = M \cap N_{p'}$ if $p \subseteq p'$.

**Proof:** $M_{p'}/N_{p'} = (M/N)_{p'}$, and $\text{Ass}((M/N)_{p'}) = \text{Ass}(M/N) \cap \{\text{primes contained in } p'\} = \emptyset$ by (4.2.5.20). So $M_{p'} = M_{p'}$ by (4.2.5.16).

For the second, notice it suffices to show $M/N \to M_{p'}/N_{p'}$ is injective. But this is because $A - p'$ contains no nonzero-divisor, by (4.2.5.17).

**Cor.** (4.2.5.32) [Second Uniqueness of Primary Decomposition]. For an irredundant primary decomposition $N = \cap Q_i$, if $Q_1$ corresponds to $p_1$ and $p_1$ is minimal in $\text{Ass}(M/N)$, then $Q_1 = M \cap N_{p_1}$. In particular, the minimal prime part of a irredundant primary decomposition is uniquely determined.

**Proof:** By the above proposition, there are elements $u_i$ of $Q_i$, $i \neq 1$ that are mapped to units in $M_{p_1}$, so $Q_1 \cdot u_2 u_3 \ldots u_r$ is mapped onto the image of $Q_1 \to M_{p_1}$. Then $Q_1 = M \cap (Q_1)_{p_1} = M \cap N_{p_1}$.

**Prop.** (4.2.5.33). If $R$ is Noetherian and $M$ is a $R$-module, there are $p$-primary submodules $Q(p)$ for each $p \in \text{Ass}M$ that $(0) = \bigcap_{p \in \text{Ass}M} Q(p)$. 

Proof: For a $p \in \text{Ass}M$, we seek $Q(p)$ to be the maximal submodule $N$ that $p \notin \text{Ass}N$. This has a maximal ideal because of Zorn and the fact $\text{Ass}(\bigcup N_\lambda) = \bigcup \text{Ass}(N_\lambda)$. Then we have $\text{Ass}(M/Q(p)) = \{p\}$, otherwise there is another $p'$, then there is a $Q'/Q(p) \cong A/p'$. Now $Q'$ is bigger than $Q(p)$.

Finally, $(0) = \cap_{p \in \text{Ass}M} Q(p)$ because it has no associated primes. □

Cor. (4.2.5.34) [Primary Decomposition]. If $M$ is f.g. over a Noetherian ring $R$, then any submodule has a primary decomposition. (Notice $M$ has only f.m. associated primes).

Def. (4.2.5.35) [Symbolic Power]. For a prime ideal $p$ in a Noetherian ring, The $n$-th symbolic power $p^{(n)}$ is defined to be the $p$-primary component of $p^n$, who has only one minimal prime(hence one associated prime). The symbolic power is giving by $p^n A_p \cap A$ by (4.2.5.32).

6 Jacobson Radical and Nilradical

Nilradical

Def. (4.2.6.1) [Nilradical]. The nilradical of a commutative ring $R$ is defined to be the ideal consisting of nilpotent elements.

Prop. (4.2.6.2). The nilradical $\mathfrak{n}$ of a ring $A$ (4.2.6.1) is the intersection of all prime ideals.

Proof: Every nilpotent element is contained in every prime, and if $a$ is not nilpotent, then the localization $A_a$ is nonzero, hence there is a maximal ideal, i.e. there is a prime of $A$ not containing $a$. □

Cor. (4.2.6.3). In particular, $\text{Spec} A/\mathfrak{n} \to \text{Spec} A$ is a homeomorphism, and $A \to A/\mathfrak{n}$ induces a bijection on idempotents and units.

Jacobson Ring

Def. (4.2.6.4) [Jacobson Ring]. A commutative ring is called Jacobson if every prime ideal is an intersection of maximal ideals. In particular, the Jacobson radical equals the nilradical. This is equivalent to every radical ideal is an intersection of maximal primes.

Prop. (4.2.6.5). $R$ is Jacobson iff $\text{Spec} R$ is Jacobson space (3.8.3.21). In particular, the closed pts are dense in any closed subsets (Hilbert’s Nullstellensatz satisfied).

Proof: We need to show that a locally closed subset contains a closed pt, we assume this set is of the form $V(I) \cap D(f)$, $I$ is radical, then $f \notin I$, then by the condition, there is a $I \subset \mathfrak{m}$ that $f \notin \mathfrak{m}$, thus the result.

Conversely, for a radical ideal, let $J = \cap_{I \subset \mathfrak{m}} \mathfrak{m}$, then $J$ is radical and $V(J)$ is the closure of $V(I) \cap X_0$, $V(I) = V(J)$, and because they are both radical, $I = J$. □

Cor. (4.2.6.6). Being Jacobson is a local property, and quotient of Jacobson ring is Jacobson, and maximal ideals of $R_f$ are maximal in $R$. (Immediate from (4.2.6.5) (3.8.3.22) and (3.8.3.23)).

Prop. (4.2.6.7). If a Jacobson ring $A$ has f.m. maximal ideals, then it is the product of its localizations at maximal primes and $\dim A = 0$.

Proof: Any prime ideal $p$ is a finite intersection of maximal ideals, so it equals one of them, so $\dim A = 0$. Now $A/I = \oplus A/\mathfrak{m}_i$ by Chinese remainder theorem, so $\text{Spec} A/I$ is discrete with $n$ pts, so by (4.1.7.8) there are $n$ idempotents $e_i$ that $e_i \equiv \delta_{ij} \mod \mathfrak{m}_j$, $\sum e_i = 1$. Thus $R = \prod Re_i$. And $Re_i$ is just the localization at a maximal prime. □
Lemma (4.2.6.8). If \( R \) is a Jacobson domain and \( R \subset K \) where \( K \) is a field, and \( K \) is f.g. over \( R \), then \( R \) is a field and \( K/R \) is a finite field extension.

**Proof:** By induction, it suffices to consider the monogenic case \( A = R[a] \). So \( a \) is algebraic over quotient field of \( R \) because \( A \) is a field. Let \( \sum r_it^i \) be a polynomial satisfied by \( a \), and let \( \mathfrak{m} \) be a maximal ideal of \( R \) that \( r_n \notin R \)(exists because \( \text{rad } R = 0 \)). Then Nakayama says \( \mathfrak{m}A \notin A \). Then \( \mathfrak{m} = 0 \) because \( A \) is a field, hence \( R \) is a field. \( \square \)

Lemma (4.2.6.9). Let \( R \subset A \) be commutative domains s.t. \( A \) is f.g. over \( R \), then \( \text{rad } A = 0 \) if \( \text{rad } R = 0 \).

**Proof:** By induction, it suffices to consider the case \( A = R[a] \). If \( a \) is transcendental over quotient field of \( R \), then we finish by (2.4.2.12). Now assume \( a \) is algebraic over quotient field of \( R \), let \( \sum s_it^i, \sum t_it^i \) be the polynomials satisfied by \( a, b \) of minimal degrees, then \( s_0 = -\sum_{i=1}^{m} s_ib^i \neq 0 \in \text{rad } A \), and \( r_ns_0 \neq 0 \).

From the fact \( \text{rad } R = 0 \), we can find a maximal ideal \( \mathfrak{m} \) that \( r_ns_0 \notin \mathfrak{m} \). Then Nakayama says \( \mathfrak{m} \cdot S^{-1}A \notin S^{-1}A \).

In particular, \( \mathfrak{N} \notin A \). Choose a maximal ideal of \( A \) containing \( mA \), then it cannot contain \( s_0 \), contradicting \( s_0 \in \text{rad } A \). \( \square \)

**Prop. (4.2.6.10)** [Generalized Nullstellensatz]. If \( R \) is Jacobson and \( S \) is a finitely generated \( R \)-algebra, then:

- \( S \) is Jacobson.
- The maximal ideal of \( S \) intersect with \( R \) a maximal ideal, and the quotient ring extension is finite, (in particular algebraic).

In particular, a f.g. algebra over a ring of dimension 0, (e.g. Artinian ring or field) is Jacobson.

**Proof:** To show \( S \) is Jacobson, consider for any prime \( p \subset A \), \( A/p \) is a f.g. domain over \( R/p \cap R \). Because \( R \) is Jacobson, \( \text{rad}(R/p \cap R) = 0 \), so \( \text{rad}(A/p) = 0 \), by (4.2.6.9). And this shows \( A \) is Jacobson.

If \( \mathfrak{m} \) is maximal in \( S \), then \( R/\mathfrak{m} \cap R \rightarrow S/\mathfrak{m} \) satisfies the condition of (4.2.6.8), by (4.2.6.6), so the first two assertions are proved. \( \square \)

**Cor. (4.2.6.11).** If \( R \) is Jacobson and \( S \in \mathcal{CAlg}_{fg}(R) \) is reduced, then \( \cap_{\mathfrak{m} \subset R} \text{maximal } \mathfrak{m}S = 0 \).

**Proof:** This is because
\[
\cap_{\mathfrak{m} \subset R} \text{maximal } \mathfrak{m}S \subset \cap_{\mathfrak{M} \subset S} \text{maximal } (\mathfrak{M} \cap R)S \subset \cap_{\mathfrak{M} \subset S} \text{maximal } \mathfrak{M} = 0.
\]

**Zariski Pairs**

**Def. (4.2.6.12).** A pair \((A, I)\) is called a **Zariski pair** iff \( I \) is contained in the Jacobson radical of \( A \).

**Prop. (4.2.6.13).** If \((A, I)\) is a Zariski pair, then the map \( A \rightarrow A/I \) induces a bijection between the idempotents.

**Proof:** idempotents are determined by the maximal ideals that it vanishes (4.1.7.6), and \( A \rightarrow A/I \) induces a bijection on the maximal ideals. \( \square \)
7 Dedekind Domain

References are

Def. (4.2.7.1) [Dedekind Domain]. A Dedekind domain is an integrally closed Noetherian domain of dimension 1. A UFD is a Dedekind domain by (4.3.5.2).

Prop. (4.2.7.2) [Characterizing]. For a domain R, the following are equivalent:
1. R is a Dedekind domain.
2. R is Noetherian and each \( R_\mathfrak{m} \) is DVR for any maximal ideal \( \mathfrak{m} \).
3. each ideal of \( R \) can be written as a product of prime ideals uniquely.

Proof: \( 1 \iff 2 \) as normal is a stalkwise and (4.3.5.20).

\( 3 \rightarrow 2 \): If 3 is true, then \( \mathfrak{p} \neq \mathfrak{p}^2 \) for each prime \( \mathfrak{p} \), so choose \( x \in \mathfrak{p} - \mathfrak{p}^2 \), then for each \( y \in \mathfrak{p} \), \( (x, y) = \prod p_i \), then exactly one \( p_i \) (may assume \( p_1 \)) is contained in \( \mathfrak{p} \), so \( (x, y)\mathfrak{R}_p = p_1\mathfrak{R}_p \). Now in fact \( (x)\mathfrak{R}_p = p_1\mathfrak{R}_p \), because \( (x, y^2)\mathfrak{R}_p \) is also a prime, so \( y = ax + by^2 \) in \( \mathfrak{R}_p \), \( (1 - by)y = ax \in (x)\mathfrak{R}_p \) is a prime, so \( y \in (x)\mathfrak{R}_p \). This is for all \( y \in \mathfrak{p} \), so \( (x)\mathfrak{R}_p = p_1\mathfrak{R}_p \).

Now if \( (x) = p_1 \cdots p_r \), then \( p_1\mathfrak{R}_p = \mathfrak{p}\mathfrak{R}_p \), so \( p_1 = p \), and \( p \) is f.g. by the lemma (4.2.7.3) below. \( \mathfrak{p} \) is arbitrary, so \( R \) is Noetherian and \( R_\mathfrak{m} \) is DVR for \( \mathfrak{m} \) maximal, by (4.3.5.20).

\( 1 \rightarrow 3 \): if 1 is true, then any ideal is a unique intersection of primary ideals, and primary ideals are their radical are different, so they are coprime (4.1.1.7), so this is in fact a unique decomposition into products of primary ideals. And any primary ideal is a power of its radical, because this is the case after localization.

\[ \square \]

Lemma (4.2.7.3). \( I, J \) be ideals in a ring \( A \) and \(IJ = (f)\) where \( f \) is a non-zero-divisor, then \( I, J \) are f.g. and finitely locally free of rank 1 as \( A \)-modules.

Proof: The second assertion implies the first, by (4.3.1.7). \( f = \sum x_iy_i \), and \( x_iy_i = a_if \), so \( \sum a_i = 1 \) as \( f \) is non-zero-divisor. Now we show \( I_{a_i} \) as \( J_{a_i} \) is free of rank 1. Now after localization, \( f = xy \), so \( x, y \) are non zero divisors. Now if \( x' \in I \), then \( x'y = af = axy \) for some \( a \), so \( x' = ax \).

\[ \square \]

Fractional Ideals

Def. (4.2.7.4) [Fractional Ideals]. For \( A \) an integral domain and \( K \) its quotient field, then an \( A \)-submodule \( M \) of \( K \) is called a fractional ideal if \( xM \subset A \) for some \( x \neq 0 \).

Every f.g. submodule in \( K \) is a fractional ideal, and if \( A \) is Noetherian, then the converse is true, because it is of the form \( x^{-1}a \).

Prop. (4.2.7.5). An \( A \)-submodule \( M \) of \( K \) is called an invertible ideal if there is a submodule \( N \) that \( MN = A \). It follows that \( M, N \) are f.g., because there are \( \sum x_iy_i = 1 \), so \( M \) is generated by \( x_i \) and \( N \) is generated by \( y_i \).

Prop. (4.2.7.6). Invertibility is a stalkwise property.

Proof: Notice \( (A : M)_p = (A_p : M_p) \), and \( M \) is invertible iff \( M(A : M) = A \). Then use the fact isomorphism is stalkwise (4.1.4.2).

Prop. (4.2.7.7). A local domain is a DVR iff every non-zero fractional ideal of \( A \) is invertible.
Proof: If is a DVR, let \( m = (x) \), for any fractional ideal \( M < A = (x^r) \), then \( M = (x^{r-s}) \), where \( v(y) = s \). Conversely, if every non-zero fractional ideal of \( A \) is invertible, then they are all f.g. (4.3.5.20). If this is not true, choose a maximal element \( a \) in the set of ideals that is not a power of \( (x) \) (by Noetherian), then \( m^{-1}a \subset A = (x^r) \), then \( m^{-1}a = m^k \) for some \( k \), so \( a = m^{k+1} \), contradiction. □

Cor.(4.2.7.8) [Dedekind Domain Fractional Ideals are Invertible]. An integral domain is a Dedekind domain iff every non-zero fractional ideal is invertible.

Proof: Immediate from the proposition and (4.2.7.2). □

Def.(4.2.7.9) [Class Group]. Let \( \mathcal{O} \) be a Dedekind domain, we denote \( \text{Cl}(\mathcal{O}) \) the Abelian group of fractional ideals of \( \mathcal{O} \) modulo principal fractional ideals, called the class group of \( \mathcal{O} \).

Prop.(4.2.7.10) [Localizations of Dedekind Domains]. Let \((\mathcal{O}, F)\) be a Dedekind domain and \( S \subset \text{Spec} \mathcal{O} \) be a finite subset of maximal ideals of \( \mathcal{O} \), let \( \mathcal{O}_S \) denote the localization of \( \mathcal{O} \) at all such \( p_i \). Then there is an exact sequence of Abelian groups:

\[
1 \to \mathcal{O}^* \to \mathcal{O}_S^* \to \bigoplus_{p \in S} F^*/\mathcal{O}_p^* \to \text{Cl}(\mathcal{O}) \to \text{Cl}(\mathcal{O}_S) \to 1.
\]

Proof: The only non-trivial map is the map \( \bigoplus_{p \in S} F^*/\mathcal{O}_p^* \to \text{Cl}(\mathcal{O}) \) given by \( (\pi_p) \) mapsto \( \prod_{x \in S} p^{v_x(a_x)} \). □

Extensions of Dedekind Domains

References are [Neu99] Chap1.8..

Prop. (4.2.7.11) [Krull-Akizuki]. If \( A \) is a Noetherian domain of dimension 1 with fraction field \( K \) and \( L/K \) is a finite field extension, then the integral closure \( B \) of \( A \) in \( L \) is a Dedekind domain with fraction field \( L \), and \( \text{Spec} B \to \text{Spec} A \) is surjective, and have finite fibers and induces finite residue field extension.

Proof: Cf.[Sta]09IG or [Neu99]P77. □

Cor. (4.2.7.12). The integral closure of a Dedekind domain in a finite extension fields of its quotient fields is again a Dedekind domain.

Def.(4.2.7.13) [Situation]. Let \( \mathcal{O}_K \) be a Dedekind domain with quotient field \( K \), \( L/K \) a finite field extension, and \( \mathcal{O}_L \) the integral closure of \( \mathcal{O}_K \) in \( L \), which is also a Dedekind domain by (4.2.7.11).

Def.(4.2.7.14) [Conductors]. Let \( R \subset S \subset \text{Ring} \) the conductor of \( R \) in \( S \) is defined to

\[
c = \{ \alpha \in R | \alpha S \subset R \}.
\]

And if \((R, K)\) is an integral domain, the conductor of \( R \) is defined to be the conductor of \( R \) in the integral closure of \( R \) w.r.t. \( K \).

Prop. (4.2.7.15). Let \( R \) be a Noetherian integral domain with integral closure \( S \), then the conductor of \( R \) in \( S \) is nonzero iff \( S \) is f.g. as a \( R \)-module.
Proof: This follows from (4.2.7.4). □

Def. (4.2.7.16) [Conductors of an Element]. In situation (4.2.7.13) and \( \alpha \in \mathcal{O}_L \), then the conductor of \( \alpha \) w.r.t \( K \) is the conductor of \( \mathcal{O}_K[\alpha] \) in \( \mathcal{O}_L \), denoted by \( \mathfrak{d}(\alpha) \). It is non-zero by (4.2.7.4) as \( \mathcal{O}_L \) is f.g. over \( \mathcal{O}_K[\alpha] \).

Prop. (4.2.7.17) [Inertia and Ramification]. Situation as in (4.2.7.13), let \( p \) be a maximal prime of \( \mathcal{O}_K \), then \( p\mathcal{O}_L \cap \mathcal{O}_L \) by (4.2.1.5). Let \( p\mathcal{O} = \prod_i \mathfrak{P}_i^{e_i} \) be a decomposition. Denote \( e_i \) the ramification degree of \( \mathfrak{P}_i \) over \( p \), and \( f_i = [\mathcal{O}_L/\mathfrak{P}_i : \mathcal{O}_K/p] \) the inertia degree of \( \mathfrak{P}_i \) over \( p \).

Prop. (4.2.7.18) [Fundamental Identity]. Situation as in (4.2.7.13), if \( \mathcal{O}_L \) is a finite \( \mathcal{O}_K \)-module, then for any \( p = \prod_i \mathfrak{P}_i^{e_i} \),
\[
\sum e_if_i = [L : K].
\]

In particular, this applies to the case that \( L/K \) is separable.

Proof: By hypothesis, \( \mathcal{O}_{L,p} \) is a finite \( \mathcal{O}_Kp \)-module of rank \( [L : K] \), thus \( \mathcal{O}_L/p \) is an \( \mathcal{O}_K/p\mathcal{O}_L \)-module of rank \( n \). Notice there is an isomorphism \( \mathcal{O}_L/p\mathcal{O}_L \cong \prod_i \mathcal{O}_L/\mathfrak{P}_i^{e_i} \), thus
\[
[L : K] = \sum_i \dim_{\mathcal{O}_L/p} \mathcal{O}_L/\mathfrak{P}_i^{e_i} = \sum_i e_if_i.
\]

If \( L/K \) is separable, let \( \{\alpha_1, \ldots, \alpha_n\} \) be a basis of \( L/K \) with \( \alpha_i \in \mathcal{O}_K \), then any \( \alpha = a_1\alpha_1 + \ldots + a_n\alpha_n \in \mathcal{O}_L \) satisfies the following equations
\[
\text{tr}_{L/K}(\alpha_i \alpha) = \sum_j \text{tr}_{L/K}(\alpha_i \alpha_j) a_j
\]
for any \( i \). Notice \( \text{tr}(\alpha_i \alpha) \in \mathcal{O}_K \), so \( da \in \mathcal{O}_K \) by linear algebra, where \( d = \det(\text{tr}_{L/K}(\alpha_i \alpha_j)) \neq 0 \) by (2.2.5.34). So \( \mathcal{O}_L \subset d^{-1}(\alpha_1\mathcal{O}_K + \ldots + \alpha_n\mathcal{O}_K) \), so it is a finite \( \mathcal{O}_K \)-module, as \( \mathcal{O}_K \) is Noetherian. □

Thm. (4.2.7.19) [Dedekind-Kummer]. Situation as in (4.2.7.13), suppose \( L = K(\theta) \), where \( \theta \in \mathcal{O}_L \) has minimal polynomials \( p(X) \in \mathcal{O}_K[X] \)(such a \( \theta \) exists if \( L/K \) is separable, by (2.2.5.20)). Let \( \mathfrak{d} \) be the conductor of \( \theta \), then for any prime ideal \( p \) of \( \mathcal{O}_K \) prime to \( \mathfrak{d} \), let
\[
\mathfrak{p}(X) = \prod_i \mathfrak{p}_i(X)^{e_i}
\]
be the decomposition of \( \mathfrak{p}(X) \) into irreducible factors in \( \mathcal{O}_K/p[X] \), where \( \mathfrak{p}_i(X) \in \mathcal{O}_K[X] \) are monic polynomials, then
\begin{itemize}
\item \( \mathfrak{P}_i = p\mathcal{O} + p_i(\theta)\mathcal{O}_L \) are different primes ideals in \( \mathcal{O}_L \).
\item \( p\mathcal{O}_L = \prod_i \mathfrak{P}_i^{e_i} \).
\item The inertia degree \( f_i \) equals \( \text{deg}(\mathfrak{p}_i(X)) \).
\end{itemize}

Def. (4.2.7.20) [Ramification Notations]. Situation as in (4.2.7.17), let \( p\mathcal{O} = \prod_i \mathfrak{P}_i^{e_i} \), then
\begin{itemize}
\item splits completely in \( L \) if \( r = [L : K] \).
\item \( p \) is non-split in \( L \) if \( r = 1 \).
\end{itemize}
• $\mathfrak{P}_i$ is **unramified** over $\mathfrak{p}$ if $e_i = 1$ and the residue fields extension $(O_L/\mathfrak{P}_i)/(O_K/\mathfrak{p})$ is separable.

• $\mathfrak{P}_i$ is **ramified over** $\mathfrak{p}$ if it is not unramified over $\mathfrak{p}$.

• $\mathfrak{P}_i$ is **totally ramified** over $\mathfrak{p}$ if it is ramified over $\mathfrak{p}$ and $f_i = 1$.

• $\mathfrak{p}$ is called **unramified in** $L$ if all $\mathfrak{P}_i$ are unramified over $\mathfrak{p}$.

• $L/K$ is called a **unramified extension** if all primes of $O_K$ are unramified.

**Prop.(4.2.7.21)** [Almost Every Prime is Unramified]. Situation as in $(4.2.7.19)$, then a.e. prime $\mathfrak{p}$ of $O_K$ is unramified in $L$, by $(4.2.7.35)$.

**Prop.(4.2.7.22)**. Situation as in $(4.2.7.13)$, $O_L \otimes_{O_K} O_K, \mathfrak{p} = \prod_i O_L, \mathfrak{P}_i$.

*Proof:* Cf.[MIT notes, 11.7].

**Prop.(4.2.7.23)**. If a prime $\mathfrak{p}$ splits completely in two separable extension $LM$ of $K$, then it also splits completely in the composite $LM$.

*Proof:* We use the language of valuation. The extension of a valuation $v$ of $K$ corresponds to the set of equivalent classes of algebra map from $L$ to $K_v$ module conjugacy over $K_v$. So We only need to show that two different maps of $LM$ are not conjugate over $K_v$. But the restrict of them to $L$ or $M$ is different, thus not conjugate over $K_v$ by the assumption.

**Cor.(4.2.7.24)**. A prime splits completely in a separable extension $L$ if it splits completely in the Galois closure $N$ of $L$.

*Proof:* This is because the Galois closure is the composite of the conjugates of $L$.

But it also can be proven directly : Set $H = \text{Gal}(N/L), \mathcal{P}$ a prime of $N$ over $\mathfrak{p}$, then

$$H \backslash G/G_\mathcal{P} \rightarrow \{\text{Primes of } L \text{ over } \mathfrak{p}\}, \quad H \sigma G_\mathcal{P} \mapsto \sigma \mathcal{P} \cap L$$

is a bijection. So it splits completely in $L$ $\iff$ $G_\mathcal{P}$ is trivial $\iff$ it splits completely in $N$ by counting numbers.

**Differents and Discriminants**

**Def.(4.2.7.25)** [Differents]. Let $L/K$ be a finite separable field extension with separable residue field extension, and $O_K$ is a Dedekind domain with integral closure $O_L$ in $L$, there is a **trace form** on $L$: $(x, y) \rightarrow \text{tr}(xy)$, which is non-degenerate.

We define the **dual module** for a fractional ideal $I$ as $I^\vee = \{x \in L | \text{tr}(xI) \in O_K\}$. This is truly a fractional ideal because if $\alpha_i \in O_L$ is a basis of $L/K$, and let $d = \text{det}(\text{tr}(\alpha_i \alpha_j))$, then for any $a \in I \cap O_L$, $ad \cdot I^\vee \in O_L$, because if $x = \sum x_i \alpha_i \in I^\vee$, then $\sum ax_i \text{tr}(\alpha_i \alpha_j) = \text{tr}(x\alpha_j) \in O_K$, so solve the equation shows $dax_i \in O_K$.

The **different** of $K/L$ is defined to be $\mathcal{D}_{L/K} = ((O_L)^\vee)^{-1}$.

**Prop.(4.2.7.26)** [Properties of Differents]. Different is compatible with composition, localization w.r.t. a prime ideal and completion.

**Cor.(4.2.7.27)**. $\mathcal{D}_{L/K} = \prod \mathcal{D}_{L_{\overline{\mathfrak{p}}}/K_{\overline{\mathfrak{p}}}}$. 
Prop. (4.2.7.28). If $\mathcal{O}_L = \mathcal{O}_K[\alpha]$, then $\mathfrak{D}_{L/K} = (f'(\alpha))$, where $f(X) = \text{Irr}(\alpha, K; X)$.

Proof: By (2.2.5.30), if $f(X)/(X - \alpha) = \beta_0 + \beta_1X + \ldots + \beta_{n-1}X^{n-1}$, then $\mathcal{O}_L^\gamma = f'(\alpha)^{-1}(\beta_0, \ldots, \beta_{n-1})$. Now the result follows if $(\beta_0, \ldots, \beta_{n-1}) = \mathcal{O}_L$, which is easy to see if we write $\beta_i$ as polynomials of $\alpha$. □

Cor. (4.2.7.29). If $L/K$ is a finite separable extension of local fields, then

$$v_L(\mathfrak{D}_{L/K}) = \sum_{\sigma \in G, \sigma \neq 1} i_{L/K}(\sigma) = \int_{-1}^{\infty} |G(L/K)| - 1 dt.$$

Notation as in (12.2.2.27).

Prop. (4.2.7.30) [Different as Annihilator of Kähler Differential]. The different $\mathfrak{D}_{L/K}$ is the annihilator of $\Omega_{\mathcal{O}_L/\mathcal{O}_K}$.

Proof: It suffices to show the exact sequence

$$0 \rightarrow \mathfrak{D}_{L/K} \rightarrow \mathcal{O}_L \rightarrow \Omega_{\mathcal{O}_L/\mathcal{O}_K},$$

but because exactness is stalkwise (4.1.4.2), we can localized at a maximal ideal, then by (12.2.2.2), $\mathcal{O}_L = \mathcal{O}_K[x]$ is monogenous, thus $\Omega_{\mathcal{O}_L/\mathcal{O}_K}$ is cyclic, and the annihilator of $dx$ is $f'(x)$. So by (4.2.7.28) we are done. □

Prop. (4.2.7.31) [Ramification and Different]. A prime ideal $\mathfrak{p}$ of $L$ is ramified over $K$ iff $\mathfrak{p} | \mathfrak{D}_{L/K}$.

Let $e$ be the ramification of $\mathfrak{p}$, then the power $s$ of $\mathfrak{p}$ in $\mathfrak{D}_{L/K}$ is

$$s = e - 1 \quad \mathfrak{p} \text{ tamely ramified}$$

$$e \leq s \leq e - 1 + v_{\mathfrak{p}}(e) \quad \mathfrak{p} \text{ wildly ramified}.$$

Def. (4.2.7.32) [Discriminants]. Let the situation the same as in (4.2.7.25), the discriminant of $L/K$ $\delta_{L/K}$ is defined to be the set of discriminants $d(\alpha_1, \ldots, \alpha_n)(2.2.5.33)$ where $\alpha_i$ is a basis of $L/K$ that $\alpha_i \in \mathcal{O}_L$.

Because $d(\alpha_1, \ldots, \alpha_n) \subset \mathcal{O}_K$ and $\text{tr}_{L/K}$ is $\mathcal{O}_K$-linear, $\delta_{L/K}$ is an ideal of $\mathcal{O}_K$.

Prop. (4.2.7.33) [Differents and Discriminants].

$$\delta_{L/K} = N_{L/K} \mathfrak{D}_{L/K}.$$

Cor. (4.2.7.34) [Compositions and Discriminants]. For a tower of fields $K \subset L \subset M$, we have

$$\delta_{M/K} = \delta_{L/K}^{[M:L]} N_{L/K}(\delta_{M/L}).$$

Proof: Apply $N_{M/K} = N_{L/K} N_{M/L}$ to the equation $\mathfrak{D}_{M/K} = \mathfrak{D}_{M/L} \mathfrak{D}_{L/K}(4.2.7.26)$, we get

$$\delta_{M/K} = N_{L/K}(\delta_{M/L}) N_{L/K}(\mathfrak{D}_{L/K}^{[M:L]}) = N_{L/K}(\delta_{M/L}) \delta_{L/K}^{[M:L]}.$$
Cor. (4.2.7.35) [Ramification and Discriminant]. Let $L/K$ be a separable finite field extension, then a prime ideal $p$ of $K$ ramifies in $L$ iff $p | d_{L/K}$.

In particular, only f.m. primes are ramified in $L/K$, and the extension is unramified iff $d_{L/K} = 1$.

Proof: This follows from (4.2.7.31) and (4.2.7.33).

Cor. (4.2.7.36). $d_{L/K} = \prod \mathcal{P} d_{L_{\mathcal{P}}/K_{\mathcal{P}}}$.

Proof: This follows from (4.2.7.27) and (4.2.7.33).

Orders

Def. (4.2.7.37) [Orders]. An order is a Noetherian integral domain $O$ of dimension 1 whose conductor (4.2.7.14) is non-zero, or equivalently its integral closure in fraction field is finite over $O$ by (4.2.7.15). A Dedekind domain is an order.

Def. (4.2.7.38). If $A$ is Noetherian domain with fraction field $K$ and $L$ is a f.d. $K$-algebra, then an $A$-order is an $A$-lattice (12.2.4.17) in $L$ that is also a ring.

Prop. (4.2.7.39). Situation as in (4.2.7.13), if $L/K$ is separable, then a subring $O$ of $L$ is an $A$-order iff it is an order with integral closure $O_L$.

In particular, if $F$ is a number field, then the orders of $F$ are exactly subrings of $O_F$ that contains a basis of $F$.

Proof: If $O$ is an $A$-order, then every element of $O$ is integral over $A$, by acting on $O$. $O_K$ is contained in $O$, and $O \otimes_{O_K} K = L$, so the fraction field of $O$ is $L$. Thus the integral closure of $O$ in $L$ is $O_L$. Then $\dim O = 1$ as $\dim O_L = 1$ (4.2.4.14), and it is Noetherian because it is f.g. over $A$ (4.1.1.40). And $O_L$ is finite over $O_K$ by (4.2.7.18), thus is also f.g. over $O$. Thus $O$ is an order.

If $O$ is an order with integral closure $O_L$, then it is f.g. over $O_K$ as it is contained in the f.g. $O_K$-module $O_L$. And it contains a $K$-basis of $L$ because $L = K \mathcal{O}_L$ and $a \mathcal{O}_L \subset O$ for some $a \in O^\times$ because $O$ is an order. Thus $O$ is an $A$-lattice in $L$ that is a ring, so it is an $A$-order.

For the last assertion, notice that if it contains a basis of $F$ and is contained in $O_F$, then it must be a $\mathbb{Z}$-lattice of $F$, as $O_F$ is free because it is finite over $\mathbb{Z}$ (4.2.7.18).

Prop. (4.2.7.40). Let $F \in \mathbb{NField}$ and $\Lambda$ is a $\mathbb{Z}$-lattice in $F$, then the ring of multipliers

$$O = \{ \alpha \in O_F | \alpha \Lambda \subset \Lambda \}$$

is an order in $F$.

Proof: $O$ contains $(d)$ for some $d \in \mathbb{Z}_+$, because for any $\alpha \in O_F$, $\alpha \Lambda \subset F = \Lambda \otimes \mathbb{Q}$, so for some $d_\alpha \in \mathbb{Z}_+$, $d_\alpha \Lambda \subset \Lambda$.

Thus $O$ contains a basis of $F$. And $O$ is contained in $O_F$: if $\alpha \Lambda \subset \Lambda$, then $\alpha$ satisfies the equation of its characteristic polynomial, which has coefficients in $\mathbb{Z}$. So $\alpha \in O_F$. Thus $O$ is an order, by (4.2.7.39).
4.3 Commutative Algebra III

1 Projective

References are [Projective Modules], [Sta] and [Vak17].

Def.(4.3.1.1)[Projective Modules]. A module $P$ over a ring $R$ is called projective iff $\text{Hom}(P, -)$ is exact, or equivalent, for any surjective map of modules $F \to Q \to 0$, $\text{Hom}(P, F) \to \text{Hom}(P, Q)$ is surjective.

Prop.(4.3.1.2). Localization and tensor product preserves projective because they are left adjoints. And when tensoring f.f. map, then the converse is also true (4.4.2.1).

Prop.(4.3.1.3). A module over a ring is projective iff it is a direct summand of a free module, in particular, it is flat. Moreover, there is a free module $Q$ that $P \oplus Q = F$ free.

Proof: For the second assertion, we can choose an arbitrary $Q$ that $P \oplus Q$ free, and see $\bigoplus_{N}(P \oplus Q)$ is free. □

Lemma(4.3.1.4). A projective module is a direct sum of countably generated projective modules.

Proof: This follows from (2.2.4.28). □

Prop.(4.3.1.5)[Projective over Local Ring]. A projective module $P$ over a local ring $R$ or a PID is free.

Proof: Local ring case: By (4.3.1.4) and (2.2.4.29), it suffices to show that any element $x$ of $P$ is contained in a free direct summand of $P$. Because $P$ is projective, it is a direct summand of a free module $F, F = P \oplus Q$. Let $B$ be a basis of $F$ that the number of basis element in the expression of $x$ is minimal. Let $x = \sum a_i e_i$. Then no $a_i$ is contained in the ideal generated by other $a_j$, otherwise we can choose another basis to show this is minimal. Let $e_i = y_i + c_i$ be decompositions into $P$ and $Q$ components, and write $y_i = \sum a_{ij} e_i + t_i$, where $t_i$ is combination of elements in $B$ other than $e_i$. Now it suffices to show $\det(a_{ij})$ is invertible, because in this way $\{y_i\} \cup (B \setminus \{x_1\})$ is a basis of $F$ and $x = \sum a_i y_i$ because $x \in P$. And $N = \span\{y_i\}$ is a summand of $P$ because $N \subset P$ and both $N, P$ are summands of $F$.

To show $\det(a_{ij})$ is invertible, notice that by plugging $y_i = \sum b_{ij} e_j + t_i$ into $\sum a_i e_i = \sum a_i y_i$ shows $a_j = \sum a_{ij}$, thus by the argument before, $a_{ij}$ are non-invertible for $i \neq j$ and $1 - a_i$ is non-invertible, so $a_{ii}$ is invertible. Because $R$ is a local ring, we can easily see $\det(a_{ij})$ is invertible. □

PID case: directly from (2.2.4.21).

Prop.(4.3.1.6). If $R$ is a ring and $I$ is nilpotent ideal and $\overline{P}$ is a projective $R/I$-module, then there exists a projective $R$-module $P$ that $P/IP \cong \overline{P}$.

Proof: Cf. [Sta] P07LV. □

Finite Projective Modules

Prop.(4.3.1.7)[Finite Projective Modules]. Let $M$ be a $R$-module, the following are equivalent:

1. $M$ is finite projective.
2. $M$ is f.p. and flat.
3. $M$ is f.p. and all its localizations at (maximal)primes are free.
4. $M$ is finite locally free.
5. $M$ is finite and locally free.
6. $M$ is finite and all its localizations at primes are free and the function $p \rightarrow \dim_{k(p)} M \otimes_R k(p)$ is a locally constant function on $\text{Spec } R$.

Proof: 1 $\rightarrow$ 2: $M \otimes K = R^n$ for some $K$ and $n$, so $K$ is finite and $M = R^n/K$ is f.p. And $M$ is flat because it is a summand of $R^n(4.4.1.4)$.

2 $\rightarrow$ 4: For any prime $p$, choose a basis for the $k(p)$-vector space $M \otimes k(p)$, then by Nakayama, their inverse image generate $M$ for some $g \in p(2.2.4.8)$, and the kernel $K$ of this generation is finite because $M_g$ is f.p. And $K \otimes k(p) = 0$ by the flatness of $M_g$. Then by Nakayama again there is a $g' \in p$ that $M_{gg'} = 0(2.2.4.8)$.

4 $\rightarrow$ 3: Because f.p. is local(4.1.4.4).
3 $\rightarrow$ 2: Because flatness is trivial.
4 $\rightarrow$ 5: Because finite is local(4.1.4.4).
5 $\rightarrow$ 4, 4 $\rightarrow$ 6: Trivial.
6 $\rightarrow$ 4: Cf.[Sta]00NX.

2 + 3 + 4 + 5 + 6 $\rightarrow$ 1: Cf.[Sta]00NX.

Consider the stalk, it is all free by $(4.3.1.2)$ and $(4.3.1.5)$, thus by $(5.5.1.38)$, it is locally free. □

Cor.(4.3.1.8)[Partially Stalkwise]. If $P$ is a f.p., then finite projectiveness is a stalkwise property for $P$.

Cor.(4.3.1.9)[Projective and Flat]. A finite module over a Noetherian ring is projective iff it is flat.

Cor.(4.3.1.10). If $M$ is finite projective, then the canonical map $\text{Hom}(M, N) \otimes L \rightarrow \text{Hom}(M, N \otimes L)$ is an isomorphism.

Proof: By proposition above $M$ is f.p. and finite locally free, so by(4.3.7.7) and tensor commutes with localization, we can check locally, where $M$ is finite free so the isomorphism is obvious. □

Def.(4.3.1.11)[Characteristic Polynomials for Finite Projective Modules]. Let $M$ be a finite projective module over a ring $A$. then we can define a characteristic polynomial in $A[X]$ for any map of $A$-modules $M \rightarrow M$: if $M$ is free, then this map is defined as usual. In general, we can find an open covering $\text{Spec } A_{f_i}$ of $\text{Spec } A$ that $M_{f_i}$ is free over $A_{f_i}$. Thus we can define the characteristic polynomial locally and glue them together to get a characteristic polynomial in $A[X]$.

In particular, we can also define trace and norm of a $A$-module map $M \rightarrow M$. And when $B$ is a locally free $A$-algebra, then there are trace and norm maps $\text{tr}: B \rightarrow A$ and $\text{Nm}: B \rightarrow A$.

Prop.(4.3.1.12). Let $R$ be a ring and $I$ be a locally nilpotent ideal. If $\mathcal{P}$ is a finite projective module over $R/I$, then there exists a finite projective $R$-module $P$ that $P/IP \cong \mathcal{P}$.

Proof: Cf.[Sta]0D47. □

Prop.(4.3.1.13). Let $M$ be a $R$ module and $I$ a nilpotent ideal of $R$. If $M/IM$ is a projective $R/I$-module and $M$ is flat over $R$, then $M$ is a projective $R$-module.

Proof: Cf.[Sta]05CG. □
Thm. (4.3.1.14)[Serre-Suslin]. Every finite projective module over the polynomial ring \( k[x_1, \ldots, x_n] \) is free.

Proof: Cf.[Lan05]P850. □

Duality of Projective Modules

Prop.(4.3.1.15)[Basis Criterion of Projectiveness]. An \( A \)-module \( P \) is projective iff there are elements \( x_i \) in \( P \) and \( f_i \) in \( P^* \) that for any \( x \), \( f_i(x) = 0 \) a.e. \( i \), and \( \sum f_i(x)x_i = x \). Moreover, \( P \) is finite projective iff there are f.m. of them.

Proof: If \( P \) is projective, as a summand of a free module, then we can choose the coordinates of the inclusion map as \( f_i \), and choose the image of the quotient map of the coordinate as \( x_i \). The converse is verbatim. □

Cor.(4.3.1.16)[Finite Projective Duality]. If \( P \) is projective, then \( P \to P^{**} \) is injective, and if \( P \) is finite projective, then it is an isomorphism.

Proof: If \( f(x) = 0 \) for all \( f \in P^* \), then the proposition says \( x = 0 \). And if \( P \) is finite projective, it can be seen \( x_i, f_i \) forms a "basis" of \( P^* \)(finiteness used), so \( f_i \) generate \( P^* \), and similarly \( x_i \) generate \( P^* \), so \( P \to P^{**} \) is surjective. □

Cor.(4.3.1.17). If \( P \) is projective over \( R \), then \( P^* \neq 0 \).

Cor.(4.3.1.18). In the meanwhile of the proof, we already get: if \( P \) is finite projective, then \( P^* \) is finite projective, by(4.3.1.15).

Cor.(4.3.1.19). If \( P \) is finite projective, the the map \( P \otimes M \to \text{Hom}(P^*, M) \) is an isomorphism.

Proof: In(4.3.1.10), let \( N = R \) and let \( M = P^* \), then use the fact \( P \cong P^{**} \). □

Thm. (4.3.1.20)[Quillen-Suslin]. For \( k \in \text{Field} \), any finite projective module over \( k[X_1, \ldots, X_k] \) is free. (Highly nontrivial).

Proof: Cf.[Lan05]P850. □

Prop.(4.3.1.21). \( \prod Z \) is not free over \( Z \), by(2.1.4.4).

2 Injective

Prop.(4.3.2.1)[Baer’s Criterion]. A right \( R \)-module \( I \) is injective iff for every right ideal \( J \) of \( R \), every map \( J \to I \) can be extended to a map \( R \to I \). (Directly from (3.3.5.6)).

Cor.(4.3.2.2). A module over a PID is injective iff it is divisible.

Cor.(4.3.2.3). \( A \) is injective iff \( \text{Ext}^1(R/I, A) = 0 \) for every ideal \( I \) of \( R \).

Cor.(4.3.2.4)[Rank]. Let \( M \) a finite projective \( R \)-module, then \( M \) is said to have rank \( n \) if \( M/\mathfrak{m}M \) is of rank \( n \) over the field \( R/\mathfrak{m} \) for any arbitrary maximal ideal \( \mathfrak{m} \) of \( R \).

Prop.(4.3.2.5). The category of \( R \)-mod has enough injectives by(3.3.2.27), and it has enough projectives trivially.
Prop. (4.3.2.6). If $I$ is an injective $A$-module, then for any ideal $\alpha$ of $A$, $\Gamma_\alpha(I) = \{m|\alpha^nm = 0\}$ for some $n$ is injective.

Proof: Use Baer criterion, for any ideal $b$ of $A$, it is f.g. so there is a $n$ that $\phi(\alpha^n b) = 0$, and Artin-Rees tells us that $\phi(\alpha^N \cap b) = 0$ for some $N$. So we have an extension of $\phi$ over $b/b \cap \alpha^N$ to $A/\alpha^N \rightarrow I$, and this obviously factor through $\Gamma_\alpha(I)$, so it is done. □

Prop. (4.3.2.7). For an injective module $A$-module $I$, $I \rightarrow I$ if is surjective.

Proof: we have the sheaf of modules $\tilde{I}$ is flabby (5.7.1.4), thus the map to the stalk is surjective. □

Pontryagin Duality

Basic references are [Weibel Homological Algebra].

Def. (4.3.2.8). The Pontryagin dual $M^\vee$ of a left $R$-module $M$ is the right $R$-module $\text{Hom}_{ab}(M, Q/\mathbb{Z})$, where $(fr)(b) = f(rb)$.

It is easily verified that if $A \neq 0$, then $A^\vee \neq 0$, and $Q/\mathbb{Z}$ is an injective $\mathbb{Z}$-module, thus the Pontryagin dual is faithfully exact.

Prop. (4.3.2.9). $M$ is flat $R$-module iff $M^\vee$ is an injective right $R$-module (Because $\text{Hom}(-, Q/\mathbb{Z})$ is exact).

3 Homological Dimension

Def. (4.3.3.1). For a $R$-mod $A$, the projective dimension $\text{pd}(A)$ is the minimal length of a projective resolution of $A$. The injective dimension $\text{id}(A)$ is the minimal length of a injective resolution of $A$. The flat dimension $\text{fd}(A)$ is the minimal length of a flat resolution of $A$.

Prop. (4.3.3.2). If $R$ is Noetherian, then $\text{fd}(A) = \text{pd}(A)$ for every f.g. module $A$.

Proof: Use (4.3.3.3), we see that if we choose a syzygy and look at the $n$-th term, then it is f.p and flat, so we have it is projective by (4.4.1.14). □

Lemma (4.3.3.3)[pd]. If $\text{Ext}^{d+1}(A, B) = 0$ for every $B$, then for every resolution

$$0 \rightarrow M \rightarrow P_{d-1} \rightarrow \ldots, P_1 \rightarrow P_0 \rightarrow A \rightarrow 0$$

where $P_k$ is projective, then $M$ is projective. Hence we have $\text{pd}(A) \leq d$. (Use dimension shifting, the following two are the same).

Lemma (4.3.3.4)[id]. If $\text{Ext}^{d+1}(A, B) = 0$ for every $A$, then for every resolution

$$0 \rightarrow B \rightarrow P_0 \rightarrow \ldots, P_{n-1} \rightarrow M \rightarrow 0$$

where $P_k$ is injectives, then $M$ is injective. Hence we have $\text{id}(B) \leq d$

Lemma (4.3.3.5)[fd]. If $\text{Tor}^{d+1}(A, B) = 0$ for every $B$, then for every resolution

$$0 \rightarrow M \rightarrow F_{d-1} \rightarrow \ldots, F_1 \rightarrow F_0 \rightarrow A \rightarrow 0$$

where $F_k$ is flat, then $M$ is flat. Hence we have $\text{fd}(A) \leq d$
Prop. (4.3.3.6) [Global Dimension Theorem]. The following are the same for any ring $R$ and called the left global dimension of $R$:
1. $\sup \{id(B)\}$
2. $\sup \{pd(A)\}$
3. $\sup \{pd(R/I)\}$
4. $\sup \{d : \Ext_R^d(A, B) \neq 0 \text{ for some module } A, B\}$.

Proof: This follows from (4.3.3.3), (4.3.3.4) and (4.3.2.3). □

Prop. (4.3.3.7). A $\mathbb{Z}$ has global dimension 1 because injective is equivalent to divisible, and this shows that a quotient of an injective is injective.

Prop. (4.3.3.8) [Tor Dimension Theorem]. The following are the same for any ring $R$ and called the Tor dimension of $R$:
1. $\sup \{fd(A)\}$ for $A$ a left module.
2. $\sup \{fd(B)\}$ for $B$ a right module.
3. $\sup \{pd(R/I)\}$ for $I$ a left ideal.
4. $\sup \{pd(R/J)\}$ for $J$ a right ideal.
5. $\sup \{d : \Tor_R^d(A, B) \neq 0 \text{ for some module } A, B\}$.

Proof: This follows from (4.3.3.5) applied to $R$ and $R^{op}$ and also (4.4.1.2). □

Prop. (4.3.3.9) [Change of Rings]. Let $S \to R$ be a ring map, let $A \in \text{Mod}_R$, then we have $pd_S(A) \leq pd_R(A) + pd_S(R)$.

Proof: Use the Cartan-Eilenberg resolution and the total complex has length $pd_R(A) + pd_S(R)$. □

4 Depth

Regular sequences

Def. (4.3.4.1) [Regular Sequences]. If $R$ is a commutative ring and $M$ is an $R$-module, then a sequence $(f_1, \ldots, f_n)$ of elements of $R$ is called a $M$-regular sequence if $f_k$ is a nonzero-divisor of $M/(f_1, \ldots, f_{k-1})$ and $M/(f_1, \ldots, f_n) \neq 0$. If $M = R$, then it is simply called a regular sequence.

Prop. (4.3.4.2). If $R$ is a local ring, $M$ a finite $R$-module, and $(f_1, \ldots, f_n)$ is a $M$-regular sequence, then a permutation of this sequence is also an $M$-regular sequence.

Proof: By transposition of adjacent indices, we can assume $n = 2$. Then $x$ is a non-zero-divisor, and $x \in \mathfrak{m}$, so Now $(x, y)$ is an $M$-regular sequence iff $M \otimes_R \mathfrak{m} R/x$ is discrete and $M \otimes_R \mathfrak{m} R/y$ is discrete. Then it suffices to prove $y$ is injective on $M$: If $ym = 0$, then $m = xm'$ for some $m'$, because $y$ is injective on $M/x$, and then $ym' = 0$ also because $x$ is injective on $M$. Then $x$ is surjective on $\ker(y)$, thus $\ker(y) = 0$ by Nakayama. □

Prop. (4.3.4.3). Let $R$ be a ring and $0 \to M_1 \to M_2 \to M_3 \to 0$ be an exact sequence of $R$-modules. Then if a sequence $(f_1, \ldots, f_r) \in R^r$ is both $M_1$-regular and $M_3$-regular, then it is also $M_2$-regular.
4.3. COMMUTATIVE ALGEBRA III 407

**Proof:** Use the snake lemma, \( \ker(f_1|_M) = 0 \), and \( 0 \to M_1/fM_1 \to M_2/fM_2 \to M_3/fM_3 \to 0 \), then use induction. \( \square \)

**Prop.(4.3.4.4).** For any integers \( e_i \geq 1 \), \( (f_1, \ldots, f_n) \) is a \( M \)-regular iff \( (f_1^{e_1}, \ldots, f_n^{e_n}) \) is \( M \)-regular.

**Proof:** Use induction on \( n \). \( n = 1 \) is trivial, and it suffices to show that \( (f_1, f_2, \ldots, f_n) \) is \( M \)-regular. Then we use induction on \( e \): There is an exact sequence \( 0 \to M/f_1M \to M/f_1^2M \to M/f^{e-1}M \to 0 \), so by (4.3.4.3), if \( (f_1, \ldots, f_n) \) is \( M \)-regular, then \( (f_1, f_2, \ldots, f_n) \) is \( M \)-regular. Conversely, if \( (f_1, f_2, \ldots, f_n) \) is \( M \)-regular, then \( f_2 \) is injective on \( M/f_1^2M \), so also injective on \( M/f_1M \), thus injective on \( M/f^{e-1}M \) by induction hypothesis, and also there is a further exact sequence \( 0 \to M/(f_1, f_2)M \to M/(f_1^2, f_2)M \to M/(f^{e-1}, f_2)M \to 0 \), so we can consider \( f_3 \), and then so on, thus show \( (f_1, f_2, \ldots, f_n) \) is \( M \)-regular. \( \square \)

**Prop.(4.3.4.5).** Let \( R \) be a ring, then the following are equivalent:

- any permutation of \( (f_1, \ldots, f_r) \) is a regular sequence.
- Any subsequence of \( (f_1, \ldots, f_r) \) is a regular sequence.
- \( (f_1X_1, \ldots, f_rX_r) \) is a regular sequence of \( R[X] \).

**Proof:** 1 \( \to \) 2: Trivial. 2 \( \to \) 1: Use induction on \( r \): If \( r = 2 \) and \( (x, y) \) is regular, we have \( M \otimes_R R/x, M \otimes_R R/y \) are both discrete, and \( M \otimes_R R/x \otimes_R R/y \) is also discrete, thus \( M \otimes_R R/x \otimes_R R/y \) is also discrete and \( (y, x) \) is regular. For \( r > 2 \), it suffices to show \( f_{\sigma(r)} \) is regular in \( M/(f_{\sigma(1)}, \ldots, f_{\sigma(r-1)}) \). If \( \sigma(r) = r \), then we are done, otherwise, \( f_r \) and \( f_{\sigma(r)} \) are both injective on \( M/(f_1, \ldots, f_{\sigma(r)}, \ldots, f_{r-1}) \) by induction hypothesis, and \( (f_{\sigma(r)}, f_r) \) is a regular sequence for this ring, then so is \( (f_{\sigma(r)}, f_r) \) by the \( r = 2 \) case, thus we are done.

3 \( \iff \) 2: Notice as a \( R \)-module, \( R[X_1, \ldots, X_r]/(f_1X_1, \ldots, f_iX_i) \) is a direct sum of the modules \( R/I(EX_1^{i_1} \ldots X_r^{i_r}) \), where \( I_E \) is generated by those \( f_j \) that \( j \leq i \) and \( e_j > 0 \). Then \( f_{i+1}X_{i+1} \) is injective on this iff \( f_{i+1} \) is injective on \( R/I_e \) for \( E \). Then it is clear that this is equivalent to 2. \( \square \)

**Def.(4.3.4.6) [Quasi-Regular Sequence].** Let \( f_1, \ldots, f_c \in R \) and \( J = (f_1, \ldots, f_c) \), let \( M \) be a \( R \)-module, then there is a canonical map \( M/JM \otimes_R R/J[X_1, \ldots, X_c] \to \otimes_{n \geq 0} J^n M/J^{n+1} M \). Then \( (f_1, \ldots, f_c) \) is called \( M \)-quasi-regular sequence iff this is an isomorphism.

**Depth**

**Prop.(4.3.4.7) [Rees].** For a f.g. module \( M \) and \( IM \neq M \),

\[
\text{depth}_I(M) = \min \{ i | \text{Ext}_A^i(A/I, M) \neq 0 \} = \min \{ i | \text{Ext}_A^i(N, M) \neq 0 \}
\]

where \( \text{depth}_I(M) \) is the length of the maximal \( M \)-regular sequence in \( I \), \( N \) is a finite \( A \)-module with \( \text{Supp}(N) \subset V(I) \).

**Proof:** If No elements of \( I \) are \( M \)-regular, then \( i \subseteq \cup \text{Ass}(M) \) thus in one of them, so \( \text{Hom}_A(k, M_p) = 0 \), and we have \( N_p/PN_p = N \otimes_A k_p \) nonzero by Nakayama, thus \( \text{Hom}_k(N \otimes_A k_p, k_p) \neq 0 \), thus \( \text{Hom}_A(N_p, M_p) = (\text{Hom}_A(N, M))_p \neq 0 \), so \( \text{Ext}_A^0(N, M) \neq 0 \). Other dimensions follows by induction, consider the cokernel of \( M \xrightarrow{\alpha} M \).

Conversely, use induction, then we have an injection \( \text{Ext}_A^i(N, M) \xrightarrow{a_i} \text{Ext}_A^i(N, M) \) for \( i < n \). And the condition shows that \( I \subset \sqrt{\text{Ann}(M)} \), so \( a_i N = 0 \), thus the result. \( \square \)
Cor. (4.3.4.8). Two maximal regular sequence in a f.g. module have the same length.

Cor. (4.3.4.9). For a module \( M \) over a Noetherian ring \( A \), we know \( \Gamma_I(M) = \{ m | I^nm = 0 \text{ for some } n \} \), and \( H^i_I \) is its right derived functor, then we have \( \text{depth}_I(M) \geq n \iff H^i_I(M) = 0 \) for \( i < n \). (Because derived functor commutes with colimits, consider \( N = A/I^k \)).

Lemma (4.3.4.10) [Ischebeck]. For a Noetherian local ring \( A \), if \( M, N \) are finite modules, then we have \( \text{Ext}^i_A(N, M) = 0 \) for \( i < \text{depth} \). (Proof: □)

Prop. (4.3.4.11). Let \( A \) be a local ring and \( M \) is finite \( A \)-module, then \( \text{depth}(M) \leq \text{dim} A/P \leq \text{dim} M \) for every \( P \in \text{Ass}(M) \). (Because \( \text{Hom}(A/P, M) \neq 0 \).)

Proof: □

Prop. (4.3.4.12) [Auslander-Buchsbaum Formula]. For a local ring \( R \), if \( M \) is a finitely generated \( R \)-module, then \( \text{pd}(M) < \infty \), then we have \( \text{depth}(R) = \text{depth}(M) + \text{pd}(M) \).

Proof: Cf. [Weibel P109]. □

### Cohen-Macaulay

Def. (4.3.4.13) [Cohen-Macaulay Modules]. For a Noetherian local, a f.g. \( A \)-module \( M \) is called **Cohen-Macaulay** if \( \text{depth}(M) = \text{dim} M \). In view of (4.3.4.11), this is equivalent to \( \text{depth}(M) = \text{dim} A/P \) for all \( P \in \text{Ass}(M) \). A **Cohen-Macaulay ring** is a ring \( A \) that is Cohen-Macaulay over itself.

A localization of a C.M local ring is C.M, so we call a ring **Cohen-Macaulay** if all its localization at primes are C.M.

Prop. (4.3.4.14) [Gorenstein Ring]. A ring \( R \) is called **Gorenstein** iff \( \text{id}_R < \infty \). A Gorenstein local ring is C.M. In this case, \( \text{depth}(R) = \text{id}_R = \text{dim} R \), and \( \text{Ext}^q_R(R/m, R) \neq 0 \iff q = \text{dim} R \).

Proof: Cf. [Weibel P107]. □

Prop. (4.3.4.15). A ring is C.M. iff for all ideals, the associated primes of \( A/I \) all have the same height as \( I \), i.e. unmixed.

Proof: □

Prop. (4.3.4.16). If a local ring is C.M. and \( I = (x_1, \ldots, x_r) \) is a regular sequence, then \( (x_1, \ldots, x_r) \) is .

Proof: \(?\) Isn’t this always true? □

Prop. (4.3.4.17). Let \( A \) be a Noetherian local ring and \( M \) a f.g. module, if a set of elements \( (x_1, \ldots, x_r) \) forms a regular sequence for \( M \), then \( \text{dim} M/(x_1, \ldots, x_r) = \text{dim} M - r \). The converse is also true when \( A \) is C.M. If this is the case, then \( A/(x_1, \ldots, x_r) \) is also C.M.

Proof: By (4.2.2.19), we have \(<\), for the converse, \( \text{Supp}(M/fM) = \text{Supp}(M) \cap \text{Supp}(A/fA) = \text{Supp}(M) \cap V(f) \), and when \( f \) is \( M \)-regular, \( V(f) \) doesn’t contain any \( \text{Ass}(M) \) thus no minimal elements of \( \text{Supp}(M) \), so \( \text{dim}(M/fM) < \text{dim} M \), thus we have \( >\).

When \( A \) is C.M.: \(?\) □
Prop. (4.3.4.18). Let \( R \to S \) be a local homomorphism of Noetherian local rings, if \( R \) is C.M. and \( S \) is finite flat over \( R \) or \( S \) is flat over \( R \) and \( \dim S \leq \dim R \), then \( S \) is C.M., and \( \dim R = \dim S \).

Proof: Cf.[Sta]00R5.

5 Normal & Regular Rings

Normal Ring

Def. (4.3.5.1) [Normal Rings]. A normal domain is a domain and is integrally closed in its fraction field.

A domain is normal iff all its localizations are normal, so we can define a normal ring to be a ring that all its stalks are normal local rings. In particular, a normal ring is reduced.

Proof: The localization of a normal domain is normal, and the converse follows from \( A = \cap A_m \) (4.1.1.33).

Prop. (4.3.5.2) [UFD is Normal]. A UFD is a normal domain.

Proof: If \( A \) is a UFD, then for any \( x \in \text{Frac}(A) \) integral over \( A \), checking the primes dividing the coefficients, we see \( x \in A \).

Prop. (4.3.5.3). A normal ring \( R \) is integrally closed in its ring of fractions.

Proof: Let \( x \in \text{Q}(R) \) be integral over \( R \), and \( I = \{ f \in R | fx \in R \} \), then for any prime \( p \) of \( R \), \( R \to R_p \) is injective, so \( R_p \subset \text{Frac}(R) \otimes_R R_p \), and \( x \otimes 1 \) is integral over \( R_p \), thus \( x \otimes 1 \in R_p \), which means \( x \otimes 1 = 1 \otimes a/f \) for some \( a, f \in R, f \notin p \). This means \( f'(fx - a) = 0 \in Q(R) \) for some \( f' \notin p \), so \( f f' \in I \), and thus \( I \) is not contained in any prime ideal, so \( I = 1 \) and \( x \in R \).

Prop. (4.3.5.4). Let \( R \) be a reduced ring with f.m. minimal prime ideals, then the following are equivalent:

- \( R \) is a normal ring.
- \( R \) is integrally closed in its ring of fractions.
- \( R \) is a finite product of normal domains.

In particular, a Noetherian normal domain is a finite product of normal domains (4.1.1.46).

Proof: 3 \( \to 1 \) is trivial, 1 \( \to 2 \) is by (4.3.5.3), for 2 \( \to 3 \): let \( p_i \) be the minimal prime ideals of \( R \), then \( \text{Frac}(R) = \prod_{i=1}^{r} Q_{p_i} \) (4.1.7.22), with each \( Q_{p_i} \) field because \( R \) is reduced. Denote the idempotents of \( \text{Frac}(R) \) by \( e_i \). Then \( e_i \) is integral thus in \( R \). These idempotents make \( R \) into a product of domains, which are just \( R/p_i \), because the kernel of the map \( R \to R_{p_i} \) is \( p_i \). Now \( R \) is integrally closed in \( \text{Frac}(R) \) implies each \( R/p_i \) is integrally closed in \( R_{p_i} \), thus \( R \) is a finite product of normal domains.

Def. (4.3.5.5) [Normalization]. The normalization of an integral domain is the alg.closure of it in its quotient field. It commutes with localization.

Def. (4.3.5.6) [Completely Normal Domains]. A domain is called completely normal iff all almost normal elements are in \( A \), i.e. \( \{ u | \exists a, au^n \in A \forall n \} \in A \). For Noetherian ring, completely normal is equivalent to normal.

Proof: Cf.[Sta]00GX.
Prop. (4.3.5.7). A is a normal domain, then so does $A[X]$. If $A$ is Noetherian normal domain, then so does $A[[X]]$.

Proof: Cf.[Sta]030A, 0BI0.

Prop. (4.3.5.8). Direct limits of normal rings are normal.

Proof: Let $p$ be an ideal of $R = \lim\rightarrow R_i$, $p_i = p \cap R_i$, then $R_p = \lim\rightarrow (R_i)_{p_i}$, so it suffices to prove for normal domains, the rest is easy.

Prop. (4.3.5.9) [Closure in Separable Extension]. Let $R$ be a Noetherian normal domain with field of fraction $K$ and $L/K$ is a finite separable field extension, then the integral closure $S$ of $R$ in $L$ is finite over $R$.

Proof: Let $\text{tr} : L \times L \rightarrow K : (x, y) \mapsto \text{tr}(xy)$ be the trace pairing, then as $L/K$ is finite separable, this is non-degenerate. Now if $x \in L$ is integral over $R$, then $\text{tr}(x) \in R$. So if $x_1, \ldots, x_n$ are integral and form a basis of $L$ over $K$, then $M = \{y \in L | \langle x_i, y \rangle \in R\}$ is an $R$-module and $M \cong R^n$, and $S \subset M$, so $S$ is finite over $R$ as $R$ is Noetherian.

Prop. (4.3.5.10) [Field Extension]. Let $A$ be a $K$-algebra, and $L/K$ is a field extension, then if $A_L$ is a normal integral domain, so is $A$. And the converse is also true if $L/K$ is separable.

Prop. (4.3.5.11) [Algebraic Hartogs’s Lemma]. Principal ideals in a Noetherian normal domain is unmixed and $A = \bigcap_{ht} p=1 A_p$.

Proof: Cf.[Matsumura P124], [Rising Sea, P320], [Sta]031T.

Prop. (4.3.5.12) [Krull]. If $A$ is a normal domain with fraction field $K$, $L$ is a normal extension field of $K$ and $B$ is the integral closure of $A$ in $L$ that $A \subset B$ is integral, then any two prime ideals of $B$ lying over a prime in $A$ are conjugate by an action of $G_{L/K}$.

Proof: Firstly if $G_{L/K}$ is finite, and $P, P'$ be primes of $B$ that $P \cap A = P' \cap A$. Let $P_i = \sigma_i(P)$. If $P' \neq P_i$ for any $i$, then $P' \nsubseteq P_i$ for any $i$ by(4.2.1.5), so there is some $x \in P'$ not in any of $P_i$. Now let $y = (\prod_i \sigma_i(x))^q$ where $q = 1$ if char$(K) = 0$ and $q = p^r$ for $r$ large if char$(K) = p$, then $y \in K$ thus in $A$ because $A$ is normal, and it is not in $P$ by hypothesis. But $y \in P' \cap A = P \cap A$, contradiction.

For the infinite field extension case, let $K'$ be the fixed field of $G_{L/K}$ so that $K'/K$ is purely inseparable, then there is clearly exactly one prime of $K'$ over any prime of $A$. So we can assume $L/K$ is Galois, then use profinite group technique to find a $\sigma \in G_{L/K}$ that $\sigma(P) = P'$. 

Prop. (4.3.5.13) [Hironaka]. Let $A$ be a local Noetherian domain that is a localization of an algebra of f.t. over a field $k$. Let $t \in A$ that

- $tA$ has only on eminimal associated prime ideal $p$.
- $t$ generate the maximal ideal of $A_p$.
- $A/p$ is normal.

Then $p = tA$ and $A$ is normal.

Proof: Cf.[Hartshorne P264].

Prop. (4.3.5.14) [Quadratic Extension is Normal]. If $A$ is a UFD that $2$ is invertible in $A$ and $f \in A \setminus A^2$, then $A[Z]/(Z^2 - f)$ is integral and normal.
Proof: It is integral by (2.2.3.13). To show it is normal, assume $F(T) \in B[T]$ that $f(\alpha) = 0$, where $\alpha \in K(B) \backslash B$, then by replacing $F$ by $\overline{F}$, we can assume $F(T) \in A[T]$. We can assume $\alpha \notin K(A)$, thus $\alpha = g+hZ$, then the minimal polynomial of $\alpha$ is $Q(T) = T^2 - 2gT + (g^2 - h^2 f) \in K(A)[T]$. Then $F(T) = P(T)Q(T)$ in $K(A)[T]$. By Gauss’s lemma, $2g, g^2 - h^2 f \in A$, so $g, f \in A$ by hypothesis. □

Cor. (4.3.5.15). If $k$ is a field of characteristic $\neq 2$, then
- $k[x_1, \ldots, x_n]/(x_1^2 + \ldots + x_m^2)$ is integral normal for $n \geq m \geq 3$.
- $k[x, y, z, w]/(wz - xy)$ is normal. (Diagonalize).

Prop. (4.3.5.16). $\mathbb{Z}[\sqrt{n}]$ is integrally closed for $n \equiv 3 \mod 4$, and $\mathbb{Z}[1+\sqrt{n}]$ is integrally closed for $n \equiv 1 \mod 4$, by (12.2.4.14).

Regular Ring

Def. (4.3.5.17) [Regular Rings]. A Noetherian local ring $(A, \mathfrak{m}, k)$ is called regular local if it $\dim A = \dim k[\mathfrak{m}/\mathfrak{m}^2]$. This is equivalent to $\text{rank}_k \mathfrak{m}/\mathfrak{m}^2 \leq \dim A$, or $A \cong k[X_1, \ldots, X_d]$ by (4.2.2.19).

Localization of a regular local ring at primes are regular local, Cf.[Sta]0AFS. Hence we define a regular ring to be a Noetherian ring that all its localization at primes are regular local.

Proof: Cf. [Matsumura P139]. □

Prop. (4.3.5.18). If $A$ is regular, then $A[X_1, \ldots, X_n]$ is regular, and $A[[X_1, \ldots, X_n]]$ is regular.

Proof: Cf. [Matsumura P176]. □

Prop. (4.3.5.19)[Auslander-Buchsbaum]. A regular local ring is UFD. In particular it is a normal domain. Thus a regular ring is normal and thus reduced (4.3.5.1).

Proof: Cf. [Matsumura P142],[Weibel P106]. □

Cor. (4.3.5.20). A regular local ring of dimension 0 is a field, and a regular local ring of dimension 1 is a DVR.

Prop. (4.3.5.21). A regular local ring is Gorenstein hence C.M..

Proof: □

Prop. (4.3.5.22)[Regular Local Ring and Regular Sequences]. Let $(R, \mathfrak{m})$ be a regular local ring of dimension $d$,
- If $x_1, \ldots, x_c$ be a sequence that maps to linearly independent elements in $\mathfrak{m}/\mathfrak{m}^2$, then $(x_1, \ldots, x_c)$ is a regular sequence, and $R/(x_1, \ldots, x_c)$ is a regular local ring of dimension $d-c$.
- If $I \subset \mathfrak{m}$ and $R/I$ is a regular local ring, then $I = (x_1, \ldots, x_c)$ where $(x_1, \ldots, x_c)$ is a regular sequence.
- If $(x_1, \ldots, x_c)$ is a regular sequence in $\mathfrak{m}$ and $R/(x_1, \ldots, x_c)$ is a regular local ring, then $R$ is also a regular local ring.
Proof: 1: We can complete it to a sequence \((x_1, \ldots, x_d)\) that \((x_1, \ldots, x_d)\) generate \(m/m^2\), then by Nakayama \((x_1, \ldots, x_d) = m\). Now by Krull’s height theorem (4.2.4.18), \(R/(x_1)\) has dimension \(\geq d - 1\) and \((x_2, \ldots, x_d)\) generate the maximal ideal, so \(R/(x_1)\) is a regular local ring by definition. Now \(x_1 \neq 0\) because \(R\) is a domain (4.3.5.19), thus we can use induction to show \((x_1, \ldots, x_c)\) is a regular sequence.

2: Let \(\dim(R/I) = d - c\), then the hypothesis shows \((I + m^2)/m^2 \cong I/mI\) has rank \(c\), thus we can choose \((x_1, \ldots, x_c) \in I\) that generate \(I/mI\). Thus by Nakayama \(I = (x_1, \ldots, x_c)\), and \((x_1, \ldots, x_c)\) is a regular sequence by item 1.

3: By induction, it suffices to prove the \(c = 1\) case, then any lift of \(x_1\) together with \(d - 1\) generator of the maximal ideal of \(R/m\) is a set of generator of \(m\).

\[\square\]

Cor. (4.3.5.23). A regular local ring is C.M., by item 1.

Prop. (4.3.5.24). If a quotient of a Noetherian local ring by a non-zerodivisor is regular, then it is itself regular.

Prop. (4.3.5.25) [Serre]. A Noetherian local ring \(A\) is regular iff the global dimension of \(A\) is finite.

\[\text{Proof:} \quad \text{Cf.} \{\text{Mat P139}\}. \quad \square\]

Prop. (4.3.5.26). For \(A\) a regular local ring and \(M\) a f.g. \(A\)-module,

\[pd(M) + \text{depth } M = \dim A.\]

\[\text{Cf.} \{\text{Hartshorne P237}\}.\]

Cor. (4.3.5.27). For a f.g. module \(M\) over a regular local ring \(A\), \(pd(M) \leq n\) iff \(\text{Ext}^i(M, A) = 0\) for all \(i > n\).

\[\text{Proof:} \quad \text{This is because we can use dimension shifting to show} \ \text{Ext}^i(M, N) = 0 \quad \text{for all } N \text{ f.g., then (4.3.3.3) says that} \ pd(M) \leq n. \quad \square\]

Prop. (4.3.5.28) [Regular and Regular Sequence]. Let

Prop. (4.3.5.29). Let \(R \to S\) be a flat local homomorphism of Noetherian local rings that \(R\) is regular, \(S/mS\) is regular, then \(S\) is also regular.

\[\text{Proof:} \quad \text{Cf.} \{\text{Sta}031E\}. \quad \square\]

Serre Conditions \(R_k \& S_k\)

Def. (4.3.5.30). A ring is called \(R_k\) if for all prime \(p\) of height \(\leq k\), \(A_p\) is regular.

A ring is called \(S_k\) if \(\text{depth}(A_p) \geq \min(k, \text{ht}(p))\) for all prime \(p\).

A module \(M\) is called \(S_k\) if \(\text{depth}(M_p) \geq \min(k, \dim \text{Supp } M_p)\) for all prime \(p\).

Prop. (4.3.5.31).

- \(M\) is \(S_1\) if \(M\) has no associated embedded primes. Cf. [Sta]031Q.
- A Noetherian ring is reduced iff it is \(R_0\) and \(S_1\). Cf. [Sta]031R.
- (Serre Criterion) A Noetherian ring is normal iff it is \(R_1\) and \(S_2\). Cf. [Sta]031S.
- A ring is C.M. iff it is \(S_N\).
4.3. COMMUTATIVE ALGEBRA III

Proof: □

Cor. (4.3.5.32) [Regular and Normal]. A regular ring is normal, and normal ring is regular in codimension 1.

Proof: By (4.3.5.31), it suffices to prove that a regular ring satisfies R1 and S2. A regular ring is C.M. (4.3.5.21) so it is S2 by (4.3.5.31), it is R1 by (4.3.5.17) □

Cor. (4.3.5.33) [Normal and Regular Dimension 1]. A Noetherian local ring of dim 1 is normal iff it is regular. i.e. integral domain and integrally closed iff maximal ideal is principal.

6 Geometric Properties

Def. (4.3.6.1).
- A k-algebra S is called geometrically reduced/integral/connected... over a field k iff for any field extension k'/k, Spec S_{k'} is reduced/integral/connected...
- A Noetherian k-algebra S is called geometrically regular iff for any f.g. field extension K/k, S_{K} is regular (Notice A \otimes k k' is Noetherian (4.1.1.44), so this makes sense).

Prop. (4.3.6.2) [Geometrically reduced]. If S is a k-algebra, the following are equivalent.
1. S is geometrically reduced.
2. S \otimes_k \overline{k} is reduced.
3. S \otimes_k k^{per} is reduced.
4. S \otimes_k k' is reduced for any finite purely inseparable field extension k'/k.
5. S \otimes_k k^{1/p} is reduced.
6. residue fields of S at maximal points are reduced.
7. S \otimes_k R is reduced for every reduced k-algebra R.

Proof: 1 \rightarrow 7: We can assume R is f.g., thus R is contained in a finite product of fields Cf.[Sta]030V?, and then we can assume R is a product of fields, and we are done.
1 \rightarrow 2 \rightarrow 3 \rightarrow 4 is clear. 3 \rightarrow 5 is clear.
4 \rightarrow 1: For any field extension K/k, we can assume WLOG K/k is f.g., thus?
5 \rightarrow 1: ? 6: Cf.[Sta]030V and [Gortz 135]. □

Prop. (4.3.6.3) [Geometrically Irreducible]. Let S be a k-algebra, the following are equivalent:
1. S is geometrically irreducible.
2. For any finite separable field extension k'/k, the spectrum of S_{k'} is irreducible.
3. The spectrum of S_{k^{sep}} is irreducible.
4. The spectrum of S_{k} is irreducible.

Proof: Cf.[Sta]037K.? □

Prop. (4.3.6.4). Let S be a geometrically irreducible k-algebra and R is a k-algebra, then the map

\text{Spec}(R \otimes_k S) \rightarrow \text{Spec} R

induces a bijection on irreducible components.
Proof: Cf.[Sta]037O. □

**Prop.(4.3.6.5)[Geometrically Integral].** Let $S$ be a $k$-algebra, the following are equivalent:
1. $S$ is geometrically integral.
2. For any finite separable field extension $k'/k$, $S_{k'}$ is an integral domain.
3. $S_k$ is an integral domain.
4. $S \otimes_k R$ is an integral domain for any integral domain $R$ over $k$.

Proof: This follows from(4.3.6.3)(4.3.6.2) and(4.3.6.4). □

**Prop.(4.3.6.6).** It suffices to check geometrically regular for $k'/k$ finite purely inseparable.

Proof: Cf.[Sta]0381. □

7 Finitely Presentedness

**Finite Presented Modules**

**Def.(4.3.7.1)[Finitely Presented Modules].** A finitely presented module is a module of the form $R^m/R^n$.

Finite presentation is stable under base change because tensoring is right exact.

**Prop.(4.3.7.2).** Given an exact sequence of $R$-modules $0 \rightarrow M_1 \rightarrow M_2 \rightarrow M_3 \rightarrow 0$,
- If $M_1, M_3$ are f.p., then so does $M_2$.
- If $M_3$ is f.p. and $M_2$ is f.g., then $M_1$ is f.g.
- If $M_2$ is f.p. and $M_1$ is f.g., then $M_3$ is f.p.

Proof: 1: e can find an commutative diagram

$$
\begin{array}{cccc}
0 & \rightarrow & R^m & \rightarrow & R^{m+n} & \rightarrow & R^m & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & M_1 & \rightarrow & M_2 & \rightarrow & M_3 & \rightarrow & 0
\end{array}
$$

and use the snake lemma to see the kernel is f.g..

2: Use the diagram

$$
\begin{array}{cccc}
R^m & \rightarrow & R^n & \rightarrow & M & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow_{id} & & \\
0 & \rightarrow & M_1 & \rightarrow & M_2 & \rightarrow & M_3 & \rightarrow & 0
\end{array}
$$

cokernel of $\alpha$ are all finite, so $M_1$ is finite.

3: Choose a presentation $R^m \rightarrow R^n \rightarrow M_2$ and a surjection $f : R^k \rightarrow M_1$, then we can lift $f$ to $R^k \rightarrow R^m$, and then $M_3$ can be written as a quotient $R^{m+k} \rightarrow R^m \rightarrow M_3$. □

**Cor.(4.3.7.3).** A direct summand of a f.p. module is f.p..

**Prop.(4.3.7.4).** If $R \rightarrow S$ is a f.g. ring map and a $S$-module $M$ is f.p. over $R$, then it is f.p. over $S$.

Proof: Let $S = R[x_1, \ldots, x_n]$, and $M = R[y_1, \ldots, y_m]/(\sum a_{ij}y_j), 1 \leq i \leq t$, then as $M$ is a $S$-module, we let $x_iy_j = \sum a_{ijk}y_k$, and forms a quotient $S^{m+n+t} \rightarrow S^m \rightarrow N \rightarrow 0$, where $S^{m+n+t}$ corresponds to the relations $\sum a_{ij}y_j$ and $x_iy_j - \sum a_{ijk}y_k$. Then there is a surjective $A$-module map $N \rightarrow M$, and we check it is injective: if $z = \sum b_jy_j$ are mapped to 0, where $b_j \in S$, then we can transform $z$ into the shape $\sum c_jy_j$, where $c_j \in R$ by relations $x_iy_j - \sum a_{ijk}y_k$. Thus it is zero by definition.
Prop. (4.3.7.5) [Direct Limits of F.P. Modules]. Any module is a direct limit of f.p. modules. This can be seen by considering all finite submodules and f.m relations between them.

Prop. (4.3.7.6) [Characterizing Finite and F.P. Modules]. Let $N$ be an $R$-module, then

- $N$ is finite $R$-module iff for any filtered colimits $M = \varinjlim M_i$ of $R$-modules, the map $\varinjlim \text{Hom}(N, M_i) \to \text{Hom}(N, \varinjlim M_i)$ is injective.
- $N$ is a f.p. $R$-module iff for any filtered colimits $M = \varinjlim M_i$ of $R$-modules, the map $\varinjlim \text{Hom}(N, M_i) \to \text{Hom}(N, \varinjlim M_i)$ is a bijection.

Proof: \[ \text{If } N \text{ is generated by } x_i \text{ and a map } f : N \to M_i \text{ maps to } 0 \in \text{Hom}(N, \varinjlim M_i), \text{ then there is a } j \text{ that } f : M_j \to M_i \to M_j = 0. \text{ Thus } f = 0. \text{ Conversely, } N \text{ is the sum of its f.g. submodules } N', \text{ thus } N \to \varinjlim N/N_i = 0, \text{ which implies the identity map } N \to N \text{ vanishes for some } N/N' \text{ where } N' \text{ is a finite submodule of } N, \text{ so } N = N' \text{ and } N \text{ is a finite.} \]

2: If $M$ is f.p., we can get the assertion by writing $M$ as a quotient of free modules and use the fact filtered colimit is exact (4.1.4.24). Conversely, write $N$ as a filtered colimits of f.p. modules (4.3.7.5), then $\text{id} : M \to M$ factors through some f.p. module, so it is a direct summand of a f.p. module, thus f.p. by (4.3.7.3). \qed

Cor. (4.3.7.7) [FP and Localization]. For $M$ f.p., $S^{-1} \text{Hom}_R(M, N) = \text{Hom}_{S^{-1}R}(S^{-1}M, S^{-1}N)$ for any $R$-module $N$. (Use the presentation and Hom is left exact).

Proof: $\text{Hom}_{S^{-1}R}(S^{-1}M, S^{-1}N) \cong \text{Hom}_R(M, S^{-1}N)$ by duality, and then we can use (4.3.7.6), as localization is a filtered colimit. \qed

Finitely Presented Ring Map

Def. (4.3.7.8) [Finitely Presented Ring Map]. A ring map is called of finite presentation iff it is a quotient of a free algebra by a free algebra.

Prop. (4.3.7.9). Finite presentation is stable under composition (choose a presentation form to see) and base change because tensoring is right exact.

It is local on the source and target by (4.1.4.4).

Prop. (4.3.7.10). For $S$ f.p. over $R$, then the kernel of any surjective ring map $R[X_1, \ldots, R_n] \twoheadrightarrow S$ is f.g.

Proof: Let $S = R[Y_1, \ldots, Y_m]/(f_1, \ldots, f_k)$, then if $\alpha(X_i) \cong g_i(Y)$, then $\alpha : R[X_1, \ldots, R_n] \to R[Y_1, \ldots, X_m, Y_1, \ldots, Y_m](f_1, \ldots, f_k, X_i - g_i).$ And the $Y_i$ are in the image, thus we let $Y_i$ are mapped onto by $h_j(X)$, then $\ker \alpha = (f_i(h_j(X)), X_i - g_i(X)).$ \qed

Prop. (4.3.7.11). If $g \circ f : R \to S' \to S$ is of finite presentation and $f$ is of finite type, then $g$ is of finite presentation.

Proof: Let $S' = R[y_1, \ldots, y_n]$ and $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_m)$, then let $h_i(X) \cong y_i$ in $S$, then $S = S'[X_1, \ldots, X_n]/(f_1, \ldots, f_m, h_i - y_i).$ \qed

Prop. (4.3.7.12) [Normal Form of F.P.]. If $S$ is f.p. over $R$ that $S$ has a presentation $S = R[X_1, \ldots, X_n]/I$ that $I/I^2$ is free over $S$, then $S$ has a presentation $R[X_1, \ldots, X_m]/(f_1, \ldots, f_c)$ that $(f_1, \ldots, f_c)/(f_1, \ldots, f_c)^2$ is freely generated by $f_1, \ldots, f_c$. 

Proof. Cf. [Sta]07CF.

Prop. (4.3.7.13) [Finite Type Locally of Finite Presentation]. If $R \to S$ is a injective map of f.t. of domains, then there are $f \neq 0 \in R, g \neq 0 \in S$ that $R_f \to S_f g$ is of f.p.

Proof: Use induction on the number of generators of $S/R$. If $S = R[x]$, then $S = R[X]/q$. If $q = 0$, then $S$ is of f.p. If $g = fx^d + a_d x^{d-1} + \ldots + a_0$ be a polynomial of minimal degree in $q$, then $R \to S_f$ is of f.p.

The more generator case can be reduced to the single generator case, because f.p. ring map is stable under composition (4.3.7.9).

Lemma (4.3.7.14) [Filtered Colimits and F.P.]. Let $R \to A$ be a ring map, then the category of f.p. $R$-algebras $A'$ with an $R$-algebra map $A' \to A$ is filtered, and the colimit is just $A$.

Proof: Cf. [0BUF].

8 Nagata & Excellent Rings

Def. (4.3.8.1) [Japanese & Nagata Rings]. Let $R$ be a domain with quotient field $K$, then $R$ is called N-1 iff the integral closure of $R$ in $K$ is a finite $R$-module.

$R$ is called N-2 or Japanese iff for any finite field extension $L/K$, its integral closure in $L$ is a finite $R$-module.

A ring $R$ is called universally Japanese if for any domain $S$ of f.t. over $R$, $S$ is Japanese.

A ring $R$ is called Nagata if it is Noetherian and for any prime $p$, $R/p$ is Japanese.

All these properties are local properties (4.1.4.4). And they are in fact stable under any localizations.

Prop. (4.3.8.2) [Nagata]. Let $R$ be a ring, the following are equivalent:

- $R$ is Nagata,
- any f.g. $R$-algebra is Nagata.
- $R$ is universally Japanese and Noetherian.

Proof: Cf. [Sta]0334.

Prop. (4.3.8.3) [Nagata and Formal Fibers]. Let $(A, m)$ be a Noetherian local ring, then $A$ is Nagata iff the formal fibers of $A$ are geo.reduced.

Proof: Cf. [Sta]0BJ0.

Excellent Rings

Def. (4.3.8.4) [G-Rings]. A G-ring is a Noetherian ring s.t. for any prime $p \subset R$, the map $R_p \to R_p$ is regular.

Def. (4.3.8.5) [Excellent Rings]. A quasi-excellent ring is a ring that is Noetherian, G-ring and J-2. A excellent ring is a quasi-excellent ring that is universally catenary.

Prop. (4.3.8.6). Quasi-excellent rings are Nagata.

Proof: Cf. [Sta]07QV.
Prop. (4.3.8.7) [Examples]. The following rings and f.g. algebras over them are excellent rings:
- fields.
- Noetherian complete local rings
- Dedekind domain with fraction field of characteristic 0.
In particular, ring of integers in all local fields and number fields are excellent.

Proof: Cf.[Sta]0335. □

Cor. (4.3.8.8). The above rings are all Nagata, by (4.3.8.6).

9 Separability

Main references are [Matsumura Ch10], [Weibel Chap P309] and [Sta]10.41, 10.43.

Def. (4.3.9.1) [Separable Algebra]. A f.d semisimple algebra $R$ over a field $k$ is called separable iff for every field extension $K/k$, $R \otimes_k K$ is semisimple.

Def. (4.3.9.2). A field extension $K/k$ is called separably generated iff it $K$ is a separable algebraic extension of a purely transcendental field $L/k$.

A field extension $K/k$ is called separable iff all f.g. subextensions are separably generated.

An algebra $A/k$ is called separable iff $A \otimes_k k'$ is reduce for any $k'/k$ algebraic.

Prop. (4.3.9.3). If $k \subset K$ is a f.g. field extension, then there is a finite purely inseparable field extension $k \subset k'$ that $k' \subset k'K$ is separable.

Proof: □

Prop. (4.3.9.4) [Separable and Geo.Reduced]. Let $K/k$ be a field extension, then $K/k$ is separable iff $K/k$ is geometrically reduced.

Proof: Cf.[Sta]030W. □

Cor. (4.3.9.5). If $K/k$ is a separable field extension and $S$ is a reduced $k$-algebra, then $S \otimes_k K$ is reduced.

Proof: Cf.[Sta]030U. □

Cor. (4.3.9.6). A separably generated field extension is separable.

10 Henselian Ring

Main References are [Sta]Chap10.148.

Def. (4.3.10.1). A local ring $(R, m, k)$ is called Henselian iff for every $f \in R[X]$ and $a_0 \in k$ that $f(a_0) = 0$ and $f'(a_0) \neq 0$, then there is a root $\alpha$ of $f$ lifting $a_0$. It is called strict Henselian if moreover its residue field is separably closed.
**Henselian Pairs**

**Def. (4.3.10.2).** A **Henselian pair** is a pair \((A, I)\) that is Zariski and for any \(f, g\) in \(A[T]\) monic and \(\overline{f} = \overline{g}h \in A/I[T]\) that is coprime and monic, there is a factorization \(f = gh\) lifting the decomposition.

In particular, if \(f\) has a simple root \(\overline{x}\) in \(A/I\), then it has a root \(x \in A\) lifting \(\overline{x}\).

**Prop. (4.3.10.3).** Filtered limits of Henselian pairs is Henselian, this is clear from the definition (4.3.10.2).

**Lemma (4.3.10.4).** If \(A\) is a ring with ideal \(I\), if \(\overline{f} = \overline{g}h\) be a factorization of a polynomial \(f \in A[T]\) in \(A/I[T]\), then there is an étale ring map \(A \to A'\) that \(A/IA \cong A'/IA'\), and a factorization \(f = gh' \in A'[T]\) lifting the factorization.

**Proof:** Cf. [Almost Ring Theory, 5.1.9].

**Prop. (4.3.10.5) [Topological Invariance of Étale Sites].** If \(I\) is locally nilpotent, then \((A, I)\) is Henselian, in particularly \(A_{et} \cong (A/I)_{et}(4.3.10.9)\).

**Proof:** First if \(A \to S\) is étale, then \(A/I \to S/IS\) is étale by base change (4.4.7.5) and the map is essentially surjective by (4.4.7.15). And any map \(B/IB \to B'/IB'\) can be lifted to \(B \to B\) because étale is smooth and use (4.4.5.16). And the lifting is unique, otherwise if \(f, g\) are two lifting, because étale is unramified, so if we choose an idempotent \(e\) generating the kernel of \(B \otimes_A I \to B \to B'\), then \(f \otimes g(e) \in IB'\), which is locally nilpotent, thus \(f \otimes g(e) = 0\), thus \(f = g\).

For then Henselian, \(I\) is clearly contained in the Jacobson radical, and for the decomposition, by (4.3.10.4) these is an étale map \(A \to A'\) that \(A/IA \cong A'/IA'\) that lifts the factorization, but \(A = A'\), by what we have seen above.

**Cor. (4.3.10.6) [Complete Pair is Henselian].** If \((A, I)\) is a pair that \(A\) is \(I\)-adically complete, then \((A, I)\) is Henselian.

**Proof:** \(I\) is in the Jacobson radical because \(1 + I\) consists of units, and by (4.3.10.5) and (4.3.10.4) we can lift the decomposition to \(A/I^n\) inductively. As \(A = \lim A/I^n\), we are done.

**Prop. (4.3.10.7) [Equivalent Definitions of Henselian Pair].** The following are all equivalent to \((A, I)\) being Henselian:
- Given any étale ring map \(A \to A'\), then any \(A' \to A/I\) lifts to an \(A\)-algebra map \(A' \to A\).
- For any finite/integral \(A\)-algebra \(B\), the map \(B \to B/IB\) induces a bijection on idempotents.
- (Gabber) \((A, I)\) is Zariski and every monic polynomial \(f(T) \in A[T]\) of the form \(T^n(T - 1) + a_nT^n + \ldots + a_1T + a_0\) with \(a_i \in I\) has a root \(\alpha \in 1 + I\).

Moreover, root in item 3 is unique.

**Proof:** Cf. [Sta]09XI.

**Cor. (4.3.10.8).** If \((A, I)\) is Henselian and \(A \to B\) is integral, then \((B, IB)\) is also Henselian.

**Prop. (4.3.10.9) [Henselian Lifting].** If \((A, I)\) is a Henselian pair, then there is a natural equivalence of categories: \(A_{et} \cong (A/I)_{et}\).

**Proof:** Cf. [Sta]09ZL.

**Prop. (4.3.10.10).** A Zariski pair \((R, I)\) is Henselian iff the pair \((\mathbb{Z} \oplus I, I)\) is Henselian. In particular, the property of being Henselian only depends on the non-unital ring \(I\).

**Proof:** Cf. [Almost Ring Theory, 5.1.9].
4.4 Commutative Algebra IV

1 Flatness

Def. (4.4.1.1) [Flatness]. A module $M$ over a ring $R$ is called flat if $M \otimes_R - : \text{Mod}_R \rightarrow \text{Mod}_R$ is an exact functor. This is compatible with the definition (5.2.2.15).

Prop. (4.4.1.2). Flatness need only be checked for finite modules, and it is equivalent to $\text{Tor}_1(M, A/I) = 0$ for any $f.g.$ ideal $I$ (i.e., $I \otimes M \rightarrow M$ is injective).

Proof: This is because of (5.3.3.12) and the fact tensor product commutes with colimit. □

Cor. (4.4.1.3). If $0 \rightarrow M' \rightarrow M \rightarrow M'' \rightarrow 0$, then $M'$ and $M''$ flat implies $M$ is flat.

Prop. (4.4.1.4). If $M$ is flat then $\text{Tor}_i^R(M, N) = 0$ for all $i > 0$, because we have: if $0 \rightarrow M_1 \rightarrow M_2 \rightarrow M_3 \rightarrow 0$ with $M_2, M_3$ flat, then $M_1$ is flat (Use 9 entry sequence and the fact that $\text{Tor}$ is symmetric (4.6.2.5)). So $\text{Tor}_{n+1}(M_3, N) = \text{Tor}_n(M_1, N) = 0$ by induction.

And a direct summand of a flat module is flat. Thus we have the class of flat modules is adapted $- \otimes N$ for all $N$ (because free is flat).

Prop. (4.4.1.5) [Faithfully Flatness]. The following are equivalent:

- $M$ is flat and for any $N \neq 0$, $N \otimes_R M \neq 0$.
- $M$ is flat and for any (maximal) prime ideal $\mathfrak{m}$ of $R$, $k(\mathfrak{m}) \otimes_R M \neq 0$. (When $\mathfrak{m}$ is maximal, which means $\mathfrak{m}M \neq M$).

And such a $M$ is called faithfully flat over $R$.

Proof: $1 \rightarrow 2$ is easy. $2 \rightarrow 1$: any nonzero module has a submodule $R/I$, choose a maximal ideal $\mathfrak{m}$ containing $I$, then $(A/I) \otimes_A M \subset N \otimes_A M$ surjects to $k(\mathfrak{m}) \otimes_A M \neq 0$. □

Prop. (4.4.1.6) [Flatness and Base Change].

- (Faithfully) Flatness is stable under base change.

Flatness satisfies f.f. descent (4.4.2.1).

- Flatness is stable under filtered colimit because filtered colimit commutes with tensoring (2.2.4.13) and is exact (4.1.1.24). In particular, $S^{-1}A$ is flat (4.1.1.27).

- Let $S \rightarrow S'$ be a map of $R$-algebras, $M$ is an $S$-module, $M' = M \otimes_S S'$, then if $M$ is flat over $R$, so does $M'$. The converse also holds if $S \rightarrow S'$ is f.f.

- If $R \rightarrow S$, and a $S$-module $M$ is $R$-flat and $S$-f.f., then $R \rightarrow S$ is flat.

Proof:

4: For any injection of $R$-modules $N \rightarrow N'$, use the fact $\text{ker}(N \otimes_R M \rightarrow N' \otimes_R M) \otimes_S S' = \text{ker}(N \otimes_R M' \rightarrow N' \otimes_R M')$.

5: For any injection of $R$-modules $N \rightarrow N'$, use the fact $\text{ker}(N \otimes_R S \rightarrow N' \otimes_R S) \otimes_S M = \text{ker}(N \otimes_R M \rightarrow N' \otimes_R M')$. □

Prop. (4.4.1.7) [Equational Criterion of Flatness]. For a $R$-module $M$, a relation $\sum f_i x_i = 0$ where $f_i \in R, x_i \in M$ are called trivial iff $\overrightarrow{f} = A \overrightarrow{y}$ for some $A \in M_{n \times n}(R), \overrightarrow{y} \in M^n$, and $\overrightarrow{f^t} A = 0$. Then $M$ is flat iff all relations of elements of $M$ is trivial.
Proof: Assume $M$ if flat over $R$, and $\sum f_i x_i = 0$ is a relation in $M$, Let $I = (f_1, \ldots, f_n)$ and let $K = \ker(R^n \to I : (x_i) \mapsto \sum x_i f_i)$, then $\sum f_i \otimes x_i = 0 \in I \otimes_R M$ by flatness, then $\sum e_i \otimes x_i \in K \otimes_R M$. Let $\sum e_i \otimes x_i = \sum k_j \otimes y_j$, and $k_j = \sum_i a_{ij} e_i$, then this is the desired relations.

Conversely, suppose every relation is trivial, and $I$ is an ideal of $R$, let $x = \sum f_i \otimes x_i \subset I \otimes M$ be an element mapping to $0 \in R \otimes M = M$, then $\sum f_i x_i$ is a relation, so it is trivial, and then $x = \sum f_i \otimes x_i = \sum f_i \otimes (a_{ij} y_j) = (\sum (f_i a_{ij}) y_j) = 0$. \hfill \qed

Prop. (4.4.1.8) [Gororov-Lazard]. Any flat $A$-module is isomorphic to a direct limit of finite free modules.

Proof: Cf. [Sta] 058G.

Prop. (4.4.1.9). Flat module is torsion-free.

Proof: If $x \in R$ is a nonzero-divisor, $R \xrightarrow{\cong} R$ is injective, thus $M \xrightarrow{\cong} M$ is also injective. \hfill \qed

Prop. (4.4.1.10) [Flat over Local Rings]. A finite module $M$ over a local ring $A$ is flat iff it is free. In particular, finite modules over a field are all flat.

Proof: Let $A/\mathfrak{m} = k$, choose a $k$-basis $x_i$ of $M/\mathfrak{m}M$, then they generate $M$ by Nakayama. It suffices to prove that $x_i$ are independent over $R$. For this, use equational criterion of flatness (4.4.1.7), we prove that if $x_i$ is independent over $k$, then they are independent over $A$. Use induction, if $x \neq 0$ in $M/\mathfrak{m}$, if $fx = 0$ for some $f \in A$, then $x = \sum a_j y_j$, it $fa_j = 0$, but then some $a_j$ is a unit, so $f = 0$.

If $\sum f_i x_i = 0$, then by hypothesis, $f_i \in \mathfrak{m}$, and there are $y_j$ such that $x_i = \sum a_{ij} y_j$, $\sum f_i a_{ij} = 0$. As $x_n \notin \mathfrak{m}M$, there is a $a_{nj} \notin \mathfrak{m}$, so $f_n = \sum (-a_{ij}/a_{nj}) f_i$. Then $\sum_{i \neq n} f_i(x_i - a_{ij}/a_{nj} x_n) = 0$, but $x_i - a_{ij}/a_{nj} x_n$ is also independent over $k$, so by induction, $f_i = 0$, also does $f_n$, so we are done. \hfill \qed

Prop. (4.4.1.11) [Flat over Bézout Domains]. A module $M$ over a Bézout domain $R$ is flat iff it is torsion-free.

Proof: One direction is clear by (4.4.1.9). If it is torsion-free, we use the equational criterion of flatness (4.4.1.7):

Let $\sum a_i x_i = 0$ where $a_i \in R^*$, $x_i \in M$, then consider $(a_1, \ldots, a_n) = (a)$, thus $a_i = ab_t$ for some $b_t \in R$, and $\sum c_i b_t = 1$ for some $c_i \in R$ as $R$ is a domain. Because $M$ is torsion-free, $\sum a_i x_i = 0$. Notice $\overrightarrow{x} = (1 - \overrightarrow{c} \overrightarrow{b}^t) \overrightarrow{x}$, so we can take $\overrightarrow{y} = \overrightarrow{x}$, $A = 1 - \overrightarrow{c} \overrightarrow{b}^t$. Then $\overrightarrow{b}^t A = \overrightarrow{b}^t - \overrightarrow{b}^t \overrightarrow{c} \overrightarrow{b}^t = 0$. \hfill \qed

Cor. (4.4.1.12) [Flat over Valuation Rings]. A module over a valuation ring is flat iff it is torsion free. In particular, if $(A, \mathfrak{m})$ is a DVR with a uniformizer $t$, then $M \in \text{Mod}_A$ is flat iff $t$ is injective on $M$.

Proof: Because valuation ring is Bézout (10.3.2.8), we can use (4.4.1.11). \hfill \qed

Cor. (4.4.1.13) [Flat Module over a Dedekind Domain]. If $A$ is a Dedekind domain, then an $A$-module is flat iff it is torsion-free.

Proof: Because flatness and torsion-freeness is stalkwise (4.1.4.2), so it suffices to prove for its localization, which is DVR (4.2.7.2), so the result follows from (4.4.1.12). \hfill \qed

Prop. (4.4.1.14) [Finite Flat is Locally Free]. Finitely presented flat module is equivalent to finite projective and equivalent to finite locally free. (Immediate from (4.3.1.7)).
Prop. (4.4.1.15). if $M$ is a flat $R$-module, then $IM \cap JM = (I \cap J)M$ for ideals of $A$.

Proof: Tensoring the exact sequence $0 \to I \cap J \to I \oplus J \to J \cup J \to 0$ with $M$. □

Prop. (4.4.1.16) [Local & Infinitesimal Criterion of Flatness]. Let $(A, \mathfrak{m}) \to (B, \mathfrak{n})$ be a local homomorphism of Noetherian local rings, and $M$ is a finite $B$-module, then the following are equivalent:

- $M$ is flat over $A$.
- $\text{Tor}_1^A(M, A/\mathfrak{m}) = 0$.
- $M/\mathfrak{m}^nM$ is flat over $A/\mathfrak{m}^n$ for sufficiently large $n$.

Proof: 1 $\to$ 2, 1 $\to$ 3 is trivial. For the converse, we need to prove $\text{Tor}_1^A(M, A/I) = 0$ for any ideal $I \subset A$, or $I \otimes M \to M$ is injective.

If 2 holds, then $\text{Tor}_1^A(M, N) = 0$ for any $A$-module of finite length, because by devissage we can reduce $N$ to $A/\mathfrak{m}$.

Tensoring the exact sequence $0 \to \mathfrak{m}^n \cap I \to I \to I/I \cap \mathfrak{m}^n \to 0$ with $M$, we get

$$\mathfrak{m}^n \cap I \otimes M \to I \otimes M \to (I/I \cap \mathfrak{m}^n) \otimes M \to 0$$

and also the exact sequence $0 \to I/I \cap \mathfrak{m}^n \to R/\mathfrak{m}^n \to R/(I + \mathfrak{m}^n) \to 0$ gives

$$0 \to (I/I \cap \mathfrak{m}^n) \otimes M \to M/\mathfrak{m}^nM \to M/(I + \mathfrak{m}^n)M \to 0$$

by the fact $R/(I + \mathfrak{m}^n)$ has finite length in case 2 or the fact they are all $R/\mathfrak{m}^nM$ modules in case 3.

Thus the kernel of $I \otimes M \to M$ is contained in $(\mathfrak{m}^n \cap I) \otimes M$ for any $n$, which means it is contained in $\mathfrak{m}^n(I \cap M)$ for any $n$ by Artin-Rees (4.2.2.13). Thus the kernel is trivial by Krull’s intersection theorem (4.2.2.14) as $I \otimes M$ is finite over $S$. □

Prop. (4.4.1.17).

Flat ring extension

Prop. (4.4.1.18) [Flatness is Local]. Flatness is stalkwise both on the target and source, thus flatness is local both on the target and the source (4.1.4.2).

Cor. (4.4.1.19) [Going-down]. Going-down holds for flat ring map.

Proof: The ring map $R_{p'} \to S_{q'}$ is flat by (4.4.1.18), thus it is f.f. by (4.4.1.23). Then (4.4.1.21) says $p \subset p'$ is in the image. □

Prop. (4.4.1.20). if rings $A \subset B \subset C$ and $C/A, C/B$ is flat, then $B/A$ is flat.

Proof: Cf. [GAGA Serre P26]. □

Prop. (4.4.1.21). The following are equivalent:

- $A \to B$ is f.f.
- It is flat and $\text{Spec} B \to \text{Spec} A$ is surjective.
- It is flat and $\text{Spec}$ map contains all the closed pts.
Proof: This follows form (4.4.1.5) as we see that \( p \) is in the image of Spec map iff \( k(p) \otimes_A B \neq 0 \).

\[ \square \]

Cor. (4.4.1.22). Integral flat injective ring extension is f.f., by (4.2.1.5).

Cor. (4.4.1.23). Flat local ring map of local rings is f.f.

Cor. (4.4.1.24). Filtered colimits of f.f. rings over \( R \) is f.f.

Proof: If is flat by (4.4.1.6), and for a maximal ideal \( m \) of \( R \), \( S_i/mS_i \) is non-zero, hence there direct limit is non-zero because 1 is contained. So \( m \) is in the image, hence it is f.f. by (4.4.1.21).

\[ \square \]

Cor. (4.4.1.25) [Filtered Colimit of Flat Ring Maps]. If \( I \) is filtered and \( R_i \to S_i \) are (faithfully) flat ring maps, then \( \text{colim}_I R_i \to \text{colim}_I S_i \) is (faithfully) flat.

Proof: For any \( \text{colim}_I R_i \)-module \( M \), \( (\text{colim}_I S_i) \otimes_{\text{colim}_I R_i} M = \text{colim}(S_i \otimes_{R_i} M) \), so it is flat, because colim is exact. For the faithfully flatness, for any maximal ideal \( m \) of colim \( R_i \), let \( m_i = m \cap R_i \), then \( S_i/m_i S_i \neq 0 \), thus the direct limit is also \( \neq 0 \), so \( m \) is in the image, hence it is f.f. by (4.4.1.21).

\[ \square \]

Prop. (4.4.1.26). If \( R \to S \) is (faithfully) flat ring map and \( M \) is a (faithfully) flat \( S \)-module, then \( M \) is a (faithfully) flat \( R \)-module. In particular, (faithfully) flatness is stable under composition. Also (faithfully) flatness is stable under base change.

Prop. (4.4.1.27). If \( B \) is flat over \( A \), then

\[
\text{Tor}_i^A(M, N) \otimes B = \text{Tor}_i^B(M(B), N(B)), \quad \text{Ext}_i^A(M, N) \otimes B = \text{Ext}_i^B(M(B), N(B)).
\]

Prop. (4.4.1.28) [Faithfully Flat Ring Map is Injective]. A f.f. ring map \( R \to S \) is universally injective. In particular, tensoring with \( R/I \), we get \( R \cap IS = I \) for an ideal \( I \) of \( R \).

Proof: Because \( R \to S \) is f.f., we only need to show that \( N \otimes_R S \to N \otimes_R S \otimes_R S \) is injective for any \( N \), but this is true because it has a left inverse.

\[ \square \]

Prop. (4.4.1.29). A f.f. map between valuation rings is equivalent to an injective local homomorphism.

Prop. (4.4.1.30). A flat ring map maps a non-zero-divisor to a non-zero-divisor, because if we consider the principal ideal generated by it, then (4.4.1.2) shows the ideal in \( M \) is also injective, so it is not a zero-divisor.

Prop. (4.4.1.31) [Noetherian Completion is Flat]. If \( A \) is Noetherian and \( I \) is an ideal, then the \( I \)-adic completion \( A^\wedge \) is flat over \( A \) by (4.2.3.14).

Prop. (4.4.1.32) [Flat Map is Open]. The Spec map of a ring map \( R \to S \) of f.p. that satisfies going-down (e.g. flat), is open.

Proof: \( S \to S_f \) satisfies going-down and is of f.p, so we see that \( R \to S_f \) satisfies going down. It suffice to prove the image of this map is open. By Chevalley, the image is constructible, and it is stable under generalization. So it is open by (3.8.4.8).

\[ \square \]

Cor. (4.4.1.33). The Spec map \( f \) of a f.f. ring map is an quotient map.
Prop. (4.4.1.34) [Generic Freeness + F.P.]. Let $R$ be a reduced ring, $S$ a f.g. $R$-algebra, $M$ a finite $S$-module, and $R$ is reduced, then there exists an open dense subset $U \subset \text{Spec } R$ that there is a covering of $U$ by standard opens $D(f)$ s.t.
- $M_f$ and $S_f$ are free over $R_f$.
- $S_f$ is a f.p. $R_f$-algebra.
- $M_f$ is a f.p. $S_f$-module.
In particular, it is generically flat.

Proof: Cf. [Sta]051Z. □

Prop. (4.4.1.35) [Miracle Flatness]. Let $f : A \to B$ be a local map of local Noetherian rings s.t.
- $A$ is regular.
- $B$ is Cohen-Macauley.
- $\dim B = \dim A + \dim(A/f(\mathfrak{m}_A)B)$.
Then $f$ is flat.

Proof: Cf. [Sta]00R4. □

Prop. (4.4.1.36) [Slicing Criterion for Flat Modules on the Target]. Let $R \to S$ be a local homomorphism of local rings s.t.
- $S$ is essentially of f.p. over $R$,
- $M$ is of f.p. over $S$,
- $\text{Tor}_1^R(M, R/I) = 0$.
- $M/IM$ is flat over $R/I$.
Then $M$ is flat over $R$.

Proof: Cf. [Sta]0471. □

Prop. (4.4.1.37) [Slicing Criterion for Flatness on the Source]. Let $(R, \mathfrak{m}) \to (S, \mathfrak{n})$ be a local homomorphism of local rings s.t.
- $S$ is essentially of f.p. over $R$,
- $S$ is flat over $R$,
- $\mathfrak{t}$ is a non-zero divisor of $S/\mathfrak{m}S$.
Then $S/\mathfrak{t}S$ is flat over $R$, and $\mathfrak{t}$ is a non-zero divisor in $S$.

Proof: Cf. [Sta]046Z. □

Prop. (4.4.1.38) [Fibral Criterion of Flat Modules]. Let $R \to S \to S'$ be local homomorphisms of local rings and $\mathfrak{m}$ is the maximal ideal of $R$. If
- $R \to S'$ is essentially of f.p.
- $R \to S$ is essentially of f.t.
- $M \neq 0 \in \text{Mod}(S')$ is of f.p. over $S$.
- $M/\mathfrak{m}M$ is flat over $S/\mathfrak{m}S$.
- $M$ is flat over $R$.
Then $S$ is essentially of f.p. and flat over $R$ and $M$ is flat over $S$.

Proof: [Sta]05UV. □
2 Faithfully Flat Descent

Prop. (4.4.2.1) [Faithfully Flat Descent]. List of properties that descent through faithfully flat morphism. Let \( R \to R' \) be a f.f. ring map.

1. Finiteness for modules over a ring.
2. F.p. for modules over a ring.
3. Flatness for modules over a ring.
4. Finite locally freeness and invertibility for modules over a ring.
5. Mittag-Leffler for modules over a ring.
6. Projectiveness for modules over a ring.
7. F.g. for ring maps.
8. F.p. for ring maps, both on the target and source.
9. (Formal) Smoothness for ring maps.
11. Reducedness for rings.
13. Regular for rings.
14. Being Noetherian and has property \((R_k)\) for rings.
15. Local Complete Intersection ring maps.

Proof:

3. Let \( M \) be a \( R \)-module, and \( M' = M \otimes_R R' \), if \( M' \) is \( R \)-flat, then for any \( R \)-module \( N \),
   \( (N \otimes_R M) \otimes_R S = (N \otimes_R S) \otimes_S M' \), so as \( \cdot \otimes_R S \) is exact and reflects exactness, \( \cdot \otimes_R M \) is
   exact, so \( M \) is \( R \)-flat.
4. This follows from f.f. descent for f.p. and flatness and (4.3.1.7).
5. Cf. [Sta]05A5.
7. Cf. [Sta]00QP.
8. Cf. [Sta]00QQ, 00EP.
9. Use criterion (4.4.5.3), we see by flatness that the sequence \( I/I^2 \to \Omega_{P/R} \otimes_P S \to \Omega_{S/R} \to 0 \) commutes with flat base change, and when it is f.f., then use (4.4.3.6) and descent for projectiveness (4.4.2.1) that \( \Omega_{S/R} \) is projective, so it is a split exact sequence. The smooth case follows from definition (4.4.5.12) as f.p. can descend.
10. Because for \( S \to S' \) faithfully flat and a chain of ideals \( I_k \) in \( S \), \( I_kS' = I_k \otimes_S S' \), and \( I_kS' \) is
    stable if \( S' \) is Noetherian, so also \( I_k \) is stable because it is faithfully flat.
11. \( S \to S' \) is f.f. hence injective (4.4.1.28).
12. Normality is stalkwise, so it suffices to assume $R \rightarrow S$ is f.f. and $R, S$ are both local. Then $S$ is normal integral thus by (4.4.1.28), $R$ is also normal integral. Now if $a/b \in R$, then $a/b \in S$, $a \in bS$, thus $a \in bS \cap R = bR$ by (4.4.1.28), so $a/b \in R$.

13. Cf. [Sta]07NG.?

15. flatness and f.p. both satisfies f.f. descent, so it suffices to show that if $\mathfrak{p}' \subset R'$ is a prime lying over $\mathfrak{p} \subset R$, then $S \otimes_R k(\mathfrak{p})$ is a local complete intersection iff $S' \otimes_{R'} k(\mathfrak{p}') = S \otimes_R k(\mathfrak{p}) \otimes_{k(\mathfrak{p})} k(\mathfrak{p}')$ is a local complete intersection, and this follows from [Sta]00SI.

\[\square\]

\textbf{Prop. (4.4.2.2)[fpqc-Poincaré Lemma].} If a ring map $A \rightarrow B$, either has a section $B \rightarrow A$, or it is faithfully flat, then the Amitsur complex $s(M)$ for the canonical descent datum (with augmentation):

\[0 \rightarrow M \rightarrow B \otimes_A M \rightarrow B \otimes_A B \otimes_A M \rightarrow \ldots\]

with Čech-like maps, is exact.

\textit{Proof:} In the case $A \rightarrow B$ has a section $s$, It suffices to construct a nullhomotopy of the case $M = A$. Then we can just let $h(e_0 \otimes e_1 \otimes \ldots \otimes e_r) = s(e_0) e_1 \otimes \ldots \otimes e_r$.

The f.f. case can be reduced to the first case by tensoring $B$ to consider $B \rightarrow B \otimes_A B$, because it has a section. \[\square\]

\textbf{Cor. (4.4.2.3)[Glueing Functions].} Let $R$ be a commutative ring, $M$ a $R$-module, and $(f_1, \ldots, f_n) = (1)$, then there is an exact sequence

\[0 \rightarrow M \rightarrow \prod M_{f_i} \Rightarrow \prod M_{f_i f_j}.\]

In particular this holds for $M = R$.

\textit{Proof:} This is just (4.4.2.2) applied to $A \rightarrow \prod_i A_{f_i}$, which is faithfully flat. \[\square\]

\section*{Formal Glueing of Modules}

Main references are [Sta]Chap15.80 and 15.81.

\textbf{Lemma (4.4.2.4).} Let $R \rightarrow S$ be a ring map and $I = (f_1, \ldots, f_r) \subset R$ be an ideal, then for any $R$-module $M$ we can define a complex

\[0 \rightarrow M \otimes_R S \times \prod M_{f_i} \xrightarrow{\beta} \prod (M \otimes_R S)_{f_i} \times \prod M_{f_i f_j}\]

where $\alpha(m) = (m \otimes 1, m, \ldots, m)$, $\beta(m', m_1, \ldots, m_t) = (m' - m_1 \otimes 1, m' - m_2 \otimes 1, \ldots, m' - m_t \otimes 1, m_1 - m_2, \ldots, m_{t-1} - m_t)$.

Assume that $R \rightarrow S$ is flat and $R/I \rightarrow S/IS$ is an isomorphism, then this complex is exact.

\textit{Proof:} Cf. [Sta]05EK. \[\square\]

\textbf{Def. (4.4.2.5)[Category of Glueing Data].} Let $R \rightarrow S$ be a ring map and $I = (f_1, \ldots, f_r) \subset R$ be an ideal, then we define the category $\text{Glue}(R \rightarrow S, f_1, \ldots, f_r)$ of glueing data $\text{Glue}(R \rightarrow S, f_1, \ldots, f_i)$ consisting of objects $M = (M', M_i, \alpha_i, \alpha_{ij})$ where $M'$ is a $S$-module, $M_i$ are $R_{f_i}$-modules, $\alpha_i : (M')_{f_i} \rightarrow M_i \otimes_R S$ and $\alpha_{ij} : (M_i)_{f_j} \rightarrow (M_j)_{f_i}$ are isomorphisms that
• $\alpha_{ij} \circ \alpha_i = (\alpha_j)_{f_i}$.
• $\alpha_{jk} \circ \alpha_{ij} = \alpha_{ik}$.

There is a canonical functor $\text{Can} : \text{Mod}_R \rightarrow \text{Glue}(R \rightarrow S, f_1, \ldots, f_r)$ and also a morphism $H^0 : \text{Glue}(R \rightarrow S, f_1, \ldots, f_r) \rightarrow \text{Mod}_R$ where

$$H^0(M) = \ker(M' \times \prod M_i \rightarrow \prod M'_{f_i} \times \prod(M_i)_{f_j}).$$

$H^0$ is a left inverse of Can, by (4.4.2.4).

**Lemma (4.4.2.6).** If $R \rightarrow S$ is flat, then $\text{Glue}(R \rightarrow S, f_1, \ldots, f_r)$ is an Abelian category, and Can is an exact functor that commutes with arbitrary colimits.

If moreover $(f_1, \ldots, f_r) = R$, then Can and $H^0$ induces an equivalence of categories.

**Proof:** The kernels and cokernels can be constructed because $- \otimes_R S$ is exact, and Can is exact because $R_{f_i}$ and $S$ are flat over $R$, and also tensoring commutes with taking colimits.

For the last assertion, by (4.4.2.5) it suffices to show that Can is essentially surjective. For this, just use (4.4.2.3) on both $R$ and $S$. \qed

**Prop. (4.4.2.7).** In the setting of (4.4.2.5), if $R/I \rightarrow S/IS$ is an isomorphism, then Can and $H^0$ induces an equivalence of categories.

**Proof:** Cf. [Sta]05ER. \qed

**Cor. (4.4.2.8).** If $R \rightarrow S$ is a flat ring map and $f \in R$ that $R/fR \cong S/fS$ is an isomorphism, then there is a pullback diagram of categories:

$$
\begin{array}{ccc}
\text{Mod}_R & \longrightarrow & \text{Mod}_{R_f} \\
\downarrow & & \downarrow \\
\text{Mod}_S & \longrightarrow & \text{Mod}_{S_f}
\end{array}
$$

and we can also restrict to the category of f.g./f.p/flat/projective(any property satisfying f.f. descent) modules.

**Proof:** For the last assertion, notice $R \rightarrow R^{\wedge} \times \prod R_{f_i}$ is f.f. by (4.2.3.7), then use f.f. descent (4.4.2.1). \qed

**Cor. (4.4.2.9).** If $R$ is a Noetherian ring, $f \in R$ and $R^{\wedge}$ the $f$-adic completion of $R$, then there is a pullback of categories:

$$
\begin{array}{ccc}
\text{Mod}_R & \longrightarrow & \text{Mod}_{R_f} \\
\downarrow & & \downarrow \\
\text{Mod}_{R^{\wedge}} & \longrightarrow & \text{Mod}_{R_{f}^{\wedge}}
\end{array}
$$

and we can also restrict to the category of f.g./f.p/flat/projective(any property satisfying f.f. descent) modules.

**Proof:** This satisfies the hypothesis of (4.4.2.7) by (4.2.3.14). \qed
Def. (4.4.2.10) [Gluing Pairs]. Let $R \to R'$ be a ring map and $f \in R$ that induces an isomorphism $R/f^n R \cong R'/f^n R'$ for any $n > 0$, then $(R \to R', f)$ is called a gluing pair if the sequence

$$0 \to R \to R' \oplus R_f \to R'_f \to 0$$

is exact. The pair $(R, f)$ is called a gluing pair if $(R \to \hat{R}, f)$ is a gluing pair (This makes sense by (4.2.3.6)).

This is equivalent to $R[f^\infty] \to R'[f^\infty]$ is bijective.

Let $M$ be an $R$-module, then $M$ is called a glueable module for $(R \to \hat{R}, f)$ if the sequence

$$0 \to M \to M_{R'} \oplus M_{R_f} \to M_{R'_f} \to 0$$

is exact.

This is equivalent to $M[f^\infty] \to M_{R'}[f^\infty]$ is a bijection. And when $(R \to R', f)$ is a gluing pair, this is equivalent to $M[f^\infty] \to M_{R'}[f^\infty]$ is injective.

Proof: Cf. [Sta]0BNR, 0BNW.

Prop. (4.4.2.11) [Flatness and Gluing]. $(R \to R', f)$ is a gluing pair when $R \to R^\wedge$ is flat. In particular $(R, f)$ is a gluing pair then $R$ is Noetherian or $f$ is a nonzero-divisor (4.2.3.10), Cf. [Sta]0BNT.

If $(R \to R', f)$ is gluing, then $M$ is glueable if $\text{Tor}_1^R(M, R')$ is $f$-power torsion, or equivalently $\text{Tor}_1^R(M, R'_f) = 0$. In particular this is the case when $M$ is flat $R$-module or $f$ is not a zero-divisor. And when $R \to R'$ is flat, any $R$-module $M$ is glueable, in particular this is the case for $(R, f)$ when $R$ is Noetherian. Cf. [Sta]0BNX.

Prop. (4.4.2.12) [Beauville-Laszlo]. Let $A$ be a commutative ring and $f \in A$ is a nonzero-divisor, let $\hat{A}$ be the $f$-adic completion, then there is a pullback diagram of categories:

\[
\begin{array}{ccc}
\text{Mod}_A & \longrightarrow & \text{Mod}_{\hat{A}}[1/f] \\
\downarrow & & \downarrow \\
\text{Mod}_{\hat{A}} & \longrightarrow & \text{Mod}_{\hat{A}}[1/f] \\
\end{array}
\]

Proof: Cf. [Sta]Ch15.81.

3 Kähler Differentials

Def. (4.4.3.1) [Derivations]. A derivation over $S$ from an $S$-algebra $R$ to an $S$-module $M$ is a morphism of $S$-modules $\delta: R \to M$ that $\delta(ab) = a\delta(b) + b\delta(a)$. The set of all derivatives from $R$ to $M$ is denoted by $\text{Der}_S(R, M)$

Def. (4.4.3.2) [$A \times_R M$]. For any $R$-algebra $A$, there is a functor $A \times -$ from $\text{Mod}_R$ to $(\text{Alg}_R)_A$ that $A \times_R M = A \otimes_R M$ with the algebra given by

$$(a, x)(b, y) = (ab, ay + bx).$$

Then there is a bijection of sets

$$\text{Der}_R(X, A \times_R M) \cong \text{Der}_R(X, M).$$
Def. (4.4.3.3) [Kähler Differential]. Let \( S \to R \) a ring map, then the **Kähler Differential** \( \Omega_{R/S} \) is defined as a \( R \)-module that \( \operatorname{Der}_S(R, M) \cong \operatorname{Hom}_S(\Omega_{R/S}, M) \). In particular, \( \operatorname{Der}_S(R, R) \) is the \( R \)-dual of \( \Omega_{R/S} \).

**Prop. (4.4.3.4).** One construction is by the free group generated by elements of \( R \) module some relations. It can also be constructed as follows: there are two ring maps \( \lambda_i \) from \( S \) to \( R \otimes_R S \), and one map \( \varepsilon \) from \( S \otimes_R S \) to \( S \). Let \( I = \ker \varepsilon \) as a \( R \)-module by \( \lambda_1 \), then \( I \triangleleft I^2 \cong \Omega_S \otimes_R S \otimes_R S \otimes_R S \cong \Omega_{S/R} \) by (4.4.3.8).

So \( I \otimes \Omega_I^2 = \Omega_S \otimes_R S \otimes_R S \otimes_R S \cong \Omega_{S/R} \). And it can be verified that \( a \otimes 1 - 1 \otimes a \) corresponds to \( da \).

**Prop. (4.4.3.5) [Adjointness].** The functor \( X \to A \otimes_X \Omega_{X/R} \) is left adjoint to the functor \( A \leftarrow_R R \) defined in (4.4.3.2) as a functor from \( (\mathbb{C}_{\operatorname{Alg}}_R)_A \to \operatorname{Mod}_A \).

**Proof:** Because they are both equivalent to \( \operatorname{Der}_R(X, M) \).

**Cor. (4.4.3.6) [Functoriality].** From the first construction, we can see directly that for a family of morphisms \( R_i \to S_i \),

\[
\Omega_{\operatorname{colim} S_i/\operatorname{colim} R_i} = \operatorname{colim} \Omega_{S_i/R_i}.
\]

In particular, we have:

\[
T^{-1} \Omega_{B/A} = \Omega_{T^{-1} B/A}, \quad \Omega_{S^{-1} B/S^{-1} A} = S^{-1} \Omega_{B/A}.
\]

Moreover, we have

\[
\Omega_{S/R} \otimes_R R' = \Omega_{S \otimes_R R' \otimes R'}, \quad (S \otimes_R \Omega_{T/R}) \oplus (T \otimes_R \Omega_{S/R}) \cong \Omega_{S \otimes_R T/R}
\]

by universal properties.

**Proof:** We prove for the localization: it suffices to show the following two assertions:

1. \( S^{-1} \Omega_{A/B} \cong \Omega_{S^{-1} A/B} \).
2. If \( T \subset B \) is a multiplicatively closed subset that \( i(t) \) are all invertible in \( A \), then \( \Omega_{A/T^{-1} B} \cong \Omega_{A/B} \).

We check the universal properties: For any \( S^{-1} A \)-module \( M \),

\[
\operatorname{Hom}_{S^{-1} A}(S^{-1} \Omega_{A/B}, M) \cong \operatorname{Hom}_{S^{-1} A}(S^{-1} A \otimes_A S^{-1} A, M) \cong \operatorname{Hom}_A(\Omega_{A/B}, M) \cong \operatorname{Der}_B(A, M),
\]

\[
\operatorname{Hom}_{S^{-1} A}(\Omega_{S^{-1} A/B}, M) \cong \operatorname{Der}_B(S^{-1} A, M)
\]

There is a map \( \operatorname{Der}_B(S^{-1} A, M) \to \operatorname{Der}_B(A, M) \) by restriction, and the converse is given by

\[
d \mapsto d \left( \frac{a}{s} \right) = \frac{sd a - ads}{s^2},
\]

This is well-defined as

\[
d \left( \frac{at}{st} \right) = \frac{std(at) - atds}{s^2 t^2} = \frac{sd a - ads}{s^2},
\]
and it satisfies
\[
d\left(\frac{a_1}{t_1} + \frac{a_2}{t_2}\right) = d\left(\frac{a_1 t_2 + a_2 t_1}{t_1 t_2}\right) = \left(\frac{(a_1d(t_2) + t_2d(a_1) + a_2d(t_1) + t_1d(a_2))t_1 t_2 - (a_1 t_2 + a_2 t_1)(t_1 d(t_2) - t_2 d(t_1))}{t_1^2 t_2^2}\right)
= \frac{t_1^2 t_2^2 d(a_1) + t_1^2 t_2^2 d(a_2) - a_2 t_2^2 d(t_2) + a_1 t_2^2 d(t_1)}{t_1^2 t_2^2}
= d\left(\frac{a_1}{t_1}\right) + d\left(\frac{a_2}{t_2}\right)
\]
\[
d\left(\frac{a_1 a_2}{t_1 t_2}\right) = \frac{(a_1 d(a_2) + a_2 d(a_1)) t_1 t_2 - a_1 a_2 (t_1 d(t_2) + t_2 d(t_1))}{t_1^2 t_2^2}
= \frac{a_1 (t_2 d(a_1) - a_2 d(t_2))}{t_1 t_2^2} + \frac{a_2 (t_1 d(a_2) - a_1 d(t_1))}{t_2 t_1^2}
= \frac{a_1}{t_1} d\left(\frac{a_2}{t_2}\right) + \frac{a_2}{t_2} d\left(\frac{a_1}{t_1}\right)
\]

Thus this \(d\) is an extension of the derivative to \(S^{-1}A\). Thus we get the desired isomorphism by Yoneda lemma. \(\square\)

**Prop. (4.4.3.7) [Jacobi-Zariski Sequences].** For a sequence of commutative rings: \(A \to B \to C\), there is an exact sequence
\[
C \otimes_B \Omega_{B/A} \to \Omega_{C/A} \to \Omega_{C/B} \to 0
\]
of \(C\)-modules. It has a left inverse and splits iff any derivation over \(A\) from \(B\) to a \(C\)-module can be extended to a derivation over \(A\) from \(C\) to \(M\). This is trivially true when \(B \to C\) has a retraction, and true when \(C/B\) is formally smooth by (4.4.5.5).

**Proof:** Taking Hom with an arbitrary \(C\)-module \(M\), by universal property, we need to check the exactness of \(0 \to \text{Der}_B(C, M) \to \text{Der}_A(C, M) \to \text{Der}_A(B, M)\), which is easy. \(\square\)

**Prop. (4.4.3.8) [Second Exact Sequence].** (This is a special case of (8.2.1.5)). If \(S' = S/I\), then there is an exact sequence of \(R'\)-modules:
\[
I/I^2 \to \Omega_{S/R} \otimes_S S' \to \Omega_{S'/R} \to 0.
\]
Where \(f \in I\) is mapped to \(df \otimes 1\) and it has a left inverse and splits iff \(S/I^2 \to S'\) has a right inverse.

And in fact \(\Omega_{S/R} \otimes S' \cong \Omega_{(S/I^2)/R} \otimes S'\).

**Proof:** For a \(S/I\)-module \(M\), we check:
\[
0 \to \text{Der}_R(S/I, M) \to \text{Der}_R(S, M) \to \text{Hom}_{S/I}(I/I^2, M)
\]
To prove \(\Omega_{S/R} \otimes S' \cong \Omega_{(S/I^2)/R} \otimes S'\), we apply Hom for a \(S'\)-module \(M\).

So to prove the left exactness, we may assume \(I^2 = 0\). If we have an inverse \(\Omega_{S/R} \otimes S' \to I\), then it gives a derivation \(D : A \to I\) that is identity on \(I\), so \(a - D(a)\) gives a \(R\)-ring map \(S \to S\) that is trivial on \(I\) (because \(I^2 = 0\)). Hence it gives a \(S/I \to S\) that is inverse to the projection.

For the converse, if \(d : S/I \to S\) is a right inverse, then \(a - d(\pi)\) is a derivation \(S \to I\), which is identity on \(I\), so it gives a inverse map \(\Omega_{S/R} \otimes S' \to I\) by universal property. \(\square\)
Cor. (4.4.3.9). If \( R \to S \) is of f.p., then \( \Omega_{S/R} \) is of f.p. over \( S \). If \( R \to S \) is of f.t., then \( \Omega_{S/R} \) is of f.t. over \( S \). (Follows from the second exact sequence (4.4.3.8) and (4.4.3.10)).

Cor. (4.4.3.10) [Examples].
1. \( \Omega_{A[X_1, \ldots, X_n]/A} = A[X_1, \ldots, X_n]\{dX_1, \ldots, dX_n\} \).
2. If \( S = A[X_i]/\langle f_j \rangle \), then \( \Omega_{S/A} = S[dX_i]/\langle df_j \rangle \).
3. \( \Omega_{A[X_i]/k} = \Omega_{A/k} \otimes_A A[X_i] \oplus A[X_i]\{dX_1, \ldots, dX_n\} \).
4. (Standard Étale Algebra) For \( A = R[x]/(f) \), where \( f' \) has image invertible in \( A, \Omega_{A/R} = 0 \).
5. The differential for the inclusion \( k[y^2, y^3] \to k[y] \) is \( k[y]/(2y, 3y^2)\{dy\} \).

Cor. (4.4.3.11). 1: Use the differential operator and universal property.
2: Use item 1 and (4.4.3.8).
3: Use item 1 and the fact (4.4.3.8) splits because any derivative of \( A/k \) can be extended to derivative of \( B/k \) by acting on the coefficients.
4:
5: Use definition.

Cor. (4.4.3.12). If \( S/I \) is a field \( k \) that embeds in \( S \), then \( I/I^2 \cong \Omega_{S/k} \otimes_S k \).

Prop. (4.4.3.13). Let \( k \subset K \subset L \) be fields, and \( L/K \) f.g., then
\[
\dim_L \Omega_{L/k} \geq \dim_K \Omega_{K/k} + \deg(L/K).
\]
Equality holds if \( L/K \) is separably generated, i.e. separable over a transcendental basis. If \( K = k \), then the equality hold iff \( L/k \) is separably generated. In particular, \( L/k \) is separable algebraic extension iff \( \Omega_{L/k} = 0 \).

Proof: Take a subfield \( K \subset K(t_1, \ldots, t_n) \subset L \) that \( L \) is separable algebra over \( K(t_1, \ldots, t_n) \). Then it suffices to add one element a time, so we may assume \( L = K(\alpha) \).
1: If \( \alpha \) is transcendental over \( K \), then \( \Omega_{K(\alpha)/t} \cong \Omega_{K(\alpha)} \otimes K[\alpha] /\alpha dt \) by (4.4.3.10), and by localization (4.4.3.6) we get \( \Omega_{L/K} \cong \Omega_{K/k} \otimes K L \oplus Ld\alpha \), thus \( \text{rank} \, \Omega_{L/k} = \text{rank} \, \Omega_{K/k} + 1 \).
2: If \( \alpha \) is separable over \( K \), then there is a monic polynomial \( f \in K[X] \) such that \( K[\alpha] \cong K[X]/(f) \). Then \( f' \) is invertible in \( K[\alpha] \), and by (4.4.3.10) \( \Omega_{K[\alpha]/k} = \Omega_{K/k} \otimes K L \oplus LdX/(d(f) + f'dX) \cong \Omega_{K/k} \otimes K L \). Thus \( \text{rank} \, \Omega_{L/k} = \text{rank} \, \Omega_{K/k} \).
3: If \( K \) has characteristic \( p \) and \( L = K[X]/(X^p - a) \) and \( d_{K/k}(a) = 0 \), then \( \Omega_{K[a]/k} = \Omega_{K/k} \otimes K L \oplus LdX/(d(a)) \cong \Omega_{K/k} \otimes K L \oplus LdX/(d(a)) \). Thus \( \text{rank} \, \Omega_{L/k} = \text{rank} \, \Omega_{K/k} + 1 \).
4: If \( K \) has characteristic \( p \) and \( L = K[X]/(X^p - a) \) and \( d_{K/k}(a) \neq 0 \), then \( \Omega_{K[a]/k} = \Omega_{K/k} \otimes K L \oplus LdX/(d(a)) \) has rank \( \text{rank} \, \Omega_{K/k} \).
Thus the assertion is clear.

Prop. (4.4.3.14) [Differential and Regularity]. Let \( B \) be a Noetherian local ring containing its residue field \( k \) and \( k \) is perfect, then \( \Omega_{B/k} \) is a free \( B \)-module of rank \( \dim B \) iff \( B \) is regular. [Hartshorne Ex.2.8.1] has a generalization of this fact.

Proof: One way is by (4.4.3.12). Conversely, if \( B \) is regular, then it is integral (4.3.5.19), so \( \Omega_{B/k} \otimes B K = \Omega_{K/k}(4.4.3.6) \) is of \( K \)-dimension \( \text{deg} \, K/k = \dim B \), where \( K \) is the quotient field of \( B \), and \( \Omega_{B/k} \otimes k \cong m/m^2 \) is of \( k \)-dimension \( \dim B \) once again. These two facts shows that \( \Omega_{B/k} \) is free \( B \)-module of rank \( \dim B \) by (4.4.8.1).

Prop. (4.4.3.15). The Kähler differential \( \Omega_{O_L/O_K} \) for an extension of number fields is cyclic.

Proof: Because it is locally cyclic (4.2.7.30).
4 Complete Intersections

Koszul Complex

**Prop. (4.4.4.1) [Koszul Complex].** The complex of $\mathbb{Z}[X_1, \ldots, X_n]$-modules $K_\bullet$, where

$$K_r = \wedge^{r+1} \mathbb{Z}[dX_1, \ldots, dX_n] \otimes_{\mathbb{Z} A, f_1, \ldots, f_n} \mathbb{Z}[X_1, \ldots, X_n]$$

and the morphism is given linearly by

$$\iota : dX_i \wedge dX_{i_1} \wedge \ldots \wedge dX_i \mapsto \sum_k X_{i_k}dX_{i_0} \wedge \ldots \wedge dX_{i_{k-1}} \wedge dX_{i_{k+1}} \wedge \ldots \wedge dX_i$$

Then this is a free resolution of $\mathbb{Z}$ over $\mathbb{Z}[X_1, \ldots, X_n]$.

**Proof:** We can use induction. If $r = 1$, then this is clear. For the induction process, if $\iota(dX_1 \wedge \alpha + \beta) = 0$, and $\beta \in K_i$, where $\beta, \alpha$ has no $dX_1$ involved. Notice if $dX_1 \wedge \alpha \in K_0$, then we may assume $\alpha$ has no constant coefficient, because this is impossible.

then $X_1\alpha - dX_1 \wedge \iota(\alpha) + \iota(\beta) = 0$. Then we see that $\iota(\alpha) = 0$. We can write $\alpha = \alpha_0 + X_1\alpha_1 + X_2\alpha_2 + \ldots$, where $\alpha_i$ has no $X_1$ involved, then we see that $\iota(\alpha_i) = 0$, then by induction hypothesis $\alpha = \iota(\alpha')(notice \, \alpha_0 \, has \, no \, constant \, coefficient)$, and $\iota(\beta) + X_1\iota(\alpha') = 0$. If $\beta = X_1\beta_1 + \beta_2$, where $\beta_2$ has no $X_1$ involved, then $\iota(\beta_2) = 0$, so $\beta_2 = \iota(\beta_2')$, and $\iota(\beta_1 + \alpha') = 0$, so $\beta_1 + \alpha' = \iota(\beta')$. So

$$dX_1 \wedge \alpha + \beta = dX_1 \wedge \iota(\alpha') + \iota(X_1\beta'_1 + \beta'_2) - X_1\alpha' = \iota(X_1\beta'_1 + \beta'_2 - dX_1 \wedge \alpha').$$

And in degree 0, this is clear. \qed

**Def. (4.4.4.2) [Koszul Complex].** Let $A$ be a ring and $I = (f_1, \ldots, f_n) \subseteq A$ is an ideal, then the Koszul complex for $Kos(A, f_1, \ldots, f_n)$ is an object in $D(A)$ defined by

$$Kos(A, f_1, \ldots, f_n) = A \otimes_{\mathbb{Z}[X_1, \ldots, X_n]} \mathbb{Z},$$

where $A$ is a $\mathbb{Z}[X_1, \ldots, X_n]$-algebra by mapping $X_i \mapsto f_i$. If $M$ is an $A$-module, then we define $Kos(M, f_1, \ldots, f_n) = M \otimes_{\mathbb{Z}} Kos(A, f_1, \ldots, f_n)$.

**Prop. (4.4.4.3).** If $f_1, \ldots, f_n \in R$, then $I = (f_1, \ldots, f_n)$ annihilates $H^*(K(f_1, \ldots, f_n))$. In particular, $Kos(A, f_1, \ldots, f_n)$ is in the image of $D(A/I) \subset D(A)$.

**Proof:** This is because every $H^i(A \otimes_{\mathbb{Z}[X_1, \ldots, X_n]} \mathbb{Z})$ is an $H^0(A \otimes_{\mathbb{Z}[X_1, \ldots, X_n]} \mathbb{Z}) = A/I$-algebra, because it is a simplicial algebra. \qed

**Prop. (4.4.4.4).** $K(A, f_1, \ldots, f_n, g_1, \ldots, g_m) = K(A, f_1, \ldots, f_n) \otimes_A K(A, g_1, \ldots, g_m)$. (Easy).

**Prop. (4.4.4.5).** The cone of the map

$$f_n : K(f_1, \ldots, f_{n-1}) \to K(f_1, \ldots, f_{n-1})$$

is isomorphic to $K(f_1, \ldots, f_n)$.

**Proof:** This is because $\mathbb{Z}[X] \xrightarrow{X} \mathbb{Z}[X] \to \mathbb{Z}$ is an exact triangle, so $A \xrightarrow{f_n} A \to A \otimes_{\mathbb{Z}[X]} \mathbb{Z}$ is an exact triangle, so $Kos(A, f_1, \ldots, f_{n-1}) \xrightarrow{f_n} K(A, f_1, \ldots, f_{n-1}) \to K(A, f_1, \ldots, f_n)$ is an exact triangle. \qed
Prop. (4.4.4.6). Let $A$ be a ring and $M$ be an $A$-module. Let $f_1, \ldots, f_{r-1}, f, g$ be elements of $A$, then there is a natural distinguished triangle

$$Kos(M, f_1, \ldots, f_{r-1}, f) \rightarrow Kos(M, f_1, \ldots, f_{r-1}, fg) \rightarrow Kos(M, f_1, \ldots, g).$$

Proof: We use (4.4.4.5) to consider $Kos(M, f_1, \ldots, f_{r-1}, f)$ as a cone of $f_n : Kos(M, f_1, \ldots, f_{r-1}) \rightarrow Kos(M, f_1, \ldots, f_{r-1})$. Then this distinguished triangle is given by (3.4.1.15) applied to the diagram

$$
\begin{array}{ccc}
Kos(M, f_1, \ldots, f_{r-1}) & \rightarrow & Kos(M, f_1, \ldots, f_{r-1}) \\
f & \downarrow & fg \\
Kos(M, f_1, \ldots, f_{r-1}) & \rightarrow & Kos(M, f_1, \ldots, f_{r-1}) \\
\end{array}
$$

□

Prop. (4.4.4.7) [Koszul Complex and Čech Complex]. Let $A$ be a commutative ring and $I = (f_1, \ldots, f_n) \subset A$, $K_n^\bullet = Kos(A, f_1^n, \ldots, f_n^n) = A \otimes_{\mathbb{Z}[X_1, \ldots, X_r]} \mathbb{Z}$. Then there are natural maps

$$\ldots \rightarrow K_n^0 \rightarrow K_n^1 \rightarrow K_n^2 \rightarrow \ldots$$

compatible with the inverse system $H^0(K_n^\bullet) = A/(f_1^n, \ldots, f_n^n)$. Then there is a description of $R \colim K_n^\bullet$ (4.6.5.6) as the alternating Čech complex

$$R \rightarrow \bigoplus_{i_0} R_{f_{i_0}} \rightarrow \bigoplus_{i_0 < i_1} R_{f_{i_0}f_{i_1}} \rightarrow \ldots \rightarrow R_{f_1f_2...f_r}$$

where $R$ sits in degree 0.

Proof: Cf. [Sta]0913, which is not hard. □

Def. (4.4.4.8) [Koszul-Regular Sequence]. Let $A$ be a ring and $(f_1, \ldots, f_n) \in A$ be a sequence, then $f_1, \ldots, f_n$ is called $M$-Koszul-regular iff $Kos(M, f_1, \ldots, f_n) = 0$. It is called Koszul-regular iff $Kos(A, f_1, \ldots, f_n) = 0$.

Prop. (4.4.4.9). If $(f_1, \ldots, f_r)$ is (M-Koszul)regular and $n_i > 0$, then $(f_1^{n_1}, \ldots, f_r^{n_r})$ is also (M-Koszul)regular.

Proof: This follows from (4.4.4.6). □

Prop. (4.4.4.10) [Regular and Koszul-Regular]. A $M$-regular sequence (4.3.4.1) is $M$-Koszul-regular. A regular sequence is Koszul-regular.

Proof: Let $(f_1, \ldots, f_r)$ be a regular sequence. The assertion is clear when $r = 1$. For the induction:

$$Kos(M, f_1, \ldots, f_n) = Kos(M, f_2, \ldots, f_n) \otimes_{\mathbb{Z}[X]} \mathbb{Z} = Kos(A, f_2, \ldots, f_n) \otimes_A M \otimes_{\mathbb{Z}[X]} \mathbb{Z}$$

$$= Kos(A/f_1, f_2, \ldots, f_n) \otimes_{A/f_1 M/f_1 M} M/f_1 M = Kos(M/f_1 M, f_2, \ldots, f_n)$$

so we can use induction. □
Complete Intersections

Def.(4.4.4.11)[Global Complete Intersections]. A ring map \( R \to S \) is called global intersection if \( S = R[x_1, \ldots, x_n]/(f_1, \ldots, f_c) \) that every non-empty fiber of \( \text{Spec} \, S \to \text{Spec} \, R \) has dimension \( n - c \).

Prop.(4.4.4.12). Global intersection is stable under base change and composition. And \( S \to S_f \) a global intersection, so it is stable under localization.

Proof: Base change: this is because flatness, f.p. is stable under base change, and the fibers are the same.
Composition: It suffices to assume \( R \) is a field and calculate the dimension of the fibers, which is true by dimension formula (4.2.4.13).

Prop.(4.4.4.13)[Noetherian Approximation]. Let \( R \) be a ring and \( S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c) \) be a global complete intersection, then there is a f.g. \( \mathbb{Z} \)-algebra \( R_0 \subset R \) that \( f_i \in R_0[X_1, \ldots, X_n] \), and \( S_0 = R_0[X_1, \ldots, X_n]/(f_1, \ldots, f_c) \) is a global intersection over \( R \).

Proof: Cf.[Sta]00SU.

Prop.(4.4.4.14) [Complete Intersection is Regular]. Let \( R \) be a ring and \( S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c) \) be a complete intersection, then \( \text{Spec} \, S \to \text{Spec} \, R[X_1, \ldots, X_n] \) is a regular embedding (5.6.8.1), and \( S \) is flat over \( R \).

Proof: Cf.[Sta]00SV.

Local Complete Intersections

Def.(4.4.4.15)[Local Complete Intersections]. Let \( S \) be a \( R \)-algebra, then \( S \) is a local complete intersection over \( R \) iff \( S \) is locally a global complete intersection over \( R \). Local complete intersection is flat, by (4.4.4.14).

Prop.(4.4.4.16). Local complete intersection is local on the source and target. In fact satisfies f.f. descent (4.4.2.1).

Lemma(4.4.4.17). If \( S \) is a f.t. \( k \)-algebra and \( K/k \) is a field extension, then \( S \) is a local complete intersection iff \( S_K \) is a local complete intersection.

Prop.(4.4.4.18)[Global Intersections and Fibers]. Let \( R \to S \) be a ring map and \( q \subset S \) be a prime lying over \( p \subset R \), then the following are equivalent:
- \( R \to S \) is a global complete intersection around \( q \).
- \( R \to S \) is a f.p. around \( q \), \( S_q/R_p \) is flat, and (the fiber) \( S_q/pS_q \) is a local complete intersection ring over \( k(p) \).

Proof: 1 \( \to \) 2 follows from (4.4.4.14). For 2 \( \to \) 1, Cf.[Sta]00SY.

Prop.(4.4.4.19)[Local Complete Intersection over Fields is Stalkwise]. For a f.g. \( k \)-algebra \( S \), \( S \) is a local complete intersection iff all localization at (maximal)primes are complete intersection local rings over \( k \). In particular, being local complete intersection is a stalkwise property.
Proof: This is because over field everything is f.p. and flat, and use (4.4.4.18). □

Prop. (4.4.4.20). If $S$ is a f.g. local complete intersection over a field $k$, then it is a CM ring.

Proof: Cf. [Sta]00SB. □

Def. (4.4.4.21) [Complete Intersection Local Rings]. Let $A$ be a local ring essentially of f.t. over a field $k$, then $A$ is called a complete intersection local ring over $k$ if there exists a surjection $R \to A$ from a regular local ring essentially of f.t. over $k$ that the kernel is generated by a regular sequence.

Prop. (4.4.4.22). When $A$ is f.g. local ring over a field $k$, then $A$ is a complete intersection local ring iff $A$ is local complete intersection over $k$ (4.4.4.11).

Proof: Cf. [Sta]00SC. See more in [Sta] Chap 23.8.

5 Smoothness

Formally Smoothness

Def. (4.4.5.1). A ring map $R \to S$ is called formally smooth if has right lifting property w.r.t all ring maps $A \to A/I$ where $I^2 = 0$.

Formal smooth is stable under base change and composition, by universal arguments. A polynomial algebra is formally smooth.

Prop. (4.4.5.2). Giving a presentation $S = P/J$ where $P$ is formally smooth (e.g. polynomial algebra), $S$ is formally smooth iff there is a map $S \to P/J^2$ that is right converse to the obvious projection.

Proof: One way is from the definition of formally smooth applied to $P/J^2$ and $J$. Conversely, for any $A$ and $I$, we notice the map $P \to S \to A/I$ can be lifted to $P \to A$, and $J$ is mapped to $I$, so $J^2$ is mapped to 0, so we have a map $P/J^2 \to A$. Then $S \to P/J^2 \to A$ is the lifting. □

Cor. (4.4.5.3). If $P \to S$ is a presentation of $S/R$ by polynomial algebra with kernel $I$, then $S/R$ is formal smooth iff

$$0 \to I/I^2 \to \Omega_{P/R} \otimes_P S \to \Omega_{S/R} \to 0$$

is split exact as in (4.4.3.8).

Proof: This sequence is split exact iff $P/J^2 \to S$ has a right converse, by (4.4.3.8). □

Now we consider the relation of Formal Smoothness and Kahler Differentials.

Cor. (4.4.5.4) [Equivalence Definition]. $S/R$ is formally smooth iff $NL_{S/R}$ is quasi-isomorphic to a projective $S$-module at degree 0.

Proof: If $S/R$ is formally smooth, then choose a presentation will suffice by (4.4.5.3). The converse is also true by projectiveness and (4.4.5.3).

Cor. (4.4.5.5). If $C/B$ is formally smooth, then the Jacobi-Zariski sequence

$$0 \to C \otimes_B \Omega_{B/A} \to \Omega_{C/A} \to \Omega_{C/B} \to 0$$

as in (4.4.3.7) is split exact, by (8.2.1.5). In particular, any derivation of $B$ to a $C$-module can be extended to a derivation $C$ to a $C$-module.
Cor. (4.4.5.6). If $A \to B \to C$ with $A \to C$ formally smooth and $B \to C$ surjective with kernel $I$, then there is a split sequence

$$0 \to I/I^2 \to \Omega_{B/A} \otimes_B C \to \Omega_{C/A} \to 0$$

by (8.2.2.6).

Standard Smooth Algebra

Def. (4.4.5.7). A standard smooth algebra over $R$ is a algebra $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)$, where $c \leq n$ and $J(f_1, \ldots, f_c)$ is invertible in $S$.

Prop. (4.4.5.8) [Standard Smooth Localization]. If $R \to S$ is standard smooth, then $R \to S_g$ is standard smooth, and $R_f \to S_f$ is standard smooth (because stable under base change (4.4.5.9)).

Proof: For localization at $g \in S$, let $h$ be an inverse image of $g$ in $R[X_1, \ldots, X_n]$, then $S_g = R[X_1, \ldots, X_n, X_{n+1}]/(f_1, \ldots, f_c, X_{n+1}h - 1)$, and it is standard smooth. □

Prop. (4.4.5.9). Standard smoothness is stable under base change and composition.

Proof: For base change, notice the Jacobi matrix is the base change of the Jacobi matrix, so it is also invertible. For composition, write out the presentation, the determinant is the product of the presentation. □

Lemma (4.4.5.10) [Kähler Differential of Smooth Algebra is Free]. The Kähler differential of a standard smooth algebra $S$ over a field $k$ is free of rank $\dim S$, and $(f_1, \ldots, f_c)/(f_1, \ldots, f_c)^2$ is free over $S$ with basis $f_1, \ldots, f_c$. Moreover, $S$ is pure dimensional.

Proof: The naive cotangent complex for $S/R$ is

$$d : (f_1, \ldots, f_c)/(f_1, \ldots, f_c)^2 \to S[dX_1, \ldots, dX_n].$$

By hypothesis and linear algebra it is a split injection, and $\Omega_{S/R} = S[dX_{c+1}, \ldots, dX_n]$, so it is free of rank $n - c = \dim S$, because $S$ is a global complete intersection (4.4.5.11). □

Prop. (4.4.5.11) [Standard Smooth and Complete Intersection]. A standard smooth algebra $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)$ is a global complete intersection (4.4.4.11).

Proof: It suffices to show any fiber of $S$ has dimension $n - c$. For this, notice $S \otimes_R k(p)$ is also standard smooth, then we reduce to the field case. Now $I = (f_1, \ldots, f_c)$ satisfies $I/I^2 \to \oplus Sdx_i$ is a split injection. For any maximal ideal $m$ containing $I$, tensoring $k(m)$, we get an injection $I/mI \to \oplus k(m)dx_i$. Notice there is a commutative diagram

$$I \xrightarrow{d} S/m \otimes I \cong I/mI$$

$$\oplus Sdx_i \xrightarrow{dx_i \mapsto 1 \otimes x_i} S/m \otimes m \cong m/m^2$$

And the lower horizontal map is an isomorphism by Hilbert’s Nullstellensatz, so the image of $f_i$ in $m_i/m_i^2$ are linearly independent over $k(m)$, thus we can use (4.3.5.22) to show that $\dim S = n - c$. □
Smoothness

Def. (4.4.5.12)[Smooth Ring Map]. A ring map $R \rightarrow S$ is called smooth if it satisfies the following equivalent conditions:

- It is of f.p. and the naive cotangent complex $NL_{S/R}$ is quasi-isomorphic to a finite locally free $S$-module placed at degree 0. In other words,
  $$0 \rightarrow I/I^2 \rightarrow \Omega_{P/R} \otimes_P S \rightarrow \Omega_{S/R} \rightarrow 0$$
  is exact and $\Omega_{S/R}$ is finite locally free. By (8.2.1.1), we only need to prove for a single presentation of $S$.
- It is locally standard smooth.
- It is formally smooth and of f.p.

We say $S$ is smooth at $x$ if it is smooth on a nbhd of $x$.

Proof: 1 $\rightarrow$ 3: by (4.4.5.4). 3 $\rightarrow$ 1: By (4.4.5.4), $\Omega_{S/R}$ is f.p. and projective, so it is finite projective.

At this point we already know that the first definition is stable under base change and composition, because f.p. and formally smoothness both do (4.4.5.1)(4.3.7.9).

And also the first definition is local on source because f.p. does (4.1.4.4) and $NL$ commutes with localization (8.2.1.6) so we can use the local properties of triviality (4.1.4.2) and finite projectiveness (4.3.1.7).

Now it is also local on the source because it is stable under base change and composition and $R \rightarrow R_f$ does by locality on the source.

2 $\rightarrow$ 1: Now the property are all local on source. It suffices to prove a standard smooth map is smooth. This follows from (4.4.5.10).

1 $\rightarrow$ 2: We need to prove, assuming the first definition, it is locally standard smooth. For this, Cf.[Sta]00TA?

Cor. (4.4.5.13). Smoothness is stable under composition and base change. Smoothness is local on the source and target (In particular, $R \rightarrow R_f$ is smooth). (Already proved in the proof of (4.4.5.12)).

Prop. (4.4.5.14). A smooth map is a local complete intersection (4.4.4.15), hence flat.

Proof: Clear from (4.4.5.12).

Prop. (4.4.5.15)[Noetherian Descent]. A smooth ring map $R \rightarrow S$ is a base change of smooth ring map over a ring f.g. over $\mathbb{Z}$.

Proof: Use the equivalence definition (4.4.5.2), we know that there is a map

$$S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c) \rightarrow R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)^2,$$

which if we write $\sigma(X_i) = h_i$, then must satisfy

$$f_i(h_1, \ldots, h_n) = \sum a_{ijk} f_j f_k.$$

Then we consider the subalgebra generated by $f_i, h_i, a_{ijk}$, then by the same reason, they form a smooth algebra over $\mathbb{Z}$, and its tensor with $R$ gives out $S$.

Cor. (4.4.5.16)[Strong Lifting Property]. For a smooth ring map, the lifting property is true for $A \rightarrow A/I$, where $I$ is locally nilpotent.
Lemma (4.4.5.19). Let $S$ be f.g. over a alg. closed field $k$ and $m$ a maximal ideal, then the following are equivalent:

- $S_m$ is regular.
- $\dim_k \Omega_{S/k} \otimes_S k \leq \dim S_m$
- $\dim_k \Omega_{S/k} \otimes_S k = \dim S_m$

Smooth over Fields

Lemma (4.4.5.22). Let $S$ be f.g. over a alg. closed field $k$ and $m$ a maximal ideal, then the following are equivalent:

- $S_m$ is regular.
- $\dim_k \Omega_{S/k} \otimes_S k \leq \dim S_m$
- $\dim_k \Omega_{S/k} \otimes_S k = \dim S_m$
• $S/k$ is smooth at $m$.

Proof: Cf.[Sta]00TS.

Prop.(4.4.5.23) [Differential Criterion of Smoothness]. For a ring $S$ f.g. over a field $k$, $S$ is smooth in a nbhd of $q$ iff \( \dim_{k(q)} \Omega_{S/k} \otimes k(q) \leq \dim_q(S) \).

And in this case, equality hold, and $S_q$ is regular.

Proof: Cf.[Sta]00TT.

If $S$ is smooth at $x$, then $\Omega_{S/R}$ is finite free on a nbhd of $x$ of rank equals to the dimension(4.4.5.10), so the equation holds.

Conversely, if $\dim_{k(x)} \Omega_{S/k} \otimes k(x) \leq \dim_x(X)$, then

Cor.(4.4.5.24) [Jacobian Criterion of Smoothness]. For a f.p. ring $S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_c)$ and $q \subset S$, $S$ is smooth at $q$ iff the Jacobian has rank $\leq n - \dim_q(S)$ at $q$ iff the Jacobian has rank $\leq n - \dim_q(S)$ at $q$.

Lemma(4.4.5.25). Let $k$ be a field and $(R, m, \kappa)$ be a Noetherian local ring containing $k$. If the residue field of $R$ is a f.g. field extension of $k$, then the derivation map

\[
m/m^2 \to \Omega_{R/k} \otimes_R \kappa
\]

is injective.

Proof: Cf.[Sta]00TU.

Prop.(4.4.5.26) [Smooth and Regular at Geometric Points]. Let $S$ be f.g. over a field $k$, if $k(q)/k$ is separable(e.g. char 0) for $q$ a prime of $S$, then $S$ is smooth at $q$ iff it is regular at $q$.

Proof: Let $R = S_q$ with maximal ideal $m$. By(4.4.5.25) and(4.4.3.8) there is an exact sequence\[
0 \to m/m^2 \to \Omega_{R/k} \otimes_R k(q) \to \Omega_{k(q)/k} \to 0.
\]

Since $k(q)/k$ is separable, $\dim_{k(q)} \Omega_{k(q)/k} = \text{tr} \cdot \deg(k(q)/k)$. So

\[
\dim_{k(q)}(\Omega_{R/k} \otimes_R k(q)) = \dim_{k(q)} m/m^2 + \text{tr} \cdot \deg(k(q)/k) \geq \dim R + \text{tr} \cdot \deg(k(q)/k) = \dim_q(S)
\]

with identity iff $R$ is regular(The last identity comes from(5.6.3.7)). So we are done by differential criterion of smoothness(4.4.5.23).

Prop.(4.4.5.27) [Smooth over Fields and Geo.Regular]. Let $S$ be f.g. over a field $k$, then $S$ is smooth over $k$ iff $S$ is geo.regular(4.3.6.1).

Proof: If $S$ is smooth at $x$, then all its base change is smooth at $x$(4.4.5.13), and the stalk is regular by(4.4.5.23), so it is geometrically regular at $x$.

Conversely, if $X$ is geometrically regular, then for any point $x \in X$, $k(x)$ is f.g. over $k$, so by(4.3.9.3) there is a finite purely inseparable extension $k'/k$ that the compositum $k'k(x)$ is separable over $k'$. Then by(4.1.7.26), Spec $A \otimes_k k'$ is homeomorphic to Spec $A$, so there is a unique prime $p'$ of $X_{k'}$ over $X$, and its residue field is $k'k(x)$. So by(4.4.5.26), as $k'k(x)/k'$ is separable, $X_{k'}$ is smooth over $k'$ at $p'$. And f.f. descent for smoothness(4.4.2.1) says $X$ is also smooth over $k$ at $p$. □
Cor. (4.4.5.28) [Differential and Smoothness]. Let $k$ be a field of characteristic 0 and $S$ a f.g. algebra over $k$, and $q$ a prime ideal of $S$, if $\Omega_{S/k,q}$ is free over $S_q$, then $S$ is smooth in a nbhd of $q$.

Proof: Cf.[Sta]00TX.

Prop. (4.4.5.29) [Generic Smoothness]. Let $R \to S$ be an injective ring map of f.t. with $R,S$ domains, then it is smooth at $(0)$ iff the quotient field map is separable.

Proof: If $S$ is smooth at 0, then replacing $S$ by $S_g$ for some $g$, we can assume $R \to S$ is smooth. Then $K \to S \otimes_R K$ is also smooth(4.4.5.13), and also for any field extension $K'$ of $K$. Then $S \otimes_R K'$ is regular, by(4.4.5.23), a priori reduced(5.4.1.5). Thus $S \otimes_R K$ is geometrically reduced. Hence also $L$ is geometrically reduced over $K$, thus separable, by(4.3.9.4).

Conversely, by(4.4.1.34), we may assume $R \to S$ is of f.p., thus to show it is smooth at $(0)$, it suffices to show $S \otimes_R K$ is smooth at $(0)$, by(4.4.5.20). Then this follows from(4.4.5.26).

□

6 Unramified

Formally Unramified

Def. (4.4.6.1). A ring map $R \to S$ is called formally unramified if for every $R$-ring $A$ and an ideal $I$ of $A$ that $I^2 = 0$, a map $S \to A/I$ has at most one extension to a map $S \to A$.

Formally unramified is equivalent to $\Omega_{S/R} = 0$. So it is stable under composition by Jacobi-Zariski sequence(4.4.3.7).

Proof: Let $J = \ker(S \otimes_R S \to S)$, let $A_{univ} = S \otimes_R S/J^2$, then $J/J^2 \cong \Omega_{S/R}(4.4.3.4)$, so we have two natural maps from $S$ to $A_{univ}$, they differ by the universal differential $S \to \Omega_{S/R}$. If $S/R$ is unramified, then $ds = 0$ for all $s \in S$, so $\Omega_{S/R} = 0$.

Conversely, if there is a $A$ and $A/J$ that there are two liftings $\tau_1, \tau_2$, then we let $A_{univ} \to A$ defined by $s_1 \otimes s_2 \to \tau_1(s_1)\tau_2(s_2)$, this is well-defined, and because $A_{univ} \cong S$, this map descends to $S$, so $\tau_1(s_1s_2) = \tau_2(s_1s_2)$.

□

Prop. (4.4.6.2) [Formally Unramified Stalkwise]. Formally unramified is stalkwise both on the source and target(4.1.4.2).

Prop. (4.4.6.3). Colimits of formally unramified rings over $R$ is formally unramified. (Trivial as one renders on the diagram in the definition of formally unramified).

Unramified Map

Def. (4.4.6.4) [Unramified Maps]. A ring map is called unramified iff it is formally unramified and f.g..

A ring map is called $G$-unramified iff it is formally unramified and of f.p.. In particular, an étale map is $G$-unramified.

These two notions are stable under composition and base change. These two notions are local on the source and target. $R \to R_f$ is $G$-unramified.(4.4.6.1)(4.1.4.2)
Prop. (4.4.6.5). $R \to R/I$ is unramified, and if $I$ is f.g., then it is $G$-unramified. (Trivial).

Prop. (4.4.6.6) [Stalkwise and Fiberwise]. If $R \to S$ is of f.t.(f.p.), then it is unramified ($G$-unramified) at a prime $q$ of $S$ iff $(\Omega_{S/R})_q = 0$ iff $\Omega_{S/R} \otimes_S k(q) = 0$ iff $\Omega_{S \otimes k(p)/k(p)} \otimes k(q) = 0$.

Proof: By Nakayama, two pair of them are equivalent, and if $\Omega_{S/R,q} = 0$, then $\Omega_{S/R,g} = 0$ for some $g \notin q$ (because support of finite module is open), so $R \to S_g$ is ($G$-)unramified. And notice in fact $\Omega_{S/R} \otimes_S k(q) = \Omega_{S \otimes k(p)/k(p)} \otimes k(p) k(q)$.

Prop. (4.4.6.7) [Equivalent Definition of Unramifiedness]. A f.g. ring map $R \to S$ is unramified at a prime $q$ of $S$ over $p$ iff $pS_q = qS_q$ and $k(q)/k(p)$ is finite separable.

Proof: Suppose $R \to S_g$ is unramified, then $S \otimes k(p)$ is unramified over $k(p)$, hence by (4.4.5.23), it is also smooth, so it is étale, and (4.4.7.9) gives the result.

For the converse, Cf[Sta][02FM].

Prop. (4.4.6.8). A ring map is unramified iff it is locally a quotient of a standard étale map.

Proof: Cf.[Sta][0395].

Prop. (4.4.6.9). Any $G$-unramified map is a base change of a $G$-unramified map over a ring $R_0$ f.g. over $\mathbb{Z}$. And similarly any unramified map is a quotient of a base change of a $G$-unramified map over a ring $R_0$ f.g. over $\mathbb{Z}$.

Proof: Let $S = R[X_1,\ldots, X_n]/(g_1,\ldots, g_c)$, then we have $dX_i = \sum a_{ij}dg_j + a_{ijk}g_jdX_k$, so we let $R_0$ be generated by $g_i, a_{ij}, a_{ijk}$, so $S_0 = R_0[X_1,\ldots, X_n]/(g_1,\ldots, g_c)$ is $G$-unramified. (Trivial).

Prop. (4.4.6.10) [Unramifiedness and Idempotent]. If $R \to S$ is of f.t., then it is unramified iff $S \times_R S \to S$ is isomorphic to $S \otimes_R S \to (S \otimes_R S)_e$ for some diagonal idempotent $e \in S \otimes_R S$ that $e \ker(\mu) = 0$, i.e. $S \otimes_R S \cong S \times S'$.

Proof: If it is $G$-unramified, the kernel $I$ satisfies $I/I^2 = 0$, and $I$ is f.g. (by $x_i \otimes 1 - 1 \otimes x_i$) so we can use (4.1.7.7).

Conversely, the existence of the diagonal idempotent $e$ implies that $I = I^2$. (Trivial).

7 Étale

Formally Étale

Def. (4.4.7.1). A ring map $R \to S$ is called formally étale iff it is formally smooth and formally unramified.

Prop. (4.4.7.2). Colimits of formally étale rings over $R$ is formally étale. (The lifting are compatible because of uniqueness).

Prop. (4.4.7.3). $R \to S^{-1}R$ is formally étale.

Proof: It suffice to prove that if $\varphi(s)$ is invertible modulo $I$, then $\varphi(s)$ is invertible, but this is true because $I$ is nilpotent.
Étale Map

**Def. (4.4.7.4).** A ring map \( R \to S \) is called \( \text{étale} \) if it is of f.p. and the naive cotangent complex is exact, i.e. \( I/I^2 \cong \Omega_{P/R} \otimes_R S \).

In particular, \( \text{étale} \) is equivalent to smooth+formally unramified (\( \Omega_{R/S} = 0 \)).

**Cor. (4.4.7.5) [Properties of Étale].**
1. Étale map is stable under base change and composition.
2. Étale map is local on the source and target. In particular, \( R \to R_f \) is étale.
3. If \( R \to S \) is of f.p. and \( R \to R' \) is flat. Then the set of primes in \( S' = S \otimes_R R' \) that has a nbhd that is étale over \( R' \) is the inverse image of set of primes in \( S \) that has a nbhd that is étale over \( R \). (The same as (4.4.5.18)).
4. Étale map is syntomic, hence flat.
5. Any Étale map is a base change of an étale map over a ring \( R_0 \) f.g. over \( 
\mathbb{Z} \). (Cf. [Sta]00U2).

**Cor. (4.4.7.6) [Étale Localness of Differential].** For ring morphisms \( A \to R \to S \), if \( R \to S \) is étale, then \( \Omega_{S/A} = \Omega_{R/A} \otimes_R S \).

**Proof:** This follows from (4.4.7.4) and (4.4.5.5). \( \square \)

**Prop. (4.4.7.7) [Jacobson Criterion].** Any étale map is equivalent to a standard smooth ring map \( S = R[X_1, \ldots, X_n]/(f_1, \ldots, f_n) \) that \( J(f_1, \ldots, f_n) \) is invertible in \( S \).

**Proof:** \( I/I^2 \cong \Omega_{P/R} \otimes_R S \), so \( I/I^2 \) is free, so by (4.3.7.12), there is a presentation of \( S \) that \( f_1, \ldots, f_c \) freely generate \( I/I^2 \), then obviously \( c = n \) and \( J(f_1, \ldots, f_n) \) is invertible in \( S \), i.e. \( S \) is standard smooth. \( \square \)

**Cor. (4.4.7.8) [Example of Étale Maps].** The ring
\[
S = R[X_1, \ldots, X_n, X_{n+1}]/(f_1, \ldots, f_n, X_{n+1} \det(\frac{f_1, \ldots, f_n}{X_1, \ldots, X_n}) - 1)
\]
is étale over \( R \).

**Prop. (4.4.7.9).** If \( R \to S \) is étale at a nbhd of a prime \( q \) of \( S \) over \( p \), then \( pS_q = qS_q \), and \( k(q)/k(p) \) is finite separable.

**Proof:** We can replace \( S \) by \( S_q \) so \( S_q/R \) is étale. Then \( S \otimes k(p)/k(p) \) is étale, that is \( S_p/pS_p \) is a finite product of finite separable fields, so \( S_q/pS_q = (S_p/pS_p)_q = \text{some separable closed field}. \) \( \square \)

**Lemma (4.4.7.10).** If \( R \to S \) is an étale map and \( q \) is a prime of \( S \) over \( p \), then \( S/R \) is étale in a nbhd of \( q \) if
- \( R \to S \) is of f.p.
- \( R_p \to S_q \) is flat.
- \( pS_q = qS_q \).
- \( k(q)/k(p) \) is a finite separable field extension.

**Proof:** Cf. [Sta]00U6. \( \square \)
Prop. (4.4.7.11) [Equivalent Definition of Étale]. A ring map $R \to S$ is étale iff it is flat, of f.p. and $\Omega_{S/R}$ vanishes.

Proof: One direction is by definition, and the converse is by (4.4.7.10) and (4.4.6.7). □

Prop. (4.4.7.12). A ring map of f.p. is formally étale iff it is étale. (Because in this case, formally smooth is equivalent to smooth (4.4.5.12).)

Prop. (4.4.7.13). If $S/R$ and $S'/R$ are étale, then any $R$-algebra map $S \to S'$ is étale.

Proof: $S \to S'$ is of f.p. by (4.3.7.11), the rest Cf.[Sta]00UE.

Prop. (4.4.7.14) [Étale Algebra seen explicitly as Finite Projective Modules]. Étale algebras are finite projective, by (4.3.1.7). And we can see this clearly as follows: There is a diagonal idempotent as it is unramified (4.4.6.10), if $e = \sum a_i \otimes b_i$, then we can realize $S$ as a direct command of $R^n$ through maps

$$S \xrightarrow{\alpha} R^n \xrightarrow{\beta} S$$

where $\alpha(f) = (\text{tr}_{S/R}(fa_i))$, and $\beta(g_i) = \sum g_i b_i$.

Proof: We check that $\beta \circ \alpha = \text{id}$: Notice first that $\text{tr}_{S/S}(e) = \text{tr}_{S/S}(1) = 1$, following from the decomposition above, so $\sum \text{tr}_{S/R}(a_i)b_i = 1$, thus shows that $\beta \alpha(1) = 1$.

Now for general $f$, using the formula $(f \otimes 1)e = (1 \otimes f)e$, we get $\sum \text{tr}(fa_i)b_i = \sum \text{tr}(a_i)b_i f = f$. □

Prop. (4.4.7.15). If $R$ is a ring and $I$ is an ideal, then any étale ring map $R/I \to \overline{S}$ comes from an étale ring map $R \to S$.

Proof: Use (4.4.7.7), an étale map is of the form $\overline{S} = R/I[X_1, \ldots, X_n]/(J_1, \ldots, J_n)$ that $\delta = J(\frac{f_1}{X_1}, \ldots, \frac{f_n}{X_n})$ is invertible in $S$, then we take $S = R[X_1, \ldots, X_n, X_{n+1}]/(f_1, \ldots, f_n, X_{n+1}\delta - 1)$, then it is étale by (4.4.7.8) and maps to $\overline{S}$. □

Standard Étale

Def. (4.4.7.16). A ring map $R \to R' = R[X]/g/f$ is called standard étale iff $f$ is monic and the derivative $f'$ is invertible in $R'$.

Standard étale is stable under base change and principal localization, but not stable under composition.

Prop. (4.4.7.17) [Étale and Standard Étale]. A ring map is étale iff it is locally standard étale.

Proof: For a standard étale algebra $R[X]/g/f = R[X, Y]/(f, gY - 1)$ which is standard smooth and $\Omega_{R'/R} = 0$ (4.4.3.10), so it is étale. To prove if it is locally standard étale then it is étale, Cf.[Sta]00UE.

Prop. (4.4.7.18). Giving any ring $R$ and a prime $p$, if there is a finite separable extension $L/k(p)$, then there is a standard étale map $R \to R'$ that for some $q'$, $k(q') \cong L$ over $k$.

Proof: $L = k(p)[\alpha]$ by primitive element theorem, so the minimal polynomial of $\alpha$ is separable, and if we change $\alpha$ to $c\alpha$ for some $c \in k(p)$, we can assume $f$ can be lifted to a $f \in R[X]$. Now $f'(\alpha)$ is invertible in $L$, so there is a map from $R[X]/f/(f)$ to $L$, whose kernel gives the desired prime $q$. □
Étale over Fields

Prop. (4.4.7.19) [Étale over Fields]. An algebra over a field \( k \) is étale iff it is a finite product of finite separable extensions of \( k \).

Proof: If \( k'/k \) is finite separable, then \( k' = k(\alpha) \) for some \( \alpha \) by primitive element theorem, thus \( k' = k[X]/(f) \) that \( f' \) is invertible in \( k' \), thus it is étale by (4.4.7.7).

Conversely, Cf. [Sta]00U3.

Cor. (4.4.7.20) [Étale over Perfect Fields]. Let \( k \) be a perfect field. If \( R \) is a \( k \)-algebra that is a finite as a \( k \)-module, then it is étale over \( k \) iff it is reduced.

Proof: If it is étale, then it is reduced, by (4.4.7.19). Conversely, if it is finite and reduced, then it is a reduced Artinian ring (4.1.3.4), so a product of fields over \( k \), so étale as \( k \) is perfect.

Prop. (4.4.7.21) [Étale and Trace Form]. Let \( A \) be a f.d. \( k \)-algebra, then \( A \) is étale over \( k \) iff the trace form: \( A \times A \to k : (a,b) \mapsto \text{tr}_{A/k}(ab) \) is non-degenerate.

Proof: If it is étale, then the trace form is non-degenerate by (4.4.7.19) and (2.2.5.32). Conversely, if the trace form is non-degenerate, then \( A \) is reduced, because if \( a \in A \) is nilpotent, then \( ab \) are nilpotent for any \( b \in A \), and \( \text{tr}_{A/k}(ab) = 0 \). Then as a reduced Artinian ring, \( A \) is isomorphic to a product of fields, then by (2.2.5.32), all the fields are separable over \( k \).

Prop. (4.4.7.22) [Étale and Unramified over Fields]. For \( k \in \text{Field} \), a f.g. \( k \)-algebra is étale iff it is \((G-)\)unramified over \( k \), by (4.4.5.23).

Prop. (4.4.7.23) [Maximal Étale Subalgebra]. Let \( A \) be an algebra of f.t. over a field \( k \), then there is a maximal étale \( k \)-subalgebra of \( A \). Also this subalgebra commutes with arbitrary field base change.

Proof: If \( R \) is an étale subalgebra of \( A \), then \( R_{\overline{k}} \) is étale over \( \overline{k} \), thus isomorphic to \((\overline{k})^n \) for some \( n \). Now \( n \) is smaller than the number of connected components of \( \text{Spec } A_{\overline{k}} \), which is finite. So it suffices to show the composite of two étale subalgebras of \( A \) is étale. For this, notice \( RR' \) is a quotient of \( R \otimes_k R' \), which is a finite product of finite separable fields over \( k \), thus its quotient is also a finite product of finite separable fields over \( k \), which is étale.

8 Local Algebras

Main references are [Local Algebra, Serre].

Prop. (4.4.8.1). If \( A \) is a Noetherian local integral domain with residue field \( k \) and quotient field \( K \), if \( M \) is a f.g. \( A \)-module that \( \dim_k M \otimes_A k = \dim_K M \otimes_A K = r \), then \( M \) is free of rank \( r \).

In other words, if the rank of \( M \) at the generic point and closed pt of \( B \) are the same, then \( M \) is free.

Proof: First \( M \) is generated by \( r \) elements by Nakayama and the kernel \( R \) of \( A^r \to M \) vanishes when tensoring \( K \), thus vanish because it is torsion-free.

Prop. (4.4.8.2). Let \( A \to B \) be a local ring map of local rings that

- \( B \) is finite as an \( A \)-module.
• $m_B$ is a f.g. ideal.
• $A/m_A \cong B/m_B$.
• $m_A/m_A^2 \cong m_B/m_B^2$.
Then $A \to B$ is surjective.

Proof: By Nakayama, to show it is surjective, it suffices to show $A/m_A \to B/m_A B$ is surjective, then it suffices to show $m_A \otimes_A B \to m_B$ is surjective. For this, use Nakayama again on $B$ to reduce to the fact $m_A \otimes_A B/m_B \to m_B \otimes B/m_B$ is surjective, which is satisfied because this is just $m_A/m_A^2 \to m_B/m_B^2$. □
4.5 \( p \)-adic Commutative Algebras

1 \( \mathbb{F}_p \)-Algebras

Def.(4.5.1.1)[relative Frobenius]. Let \( S \to R \) be a ring map, then the relative Frobenius \( \varphi_{R/S} \) is the map \( R \otimes_{S, \text{Frob}} S \to R \) induced by universal property.

Def.(4.5.1.2)[Perfect Rings]. A ring of characteristic \( p \) is called perfect iff the Frobenius \( \text{Frob}/\varphi : P \to P \) is an isomorphism. It is called semi-perfect iff Frob is surjective.

Prop.(4.5.1.3)[Perfection and Coperfection]. If \( R \) is of char \( p \), we define \( R_{\text{perf}} \) and \( R_{\text{coperf}} \) are perfect: for \( R_{\text{perf}} \) every element in \( R_{\text{perf}} \) is represented by an element \( a_n \in R_n \), and this element is equivalent to \( a_n^p \in R_{n+1} \), so its \( p \)-th root is \( a_n \in R_{n+1} \). For \( R_{\text{coperf}} \), an element \( (\ldots, x_n, \ldots, x_0) \) has \( p \)-th root \( (\ldots, x_{n+1}, \ldots, x_1) \).

In particular, the category of perfect rings admits limits and colimits, and it equals the limits and colimits in the category of rings.

Proof: First both \( R_{\text{perf}} \) and \( R_{\text{coperf}} \) are perfect: for \( R_{\text{perf}} \) every element in \( R_{\text{perf}} \) is represented by an element \( a_n \in R_n \), and this element is equivalent to \( a_n^p \in R_{n+1} \), so its \( p \)-th root is \( a_n \in R_{n+1} \). For \( R_{\text{coperf}} \), an element \( (\ldots, x_n, \ldots, x_0) \) has \( p \)-th root \( (\ldots, x_{n+1}, \ldots, x_1) \).

Second it is easily checked to be a functor because Frobenius is natural. The universal property is easy. □

Prop.(4.5.1.4)[Perfection Kills Nilextensions]. If \( f : R \to S \) is a map of rings of characteristic \( p \) that is surjective with nilpotent kernel, then \( R_{\text{perf}} \to S_{\text{perf}} \) and \( R_{\text{coperf}} \to S_{\text{coperf}} \) are both isomorphisms.

Proof: \( R_{\text{perf}} \) map is clearly surjective, and it is injective because if \( a \) maps to 0, then Frobenius \( \text{Frob}^k(a) \in \ker f \) for some \( k \), so it is nilpotent, so Frobenius \( \text{Frob}^{k+n}(a) = 0 \).

\( R_{\text{coperf}} \) is clearly injective, and it is surjective because: suppose \( \ker f^n = 0 \), then for \( a_n \in S \), let \( t_m \) be the inverse image of \( s_m \), for each \( m \), and let \( x = (x_n), x_{m-n} = \text{Frob}_m t_m \), then \( x \in R_{\text{coperf}} \) and \( x \) maps to \( s \).

Prop.(4.5.1.5)[Examples of Tilting].

- \( \mathbb{F}_p[[t]]_{\text{perf}} = \mathbb{F}_p[t^{1/p}] \), \( \mathbb{F}_p[[t]]_{\text{coperf}} = \mathbb{F}_p \).
- \( \mathbb{Z}_p^* \to \mathbb{Z}_p \).
- If \( R \) is a perfect ring of char \( p \) and \( f \in R \) is a non-zero divisor, then \( (R/f)_{\text{perf}} \) is the \( f \)-adic completion of \( R \). In particular, \( (\mathbb{F}_p[[t^{1/p}]]/(t))_{\text{perf}} \equiv \mathbb{F}_p[[t^{1/p}]] \).
- \( (\mathbb{Z}_p[[t^{1/p}]]_{\text{perf}} \equiv \mathbb{F}_p[[t^{1/p}]] \equiv \mathbb{F}_p[[t]_{\text{perf}}] \equiv (\mathbb{F}_p[[t]]/(t))_{\text{perf}} \).

Proof: The first two are trivial, for the third, notice \( \hat{R}_f = \lim_n R/f^n = \lim_n R/f^n \), and there are commutative diagram

\[
\begin{array}{ccc}
R/f & \xrightarrow{\varphi} & R/f \\
\downarrow{\varphi^{k+1}} & & \downarrow{\varphi^k} \\
R/fp^{k+1} & \xrightarrow{i} & R/fp^k
\end{array}
\]

so \( \lim_n R/f^n \equiv (R/f)_{\text{perf}} \).
For the fourth, only the first equivalence needs proving, the others are consequences of the first three items. Then notice

\[(\mathbb{Z}_p[p^{1/\infty}])^\flat \cong \lim_{\leftarrow}(\mathbb{Z}_p[p^{1/\infty}]/p^k)^{\text{perf}} \cong \left(\mathbb{Z}_p[p^{1/\infty}]/p\right)^{\text{perf}} \cong (F_p[t^{1/\infty}]/t)^{\text{perf}} \cong F_p[t^{1/\infty}].\]

The last isomorphism by item 3.

\[\square\]

Def. (4.5.1.6) [Perfectly Finitely Presented]. A map of perfect \(F_p\)-algebras \(B \to A\) are called perfectly finitely presented if \(A = (A_0)_{\text{per}}\) for some \(f.p.\ \)\(B\)-algebra \(A_0\).

Prop. (4.5.1.7) [Aberbach-Hochster]. Let \(R\) be a perfect \(F_p\)-algebra, \(f_1, \ldots, f_r \in R\), and consider the ideal \(I = \sqrt{(f_1, \ldots, f_r)} \in R\). Then \(R\downarrow I\) has flat dimension \(\leq r\) as an \(R\)-module.

Proof: We only prove for \(r = 1\).

We show \(I = \lim_{\leftarrow} f_1^{p^{n-1}/p^{n+1}} R\). The map is given by \((a_n) \mapsto f_1^{p^n} a_n\). This is injective because if \(f_1^{p^n} a = 0\), then \(f_1^{p^{n+1}} a = 0\) by perfectness, thus \(a\) is killed by the transition map \(f_1^{p^{n-1}/p^{n+1}}\).

\[\square\]

Prop. (4.5.1.8) [Perfect Algebras are Tor Independent]. For any two perfect \(A\)-algebras \(B, C\) where \(A\) is a perfect \(F_p\)-algebra, \(\text{Tor}_i^A(B, C) = 0\) for \(i > 0\).

Proof: \(A \to B\) can be written as a composition of a perfection of a free \(A\)-algebra and a quotient. The perfection of free algebra is flat, thus we can assume \(B = A/I\). By a filtered colimit argument again, we can assume \(I = (f_1^{1/\infty}, \ldots, f_r^{1/\infty})\) is perfectly f.p. By induction, we can assume \(r = 1\). Now the lemma (4.5.1.7) applied to \(R = C\) shows that \(IC = \lim_{\leftarrow} f_1^{p^n-1/p^{n+1}} C = I \otimes_A^L C\), so \(B \otimes_A^L C = C/IC\) is discrete.

\[\square\]

Prop. (4.5.1.9). If \(R\) is a perfect \(F_p\)-algebra, \(I\) is a radical ideal, and \(J = R[I] \subset R\), then \(J\) and \(I + J\) are both radical, and the square

\[
\begin{array}{ccc}
R & \longrightarrow & R/I \\
\downarrow & & \downarrow \\
R/J & \longrightarrow & R/I + J
\end{array}
\]

is both a fiber pullback and pushout square of commutative rings.

Proof: \(J\) is clearly a radical, and notice that \(I + J\) is the kernel of the map \(R \to R/I \otimes_R R/J = R/I + J\) (4.1.1.22), and the target is a colimit of perfect rings thus perfect, by (4.5.1.3). Thus \(I + J\) is also perfect, thus a radical ideal.

By (4.1.1.23), to show the map is a pullback square, it suffices to show that \(I \cap J = 0\). If \(x \in I \cap J\), then \(x^2 = 0\), thus \(x^p = 0\), so \(x = 0\).

\[\square\]

Tilting

Def. (4.5.1.10) [Tilting]. For any ring \(R\), let the tilting of \(R\) be defined to be \(R^\flat = (R/p)^{\text{perf}}\), endowed with the profinite topology.

Prop. (4.5.1.11). If \(R\) is a f.g. algebra over an alg. closed field \(k\) of char \(p\), then \(R^\flat \cong k^{\pi_0(\text{Spec } R)}\).
Proof: It suffice to prove for Spec $R$ connected and reduced, because by (4.5.1.4). We first prove the case Spec $R$ is irreducible, i.e. $R$ is integral:

In this case, choose a closed point $x$, then there is a map $R \to \hat{R}_x$, where $\hat{R}_x$ is the $\mathfrak{m}_x$-adic completion. By Krull(4.2.2.15) and the fact $R$ is integral, this map is injective, so it suffices to show that $0 = (\hat{R}_x)_{\text{perf}} = \lim_{\to}(R_x/\mathfrak{m}_x^n)_{\text{perf}}$. But $(-)_{\text{perf}}$ is a right adjoint so commutes with colimits and $\hat{R}_x = \lim_{\to} R_x/\mathfrak{m}_x^n$. But $(R_x/\mathfrak{m}_x^n)_{\text{perf}} = (R_x/\mathfrak{m}_x)_{\text{perf}} = k_{\text{perf}} = k$, by (4.5.1.4) again.

If $R$ is not irreducible,?

Prop.(4.5.1.12). If $R$ is a $p$-adically complete commutative ring, $\pi \in \text{rad}(p)$, then the map $R \to R/p$ induces an homeomorphism of monoids:

$$\lim_{\to} x \mapsto x^p \equiv \lim_{\to} R/\pi \equiv \lim_{\to} R/p(4.5.1.4) = R^p$$

Proof: Injectivity: if $(a_n), (b_n) \in \lim_{\to} x \mapsto x^p R$ satisfies $a_n \equiv b_n \mod \pi$ for all $n$, then applying power lifting(20.1.2.8), $a_n \equiv b_n \mod \pi^{n+k}$ for all $k$, so $a_n = b_n$.

Surjectivity: for $(\bar{a}_n) \in R^p$, choose arbitrary lifting $a_n$, then $a_n^{p+k} \equiv a_n+k \mod \pi$ for all $n+k$, so $k \mapsto a_n^{p+k}$ is a Cauchy sequence by power lifting(20.1.2.8) again, thus converging to some point $b_n$. then it’s easily checked that $b_n = (\lim_{\to} a_n^{p+k})^p = \lim_{\to} a_n^{p+k+1} = b_n$. so $(b_n)$ maps to $(\bar{a}_n)$.

For the topology: it is clearly continuous, and for the reverse, if $(a_i), (b_i)$ satisfies that $a_i \equiv b_i \mod \pi$ for $i < k$, then the image in $\lim_{\to} x \mapsto x^p R$ satisfies $x_i \equiv y_i \mod p^{k-i}$ for $i < k$, thus it is open.

Cor. (4.5.1.13)[Sharp Map]. From this proposition, we get a multiplicative sharp map: $\sharp: R^p \to R$, and its image is just the elements that has a compatible system of $p$-th roots $x^{1/p}$. These elements are also called perfect.

Cor. (4.5.1.14) [Addition in $R^p$]. From the isomorphism(4.5.1.12) above, we can read what the addition looks like in the presentation $\lim_{\to} x \mapsto x^p R$: if $(f_n), (g_n)$ are two elements, then their addition is given by $(h_n)$, where $h_n = \lim_{\to} (f_n + g_n)^{p^k}$.

Cor. (4.5.1.15) [Fontaine’s Map]. By (8.2.4.4), the natural map $R^p \to R/\pi$ induces a map $\theta_R : W(R^p) \to R$ of rings, called the Fontaine’s functor, which writes as $\sum [a_i] p^i \mapsto \sum a_i^\flat p^i$. And we denote $A_{\text{inf}}(R) = W(R^p)$ the Fontaine’s ring of $R$.

Prop. (4.5.1.16). Fontaine’s map $\theta_R$ is surjective iff $R/p$ is semiperfect.

Proof: By Nakayama, $\theta$ is surjective iff it is surjective modulo $o$. Because its reduction mod $p$ is $R^p \to R/p$ is surjective as $\varphi : R/p \to R/p$ does.

Prop.(4.5.1.17)[ Tilting as a Valuation Ring]. If $R$ is a domain or a valuation ring, then the same is true for $R^p$. In the valuation case, the valuation of $R^p$ can in fact be chosen to be $| \cdot | \circ \sharp$, so in particular, the rank of $R^p$ is no more than the rank of $R$.

Proof: Use the isomorphism $\lim_{\to} x \mapsto x^p R \equiv \lim_{\to} x \mapsto x^p R/p = R^p(4.5.1.12)$.

For the domain case, if $(a_n)(b_n) = 0$, then $a_nb_n = 0$, so $a_0 = 0$ or $b_0 = 0$, so $(a_n) = 0$ or $(b_n) = 0$. Similarly, if $R$ is a valuation ring, then $R^p$ is firstly a domain, and it suffices to prove that for any $(a_n), (b_n) \in R^p$, the quotient of one by another is in $R^p$, by (10.3.2.3). For this, because $R$ is
valuation ring, we may assume \( a_0/b_0 \in R \), so \( a_n/b_n \) is also in \( R \), because their power do, and \( R \) is normal\(^{\text{(10.3.2.6)}} \), thus \( (a_n)/(b_n) \in R^\flat \).

For the valuation given, notice in the above proof, \(|(a_n)| \leq |(b_n)|\) iff \(|a_0| \leq |b_0|\), so the valuation are equivalent to \(|\cdot| \circ \sharp\) by\(^{\text{(10.3.3.14)}} \), so it can be chosen to be so. \(\square\)

**Prop.(4.5.1.18)**[Tilting and Completion]. If \( R = A/I \) with \( A/p \) perfect, then \( R^\flat \) identifies with the \( I \)-adic completion of \( A/p \).

*Proof:* \( R^\flat = \varprojlim R/p = \varprojlim A/(p, I) \). But there are commutative diagrams

\[
\begin{array}{ccc}
A/(p, I) & \xrightarrow{\varphi} & A/(p, I) \\
\downarrow^{\varphi^{n+1}} & & \downarrow^{\varphi^n} \\
A/(p, I^{p^{n+1}}) & \xrightarrow{\phi^n} & A/(p, I^p)
\end{array}
\]

where the vertical arrows are isomorphisms because \( A/p \) is perfect. So the conclusion follows. \(\square\)

2 **\( p \)-Local Rings**

**Def.(4.5.2.1)**[\( p \)-Local Rings]. A commutative ring is called \( p \)-local if \( p \in \text{rad} \ A \).

**Prop.(4.5.2.2).** Let \( A \) be a \( p \)-adically complete ring, then \( A \) is \( p \)-local, by\(^{\text{(4.2.3.18)}} \).

**Prop.(4.5.2.3).** If \( A \) is \( p \)-adically complete and has bounded \( p \)-torsions, the \( p \)-completion of a smooth \( A \)-algebra is \( p \)-completely smooth.

*Proof:* This follows from\(^{\text{(4.6.7.4)}} \) and\(^{\text{(4.6.6.16)}} \). \(\square\)

**Def.(4.5.2.4)**[\( p \)-Normal Rings]. A \( p \)-torsion-free ring \( R \) is called \( p \)-normal if \( R \) is \( p \)-root closed in \( R[z]/z \).

**Complete Discrete Valuation Rings**

Structure of complete \( p \)-local DVRs will be studied in this subsubsection.

Main references are \([\text{Ser79}]\), [Integral \( p \)-adic Hodge, BMS].

**Def.(4.5.2.5)**[Strict \( p \)-Ring]. A \( p \)-ring \( A \) is a ring which is complete Hausdorff in the topology defined by the decreasing chain of ideals \( \alpha_1 \supset \alpha_2 \supset \cdots \) such that \( \alpha_m \alpha_n \subset \alpha_{m+n} \) that \( k = A/\alpha_1 \) is a perfect ring of characteristic \( p \).

It is called a **strict \( p \)-ring** if moreover \( \alpha_n = (p^n) \) and \( p \) is a non-zero divisor of \( A \).

**Prop.(4.5.2.6)**[Teichmüller Lifts]. For a \( p \)-ring, there exists a unique section map \( [\cdot] : k \rightarrow A \) that is multiplicative, called the **Teichmüller lifts**.

If char \( A = p \), then the Teichmüller lift is also additive (but not in general). And an element is in the image of \( f \) iff it is a \( p^n \)-th power for any \( n \).

*Proof:* For any \( \lambda \in k \), the \( \lambda^{p^n} - \lambda \) is unique in \( k \), and if we consider \( U_n \) the set of all \( x^{p^n} \) where \( x \) is a lift of \( \lambda^{p^n} - \lambda \), then \( U_n \) is a descending set. Moreover, the diameter converges to 0, because \( a \equiv b \mod \alpha_1 \) implies \( a^{p^n} \equiv b^{p^n} \mod \alpha_{n+1} \) as \( p \in \alpha_1 \). So it converges to a unique point \( f(\lambda) \) in \( A \). And we see that any other \( f' \) maps \( \lambda \) to a \( p^n \)-th root hence in \( U_n \) for any \( n \), hence it map be equal to \( f(\lambda) \). The rest is easy. \(\square\)
Cor. (4.5.2.7) [Equal Characteristic case]. If \( A \) is a complete discrete valuation ring with residue field \( k \). If \( k \) and \( A \) have the same characteristic and \( k \) is perfect, then \( A \cong k[[T]] \).

Def. (4.5.2.8) [(0, \( p \))-type case]. When \( A \) is a complete DVR with residue field \( k \) and quotient field \( K \). If \( \text{char}K = 0 \) and \( \text{char}k = p \), then \( p \) goes to 0 in \( k \), so \( e = v(p) \geq 1 \), called the absolute ramification index of \( A \). It is called absolutely unramified iff \( e = 1 \).

Remark (4.5.2.9) [Universal Strict \( p \)-Ring]. The canonical strict \( p \)-ring is the ring \( \hat{S} = \hat{\mathbb{Z}}[X_i^{p^{-n}}] \). Its residue ring is \( \mathbb{F}_p[X_i^{p^{-n}}] \) which is perfect. \( X_i \) are all Teichmüller lifts, as they all has \( p^i \) roots.

Now we consider the \( * = + - \times \) in \( \hat{S} \). Then there are elements \( Q_i^* \in \mathbb{F}_p[X_i^{p^{-n}}, Y_i^{p^{-n}}] \) that \( x * y = \sum f(Q_i^*)p^i \) where \( f \) is the Teichmüller lift.

Prop. (4.5.2.10) [Universal Law of \( p \)-Rings]. For any \( p \)-ring \( A \) with residue ring \( k \), the calculation in \( A \) is dominated by \( Q_i^* \) defined in (4.5.2.9), i.e.

\[
\left( \sum f(\alpha_i)p^i \right) * \left( \sum f(\beta_i)p^i \right) = \sum f(\gamma_i)p^i
\]

where \( \gamma_i = Q_i^*(\alpha_0, \alpha_1, \ldots, \beta_0, \beta_1, \ldots) \).

Proof: There is a map \( \theta \) from \( \hat{S} = \hat{\mathbb{Z}}[X_i^{p^{-n}}, Y_i^{p^{-n}}] \) to \( A \) induced by \( f(\alpha_i), f(\beta_i) \) as they all has \( p^{-n} \)-th roots. Then notice \( \theta \) induce a \( \bar{\theta} \) on residue ring and these two \( \theta \) commutes with Teichmüller lift, as seen by the definition of the latter. Then the theorem follows immediately.

Prop. (4.5.2.11) [Universal Properties of Strict \( p \)-Rings]. For two \( p \)-ring \( A, A' \) that \( A \) is strict, then any map \( \varphi \) of their residue ring induces a unique ring homomorphism \( A \to A' \). In particular, two strict \( p \)-ring with the same residue ring is canonically isomorphic.

Proof: We have already seen that ring homomorphism commutes with Teichmüller lift. Now we define

\[
g(a) = \sum g(f(\alpha_i))p^i = \sum f(\varphi(\alpha_i))p^i
\]

and this is the unique choice. It is a ring homomorphism by universal law of (4.5.2.10).

3 Witt Theory

References are [Michiel Hazewinkel, Formal Groups and Applications] and [Rab14].

Witt Vectors

Def. (4.5.3.1) [Divisor Stable Subsets]. A non-empty subset \( P \subset \mathbb{Z}_+ \) is called divisor-stable if it is stable under taking divisors.

For a divisor-stable subset \( P \) and \( n \in \mathbb{Z}_+ \), define \( P(n) = \{ m \in P | m \leq n \} \).

Def. (4.5.3.2) [Witt Polynomials]. For \( n \in \mathbb{N} \), the \( n \)-th Witt polynomial is defined to be

\[
W_n = \sum_{d|n} dX_d^{n/d} \in \mathbb{Z}[[X_d : d|n]].
\]

For example,

\[
W_{p^k} = X_1^{p^k} + pX_{p^{k-1}} + \ldots + p^nX_p.
\]
Prop. (4.5.3.3) [Commutative Coalgebra $\Delta_P$]. For a divisor-stable set $P$, let $\Delta_P = \mathbb{Z}[[X_n | n \in P]]$, then there is a unique commutative ring scheme structure on $\text{Spec} \Delta_P$ s.t. the map

$$W_* : \mathbb{Z}[X_P] \to \Delta_P : n \mapsto W_n \in \Delta_P$$

induces a homomorphism of ring schemes $\text{Spec} \Delta_P \to \text{Spec} \mathbb{Z}[X_P]$, where the ring structure on $\text{Spec} \mathbb{Z}[X_P]$ is given by

$$\times : \mathbb{Z}[X_P] \to \mathbb{Z}[X_P] \otimes \mathbb{Z}[Y_P] : X_n \mapsto X_n \otimes Y_n, \quad + : \mathbb{Z}[X_P] \to \mathbb{Z}[X_P] \otimes \mathbb{Z}[Y_P] : X_n \mapsto X_n \otimes 1 + 1 \otimes Y_n.$$

Then for another divisor-stable set $P' \subset P$, there is a natural map $\Delta_{P'} \to \Delta_P$ that induces a homomorphism of ring schemes.

If $P = \mathbb{Z}_+$, denote $\Delta_P = \Delta$, if $P = \{1, p, p^2, \ldots\}$, denote $\Delta_P = \Delta_p$, and if $P = \{1, p, \ldots, p^k\}$, denote $\Delta_P = \Delta_{p,k}$.

Proof:

Cor. (4.5.3.4). $S_n$ is of the form $S_n(X_P, Y_P) = X_n + Y_n + f_n(X_{P(n-1)}, Y_{P(n-1)})$.

Proof:

Def. (4.5.3.5) [Witt Vectors]. For a divisor-stable set $P$, consider the functor

$$W_P : \mathcal{C}_{\text{Alg}} \to \mathcal{C}_{\text{Alg}} : A \mapsto W_P(A) = \text{Hom}(\Delta_P, A),$$

then it is an exact functor, and by (4.5.3.3), there are natural ring homomorphism

$$W_* : W_P(A) \to \prod_P A : f \mapsto (f(W_n))_W$$

For $x \in W_P(A)$, $W_n(x)$ are called the ghost components of $x$, and $W_* (x)$ is called the Witt coordinate of $x$.

If $P = \mathbb{Z}_+$, $W_P(A)$ is denoted by $W(A)$, if $P = \{1, p, p^2, \ldots\}$, $W_P(A)$ is denoted by $W_p(A)$, and if $P = \{1, p, \ldots, p^k\}$, denote $W_P(A) = W_{p,k}(A)$.

Prop. (4.5.3.6) [Natural Coordinates]. There is another map

$$\varphi_* : W_P(A) \to \prod_P A : f \mapsto (f(X_i))$$

which is an isomorphism of sets, whose components are maps of sets $\varphi_n : W_P(A) \to A, n \in P$. WARNING: it is not an isomorphism of groups. For $x \in W_P(A)$, $\varphi_n(x)$ are called the ghost components of $x$, and $\varphi_*(x)$ is called the Witt coordinate of $x$. All coordinates of elements in $x$ will be assumed to be in the natural coordinates by default.

Then the map $W_* \varphi^{-1}_*$ is given by

$$W_* \varphi^{-1}_* : \prod_P A \to \prod_P A : (x_n)_\varphi \mapsto (W_n(\{x_P\}))_W.$$

Cor. (4.5.3.7) [Witt Coordinates are Injective]. $W_* : W_P(A) \to \prod_P A$ is injective if $A$ is $n$-torsion-free for any $n \in P$, and an isomorphism iff $n$ is invertible in $A$ for any $n \in P$.

This is very useful because it can prove equations by checking on each $W_n$. Also when checking universal equations, it is even not necessary that $A$ is $n$-torsion-free, because any ring $A$ is a quotient of a free $\mathbb{Z}$-algebra.
4.5. P-ADIC COMMUTATIVE ALGEBRAS

Proof: It suffices to prove for $W_s\varphi^{-1}_s$. Using the Witt polynomials and prove inductive on $n \in P$ s.t. if $x = (x_n)$ is mapped to 0, then $x_n = 0$ for any $n \in P$.

In case $n$ is invertible in $A$ for any $n \in P$, solve $x_n$ out of $W_s(x)$ inductively. 

**Def. (4.5.3.8) [Topology on $W_P(A)$].** Let $P$ be a divisor-stable set, then for any $A \in \mathcal{C}Alg$, the natural map

$$W_P(A) \to \lim_{n \in \mathbb{Z}^+} W_P(n)(A)$$

is an isomorphism of rings, so we can define the **natural topology** on $W_P(A)$ is as the profinite topology.

Then this topology makes $W_P(A)$ a topological ring, and it is discrete iff $\# P < \infty$, and $W_P$ is a functor from $\mathcal{C}Alg$ to the category of profinite rings.

**Prop. (4.5.3.9).** Let $P$ be a divisor-stable set and $A \in \mathcal{C}Alg$, then for $x = (x_n)$, $y = (y_n) \in W_P(A)$, if $x_n y_n = 0$ for any $n \in P$, then

$$x + y = (x_n + y_n) \in W_P(A).$$

**Proof:** It suffices to prove on $\Delta_P$. By (4.5.3.7), it suffices to prove $W_n((x_n + y_n)) = W_n(x) + W_n(y)$ for any $n \in P$. This is true because

$$W_n((x_n + y_n)) = \sum_{d|n} d(x_d + y_d)^{n/d} = \sum_{d|n} dx_d^{n/d} + \sum_{d|n} dy_d^{n/d} = W_n(x) + W_n(y).$$

**Prop. (4.5.3.10) [Teichmüller Lifts].** Let $P$ be a divisor-stable set and $A \in \mathcal{C}Alg$, for $a \in A$, denote $[a] = (a, 0, \ldots) \in W_P(A)$. Then for any $x = (x_n) \in W_P(A),$

$$[a]x = (a^n x_n).$$

In particular, $[\cdot] : A \to W_P(A)$ is multiplicative, called the **Teichmüller lifts** of $A$.

**Proof:** It suffices to prove on $\Delta_P$. By (4.5.3.7), it suffices to prove $W_n((a^n x_n)) = W_n([a]x)$ for any $n \in P$. This is because

$$W_n((a^n x_n)) = \sum_{d|n} d(a^d x_d)^{n/d} = a^n \sum_{d|n} dx_d^{n/d} = W_n([a]x) W_n(x) = W_n([a]x).$$

**Frobenius and Verschiebung Maps**

**Def. (4.5.3.11) [Verschiebung Maps].**

**Def. (4.5.3.12) [Frobenius Maps].**

**Prop. (4.5.3.13) [Frobenius and Verschiebung].** Let $n \in \mathbb{Z}_+$ and $P$ is a divisor-stable subset s.t. $nP \subset P$. Let $A \in \mathcal{C}Alg$, let $x, y \in W_P(A)$,

- $F_n \circ V_n = n \cdot \text{id}$,
- $V_n(F_n(x)y) = xV_n(y)$,
- If $(m, n) = 1$, then $V_m \circ F_n = F_n \circ V_m$,
- For $m \in \mathbb{Z}_+$, $(V_n(x))^m = n^{m-1}V_n(x^m)$.

**Proof:** Cf. [Rab14] P18.
\textbf{Prop.(4.5.3.14)[Structure of }\Delta_{p}\text{]}\text{. The ring structure on }\text{Spec }\Delta_{p}\text{ is given by}

\[\times : \Delta_{p} \rightarrow \Delta_{p} \otimes \Delta_{p} : X_{p}^{k} \mapsto S_{k}(X_{F}, Y_{P}), \quad + : \Delta_{p} \rightarrow \Delta_{p} \otimes \Delta_{p} : X_{p}^{k} \mapsto Z_{k}(X_{F}, Y_{P})\]

where

\[S_{1} = X_{1} + Y_{1}, \quad S_{2} = X_{p} + Y_{p} + \sum_{i=1}^{p-1} \frac{1}{p} \binom{p}{i} X_{1}^{i} Y_{1}^{p-i},\]
\[Z_{1} = X_{1} Y_{1}, \quad Z_{2} = X_{p}^{p} Y_{p} + X_{p} Y_{p}^{p} + p X_{p} Y_{p}.\]

\textit{Proof:} \[\] 

\textbf{Cor.(4.5.3.15)[W2]}\text{. Let }W_{2} = W_{P}\text{ where }P = \{1, p\}\text{, then }W_{2}(A)\text{ is the set }A \times A\text{(as the natural coordinates) with the addition and multiplication given by}

\[(x_{0}, x_{1}) + (y_{0}, y_{1}) = (x_{0} + y_{0}, x_{1} + y_{1} + \frac{x_{0}^{p} + y_{0}^{p} - (x_{0} + y_{0})^{p}}{p}), \quad (x_{0}, x_{1})(y_{0}, y_{1}) = (x_{0} y_{0}, x_{0}^{p} y_{1} + y_{0}^{p} x_{1} + p x_{1} y_{1})\]

There are two natural morphism of rings \(\varepsilon_{1}, \varepsilon_{2} : W_{2}(A) \rightarrow A:\)

\[\varepsilon_{1}((x_{0}, x_{1})) = x_{0}, \quad \varepsilon_{2}((x_{0}, x_{1})) = x_{0}^{p} + p x_{1}.\]

\textbf{Prop.(4.5.3.16). For }k \geq 1\text{ and }A \in \mathbb{C}Alg,\text{ the kernel of }W_{1} : W_{p,k}(A) \rightarrow A\text{ is a nilpotent ideal.}

\textit{Proof:} \[\text{Cf.[Basic Algebra 2, Jacobson]P508.}\]

\textbf{Cor.(4.5.3.17). An element }x \in W_{p,k}(A)\text{ is a unit iff }W_{1}(x) \in A\text{ is a unit.}

\textbf{Example(4.5.3.18)[}p\text{-Typical Witt Vectors].}

\begin{itemize}
  \item \(W_{p}(\mathbb{F}_{q})\text{ is the unramified extension of }\mathbb{Z}_{p}\text{ of degree }\log_{p} q.\)
  \item \(W_{p}(\mathbb{F}_{p})\text{ is the completion of the maximal unramified extension of }W_{p}(\mathbb{F}_{p}).\)
\end{itemize}

\textit{Proof:} \[\]

\textbf{Lemma(4.5.3.19)[Formula for }p\text{-Rings]. For }* = + \text{ or }\times\text{, there are integral polynomials }S_{*}(X_{i}, Y_{i})\text{ that}

\[\left(\sum f(\alpha_{i})p^{i}\right) * \left(\sum f(\beta_{i})p^{i}\right) = \sum f(\gamma_{i})p^{i}\]

where \(\gamma_{i} = Q_{i}^{*}(\alpha_{0}, \alpha_{1}, \ldots, \beta_{0}, \beta_{1}, \ldots).\) And for \(+\), when reduced to \(\mathbb{F}_{p}\), \(Q_{i}^{+}\) are polynomials in \(X_{i}^{p-n}, Y_{i}^{p-n}\) for \(i \leq n\) and homogenous of degree 1. And

\[Q_{i}^{+} = (X_{n} + Y_{n}) + (X_{n-1}^{p-1} + Y_{n-1}^{p-1}) R_{n,n-1} + \ldots + (X_{0}^{p-n} + Y_{0}^{p-n}) R_{n,0}.\]

\textit{Proof:} \[\text{We solve }S_{n}\text{ by induction. Notice for any lift }\tilde{S}_{i}\text{ of }S_{i},\]

\[f(S_{i}) \equiv \tilde{S}_{i}(X^{1/p^{n-i}}, Y^{1/p^{n-i}})p^{n-i} \mod p^{n-i+1}\]

so we mod \(p^{n+1}\) to solve \(S_{n}:\)

\[S_{n} \equiv 1/p^{n}(X_{0} + Y_{0} + \ldots + p^{n}X_{n} + p^{n}Y_{n} - \tilde{S}_{0}(X^{1/p^{n}}, Y^{1/p^{n}})p^{n} - \ldots - p^{n-1}\tilde{S}_{n-1}(X^{1/p}, Y^{1/p})p^{n}).\]

The rest follows by induction. \[\]
Lemma (4.5.3.20). If $k$ is a perfect field of characteristic $p$ and $R$ is a strict $p$-ring with residue field $k$, then the map

$$f : W_p(k) \to R : (x_1, x_2, x_3, \ldots) \mapsto \sum_{n=0}^{\infty} [x_{p^n}] p^n$$

is an isomorphism of topological rings.

*Proof:* We need to prove this is a ring homomorphism. That on $W(A)$ is to make $\varphi$ a ring homomorphism, and that on the right is usual. It suffice to prove for the canonical strict $p$-ring, as seen by the universal law (4.5.2.10).

For this, we let $(\sum X_i^{p^i} \cdot p^i) \ast (\sum Y_i^{p^i} \cdot p^i) = \sum f(\psi_i(X_i, Y_i)) p_i \cdot p^i$, and $W_n(a_i) \ast W_n(b_i) = W_n(\varphi_i)$, where $\psi_i \in F_p[X_i, Y_i]$ and $\varphi_i \in Z[X_i, Y_i]$, they both exist, the latter because of (4.5.4.7).

Then we mod $p^{n+1}$, and let $X_i = Y_i^{p^n}$, so $W_n(\varphi_i) = W_n(X_i) \ast W_n(Y_i) = \sum f(\psi_i(X_i^{p^n}, Y_i^{p^n})) p_i \cdot p^i = W_n(\psi_i)$ mod $p^{n+1}$

Now induction, $\varphi_i \equiv \psi_i$ mod $p$, then $p^n \varphi_n \equiv p^n \psi_n$ mod $p^{n+1}$ so this is true for $n$, too.

Cf. [Rab14] P8, 20. 

\[ \square \]

Prop. (4.5.3.21) [Witt $p$ For Perfect Rings]. For any perfect ring $k$ of char $p$, there exists uniquely a strict $p$-ring $W(k)$ that has residue ring $k$, which is just the ring of Witt vectors $W_p(k)$.

Then $W_p$ is a faithful functor from the category of perfect rings to the category of $p$-rings with perfect residue fields that is left adjoint to the functor mapping a $p$-ring with perfect residue fields to its residue field, by (4.5.2.11).

*Proof:* For a canonical ring $F_p[X_p^{-n}]$, $\tilde{Z}[X^{-n}]$ is a strict $p$-ring. Now arbitrary perfect $p$-ring is a quotient of $F_p[X_p^{-n}]$, so we can construct its strict $p$-ring $W(k)$ as the quotient of $\tilde{Z}[X^{-n}]$. Uniqueness is by (4.5.2.11).

Notice it is nothing mysterious, it is just the set of all formal sum $\sum f(x_i) p^i$ under the operation defined in (4.5.2.9). See also (4.5.3.20). 

\[ \square \]

Cor. (4.5.3.22). $W_{p,k}(F_p) \cong \mathbb{Z}/(p^k)$.

Def. (4.5.3.23) [Witt Vectors over Valued Rings]. If a perfect ring $R$ itself has a complete valuation $v$, then we can endow $W(R)$ with a finer topology: we let $w_k(x) = \inf_{i \leq k} v(x_i)$, where $x = \sum p^i f(x_i)$. Now $w_k(x + y) \geq \inf(w_k(x), w_k(y))$ by (4.5.3.19). The weak topology of $W(R)$ is defined by the semi-valuations $w_k$.

Prop. (4.5.3.24). If $a, b \in O_R + p^{n+1} W(R)$, then

$$p^n v(a_n - b_n) \geq w_n(a - b) \geq \inf_{k \leq n} p^{-k} v(a_{n-k} - b_{n-k}).$$

So we see that a sequence is Cauchy in $W(R)$ if each coordinate is Cauchy in $R$, so $W(R)$ is complete in the weak topology.

*Proof:* Firstly the last proposition follows from the first because we can always multiply by a $f(\alpha)$ to make the first $n$ coordinate in $O_R$.

The first is nearly an immediate consequence of (4.5.3.19). 

\[ \square \]
Prop. (4.5.3.25). $O_E = W(K^{1/p})$ is a complete ring with maximal ideal $pO_E$. And $O_E[1/p] = E$ is complete ring of character $p$. And the same construction of $K^{1/p}$ yields the completion of maximal unramified extension of $O_E$, and the Galois group is the same as $G_K$.

Prop. (4.5.3.26) [van Der Kallen]. If $A \to B$ is an étale morphism, then $W_r(A) \to W_r(B)$ is also étale. Moreover, if $A \to A'$ is any ring map with $B' = B \otimes_A A'$, then the natural map

$$W_r(A') \otimes_{W_r(A)} W_r(B) \to W_r(B')$$

is also an isomorphism.

Proof: Cf.[Integral $p$-adic Hodge, BMS]. \hfill \square

4 $\delta$-Rings

Def. (4.5.4.1) [$\delta$-Ring]. A $\delta$-ring structure on $R$ characterize the deficit in lifting the Frobenius action on $R/p$, i.e. $\varphi(x) = x^p + p\delta(x)$. A $\delta$-ring is a pair $(R, \delta)$ where $R$ is a commutative ring and $\delta : R \to R$ is a map that $\delta(0) = \delta(1) = 0$, and satisfies:

$$\delta(xy) = x^p\delta(y) + y^p\delta(x) + p\delta(x)\delta(y), \quad \delta(x + y) = \delta(x) + \delta(y) - \frac{(x + y)^p - x^p - y^p}{p}.$$}

$\delta$-rings naturally form a category, denoted by $CAlg^{\delta}$. And in case $A$ is $p$-torsionfree, a $\delta$-structure on $A$ is the same as a lifting of the Frobenius on $A/p$.

Def. (4.5.4.2) [$\delta$-Pairs]. The category of $\delta$-pairs consists of pairs $(A, I)$ where $A$ is a $\delta$-ring and $I$ is an ideal of $A$ that morphisms $\varphi : (A, I) \to (B, J)$ are $\delta$-ring maps $A \to B$ that $\varphi(I) \subset J$.

Prop. (4.5.4.3) [$\delta$-Rings and $W_2$]. A $\delta$-ring structure on $A$ is the same as a section of the map $W_1 : W_2(A) \to A$, and a morphism of $\delta$-rings is a commutative diagram of sections.

Proof: By the description of $W_2$ in (4.5.3.15), this is clear, the morphism is given by $A \to W_2(A) : x \mapsto (x, \delta(x))$. \hfill \square

Lemma (4.5.4.4) [Initial $\delta$-Algebra]. We usually work with $\delta$-algebras over $\mathbb{Z}_{(p)}$. Then there is an initial object in the category of $\delta$-rings, given by $Z_{(p)}$ with $\delta(x) = \frac{x - x^p}{p}$.

Prop. (4.5.4.5). For a $\delta$-ring $A$, $\varphi$ commutes with $\delta$.

Proof: We need to check $\delta(x^p + p\delta(x)) = \varphi(x)^p + p\delta(\varphi(x))$. This is hard to check, but we can check $\varphi(\frac{x^p}{p}) = \frac{x^p}{p}$, so the conclusion is true when $A$ is $p$-torsion-free. But by (4.5.4.10), every $\delta$-ring is a quotient of a free thus $p$-torsionfree ring, thus the equation is also true for arbitrary $A$. \hfill \square

Def. (4.5.4.6) [Commutative Coalgebra $\mathbb{Z}[\delta]$]. Denote $\mathbb{Z}[\delta] = \mathbb{Z}[\delta, \ldots, \delta_n, \ldots]$. Using the formulas in (4.5.4.1), we can write $\delta^n(xy)$ and $\delta^n(x + y)$ as functions of $\delta^i(x), \delta^i(y)$ for $0 \leq i \leq n$, i.e.

$$\delta^n(xy) = M_n(x, \delta(x), \delta^2(x), \ldots, \delta^n(x), y, \delta(y), \ldots, \delta^n(y))$$

$$\delta^n(x + y) = S_n(x, \delta(x), \delta^2(x), \ldots, \delta^n(x), y, \delta(y), \ldots, \delta^n(y))$$
Then we can change \( \delta^{on} \) to \( \delta_n \) to define a commutative ring scheme structure on \( \text{Spec} \, \mathbb{Z}[\delta] \):

\[
\times : \mathbb{Z}[\delta] \to \mathbb{Z}[\delta] \otimes \mathbb{Z}[\delta] : \delta_n \mapsto M_n, \quad + : \mathbb{Z}[\delta] \to \mathbb{Z}[\delta] \otimes \mathbb{Z}[\delta] : \delta_n \mapsto S_n.
\]

It is easily prove by induction that if we denote \( \mathbb{Z}[\varphi] = \mathbb{Z}[e, \varphi, \varphi_2, \ldots, \varphi_n, \ldots] \), and \( \text{Spec} \, \mathbb{Z}[\varphi] \) the commutative ring scheme with the ring structure given by

\[
\times : \mathbb{Z}[\varphi] \to \mathbb{Z}[\varphi] \otimes \mathbb{Z}[\varphi] : \varphi_n \mapsto \varphi_n \otimes \varphi_n, \quad + : \mathbb{Z}[\varphi] \to \mathbb{Z}[\varphi] \otimes \mathbb{Z}[\varphi] : \varphi_n \mapsto \varphi_n \otimes 1 + 1 \otimes \varphi_n,
\]

then the map

\[
\mathbb{Z}[\varphi] \to \mathbb{Z}[\delta] : \varphi_n \mapsto \text{expansion of } \varphi^{on} \in \mathbb{Z}[e, \delta_1, \ldots, \delta_n]
\]

induces a homomorphism of ring schemes \( \text{Spec} \, \mathbb{Z}[\delta] \to \text{Spec} \, \mathbb{Z}[\varphi] \).

There is a natural functor:

\[
[\delta] : \mathbb{Z}[\delta] \to \mathbb{Z}[\delta] : \delta_i \mapsto \delta_{i+1}
\]

**Lemma (4.5.4.7)**[\( \delta \)-Component]. Let \( \varphi = e^p + p\delta \) be a polynomial in \( e, \delta \), then there are polynomials \( \Theta_n \in \mathbb{Z}[e, \delta_1, \delta_2, \ldots, \delta_n] \) s.t.

\[
\varphi^{on} = \Theta_0^n + p\Theta_1^{p^n-1} + \cdots + p^n\Theta_n = W_{p^n}(\Theta_0, \ldots, \Theta_n), \forall n
\]

In particular, \( \Theta_0 = e, \Theta_1 = \delta \).

Moreover, \( \mathbb{Z}[\Theta_0, \Theta_1, \ldots, \Theta_n] = \mathbb{Z}[e, \delta_1, \delta_2, \ldots, \delta_n] \) for any \( n \).

**Proof:** Use equation \( \varphi \circ \varphi^n = \varphi^n \circ \varphi \) and module \( p^n\mathbb{Z}[\Theta_0, \Theta_1, \ldots, \Theta_n] \).

\( \square \)

**Prop. (4.5.4.8)**[Witt Vectors as \( \delta \)-Rings]. By (4.5.4.7), there is an isomorphism of algebras

\[
\Delta_p \cong \mathbb{Z}[\delta] : X_{p^n} \mapsto \Theta_n,
\]

but it is also an isomorphism of ring schemes because of the uniqueness property of (4.5.3.3).

Then for any \( A \in \mathcal{C} \text{Alg} \), every element of \( W_p(A) \) has a \( \delta \)-coordinates:

\[
f \in W_p(A) = \text{Hom}(\Delta_p, A) \mapsto (f(e), f(\delta_1), f(\delta_2), \ldots)_{\delta}.
\]

Let \( W_p(A) \) be defined as in (4.5.3.5), then \( [\delta] : \mathbb{Z}[\delta] \to \mathbb{Z}[\delta] \) induces a homomorphism \( \delta : W_p(A) \to W_p(A) \) that can be checked to be a \( \delta \)-functor from our definition of coalgebra structure on \( \mathbb{Z}[\delta] \).

Thus \( W_p \) is a functor \( \mathcal{C} \text{Alg} \to \mathcal{C} \text{Alg}^{\delta} \).

**Prop. (4.5.4.9)**[Witt Vectors as an Right Adjoins]. \( W_p \) is right adjoint to the forgetful functor \( \mathcal{C} \text{Alg}^{\delta} \to \mathcal{C} \text{Alg} \).

**Proof:** Given a ring homomorphism \( f : B \to A \), let

\[
f^\delta : B \to W_p(A) : x \mapsto (f(x), f(\delta(x)), f(\delta^2(x)), \ldots)_{\delta},
\]

Then \( f^\delta \) is a \( \delta \)-ring homomorphism: It is a homomorphism by our definition of the ring structure on \( \text{Spec} \, \mathbb{Z}[\delta] \) (4.5.4.6), and it is a \( \delta \)-ring homomorphism by our definition \( \delta \)-ring structure (4.5.4.8).

And it is easy to see \( f^\delta \) is the unique \( \delta \)-ring homomorphism \( B \to W(A) \) that restricts to \( f : B \to A \), thus

\[
\text{Hom}^\delta(B, W(A)) \cong \text{Hom}(B, A).
\]

\( \square \)
Prop. (4.5.4.10) [Free δ-Rings]. The ring \( \mathbb{Z}\{x_i\} \) is a ring on the free generators \( \{x, \delta(x), \delta^2(x), \ldots\} \) and the Frobenius morphism defined by asserting \( \varphi(\delta^i(x)) = \delta^i(x)p + p\delta^{i+1}(x) \).

Generally we can define the free δ-ring generated by \( \{x_i\} \) over a δ-ring \( A \) as the tensor \( A \otimes \mathbb{Z}\{x_i\} \), and it satisfies the universal property.

Then the Frobenius action is f.f.

Proof: It is easily verified that for any δ-ring \( R \) over \( A \) and a map of sets \( \{x_i\} \to R \), there is a unique morphism \( \mathbb{Z}\{p\}\{x_i\} \to R \) sending \( x \) to \( f \), thus verifying the universal property.

For the f.f., notice it is a colimit of \( \mathbb{Z}[x, \delta(x), \delta(x) \ldots, \delta(x)^n(x)] \to \mathbb{Z}[x, \delta(x), \delta(x) \ldots, \delta(x)^{n+1}(x)] \), so by (4.4.1.25), it suffices to show \( \varphi_n \) are all f.f.. We decompose this map as \( n \) maps:

\[
\mathbb{Z}[x, \delta(x), \ldots, \delta^n(x)] \cong \mathbb{Z}[x, \delta(x), \ldots, (\delta^i(x)p, \ldots, \delta^n(x)) \subset \mathbb{Z}[x, \delta(x), \ldots, \delta^n(x)]
\]

which are all f.f., so it is f.f. \( \square \)

Cor. (4.5.4.11) [Frobenius is Fpqc locally Surjective]. For a δ-ring \( A \) and an element \( x \in A \), there is a faithfully flat morphism of δ-rings \( A \to B \) that the image of \( x \) in \( B \) is of the form \( \varphi(y) \) for some \( y \in B \).

Cor. (4.5.4.12). Set \( B \) as the pushout of the diagram \( \mathbb{Z}\{p\}\{s\} \leftarrow \mathbb{Z}\{p\}\{t\} \to A \), where the arrows sends \( t \) to \( \varphi(s) \) and \( x \). \( B \) exists by (4.5.4.13) and the underlying ring is the same as the ring pushout, thus \( A \to B \) is faithfully flat by (4.5.4.10).

Prop. (4.5.4.13) [Limits and Colimits of δ-Rings]. \( \mathcal{C}\text{Alg}_\delta^\delta \) admits limits and colimits, and their underlying rings are just the ring-theoretical limit and colimit, as the forgetful functor \( \mathcal{C}\text{Alg}_\delta \to \mathcal{C}\text{Alg} \) has both left and right adjoints (4.5.4.9)(4.5.4.10).

Proof: Use (4.5.4.3), the construction of limits is straightforward, as \( W_2 \) commutes with limits.

To construct colimits, notice the morphisms \( A_i \to W_2(A_i) \) induces a morphism

\[
\lim A_i \to \lim W_2(A_i) \to W_2(\lim A_i)
\]

and clearly this map is a section of \( W_2(\lim A_i) \to \lim A_i \), thus given a δ-ring structure on \( \lim A_i \).

It is a colimit because any commutative diagrams \( \varphi_i : (A_i \to W_2(A_i)) \to (B \to W_2(B)) \) induces a unique commutative diagram

\[
\begin{array}{ccc}
\lim A_i & \xrightarrow{\varphi_i} & W_2(A_i) \\
\downarrow & & \downarrow \varphi_i \\
B & \xrightarrow{W_2(\varphi_i)} & W_2(B)
\end{array}
\]

Extension of δ-Structures

Lemma (4.5.4.14) [Quotients]. Let \( A \) be a δ-ring and \( I \) be an ideal, then if \( I \) is stable under δ, then there is a natural δ-structure on \( A/I \) compatible with \( A \). In general, if \( J \) is an ideal of \( A \), then there is a universal δ-A-algebra \( B = A/J \), where \( J = \cup_{n \geq 0} \delta^n(I) \). It is the universal δ-A-algebra that the image of \( I \) is 0.
Lemma (4.5.4.15) [Localization]. Let $A$ be a $\delta$-ring and $S$ be a multiplicative set of $A$ that $\varphi(S) \in S$, then there is a unique $\delta$-structure on $S^{-1}A$, and it satisfies the universal property.

Proof: Firstly if $A$ is $p$-torsionfree, in this case a $\delta$-structure is the same as a lifting of the Frobenius on $A/p$, thus the proposition is clear because $\varphi_{S^{-1}A} : S^{-1}A \to S^{-1}A$ is uniquely determined.

Generally, we choose a free $\delta$-ring $F$ and a surjection $\alpha : F \to A$, then $T = \alpha^{-1}S$ is multiplicative, and $T^{-1}F$ admits a unique $\delta$-structure. But now $S^{-1}A = T^{-1}F \otimes_F A$, so there is a $\delta$-structure on $S^{-1}A$ as the colimit, so compatible with that of $S^{-1}A$. Then it’s also the unique one (because if there is another one, the colimit properties gives a morphism of $\delta$-rings above $\text{id}_{S^{-1}A}$, which must by identity).

Lemma (4.5.4.16) [$p$-adic Localization]. If $A$ is a $\delta$-ring with $p \in \text{rad}(A)$, then the formula $\varphi(f) = f^p + p\delta(f)$ shows if $f$ is a unit, then $\varphi(f)$ is also a unit (2.4.2.2), so $S^{-1}A = T^{-1}A$, where $T = \{S, \varphi(S), \varphi^2(S), \ldots\}$.

Thus for any $\delta$-ring $A$ and a multiplicative set $S$, the $p$-localization (4.1.1.31) $(S^{-1}A)(p)$ is the same as the $p$-localization of $T^{-1}A$. Then (4.5.4.15) shows that $(S^{-1}A)(p)$ carries a unique $\delta$-structure compatible with that of $A$.

Lemma (4.5.4.17) [Completions]. For a $\delta$-ring $A$ and a f.g. ideal $I$, the $I$-adic completion of $A$ has a unique $\delta$-structure compatible with that of $A$.

Proof: Let $A \to W_2(A)$ corresponds to the $\delta$-structure by (4.5.4.3), then there is a natural map $A \to W_2(A) \to W_2(A)$, then by the universal property of complete, it extends to a map $\hat{A} \to W_2(A)$, which is a ring map and is a section, all by universal properties.

Lemma (4.5.4.18) [Derived Completion]. If $A$ is a $\delta$-ring and $I \subset A$ is an ideal containing $p$, then the derived $I$-completion ring $\hat{A}$ of $A$ admits a unique $\delta$-structure extending that of $A$.

Proof: The proof is similar as (4.5.4.17).

Prop. (4.5.4.19) [Étale Extension]. Let $A$ be a $\delta$-ring with a f.g. ideal $I$ containing $p$. Assume $B$ is a derived $I$-complete and $I$-completely étale $A$-algebra, then $B$ admits a unique $\delta$-structure compatible with that of $A$.

In particular, any $\delta$-structure on an algebra $A$ passes uniquely to its derived $I$-completion for any ideal $I \subset A$ containing $p$.

Proof: By Elkik’s algebraization (4.6.7.9), we can write $B$ as derived $I$-completion of some étale $A$-algebra $B'$. Then $W_2(A) \to W_2(B')$ is étale by van der Kallen’s theorem (4.5.3.26). Then $W_2(B)$ is the derived $I$-completion of $W_2(B')$, with the $A$-algebra structure given by $A \to W_2(A) \to W_2(B')$. For the rest, Cf. [Scholze, Prism, 2.18].

Distinguished Elements

Def. (4.5.4.20) [Distinguished Elements]. In a $\delta$-ring $A$, an element $d$ is called a distinguished element if $\delta(d)$ is a unit in $A$. A distinguished element is preserved by a $\delta$-ring map.

Lemma (4.5.4.21) [Distinguished up to units]. If $A$ is a $\delta$-ring, $d$ is distinguished and $u$ is a unit, then $ud$ is also distinguished, if $d, p \in \text{rad}(A)$.

Proof: $\delta(ud) = u^p\delta(d) + d^p\delta(u) + p\delta(u)\delta(d)$ is a unit.
Lemma (4.5.4.22) [Irreducibility of Distinguished Elements]. Let $A$ be a $\delta$-ring and $d$ be distinguished element in $A$. If $d = fh$ for some $f, h \in A$ that $f, p \in \text{rad}(A)$, then $f$ is also distinguished and $h$ is a unit.

Proof: Notice that $\delta(d) = f^p\delta(h) + h^p\delta(f) + p\delta(f)\delta(h)$, $\delta(d)$ is a unit, $f^p\delta(h) + p\delta(f)\delta(h) \in \text{rad}(A)$, thus $h^p\delta(f)$ is a unit, so we are done. $\square$

Prop. (4.5.4.23) [Characterization of Distinguished Elements]. Fix a $\delta$-ring $A$ and an element $d$ that $d, p \in \text{rad}(A)$, then $d$ is distinguished iff $p \in (d, \varphi(d))$. In particular, distinguished elements is stable under units.

Proof: If $d$ is distinguished, then $\delta(d)$ is a unit, thus $\varphi(d) = d^p + d^p + p\delta(d)$ shows immediately $p \in (d, \varphi(d))$. Conversely, if $p = ad + b\varphi(d)$, we show $\delta(d)$ is invertible. It suffices to show it is invertible modulo $(d, p)$ as $d, p \in \text{rad}(A)$, or equivalently $(p, d, \varphi(d)) = A$. If it is not the case, then we may take a $(p, d, \varphi(d))$-adic completion to assume $p, d, \varphi \in \text{rad}(A)$, thus the equation simplifies to $p(1 - b\delta(d)) = cd$. The left side is distinguished, by (4.5.4.21), and then $d$ is also distinguished, by (4.5.4.22), so truly $(p, d, \varphi(d)) = A$. $\square$

Prop. (4.5.4.24) [Examples of Distinguished Elements]. The element $d$ is distinguished in the following cases:

- (Crystalline cohomology) Take $A = \mathbb{Z}_{(p)}$ and $d = p$, then $\delta(p) = 1 - p^{p-1}$ is a unit.
- (q-de Rham cohomology) Take $A = \mathbb{Z}_p[[q - 1]]$ and $d = [p]_q = \sum_{i=0}^{p-1} q^i \in A$, with the $\delta$-structure determined by $\varphi(q) = q^p$.
- (Breuil-Kisin cohomology) Fix a discretely valued field $K/Q_p$ with uniformizer $\pi$, $W$ the maximal unramified subring of $O_K$. Take $A = W[[u]]$ with $\delta(u) = u^p$, then any generator of the kernel of the map of $A \to O_K : u \to \pi$ is distinguished.
- (Ainf-cohomology) Let $A$ be the $(p, q - 1)$-completion of $\mathbb{Z}_p[1/p^\infty]$. Then $A$ is $p$-torsion free and $\varphi(q) = q^p$ gives a $\delta$-structure. Then $d = [p]_q$ defined in item2 is also distinguished. And $\varphi^n(d)$ is distinguished for any $n \in \mathbb{Z}$ by (4.5.4.5).

Proof: It is clear $\varphi$ is continuous and $\delta$ stabilizes $(q - 1)$, and $d$ is distinguished because the image of $\delta(d)$ in $A/(q - 1) \cong \mathbb{Z}_q$ is $\delta(p) = 1 - p^{p-1}$ is a unit, thus it is also a unit in $A$. $\square$

Perfect $\delta$-Ring

Def. (4.5.4.25) [Perfect $\delta$-Ring]. A perfect $\delta$-ring is a $\delta$-ring that $\varphi$ is an isomorphism.

Prop. (4.5.4.26) [Perfections]. The inclusion of the category of perfect $\delta$-rings to the category of $\delta$-rings admits left and right adjoints, $A_{\text{perf}}$ and $A_{\text{perf}}^\text{perf}$ with definition similar to (4.5.1.10).

Proof: We use (4.5.4.3), the map $A \to W_2(A) \to W_2(A_{\text{perf}})$ extends uniquely to a map $A_{\text{perf}} \to W_2(A_{\text{perf}})$ lifting the $\delta$-action of $A$. Similarly, because $(-)^{\text{perf}}$ is a limit and $W_2(-)$ is a right adjoint, then $W_2(-)$ commutes with $(-)^{\text{perf}}$. In particular, there is a natural map $A_{\text{perf}} \to W_2(A_{\text{perf}})$. $\square$

Lemma (4.5.4.27) [Frobenius Kills $p$-Torsion]. If $A$ is a $\delta$-ring and $x \in A$ satisfies $px = 0$, then $\varphi(x) = 0$. In particular, if $A$ is perfect, then $A$ is $p$-torsionfree.

Proof: Applying $\delta$ to $px = 0$, we have $0 = p^\delta(x) + x^p\delta(p) + p\delta(x)\delta(p) = p^\delta(x) + \varphi(x)\delta(p)$. As $\delta(p)$ is a unit, and $p^\delta(x) = p^{p-1}(\varphi(x) - x^p) = \varphi(x)(p^{p-1}x) - p^{p-1}x^p = 0$, thus $\varphi(x) = 0$. $\square$
Prop. (4.5.4.28) [Perfect $p$-Complete $\delta$-Rings]. The following categories are equivalent:

- The category of perfect $p$-adically complete $\delta$-rings.
- The category $p$-adically complete and $p$-torsionfree rings $A$ with $A/p$ perfect.
- The perfect $F_p$-algebras.

In particular, every perfect $p$-complete $\delta$-ring is of the form $W(k)$ thus has Teichmuller expansions.

**Proof:** 2 and 3 are equivalent by Witt vector construction, by (8.2.4.3), noticing that there is a natural lifting on $W(k)$ lifting the Frobenius of $k/F_p$ that induces a $\delta$-functor. There is a forgetful functor from 1 to 2, by (4.5.4.27) (notice $A/p$ is also perfect because if $\varphi(x) \in (p)$, then $x \in \varphi^{-1}(p) = (p)$ as $\varphi(p) = p\varphi(1) = p$) and it is faithful. Now there is an equivalence from $3 \to 1 \to 2$, thus $1 \to 2$ is essentially surjective thus is an equivalence.

Prop. (4.5.4.29) [Perfect Element has Rank 1]. Fix a $\delta$-ring $A$ and an element $x \in A$, then $\delta(x^n) \in p^nA$ for any $n$. In particular, if $A$ is $p$-adically separated and $y$ is perfect in $A$, then $\delta(y) = 0$.

**Proof:** By formal calculation, it suffices to show that $p\delta(x^n) \equiv x^{pn+1} \mod p^{n+1}A$, which is true by (20.1.2.8).

Prop. (4.5.4.30) [Distinguished Element in Perfect $\delta$-Rings]. Let $A$ be a perfect $p$-complete $\delta$-ring (or perfect $F_p$-algebra by (4.5.4.28)), and $d \in A$, then $d$ is distinguished iff its coefficient of $p$ in the Teichmuller expansion (4.5.4.28) is a unit.

If $d$ is distinguished, then it is a nonzero-divisor, and $A/d[p^\infty] = A/d[p]$.

**Proof:** Let $d = \sum_{i \geq 0} [a_i]p^i$, then

$$\delta(d) = \frac{1}{p} \left( \sum_{i \geq 0} [a_i]p^i \right) \equiv [a_1] \mod pA$$

thus it is a unit iff $a_1$ is a unit, because $A$ is $p$-complete.

Now if $d$ is distinguished, and $fd = 0$. If $f \neq 0$, we may assume $p \nmid f$, because $A$ is $p$-torsionfree and $p$-adically complete (4.5.4.28). Now

$$\varphi(f)\delta(fd) = \varphi(f)(f^p\delta(d) + \delta(f)\varphi(d)) = \varphi(f)f^p\delta(d) = 0,$$

so $f^p\varphi(f) = 0$, and $f^{2p} \equiv 0 \mod p$. Hence $f \equiv 0 \mod p$, but then $p|f$, contradiction.

For the last assertion, it suffices to show that $A/d[p^2] = A/d[p]$. If $p^2f = dg$, then $\varphi(g)\delta(gd) = \varphi(g)(\delta(d)g^p + \varphi(d)\delta(g)) = \varphi(g)\delta(d)g^p + \varphi(dg)\delta(g) \in pA$, thus $\varphi(g)g^p \in pA$, hence $g^{2p} \in pA$, and hence $g \in pA$, showing $pf \in dA$. 

\[\square\]
4.6 Derived Commutative Algebras

Main references are [Sta].

[Sta] Chap15 contains many beautiful results working on the derived category of rings, and is used heavily in Scholze’s Thesis.

The basic construction of $R\text{tensor}$ and $R\text{Hom}$ should be redone at the level of ringed sites, Cf.[Sta] Chap21.

1 Basics

Prop.(4.6.1.1)[Product in $D(R)$]. Let $R$ be a ring and $K_n \in D(R)$, then the product in $D(R)$ of $K_n$ is given by $\prod I_n$, where $I_n$ are $K$-injective resolutions of $K_n$.

Proof: This is immediate from (3.4.3.7). □

Def.(4.6.1.2)[Homotopy Fiber Square]. A square of Abelian groups is called a homotopy fiber square if it is a homotopy fiber square in the derived category, or equivalently, the kernel of the two rows(or the two columns) are isomorphic.

This notion is identical to the notion of pullback square when the rows or the columns are surjective.?

Prop.(4.6.1.3)[Bockstein Differential]. Let $I$ be an invertible ideal of $A$, for any $M^\bullet \in D(A)$, we use the Breuil-Kisin Twist notation (6.7.5.1) and consider the exact triangle

$$M^\bullet \otimes^L _A A/I\{i+1\} \to M^\bullet \otimes^L _A I^i/I^{i+2} \to M^\bullet \otimes^L _A A/I\{i\}$$

obtained from the exact triangle

$$I^{n+1}/I^{n+2} \to I^n/I^{n+2} \to I^n/I^{n+1}$$

tensoring $\mathcal{O}_\Delta$. Then we get a Bockstein differential

$$\beta^n : H^n(M^\bullet \otimes^L _A A/I\{n\}) \to H^{n+1}(M^\bullet \otimes^L _A A/I\{n+1\})$$

Then these maps satisfy $\beta^{n+1} \circ \beta^n = 0$.

Proof: Consider the morphism of distinguished triangles:

$$\begin{array}{ccc}
I^{n+1}/I^{n+3} & \to & I^n/I^{n+3} \\
\downarrow & & \downarrow \\
I^{n+1}/I^{n+2} & \to & I^n/I^{n+2}
\end{array}$$

then we see for any $M^\bullet \in D(A)$, $\beta^n$ factors as

$$H^n(M^\bullet \otimes^L _A I^n/I^{n+1}) \to H^{n+1}(M^\bullet \otimes^L _A I^{n+1}/I^{n+3}) \to H^{n+1}(M^\bullet \otimes^L _A I^{n+1}/I^{n+2})$$

and also we consider the distinguished triangle

$$I^{n+2}/I^{n+3} \to I^{n+1}/I^{n+3} \to I^{n+1}/I^{n+2}$$

to see that the composition

$$H^{n+1}(M^\bullet \otimes^L _A I^{n+1}/I^{n+3}) \to H^{n+1}(M^\bullet \otimes^L _A I^{n+1}/I^{n+2}) \xrightarrow{\beta^{n+1}} H^{n+2}(M^\bullet \otimes^L _A I^{n+2}/I^{n+3})$$

is 0, and this two observation gives the result. □

**4.6. DERIVED COMMUTATIVE ALGEBRAS**

**Injective Amplitude**

**Prop.(4.6.1.4)[Injective Amplitude].** For $K \in D(A)$, the following are equivalent:

- $K$ has finite amplitude in $[a, b]$.
- $\text{Ext}^i(N, K) = 0$ for any $N \in D^0(A)$ and $i \notin [a, b]$.
- $\text{Ext}^i(A/I, K) = 0$ for any ideal $I$ of $A$.

**Proof:** $1 \to 2 \to 3$ is clear. For $3 \to 1$: Notice $\text{Ext}^n(A, K) = H^n(K), H^i(K) = 0$ for any $i \notin [a, b]$. Then $K$ is represented by a complex

$$0 \to I^a \to I^a \to I^a+1 \to \ldots \to I^b \to \ldots.$$  

Let $J = \text{ker}(I^b \to I^{b+1})$, then $K$ is also represented by

$$0 \to I^a \to I^a \to I^a+1 \to \ldots \to I^b \to J \to 0.$$  

Let $K' = (I^a \to \ldots \to I^b) \in D(A)$, then there is an distinguished triangle

$$J[-b] \to K \to K' \to J[1-b],$$

which induces an exact sequence $\text{Ext}^b(R/I, K') \to \text{Ext}^1(R/I, J) \to \text{Ext}^{b+1}(R/I, K)$ for any ideal $I \subset A$. Then by $1 \to 2$, $\text{Ext}^1(R/I, J) = 0$, implying $J$ is injective. $\square$

**Prop.(4.6.1.5)[Dedekind Domain].** Let $R$ be a Dedekind domain, then every ideal $I$ is finite torsion-free thus projective over $R$, so every $R$-module has injective dimension $\leq 1$. In particular, $\text{Ext}^i(M, N) = 0$ for any $i \geq 2$ and $M, N \in \text{Mod}_R$. In particular, by (3.4.4.26), any $K \in D^+(R)$ is isomorphic to a direct sum of their cohomology groups.

**Prop.(4.6.1.6).** Let $(R, m, k)$ be a Noetherian local ring and $K \in D^+(R)$ have finite cohomology modules, then $K$ has finite injective dimension iff $\text{Ext}^i_R(k, K) = 0$ for $i$ large.

**Proof:** Cf.[Sta]0AVJ. $\square$

**2 Derived Tensor and Tor**

**Prop.(4.6.2.1)[Differential Graded Structure].** If $K$ is a commutative $A$-algebra object in $D(A)$ in the monoidal structure defined in (5.3.3.8), then $\oplus_{n \geq 0} H^n(K^\bullet)$ carries a natural graded commutative $A$-algebra structure.

**Proof:** Compare with (8.1.2.4).

We may replace $K$ by a $K$-flat resolutions $L^1(5.3.3.3)$ that the algebra structure map for $K$ is represented by a morphism $L^1_1 \otimes_A L^1_1 \to L^2$ of complexes where $L^2$ is a complex quasi-isomorphic to $K$, hence the graded $A$-algebra structure is clear by (3.3.6.2), and it is commutative by (3.3.6.1). (How to check the structure is uniquely determined?). $\square$

**Tor**

**Def.(4.6.2.2)[Tor].** Let $M, N$ be $A$-module, then the torsion group $\text{Tor}^A_i(M, N)$ is defined to be $H^i(M \otimes_A L N)$, compatible with the definition in (5.3.3.11).
Def.(4.6.2.3) [Torsion Group]. Let \( A \) be a commutative ring, \( B \) an \( A \)-algebra and \( I \) be an ideal, then the \( I \)-torsion of \( B \) is defined to be \( \text{Tor}_I^1(A/I, B) \), denoted by \( B[I] \). In case \( I = (f) \), it can be checked that \( B[f] \) is the set of elements of \( B \) that killed by \( f \).

Also we denote \( B[I^n] = \text{colim}_{n \to \infty} B[I^n] \). And \( B \) is said to have bounded \( f \)-torsion iff \( B[f^n] = B[f^n] \) for some \( n \).

Prop.(4.6.2.4). If \( A \) is a commutative ring with bounded \( I \)-torsions and \( B \) is a flat \( A \)-module, then \( B \) also has bounded \( I \)-torsions. (Because tensoring \( B \) is exact).

Prop.(4.6.2.5) [Balancing Tor]. In the category of rings, \( \text{Tor}_n(A, B) = \text{Tor}_n(B, A) \). This can be seen using spectral sequence of the double complex of flat resolutions of \( A \) and \( B \). Similarly, we have two definitions of \( \text{Ext}^i(M, N) \) are compatible.

Proof:

Prop.(4.6.2.6) [Base Change]. For a ring extension \( R \to S \), using projective resolution and spectral sequence, there is a first quadrant homology spectral sequence:

\[
E^2_{pq} = \text{Tor}_p^S(\text{Tor}_q^R(A, S), B) \Rightarrow \text{Tor}_{p+q}^R(A, B).
\]

Similarly, for \( \text{Ext} \),

\[
E^2_{pq} = \text{Ext}_p^R(A, \text{Ext}_q^R(S, B)) \Rightarrow \text{Ext}_{p+q}^R(A, B).
\]

Prop.(4.6.2.7) [Universal Coefficient Theorem]. Let \( P \) be a free \( R \)-module so \( d(P_n) \) are all flat, then \( Z(P_n) \) are also flat and

\[
0 \to d(P_{n+1}) \to Z_n \to H_n \to 0
\]

is a free resolution. we have an exact sequence:

\[
0 \to H_n(P) \otimes_R M \to H_n(P \otimes_R M) \to \text{Tor}_1^R(H_{n-1}(P), M).
\]

and these exact sequences non-canonically split because \( Z_n \) is a direct summand of \( P_n \), thus \( Z_n \otimes M \) is a direct summand of \( P_n \otimes M \) and a fortiori \( Z_n(P_n \otimes M) \). so \( H_n(P) \otimes M \) is a direct summand of \( H_n(P \otimes_R M) \).

**Internal Hom and Derived Tensor**

Prop.(4.6.2.8). If \( R \) is a ring and \( K, L, M \in D(R) \), then

\[
R\text{Hom}_R(K, R\text{Hom}(L, M)) = R\text{Hom}_R(K \otimes^L_R L, M).
\]

Proof: This is a special case of(5.3.3.29).

Cor.(4.6.2.9).

\[
\text{Hom}_{D(R)}(K, R\text{Hom}(L, M)) = \text{Hom}_{D(R)}(K \otimes^L_R L, M),
\]

i.e., derived tensor is left adjoint to internal Hom.

Proof: This follows from taking \( H^0 \), by(3.4.4.18).

Prop.(4.6.2.10) [Derived Base Change Adjunction]. For a ring map \( R \to S \) and any \( L \subset D(R), M \subset D(S) \), there is an isomorphism

\[
\text{Hom}_R(L, M) \cong \text{Hom}_S(L \otimes^L_R S, M)
\]

Proof: This follows from(5.3.3.16).
3 Rlim

Def. (4.6.3.1) [Rlim]. Rlim is the derived limit (3.4.6.1) in $D(\text{Ab})$ restricted to the inverse systems consisting of discrete complexes.

Lemma (4.6.3.2). The set of Mittag-Leffler Complexes in $\text{Ab}(\mathbb{N})$ is adapted for $R\lim$.

Proof: Firstly, for any complex $(A_n)$, we can associate to it the complex $(B_n)$ where $B_n = A_n \oplus A_{n-1} \oplus \ldots \oplus A_1$, then $(B_n)$ is a Mittag-Leffler complex and $(A_n) \hookrightarrow (B_n)$. So ML complexes are sufficiently large.

Now for any exact sequence of complexes $0 \to (A_n) \to (B_n) \to (C_n) \to 0$, if $A_n$ is ML, then $\lim B_i \to \lim C_i$ is surjective: for an element $(c_i) \in \lim C_i$, let $E_i = \pi_i^{-1}(c_i) \in B_i$, then $(E_i)$ is an inverse system of nonempty sets, and it suffices to show $(E_i)$ is ML, because then (3.1.1.46) will show there is an element $(e_i) \in \lim E_i \subset \lim B_i$ that maps to $(c_i)$.

For this, Cf. [Sta]0598. □

Prop. (4.6.3.3) [Rlim].

- If $(A_n)$ is Mittag-Leffler, then $R^1\lim ((A_n)) = 0$.
- $R\lim ((A_n))$ is represented by the complex in degree 0,1:

$$\prod_n A_n \to \prod_n A_n : (x_n) \mapsto (x_n - f_{n+1}(x_{n+1}))$$

- for any $(A_n) \in \text{Ab}(\mathbb{N})$ we have $R^p \lim ((A_n)) = 0$ for $p > 1$.

Proof: 1 follows from (4.6.3.2) and (3.4.4.2).

2, 3: We use (3.4.4.2) again. Notice the complex $(B_n)$ where $B_n = A_n \oplus A_{n-1} \oplus \ldots \oplus A_1$ and the complex $(C_n)$ where $C_n = A_{n-1} \oplus A_{n-2} \oplus \ldots \oplus A_1$ form an exact sequence of complexes

$$0 \to (A_n) \to (B_n) \to (C_n) \to 0$$

where $B_n \to C_n : (x_i) \mapsto (x_i - f_{i+1}(x_{i+1}))$, and $(B_n), (C_n)$ are both ML, so we are done. □

4 Lifting Complexes

Prop. (4.6.4.1) [Lifting Projective Complex Along Thickening]. Let $R$ be a ring and $I$ be a nilpotent ideal, and $K \in D(R)$. Now if $K \otimes_R^L R/I$ is represented by a bounded above complex of projective $R/I$-modules, then there is a complex $P$ of bounded above complex of projective $R$-modules that $P \cong K \in D(R)$, and $P \otimes_R R/I \cong E$.

Proof: Cf. [[Sta]09AR]. □

5 Pseudo-Coherent and Perfect Modules

Def. (4.6.5.1) [Pseudo-Coherent Modules]. Let $R$ be a ring, $m \in \mathbb{Z}$, then $K \in D(R)$ is called an $m$-pseudo-coherent module iff there exists a complex $E^* \in K^b(R)$ and a morphism $\alpha : E^* \to K^*$ where $K^*$ represents $K$, s.t. $H^i(\alpha)$ is an isomorphism for $i > m$, and surjective for $i = m$.

$K \in D(R)$ is called a pseudo-coherent module if it is represented by a bounded above complex of finite free $R$-modules.
Prop.(4.6.5.2). If $A$ is Noetherian and $C^\bullet$ is a complex of $A$-modules bounded above that every cohomology group $H^i$ is a finite $A$-module, then there is a complex $L^\bullet$ of finite free $A$-modules, that $g : L^\bullet \to C^\bullet$ is a quasi-isomorphism.

Moreover, if $C^i$ are all flat $A$-modules, then $L^\bullet \otimes_A M \to C^\bullet \otimes_A M$ is quasi-isomorphism for every $M$.

Proof: $C^\bullet$ is bounded above so we choose $L^n = 0$, and use induction to construct $L^n$ that $H^i(L) \to H^i(C)$ is isomorphism for $i > n+1$ and surjection for $i = n+1$. For this, choose a generator $x_1, \ldots, x_r$ of $H^n(C)$ in $Z^n(C)$, and let $y_{r+1}, \ldots, y_s$ be a generator of $g^{-1}(B^{n+1}(C))$(Noetherian used), and let $g(y_i) = dx_i$ for $x_i \in C^n$.

Now let $L^n$ be freely generated by $e_1, \ldots, e_s$ and $de_i = 0$ for $i \leq r$ and $de_i = y_i$ for $i > r$, and let $g : L^n \to C^n$ be $ge_i = x_i$. Then it can be verified to be a quasi-isomorphism.

If $C^i$ are all flat, we check isomorphism for all f.g. modules $M$, because $\otimes$ and cohomology all commutes with direct limits. Use induction, for $n$ large, both are 0, and if we write $0 \to R \to F \to M \to 0$, for $F$ finite free, then there is a commutative diagram of long exact sequences, and for $F$, $H^i$ are obviously isomorphism, so I can use five lemma. □

Def.(4.6.5.3) [Perfect Complexes of Modules]. Let $R$ be a ring, then $K \in D(R)$ is called a perfect module if $K$ is quasi-isomorphic to a bounded complex of finite projective $R$-modules. An $R$-module $M$ is called perfect iff $M[0]$ is perfect.

Prop.(4.6.5.4) [Perfectness and Pseudo-Coherence]. An object $K \in D(R)$ is perfect iff it is pseudo-coherent and has finite Tor amplitude.

Proof: Cf.[Sta]0658. □

Prop.(4.6.5.5). If $R$ is a regular ring of finite dimension, then an object $K \in D(R)$ is perfect iff $K \in D^b(R)$ and each $H^i(K)$ is a finite $R$-module.

Proof: Cf.[Sta]066Z. □

Prop.(4.6.5.6) [Duality of Perfect Complexes]. Let $K$ be a perfect complex of $D(A)$, then the dual complex $K^\vee = R \text{Hom}(K,A)$ is also a perfect complex and $(K^\vee)^\vee \cong K$. Also, there is a functorial isomorphism

$$L \otimes^L_A K^\vee = R \text{Hom}_A(K,L)$$

Proof: Cf.[Sta]07VI. □

Prop.(4.6.5.7). If $A$ is a ring and $K_n$ is a system of perfect objects in $D(A)$, then for any $E \in D(A)$, there is an isomorphism

$$R \text{Hom}_A(\text{ho colim } K_n, E) \cong R \text{lim } E \otimes^L_A K_n$$

Proof: By(4.6.5.6), $R \text{lim } E \otimes^L_A K_n = R \text{lim } R \text{Hom}(K_n, E)$ which fits into a distinguished triangle

$$R \text{lim } R \text{Hom}(K_n, E) \to \prod \text{Hom}(K_n, E) \to \prod \text{Hom}(K_n, E)$$

. So it suffices to show that

$$\prod \text{Hom}(K_n, E) \cong R \text{Hom}_A(\oplus K_n, E).$$

This follows from Yoneda lemma and(5.3.3.28)(5.3.3.29). □
Prop. (4.6.5.8) [Perfectness and Thickening]. If $R$ is a ring, $I \subset R$ is a nilpotent ideal, and $K \in D(R)$. If $K \otimes_{R}^{} R/I$ is perfect in $D(R/I)$, then $K$ is perfect in $R$. Moreover, if $K \otimes_{R}^{} R/I = 0$, then $K = 0$.

Proof: Let $P^\bullet \cong K \otimes_{R}^{} R/I$ where $P$ is a complex of finite projective $R/I$-modules, then by (4.6.4.1) there is a complex of projective $R$-modules $P$ that $P/IP \cong P$. Then it follows from Nakayama that $P$ is bounded.

Pseudo-Coherent Modules

Def. (4.6.5.9) [Pseudo-Coherent Complexes of Modules]. Let $R \in \mathcal{C}_{\text{Alg}}$, $K \in D(R)$ is called an $m$-pseudo-coherent module if there exists a perfect object $E \in D(R)$ and a morphism $E \to K$ that induces isomorphisms on $H^i$ for $i > m$ and surjection on $H^m$.

$K \in D(R)$ is called a pseudo-coherent module if it is represented by a bounded above complex of finite free $R$-modules.

6 Derived Completeness

Cf. [Sta] Chap 15.90.

Def. (4.6.6.1). For a ring $A, f \in A$ and a complex $K \in D(A)$, we denote by $T(K, f)$ a derived limit of the system

$$\ldots \to K \xrightarrow{f} K \xrightarrow{f} K$$

Prop. (4.6.6.2) [Properties of $T(K, f)$]. For a ring $A, f \in A$ and $K \in D(A)$, the following are equivalent:

1. $T(K, f) = 0$.
2. $R\text{Hom}_A(A_f, K) = 0$.
3. $\text{Ext}^n_A(A_f, K) = 0$ for all $n$.
4. $\text{Hom}_{D(A)}(E, K) = 0$ for all $E \in D(A_f)$.
5. For any $p \in \mathbb{Z}$, $\text{Hom}_A(A_f, H^p(K)) = 0$ and $\text{Ext}^1_A(A_f, H^p(K)) = 0$.
6. For any $p \in \mathbb{Z}$, $T(H^p(K), f) = 0$.

Proof: 2, 3 is clearly equivalent.

4 $\to$ 3 is clear, and for 3 $\to$ 4: Let $I^\bullet$ be a complex representing $K$, then 3 says $\text{Hom}_A(A_f, I^\bullet)$ is acyclic, and $\text{Hom}_{D(A)}(E, K) = \text{Hom}_K(A_f)(E, \text{Hom}_A(A_f, I^\bullet))$. As $\text{Hom}_A(A_f, I^\bullet)$ is both acyclic and $K$-injective (3.3.6.6), we get it is homotopic to 0 by (3.4.3.1), thus we get 4.

1 $\iff$ 3: There is a free resolution of $A_f$ given by

$$0 \to \oplus_n A \to \oplus_n A \to A_f \to 0$$

where the first map is $(a_n) \mapsto (a_n - f a_{n-1})$, and the second map is $(a_n) \mapsto \sum a_i / f^i$. Applying $\text{Hom}_A(-, I^\bullet)$, we get a distinguished triangle

$$R\text{Hom}_A(A_f, K) \to \prod K \to \prod K.$$ 

So this shows $R\text{Hom}_A(A_f, K)$ is just $T(K, f)$, so we get 1 $\iff$ 3.
1 $\iff$ 5 $\iff$ 6: There is a spectral sequence convergence (choose a finite free resolution of $A_f$ then rotate and use (3.4.7.10)):

$$E_2^{p,q} = \text{Ext}_A^q(A_f, H^p(K)) \Rightarrow \text{Ext}_A^{p+q}(A_f, K)$$

This spectral sequence degenerates at $E_2$ because $A_f$ has a length 1 resolution by free $A$-modules hence the $E_2$ page has only 2 rows. So there is an exact sequence

$$0 \to \text{Ext}_A^1(A_f, H^{p-1}(K)) \to \text{Ext}_A^1(A_f, K) \to \text{Hom}_A(A_f, H^p(K)) \to 0.$$ 

Then we are done. $\square$

**Lemma (4.6.6.3).** Let $A$ be a ring, $K \in D(A)$, then the set $I$ of $f$ that $T(K, f) = 0$ is a radical ideal of $A$.

**Proof:** If $T(K, f) = 0$ and $g \in A$, then $A_{gf}$ is a $A_f$-module, then

$$\text{Ext}_A^n(A_{gf}, K) = \text{Hom}_{D(A)}(A_{gf}[-n], K)(5.3.3.32) = 0$$

by (4.6.6.2) item 4. Then $T(K, gf) = 0$ by (4.6.6.2) again. And if $f, g \in I$, there is an exact sequence

$$0 \to A_{f+g} \to A_{f(f+g)} \oplus A_{g(f+g)} \to A_{fg(f+g)} \to 0$$

by (4.4.2.3) and a easy check that the last term is surjective. Then from the long exact sequence of Ext, we get $\text{Ext}_A^n(A_{f+g}, K) = 0$ for any $n$. Finally if $f^n \in I$, then $f \in I$, because $A_f = A_{f^n}$. $\square$

**Def. (4.6.6.4) [Derived Completeness].** Let $A$ be a ring, $K \in D(A)$, $I$ is an ideal of $A$, then $K$ is said to be derived complete w.r.t $I$ if $T(K, f) = 0$ for any $f \in A$. Let $D_{\text{comp}}(A, I)$ denote the subcategory consisting of derived $I$-complete objects in $D(A)$.

Let $M$ be an $A$-module, then $M$ is called derived complete w.r.t $I$ if $M[0] \in D(A)$ is derived complete w.r.t $I$.

**Prop. (4.6.6.5).** A $\aleph_0$-filtered colimit of derived $I$-complete rings is also derived $I$-complete.

**Proof:** Cf. [Bhatt, Prism, 5.4.3]. $\square$

**Prop. (4.6.6.6) [Complete and Derived Complete].** Let $A$ be a ring and $I$ be an ideal, $M$ an $A$-module, then

- If $M$ is $I$-adically complete, then $T(M, f) = 0$ for any $f \in I$.
- If $T(M, f) = 0$ for all $f \in I$ and $I$ is f.g., then $M \to \lim M/I^n M$ is surjective.

In particular, if $I$ is f.g., $M$ is $I$-adically complete iff $M$ is derived $I$-adically complete and $\cap I^n M = 0$.

In particular, when $M$ is f.g., over a Noetherian and $I \subset \text{rad}(A)$, derived $I$-complete is equivalent to $I$-complete (4.2.2.14).

**Proof:** If $M$ is $I$-adically complete, by (4.6.6.2), it suffices to show that $\text{Hom}(A_f, M) = 0$ and $\text{Ext}_A^1(A_f, M) = 0$. But $M = \lim M/I^n M$, and $\text{Hom}(A_f, M/I^n M) = 0$, because $f \in I$. For Ext, use (3.4.4.24), for any extension

$$0 \to M \to E \to A_f \to 0,$$

chose arbitrary $e_n$ that maps to $1/f^n$. Then $\delta_n = fe_{n+1} - e_n \in M$. We consider

$$e'_n = e_n + \delta_n + f\delta_{n+1} + f^2\delta_{n+2} + \ldots.$$
which exist because $M$ is $I$-adically complete. Then $f e_{n+1}' = e_n'$, so this gives a splitting of the extension.

Conversely, if $I = (f_1, \ldots, f_r)$ and $T(M, f_i) = 0$ for any $i$, then by (4.2.3.16), we can assume $I = (f)$. Then consider the extension

$$0 \to M \to E \to A_f \to 0$$

where $E = (M \oplus \bigoplus A e_n)/(x_n - f e_{n+1} + e_n) \to A_f$ that maps $M$ to $0$ and $e_n$ to $1/f^n$. This extension splits by (4.6.6.2) and (3.4.4.24), thus there is an element $x + e_0$ that generate a copy of $A_f$ in $E$.

But then $x + e_0 = x - x_0 + f e_1 = x - x_0 - f x_1 + f^2 e_2 - \ldots - f^{n-1}x_{n-1} \in f^n E + A_f$ for any $n$. Then $x - x_0 - f x_1 + f^2 x_2 - \ldots - f^{n-1}x_{n-1} \in f^n M$, because $E = M \oplus A_f$. Then we are done.

**Prop. (4.6.6.7)**. If $M = D(A/I) \subset D(A)$, then $M$ is derived-$I$-complete. (This follows from the definition of $T(M, f)$).

**Prop. (4.6.6.8)** [Category of Derived Complete Modules]. Let $I$ be an ideal of $A$, then the derived $I$-complete $A$-modules form a weak Serre subcategory of $\text{Mod}_A$. In particular, $D_{comp}(A, I)$ is also a weak Serre subcategory.

**Proof**: If $f : M \to N$ is a map of derived $I$-complete $A$-modules, then we consider the complex $K = (M \to N)$, then there is an exact sequence $0 \to M[1] \to K \to N \to 0$, so we have $\text{Ext}^n(A_f, K) = 0$ for any $f \in I$, $n \in \mathbb{Z}$ because $M, N$ does (4.6.6.2), so $K$ is derived $I$-complete by (4.6.6.2) again. Then we have $\ker(f), \text{Coker}(f)$ are derived $I$-complete, by (4.6.6.2) again. Extension is also clear.

**Lemma (4.6.6.9)**. If $R$ is ring, $I$ is an ideal, and $K \in D(R)$ that $K \otimes_R^L R/I = 0$, then $K \otimes_R^L M$ for any $M \in D^b(R)$ with all the cohomology groups $I$-power torsions.

**Proof**: We use the truncation (3.3.3.6), then it suffices to prove for $M$ discrete. Now $M = \bigcup M[I^n]$, and we have $K \otimes_R^L M = \text{ho} \lim \colim K \otimes_R^L M[I^n]$, so we may assume $I^n M = 0$ for some $n$. Consider the $R$-algebra $R' = R/I^n \oplus M$, where $M^2 = 0$, then it suffices to show $K' = K \otimes_R^L R' = 0$. Now $0 = K \otimes_R^L R/I = K' \otimes_R^L R/I$, so by (4.6.6.8) $K' = 0$.

**Prop. (4.6.6.10)** [Derived Nakayama]. the derived tensor product $- \otimes_A^L A/I$ reflects isomorphism on $D_{comp}(A, I)$, i.e. if $M \otimes_A^L A/I = 0$, then $M = 0$.

**Proof**: Let $I = (f_1, \ldots, f_r)$, by (4.6.6.9), $M \otimes_A^L K_n = 0$ for any $K_n = K \otimes_A^L f_1^n, \ldots, f_r^n$, so $K = R \text{lim} K \otimes_A^L K_n = 0$.

**Cor. (4.6.6.11)**. If $I$ is f.g. and $M$ is a derived $I$-complete $A$-module that $M/IM = 0$, then $M = 0$.

**Proof**: ? This should be an immediate corollary.

Let $I = (f_1, \ldots, f_r)$, if $M \neq 0$, let $i$ be the largest integer that $M/(f_1, \ldots, f_i)M \neq 0$, then $N$ is also derived $I$-complete by (4.6.6.8). But $f_{i+1} : N \to N$ is surjective, so $T(N, f_{i+1}) \neq 0$, contradiction.

**Prop. (4.6.6.12)**. If $A$ is derived $I$-complete, then $(A, I)$ is a Henselian pair.

**Proof**: Cf. [Sta]0G3H?.
Prop. (4.6.6.13) [Derived I-Completion]. If \( I = (f_1, \ldots, f_n) \) is f.g. in \( A \), the inclusion of categories \( D_{\text{comp}}(A, I) \subset D(A) \) has a left adjoint, which maps \( K \) to

\[
\hat{K} = R\text{Hom}\left((A \to \prod_{i_0} A_{f_{i_0}} \to \prod_{i_0 < i_1} A_{f_{i_0}f_{i_1}} \to \cdots \to A_{f_1 \ldots f_r}), K\right).
\]

called the derived I-completion of \( K \).

Moreover, this construction is identical to \( K \mapsto K^{\bullet} = R\lim (K \otimes_A K^{\bullet}_n) \), by (4.6.5.7) and (4.4.4.7).

**Proof:** There is a map \( (A \to \prod_{i_0} A_{f_{i_0}} \to \prod_{i_0 < i_1} A_{f_{i_0}f_{i_1}} \to \cdots \to A_{f_1 \ldots f_r}) \to A \), which induces a morphism \( K \to \hat{K} \). Now by (5.3.3.28), \( R\text{Hom}(A_f, \hat{K}) \) is isomorphic to \( R\text{Hom}((A_f \to \prod_{i_0} A_{ff_{i_0}} \to \prod_{i_0 < i_1} A_{ff_{i_0}f_{i_1}} \to \cdots \to A_{ff_1 \ldots f_r}), K) \) as \( A_f \) is \( A \)-flat. Now this one is 0 for any \( f \in I \), by (4.4.4.7), so \( \hat{K} \) is derived I-complete.

Conversely, if \( \hat{K} \) is derived I-complete, then \( R\text{Hom}(A_f, K) = 0 \) for any \( f \in I \), thus \( K \to \hat{K} \) is an isomorphism is we inductively use the stupid truncation (3.3.3.6). \( \square \)

Cor. (4.6.6.14). If \( M \) is an \( A \)-module, then \( H^0(\hat{M}) \) is the derived-I-completion in the category of modules, by (3.4.2.12).

Cor. (4.6.6.15). (4.6.6.2) show the notion of derived I-complete and derived I-completion only depends on \( \text{rad} I \).

**Principal Ideal Case**

Prop. (4.6.6.16) [Bounded Torsion and Derived Completion]. Let \( A \) be a commutative ring and \( f \in A \). If \( M \) is an \( A \)-module that has bounded \( f^\infty \)-torsion, then the derived \( f \)-completion of \( M \) as a complex is a module and coincides with the classical \( f \)-adic completion.

**Proof:** The derived \( f \)-completion is defined to be

\[
\hat{M} = R\lim_n (M \otimes_{\mathbb{Z}[X]} \mathbb{Z}[X]/(x^n)) = R\lim_n (M \xrightarrow{f^n} M).
\]

So by (3.4.6.5), there are exact sequences

\[
R^1\lim_n M/f^n M \cong H^1(\hat{M})
\]

\[
0 \to R^1\lim_n M[f^n] \to H^0(\hat{M}) \to \lim_n M/f^n \to 0
\]

\[
H^{-1}(\hat{M}) \cong \lim_n M[f^n]
\]

Now the hypothesis implies that \( (M[f^n]) \) is Mittag-Leffler and \( \lim_n M[f^n] = 0 \), so we have the desired result. \( \square \)

Cor. (4.6.6.17). Let \( R \) be a perfect \( \mathbb{F}_p \)-algebra, then the derived \( p \)-completion and \( p \)-adic completion of \( R \) coincide.
7 Derived Completely Properties

Def. (4.6.7.1) [Derived Completely Properties]. Let $A$ be a commutative ring and $I$ is a f.g. ideal, then $M \subset D(A)$ is called $I$-completely (faithfully) flat/smooth/étale/… if $M \otimes^L_A A/I$ is discrete and is a (faithfully) flat $A/I$-module.

$M$ is said to have finite $I$-completely Tor amplitude if $M \otimes^L_A A/I$ is is a bounded complex in $D(A/I)$.

Clearly, any flat/smooth/étale $A$-module $M$ is $I$-completely flat/smooth/étale/… for any $I$. And $M$ has finite $I$-completely flatness if $M$ has a finite resolution of flat $A$-modules.

Prop. (4.6.7.2) [I-Completely F.F. Descent]. If $A \to B \to B'$ are ring maps and $I$ is an ideal of $A$,

1. If $C$ is a $B$-algebra and $B$ is $I$-completely f.f. over $A$, then $C$ is $I$-completely (f.)f. over $A$ iff $C$ is $I$-completely (f.)f. over $B$.

2. If $B \to B'$ is $I$-completely flat, $M$ is a $B$-module, then $M$ is $I$-completely flat over $A$ iff $M \otimes^L_B B'$ is $I$-completely flat over $A$.

Proof: 1: One direction is easy, for the other, if $C$ is $I$-completely (f.)f. over $A$, then

$$C \otimes^L_A A/I = C \otimes^L_B B \otimes^L_A A/I = (C \otimes^L_B B/I) \otimes_B/I (B \otimes^L_A A/I)$$

is a discrete and (f.)f. $C/I$-module iff $(C \otimes^L_B B/I)$ does, as $(B \otimes^L_A A/I)$ is f.f. over $B/I$.

2: This is because $(B' \otimes^L_B M) \otimes^L_A A/I \cong B' \otimes^L_B (M \otimes^L_A A/I)$. \hfill \Box

Prop. (4.6.7.3). If $I$ is generated by a Koszul-regular sequence, then any $A$-module $M$ has finite $I$-completely Tor amplitude.

Proof: This is because $A/i \cong A \otimes^L_{\mathbb{Z} \langle X_1, \ldots, X_n \rangle} \mathbb{Z}$ in this case, so $M \otimes^L_A A/I \cong M \otimes^L_{\mathbb{Z} \langle X_1, \ldots, X_i \rangle} \mathbb{Z}$, which has f.m. homology groups because $\mathbb{Z}$ has a finite free $\mathbb{Z}[X_1, \ldots, X_n]$-resolution (4.4.4.1). \hfill \Box

Prop. (4.6.7.4) [I-Completely Flatness and Derived Completion]. Let $A$ be a commutative ring and $I$ be f.g., then the derived $I$-completion of a $I$-completely (faithfully) flat/étale $M$ is $I$-completely (faithfully) flat/étale, both the complex and the module. In fact, $H^0(\hat{M}) \otimes^L_A A/I \cong \hat{M} \otimes^L_A A/I \cong M \otimes^L_A A/I$.

Proof: Because objects in the image of $D(A/I) \to D(A)$ are all derived $I$-complete, by (4.6.6.7), so there is an isomorphism $M \otimes^L_A A/I \cong \hat{M} \otimes^L_A A/I$ for any $M$, because they are both left adjoint to $\text{Mod}_{A/I} \subset D(A)$, by the definition of derived $I$-completion and (4.6.2.10). So $\hat{M} \otimes^L_A A/I \cong M \otimes^L_A A/I = M \otimes_A A/I$, which is a flat $A/I$-module. \hfill \Box

Prop. (4.6.7.5) [Flatness and Completed Derived Tensor]. The completed derived tensor of an $I$-completely flat/étale module is discrete and $I$-completely flat/étale.

Proof: If $M$ is an $I$-completely flat $A$-module, then $M \hat{\otimes}^L_A B$ is $I$-complete and $I$-completely flat by (4.6.7.4), and $(M \hat{\otimes}^L_A B) \otimes^L_B B/I = H^0(M \hat{\otimes}^L_A B) \otimes^L_B B/I = M \otimes^L_A B/I$, because they are both left adjoint of the forgetful functor $\text{Mod}_{B/I} \subset D(A)$. Then we have $M \hat{\otimes}^L_A B \cong H^0(M \hat{\otimes}^L_A B)$ is discrete, as they are both $I$-complete, by (4.6.6.2) and derived Nakayama. \hfill \Box

Prop. (4.6.7.6). $A$ is derived $I$-completely flat iff $A$ is $I^n$-completely flat for any $n > 0$. Moreover, in this case, $A$ is derived $J$-completely flat for any ideal $J$ that $I \subset \text{rad } J$. 

Proof: The exact sequence
\[ 0 \to I/I^2 \to A/I^2 \to A/I \to 0 \]
induces distinguished triangles
\[ (M \otimes^L_A A/I) \otimes^L_{A/I} I/I^2 \to M \otimes^L_A I/I^2 \to M \otimes^L_A A/I^2 \to M \otimes^L_A A/I \]
which shows \( M \otimes^L_A I/I^2 \) is discrete, \( = N \). Then \( N \) is an \( A/I^2 \)-module that \( N \otimes^L_{A/I^2} A/I = M/IM \) is \( A/I \)-flat. Then \( N \) is \( A/I^2 \)-flat: for any \( A/I^2 \)-module \( L \), let \( L' = IL \) and \( L'' = L/IL \) which are both \( A/I \)-modules, then there is a distinguished triangle
\[ N \otimes^L_{A/I^2} L' \to N \otimes^L_{A/I^2} L \to N \otimes^L_{A/I^2} L'' \]
and
\[ N \otimes^L_{A/I^2} L' = (N \otimes^L_{A/I^2} A/I) \otimes^L_{A/I} L' = (M/IM) \otimes^L_{A/I} L' \]
\[ N \otimes^L_{A/I^2} L'' = (N \otimes^L_{A/I^2} A/I) \otimes^L_{A/I} L'' = (M/IM) \otimes^L_{A/I} L'' \]
are both discrete, hence so does \( N \otimes^L_{A/I^2} L \), implying it is \( A/I^2 \)-flat.

In a similar fashion, we can show \( M \) is \( I/I^n \)-flat for any \( n \). And if \( I \subseteq \text{rad} J \), then \( I^n \subseteq J \), so \( M \otimes^L_A A/J = (M \otimes^L_A A/I^n) \otimes^L_{A/I^n} A/J \) is discrete and \( A/J \)-flat. \( \square \)

Prop. (4.6.7.7). Let \( A \) be a ring and \( I \) be an invertible ideal, then any derived \( (p, I) \)-complete and \( (p, I) \)-completely flat \( A \)-complex \( \mathcal{M} \in \mathcal{D}(A) \) is discrete and \( (p, I) \)-complete. Moreover, for any \( n \geq 0 \), we have \( M[I^n] = 0 \) and \( M/I^n M \) has bounded \( p^\infty \)-torsion.

Proof: \( M \) is \( (I^n, p) \)-completely flat by (4.6.7.6), so we have \( M \otimes^L_A A/I^n \) is \( p \)-completely flat in \( D(A/I^n) \). Notice that \( A/I^n \) has bounded \( p^\infty \)-torsion by induction (\( I \) invertible used), (4.6.7.11) says \( M \otimes^L_A A/I^n \) is discrete in \( D(A/I^n) \) and has bounded \( p^\infty \)-torsion, and is \( p \)-adically complete. In particular,
\[ M \otimes^L_A A/I^n = (M \otimes^L_A A/I^{n+1}) \otimes^L_{A/I^{n+1}} A/I^n \]
So if we denote \( M \otimes^L_A A/I^n = M_n \), then \( M_n = M_{n+1}/I^n M_{n+1} \), as \( M \) is derived \( I \)-complete, we have \( M = R \text{lim} (M \otimes^L_{A/I^n} A/I^n) \), so clearly \( M \) is discrete. And then we have \( M \otimes^L_{A/I^n} A/I^n = M/I^n M \), which means \( M[I^n] = 0 \), and \( M/I^n M \) has bounded \( p^\infty \)-torsion. Now because \( M \) is derived \( (p, I) \)-complete,
\[ M = R \text{lim}((M \otimes_{A/I^n} A/I^n \xrightarrow{p^n} A/I^n)) = R \text{lim}(M/I^n \xrightarrow{p^n} M/I^n) = R \text{lim}(M/(I^n, p^n)) \]
is \( (p, I) \)-complete. \( \square \)

Lemma (4.6.7.8). Let \( C \) be a commutative ring with a f.g. ideal \( J \), and \( D \) a \( C \)-algebra that has finite \( J \)-complete Tor amplitude, then the \( J \)-completed base change operator \( - \otimes^L_C D \) commutes with totalization in \( \mathcal{D}^{\geq 0}(C) \) and \( \mathcal{D}^{\geq 0}(D) \), i.e. \( M \) is a cosimplicial object with in \( \mathcal{D}^{\geq 0}(C) \) with totalization \( M \), then
\[ \text{Tot}(M^\bullet) \otimes^L_C D \cong \text{Tot}(M^\bullet \otimes^L_C D) \]
via the natural map.

Proof: Cf. [Scholze, Prism, 4.22]. \( \square \)
Prop. (4.6.7.9) [Elkik’s Algebrization Theorem]. Let $A$ be a commutative ring and $I$ is a f.g. ideal, then an $A$-algebras is derived $I$-completely étale/smooth iff it is the derived $I$-completion of some étale/smooth $A$-algebra.

Proof: if it is the derived $I$-completion of some étale/smooth algebra, then it is derived $I$-completely étale/smooth by (4.6.7.4). Converse, Cf. [A. Arabia, “Relèvements des algèbres lisses et de leurs morphismes”, Commentarii Mathematici Helvetici 76 (2001), 607–639.]. □

Lemma (4.6.7.10). Let $A$ be a ring, if $M$ is an $A$-module with bounded $f^\infty$-torsion, i.e. $M[f^\infty] = M[f^c]$ for some $c > 0$, then there are maps

$$(M \xrightarrow{f^n} M) \to M/f^n M, \quad M/f^{n+c} \to (M \xrightarrow{f^n} M)$$

in $D(A)$ inducing an equivalence between two pro-objects $\{M \xrightarrow{f^n} M\}$ and $\{M/f^n\}$.

Proof: The first map is obvious, for the second map, use the following commutative diagram:

$$
\begin{array}{ccc}
M/M[f^c] & \xrightarrow{f^{n+c}} & M \\
\downarrow{f^c} & & \downarrow \\
M & \xrightarrow{f^n} & M
\end{array}
$$

the upper row is injective thus isomorphic to $M/f^{n+c}M$, then this gives the map. It can be checked that this is an equivalence of pro-objects. □

Prop. (4.6.7.11). Let $A$ be a commutative ring that has bounded $f^\infty$-torsion, then for a $M \in D(A)$, the following is equivalent:

- $M$ is derived $f$-complete and $f$-completely flat.
- $M$ is discrete and is represented by a $f$-adically complete module that $M/f^n M$ is $A/f^n$-flat for any $n > 1$ and $M$ has bounded $f^\infty$-torsion.

Furthermore, in this case, $M \otimes_A A[f^\infty] = M[f^\infty]$.

Proof: By (4.6.7.10), $\{A/f^n A\}$ and $\{Kos(A, f^n)\}$ are two equivalence pro-objects in $D(A)$. So if 1 or 2 holds, then $M$ is derived $f$-complete, so

$$M = R\lim(M \otimes^L_A Kos(A, f^n)) = R\lim(M \otimes^L_A A/f^n A).$$

Now if 1 holds, then $M_n = M \otimes_A A/f^n A$ is discrete by (4.6.7.6), and $M_n = M_{n+1}/f^n M_{n+1}$ is surjective:

$$M \otimes^L A A/f^n A = (M \otimes^L_A A/f^{n+1} A) \otimes^L_{A/f^{n+1}} A/f^n.$$

So $M = R\lim(M \otimes^L_A A/f^n A)$ is discrete. Then $M \otimes_A A/f^n = M \otimes^L_A A/f^n$ is flat over $A/f^n$.

Next we prove $M \otimes_A A[f^\infty] = M[f^\infty]$: There is an exact sequence

$$0 \to (A[f^n])[1] \to Kos(A, f^n) \to A/f^n \to 0$$

Then tensoring $M \otimes^L_A$ gives a distinguished triangle

$$(M \otimes^L_A A[f^n])[1] \to Kos(M, f^n) \to M \otimes^L_A A/f^n.$$
Notice that
\[ M \otimes_A^L A[f^n] = (M \otimes_A^L A/f^n) \otimes_{A/f^n}^L A[f^n] = M \otimes_A^L A[f^n] \]
by flatness, so the distinguished triangle shows \( M \otimes_A^L A[f^n] \sim H^{-1}(Kos(M, f^n)) = M[f^n]. \)
Conversely, if 2 holds, then there are equivalences of pro-objects
\[ \{ M \otimes_A^L A[f^n] \} \sim \{ M \otimes_A^L Kos(A, f^n) \} = \{ Kos(M, f^n) \} \sim \{ M/f^nM \} \]
by (4.6.7.10) as \( M \) has bounded \( f^\infty \)-torsion. So
\[ \hat{M} = R\lim \{ M \otimes_A^L Kos(A, f^n) \} = R\lim \{ M/f^nM \} = M[0] \]
so \( M \) is derived \( p \)-complete. And the constant system
\[ \{ M \otimes_A^L A/f \} = \{ M \otimes_{A/f^n}^L A/f^n \otimes_{A/f^n}^L A/f \} \sim \{ M/f^nM \otimes_{A/f^n}^L A/f \} = \{ M/fM \} \]
where we used \( M/f^nM \) is \( A/f^n \)-flat. So \( M \otimes_A^L A/f \sim M/fM \) is flat over \( A/f \). \( \square \)

8 Duality

Def. (4.6.8.1) [Dualizing Complexes]. Let \( A \) be a Noetherian ring, then a dualizing complex for \( A \) is a complex \( \omega_A \in D(A) \) s.t.
- \( \omega_A \) has finite injective dimension.
- \( H^i(\omega_A) \) are all finite \( A \)-modules.
- \( A[0] \rightarrow \text{RHom}(\omega_A, \omega_A) \) is a quasi-isomorphism.

Prop. (4.6.8.2) [Dualizing Complex is Local]. Let \( A \) be a Noetherian ring,
- If \( B = S^{-1}A \) and \( \omega_A \in D(A) \) is a dualizing complex for \( A \), then \( \omega_A \otimes_A^L B \) is a dualizing complex for \( B \).
- If \( (f_1, \ldots, f_n) = (1) \in A \), and \( \omega_A \in D(A) \) satisfies \( (\omega_A)_{f_i} \) are dualizing complexes for \( A_{f_i} \) for any \( i \), then \( \omega_A \) is a dualizing complex for \( A \).

Proof: Cf. [Sta]0A7G, 0A7H. \( \square \)

Def. (4.6.8.3) [Dualizing Modules]. Let \( (A, \mathfrak{m}, k) \) be a Noetherian local ring and \( \omega_A \) a normalized dualizing complex for \( A \), then \( [\omega_A] = H^{-\dim A}(\omega_A) \) is called a dualizing module for \( A \).

Def. (4.6.8.4) [Relative Dualizing Complex]. Cf. [Sta]0E9M.

Quasi-Finite Case
Cf. [Sta]Chap49.4.

Prop. (4.6.8.5).
4.7 Divided Power Algebras

Basics

Def. (4.7.0.1) [PD-Structures]. Let \( I \) be an ideal of a commutative ring \( A \), a divided power structure or \( \text{pd-structure} \) on \( I \) is a collection of maps \( I_n : I \to A, n \geq 0 \) that

- \( \gamma_0(x) = 1, \gamma_1(x) = x, \gamma_n(x) \in I \forall n. \)
- \( \gamma_n(x + y) = \sum \gamma_{n-i}(x)\gamma_i(y). \)
- \( \gamma_n(\lambda x) = \lambda^n \gamma_n(x), \lambda \in A, x \in I. \)
- \( \gamma_n(x)\gamma_n(y) = \binom{m+n}{n} \gamma_{m+n}(x). \)
- \( \gamma_n(\gamma_m(x)) = \binom{m+n}{m}\gamma_{m+n}(x). \)

It is a simulation of the divided power \( \gamma_n(x) = x^n \) in case \( n! \) is definable.

A divided power ring is a triple \((A, I, \gamma)\) where \( I \) is an ideal of a commutative ring \( A \) and \( \gamma \) is a pd-structure on \( I \). A morphism of divided power rings is a morphism of pairs \((A, I)\) that preserves pd-structures.

For a pd-structure \((A, I)\), denote \( I[n] \) the ideal generated by \( \prod_i \gamma_n(x_i) \) where \( x_i \in I \) and \( \sum n_i \geq n \).

Prop. (4.7.0.2) [Limits and Colimits]. The category of divided power rings has all limits and colimits, the limits commute with forget functors but the colimits don’t. However, the colimit always commutes with the functor taking \((A, I)\) to \( A/I \). This can be seen from the universal property of colimit applied to the pd-structures that \( I = 0 \).

Proof: The construction of the limit is clear. For the colimits, we use representability criterion (3.1.1.28), Cf. [[Sta]07GX]?

Prop. (4.7.0.3). Let \( A \) be a ring and \( I \) an ideal of \( A \), then if \( \gamma \) is a pd-structure on \( I \), then \( n!\gamma(x) = x^n \).

Proof: If \( \gamma \) is a pd-structure, then we have \( n\gamma_n(x) = \gamma_1(x)\gamma_{n-1}(x) \), so we can use induction.

Prop. (4.7.0.4). If \( I, J \) are two ideals of \( A \) and \( \gamma \) a pd-structure on \( I \) and \( \delta \) a pd-structure on \( J \), then

- \( \gamma, \delta \) agree on \( IJ \).
- \( \gamma, \delta \) agree on \( I \cap J \), then they extends to a pd-structure on \( I + J \).

Proof: 1: for \( x \in I, y \in J, \gamma_n(xy) = y^n\gamma_n(x) = n!\delta_n(y)\gamma_n(x) = \delta(xy). \)

2: direct calculation.

Prop. (4.7.0.5) [p-Nilpotent and Thickening]. Let \( p \) be a prime and \((A, I, \gamma)\) a pd-structure. Assume \( p \) is nilpotent in \( A/I \), then \( I \) is locally nilpotent iff \( p \) is nilpotent in \( A \), equivalently \((A, I, \gamma)\) is a pd-thickening.

Proof: If \( p^N = 0 \in A \), then for any \( x \in I, x^{pN} = (pN)!\gamma_{pN}(x) = 0. \) Then converse is trivial.

Constructing PD-Structures

Prop. (4.7.0.6) [\( \mathbb{Z}_p \)-Algebras]. Cf. [[Sta]07GN].

Prop. (4.7.0.7). Let \( A \) be a \( \mathbb{Z}_p \)-algebra and \( I \) is an ideal, then two pd-structures \( \gamma, \gamma' \) on \( \gamma \) are equal iff \( \gamma_p = \gamma' \). Moreover, given a map \( \delta : I \to I \) that
\begin{itemize}
\item $p!\delta(x) = x^p$,
\item $\delta(ax) = a^p \delta(x)$ for any $a \in A, x \in I$,
\item $\delta(x + y) = \delta(x) + \delta(y) + \sum_{i+j=p,i,j>0} \frac{1}{i!j!} x^i y^j$.
\end{itemize}

Then there exists a unique pd-structure on $I$ that $\gamma_p = \delta$.

\textbf{Proof:} Just notice that $\gamma_n(x) = dx\gamma_{n-1}(x)$ for some $c$ invertible in $\mathbb{Z}_{(p)}$, and also $\gamma_{pm}(x) = c\gamma_m(\gamma_p(x))$ for some $c$ invertible in $\mathbb{Z}_{(p)}$, thus $\gamma$ is uniquely determined, and we can also define $\gamma_n$ inductively in this way, and the verification of axioms in in[[Sta]07GS].

\textbf{Prop. (4.7.0.8).} Let $A$ be a $\mathbb{Z}$-torsion-free ring and $I$ an ideal of $A$, then:
\begin{itemize}
\item $I$ has at most one pd-structure.
\item if $\gamma_n : I \to I$ are maps, then $\gamma$ is a pd-structure iff $n!\gamma_n(x) = x^n$.
\item $I$ has a pd-structure iff there is a set of generators $\{x_i\}$ of $I$ that $x_i^n \in n!I$.
\end{itemize}

\textbf{Proof:} 1 is clear from (4.7.0.3).
2: because $A \subset A \otimes_{\mathbb{Z}} \mathbb{Q}$, we can verify in $A \otimes_{\mathbb{Z}} \mathbb{Q}$, then the verifications are trivial.
3: Use the axioms to extend linearly and additively.

\textbf{Prop. (4.7.0.9) [DVR].} If $R$ is a DVR in char $0$ with residue field of char $p$ and ramification $p$ and maximal ideal $m$, then $m$ has a pd-structure iff $e \leq p - 1$.

\textbf{Proof:} As $R$ has char $0$, it has at most one pd-structure by (4.7.0.8), and we need to show that $x^n/n!$ is in $m$ for any $x \in m$. And using (20.1.2.2), we are done.

\textbf{Extending PD-Structure}

\textbf{Def. (4.7.0.10) [Extending PD-Structure].} Let $(A, I, \gamma)$ be a pd-structure and $B$ is an $A$-algebra, we say that $\gamma$ extends to $B$ if $A \to B$ extends to a morphism of pd-structures $(A, I, \gamma) \to (B, IB, \gamma')$.

Let $(A, I), (B, J)$ be two pd-structures and $B$ is an $A$-algebra, then these two pd-structures are said to be compatible iff the pd-structure on $A$ extends to $B$ and the pd-structure on $J$ and $IB$ coincides, or equivalently, there is a pd-structure on $IB + J$ compatible with $IB$ and $J$, by (4.7.0.4).

\textbf{Prop. (4.7.0.11) [Extendability].} Let $(A, I)$ is a pd-structure and $B$ an $A$-algebra, if any of the following holds:
\begin{itemize}
\item $IB = 0$,
\item $I$ is principal,
\item $B[I] = 0$, (e.g. $A \to B$ is flat).
\end{itemize}

then $\gamma$ extends to $B$.

\textbf{Proof:} 1 is trivial.
2: if $I = (x)$, we define $\gamma_n(bx) = b^n \gamma_n(x)$. This is well defined: if $(b - b')x = 0$, then $(b^n - (b')^n)\gamma_n(x) = 0$ because $\gamma_n(x) \in (x)$. Verifications of axioms is routine.
3: the condition shows $I \otimes_A B \cong IB$, thus it suffices to define $\gamma$ on $I \otimes_A B$. For this we define on $I \otimes B$ and descend: let $\gamma_n((x, b)) = b^n \gamma_n(x)$ and extend by freeness and axioms in (4.7.0.1), then it is easy to show it is bi-additive and $A$-linear, so descend to $I \otimes B$ by (2.2.4.13).
Prop. (4.7.0.12) [PD-Structure and Completions]. Let \((A, I, \gamma)\) be a pd-structure that \(p\) is nilpotent in \(A/I\), then each \(\gamma_n\) is continuous in the \(p\)-adic topology and extends to a pd-structure \(\hat{\gamma}\) on \(\hat{I}\).

If moreover \(A\) is a \(\mathbb{Z}(p)\)-algebra, then for \(e\) large, \(p^e A \in I\) is preserved by \(\gamma\) and

\[
(\hat{A}, \hat{I}, \hat{\gamma}) = \text{colim}_e (A/p^e A, I/p^e A, \gamma).
\]

**Proof:** Let \(p^t \in I\), then 1 follows from (4.2.3.8). \(\gamma_n\) is clearly continuous, and \(\gamma_n\) preserves \(p^e A\) because

\[
\gamma_n(p^e a) = p^n \gamma_n(p^{e-1} a) = \frac{p^n}{n!} p^{n(e-1)} a^n \in p^e A.
\]

The limit equation follows from (4.7.0.2). \(\square\)

Prop. (4.7.0.13) [Quotient]. Let \((A, I, \gamma)\) be a pd-structure and \(a \subset A\) is an ideal, and \(I' = I \cap a\), then the following are equivalent:

1. \(\delta\) extends to \(A/a\).
2. \(I'\) is preserved by \(\gamma\).
3. There is a set of generator \(x_i\) of \(I'\) that \(\gamma_n(x_i) \in I'\) for all \(n, i\).

**Proof:** \(1 \rightarrow 2 \rightarrow 3\) is clear. \(2 \rightarrow 1\): we can just define \(\gamma(x + I) = \gamma(x) + I\), which is well defined by axiom 2 of (4.7.0.1). \(3 \rightarrow 2\) is clear. \(\square\)

Def. (4.7.0.14) [Free PD-Algebra]. For a pd-structure \((A, I, \delta)\), the **free pd-algebra** \(A(t_1, \ldots, t_n)\) is defined to be the \(A\)-algebra generated by symbols \(t_i^{[n]}\), where \(n > 0\), modulo the algebraic relations \(t_i^{[m]} t_j^{[n]} = (m+n) t_i^{[m+n]}\). Denote by \(A(t_1, \ldots, t_n)_+\) the ideal generated by \(t_i^{[n]}\) where \(n > 0\).

Then the ideal \(J\) generated by \(I\) and \(A(t_1, \ldots, t_n)_+\), where \(n > 0\) has a unique pd-structure that \(\gamma_n(t_i) = t_i^{[n]}\) and \((A, I, \delta) \rightarrow (A(t_1, \ldots, t_n), J, \gamma)\) is a morphism of pd-structures.

It has a universal property that \(\text{Hom}((A(t_1, \ldots, t_n), J, \gamma), (C, K, \varepsilon))\) is the same as \(\text{Hom}((A, I, \delta), (C, K, \varepsilon))\) with specified \(n\) elements in \(K\).

**Proof:** Because \(IA(t_i) \cap A(t_1, \ldots, t_n)_+ = IA(t_i) + A(t_1, \ldots, t_n)_+,\) by (4.7.0.4), it suffices to construct pd-structures on \(IA(t_i)\) and \(A(t_1, \ldots, t_n)_+\). The former is by (4.7.0.11) and for the latter: if \(A\) is torsion-free, then we can use (4.7.0.8) because \(\gamma_m(x)^n = n! \gamma_n(\gamma_m(x)) = \frac{(mn)!}{(m!)^n} \gamma_{mn}(x) \in n! A(t_1, \ldots, t_n)_+\). In general, we write \(A = R/a\) where \(R\) is a torsion-free pd-structure (can choose \(\mathbb{Z}(A)\)), so there is a pd-structure on \(R(t_i)\), and \(\gamma(t_i)^+/a(t_i) = A(t_i)\), then we can use (4.7.0.13) to construct a pd-structure on \(A(t_i)\) compatible with that of \(A\).

The verification of universal property is omitted. \(\square\)

PD-Envelopes

Prop. (4.7.0.15) [PD-Envelope]. Let \((A, I, \gamma)\) be a pd-structure, then there is a **pd-envelope** functor \((B, J) \rightarrow (D_B(J), \overline{J}, J)\) from the the category of pairs over \((A, I)\) to the category of pd-structures over \((A, I, \gamma)\) that is left adjoint to the forgetful functor.

In particular, by the universal property of pd-envelope, there is a morphism \((B, J) \rightarrow (D_B(J), \overline{J}) \rightarrow (B/J, 0)\) of pairs, so in particular \(D/\overline{J} \rightarrow B/J\) is surjective.
Proposition (4.7.0.16) [PD-Envelope of Quotients]. Let \((A, I, \gamma)\) be a pd-structure and \(\varphi : B' \to B\) be a surjection of \(A\)-algebras with kernel \(K\). Let \(IB \subset J \subset B\) be an ideal and \(J' = \varphi^{-1}(J)\) and \(D_{B', \gamma}(J') = (D', \mathcal{J}', \gamma)\), then \(D_{B, \gamma}(J) = (D'/K', \mathcal{J}'/K', \gamma)\) where \(K'\) is the ideal generated by all \(\gamma(k)\) for \(n \geq 0\) and \(k \in K\).

Proof: There is a pd-structure on \((D'/K', \mathcal{J}'/K', \gamma)\) by (4.7.0.13). A map of pairs \((B', J') \to (T, I', \gamma)\) is equivalent to a map of pairs \((B', J') \to (T, I', \gamma)\) that vanishes on \(K\), or a map of pd-structures \((D', \mathcal{J}', \gamma) \to (T, I', \gamma)\) that vanishes on \(\gamma(k)\), thus this is clearly represented by \((D'/K', \mathcal{J}'/K', \gamma)\).

Proposition (4.7.0.17). If \((A, I)\) is a pd-structure and \((B, J)\) is a pair over \((A, I)\), then

\[D_{B[X_i], \gamma}(JB[X_i] + (X_i)) \cong D_{B, \gamma}(J)(X_i)\]

Proof: This follows from the universal property of free pd-structure (4.7.0.14).

PD-Structures and \(\delta\)-Rings

Lemma (4.7.0.18). If \(A\) is a \(p\)-torsionfree \(\mathbb{Z}_p\)-\(\delta\)-ring, denote \(\gamma_n(z) = \frac{z^n}{n!}\). If \(z \in A\) satisfies \(\gamma_p(z) \in A\), then \(\gamma_n(z) \in A\) for any \(n\).

Proof: WARNING: this is not an easy consequence of power counting. We first prove for \(n = p^2\); as \(A\) is a \(\delta\)-ring, \(\delta(\frac{z^p}{p}) \in A\)

\[\delta(\frac{z^p}{p}) = \frac{1}{p} (\frac{\varphi(z)^p}{p} - \frac{z^{p^2}}{p^2}) = \frac{(zp^p + p \delta(z))^p - z^{p^2}}{p^{p+1}} \in A.\]

The first term is \(A\) by assumption, thus the second term is also in \(A\), proving the case for \(n = p^2\).

Now for general \(n\), it suffices to prove for \(n = kp\). But it can be checked that \(\gamma_{nk}(z) = u\gamma_k(\gamma_p(z))\) where \(u\) is a unit. Now by what we just proved, we can use induction hypothesis for \(z = \gamma_p(z)\), and conclude that \(\gamma_{nk}(z) \in A\).

Proposition (4.7.0.19). The ring \(C = \mathbb{Z}_p\{x, \frac{\varphi(x)}{p}\}\) identifies with the pd-envelope \(D = D_{\mathbb{Z}_p\{x\}}(x) = \mathbb{Z}_p\{x\}[[\gamma_n(x)]]\) where \(\gamma_n(x) = \frac{x^n}{n!}\). Moreover, it also equals to \(\mathbb{Z}_p\{X_1, X_2, \ldots\}/(x, x^p, pX_2 - X_1, \ldots)\).

Proof: It suffices to show that the smallest \(\delta\)-ring of \(\mathbb{Z}_p\{x\}\) containing \(\mathbb{Z}_p\{x\}\) and \(\frac{\varphi(x)}{p}\) is the same as the smallest ring of \(\mathbb{Z}_p\{x\}\) containing \(\mathbb{Z}_p\{x\}\) and \(\frac{\varphi(x)}{p}\).

\(D \subset C\) is immediate from (4.7.0.18). To show \(C \subset D\), notice \(\frac{\varphi(x)}{p} \in D\), it suffices to show \(\varphi\) preserves \(D\), or equivalently, \(\varphi(y) - y^n \in pD\) for any \(y \in D\). Now

\[\varphi(x^n) = \frac{(x^p + p \delta(x))^n}{n!} = \sum_{i=0}^{n} \binom{n}{i} \frac{(p)^i (x^{n-i})}{n!}, \delta(x)^{n-i}\]
The coefficients
\[
\frac{\binom{n}{i}(p)^i}{n!}p^{n-i}
\]
are all in \(p\mathbb{Z}(p)\), thus \(\varphi\left(\frac{x^n}{m!}\right) \in pD\). On the other hand,
\[
\left(\frac{x^n}{n!}\right)^p = \gamma_p(\gamma_n(x)) = u\gamma_{pn}(x) \cdot p! \in pD
\]
where \(u\) is a unit in \(\mathbb{Z}(p)\) by (4.7.0.1), thus we are done. \(\square\)

**Lemma (4.7.0.20).** If \(A\) is a \(p\)-torsionfree (equivalently, flat) \(\mathbb{Z}(p)\)-algebra and \((a, p)\) is a regular sequence in \(A\), then \(D_A((a)) \cong A \otimes_{\mathbb{Z}(p)} D_{\mathbb{Z}(p)}((x)) = A[X_1, X_2, \ldots]/(pX_1 - a^p, pX_2 - X_1^p, \ldots)\).

**Proof:** By (4.7.0.19),
\[
A \otimes_{\mathbb{Z}(p)} D_{\mathbb{Z}(p)}((x)) = A \otimes_{\mathbb{Z}(p)} \{ [\gamma_n(x)] \} = A[X_1, X_2, \ldots]/(a^p - pX_1, X_1^p - pX_2, X_2^p - pX_3, \ldots)
\]
thus there is a natural map from \(A \otimes_{\mathbb{Z}(p)} D_{\mathbb{Z}(p)}((x))\) to \(D_A((a))\) given by
\[
X_k \mapsto \frac{a^p}{p^{\text{ord}_p(n)}} = \frac{a^p}{p^1 + p^2 + \cdots + p^{k-1}} \in D_A((a)).
\]
It is surjective, and it is an isomorphism when inverting \(p\). Thus the kernel are all \(p^\infty\)-torsions. Then to show it is an isomorphism, it suffices to show \(A[X_1, X_2, \ldots]/(a^p - pX_1, X_1^p - pX_2, X_2^p - pX_3, \ldots)\) is \(p\)-torsion-free. It is a filtered colimit, so it suffices to show \(A[X_1, \ldots, X_n]/(a^p - pX_1, X_1^p - pX_2, X_2^p - pX_3, \ldots, X_n^p - pX_n)\) is \(p\)-torsionfree.

For this, it suffices to prove \(A' = A[X_1, \ldots, X_k]/(px_1 - a^k, px_2 - x_1^k, \ldots, px_k - x_{k-1}^p)\) is \(p\)-torsionfree. If we denote \(K(R) = K(R[X_1, \ldots, X_n], px_1 - a^k, px_2 - x_1^k, \ldots, px_k - x_{k-1}^p)\) for any ring \(R\), then we have a distinguished triangle
\[
K(A) \xrightarrow{p} K(A) \rightarrow K(Kos(A[X_1, \ldots, X_k], p)) = K(A/p)
\]
as \(A\) is \(p\)-torsionfree. Now we can consider the spectral sequence associated to this distinguished triangle. Notice first that \((px_1 - a^k, px_2 - x_1^k, \ldots, px_k - x_{k-1}^p)\) is a regular sequence in \(A'/p\), which is clear. So the \(E_1\) page looks like
\[
\begin{array}{cccc}
A' & \overset{p}{\longrightarrow} & A' & \longrightarrow A'/p \\
\uparrow & & \uparrow & \\
* & \longrightarrow & * & \longrightarrow 0 \\
\uparrow & & \uparrow & \\
* & \longrightarrow & * & \longrightarrow 0 \\
\uparrow & & \uparrow & \\
\vdots & \longrightarrow & \cdots & \longrightarrow \cdots
\end{array}
\]
and the \(E_2\) page is of the form
\[
\begin{array}{cccc}
A'[p] & \overset{p}{\longrightarrow} & 0 & \longrightarrow 0 \\
\uparrow & & \uparrow & \\
* & \longrightarrow & * & \longrightarrow 0 \\
\uparrow & & \uparrow & \\
* & \longrightarrow & * & \longrightarrow 0 \\
\uparrow & & \uparrow & \\
\vdots & \longrightarrow & \cdots & \longrightarrow \cdots
\end{array}
\]
This spectral sequence converges to 0, so $A'[p] = 0$, we win. □

Prop.(4.7.0.21) [PD-Envelope for Regular Sequence]. Let $A$ be a $p$-torsionfree $\delta$-ring and $p, f_1, \ldots, f_r$ define a regular sequence in $A$, then $A\{\frac{\varphi(f_1)}{p}, \ldots, \frac{\varphi(f_r)}{p}\}$ identifies with the pd-envelope $D_A(I)$ of $I = (f_1, \ldots, f_r)$ as a subring of $A[\frac{1}{p}]$.

Proof: In case $r = 1$, $A\{\frac{\varphi(f_1)}{p}\} = A \otimes_{\mathbb{Z}(p)} \mathbb{Z}(p) \{x, \varphi(x)\} = A \otimes_{\mathbb{Z}(p)} \mathbb{Z}(p)((x)) \cong D_A((f_1))$ by (4.7.0.20).

The general case follows from this, by considering the tower

$$
(A, (f_1)) \to (A, (f_2)) = (A\{\frac{\varphi(f_1)}{p}\}, (f_2))
$$

$$
\to (D_A\{\frac{\varphi(f_1)}{p}\}(f_3)) = (A\{\frac{\varphi(f_1)}{p}, \frac{\varphi(f_2)}{p}\}, (f_3))
$$

$$
\to \ldots = A\{\frac{\varphi(f_1)}{p}, \ldots, \frac{\varphi(f_r)}{p}\}
$$

The equations are true because $(p, f_k)$ are regular in $A\{\frac{\varphi(f_1)}{p}, \ldots, \frac{\varphi(f_{k-1})}{p}\}$:

$$
A\{\frac{\varphi(f_1)}{p}, \ldots, \frac{\varphi(f_{k-1})}{p}\}/p = A/p[X_{11}, X_{12}, \ldots, X_{21}, X_{22}, \ldots, X_{k-1,1}, X_{k-1,2}, \ldots]
$$

and $f_k$ is a nonzero-divisor in it because it is a non-zero divisor in $A/(p, f_{k-1}^p)$, as $(p, f_{k-1}^p, \ldots, f_k^p)$ is also a regular sequence by (4.3.4.4). Then a map of pairs of rings $(A, I) \to (C, J)$ will lift through this tower uniquely by the universal property of pd-envelope.

then we see $A\{\varphi(f_1)/p, \ldots, \varphi(f_r)/p\}$ is just the pd-envelop of $(A, I)$, by the universal property. □

Lemma (4.7.0.22). Let $A$ be an $\mathbb{F}_p$-algebra and $B$ an $A$-algebra. If $(x_1, \ldots, x_n) \in B$ is regular w.r.t. $A(8.1.3.7)$, then $D_B((x_1, \ldots, x_n))$ is $A$-flat.

Proof: By (4.7.0.19) and base change, it is clear that $D_B(I)$ is a free $B/I^p$-algebra. Thus we need to show that $B/I^p$ is a flat $A$-module. And this is true as the sequence $x_1^p, \ldots, x_n^p$ is also regular w.r.t. $A(8.1.3.8)$.

Prop.(4.7.0.23) [Flatness of PD-Envelope]. If $A \to B$ is a map of simplicial rings, $A$ is naturally a simplicial pd-structure with $I_\bullet = pA_\bullet$, and $B$ is $p$-completely flat over $A(8.1.3.5)$, and $(x_1, \ldots, x_n) \in \pi_0(B)$ is $p$-completely regular w.r.t $A(8.1.3.7)$, then the completed pd-envelope $D = D_B((x_1, \ldots, x_n))$ is $p$-completely flat over $A$.

Proof: By definition (8.1.3.5), to check it is $p$-completely flat, it suffices to check

$$
Kos(A, p) \to Kos(A, p) \otimes_A^L D
$$

is flat. and by (8.1.3.4) it suffices to check that

$$
\pi_0(Kos(A, p)) \to \pi_0(Kos(A, p)) \otimes_A^L D
$$
is flat. The formation of pd-envelope commutes with derived base change by universal property, and tensor with $A/p$-algebra undoes the completions, so we are reduced to the the case $A' = \pi_0(\text{Kos}(A,p))$ and $B' = A' \otimes^L_A B$ is flat over $A'$ and to show that

$$A' \to D_{B'}((x_1, \ldots, x_n))$$

is flat. Notice $B'$ is a discrete flat $A'$-algebra by definition(8.1.3.5), and $(x_1, \ldots, x_n)$ is a sequence in $B'$ that $\text{Kos}(B, x_1, \ldots, x_n)$ is a sequence regular w.r.t. $A'$:

$$\text{Kos}(B, x_1, \ldots, x_n) = \text{Kos}(B' = A' \otimes^L_A B, x_1, \ldots, x_n) = A' \otimes^L_{\text{Kos}(A,p)} \text{Kos}(A, p) \otimes_A \text{Kos}(B, x_1, \ldots, x_n)$$

is flat because $\text{Kos}(A, p) \to \text{Kos}(B, p, x_1, \ldots, x_n)$ does by definition(8.1.3.7) and(8.1.3.3). So we are done by(4.7.0.22).

**Cor. (4.7.0.24).** If $A$ is a p-complete simplicial $\delta$-ring and $B$ is a p-completely flat simplicial $\delta$-$A$-algebra, and if $x_1, \ldots, x_r \in \pi_0(B)$ is p-completely regular w.r.t. $A$, then

$$C_* = B_*\{\frac{x_1}{p}, \ldots, \frac{x_r}{p}\}$$

is p-completely flat over $A$.

**Proof:** Let $C'_* = B_*\{\frac{\varphi(x_1)}{p}, \ldots, \frac{\varphi(x_r)}{p}\}$, then $C'_*$ is p-completely flat over $A$, by(4.7.0.21) (? why $B$ is p-torsionfree and $(p, x_1, \ldots, x_n)$ is regular sequence) and(4.7.0.23). Now there is a commutative diagram

$$
\begin{array}{c c c c c c c c c c}
A & \longrightarrow & A\{x_1, \ldots, x_r\} & \longrightarrow & B & \longrightarrow & B\{\frac{x_1}{p}, \ldots, \frac{x_r}{p}\} & \longrightarrow & C_* \\
\downarrow & & \downarrow\psi & & \downarrow\psi_B & & \downarrow\psi' & & \downarrow\psi_C \\
A & \longrightarrow & A\{\varphi(x_1), \ldots, \varphi(x_r)\} & \longrightarrow & B' & \longrightarrow & B'\{\frac{\varphi(x_1)}{p}, \ldots, \frac{\varphi(x_r)}{p}\} & \longrightarrow & C'_*
\end{array}
$$

where $\psi$ is the relative Frobenius and $\psi_B, \psi_C$ is the derived base change and completed derived base change. Then $\psi$ is f.f. as it is the base change of the Frobenius on the free $\delta$-ring $\mathbb{Z}\{x_1, \ldots, x_r\}$.(4.5.4.10), thus so does $\psi'$. Then $\psi_C$ is p-completely flat, because it is the completion(use(4.6.7.2)) (4.6.7.4). Now the conclusion follows, by completely f.f. descent(4.6.7.2).

#### 1 de Rham Complex

**Def. (4.7.1.1) PD-Differentials.** Let $B$ be an $A$-algebra and $(B, J, \delta)$ be a pd-structure and $M$ a $B$-module, then a **pd-$A$-derivation** from $B$ to $M$ is a an element $\theta$ of $\text{Der}_A(B, M)$ that $\theta(\delta_n(x)) = \delta_{n-1}(x)\theta(x)$ for $n \geq 1$ and $x \in J$.

As in(4.4.3.4), there is a **pd-differential** $\Omega_{B/A,\delta}$ that

$$\text{Hom}_B(\Omega_{B/A,\delta}, M)$$

is isomorphic to the set of pd-$A$-derivations of $B$ to $M$, functorially in $M$.

**Prop. (4.7.1.2) PD-Differential of PD-Envelope.** Let $(A, I, \gamma)$ be a pd-structure and $(B, J)$ be a pair over $(A, I)$, and let $D_{B/A,\gamma}(J) = (D, \overline{T}, \overline{\gamma})$ be the pd-envelope, then $\Omega_{D/A,\overline{\gamma}} = \Omega_{B/A} \otimes_B D$. 

Proof: It suffices to show that for any $D$-module $M$, the set of $A$-derivations $B \to M$ is isomorphic to the set of pd-$A$-derivations $D \to M$.

Let $D \otimes M$ be the ring that $M^2 = 0$ and a pd-structure on $J \oplus M$ is given by $\delta_n(x + m) = \delta_n(x) + \delta_{n-1}(xm)$. Then a pd-$A$-derivations $D \to M$ is equivalent to a pd-ring map $(D, J) \to (D \oplus M, J \oplus M)$, and an $A$-derivations $B \to M$ is also equivalent to a map of pairs $(B, J) \to (D \oplus M, J \oplus M)$, thus we are done by the universal property of $D$. □

**Prop. (4.7.1.2)**. Let $B$ be an $A$-algebra and $(B, J, \delta)$ be a pd-structure, then

- if $(B[X], JB[X], \delta')$ is the $\delta$-structure extended from that of $(B, J, \delta)$ as in (4.7.0.11), then
  \[ \Omega_{B[X]/A,\delta'} = \Omega_{B/A,\delta} \otimes_B B[X] \oplus B[X]dx. \]

- Let $B\langle x \rangle$ be the free pd-algebra over $B$ (4.7.0.14), then
  \[ \Omega_{B\langle x \rangle/A,\delta'} = \Omega_{B/A,\delta} \otimes_B B\langle x \rangle \oplus B\langle x \rangle dx. \]

- Let $K \subset J$ be an ideal preserved by $\delta$ and then consider the quotient $(B' = B/K, J = J/K, \delta)$, then $\Omega_{B'/A,\delta}$ is quotient of the module $\Omega_{B/A,\delta} \otimes_B B'$ by the $B'$-submodule generated by $dk$ where $k \in K$.

Proof: These are all somewhat trivial. □

**Prop. (4.7.1.3)**. Let $A$ be a $\mathbb{Z}(p)$-algebra, $B$ be an $A$-algebra and $(B, J, \delta)$ be a pd-structure, then

\[
\Omega^i_{B/A,\delta} = (\Omega^i_{B/A,\delta})^\wedge = (\Omega^i_{B/A,\delta}^\wedge).
\]

where $B_e = B/p^e$.

Proof: By (4.7.0.12), the terms make sense. Now by (4.7.1.3) and the observation $d(p^e) = 0$, we have $\Omega^i_{B_e/A,\delta} = \Omega^i_{B/A,\delta}/p^e = \Omega^i_{B/A,\delta}/p^e$, thus we are done. □

**Def. (4.7.1.4)**. Let $\Omega^i_{B/A,\delta} = \wedge^i \Omega_{B/A,\delta}$, then the surjection $\Omega_{B/A} \to \Omega^i_{B/A,\delta}$ satisfies the condition of (6.2.1.2), thus there is a **pd-de Rham complex** $\Omega^*_{B/A,\delta}$.

**PD-Poincaré Lemma**

**Lemma (4.7.1.6)**. Let $A$ be a ring, $P = A \langle X_i \rangle$ is the free PD-algebra over $A$, then for any $A$-module, the complex

\[
0 \to M \to M \otimes_A P \to M \otimes_A \Omega^\wedge_{P/A,\delta} \to \ldots
\]

is exact. And if $D = \widehat{P}$ and let $\Omega^n_D = \Omega^n_{P/A,\delta}$, then for any $p$-complete $A$-module $M$, the complex

\[
0 \to M \to M \widehat{\otimes}_A P \to M \widehat{\otimes}_A \Omega^\wedge_{P/A,\delta} \to \ldots
\]

is exact.
Proof: It suffices to show that $0 \to M \to M \otimes_A P \to M \otimes_A \Omega^1_{P/A,\delta} \to \ldots$ is homotopic to 0. For this, notice every element of $\Omega^n_{P/A,\delta}$ is of the form $\sum P \prod_{j=0}^n dx_{i_0} dx_{i_1} \ldots dx_{i_n}$, so we can let

$$f(\omega) = f(\gamma_{i_0}(x_{i_0}) dx_{i_0} \wedge \omega) = \gamma_{i_0+1}(x_{i_0}) \omega$$

where $\omega$ doesn’t divides $dx_k$ for $k < i_0$. Then it can be checked that $df + fd = \text{id}$, so we are done.

□

Prop. (4.7.1.7). If $A$ is a ring and $(B,J,\delta)$ is a pd-structure, and let $P = B\langle X_i \rangle$ be the free pd-structure. Let $M$ be a $B$-module endowed with an integrable connection $\nabla : M \to M \otimes_B \Omega^1_B\langle X_i \rangle$, then the map of de Rham complexes

$$M \otimes_B \Omega^*_{B/A,\delta} \to M \otimes_B \Omega^*_{P/A,\delta}$$

is a quasi-isomorphism. And if we denote $D, D'$ the $p$-adic completions of $B, P$, and $\Omega_D, \Omega_{D'}$ the $p$-adic completion of $\Omega_{B/A,\delta}, \Omega_{P/A,\delta}$, and $M$ is a $p$-complete $B$-module endowed with an integrable connection $\nabla : M \to M \otimes_D \Omega_D$, then the map of de Rham complexes

$$M \otimes_D \Omega^*_{D} \to M \otimes_{D'} \Omega^*_{D'}$$

is a quasi-isomorphism.

Proof: Consider the filtration $F^*$ on $\Omega^*_{B/A,\delta}$ given by the stupid truncation $\sigma_{\geq i} \Omega^*_{B/A,\delta}$, and consider the filtration on $\Omega^*_{P/A,\delta}$ given by

$$F^*(\Omega^*_{P/A,\delta}) = F^*(\Omega^*_{B/A,\delta}) \wedge \Omega^*_{P/A,\delta}.$$ 

Notice that we have a split exact sequence

$$0 \to \Omega^1_{B/A,\delta} \otimes_B P \to \Omega^1_{P/A,\delta} \to \Omega^1_{P/B,\delta} \to 0$$

and $\Omega^1_{P/B,\delta}$ is free on $X_i$ over $B$ (pondering the universal property, this is for the same reason as (4.4.3.7).

Then we see that $F^i(\Omega^*_{P/A,\delta}) \to \Omega^*_{P/A,\delta}$ is termwise split injection for any $i$, and the graded is $\Omega^i_{B/A,\delta} \otimes_B \Omega^i_{P/B,\delta}$. Thus if we let $F^i(M \otimes_B \Omega^*_{P/A,\delta}) = M \otimes F^i(\Omega^*_{P/A,\delta})$, then the graded is $M \otimes_B \Omega^i_{B/A,\delta} \otimes_B \Omega^i_{P/B,\delta}$, which is quasi-isomorphic to $M \otimes_B \Omega^i_{B/A,\delta}$ by (4.7.1.6). Then the original map is a filtered complexes that induces quasi-isomorphism on gradeds, so it induces a quasi-isomorphism, because it induces a morphism between two convergent spectral sequences, by (3.4.7.6) and (3.4.7.5). □
4.8 Almost Ring Theory

References are [Almost Ring Theory Gaber/Ramero] and [Almost Ring Theory Foundations Gaber/Ramero].

Def.(4.8.0.1). The setup of most mathematics is an flat ideal $I \subset R$, that $I^2 = I$. This implies that $I \otimes I \cong I^2 = I$.

Denote $i : R \to R/I$. Then there is a map $i_* : M \to MR$, which has a left adjoint $i^* : N \to N \otimes_R R/I$, and a right adjoint $i^!: N \to \text{Hom}(R/I, N)$.

1 Homological Theory

Almost Modules

Prop.(4.8.1.1)[Examples].

- If $K$ is a perfectoid field, $R = K^0, I = K^{00}$, then $I$ is flat over $R$, because if $\pi$ is a pseudo-uniformizer of $K(10.3.8.9)$, then $I = (\pi^{1/p^n})$, which is a colimit of free modules thus flat, and $I^2 = I$ clearly.

- Let $R$ be a ring and $f$ is an arbitrary element with compatible $p^n$-th roots, let $I = (f^{1/p^n})$, then $I^2 = I$. To show $I$ is flat, consider:

\[
\begin{align*}
M_0 &\xrightarrow{f^{1/p^n}} M_1 \xrightarrow{f^{1/p^n}} M_2 \to \ldots \to M_n \xrightarrow{f^{1/p^{n+1}}} M_{n+1} \to \ldots
\end{align*}
\]

where $M_i \cong R$, and $M = \text{colim} M_i$, then $M$ is flat, and there is a map $M \to I : 1 \in M_n \to f^{1/p^n}$, then this map is surjective, and it is injective: if $\alpha$ maps to 0, then $\alpha f^{1/p^n} = 0$, so $\alpha p^n f = 0$ for all $m \geq n$, and by perfectness of $R$, $\alpha f^{1/p^n} = 0$, so in particular, $\alpha = 0 \in M_{n+1}$.

Prop.(4.8.1.2)[The Category of Almost $R$-Modules in disguise]. Let $\mathcal{A} \subset \text{Mod}_R$ be the category of all $R$-modules $M$ that the action $I \otimes M \to M$ is an isomorphism(If $I \otimes I = I$ this is equivalent to $M = I \otimes N$ for some $N$) then:

- The inclusion $j_! : \mathcal{A} \to \text{Mod}_R$ is exact, i.e. the cokernel, kernel of objects in $\mathcal{A}$ are also in $\mathcal{A}$.

- $j_!$ has a right adjoint $j^* : M \to I \otimes M$, and the unit map $N \to j^* j_! N$ is an isomorphism on $\mathcal{A}$.

- $j^*$ has its right adjoint $j_*(M) = \text{Hom}(I, M)$, and the counit $j^* j_! M \to M$ is an isomorphism on $\mathcal{A}$.

Proof: 1: an easy consequence of five-lemma.

2: We need to show for $N \in \mathcal{A}$, $\text{Hom}(N, I \otimes M) \cong \text{Hom}(N, M)$. Notice there is a distinguished triangle

\[
I \otimes M \to M \to M \otimes R/I,
\]
as $- \otimes_R^L M$ is a derived functor and $I$ is flat. So it suffices to show

\[
R \text{Hom}_R(N, M \otimes_R^L R/I) = 0 = R \text{Hom}_{R/I}(N \otimes_R^L R/I, M \otimes_R^L R/I).
\]

And in fact $N \otimes_R^L R/I = 0$, because $N \otimes_R^L R/I = N \otimes_R^L I \otimes_R^L R/I$, and $I \otimes_R^L R/I = I \otimes_R R/I = I/I^2 = 0$ by flatness and hypothesis.

$N \cong j^* j_! N$ is an easy consequence of $I \otimes I = I$. 

Prop. (4.8.1.3) [Category of Almost \( R \)-modules].

- The image of the functor \( i_* : \text{Mod}_{R/I} \to \text{Mod}_R \) is a Serre subcategory of \( \text{Mod}_R \), so the quotient \( \text{Mod}^a_R = \text{Mod}_R / \text{Mod}_{R/I} \) exists by (3.3.2.14),
- The quotient \( q : \text{Mod}_R \to \text{Mod}^a_R \) admits fully faithful left and right adjoints. In particular, \( q \) preserves all limits and colimits.
- The image of \( i \) is a ‘tensor ideal’ of \( \text{Mod}_R \), so the quotient \( \text{Mod}^a_R \) inherits a natural symmetric monoidal \( \otimes \)-product structure.
- There is a functor \( \text{alHom} : (\text{Mod}^a_R)^{\text{op}} \times \text{Mod}^a_R \to \text{Mod}^a_R : (X,Y) \to \text{alHom}(X,Y) \) that \( \text{alHom}(X,-) \) is right adjoint to \( - \otimes X \):

\[
\text{Hom}(Z \otimes X, Y) \cong \text{Hom}(Z, \text{alHom}(X,Y)).
\]

Proof: 1: the image of \( i_* \) is just the category of modules killed by \( I \), if \( M \) is killed by \( I \), then subobjects and quotients of \( M \) is killed by \( I \), and if \( M \) is an extension of two elements killed by \( I \), then \( IM = I^2M = 0 \).

2: In fact we show that the category \( A \) in (4.8.1.2) and the functor \( j^* \) is just equivalent to \( \text{Mod}^a_R \):

First: \( j^*(\text{Mod}_{R/I}) = 0 \), because \( I \otimes M = I \otimes R/I \otimes R/I M = I/I^2 \otimes R/I M = 0 \) as \( I = I^2 \), and \( j^* \) is exact because \( I \) is flat.

And for any \( R \)-module \( M \), consider \( I \otimes M \to M \), it has kernels and cokernels, then tensoring \( I \), it becomes \( I \otimes M \to I \otimes M (4.8.0.1) \). as \( I \) is flat, the kernel and cokernels are killed by \( I \), so for any functor \( q \) to another category that kills \( \text{Mod}_{R/I} \), \( q(M) = q(I \otimes M) = qj_0j^*(M) \), so \( q \) factors through \( M \), uniquely, as \( j^* \) is surjective.

Now the left/right adjoints exist by (4.8.1.2).

3: if \( IM = 0 \), then \( IM \otimes N = 0 \), so the tensor products pass to the quotient, and \( j^* \) is a map between symmetric monoidal categories.

4: \( \text{alHom} \) is defined by \( \text{alHom}(j^*M, j^*N) = j^*(\text{Hom}(M,N)) = \text{Hom}(M,N)^a \). This is well defined, because if \( IM = 0 \) or \( IN = 1 \), then \( I \text{Hom}(M,N) = 0 \). □

Cor. (4.8.1.4).

- \( i^*j_! = 0 \).
- \( i^!j_* = 0 \).
- \( j^*i_* = 0 \), and the kernel of \( j^* \) is just \( i_*(\text{Mod}_{R/I}) \).

Proof: 1: \( R/I \otimes I \otimes M = 0 \), because \( I \otimes R/I = 0 \).

2: \( \text{Hom}(R/I, \text{Hom}(I, M)) = 0 \), because \( I \otimes R/I = 0 \).

3: This is by 2 of the proposition (4.8.1.3). □
**Remark (4.8.1.5).** The construction above can be summarized as the following diagram:

\[
\begin{array}{ccc}
\text{Mod}_{R/I} & \xrightarrow{i^*} & \text{Mod}_R \\
\downarrow{i_!} & & \downarrow{j_!} \\
\text{Mod}_R & \xrightarrow{j^*} & \text{Mod}_R^a
\end{array}
\]

with four adjoint pair and three vanishing. This should be seen as an analogy of the case of topology: \(X\) is a space and \(i: U \to X\) is open in \(X\), and \(j: Z \to X\) is closed, \(Z = X - U\), then the defined sheaf operations are the same as written above.

However, one should not consider \(\text{Mod}_R^a\) as the sheaf of modules on the open subscheme \(\text{Spec} R_f\) for some pseudo uniformizer, because the map \(M \to M \otimes R_f\) factors through \(\text{Mod}_R^a\) as it vanishes on \(\text{Mod}_{R/I}\), but it is not \(\text{Mod}_{R/I}^a\). For example, if \(k\) is a perfect field, and consider \(R = k[t^{1/p}]\), then the module \(M = R/(t)\) is also killed by \(\otimes R_f\), but it is not killed by \(I\).

Then one may consider it is the category of \(\text{Qco}\) sheaves on \(D(I)\), but first this is not an affine scheme, and second this is false, anyway. And we should imagine an non-existent open subscheme \(U\) bigger than \(U\), as it contains any affine opens of \(U\).

**Remark (4.8.1.6).** Notice \(j^*\) is both left exact and right exact, so it preserves both arbitrary limits and colimits, so almostification nearly loses anything. In particular, the category \(\text{Mod}_R^a\) has all colimits and limits.

**Def. (4.8.1.7) [Almost Commutative Algebras].** As \(\text{Mod}_R^a\) has a symmetric monoidal structure, it is possible to define the category of almost commutative algebras as the category of commutative unitary monids in \(\text{Mod}_R^a\), denoted by \(CAlg(\text{Mod}_R^a)\). Notice that its unit object is \(I = R^a\).

There is an obvious map

\((-)^a : \text{Alg}(\text{Mod}_R) \to \text{Alg}(\text{Mod}_R^a)\),

and yet another functor

\((-)_* : \text{Alg}(\text{Mod}_R^a) \to \text{Alg}(\text{Mod}_R),

because \(M \to M_*\) is lax symmetric monoidal, i.e. there are natural map \(M_* \otimes N_* \to (M \otimes N)_*\).

This is a right adjoint of \((-)^a\), as \(j^*\) and \(j_*\) is adjoint.

Finally there is a functor

\((-)!! : \text{Alg}(\text{Mod}_R^a) \to \text{Alg}(\text{Mod}_R),

whose construction is a little complicated, first notice the functor \((-)_!\) preserves multiplication but it has no units, so in order to give it a unit, consider the module pushout: \((A! \oplus V)/I\), which has a natural multiplicative structure that can be made into a \(R\)-module, and \((-)!!\) is left adjoint to \((-)^a\), Cf.[Almost Ring Theory P22].

**Prop. (4.8.1.8).** \((-)!!\) preserves faithfully flatness.

**Proof:** Cf.[Almost Ring theory P52]? \(\square\)

**Def. (4.8.1.9).** For an almost commutative algebra \(A\), a left module is an almost module \(M \subset \text{Mod}_R^a\) that has a left action \(A \otimes M \to M\) that has natural commutative diagrams as one expects. And for any \(R\)-algebra \(A\), there are natural maps \(\text{Mod}_A \to \text{Mod}_R^a A\).
Almost Homological Algebra

2 Almost Commutative Algebra

Def. (4.8.2.1) [Almost Notations]. Given a $R$-module $M$, an element $f \in M$ is called **almost zero** if $I \cdot f = 0$, and $M$ is called **almost zero** if all $f \in M$ is almost zero.

Denote

$$M^a = j^* M \in \text{Mod}^a_R, \quad M_s = j_s M^a = \text{Hom}(I, M), \quad M_t = j_t M^a = I \otimes M.$$  

Then there are morphisms $M_t \to M \to M_s$, which becomes isomorphisms after almostification.

Prop. (4.8.2.2). If $I = (f \frac{1}{f^n})$, then $M_s = \{x \in M[f^{-1}] | f^{\frac{1}{f^n}} x \in A\}$ for all $n$.

Prop. (4.8.2.3). If $M \to N$ is almost surjective maps of $K^0$-algebras that $M/I \to N/I$ is surjective, then $M \to N$ is surjective.

Proof: As $I$ is flat over $K^0$, if $M \to N \to Q \to 0$ is the cokernel, tensoring $A/I$, as $M/I \to N/I$ is surjective, $Q/IQ = 0$, but $Q$ is almost zero thus $IQ = 0$, so $Q = 0$. □

Def. (4.8.2.4) [Almost Properties]. Something is called **almost XXX** if it is XXX when passed to the category of almost $R$-modules. For example,

- elements of $M_s$ are called **almost elements** of $M$.
- $M$ is called **almost flat** iff $M^a \otimes -$ is exact on $\text{Mod}^a_R$, which is equivalent to $\text{Tor}^R_{>0}(M, N)$ is almost zero for all $N$.
- $M$ is called **almost projective** iff allHom$(M, -)$ is exact on $\text{Mod}^a_R$, which is equivalent to $\text{Ext}^R_{>0}(M, N)$ is almost zero for all $N$.

Notice this is not equivalent to projective in $\text{Mod}^a_R$, because $R$ is almost projective, but $\text{Hom}_{R^a}(R^a, M^a) = \text{Hom}(I, M)$ is not exact as $I$ is not projective: $\text{Ext}^1_R(R^a, M^a) = \text{Ext}^1_R(I, R) = \text{Ext}^2(k, R)$, which is not 0 if $R$ is the valuation ring of a non-spherically complete perfectoid field $K$, like $\widehat{Q_p}$?

- $M$ is called **almost finitely generated/ almost finitely presented** if for any $\varepsilon \in I$, there is a f.g./f.p. $M_\varepsilon \to M$ with $N_\varepsilon$ generators that the kernel and cokernel are killed by $\varepsilon$. It is called **uniformly almost finitely generated** iff $N_\varepsilon$ is independent of $\varepsilon$.

Notice this definition doesn’t depends on $M$ chosen?

- If $S$ is of charp, it is called **almost perfect** iff $S_\varepsilon$ is perfect.

Prop. (4.8.2.5) [Enough Almost Injectives]. The category $\text{mod}^a_R$ has enough injectives. In fact $j^*, j_s$ both preserves injectives, because they have exact left adjoints, so $I$ is injective $R$-module iff $I^a$ is injective $R^a$-module, and $J$ is injective $R^a$-module iff $J_s$ is injective $R$-module. So to construct an injective resolution in $R^a$, pass to $R$-modules using either $(-)_s$ or $(-)_t$; and find an injective resolution, then almostificate it.

Prop. (4.8.2.6) [Derived Functors of $(-)_s$]. Notice that $\text{Hom}_{R^a}(M^a, N^a) = \text{Hom}_R(I \otimes M, N)$ by adjointness, so using (4.8.2.5),

$$\text{Ext}^k_{R^a}(M^a, N^a) = \text{Ext}^k_R(M_s, N) = \text{Ext}^k_R(M, R \text{Hom}(I, N)),$$

then as $M_s = \text{Hom}(I, M)$, the derived functor of $(-)_s$ is just $\text{Ext}^k_R(I, M) = \text{Ext}^k_R(R^a, M^a)$.

Notice that $\text{Ext}^k_{R^a}(M, N)$ are all almost zero, as $j^a j_s = \text{id}$, and use trivial Grothendieck spectral sequence.
Prop. (4.8.2.7) [(Example) A Quadratic Extension of a Perfectoid Field]. If \( K = \hat{Q_p[p^{1/2}]} \) and \( L = K(\sqrt[p]{b}) \) with \( p \neq 2 \), then \( L^0 \) is a uniformly almost f.p. projective \( K^0 \)-module.

**Proof:** It suffices to find for each \( n \) a \( K^0 \)-module \( R_n \) of rank 2 that \( R_n \rightarrow L^0 \) is injective with cokernel annihilated by \( p^\frac{1}{2n+1} \). For this, consider \( R_n = K^0 \oplus K^0 p^\frac{1}{2n+1} \), then \( L^0 = \text{colim}_n R_n \).

Notice that the cokernel of \( R_n \rightarrow R_{n+1} \) is killed by \( p^{\frac{1}{2n+1}} \), because

\[
p^{\frac{1}{2n+1}} \cdot p^{\frac{1}{2n+1}} = p^{\frac{1}{2n+1} + \frac{1}{2n+1}} \subset R_n.
\]

So by killing one by one, the cokernel of \( R_n \rightarrow \text{colim}_n R_n \) is killed by any \( p \)-power with power larger than \( \sum \frac{1}{2n+1} \), in particular by \( p^{\frac{1}{2n+1}} \). So \( \text{colim}_n R_n \) is an extension of \( R_0 \) by a cokernel killed by \( p \), so it is also \( p \)-adically complete, and \( L^0 = \text{colim}_n R_n \). Now Consider \( 0 \rightarrow R_n \rightarrow \text{colim}_n R_n \rightarrow \text{Coker} \), then \( \text{Ext}^n(\text{colim}_n R_n, N) = \text{Ext}^n(\text{Coker}, N) \) is killed by \( p^{\frac{1}{2n+1}} \) for all \( n \), so it is killed by \( I \), thus \( \text{colim}_n R_n \) is almost projective.

**Completions and Closures**

Prop. (4.8.2.8) [\( \text{prc and Completion} \)]. If \( A \) is a ring with a non-zero-divisor \( f \) that \( A \subset A[f^{-1}] \) is \( p \)-root closed (prc), then:

- \( \hat{A} \subset \hat{A}[f^{-1}] \) is \( p \)-root closed.

- If \( f \) admits a compatible \( p \)-power roots, then \( A_s \subset A_s[f^{-1}] \) is \( p \)-root closed (where almost mathematics is performed w.r.t \( f^{\frac{1}{2n+1}} \)).

**Proof:** We first replace \( A \) with its maximal separated quotient \( A/(\cap_n f^n A = I) \): \( f \) is still non-zero-divisor, because if \( fg \in I \), then \( fg \in f^n A \) for all \( n \), so \( g \in f^{n-1} A \) as \( f \) is non-zero-divisor. And it is \( p \)-root closed, because if \( a^n \in A/I[f^{-1}] \), then \( a^n = b + f^{-c}d \) for \( c \) integer and \( d \in I \). Notice \( I = fI = f^c I \) by (4.2.2.16), so \( f^{-c}d \in I \) as well, so \( a \in A \).

Now \( \hat{A} \) is \( f \)-separated, in particular, \( A \hookrightarrow \hat{A} \).

1: If \( g \in \hat{A}[f^{-1}] \) and \( g^n \in \hat{A} \), then \( f^N g \in \hat{A} \) for some \( N \) and choose a \( m \geq N(p - 1) \), then by the density, \( g = g_0 + f^m g_1 \) for some \( g_0 \in A[f^{-1}] \), \( g_1 \in \hat{A} \). Notice \( f^N g_0 \in \hat{A} \), now

\[
g^n = g_0^n + p g_0^{n-1} f^m g_1 + \ldots + (f^m g_1)^n,
\]

By definition of \( m \), all terms except \( g_0^n \) are in \( \hat{A} \), so \( g_0 \in A \), so \( g_0 \in A \), and \( g \in \hat{A} \).

2: Use the convention (4.8.2.2), if \( g \in A_s[f^{-1}] \) that \( g^n \in A_s \), then \( f^{\frac{1}{2n}} g^n \in A \) for all \( n \), so \( (f^{\frac{1}{2n+1}} g)^n \in A, \) thus \( f^{\frac{1}{2n+1}} g \in \hat{A} \), hence \( g \in A_s \). \( \square \)

Prop. (4.8.2.9) [\( \text{ic and Completion} \)]. Let \( A \) be a ring with a non-zero-divisor \( f \), if \( A \subset A[f^{-1}] \) is integrally closed, then:

- \( \hat{A} \subset \hat{A}[f^{-1}] \) is integrally closed.

- If \( f \) admits a compatible \( p \)-power roots, then \( A_s \subset A_s[f^{-1}] \) is integrally closed (where almost mathematics is performed w.r.t \( f^{\frac{1}{2n+1}} \)).

**Proof:** We first replace \( A \) with its maximal separated quotient \( A/(\cap_n f^n A = I) \): \( f \) is still non-zero-divisor and \( I \) is \( f \)-divisible as in the proof of (4.8.2.8). And it is integrally closed, because if \( g \)
satisfies a monic polynomial \( h(X) \in A/I[f^{-1}][X] \), then choose a lifting, \( h(g) \in I[f^{-1}] = I \subset A \), so \( g \) is integral over \( A \) thus \( g \in A \), and \( g \in A/I \). Now \( A \) is \( f \)-separated and \( A \hookrightarrow \hat{A} \).

1. If \( g \in \hat{A}[f^{-1}] \) satisfies a polynomial \( H \in \hat{A}[X] \), then \( g = f^{-c}h \) for \( h \in \hat{A} \), and then \( h \) satisfies a polynomial \( H(f^c x) \), and choose an approximation of coefficients of \( H(x) \) and \( h_0 \) of \( h \) mod \( f^{cn} \), then it is clear that \( H(f^c h_0) \in f^{cn} \hat{A} \cap A = f^{cn} A \), so when dividing back, \( g_0 = f^{-c} h_0 \) is integral over \( A \) thus \( g_0 \in A \), thus \( h_0 \in f^c A \), and \( h \equiv h_0 \) mod \( f^{cn} \), thus \( h \in f^c A \), and \( g \in A \).

2. Use the convention (4.8.2.2), if \( g \in A_\ast[f^{-1}] \) is integral over \( A_\ast \), then there are polynomial \( H \) that \( H(g) = 0 \), now if \( \varepsilon = f^{\frac{1}{p^n}} \) consider another polynomial \( H(x/\varepsilon) \), then its coefficients are all in \( A \), thus \( \varepsilon g \) is integral over \( A \) thus \( \varepsilon g \in A \), and then \( g \in A_\ast \).

\[
\text{Prop. (4.8.2.10) [tic and Completion].} \text{Let } A \text{ be a ring with a non-zero-divisor } f \text{ that admits a compatible system of } p\text{-power roots } f^{\frac{1}{p^n}} \text{ for all } n > 0, \text{ and } A \text{ is totally integrally closed (tic) in } A[f^{-1}] \text{, then } \hat{A} \text{ is totally integrally closed in } \hat{A}[f^{-1}] \text{ and } A = A_\ast.
\]

\[
\text{Proof:} \quad 1: \text{Notice totally integrally closed is } p\text{-root closed, so } \hat{A} \subset \hat{A}[f^{-1}] \text{ is } p\text{-root closed. Now if } f^{k} g^N \subset \hat{A} \text{ for some } k, \text{ then by prc, } f^{\frac{1}{p^n}} g \in \hat{A} \text{ for all } n, \text{ thus } g \text{ in an almost zero element in } \hat{A}[f^{-1}]/A \cong A[f^{-1}]/A, \text{ and then } g \text{ is totally integrally closed over } A, \text{ because for any } n, \text{ let } n < p^k, \text{ then } f^{\frac{1}{p^n}} g \in A, \text{ thus } f^{\frac{1}{p^n}} g \in A, \text{ and } fg^n \in A.
\]

\[
\begin{align*}
\text{2: Because } f^{\frac{1}{p^n}} A_\ast & \subset A \text{ by convention (4.8.2.2), clearly } A_\ast \text{ is totally integrally closed in } A, \text{ thus } A_\ast \subset A. \\
\end{align*}
\]

**Almost Étale Map**

\[
\text{Def. (4.8.2.11). A map } A \to B \text{ of } R\text{-algebras is called almost étale iff:
\begin{itemize}
\item \( B \) is almost f.p. projective over \( A \).
\item \( \mu \) is almost f.p. projective over \( A \).
\end{itemize}
}\]

\[
\text{Prop. (4.8.2.12) [Example of Almost Étale Maps]. Let } K = Q_p[p^{\frac{1}{p^n}}] \text{ and } L = K(\sqrt[p]{p}) \text{ with } p \neq 2, \text{ then } L^0/K^0 \text{ is uniformly almost f.p projective } K^0\text{-module, by (4.8.2.7). We show it is finite étale: flatness is clear, as } L^0/K^0 \text{ is torsion-free and } K^0 \text{ is a valuation ring and use (4.8.3.3).}
\]

**Lemma (4.8.2.13) [Lemma for Almost Purity in Characteristic } p]. \text{If } \eta : R \to S \text{ is an integral map of perfect rings. If } \eta[t^{-1}] \text{ is finite étale for some } t \in R, \text{ then } \eta \text{ is almost finite étale w.r.t the ideal } I = (t^{\frac{1}{p^n}}).
\]
Proof: Firstly, we may assume $R, S$ are both $t$-torsion-free, because the $t$-torsion part $R[t^\infty]$ and $S[t^\infty]$ is almost zero: if $t^c\alpha = 0$, then $t^c\alpha^{p^n} = 0$, so $t^{\frac{c}{p^n}}\alpha = 0$. So we reduce to $R/R[t^\infty] \to S/S[t^\infty]$, which doesn’t change anything.

Now we reduce to the case that $R, S$ are integrally closed in $R[t^{-1}]$ and $S[t^{-1}]$: it suffices to show that $R_{int} \subset R_*$, thus they are almost isomorphic. For this, an element $f \in R_{int}$ satisfies $f^{R_0} t^k \in R$ for some $k$, so by perfectness, $ft^{\frac{1}{pm}} \in R$ for all $n$, so $f \in R_*$.

Now check unramifiedness: let $e \in (S \otimes_R S)[t^{-1}]$ be a diagonal idempotent, then $\alpha e \in S \otimes_R S$ for some $c$, now $e^2 = e$, so easily $e \in (S \otimes_R S)_*$.

Now check almost finite projective: for $m > 0$, represent $t^{\frac{1}{pm^m}} e = \sum a_i \otimes b_i \in S \otimes_R S$, then use the map $S \overset{\alpha}{\to} R^n \overset{\beta}{\to} S$ as in (4.4.7.14), then $\beta \alpha = t^{\frac{1}{pm}}$ on $S$, as $S$ is $t$-torsion free, $R^n \to S$ is injective with $t^{\frac{1}{pm}}$-torsion cokernel, for any $m$. So $S$ is almost finite projective. □

Prop.(4.8.2.14)[Almost Purity in Characteristic $p$]. If $R$ is a perfect ring of char $p$, then using the almost mathematics w.r.t. $I = (t^{\frac{1}{pm}})$, $S \to S_*[t^{-1}]$ gives an isomorphism of categories: $R_{af\ell t} \cong R[t^{-1}]_f\ell t$.

Proof: As in the proof of (4.8.2.13), we may assume $R$ is $t$-torsion-free. Notice that any integral extension of $R[t^{-1}]$ comes from an integral extension of $R$(choose the integral closure), so the lemma above (4.8.2.13) tells us the functor is essentially surjective.

Now we construct an inverse functor, $S_*[t^{-1}]$ maps to $T^a$, where $T$ is the integral closure of $R$ in $S_*[t^{-1}]$. By lemma (4.8.2.15) below, $S$ is almost perfect. So $S_*$ is $t$-torsion-free, as if $t^c f = 0$, then $t^{\frac{1}{pm}} f = 0$ for all $n$, so $f = 0 \in (S_*)_s = S_*$. So now $S_* \subset S_*[t^{-1}]$. Clearly $T$ is also perfect and $t$-torsion-free. So $R \to T$ is an integral extension that is identified with $R[t^{-1}] \to S_*[t^{-1}]$ after inversion of $t$.

To show that $T^a = S$, it suffices to show $T_* = S_*$. for $f \in T$, $f^{R_0}$ spans a finite module of $T[t^{-1}] = S_*[t^{-1}]$, so $t^c f^{R_0} \subset S_*$, then by perfectness, $f \in (S_*)_s = S_*$, so $T_* \in S_*$. Conversely, if $g \in S_*$, then $t^c g^{R_0}$ lies in a f.g. $R$-module of $S_*[t^{-1}]$, by almost f.g.. So $t^c g^{R_0} \subset T$, and then by perfectness $g \in T_*$. □

Lemma (4.8.2.15). Almost finite étale map of rings of char $p$ is almost relatively perfect.

Proof: Cf.[Bhatt notes on Perfectoid Spaces P28]. □

3 Almost Mathematics on Perfectoid Fields

Prop. (4.8.3.1)[Almost Elements]. If $K$ is a perfectoid field, $R = K^0$ and $I = K^{00}$, $M$ is an $R$-module, then

- If $M$ is torsion-free, then $M_* = \{m \in M \otimes_{K^0} K \mid Im \in M\} = \{m \in M \otimes_{K^0} K \mid t^{\frac{1}{pm}} m \in M\}$, by (10.3.8.12) and (4.8.2.2).
- $I_* = R_* = R$. More generally, for an ideal $J \subset R$, let $c = \sup \{|x| \mid x \in J\}$, then $J_* = \{a \in K_* \mid |a| \leq c\}$.

Prop. (4.8.3.2). Let $K$ be a perfectoid field with a pseudo-uniformizer $\pi$. If $\alpha : M \to N$ is an almost surjective map of $K^0$-algebras that $M$ is $\pi$-adically separated and $N$ is $\pi$-torsion-free that $\alpha \mod \pi$ is an almost isomorphism, then $\alpha$ is an almost isomorphism.
Prop. (4.8.3.3) [Almostification and Completeness]. Let \( K \) be a perfectoid field with a pseudo uniformizer \( t \) and \( R = K^0_1, I = K^{00}_1 \), let \( M \in \text{Mod}_R^a \), then:

- \( M \) is almost flat iff \( M_* \) is \( R \)-flat iff \( M_t \) is \( R \)-flat.
- Assume \( M \) is almost flat, then \( M \) is \( t \)-adically complete iff \( M_* \) does.
- Assume \( M \) is almost flat, then for each \( f \in K^0_1 \), \( fM_* \cong (fM)_* \), and \( M_*/fM_* \subset (M/fM)_* \).

And for any \( \varepsilon \in I \), the image of \((M/f\varepsilon M)_* \) and \( M_*/fM_* \) in \((M/fM)_* \) are identical.

**Proof**: 1: \( R \) is a valuation ring, so \( M_* \) is \( R \)-flat iff \( M_*[t] \) is flat by (4.4.1.12), as \( t \) is a pseudo uniformizer. As \((-)_* \) is left exact, \( M_*[t] = (M[t])_* \), so if \( M \) is almost flat, then \( M[t] = 0 \) as \( t \) is nonzero-divisor, so \( M_* \) is \( R \)-flat. The converse is true as \( M = (M_*)^a \), and the tensor is compatible.

For \((-)_t \), this follows from the observation that \((-)_t \) and \((-)_a \) are both exact and commute with tensor products, and notice \( M_t \otimes N = (M \otimes N)^a \).

2: As \((-)_a \) commutes with all limits and colimits, if \( M_* \) is \( t \)-adically complete then so does \( M = (M_*)^a \). Conversely, if \( M \) is \( R \)-flat and \( t \)-adically complete, then \( M_t, M_* \) are also \( R \)-flat, and consider the commutative diagram:

\[
\begin{array}{c}
M_t \xrightarrow{a} \lim(M/t^nM)_t = \lim M_t/t^nM_t = \hat{M}_t \\
\downarrow d \quad \quad \quad \downarrow b \\
M_* \xrightarrow{c} \lim(M/t^nM)_* 
\end{array}
\]

then \( d \) is almost isomorphism by (4.8.1.2) and so does \( b \) because \((-)_a \) commutes with all limits, and \( c \) is an isomorphism as \((-)_* \) commutes with limits and \( M \) is \( t \)-adically complete. So \( a \) is also almost isomorphism.

Now notice \( M_t \) is flat hence \( t \)-torsion-free, so the kernel of \( a, d \) must be 0, with almost zero cokernels. Now (4.2.3.9) shows first \( M_t \) is complete and next \( M_* \) is complete.

3: Notice \((fM)_* = fM \) as \((-)_a \) is exact, so

\[
(fM)_* = \text{Hom}(I, fM_*) = \{ y \in M_*[t^{-1}] | Iy \subset fM_* \} = f\{ y \in M_*[t^{-1}] | Iy \subset M_* \} = fM_*
\]

and \( M_*/fM_* \subset (M/fM)_* \) follows from the left exactness of \((-)_* \).

For the last assertion, consider the commutative diagram

\[
\begin{array}{c}
0 \longrightarrow M \xrightarrow{f} M \longrightarrow M/fM \longrightarrow 0 \\
0 \longrightarrow M/\varepsilon M \xrightarrow{f} M/f\varepsilon M \longrightarrow M/fM \longrightarrow 0
\end{array}
\]

and apply \((-)_* = \text{Hom}_{R^a}(R^a, -) \) and use (4.8.2.6), then

\[
\begin{array}{c}
0 \longrightarrow M_*/fM_* \xrightarrow{a} (M/fM)_* \longrightarrow \text{Ext}_{R^a}^1(R^a, M)[f] \longrightarrow 0 \\
0 \longrightarrow (M/f\varepsilon M)_* \xrightarrow{b} (M/fM)_* \longrightarrow \text{Ext}_{R^a}^1(R^a, M/\varepsilon M)
\end{array}
\]
To show \( a, b \) has the same image, it suffices to show that \( c \) is injective. For this, it suffices to show \( \text{Ext}^1_{R^a}(R^a, M) \rightarrow \text{Ext}^1_{R^a}(R^a, M/\varepsilon M) \) is injective. Consider the exact sequence \( 0 \rightarrow M \xrightarrow{\varepsilon} M \rightarrow M/\varepsilon M \rightarrow 0 \), it suffices to show that \( \varepsilon \text{Ext}^1_{R^a}(R^a, M) = 0 \), and this is obvious as \( \varepsilon \in I(4.8.2.6) \).

\[ \Box \]

Prop. (4.8.3.4) [General Completeness and Almostification]. More generally, if \( J = (f_1, \ldots, f_r) \subset R \) is a f.g. ideal, then an \( R^a \)-module \( M \) is \( J \)-adically complete if \( M^* \) does.

Proof: Cf.[Perfectoid Spaces Bhatt P32].

Banach Space

Prop. (4.8.3.5) [Uniform Banach \( K \)-Algebra]. If \( K \) is a non-Archimedean perfectoid(perfect) field with a pseudo uniformizer \( t \), then the following categories are equivalent:

- The category \( \mathcal{D}_{tic} \) of \( t \)-adically complete and \( t \)-torsionfree \( K^0 \)-algebras \( A \) with \( A \) totally integrally closed in \( A[t^{-1}] \).
- The category \( \mathcal{D}_{ic} \) of \( t \)-adically complete and \( t \)-torsionfree \( K^0 \)-algebras that \( A \) is integrally closed in \( A[t^{-1}] \) and \( A = A_* \).
- The category \( \mathcal{D}_{prc} \) of \( t \)-adically complete and \( t \)-torsionfree \( K^0 \)-algebras that \( A \) is \( p \)-root closed in \( A[t^{-1}] \) and \( A = A_* \).

Proof: The last three are equivalent, because if \( A \in \mathcal{D}_{tic} \), then \( A = A_* \) by (4.8.2.10), as \( K \) is perfect by (10.3.8.4). So \( \mathcal{D}_{tic} \subset \mathcal{D}_{ic} \subset \mathcal{D}_{prc} \), so it suffices to show that \( \mathcal{D}_{prc} \subset \mathcal{D}_{tic} \). Now for any \( f \) that \( f^N \subset t^{-k}A \), then \( t^k f^N a \subset A \), and \( A \) is \( p \)-root closed, so \( t^{\frac{k}{n}} f \subset A \) for all \( n \), so \( f \in A_* \) (4.8.2.3), but \( A_* = A \).

The equivalence of 1, 2 is general, by (12.1.2.7).

\[ \Box \]

Prop. (4.8.3.6). If \( K \) is a perfectoid field, then the category of uniform Banach spaces has all colimits and limits.

Proof: Cf.[Bhatt P38].

\[ \Box \]

5.1 Sites, Sheaves and Stacks

References are [Sta], [Ols16], [Vis08] and [Fibered Category to Algebraic Stacks Lamb].

1 Sites

Def. (5.1.1.1) [Sites]. A site is given by a category \( \mathcal{C} \) and a set \( \text{Cov}(\mathcal{C}) \) of families of morphisms with fixed target, called the coverings of \( \mathcal{C} \) that:

- An isomorphism is a covering.
- Coverings of covering is a covering.
- Base change of a covering is a covering.

Sometimes a site is wrongly called a topology, the difference is that the morphism of site is looks like a reverse of a morphism of topology (5.1.1.5).

Def. (5.1.1.2) [Discrete Topology]. A discrete topology or chaotic topology is a site that the only coverings are identities. In this way, we can regard any category as a site.

Def. (5.1.1.3) [Noetherian Topology]. An object \( U \) in a site \( \mathcal{C} \) is called quasi-compact if for each covering of \( U \), f.m. of them still forms a covering of \( U \). The site \( \mathcal{C} \) is called Noetherian if each object of \( \mathcal{C} \) is quasi-compact.

Given a site \( \mathcal{C} \), we can define a new site \( \mathcal{C}' \) whose coverings are coverings of \( \mathcal{C} \) that are finite. Then this is truly a site and it is Noetherian.

Def. (5.1.1.4) [Comma Topology]. For a site \( \mathcal{C} \) and an object \( S \), we have the comma category \( \mathcal{C}/S(3.1.1.17) \), and we can define a topology on it where the coverings are coverings of \( \mathcal{C} \) that is compatible over \( S \).

Def. (5.1.1.5) [Continuous Functor]. A continuous functor between sites \( \mathcal{C} \to \mathcal{D} \) is a functor that preserves covering and any base change by morphisms in a covering.

A morphism of sites \( \mathcal{C} \to \mathcal{D} \) is given by a continuous functor \( u : \mathcal{D} \to \mathcal{C} \) that \( u_*(5.1.2.11) \) is exact.

This exact condition is easy to be satisfied, by (5.1.2.14).

Def. (5.1.1.6) [Cocontinuous functors]. A cocontinuous functor between sites \( u : \mathcal{C} \to \mathcal{D} \) is a functor that for any \( U \in \mathcal{C} \) and any covering \( \{V_i \to u(U)\} \) in \( \mathcal{D} \), there is a covering \( \{U_i \to U\} \in \mathcal{C} \) that refines \( \{V_i \to u(U)\} \) after the functor \( u \).
Topologies and Sieves

Def. (5.1.1.7) [Sieves]. For a covering $U = \{U_i \to U\}$ in a category $\mathcal{C}$, define a subfunctor $h_U \subset h_U$, where for each $X$ $h_U(X)$ consists of elements in $\text{Hom}(X,U)$ that factor through some $U_i \to U$.

A sieve $S$ on $U$ is a subfunctor of $h_U$. Notice that any sieve must be of the form $h_U$, by choosing $U$ to consist of all arrows in $\{S(T)\}_{T \in \mathcal{C}}$.

Def. (5.1.1.8). If $\mathcal{T}$ is a Grothendieck topology on a category $\mathcal{C}$, then a sieve $S \subset h_U$ over $U$ is said to belong to $\mathcal{T}$ or just a sieve of the site $\mathcal{C}$ if there exists a covering $\mathcal{U}$ of $U$ that $h_U \subset S$.

$G$-Spaces

Def. (5.1.1.9) [G-Spaces]. A $G$-space is a set $X$ with a family of subsets of $X$ that they form a site w.r.t inclusions and that covering are all set-theoretic coverings (but not necessarily conversely). These subsets are called admissible opens of $X$ and covers are called admissible covers. (In other words, a $G$-topological space is a "topological space without unions"). Morphisms of $G$-spaces is simultaneously a continuous map and a morphism of sites.

Def. (5.1.1.10) [Completeness]. The completeness of a $G$-topological space $X$:

- G0: $\emptyset$ and $X$ are admissible open.
- G1: Let $\{U_i \to U\}$ be an admissible cover, then a subset $V \subset U$ is admissible if $V \cap U_i$ are all admissible.
- G2: Let $\{U_i \to U\}$ be a cover of admissible opens for $U$ admissible, then the cover is admissible if it has an admissible cover as a refinement.

Lemma (5.1.1.11) [Admissible is Local]. If $G_2$ is satisfied for a $G$-topological space $X$, then for an admissible covering $\{X_i \to X\}$ and another covering $\{U_i \to X\}$ between admissible opens, it is admissible iff $U_i \cap X_j$ is an admissible covering for $X_j$ for each $j$. (By composition, $\{U_i \cap X_i \to X\}$ is admissible, and it refines $\{U_i \to X\}$).

Prop. (5.1.1.12) [Glue of Complete G-topological spaces]. For sets $\cup X_i = X$, if there are Grothendieck category $\mathcal{I}_i$ on $X_i$ making $X_i$ into a $G$-topological space, and they all satisfies the completeness conditions $G_0$, $G_1$, $G_2$ of (5.1.1.10). Assume that $X_i \cap X_j$ is $\mathcal{I}_i$-open in $X_i$ and $\mathcal{I}_i, \mathcal{I}_j$ restrict to the same topology on $X_i \cap X_j$, then there is a unique Grothendieck category $\mathcal{I}$ on $X$ making $X$ a $G$-topological space that:

- $X_i$ is $\mathcal{I}$-open and $\mathcal{I}$ restricts to $\mathcal{I}_i$ on $X_i$,
- $\mathcal{I}$ satisfies the completeness conditions $G_0, G_1, G_2$.
- $X_i$ is a $\mathcal{I}$-covering of $X$.

Proof: By (5.1.1.10) and (5.1.1.11), the uniqueness is straightforward, for the existence,

- check Grothendieck first: Composition, base change.
- check condition 1: by hypothesis, and (5.1.1.10) applied to $X_i \cap X_j \to X_i$ (this is admissible because id$_X$, refined it).
- check condition 2: $G_0$ obvious, $G_1$ by if $V \cap U_i \cap X_i$ admissible, then $V \cap X_i$ admissible by admissibility of $U_i \to U$, then $V$ is admissible, $G_2$: obvious
- check condition 3: because $X_i \cap X_j \to X_i$ is admissible.
Def. (5.1.1.13). A $G$-topological space is called **connected** iff there isn’t two nonempty admissible open subset $X_1, X_2$ that $X_1 \cap X_2 = \emptyset$ and $\{X_1, X_2 \to X\}$ is an admissible cover.

**$G$-torsor**

Def. (5.1.1.14) [Torsors]. Let $\mathcal{C}$ be a site and $\mathcal{G}$ a sheaf of groups over $\mathcal{C}$, then a **pseudo $G$-torsor** is a sheaf of sets $\mathcal{F}$ over $\mathcal{C}$ endowed with an action $\mathcal{G} \times \mathcal{F} \to \mathcal{F}$ that $\mathcal{G} \times \mathcal{F} \to \mathcal{F} \times \mathcal{F} : (g, f) \mapsto (gf, f)$ is an isomorphism.

A pseudo $G$-torsor is called a **$G$-torsor** if for any $U \in \mathcal{C}$, there is a covering $\{U_i \to U\}$ that $\mathcal{F}(U_i)$ is non-empty for each $i$.

Prop. (5.1.1.15). A $G$-torsor on a site is trivial iff $\Gamma(\mathcal{C}, \mathcal{F}) \neq 0(5.3.1.2)$.

Proof: This is because the transitive action of $\mathcal{G}$ on the global section induces an isomorphism $\mathcal{G} \to \mathcal{F}$. □

Prop. (5.1.1.16). If $\mathcal{C}$ is a subcanonical site, and $\mathcal{G}$ a sheaf of groups over $\mathcal{C}$, then a sheaf of sets $\mathcal{F}$ together with an action $\alpha : \mathcal{G} \times \mathcal{F} \to \mathcal{F}$ is a $G$-torsor iff for any $U \in \mathcal{C}$, there is a covering $\{U_i \to U\}$ that the restrictions to $U_i$ are trivial torsors, i.e. $\alpha|_{\mathcal{C}/U_i} = \pi : \mathcal{G}|_{U_i} \times \mathcal{F}|_{U_i} \to \mathcal{F}|_{U_i}$.

Proof: If $\mathcal{F}$ is a $G$-torsor, then the restrictions of the torsor on $U_i$ are trivial because they have global sections in $\Gamma(\mathcal{C}/U_i, \mathcal{F}) = \mathcal{F}(U_i)$, by (5.1.1.15). Conversely, if there is a covering $\{U_i \to U\}$ that the restrictions to $U_i$ are trivial torsors, then the map $\mathcal{G} \times \mathcal{F} \to \mathcal{F} \times \mathcal{F} : (g, f) \mapsto (gf, f)$ are isomorphisms when restricted to $U_i$, which means $\mathcal{G}(U) \times \mathcal{F}(U) \to \mathcal{F}(U) \times \mathcal{F}(U)$ is an isomorphism for any $U$, because they are sheaves, so it is an isomorphism, and $\mathcal{F}$ is a $G$-torsor. □

Cor. (5.1.1.17) [Representable $G$-Torsor]. If $\mathcal{C}$ is a site and $\mathcal{G}$ is a group object in $\mathcal{C}$, then

- $X \to Y$ is a $G$-torsor in the category $\mathcal{C}/Y$ iff $X \to Y$ is a $G$-equivariant map(where the action of $G$ on $Y$ is trivial), $G \times X \to X \times_Y X : (g, x) \mapsto (gx, x)$ is an isomorphism, and $\{X \to Y\}$ is refined by a covering of $Y$.

- If $\mathcal{C}$ is a subcanonical site, then $X \to Y$ is a $G$-torsor in the category $\mathcal{C}/Y$ iff $X \to Y$ is a $G$-equivariant map(where the action of $G$ on $Y$ is trivial), and there exists a covering $\{Y_i \to Y\}$ that each $Y_i \times_Y X \to Y_i$ is a trivial torsor, i.e. $G$-equivariantly isomorphic to $G \times Y_i \to Y_i$.

Cor. (5.1.1.18). If $\mathcal{C}$ is a site and $\mathcal{G}$ is a group object in $\mathcal{C}$, $X \to Y$ is a $G$-torsor in the category $\mathcal{C}/Y$, then the map $G \times G \times X \to X \times_Y X \times_Y X : (g, h, x) \mapsto (ghx, hx, x)$ is an isomorphism.

**Presheaves**

Def. (5.1.1.19) [Presheaves]. On a category $\mathcal{C}$, a **presheaf** of sets/groups/* is a functor $\mathcal{C}^{op} \to \text{Ab}(\text{Set} / \mathcal{G})$. The category of presheaves of sets/groups/* on $\mathcal{C}$ is denoted by $\mathcal{PSh}(\mathcal{C})$ (or $\mathcal{PSh}^{\text{Set}}(\mathcal{C}), \mathcal{PSh}^{\text{Gp}}(\mathcal{C}), \mathcal{PSh}^{*}(\mathcal{C})$). For any $U \in \mathcal{C}$, $\Gamma(U, -)$ is the functor $\mathcal{PSh}^{\text{Set}}(\mathcal{C}) \to \text{Set} : F \mapsto F(U)$.

For a presheaf $\mathcal{F}$ with structures, $\mathcal{F}^{\text{Set}} \in \mathcal{PSh}^{\text{Set}}(\mathcal{C})$ is underlying presheaf of sets.

Prop. (5.1.1.20). The category of presheaves on a category admits all limits and colimits, and it commutes with $\Gamma(U, -)$ for any $U \in \mathcal{C}$.

Def. (5.1.1.21) [Points]. A **point of a site** is a $\text{Cf.[Sta]}00Y3$. 
2 Sheaves and Topoi

Def. (5.1.2.1) [Sheaves]. Let $\mathcal{C}$ be a site, then $F \in \mathcal{PSh}^{\text{Set}}(\mathcal{C})$ is called a sheaf (on $\mathcal{C}$) iff ?.

The category of sheaves (of sets/groups/*) on a site $\mathcal{C}$ is denoted by $\text{Sh}(\mathcal{C})$ (or $\text{Sh}^{\text{Sp}}(\mathcal{C}), \text{Sh}^{*}(\mathcal{C}))$.

Def. (5.1.2.2) [Separate Presheaves]. Let $\mathcal{C}$ be a site, then $F \in \mathcal{PSh}^{*}(\mathcal{C})$ is called a separated presheaf if $F(U) \hookrightarrow \prod_i F(U_i)$ is injective for any covering $U = \{U_i \to U\} \in \text{Cov}(\mathcal{C})$.

Def. (5.1.2.3) [Effective Epimorphisms]. An epimorphism $\{U_i \to V\}$ in a category is called a family of effective epimorphisms if $\text{Hom}(V, Z) \to \prod_i \text{Hom}(U_i, Z) \Rightarrow \prod_i \text{Hom}(U_i \times_{V} U_j, Z)$ is exact for each $Z$. Similarly for a family of universal effective epimorphisms.

Prop. (5.1.2.4) [Subcanonical Site]. The class of all families of universal effective epimorphisms in a category forms a Grothendieck topology, called the canonical topology. It is the finest topology that all representable presheaves are sheaves.

Topologies that are coarser than the canonical topology are called subcanonical topology. Equivalently, a subcanonical topology is a topology that every representable presheaf is a sheaf.

Proof: We only need to verify that family of universal effective epimorphisms is closed under composition. For this, first prove epimorphism, then use epimorphism to prove effectiveness. Universal follows routinely. Cf.[Tamme]. \qed

Prop. (5.1.2.5). For a subcanonical topology on a site $\mathcal{C}$, its restriction on a localizing category $\mathcal{C}/S$ is subcanonical.

Proof: The only nontrivial part is that the glued morphism is a morphism over $S$. For this, consider its composition that maps to $S$, then the uniqueness of the exact sequence (5.1.2.3) will show that it is truly a $S$-morphism. \qed

Prop. (5.1.2.6). Let $\mathcal{C}$ be a subcanonical site, and $f : X \to Y$ is an arrow in $\mathcal{C}/S$, suppose there is a covering $\{S_i \to S\}$ that the pullback of $f$ to $\mathcal{C}/S_i$ are all isomorphisms, then $f$ is an isomorphism.

Proof: This follows from (5.1.3.6) and (5.1.3.8). \qed

Prop. (5.1.2.7) [Sheafification]. Let $\mathcal{C}$ be a site, consider the functor

$$(\cdot)^+ : \mathcal{PSh}^{*}(\mathcal{C}) \to \text{Sh}^{*}(\mathcal{C}) : F^+(U) = \lim_{\longrightarrow} \ker(\prod_i F(U_i) \Rightarrow \prod_{i,j} F(U_i \times_{U} U_j)) = \check{H}^0(U, F).$$

Then

- For $F \in \mathcal{PSh}^{*}(\mathcal{C})$, $F^+$ is separated.
- If $F \in \mathcal{PSh}^{*}(\mathcal{C})$ is separated, $F \to F^+$ is injective and $F^+ \in \text{Sh}^{*}(\mathcal{C})$. (The problem of separated is that the cover may not be identical in $U_i \times_{U} U_j$ but only on a cover of it).
- $(\cdot)^+$ is left exact.
- Sheafification functor $(\cdot)^# : \mathcal{PSh}^{*} \to \text{Sh}^{*} : F \mapsto F^# = F^{++}$ is exact and it is left adjoint to the forgetful functor.
So the forgetful functor is left exact and it preserves injectives. Thus the sheaf cokernel is the sheafification of the presheaf kernel, the sheaf kernel is the presheaf kernel.

Proof: The separatedness is simple. For sheaf condition, an element of $F^+(U)$ is represented by a covering $\{V_{ij} \to U\}$, and there restriction to $U \times_U V_j$ coincide by separatedness hence the covering $\{V_{ij} \to U\}$ is an element of $F^+(U)$.

Sh is left exact because $(-)^+$ is left exact from $\mathcal{P}\mathcal{S}h^*$ to $\mathcal{P}\mathcal{S}h^*$ by (5.3.2.4) checked on every element $U$. It is right exact trivially, hence it is exact. □

Def. (5.1.2.8) [Constant Sheaf]. The constant sheaf $S$ for a set $S$ is the sheafification of the constant presheaf $U \mapsto S$.

Transfer of Sheaves under Morphisms of Sites

Def. (5.1.2.9) [Functoriality of Presheaves]. Given a functor of sites $u : \mathcal{C} \to \mathcal{C}'$, which should be regarded as an inverse map, there are maps

$$u^p F'(U) = F'(u(U)) : \mathcal{P}\mathcal{S}h(\mathcal{C}') \to \mathcal{P}\mathcal{S}h(\mathcal{C}), \quad u_p(F)(U') = \lim_{U_i | U' \to u(U_i)} F(U_i) : \mathcal{P}\mathcal{S}h(\mathcal{C}) \to \mathcal{P}\mathcal{S}h(\mathcal{C}')$$

Then $u_p$ is left adjoint to $u^p$.

We can also define a functor

$$p u : p u(F)(U') = \lim_{\{U_i | U' \to u(U_i)\}^{\text{op}}} F(U_i) : \mathcal{P}\mathcal{S}h(\mathcal{C}) \to \mathcal{P}\mathcal{S}h(\mathcal{C}')$$

Then this functor is right adjoint to $u^p$, by duality.

Proof: A map $f \in \text{Mor}(u_p(F), G)$ is represented by compatible maps

$$\lim_{U_i : U' \to u(U_i)} F(U_i) \to G(U'),$$

and this is represented by compatible maps $F(U_i) \to G(u(U_i))$ which is indexed over $\prod_{U' \in \mathcal{C}'} \mathcal{I}_{U'}$, where $\mathcal{I}_{U'} = \{U_i : U' \to u(U_i)\}$. Now this is equivalent to compatible maps $F(U_i) \to G(u(U_i))$, which is a map $g \in \text{Mor}(F, u^p(G))$. □

Cor. (5.1.2.10). $u^p$ is exact.

Def. (5.1.2.11) [Functoriality of Sheaves].

- Given a continuous functor $u : \mathcal{C} \to \mathcal{C}'$ between sites, there are maps

$$u_* = u^p \circ u_p \circ t : \mathcal{S} \to \mathcal{S}', \quad u^* = u^p \circ t : \mathcal{S}' \to \mathcal{S}.$$ 

$u_*$ is left adjoint to $u^*$, by adjointness of $u_p, u^p$ and $u, t$.

- Given a cocontinuous functor $u : \mathcal{C} \to \mathcal{C}'$ between sites, there are maps

$$u_* = u^p \circ u^p \circ t : \mathcal{S}' \to \mathcal{S}, \quad s u = p u \circ t : \mathcal{S} \to \mathcal{S}'.$$ 

$u^*$ is left adjoint to $s u$, by adjointness of $u^p, p u$ and $u, t$. Moreover, $u^*$ is exact.
Proof: 1: Notice if \( \mathcal{F} \) is a sheaf, then \( u^* \mathcal{F} \) is also a sheaf, by continuity (5.1.1.5).

2: \( p^* \mathcal{F} \) is a sheaf by [Sta00XK?]. \( u^p \) is clearly right exact, and it is left exact because \( \iota, \sharp \) do, and \( u^p \) is exact by (5.1.2.10).

**Cor. (5.1.2.12)** When \( u \) is continuous, \((u_\sharp(G))^* \cong (u_\sharp(G^\sharp))^* \) for any presheaf \( G \) on \( T \).

When \( u \) is cocontinuous, \((u^\sharp G)^* \cong (u^\sharp(G^\sharp))^* \) for any presheaf \( G \) on \( T \).

Proof: Use Yoneda lemma.

**Prop. (5.1.2.13)** For \( Z \in T, u_p h_Z = h_{u(Z)} \).

Proof: Use the adjointness of \( u_p, u^p \) (5.1.2.9), then for any presheaf \( F \),

\[
\text{Hom}(u_p h_Z, F) = \text{Hom}(h_Z, u^p F) = f^p(F)(Z) = F(f(Z)),
\]

thus we are done by Yoneda lemma.

**Prop. (5.1.2.14) [When is \( u_s \) Exact].** If \( f : \mathcal{C} \to \mathcal{C}' \) is a continuous functor between sites that \( U' \) is cofiltered for any \( U' \in \mathcal{C}' \), where \( U' \) the category of all pairs \( (U, \varphi) \) where \( U \in \mathcal{C} \) and \( \varphi : U' \to u(U) \), then \( u_s \) is exact.

In particular, this is the case when \( \mathcal{C}, \mathcal{C}' \) both have weakly final objects and finite fiber products and \( u \) preserves them. Notice the condition of weakly final objects can be released if we can show \( U' \) is nonempty for any \( U' \).

Proof: It suffices to show the left exactness of \( u_p \). By definition, \( u_p(U') = \lim_{\to_{U'}} F_{U'} \) where \( F_{U'} \)

is the covariant functor \( (U, \varphi) \to F(U) \). Because \( U' \text{ filters} \), this colimit process is exact form \( \text{Hom}(U', \mathcal{A}) \) to \( \mathcal{A} \) and \( u_p \) is exact. Now sheffification is also exact (5.1.2.7), so we conclude.

The last assertion is clear. (Notice the weakly-final object are used to assure \( U' \text{ is nonempty.} \)

**Prop. (5.1.2.15) [Localization Site].** For a site \( T \) and \( Z \in T \), there is a site \( T/Z \) as objects over \( T \), and \( i : T/Z \to T \) is continuous. Then \( i^* \) is exact.

Proof: \( R^i i^*(F) = (i^p(H^q(F)))^i(5.3.1.8), \) and \((H^q(F))^* = 0(5.3.2.14), \) so it suffices to show \( i^p \) and \( \sharp \) commutes. But \( i^* \) and \( \ast \) commute obviously.

**Prop. (5.1.2.16) [Sheaf Condition is Local].** To check sheaf condition for presheaf w.r.t. a topology, it suffice to show that for any covering, there is a refinement covering of it that sheaf condition hold, because by the definition of sheafification functor, \( F^+ = F, \) so \( F \) is a sheaf.

**Cor. (5.1.2.17).** For two topology on a same category that \( T' \) is finer than \( T \), then any \( T'-\text{sheaf} \) is a \( T-\text{sheaf}. \) And if any covering in \( T' \) can be refined by a covering in \( T, \) then \( S \to S' \) is an equivalence of categories. In particular, if \( T \) is Noetherian, \( S(T) \) and \( S(T') \) (5.1.1.3) are equivalent.

**Topoi**

**Def. (5.1.2.18) [Topoi].** A **topos** is an Abelian category that is equivalent to the category of sheaves \( \text{Sh}(\mathcal{C}) \) on a site \( \mathcal{C} \). A morphism of topos \( f : \text{Sh}(\mathcal{C}) \to \text{Sh}(\mathcal{D}) \) is an adjunction

\[
(f^{-1}, f_* : \text{Sh}(\mathcal{D}) \rightleftharpoons \text{Sh}(\mathcal{C}))
\]

s.t. \( f_* \) is right adjoint to \( f^{-1} \) and \( f^{-1} \) is exact. Compositions of morphisms of topos are defined routinely. A 2-morphism of topos between two morphisms of topos \( f, g : \text{Sh}(\mathcal{C}) \to \text{Sh}(\mathcal{D}) \) is a natural transformation \( t : f_* \to g_* \).
Prop. (5.1.2.19) [Continuous Maps and Topoi]. A morphism of sites \( f : \mathcal{D} \to \mathcal{C} \) consists of a continuous functor \( u : \mathcal{C} \to \mathcal{D} \) that \( u_s \) is exact, so it induces a functor of topoi \( f : \mathsf{Sh} (\mathcal{C}) \to \mathsf{Sh} (\mathcal{D}) \), if we define \( f^{-1} = u_* s, f_* = u^s \), by (5.1.2.11).

Prop. (5.1.2.20) [Cocontinuous Maps and Topoi]. Let \( u : \mathcal{C} \to \mathcal{D} \) be a cocontinuous functor between sites, then this defines a morphism of topoi \( g : \mathsf{Sh} (\mathcal{C}) \to \mathsf{Sh} (\mathcal{D}) \), if we define \( g^{-1} = u^s \) and \( g_* = u_* \), by (5.1.2.11).

Prop. (5.1.2.21) [Cocontinuous Map with a Right Adjoint]. Let \( u : \mathcal{C} \to \mathcal{D} \) be a cocontinuous functor between sites with a right adjoint \( v : \mathcal{D} \to \mathcal{C} \), then the morphism of topoi \( g : \mathsf{Sh} (\mathcal{C}) \to \mathsf{Sh} (\mathcal{D}) \) is pretty simple,

\[
g^{-1} G (U) = G (u(U)), \quad g_* F (V) = F (v(V)).
\]

This holds in particular for localization of sites.

Proof: It follows from adjunction that \( u^p h_V = h_{v(V)} \), so \( g^{-1} (h^s_V ) = (u^p h^s_V )^s = (u^p h_v )^s = h^s_{v(V)} \), and

\[
(g_* F )(V) = \text{Hom}(h^s_{v(V)}, g_* F ) = \text{Hom}(g^{-1} h^s_{v(V)}, F ) = \text{Hom}(h^s_{v(v(V))}, F ) = F (v(V)).
\]

The other identity is clear. \( \square \)

Prop. (5.1.2.22) [Continuous and Cocontinuous Maps and Topoi]. Let \( u : \mathcal{C} \to \mathcal{D} \) be a functor between sites that satisfies

- \( u \) is continuous and cocontinuous,
- \( u \) is fully faithful,
- \( \mathcal{C} \) has final objects and fiber products and \( u \) preserves them.

then there are two maps of topoi: \( f = (u_s, u^s) : \mathsf{Sh} (\mathcal{D}) \to \mathsf{Sh} (\mathcal{C}), g = (u^s, u_*) : \mathsf{Sh} (\mathcal{C}) \to \mathsf{Sh} (\mathcal{D}) \) induced by \( u \) (5.1.2.19)(5.1.2.14)(5.1.2.20). They satisfy \( f \circ g = \text{id}_{\mathsf{Sh} (\mathcal{C})} \), and \( f^{-1} = u_s \) is fully faithful.

In particular, if we define \( g_l = u_* \), then there are two adjunctions

\[
(g_l, g^{-1}) : \mathsf{Sh} (\mathcal{C}) \rightleftarrows \mathsf{Sh} (\mathcal{D}), \quad (g^{-1}, g_*) : \mathsf{Sh} (\mathcal{D}) \rightleftarrows \mathsf{Sh} (\mathcal{C}).
\]

Proof: We need to show that for any \( F \in \mathsf{Sh} (\mathcal{C}), F \cong g^{-1} g_l F \) and \( g^{-1} g_* F \cong F \). For this, Cf. [Sta]00XT.^2

Then \( f^! \) is fully faithful follows from the equality \( F \cong g^{-1} g_l F \). \( \square \)

Prop. (5.1.2.23) [Special Cocontinuous Maps and Topoi]. A functor \( u : \mathcal{C} \to \mathcal{D} \) between sites is called a special cocontinuous functor if:

- \( u \) is continuous and cocontinuous,
- Given any \( a, b : U' \to U \in \mathcal{C} \) s.t. \( u(a) = u(b) : u(U') \to u(U) \), there is a covering \( \{ f_i : U'_i \to U' \} \) that \( a f_i = b f_i \).
- Given any \( U', U \in \mathcal{C} \) and a morphism \( c : u(U') \to u(U) \in \mathcal{D} \), there exists a covering \( \{ f_i : U'_i \to U' \} \in \mathcal{C} \) and morphisms \( c_i : U'_i \to U \) that \( u(c_i) = c \circ u(f_i) \).
- Given any \( V \in \mathcal{D} \), there is a covering of the form \( \{ u(U_i) \to V \} \) in \( \mathcal{D} \).

Then the induced morphism of topoi \( g : \mathsf{Sh} (\mathcal{C}) \cong \mathsf{Sh} (\mathcal{D})(5.1.2.20) \) is an equivalence of topoi.

Proof: Cf. [Sta]03A0. \( \square \)
Cor. (5.1.2.24) [Comparing Topologies]. Let \( \mathcal{C}' \) be a fully subcategory of \( \mathcal{C} \), and
- \( i : \mathcal{C}' \to \mathcal{C} \) is continuous, i.e. \( \text{Cov}(\mathcal{C}') \to \text{Cov}(\mathcal{C}) \).
- \( i : \mathcal{C}' \to \mathcal{C} \) is cocontinuous, i.e. any covering \( \{U_i \to U'\} \in \text{Cov}(\mathcal{C}) \) s.t. \( U' \in \mathcal{C}' \) has a refinement \( \{U_j' \to U'\} \in \text{Cov}(\mathcal{C}') \).
- Each \( U \in \mathcal{C} \) has a covering \( \{U_i \to U\} \in \text{Cov}(\mathcal{C}) \) with \( U_i \in \mathcal{T}' \). Then \( i : \text{Sh}(\mathcal{C}') \to \text{Sh}(\mathcal{C}) \) is an equivalence of topoi. \( i^{-1} \) is just the restriction functor, and \( i_* \) is called the extension functor of sheaves.

In particular, this applies to the case \( i : \mathcal{C}' = \mathcal{C}/\mathcal{Z} \to \mathcal{C} \), the localization category, in with case for \( \mathcal{Z}' \in \mathcal{C}/\mathcal{Z} \), \( i^{-1}F(\mathcal{Z}') = F(\mathcal{Z}') \) is called the restriction sheaf.

Prop. (5.1.2.25) [Localizing at Sheaves]. Let \( \mathcal{C} \) be a site and \( \mathcal{F}_i \) be a set of topos on \( \mathcal{C} \), then there is an equivalence \( \text{Sh}(\mathcal{C}) \cong \text{Sh}(\mathcal{C}') \) induced by a special cocontinuous functor (5.1.2.23) that
- \( \mathcal{C}' \) has the subcanonical topology,
- A family of morphisms \( \{V_i \to V\} \) are a covering of \( \mathcal{C}' \) iff \( \prod h_{V_i} \to h_V \) is surjective.
- \( \mathcal{C}' \) has fiber products and a final object.
- Every subsheaf of a representable sheaf is representable,
- Each \( g_* \mathcal{F}_i \) is a representable sheaf.

**Proof:** Cf. [[Sta]03CI]. \( \square \)

3 Stacks

Def. (5.1.3.1) [Stacks]. Let \( \mathcal{F} \to \mathcal{C} \) be a fibered category on a site \( \mathcal{C} \). Then \( \mathcal{F} \) is called a prestack over \( \mathcal{C} \) if for each covering \( \{U_i \to U\} \) in \( \mathcal{C} \), the functor \( \text{Hom}(h_U, \mathcal{F}) \to \text{Hom}(h_{U_i}, \mathcal{F})(5.1.1.7) \) is faithfully faithful. It is called a stack over \( \mathcal{C} \) if it is moreover an equivalence of categories.

Def. (5.1.3.2) [Category of Descent Datum]. Let \( \mathcal{F} \to \mathcal{C} \) be a fibered category on a site \( \mathcal{C} \), \( U \in \mathcal{C} \) and \( \mathcal{U} \) is a covering of \( U \). Given a choice of fibered products \( U_{ij}, U_{ijk} \) in \( \mathcal{C} \), we can define the category of descent datum \( \mathcal{F}_{\text{desc}}(\mathcal{U}) \) to be the category of tuples \( (\xi_i, \xi_{ij}, \xi_{ijk}) \) where \( \xi_{ij} \in \mathcal{F}(U) \) with Cartesian morphisms between them that are commutative. A morphism in \( \mathcal{F}_{\text{desc}}(\mathcal{U}) \) is a family of morphisms \( (\varphi_i, \varphi_{ij}, \varphi_{ijk}) \) commuting with the Cartesian morphisms.

Then there is an equivalence of categories \( \text{Hom}(h_{\mathcal{U}}, \mathcal{F}) \cong \mathcal{F}_{\text{desc}}(\mathcal{U}) \).

**Proof:** For any \( F : h_{\mathcal{U}} \to \mathcal{F}, U_i \to U \in h_{\mathcal{U}}(U_i) \), applying \( F \) to the arrows \( \text{id}_{U_i}, U_{ij} \to U_i, U_{ijk} \to U_{ij} \in h_{\mathcal{U}} \), we get an element in \( \mathcal{F}_{\text{desc}}(\mathcal{U}) \). Also a natural transformation \( F \to G \) maps to a morphism in \( \mathcal{F}_{\text{desc}}(\mathcal{U}) \), so we get a functor \( T : \text{Hom}(h_{\mathcal{U}}, \mathcal{F}) \to \mathcal{F}_{\text{desc}}(\mathcal{U}) \).

Conversely, choose an arbitrary choice of pullbacks (that coincide with \( \xi_{ij} \to \xi_i \)), for any arrow \( f : T \to U \in h_{\mathcal{U}}(T) \), we choose a \( U_i \) that \( T \to U \) factors as \( T \to U_i \to U \)(also for \( f = \text{id}_{U_i} \), choose \( U_i \)), then define \( F(f) \) as the pullback of \( \xi_i \) along \( T \to U_i \). For any morphisms \( T' \to T \to U \in h_{\mathcal{U}} \) and their choice of \( U_i, U_j \) that \( T' \to U \) factors through \( U_j \to U \) and \( T \to U \) factors as \( U_i \to U \), then \( T' \to U_j \) factors through \( U_{ij} \), i.e. we have a commutative diagram

\[
\begin{array}{ccc}
T' & \to & U_{ij} \to U_j \\
\downarrow & & \downarrow \\
T & \to & U_i \to U
\end{array}
\]
Then by Cartesian properties, we get a unique map \( F(T') \to F(T) \), which is Cartesian by (3.1.7.8). It can be shown these maps make \( F \) a functor, using Cartesian property and the existence of \( \xi_{ijk} \). And also for any map of descent datum, we get a natural transformation in \( \text{Hom}(h_U, F) \). Thus we get a functor \( S : F_{\text{desc}}(U) \to \text{Hom}(h_U, F) \).

The construction of \( S \) shows \( T \) is essentially surjective and full, and also faithful, so \( (S, T) \) is an equivalence of categories.

**Def. (5.1.3.3) [Everyday Descent Datums]**. Let \( F/\cal{C} \) be a fibered category on a site \( \cal{C} \), \( U \in \cal{C} \) and \( \cal{U} \) is a covering of \( U \). Given a choice of fibered products \( U_{ij}, U_{ijk} \) in \( \cal{C} \) and a cleavage of \( \cal{F}/\cal{C} \), let \( \cal{F}(\cal{U}) \) be the category of tuples \( (\xi, \varphi_{ij}) \) where \( \xi_i \in \cal{F}(U_i) \) and \( \varphi_{ij} \) are isomorphisms \( \varphi_{ij} : \text{pr}^*_1 \xi_i \cong \text{pr}^*_2 \xi_j \in \cal{F}(U_{ij}) \) s.t.

\[
\text{pr}^*_1 \varphi_{ik} = \text{pr}^*_2 \varphi_{jk} \circ \text{pr}^*_1 \varphi_{ij} : \text{pr}^*_1 \xi_i \cong \text{pr}^*_2 \xi_k.
\]

**WARNING**: Notice this doesn’t make sense unless we insect three isomorphisms such as \( \text{pr}^*_1 \varphi_{ij} \).

Then there is a (non-canonical!)equivalence of categories \( F_{\text{desc}}(U) \to \cal{F}(\cal{U}) \).

**Proof**: For \( (\xi_i, \varphi_{ij}, \xi_{ijk}) \in F_{\text{desc}}(U) \), there are isomorphisms \( \xi_{ij} \cong \text{pr}^*_1 \xi_i \) and \( \xi_{ij} \cong \text{pr}^*_2 \xi_j \), which gives an isomorphism \( \varphi_{ij} : \text{pr}^*_1 \xi_i \to \text{pr}^*_2 \xi_j \). This gives an element of \( \cal{F}(\cal{U}) \), by comparison with \( \xi_{ijk} \).

Conversely, given \( (\xi_i, \varphi_{ij}) \in \cal{F}(\cal{U}) \), choose an ordering on \( I \), for \( i < j \), let \( \xi_{ij} = \text{pr}^*_1 \varphi_i \), and \( \text{pr}^*_2 \circ \varphi_{ij} : \xi_{ij} \to \xi_{ij} \) is Cartesian. And for \( i < j < k \), let \( \xi_{ijk} = \text{pr}^*_1 \xi_i \), then there are Cartesian morphisms \( \xi_{ijk} \to \xi_{ij}, \xi_{ijk} \to \xi_{ik}, \xi_{ijk} \to \xi_{jk} \) by Cartesian properties, and it can be verified that the cocycle condition guarantees the diagram can be completed.

**Cor. (5.1.3.4) [Cocycle Conditions]**. If \( \cal{F}/\cal{C} \) is a rigid fibered category, then there is no need to check the cocycle condition, because every automorphism over \( \text{id}_U \) is trivial.

**Cor. (5.1.3.5) [Stacks and Sheaves]**. A rigid (pre)stack over a site \( \cal{C} \) is equivalent to a (pre)sheaf on \( \cal{C} \), by (3.1.7.28).

**Cor. (5.1.3.6)**. A site is subcanonical iff any representable fibered category \( h_U \to C \) is a stack.

**Prop. (5.1.3.7) [Equivalence Categories and Stacks]**. Let \( \cal{F} \to \cal{G} \) be an equivalence of fibered categories over a site \( \cal{C} \), then \( \cal{F} \) is a prestack/stack (in groupoid) iff \( \cal{G} \) is.

**Proof**: There is a strict commutative diagram of categories

\[
\begin{array}{ccc}
\text{Hom}(h_U, \cal{F}) & \longrightarrow & \text{Hom}(h_U, \cal{F}) \\
\downarrow & & \downarrow \\
\text{Hom}(h_U, \cal{G}) & \longrightarrow & \text{Hom}(h_U, \cal{G})
\end{array}
\]

that the vertical arrows are equivalences of categories, then we are done.

**Prop. (5.1.3.8) [Prestack and Hom Functor]**. Let \( \cal{F} \) be a fibered category over a site \( \cal{C} \), then \( \cal{F} \) is a prestack iff for any object \( S \) of \( \cal{C} \) and two objects \( \xi, \eta \in \cal{F}(S) \), the presheaf \( \text{Hom}_S(\xi, \eta) : (\cal{C}/S)^{\text{op}} \to \text{Set}(3.1.7.19) \) is a sheaf in the comma site \( \cal{C}/S(5.1.1.4) \).

**Proof**: By (5.1.3.7), it suffices to show \( \text{Hom}_S(\xi, \eta) \) is a stack in the comma topology \( \cal{C}/S \). Then it can be shown that \( \text{Hom}(h_U, \text{Hom}_S(\xi, \eta)) \to \text{Hom}(h_U, \text{Hom}_S(\xi, \eta)) \) is an equivalence of categories iff \( \text{Hom}(h_U, \cal{F}) \to \text{Hom}(h_U, \cal{F}) \) is fully faithful.
**Lemma (5.1.3.9).** Let \( F \) be a prestack over a site \( \mathcal{C} \), \( S, S' \) be sieves belonging to the topology of \( \mathcal{C} \) that \( S' \subset S \), then the restriction functor

\[
\text{Hom}_\mathcal{C}(S, F) \to \text{Hom}_\mathcal{C}(S', F)
\]

is faithful.

**Proof:** it suffices to show for \( S' = h_U \) for some covering \( U \). Let \( F, G \in \text{Hom}_\mathcal{C}(S', F) \) and \( \varphi, \psi \) be two natural transformations from \( F \) to \( G \) that induce the same natural transformation from the restriction of \( F \) to \( h_U \) to the restriction of \( G \) to \( h_U \), then \( \varphi = \psi \). For this, just notice there are commutative diagrams

\[
\begin{array}{ccc}
F(T \times_U U_i/U) & \xrightarrow{\varphi_{T \times_U U_i/U}} & G(T \times_U U_i/U) \\
\downarrow & & \downarrow \\
F(T/U) & \xrightarrow{\varphi_{T/U}} & G(T/U)
\end{array}
\]

where the vertical arrows are Cartesian, and the hypothesis implies \( \varphi_{T \times_U U_i/U} = \psi_{T \times_U U_i/U} \). Then we deduce \( \varphi_{T/U} = \psi_{T/U} \) as \( \text{Hom}_\mathcal{T}(F(T/U), G(T/U)) \) is a sheaf, as \( F \) is a presheaf (5.1.3.8).

**Prop. (5.1.3.10) [Stack and Sieves].** A prestack \( F \to \mathcal{C} \) is stack iff for any \( U \in \mathcal{C} \) and any sieve \( S \) on \( U \) belonging to \( T \),

\[
\text{Hom}(h_U, F) \to \text{Hom}(S, F)
\]

is an equivalence of categories.

**Proof:** Let \( S \) be a sieve on \( U \) belong to \( \mathcal{C} \), choose a covering \( U \) of \( U \) that \( h_U \subset S \subset h_U \), then there is a factorization

\[
\text{Hom}(h_U, F) \to \text{Hom}(S, F) \to \text{Hom}(h_U, F).
\]

Then we are done by (5.1.3.9).

**Cor. (5.1.3.11).** Let \( T, T' \) be two topologies on a category \( \mathcal{C} \) that \( T' \) is subordinate to \( T \) and \( F \to C \) is a fibered category, then if \( F \) is a prestack/stack relative to \( T \), it is also true for \( T' \).

**Prop. (5.1.3.12) [2-Fiber Products of Stacks].** There is a natural 2-category of stacks over \( \mathcal{C} \) defined as a sub-2-category of the 2-category of fibered-categories over \( \mathcal{C} \), and the (2,1)-category of stacks over \( \mathcal{C} \) has 2-fibered products, which coincides with that of (3.1.7.15).

**Proof:** Let \( \mathcal{X} \to S, \mathcal{Y} \to S \) be morphisms of stacks over \( \mathcal{C} \), then the category \( \mathcal{X} \times_S \mathcal{Y} \) is a fibered category over \( \mathcal{C} \), by (3.1.7.15). It remains to show that the morphism presheaves sheaves and descent datum are effective.

For this, Cf.[Sta]026G.

**Prop. (5.1.3.13) [Associated Stack in Groupoids].** Let \( \mathcal{C} \) be a site and \( F \) be a prestack, and \( F_{\text{cart}} \) is the associated category fibered in groupoids (3.1.7.24), then \( F_{\text{cart}} \) is also a prestack. And in this case, \( F \) is a stack iff \( F_{\text{cart}} \) is a stack.

**Proof:** The categories \( F(U) \) and \( F_{\text{cart}}(U) \) have the same isomorphism classes of objects, as isomorphisms are Cartesian, so it suffices to show \( F \) is a prestack iff \( F_{\text{cart}} \) is a prestack. For this, use (5.1.3.8) and consider \( \xi, \eta \in F(U) \) and a covering \( \{U_i \to U\} \), if there are arrows \( \alpha_i : \xi_i \to \eta_i \) that
are compatible, then there is a unique arrow $\alpha : \xi \to \eta$ restricting to $\alpha_i$, thus it suffices to show $\alpha$ is Cartesian. But since $\mathcal{F}_{\text{cart}}$ is a category fibered in groupoids, each $\alpha_i$ is invertible, and their inverses glue together to a morphism $\beta : \eta \to \xi$ which is the inverse of $\alpha$, so $\alpha$ is also an isomorphism thus Cartesian.

\begin{prop}[2-Fibered Products of Stacks Fibered in Groupoids] Let $\mathcal{C}$ be a category, the 2-category of stacks fibered in groupoids over $\mathcal{C}$ (automatically a $(2,1)$-category) has 2-fiber products, and coincide with that of $(5.1.3.12)$.\end{prop}

\begin{proof}
 This is clear from $(5.1.3.12)$ and $(3.1.7.26)$.
\end{proof}

\begin{prop}[Equivalence of Stacks] Let $F : \mathcal{S}_1 \to \mathcal{S}_2$ be a morphism of stacks over a site $\mathcal{C}$. If $F$ is fully faithful, then $F$ is an equivalence iff for any $x \in \mathcal{S}_{2,U}$, there exists a covering $\{f_i : U_i \to U\}$ s.t. $f_i^*x$ is in the essential image of the functor $F : \mathcal{S}_{1,U} \to \mathcal{S}_{2,U}$.

\begin{proof}
 Easy.
\end{proof}

\end{prop}

\begin{prop}[Subcanonical Site Prestack] If $\mathcal{C}$ is a subcanonical site $(5.1.2.4)$ and $\mathcal{P}$ is a class of arrows in $\mathcal{C}$ stable under base change, then the corresponding fibered category $\mathcal{P} \to \mathcal{C}$ is a prestack.

\begin{proof}
 By $(5.1.3.8)$, we need to prove for any covering $\{U_i \to U\}$ and arrows $X \to U, Y \to U$, $X_i = U_i \times_U X$, and $X_{ij} = U_{ij} \times_U X$ and analogous for $Y$, if there are arrows $f_i : X_i \to Y_i$ over $U_i$ that the arrows $X_{ij} \to Y_{ij}$ induced by $f_i$ and $f_j$ coincide, then there is a unique arrow $f : X \to Y$ over $U$ that induces $f_i$.

Notice that the composite $X_i \xrightarrow{f_i} Y_i \to Y$ give section $g_i \in \text{h}(Y)(X_i)$, and the pullback of $g_i, g_j$ to $X_{ij}$ coincide by hypothesis. Now $\text{h}(Y)$ is a sheaf by hypothesis, so there is an arrow $f : X \to Y$ that pulls back to $f_i$ on $X_i$. Finally $f$ is compatible over $U$ because $(Y \to U) \circ f$ and $(X \to U)$ coincide when composed with $X_i \to X$, and $h_U$ is a sheaf.

\end{proof}

\end{prop}

\begin{prop}[Category of Sheaves is a Stack] Let $\mathcal{C}$ be a site, we denote $(\text{Sh}/\mathcal{C})(X) = \text{Sh}(\mathcal{C}/X)$, then $\text{Sh}/\mathcal{C}$ is a stack over $\mathcal{C}$.

\begin{proof}
 To show $\text{Sh}/\mathcal{C}$ is a prestack, by $(5.1.3.8)$, it suffices to show for any $F, G \in \text{Sh}(\mathcal{C}/X)$, $\text{Hom}_X(F, G)$ is a sheaf. For this, let $\{U_i \to U\}$ be a covering, and $\varphi_i : F_{U_i} \to G_{U_i}$ be morphisms of sheaves that their restrictions to $F_{U_{ij}} \to G_{U_{ij}}$ are compatible, then for any $T \to U$, there are commutative diagrams

\[
\begin{array}{ccc}
F(T) & \rightarrow & \prod_i F_i(T_i) \\
\downarrow & & \downarrow \\
G(T) & \rightarrow & \prod_i G_i(T_i) \\
\end{array}
\]

where $\varphi_T : F(T) \to G(T)$ is the unique function of sets that makes the diagram commutative. And it can be shown that these $\varphi_T$ defines a natural transformation $F_U \to G_U$.

Now for any covering $\{U_i \to U\}$ and a descent datum $(F_i, F_{ij})$, we need to show it is effective. We define a function $F$ on $\mathcal{C}/U$: $F(T) = \text{equal}(\prod_i F_i(T_i) \Rightarrow \prod_{ij} F(T_{ij}))$, then it can be shown that this is a sheaf by spectral sequence.

Then it suffices to check $F_{U_k} = F_k$. For any $T \to U_k$, $T_i$ maps to $U_{ik}$, so $F_i(T_i) = F_k(T_i)$, thus for any $s \in F_k(T)$, we can produce an element $(s_{T_i}) \in \prod_i F_i(T_i)$ that satisfies compatibility conditions, which gives us an element of $F(T)$. It can be shown this is a natural transformation $F_k \to F_{U_k}$, and it is an isomorphism of sheaves.

\end{proof}

\end{prop}
Prop. (5.1.3.18) [Descent Along Torsors]. Let \( \mathcal{C} \) be a site, \( G \) a group object and \( X \to Y \) a \( G \)-torsor, \( \mathcal{F} \to \mathcal{C} \) a stack. Then there exists a canonical equivalence of categories between \( \mathcal{F}(Y) \) and the category of \( G \)-equivariant objects \( \mathcal{F}^G(X) \) (3.1.7.17).

Proof: By (5.1.1.17) \( X \to Y \) is refined by a covering, thus by (5.1.3.10), \( \mathcal{F}(Y) \) is equivalent to \( \mathcal{F}(X) \cong \mathcal{F}^G(X) \). Then by (5.1.1.18), \( \mathcal{F}(X \to Y) \) consists of elements \( \xi \in \mathcal{F}(X), \eta \in \mathcal{F}(G \times X) \) and Cartesian arrows \( \varphi_1, \varphi_2 \) over \( \alpha, \pi_2 \). Cf. [Vi08] P106.

□

Stackifications

Prop. (5.1.3.19) [Stackification]. Let \( \mathcal{C} \) be a site and \( p : \mathcal{F} \to \mathcal{C} \) a fibered category over \( \mathcal{C} \), then there exists a stack \( p' : \mathcal{F}' \to \mathcal{C} \) and a morphism \( G : \mathcal{F} \to \mathcal{F}' \) of fibered categories over \( \mathcal{C} \) s.t. for any stack \( \mathcal{X} \to \mathcal{C} \), a morphism \( \mathcal{F} \to \mathcal{X} \) of fibered categories over \( \mathcal{C} \) factors through \( G \) 2-commutatively and uniquely up to 2-isomorphisms. In other words, there is a canonical equivalence of categories:

\[
\text{Mor}_{\mathcal{F}ib/\mathcal{C}}(\mathcal{F}, \mathcal{X}) \cong \text{Mor}_{\mathcal{Sta}/\mathcal{C}}(\mathcal{F}', \mathcal{X}).
\]

In particular, such a stack \( \mathcal{F}' \) is determined up to unique 2-isomorphisms, and is called the stackification of \( \mathcal{F} \).

Proof: By (3.1.7.20), we may assume \( \mathcal{F} \) is split, thus \( \mathcal{F} \) corresponds to the functor \( \mathcal{C}^{op} \to \text{Cat} : U \mapsto \text{Hom}(h_U, \mathcal{F}) \). Then we define a functor

\[
\mathcal{F}' : \mathcal{C}^{op} \to \text{Cat} : U \mapsto \lim_{U \in \text{Cov}(U)} \text{Hom}(h_U, \mathcal{F}).
\]

then there is a natural map of fibered categories \( \mathcal{F} \to \mathcal{F}' \). For any stack \( \mathcal{X} \to \mathcal{C} \), because \( \text{Hom}(h_U, \mathcal{X}) \to \text{Hom}(h_U, \mathcal{X}') \) is an isomorphism for any covering \( \mathcal{U} \) of \( U \), we get the desired equivalence of categories. □

Cor. (5.1.3.20). Let \( G : \mathcal{S} \to \mathcal{S}' \) be the stackification of a fibered category over \( \mathcal{C} \), then

- For any \( U \in \mathcal{C} \) and \( x, y \in \mathcal{S}_U \), the map

\[
\text{Hom}(x, y) \to \text{Hom}(G(x), G(y))
\]

identifies the RHS as the shiffication of the LHS.

- For any \( U \in \mathcal{C} \) and \( x \in \mathcal{S}'_U \), there exists a covering \( \{U_i \to U\} \) that for any \( i \), \( x|_{U_i} \) is in the essential image of \( G_U: \mathcal{S}_U \to \mathcal{S}'_U \).

Proof: Cf. [Sta] 0435. □

Prop. (5.1.3.21) [Stackifications Commute with 2-Fibered Products]. Stackifications commute with 2-fibered products.

Proof: Cf. [Sta] 04Y1. □

Prop. (5.1.3.22). If \( \mathcal{F}, \mathcal{G} \) are prestacks over a topological space \( X \), if there is a morphism \( \eta : \mathcal{F} \to \mathcal{G} \) that satisfies:

- \( \mathcal{F} \) is a stack and \( \mathcal{G} \) is a prestack.
- \( \eta \) induces isomorphisms on stalks.
• \(\eta(U) : \mathcal{F}(U) \to G(U)\) is fully faithful.

Then \(\eta\) is an equivalence of prestacks. In particular, \(G\) is also a stack.

Proof: Let \(\mathcal{H}\) be the stackification of \(G\), then \(\mathcal{F} \to \mathcal{G} \to \mathcal{H}\) is a morphism of stacks that is isomorphism on the stalk, so it is an isomorphism. But \(G\) is separated, so for any open \(U\), \(\mathcal{F}(U) \to \mathcal{G}(U), \mathcal{G}(U) \to \mathcal{H}(U)\) is fully faithful, and their composition is an equivalence, thus both of them are equivalences.

\[
\begin{array}{c}
\mathcal{G}|_U \\
\downarrow \\
\text{Aut}(x) \\
\end{array} \xrightarrow{\alpha \mapsto \phi \circ \alpha \circ \phi^{-1}} \begin{array}{c}
\mathcal{G}|_U \\
\downarrow \\
\text{Aut}(y)
\end{array}
\]

is commutative.

Proof: It can be checked by using the fact \(\text{Aut}(x)\) is Abelian that there are canonical morphisms \(\text{Aut}(x) \to \text{Aut}(y)\) induced by any morphism \(\varphi : x \to y\).

If there is no morphism from \(x\) to \(y\), then we can use the condition of gerbe to obtain morphisms \(\text{Aut}(x)|_{U_i} \to \text{Aut}(y)|_{U_i}\) locally, and then glue together. Similarly, if \(S_U\) is empty, then we can restrict to a covering and then glue.

Finally, notice this gives an Abelian sheaf \(\mathcal{G} = \text{Aut}\) on \(\mathcal{C}\).

\[\square\]

Gerbes

Def.(5.1.3.23)[Gerbe]. Let \(\mathcal{C}\) be a site, a gerbe over \(\mathcal{C}\) is a stack in groupoids over \(\mathcal{C}\) s.t.

• For any \(U \in \mathcal{C}\), there is a covering \(\{U_i \to U\}\) that \(S_{U_i}\) is nonempty for any \(i\).

• For any \(U \in \mathcal{C}\) and \(x, y \in S_U\), there exists a covering \(\{U_i \to U\}\) that \(x|_{U_i} = y|_{U_i}\) for any \(i\).

Prop.(5.1.3.24). Let \(p : \mathcal{S} \to \mathcal{C}\) be a gerbe over a site \(\mathcal{C}\), assume that for all \(U \in \mathcal{C}\) and \(x \in S_U\), the sheaf of groups \(\text{Aut}(x)\) on \(\mathcal{C} \leftarrow U\) is Abelian, then there exists a sheaf of Abelian groups over \(\mathcal{C}\) and for any \(x \in S_U\) an isomorphism \(G|_U \to \text{Aut}(x)\) that for any morphism \(\varphi : x \to y \in S_U\), the diagram

\[
\begin{array}{ccc}
\mathcal{G}|_U & \longrightarrow & \mathcal{G}|_U \\
\downarrow & & \downarrow \\
\text{Aut}(x) & \xrightarrow{\alpha \mapsto \phi \circ \alpha \circ \phi^{-1}} & \text{Aut}(y)
\end{array}
\]

is commutative.

Proof: It can be checked by using the fact \(\text{Aut}(x)\) is Abelian that there are canonical morphisms \(\text{Aut}(x) \to \text{Aut}(y)\) induced by any morphism \(\varphi : x \to y\).

If there is no morphism from \(x\) to \(y\), then we can use the condition of gerbe to obtain morphisms \(\text{Aut}(x)|_{U_i} \to \text{Aut}(y)|_{U_i}\) locally, and then glue together. Similarly, if \(S_U\) is empty, then we can restrict to a covering and then glue.

Finally, notice this gives an Abelian sheaf \(\mathcal{G} = \text{Aut}\) on \(\mathcal{C}\).

\[\square\]

Bands

4 Sites over Schemes

Prop.(5.1.4.1). Fiber products exist in the category of schemes, by(5.2.7.15).

Zariski Topology

Def.(5.1.4.2)[Zariski Topology]. The Zariski topology has the the covering of a scheme \(T\) as classes of open immersions \(\{T_i \to T\}\) that their images cover \(T\).

The Zariski site \(\mathcal{Sch}_{\text{Zar}} / S\) has the objects as all schemes over \(S\).

The small Zariski site \(S_{\text{Zar}}\) has the objects as all open subschemes over \(S\).

The restricted Zariski site \(S_{\text{Zar} f_p}\) has the objects as all schemes that are qcqs open subschemes of \(S\).

The big affine Zariski site \(\text{Aff}_{\text{Zar}} / S\) has the objects as all schemes affine over \(S\).

These are all topologies because open immersions satisfies base change trick(5.4.4.60).
In particular when the cover has only one element and is affine, the descent datum is equivalent to compatible isomorphisms
\[ \varphi_{13} : N \otimes_A B \otimes_A B \xrightarrow{\varphi_{12}} B \otimes_A M \otimes_B \xrightarrow{\varphi_{23}} B \otimes_A B \otimes_A M. \]

**Def. (5.1.4.3) [Zariski Stacks]**. The category of sheaves on \( \mathcal{S}ch_{\text{Zar}} / S \) is denoted by \( \text{Sh}_{\text{Zar}} / S \). The category of stacks on \( \mathcal{S}ch_{\text{Zar}} / S \) is denoted by \( \text{Sta}_{\text{Zar}} / S \).

**Prop. (5.1.4.4) [Affine and Full Sites]**. The inclusion functor \( \mathcal{A}ff_{\text{Zar}} / S \to \mathcal{S}ch_{\text{Zar}} / S \) is a special cocontinuous functor, so by (5.1.2.23), it induces an equivalence of topoi \( \text{Sh}(\mathcal{A}ff_{\text{Zar}} / S) \cong \text{Sh}_{\text{Zar}} / S \).

**Def. (5.1.4.5) [Restriction to Small Sites]**. The inclusion functor \( S_{\text{Zar}} \to \mathcal{S}ch_{\text{Zar}} / S \) satisfies the hypothesis of (5.1.2.22), thus induces morphisms of topoi
\[ \pi_S : \text{Sh}_{\text{Zar}} / S \to \text{Sh}(S_{\text{Zar}}), \quad i_S : \text{Sh}(S_{\text{Zar}}) \to \text{Sh}_{\text{Zar}} / S \]
that satisfies \( \pi_S \circ i_S = \text{id}_{S_{\text{Zar}}} \). In particular, \( i_S^{-1} \mathcal{F} \) is called the **restriction to small sites** of \( \mathcal{F} \).

**Prop. (5.1.4.6)**. A sheaf w.r.t the small Zariski topology is equivalent to a sheaf on \( S \), trivially, so the sheaf cohomology on \( \mathcal{A}ff_{\text{Zar}} / S \) is equivalent to usual sheaf cohomology on \( S \).

**Prop. (5.1.4.7) [Transfer of Big Sites]**. Let \( f : T \to S \in \mathcal{S}ch_{\text{Zar}} / S \), then \( \mathcal{S}ch_{\text{Zar}} / T \to \mathcal{S}ch_{\text{Zar}} / S \) is a localization, so by (5.1.2.21) it induces a morphism of topoi
\[ f : \text{Sh}_{\text{Zar}} / T \to \text{Sh}_{\text{Zar}} / S : f^{-1} \mathcal{G}(U/T) = \mathcal{G}(U/S), \quad f_\ast \mathcal{F}(U/S) = \mathcal{F}(U \times_S T/T). \]

**Prop. (5.1.4.8) [Transfer of Small Sites]**. Let \( f : T \to S \in \mathcal{S}ch_{\text{Zar}} / S \), then the base change functor \( S_{\text{Zar}} \to T_{\text{Zar}} \) is continuous, and by (5.1.2.14) induces a morphism of topoi
\[ f : \text{Sh}_{\text{Zar}} / T \to \text{Sh}_{\text{Zar}} / S. \]

**Prop. (5.1.4.9)**. If \( X \) is qs, then \( \text{Sh}(X_{\text{Zar}}) \to \text{Sh}(X_{\text{Zar}} fp) \) is an equivalence by \( i_s \) and \( i^s \)

*Proof:* The proof is the same proof as that of (5.1.20). \( \square \)

---

**Étale Topology**

**Def. (5.1.4.10) [Étale Topology]**. The **étale topology** has the covering of a scheme \( T \) as classes of étale morphisms that their images cover \( T \).

- The **étale site** \( \mathcal{S}ch_{\text{ét}} / S \) has the objects as all schemes over \( S \).
- The **small étale site** \( S_{\text{ét}} \) has the objects as all schemes that are étale over \( S \).
- The **restricted étale site** \( S_{\text{ét}} fp \) has the objects as all schemes that are étale and qcqs over \( S \).
- The **big affine étale site** \( \mathcal{A}ff_{\text{ét}} / S \) has the objects as all schemes affine over \( S \).

These are truly topologies because étale is stable under base change and composition.

**Prop. (5.1.4.11)**. Zariski covering is étale , because open immersions are étale.

**Prop. (5.1.4.12)**. For a family of maps in \( S_{\text{ét}} \) to be a covering, it suffices to check their image is adjointly surjective, by (5.6.6.4).

**Prop. (5.1.4.13) [Affine and Full Sites]**. The inclusion functor \( \mathcal{A}ff_{\text{ét}} / S \to \mathcal{S}ch_{\text{ét}} / S \) is a special cocontinuous functor, so by (5.1.2.23), it induces an equivalence of topoi \( \text{Sh}(\mathcal{A}ff_{\text{ét}} / S) \cong \text{Sh}_{\text{ét}} / S. \)
Def. (5.1.4.14) [Restriction to Small Sites]. The inclusion functor $S_{\text{ét}} \to \mathcal{S}_{\text{ét}}/S$ satisfies the hypothesis of (5.1.2.22), thus induces morphisms of topoi

$$
\pi_S : \mathcal{S}_{\text{ét}}/S \to \mathcal{S}(S_{\text{ét}}), i_S : \mathcal{S}(S_{\text{ét}}) \to \mathcal{S}_{\text{ét}}/S
$$

that satisfies $\pi_S \circ i_S = \text{id}_{\mathcal{S}_{\text{ét}}}$. In particular, $i_S^{-1} F$ is called the restriction to small sites of $F$.

Prop. (5.1.4.15). Any étale covering of a qc scheme can be refined a finite covering by affine étale schemes, this is because étale map are open (5.6.6.3).

Def. (5.1.4.16) [Étale Stacks]. The category of sheaves on $\mathcal{S}_{\text{ét}}/S$ is denoted by $\mathcal{S}(S_{\text{ét}})/S$. The category of stacks on $\mathcal{S}_{\text{ét}}/S$ is denoted by $\mathcal{S}_{\text{ét}}/S$.

Prop. (5.1.4.17). For a qc scheme $X$, $X_{\text{ét}}/\text{fp}$ is a Noetherian topology, because étale map is open, and any object in $X_{\text{ét}}/\text{fp}$ is qc.

Prop. (5.1.4.18) [Transfer of Big Sites]. Let $f : T \to S \in \mathcal{S}_{\text{ét}}/S$, then the functor $u : \mathcal{S}_{\text{ét}}/T \to \mathcal{S}_{\text{ét}}/S$ is cocontinuous, and has base change as a right adjoint, so by (5.1.2.21) it induces a morphism of topoi

$$
f : \mathcal{S}(T_{\text{ét}})/T \to \mathcal{S}(S_{\text{ét}})/S : f^{-1} \mathcal{G}(U/T) = \mathcal{G}(U/S), \quad f_* F(U/S) = F(U \times_S T/T).
$$

Prop. (5.1.4.19) [Transfer of Small Sites]. Let $f : T \to S \in \mathcal{S}_{\text{ét}}/S$, then the base change functor $S_{\text{ét}} \to T_{\text{ét}}$ is continuous, and by (5.1.2.14) induces a morphism of topoi

$$
f : \mathcal{S}(T_{\text{ét}}) \to \mathcal{S}(S_{\text{ét}})
$$

Prop. (5.1.4.20). If $X$ is qs, then $\mathcal{S}(X_{\text{ét}}) \to \mathcal{S}(X_{\text{ét}}/\text{fp})$ is an equivalence by $i_s$ and $i^s$.

Proof: Want to use (5.1.2.24), one condition is satisfied by (5.1.4.15), so it suffice to check any $X' \in X_{\text{ét}}$ has an étale covering by schemes étale and qcqs over $X$. For any point $p \in X'$, there is an affine nbhd $U'$ that maps to an affine nbhd $U'$ of $X$, so $U' \to U$ is étale and qcqs, and $U \to X$ is open immersion and qs, it is qc because $X$ is qs and $U$ is qc (5.4.4.27). So these affine nbhds $U'$ cover $X'$.

Prop. (5.1.4.21) [Cohomology Big and Small Sites]. The inclusion of small sites to the big sites has no infection on the sheaf cohomology, by (5.3.1.5). This is applicable to all topologies $\tau$ considered here.

Prop. (5.1.4.22) [Topological Invariance of Étale Sites]. If $f : S' \to S$ is universally homeomorphism, then $f : S'_{\text{ét}} \to S_{\text{ét}}$ is an equivalence of sites.

In particular this applies to $S' = S_{\text{red}}$.

Proof: Cf. [Étale Cohomology Conrad P18].

Smooth Topology

This topology will be shown to be identical to the étale topology, so it is not so important.

Def. (5.1.4.23) [Smooth Topology]. The smooth topology has the covering of a scheme $T$ as classes of smooth morphisms that their images cover $T$.

The big smooth site $\mathcal{S}_{\text{sm}}/S$ has the objects as all schemes over $S$.

The small smooth site $S_{\text{sm}}$ has the objects as all schemes that are smooth over $S$.

The restricted smooth site $S_{\text{ét}}/\text{fp}$ has the objects as all schemes that are smooth and qcqs over $S$.

The big affine smooth site $\mathcal{A}_{\text{ff}}/S$ has the objects as all schemes affine over $S$.

These are truly topologies because smoothness is stable under base change and composition.
Syntomic Topology

Def. (5.1.4.24) [Syntomic Topology]. The syntomic topology has the covering of a scheme $T$ as classes of syntomic morphisms that their images cover $T$.

fppf Topology

Def. (5.1.4.25) [Fppf Topology]. The fppf topology has the covering of a scheme $T$ as classes of flat locally of finite presentation morphisms that their images cover $T$. (f.f.+locally of f.p.).

The big Zariski site $\text{Sch}_{\text{fppf}}/S$ has the objects as all schemes over $S$.

The big affine Zariski site $\text{Aff}_{\text{fppf}}/S$ has the objects as all schemes affine over $S$.

They are all topologies because flatness and finite presentedness satisfy base change trick by (5.6.2.1) and (5.6.1.1).

Prop. (5.1.4.26) [Syntomic Covering is Fppf]. A syntomic covering is fppf by definition (4.4.4.18).

Prop. (5.1.4.27). A fppf covering of an affine scheme can be refined a finite affine fppf covering, because fppf map are open (5.6.2.10).

Def. (5.1.4.28) [Fppf Stacks]. The category of sheaves on $\text{Sch}_{\text{fppf}}/S$ is denoted by $\text{Sh}_{\text{fppf}}/S$. The category of stacks on $\text{Sch}_{\text{fppf}}/S$ is denoted by $\text{Sta}_{\text{fppf}}/S$.

fpqc Topology

Def. (5.1.4.29) [Fpqc Topology]. The fpqc topology has the covering of a scheme $T$ as classes of flat morphisms s.t. their images cover $T$ and for any affine open $U \subset T$, the restriction on $T$ can be refined by a finite affine cover of open affine subschemes of the covering (f.f.+qc). It is a topology by (5.6.2.1) and (5.4.4.25).

When the covering consists of affine schemes, it is called a standard fpqc covering.

Def. (5.1.4.30) [Fpqc Stacks]. Defining fpqc sites has inescapable set-theoretic difficulties, thus we don’t consider fpqc sites and fpqc cohomologies. Cf. [Sta]0BBK.

Nevertheless, we will denote the category of presheaves on $\text{Sch}/S$ satisfying the sheaf condition w.r.t. the fpqc topology by $\text{Sh}_{\text{fpqc}}/S$, and denote the category of fibered categories over $\text{Sch}/S$ satisfying the sheaf condition w.r.t. the fpqc topology by $\text{Sta}_{\text{fpqc}}/S$.

Prop. (5.1.4.31) [fppf is fpqc]. Fppf coverings are fpqc.

Proof: Use (5.6.2.10), we see that fppf covering consists of open morphisms, thus it is qc because affine scheme is quasi-compact.

Prop. (5.1.4.32). A covering consisting of flat morphisms refined by a fpqc covering is a fpqc covering.

Hence being fpqc is local on the target, because a Zariski cover is a fpqc covering.

If $U$ is a covering consisting of flat morphisms that there is a fpqc covering $V$ that $U \times V \rightarrow V$ is a fpqc covering, then $U$ is fpqc, because $U \times V$ does and it refines $U$.

Lemma (5.1.4.33) [Checking Sheaf Condition]. Let $S \in \text{Sch}$, $F \in \mathcal{P}h^{\text{Set}}((\text{Sch}_S)_{\text{fpqc}})$ is a sheaf iff it is a sheaf w.r.t the Zariski topology and satisfies sheaf property w.r.t the single covering $V \rightarrow U$ f.f. between affine schemes.

Proof: This follows from (5.1.3.5)(5.1.3.6) and (5.1.5.7).
Prop. (5.1.4.34) [fpqc Site is Subcanonical]. The coverings in $(\text{Sch}_S)_{\text{fpqc}}$ are families of universal effective epimorphisms. In other words, $(\text{Sch}_X)_{\text{fpqc}}$ is subcanonical. In particular, for any covering $\mathcal{U} = \{U_i \to X\} \in \text{Cov}((\text{Sch}_S)_{\text{fpqc}})$ and $\{V_{ijk} \to U_i \times_X U_j\} \in \text{Cov}((\text{Sch}_S)_{\text{fpqc}})$,

$$X = \text{Coeq}(\prod_{i,j,k} V_{ijk} \Rightarrow \prod_i U_i) \in \text{Sch}_S.$$ 

Proof: By (5.1.4.33), it suffices to show that any representable presheaf is a sheaf w.r.t Zariski topology and f.f. affine morphisms. The Zariski case follows from (5.1.5.3), for the second, $\text{Spec } B \to \text{Spec } Z$, for any scheme $X$, the morphism corresponds to $0 \to \text{Hom}(R,A) \to \text{Hom}(R,B) \to \text{Hom}(R,B \otimes_A B)$, but this follows immediately from (4.4.2.2), with $M = A$. □

Cor. (5.1.4.35). For $f : Y \to X$ a morphism of schemes, if $Z \in X_\tau$ for the above topologies $\tau$, then $f^* (\text{Hom}_X(-,Z)) \cong \text{Hom}(-,Z \otimes_X Y)$, in other words, the inverse sheaf of a representable sheaf is representable.

Proof: By definition, $f^* (\text{Hom}_X(-,Z))$ is the sheaf associated to the presheaf $f_* (\text{Hom}_X(-,Z))$, which by (5.1.2.13) is just the presheaf represented by $Z \otimes_X Y$, but by the proposition, it is already a sheaf. □

Prop. (5.1.4.36) [Coherent Sheaves on $\text{Sch}_{\text{fpqc}} / X$]. Let $F \in \mathcal{QCoh}(X)$, then the functor $X' \to \Gamma(X', \mathcal{F} \otimes_{O_X} O_{X'})$ satisfies the the axiom for Abelian sheaves on $\text{Sch}_{\text{fpqc}} / X$, by (5.1.5.13).

Prop. (5.1.4.37) [Qco Sheaves on Sites]. For $X \in \text{Sch}, \tau \in \{\text{fppf, étale, smooth, syntomic, Zariski}\}$, restriction defines an equivalence of categories

$$\mathcal{QCoh}(X) \cong \mathcal{QCoh}(\text{Sch}_\tau / X).$$

And if $\tau \in \{\text{Zariski, étale}\}$, restriction defines an equivalence of categories

$$\mathcal{QCoh}(X) \cong \mathcal{QCoh}(X_\tau).$$

Proof: Cf. [Sta]03DX. □

PH-Covering

Def. (5.1.4.38) [Standard PH-Covering].

Def. (5.1.4.39) [PH-Topology].

Prop. (5.1.4.40) [Zariski Covering is PH-Covering]. A Zariski covering is a PH-covering.

Proof: Cf. [Sta]0DBH. □

Prop. (5.1.4.41). A proper surjective morphism is a ph-covering.

Proof: Cf. [Sta]0DES. □
V-Topology

Def. (5.1.4.42) [Standard V-Covering]. A finite family of morphisms $T_i \to X$ of affine schemes is a covering in the standard $v$-topology if for any morphism $\text{Spec} \, V \to X$ where $V$ is a valuation ring, there is an extension of valuation rings (10.3.2.11) $V \to W$ and a morphism $\text{Spec} \, W \to \text{Spec} \, V \times_X T_i$ for some $i$.

Def. (5.1.4.43) [V-Topology]. A family of morphisms $\{T_i \to T\}$ is called a $v$-covering in the $v$-topology if for any open affine subscheme $U$ of $T$, the base change is refined by a standard $v$-covering of $U$.

The $v$-coverings form a topology, by [Sta]0ETJ.

Lemma (5.1.4.44). A standard fpqc covering is a standard $v$-covering.

Proof: Cf. [Sta]022E. □

Prop. (5.1.4.45) [fpqc Covering is V-Covering]. A fpqc covering is a $v$-covering.

Proof: This follows immediately from (5.1.4.44). □

Prop. (5.1.4.46). A standard ph-covering is a standard $v$-covering.

Proof: Cf. [Sta]0ETD □

Prop. (5.1.4.47) [ph-Covering is V-Covering]. A ph-covering is a $v$-covering.

Proof: This follows immediately from (5.1.4.46). □

Cor. (5.1.4.48). A proper and surjective map is a $v$-covering, by (5.1.4.47) and (5.1.4.41).

Arc-Topology

Def. (5.1.4.49) [Arc-Topology]. A finite family of morphisms $\{T_i \to X\}$ of schemes is a covering in the arc-topology if for any morphism $\text{Spec} \, V \to X$ where $V$ is a rank 1 valuation ring, there is a rank 1 valuation ring $W$ and a morphism $\text{Spec} \, W \to \text{Spec} \, V \times_X T_i$ for some $i$ that $V \to W$ is f.f..

Prop. (5.1.4.50). $V$-coverings are arc coverings.

Proof: This is by the definition and (10.3.2.11). □

5 Descent for Algebraic Spaces

Main references are [Sta] Chap34, 10.158.

General Principal

Prop. (5.1.5.1). A property of schemes is called local in a topology if for any covering $\{U_i \to S\}$, $S$ has $P$ iff $U_i$ has $P$. A property of morphisms is called local in a topology if for any covering $\{U_i \to S\}$, $X \to S$ has $P$ iff $X \times_S U_i \to U_i$ has $P$.

Prop. (5.1.5.2) [Twists and Čech Cohomology]. Let $\xi$ be an object of a stack $\mathcal{F}$ over a site $\mathcal{C}$ lying over an object $U$ of $\mathcal{C}$, we call an object $\xi' \in \mathcal{F}(U)$ a twist of $\xi$ if there is some covering $\{U_i \to U\}$ that the pullback of $\xi$ and $\xi'$ to $U_i \to U$ are isomorphic.

Then there is a natural bijection between $\mathcal{F}(U)$-isomorphism classes of twists of $\xi$ with $\hat{H}^1(U, \text{Aut}(\xi))$.

Proof: Cf. [Appendix of Lamb]. □
5.1. SITES, SHEAVES AND STACKS

Zariski Descent

Lemma (5.1.5.3) [Zariski Descent of Qco Sheaves]. The fibered category $X \mapsto (\mathcal{Q}\text{coh}/X)$ is a stack over $\text{Sch}_{\text{Zar}}/S$.

Proof: This is a consequence of (5.1.3.17) and the fact quasi-coherentness is a Zariski local property. □

Prop. (5.1.5.4) [Zariski Descent of Schemes]. The fibered category $X \mapsto \text{Sch}/X$ is in $\text{St}_{\text{Zar}}/S$.

Proof: Firstly it is a prestack by (5.1.3.16) and (5.1.4.34).

To show any descent datum of effective, let $\{U_i \to U\}$ be a Zariski covering, and $X_i \to U_i$ be schemes with descent datum $\varphi_{ij} : X_i \times_{U_i} U_{ij} \cong X_j \times_{U_j} U_{ij}$, then we define $X = \bigsqcup X_i/\sim$, where $x_i \sim x_j$ if $x_i \in U_{ij}, x_j \in U_{ji}$ and $\varphi_{ij}(x_i) = \varphi_{ji}(x_j)$. It can be shown this is an equivalence relation. Denote $\varphi_i : X_i \to X$ the natural map, and $U_i = \varphi_i(X_i)$. Define the topology on $X$ as the quotient topology. In particular, $\varphi_i$ is a homeomorphism onto the image. Then we can use (5.1.3.17) to glue the sheaves of rings $(\varphi_i)_*(\mathcal{O}_{X_i})$ to a sheaf of rings $\mathcal{O}_X$ on $X$ that $\varphi_i^*\mathcal{O}_X = \mathcal{O}_{X_i}$. Also we have a map $f : X \to U$ by set-theoretical and topological consideration. For the structure map $f^{-1}(\mathcal{O}_U) \to \mathcal{O}_X$, use (5.1.3.17). □

Cor. (5.1.5.5). If $\mathcal{P}$ is a subclass of arrows of schemes that is stable under base change and local on the target, then $\mathcal{P}/S$ is a stack over $(\text{Sch}/S)_{\text{Zar}}$.

Cor. (5.1.5.6) [Zariski Descent of Schemes with a Qco Sheaf]. The fibered category $X \mapsto \{$Schemes over $X$ with a Qco sheaf $\mathcal{F}\}$ is a stack in the Zariski topology $\text{Sch}_{\text{Zar}}/S$.

Proof: This is a combination of (5.1.5.4) and (5.1.5.3). □

Fpqc Descent

Prop. (5.1.5.7) [Reduction to Affine Case]. Let $S$ be a scheme and $\mathcal{F}$ be a fibered category over $\text{Sch}/S$. Suppose that

- $\mathcal{F}$ is a stack w.r.t. the Zariski topology.
- When $V \to U$ is a f.f. morphism of affine $S$-schemes, $\mathcal{F}(U) \to \mathcal{F}(V \to U)$ is an equivalence of categories.

then $\mathcal{F}$ is a stack w.r.t the fpqc topology.

Proof: Firstly, to show $\mathcal{F}$ is a prestack, using (5.1.3.8), it suffices to show for an $S$-scheme $T \to S$ and objects $\xi, \eta \in \mathcal{F}(T)$, the functor

$$\text{Hom}_T(\xi, \eta) : (\text{Sch}/T)^{\text{op}} \to \text{Set}$$

is a sheaf. But then we can use (5.1.4.33) to achieve this.

Next, according to (3.1.7.20) and (5.1.3.7), we may assume $\mathcal{F}$ is splitting.

Notice that $\mathcal{F}(\emptyset)$ is equivalent to the category pt. This is because $\mathcal{F}(\emptyset)$ is equivalent to $\mathcal{F}(\mathcal{U})$, where $\mathcal{U}$ is the null Zariski covering of $\emptyset$(with no mapping or objects at all!). Then for any disjoint union of open subschemes $U = \bigsqcup U_i$, there is a natural isomorphism of categories $\mathcal{F}(U) \cong \bigsqcup \mathcal{F}(U_i)$.

Thus for any covering $\mathcal{U} = \{U_i \to X\}$, to show $\mathcal{F}(X) \to \mathcal{F}(\mathcal{U})$ is an equivalence of categories, it suffices to show that $\mathcal{F}(X) \to \mathcal{F}(\bigsqcup U_i \to X)$ is an equivalence of categories: this is because $\bigsqcup U_i \times_X \bigsqcup U_i \cong \bigsqcup U_i \times_X U_j$, so $\mathcal{F}(\bigsqcup U_i \to X) \to \mathcal{F}(\mathcal{U})$ is an equivalence of categories.
If \( \mathcal{U} = \{ V \to U \} \) is a covering of \( F \) with a single morphism that is qc and \( U \) is affine, then by the proof of (5.1.3.10), we can choose a finite affine cover of \( V \) reduce to the case of covering of f.m. affine maps, then we finish by the case above.

If \( \mathcal{U} = \{ V \to U \} \) is a covering of \( F \) with a single morphism and \( U \) is affine, then we can find a Zariski covering \( \{ V_i \to V \} \) that each \( V_i \) is qc. and surjects onto \( U \). Then there are maps of categories \( \mathcal{F}(U) \to \mathcal{F}(\{ V \to U \}) \to \mathcal{F}(\{ V_i \to V \}) \), where \( \mathcal{F}(U) \to \mathcal{F}(\{ V_i \to V \}) \) is an equivalence and \( \mathcal{F}(U) \to \mathcal{F}(\{ V \to U \}) \) is fully faithful. Thus to show \( \mathcal{F}(U) \to \mathcal{F}(\{ V \to U \}) \) is an equivalence, it suffices to show \( \mathcal{F}(\{ V \to U \}) \) is faithful, which is true by (5.1.3.9).

For general case, Cf. [Vis08] P88. \( \square \)

**Prop. (5.1.5.8).** Mor \( /S : X \to \text{Sch} / X \) is a prestack over \( \text{Sch}_{\text{fpqc}} / S \), by (5.1.4.34) and (5.1.3.16).

**Def. (5.1.5.9) [Affine Fpqc Descent Datum].** For \( A \to B \in \mathcal{C}_{\text{Alg}} \), define a category \( \text{Mod}_{A \to B} \) as follows: its objects are pairs \( (N, \psi) \), where \( N \in \text{Mod}_B \) and \( \psi : N \otimes_A B \to B \otimes_A N \) is an isomorphism of \( B \otimes_A B \)-modules s.t. that

\[
\psi_{ij} \circ \psi_{01} = \psi_{02} : N \otimes_A B \otimes_A B \to B \otimes_A B \otimes_A N
\]

where \( \psi_{ij} \) is permuting the \( i \), \( j \)-parts using \( \psi \). The morphisms in \( \text{Mod}_{A \to B} \) are maps in \( \text{Mod}_B \) that is compatible with \( \psi \).

There is a natural functor \( \text{Mod}_{A \to B} \to \text{Mod}_B \).

**Lemma (5.1.5.10) [Affine Fpqc Descent].** For \( A \to B \in \mathcal{C}_{\text{Alg}} \), there is a functor \( F : \text{Mod}_A \to \text{Mod}_{A \to B} \), where \( M \) is mapped to \( (B \otimes_A M, \psi_M) \) with

\[
\psi_M : (B \otimes_A M) \otimes_A B \to B \otimes_A (B \otimes_A M) : b \otimes m \otimes b' \mapsto b \otimes b \otimes m.
\]

Then when \( A \to B \) is f.f., this is an equivalence of categories.

**Proof:** We construct an inverse \( T \) that maps \( (N, \psi) \) to \( \{ n | \psi(n \otimes 1) = 1 \otimes n \} \). Then \( TF \cong \text{id} \) because of the first exactness of (4.4.2.2).

And for \( FT \cong \text{id} \), let \( T((N, \psi)) = M \). Notice if \( \psi(n \otimes 1) = \sum_i b_i \otimes n_i \), then by cocycle condition,

\[
\sum_i b_i \otimes 1 \otimes n_i = \sum_i b_i \otimes \psi(n_i \otimes 1).
\]

so \( \psi(N \otimes 1) \subset \ker(\text{id}_B \otimes (n \mapsto \psi(n \otimes 1) - 1 \otimes n)) = B \otimes M \) because \( B/A \) is flat.

So we defined a map \( N \xrightarrow{\psi} B \otimes_A M \in \text{Mod}_B \), and the composition \( B \otimes_A M \xrightarrow{\text{mul.}} N \xrightarrow{\psi} B \otimes_A M \) is identity, because

\[
\psi(bm \otimes 1) = (b \otimes 1)\psi(m \otimes 1) = (b \otimes 1)(1 \otimes m) = b \otimes m.
\]

This shows \( \Psi \) is surjective. And \( \Psi \) is injective because \( n \mapsto n \otimes 1 \) is injective as \( B/A \) is f.f., and \( \psi \) is an isomorphism. So \( \Psi \) is an isomorphism of \( N \cong FT(N) \).

Finally, to show \( \psi = \psi_M \), as now \( B \otimes_A M \xrightarrow{\text{mul.}} N \) is an isomorphism, we check

\[
\psi((bm) \otimes b') = (b \otimes b')\psi(m \otimes 1) = (b \otimes b')(1 \otimes m) = b \otimes (b'm).
\]

\( \square \)
**Remark (5.1.5.11).** In fact, a descent datum is always effective iff $A \to B$ is universally injective. Cf.[Sta]. And f.f. extension is u.i.(4.4.1.28).

**Prop. (5.1.5.12) [fpqc Descent for Qco Sheaves].** Let $S$ be a scheme, then $\mathcal{QCoh}/\mathcal{Sch} \in \mathcal{St}_{\text{fpqc}}/S$.

*Proof:* We use(5.1.5.7), the first condition is satisfied by(5.1.5.3), and for the second condition, let $\text{Spec} B \to \text{Spec} A$ be a f.f. morphism of affine schemes, then $\mathcal{QCoh}(\text{Spec} B \to \text{Spec} A)$ is equivalent to $	ext{Mod}_{A\to B}$, and $\mathcal{QCoh}(\text{Spec} A)$ is equivalent to $\text{Mod}_{A}$, so the conclusion follows from(5.1.5.10). □

**Cor. (5.1.5.13).** For any $\mathcal{F} \in \mathcal{QCoh}(S)$, the functor $(\mathcal{Sch}/S)^{\text{op}} \to Ab: T \to \Gamma(T, f^{*}\mathcal{F}) \in \mathcal{St}_{\text{fpqc}}/S$, hence are also sheaves w.r.t. the fppf, étale, Zariski topologies.

*Proof:* Because this functor is just $\text{Hom}_{S}(\mathcal{O}_{S}, \mathcal{F})$, and it is a sheaf(5.1.3.8). □

**Cor. (5.1.5.14).** If $\mathcal{P}$ is a property of Qco sheaves that is stable under base change and fpqc local, then $\mathcal{QCoh}_{\mathcal{P}}/S \in \mathcal{St}_{\text{fpqc}}/S$.

**Prop. (5.1.5.15) [Descending Affine Morphisms].** For a scheme $S$, let $\mathcal{P}$ be the class of affine arrows in $\mathcal{Sch}/S$ that denote by $\text{Mor}^{\text{Aff}}$ the resulting fibered category, then $\text{Mor}^{\text{Aff}}_{S} \in \mathcal{St}_{\text{fpqc}}/S$.

*Proof:* Firstly $\text{Mor}^{\text{Aff}}/S \in \mathcal{St}_{\text{Zar}}/S$, and it satisfies the affine fpqc descent condition of(5.1.5.7)(Notice the $\{n|\psi(n \otimes 1) = 1 \otimes n\}$ is now a ring, because $\psi$ is a ring homomorphism), so we are done by(5.1.5.7). □

**Cor. (5.1.5.16).** If $\mathcal{P}$ is a subclass of affine arrows stable under base change and fpqc local on the target, then $\text{Mor}^{\mathcal{P}}/S \in \mathcal{St}_{\text{fpqc}}/S$.

**Prop. (5.1.5.17) [Descent via Ample Invertible Sheaves].** Let $S$ be a scheme and $\mathcal{P}$ be a class of flat proper morphisms of f.p. in $\mathcal{Sch}/S$ that is local in the fpqc topology. Assume that for each object $\xi: X \to U \in \mathcal{P}$, we have an invertible sheaf $\mathcal{L}_{\xi}$ on $X$ that is ample relative to $X \to U$, and for an arrow $f: (X \xrightarrow{\xi} U) \to (Y \to \eta V)$, we have an isomorphism $\rho_{f}: f^{*}\mathcal{L}_{\eta} \cong \mathcal{L}_{\xi}$ that satisfies $\rho_{gf} = \rho_{f} \circ f^{*}\rho_{g}$, then $\text{Mor}^{\mathcal{P}}/S \in \mathcal{St}_{\text{fpqc}}/S$.

*Proof:* Cf.[Vistoli, P96]. □

**Étale Descent**

**Prop. (5.1.5.18) [Galois Descent].** Let $L/K$ be a finite separable field extension with Galois group $G$, then $\text{Spec} L \to \text{Spec} K$ is a $G$-torsor in the étale topology. so Galois descent is a special case of étale descent along torsors(5.1.3.18).

Notice this is also true for arbitrary finite separable field extensions with continuity condition added, because we can take direct limits of categories over its finite normal subextensions.

*Proof:* Consider the locally constant group scheme $G = \text{Spec} (\prod_{g \in G} K)$, let $X = \text{Spec} L, Y = \text{Spec} K$, then $\{X \to Y\}$ is an étale cover, and the action $G \times X \to X$ is given by

$$L \to \prod_{g \in G} L : x \mapsto \prod_{g \in G} (g(x)).$$

Thus $X \to Y$ is a $G$-equivariant map, and there is an isomorphism $G \times X \cong X \times_{Y} X : (g, x) \mapsto (gx, x)$ that corresponds to the isomorphism

$$L \otimes_{K} L \cong \prod_{g \in G} L : (a, b) \mapsto \prod_{g \in G} (g(a)b)$$

□
Cor. (5.1.5.19) [Galois Descent of Closed Immersions]. Let $X$ be a scheme over a field $k$, and $K/k$ be a Galois field extension with Galois group $\Gamma$, $X' = X \otimes_K K$. Then the category of closed subschemes of $X$ is equivalent to the category of closed subschemes that is base change from some $X'_{k'}$ where $k'/k$ is finite, and is stable under the action of $\Gamma$. This weird finiteness condition can be removed when $X$ is locally algebraic over $k$.

Proof: This is because the class of closed immersions is a stack (5.1.5.16).

Remark (5.1.5.20). When $Y$ is a subvariety of $X$ and $K = k^s$, to check $Y$ is stable under action of $\Gamma$, it suffices to check that the geometric points is closed under action of $\Gamma$. This is because the geometric points are dense in $Y'$ (5.10.1.10).

Cor. (5.1.5.21) [Galois Descent for Ideals of Algebras]. Let $A \in \mathcal{C}_{\text{Alg}}_k$, and $K/k$ be a Galois field extension with Galois group $\Gamma$, then the category of ideals of $A$ is equivalent to the category of ideals of $A_K$ that is base change from some $A_{k'}$ where $k'/k$ is finite, and is stable under the action of $\Gamma$. This weird finiteness condition can be removed when $A$ is f.g. over $k$.

Cor. (5.1.5.22) [Galois Descent of Morphisms]. Let $X, Y$ be locally algebraic schemes over $k$ and $K/k$ a Galois field extension with Galois group $\Gamma$, $X' = X \otimes_K K, Y' = Y \otimes_K K$. If $Y$ is separated, then a morphism $\varphi' : X' \to Y'$ arises from a morphism $X \to Y$ iff its graph $\Gamma_{\varphi'} \subset X' \times_{k'} Y'$ is stable under action of $\Gamma$. In this case $\varphi$ is unique.

And when $X, Y$ are varieties and $K = k^s$, then it suffices to check the map

$$\varphi'(k^s) : X'(k^s) \to Y'(k^s)$$

commutes with action of $\Gamma$.

Cor. (5.1.5.23) [Galois Descent for Qco Sheaves]. Let $K/k$ be a Galois extension with Galois group $\Gamma$ and $X$ be a scheme over $k$ with $X' = X \otimes_K K$, then $\mathcal{Q}\text{coh}/X \to (\mathcal{Q}\text{coh}/X')^\Gamma$ is an equivalence of categories.

Proof: This is because $\mathcal{Q}\text{coh}/\text{Sch}$ is a fpqc stack (5.1.5.12).

Cor. (5.1.5.24) [Galois Descent for Vector Spaces]. Let $K/k$ be a Galois extension with Galois group $\Gamma$. Then the functor $V \mapsto K \otimes_V K$ induces an equivalence between the category of vector spaces over $k$ and the category of vector spaces over $K$ together with a continuous semi-linear action of $\Gamma$.

Prop. (5.1.5.25) [Failure of Étale Descent for proper smooth morphisms]. Cf. [Vis08] P107.

Descend Properties

Prop. (5.1.5.26) [Properties of Morphisms Local in Fpqc Topology]. The following properties of morphisms are local on the target w.r.t. the fpqc topology.

1. quasi-compact.
2. (quasi-)separated.
3. Universally closed.
4. universally open.
5. universally submersive.
6. surjective.
7. universally injective.
8. universally homeomorphism.
9. (locally)of f.t.
10. (locally)of f.p.
11. properness.
12. flatness.
13. (closed/open)immersion.
14. isomorphism/monomorphism.
15. (quasi-)affineness.
16. quasi-compact immersion.
17. integral
18. (locally)(quasi-)finite.
19. syntomic.
20. smooth, unramified, étale.
21. finite locally free.

Proof: Cf. [Sta] Chap 34.20.
18.
19. Cf. [Sta]00SM.
20.
21.

Prop. (5.1.5.27) [Properties of Schemes Local in the Fppf Topology].

Prop. (5.1.5.28) [Descending Properties that is not Fpqc Local].

- If $X \to Y$ is a faithfully flat morphism of schemes and $X$ is (geo.) reduced, then $Y$ is also (geo.) reduced.
- If $X \to Y$ is a faithfully flat morphism of f.p. between schemes and $X$ is (geo.) regular, then $Y$ is also (geo.) regular.

Proof: Looking stalkwise, these follows from (4.4.2.1).

Prop. (5.1.5.29) [Torsors]. Let $G$ be a group object in $(\text{Sch}_S)^{\tau}$ and $X \to S$ a $G$-torsor. Then if $\tau$ is a subcanonical site and $P$ is a property that is local on $(\text{Sch}_S)^{\tau}$ and $G \to S$ has $P$, then $X \to S$ has $P$.

Proof: By (5.1.1.17), there is a covering $\{Y_i \to S\}$ s.t. each $X \times_S Y_i \to Y_i \cong G \times_S Y_i$ is trivial, thus each $X \times_S Y_i \to Y_i$ has $P$, and then $X \to S$ has $P$.

Weil Restrictions

Def. (5.1.5.30) [Weil Restrictions]. Let $L/k$ be a finite extension of fields, $X \in \text{Sch}/L$, then the Weil restriction $\text{res}_{L/k}(X)$ is the scheme over $k$ representing the functor

$$\text{Sch}/k \to \text{Set} : S \mapsto X(S \times_k L).$$

Prop. (5.1.5.31). Let $L/k$ be a finite extension of fields, and $X \in \text{Sch}/L$. If every finite subset of $X$ is contained in some affine open subset of $X$, then $\text{res}_{L/K}(X)$ exists. In particular, this applies to the case that $X$ is quasi-projective.

Proof: Cf. [BLR90, Chap 7.6. Thm 4].

6 Étale Torsors

Prop. (5.1.6.1). For $X \in \text{Sch}$, $\check{H}^1(X, \text{GL}(n)) \cong \text{Vect}^n(X)$ as pointed sets, by (5.1.5.2).
5.2 Ringed Topoi, Ringed Sites, Ringed $G$-Spaces and Schemes

1 Ringed Topoi, Ringed Sites

Def.(5.2.1.1)[Ringed Topoi]. A ringed topos is a pair $(\mathcal{S}h(\mathcal{C}), \mathcal{O})$ where $\mathcal{C}$ is a site and $\mathcal{O}$ is a unital object in $\mathcal{S}h(\mathcal{C})$, called the structure sheaf. A morphism of of ringed topoi $(f, f^\#) : (\mathcal{C}, \mathcal{O}) \to (\mathcal{C}', \mathcal{O}')$ consists of a morphism of topoi (5.1.2.18) $f : \mathcal{S}h(\mathcal{C}) \to \mathcal{S}h(\mathcal{C}')$ and a map of sheaves of rings $f^\# : f^{-1}\mathcal{O}' \to \mathcal{O}$. A composition of morphism of topoi is defined to be $(g, g^\#) \circ (f, f^\#) = (g \circ f, f^\# \circ f^{-1}(g^\#))$.

Def.(5.2.1.2)[Ringed Sites]. A ringed site is pair $(\mathcal{C}, \mathcal{O})$ where $\mathcal{C}$ is a site and $\mathcal{O}$ is a sheaf of rings on $\mathcal{C}$, called the structure sheaf. A ringed site induces a ringed topos. A morphism of ringed sites is a morphism of sites that the induced morphism of topoi (5.1.2.19) is a morphism of ringed topoi (5.2.1.1).

A site is naturally a ringed site where $\mathcal{O} = \mathbb{Z}$ the constant sheaf (5.1.2.8). So we only consider ringed sites afterwards, then a morphism of ringed sites is naturally a morphism of ringed sites. So whenever we say $\mathcal{C}$ is a site, it is understood as a ringed site $(\mathcal{C}, \mathbb{Z})$.

Prop.(5.2.1.3)[Ringed Topoi and Ringed Sites]. Let $(f, f^\#) : (\mathcal{S}h(\mathcal{C}), \mathcal{O}_C) \to (\mathcal{S}h(\mathcal{D}), \mathcal{O}_D)$ be a morphism of ringed topoi, then we can find ringed sites $(\mathcal{C}', \mathcal{O}_{C'})$ and $(\mathcal{D}', \mathcal{O}_{D'})$ and a diagram

$$(\mathcal{S}h(\mathcal{C}), \mathcal{O}_C) \xrightarrow{(f, f^\#)} (\mathcal{S}h(\mathcal{D}), \mathcal{O}_D) \xleftarrow{(g, g^\#)} (\mathcal{S}h(\mathcal{C}'), \mathcal{O}_{C'}) \xrightarrow{(h, h^\#)} (\mathcal{S}h(\mathcal{D}'), \mathcal{O}_{D'})$$

where

- $(g, g^\#)$ and $(e, e^\#)$ are equivalence of ringed topoi.
- $\mathcal{C}', \mathcal{D}'$ have final objects and finite products.
- $(h, h^\#)$ is induced by a continuous functor $\mathcal{D}' \to \mathcal{C}'$ that the preserves the final object and finite products,(thus induces a morphism of sites by (5.1.2.14)).

Moreover, given a set of sheaves $\mathcal{F}_i$ on $\mathcal{C}$ and a set of sheaves $\mathcal{G}_i$ on $\mathcal{D}$, we may choose $\mathcal{C}'$ and $\mathcal{D}'$ that these sheaves are representable by objects in $\mathcal{C}'$ or $\mathcal{D}'$.

Proof: [Sta]03CR. □

Prop.(5.2.1.4)[Multiplicative Structure Sheaf]. Given a ringed topos $(\mathcal{S}h(\mathcal{C}), \mathcal{O})$, the presheaf $U \mapsto \mathcal{O}^*(U)$ is a sheaf of groups, called the multiplicative structure sheaf $\mathcal{O}^*$.

Proof: This comes from the sheaf property of $\mathcal{O}$ and the fact the inverse of an element is unique. □

Def.(5.2.1.5)[Local Ringed Site]. A ringed site $(\mathcal{C}, \mathcal{O})$ is called a local ringed site if

$$\mathcal{O}^\# \to \text{Equalizer}(0, 1 : \text{pt} \to \mathcal{O})$$

is an isomorphism of sheaves, and for any $U \in \mathcal{C}$ and $f \in \mathcal{O}(U)$, there exists a covering $\{U_i \to U\}$ s.t. for any $j$, either $f|_{U_i}$ is invertible or $(1 - f)|_{U_i}$ is invertible.
Prop. (5.2.1.6) [Characterizing Local Ringed Sites]. Let \((\mathcal{C}, \mathcal{O})\) be a ringed site, the following are equivalent:

- \((\mathcal{C}, \mathcal{O})\) is a local ringed site.
- (Partition of Unity) For any \(U \in \mathcal{C}, f_1, \ldots, f_n \in \mathcal{O}(U)\) that \((f_1, \ldots, f_n) = (1)\), there is a covering \(\{U_i \to U\}\) that for each \(j\), there exists an \(i\) that \(f_i\) is invertible on \(U_j\).
- The map of sheaves of sets:
  \[
  (\mathcal{O} \otimes \mathcal{O}) \coprod (\mathcal{O} \times \mathcal{O}) \to \mathcal{O} \times \mathcal{O}
  \]
  which maps \((f, a)\) in the first component to \((f, af)\) and \((f, b)\) in the second component to \((f, b(1 - f))\) is surjective.

Proof: Cf. [Sta]04ES.

Def. (5.2.1.7) [Local Ringed Topoi]. If \(f : \text{Sh}(\mathcal{C}') \to \text{Sh}(\mathcal{C})\) is a morphism of topoi and \((\mathcal{C}, \mathcal{O})\) is a local ringed site, then \((\text{Sh}(\mathcal{C}'), f^{-1}\mathcal{O})\) is also a local ringed site. In particular, being a local ringed site is an intrinsic property, so we can define local ringed topoi to be ringed topoi that the underlying ringed sites are local ringed.

Proof: Because \(f^{-1}\) is exact (5.1.2.18) and commutes with products and equalizers, it maps the isomorphism

\[
\emptyset \to \text{Equalizer}(0, 1 : \text{pt} \to \mathcal{O})
\]

to the corresponding isomorphism of \(\mathcal{C}'\), and also the sejection of

\[
(\mathcal{O} \otimes \mathcal{O}) \coprod (\mathcal{O} \times \mathcal{O}) \to \mathcal{O} \times \mathcal{O}
\]

in (5.2.1.6) to that of \(\mathcal{C}'\), thus \((\text{Sh}(\mathcal{C}'), f^{-1}\mathcal{O})\) is also a local ringed site.

Def. (5.2.1.8) [Morphisms of Local Ringed Topoi]. A morphism of local ringed topoi is a morphism of ringed topoi \((f, f^\#) : (\text{Sh}(\mathcal{C}), \mathcal{O}_C) \to (\text{Sh}(\mathcal{D}), \mathcal{O}_D)\) that the diagram of sheaves

\[
\begin{array}{ccc}
  f^{-1}(\mathcal{O}_D^\ast) & \xrightarrow{f^\#} & \mathcal{O}_C^\ast \\
  \downarrow & & \downarrow \\
  f^{-1}(\mathcal{O}_D) & \xrightarrow{f^\#} & \mathcal{O}_C
\end{array}
\]

is Cartesian, where \(\mathcal{O}_C^\ast\) is the multiplicative structure sheaf (5.2.1.4). Morphisms of local ringed topoi are stable under compositions.

**Ringed Spaces**

Def. (5.2.1.9) [Ringed Spaces]. A ringed space is a pair \((X, \mathcal{O}_X)\) consisting of a topological space \(X\) and a sheaf of rings \(\mathcal{O}_X\) on \(X\). A morphism of ringed spaces \((X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)\) consists of a pair \((f, f^\#)\) where \(f\) is a continuous map \(X \to Y\) and \(f^\#\), which induces a map of sites \((f^{-1}, f^\#) : X_{\text{Zar}} \to Y_{\text{Zar}}\) (5.2.6.7), and \(f^\#_s\) is a map \(f^\# : f^{-1}(\mathcal{O}_Y) \to \mathcal{O}_X\) (5.2.6.2), such that \((f, f^\#)\) is a morphism of ringed topoi (5.2.1.1).
Def. (5.2.1.10)[Local Ringed Space]. A local ringed space is a topological space $X$ with a sheaf of rings $\mathcal{O}_X$ that $(X, \mathcal{O}_X)$ forms a local ringed site $(5.2.1.5)$. A morphism of local ringed space is a morphism of ringed spaces that the corresponding morphism of ringed topoi $(\mathcal{S} \mathcal{h}(\mathcal{C}), \mathcal{O}_C) \to (\mathcal{S} \mathcal{h}(\mathcal{D}), \mathcal{O}_D)$ is a morphism of local ringed topoi $(5.2.1.8)$.

Prop. (5.2.1.11). A ringed space $(X, \mathcal{O}_X)$ is a locally ringed space iff any stalks $\mathcal{O}_{X,x}$ is either 0 or a local rings.

Proof: Cf. [Sta]04ET. □

2 Modules on Ringed Topoi

Main References are [Sta]Chap 18.

Def. (5.2.2.1)[Modules on Ringed Topoi]. Let $(\mathcal{S} \mathcal{h}(\mathcal{C}), \mathcal{O})$ be a ringed topos, then a sheaf of $\mathcal{O}$-modules is a presheaf of $\mathcal{O}$-modules that the underlying presheaf of Abelian groups is a sheaf.

Def. (5.2.2.2)[Support]. Let $(X, \mathcal{O}_X)$ be a ringed space, $\mathcal{F}$ a $\mathcal{O}_X$-module, then the support of $\mathcal{F}$ is the set of points $x$ that $\mathcal{F}_x \neq 0$. It is denoted by $\text{Supp}(\mathcal{F})$. For a section $s \in \Gamma(X, \mathcal{F})$, $\text{Supp}(s)$ is defined to be the set of points $x$ that $s_x \neq 0 \in \mathcal{F}_x$.

Prop. (5.2.2.3). Glueing sheaves is available for ringed spaces, similar to (5.1.5.3).

Proof:

Prop. (5.2.2.4). Glueing ringed spaces is available.

Proof:

Def. (5.2.2.5)[Local Properties of Modules]. On a ringed site $(\mathcal{C}, \mathcal{O})$, an $\mathcal{O}$-module $\mathcal{F}$ is called locally has property $P$ if for any object $U \in \mathcal{C}$, there is a covering $\{U_i \to U\}$ that $\mathcal{F}|_{U_i}$ has property $P$.

Def. (5.2.2.6)[Intrinsic Properties of Modules]. An intrinsic property of sheaves of modules in a ringed topos $(\mathcal{S} \mathcal{h}(\mathcal{C}), \mathcal{O})$ that is invariant under equivalence of topoi.

Def. (5.2.2.7)[Tensor Products Sheaf]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $\mathcal{F}, \mathcal{G}$ be $\mathcal{O}$-modules, then the tensor product $\mathcal{F} \otimes_{\mathcal{O}} \mathcal{G}$ is defined to be the shification of the presheaf $U \mapsto \mathcal{F}(U) \otimes_{\mathcal{O}(U)} \mathcal{G}(U)$.

The tensor product is easily seen to be an intrinsic notion $(5.2.2.6)$, so it can be defined on any ringed topos.

Prop. (5.2.2.8)[Base Change]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $\mathcal{O}_2$ be a sheaf $\mathcal{O}_1$-algebras, $\mathcal{G}$ be a sheaf of $\mathcal{O}_1$-module and $\mathcal{F}$ a sheaf of $\mathcal{O}_2$-module, then

$$\text{Hom}_{\mathcal{O}_1}(\mathcal{G}, \mathcal{F}_{\mathcal{O}_1}) = \text{Hom}_{\mathcal{O}_2}(\mathcal{G} \otimes_{\mathcal{O}_1} \mathcal{O}_2, \mathcal{F}).$$

Proof: This can be seen from the definition of tensor product and the fact shification doesn’t bother because $\mathcal{F}$ is a sheaf. □

Def. (5.2.2.9)[Transfer of Modules on Ringed Sites]. Let $(f, f^\sharp)$ be a morphism of ringed topoi $(\mathcal{S} \mathcal{h}(\mathcal{C}), \mathcal{O}) \to (\mathcal{S} \mathcal{h}(\mathcal{C}', \mathcal{O}'))$, then there are functor:

- the pushforward: $f_* : \text{Mod}(\mathcal{O}) \to \text{Mod}(\mathcal{O}') : f_* \mathcal{F} = f_* \mathcal{F}$ as a $\mathcal{O}'$-module via $\mathcal{O}' \to f_* \mathcal{O}$. 

• the pullback $f^*: \text{Mod}(O') \to \text{Mod}(O) : f^*G = O \otimes_{f^{-1}O'} f^{-1}G$ via $f^2: f^{-1}O' \to O$. $f^*$ is left adjoint to $f_*$, by the adjointness of $f^{-1}$ and $f_*(5.1.2.18)$.

If $(f, f^2)$ is a morphism of ringed sites $(C, O) \to (C', O')$, then there is an extension by zero functor:

- (Extension by zero): For the localization of sites $j_U : (C/U, O_U) \to (C, O)$ the localization map of site, $j_U^* = j_U^{-1}$ has a left adjoint $j_U^!$ defined by shifification of the presheaf $G \mapsto j_U!(G) : j_U!(G)(V) = \bigoplus_{\varphi: V \to U} G(V) \otimes O$.  

Proof: To show $j_U^!$ is left adjoint to $j_U^*$, Cf.[Sta]03DI. \hfill \square

Remark (5.2.2.10). The $f^*$ may not be exact. $f^{-1}$ is exact, but we tensored with $O_X$, it is exact when $f$ is flat(5.2.2.15).

Prop.(5.2.2.11)[Extension by Zero is Exact]. Let $(C, O)$ be a ringed site and $U \in C$, then the extension by zero functor $j_U^! : \text{Mod}(O_U) \to \text{Mod}(O)$ is exact and reflects exactness.

Proof: It is right exact because it is a left adjoint, and it is left exact by direct inspection. 

For reflection of exactness, Cf.[Sta]08E5G. \hfill \square

Prop.(5.2.2.12)[Tensor Products and Pullbacks]. Tensor products commute with pullbacks, in particular with taking stalks. So tensoring with a locally free sheaf is exact.

Proof: By (5.2.3.3) and (5.2.3.5), for any $O$-module $H$,

\[ \text{Hom}(f^*F \otimes f^*G, H) = \text{Hom}(F, f_*\text{Hom}(f^*G, H)) = \text{Hom}(F, \text{Hom}(G, f_*H)) = \text{Hom}(f^*(F \otimes G), H). \]

\hfill \square

Prop.(5.2.2.13)[$j_U^!$ Commutes with Restriction]. Let $(C, O)$ be a ringed site and $U \in C, G \in \text{Mod}(O_U), F \in \text{Mod}(O)$, then there is a natural isomorphism $j_U^!G \otimes_O F \cong j_U^!(G \otimes_{O_U} F|_U)$

Proof: By (5.2.3.3) and (5.2.3.5), for any $H \in \text{Mod}(O)$,

\[ \text{Hom}_O(j_U^!(G \otimes_{O_U} F|_U), H) = \text{Hom}_{O_U}(G \otimes_{O_U} F|_U, H|_U) = \text{Hom}_{O_U}(G, \text{Hom}_O(F|_U, H|_U)) = \text{Hom}_O(j_U^!G, \text{Hom}_O(F, H)) = \text{Hom}_O(j_U^!G \otimes_O F, H) \]

then use Yoneda lemma. \hfill \square

Prop.(5.2.2.14)[Properties of Tensor Products]. Let $(C, O)$ be a ringed site and $F, G$ be sheaves of $O$-modules, then

1. If $F, G$ are locally free, then so does $F \otimes G$.
2. If $F, G$ are locally finite free, then so does $F \otimes G$.
3. If $F, G$ are locally generated by sections, then so does $F \otimes G$.
4. If $F, G$ are of f.t., then so does $F \otimes G$.
5. If $F, G$ are quasi-coherent, then so does $F \otimes G$.
6. If $F, G$ are of f.p., then so does $F \otimes G$.
7. If $F$ is of f.p. and $G$ is coherent, then $F \otimes G$ is coherent. In particular, if $F, G$ are coherent, then so does $F \otimes G(5.2.2.27)$.

Proof: Cf.[Sta]03L6. \hfill \square
Flat Modules

Def. (5.2.2.15) [Flat Modules and Flat Morphisms]. Let \( \mathcal{C} \) be a site and \( \mathcal{O} \) a presheaf of rings, then a presheaf \( \mathcal{F} \) of \( \mathcal{O} \)-modules is called **flat** if the functor \( \text{PMod}(\mathcal{O}) \to \text{PMod}(\mathcal{O}) : \mathcal{G} \mapsto \mathcal{G} \otimes_{\mathcal{O}} \mathcal{F} \) is exact.

Let \( \mathcal{C} \) be a ringed site, and \( \mathcal{F} \) is a sheaf of \( \mathcal{O} \)-modules, then it is called **flat** if the functor \( \text{Mod}(\mathcal{O}) \to \text{Mod}(\mathcal{O}) : \mathcal{G} \mapsto \mathcal{G} \otimes_{\mathcal{O}} \mathcal{F} \) is exact.

A morphism \((f, f^\#)\) is called a **flat morphism** if the ring map \( f^\# : f^{-1} \mathcal{O}' \to \mathcal{O} \) is flat, or equivalently, the pullback functor (5.2.2.9) \( f^* \) is exact.

Prop. (5.2.2.16). Let \( \mathcal{C} \) be a site and \( \mathcal{O} \) a presheaf of rings with shiffication \( \mathcal{O}^\sharp \).
- If \( \mathcal{F} \) is a presheaf of \( \mathcal{O} \)-modules that each \( \mathcal{F}(U) \) is flat \( \mathcal{O}(U) \)-modules, then \( \mathcal{F} \) is flat.
- If \( \mathcal{F} \) is a flat presheaf of \( \mathcal{O} \)-modules, then \( \mathcal{F}^\# \) is a flat \( \mathcal{O}^\sharp \)-modules.
- A filtered colimits of flat presheaves of modules is flat. A direct sum of flat presheaves of modules is flat.
- A filtered colimits of flat sheaves of modules is flat. A direct sum of flat sheaves of modules is flat.

Prop. (5.2.2.17) [Flatness is Stalkwise]. Let \((X, \mathcal{O}_X)\) be a ringed space, then an \( \mathcal{O}_X \)-module \( \mathcal{F} \) is flat iff the stalks \( \mathcal{F}_x \) are all flat \( \mathcal{O}_{X,x} \)-modules.

Proof: Cf. [Sta]05NE. \( \square \)

Prop. (5.2.2.18) [Flat Morphism and Support]. Let \( f : (X, \mathcal{O}_X) \to (X', \mathcal{O}_{X'}) \) be a flat morphism of local ringed spaces, \( \mathcal{F} \) an \( \mathcal{O}_{X'} \)-module, then \( \text{Supp}(f^*(\mathcal{F})) = f^{-1}(\text{Supp}(\mathcal{F})) \).

Proof: Use the fact flat ring map of local rings is faithfully flat. \( \square \)

Modules of Finite Type & Finite Presentation

Def. (5.2.2.19) [Finite Type]. An \( \mathcal{O} \)-module is called **finite type** iff locally a quotient of a finite free sheaf.

Prop. (5.2.2.20) [Extension of F.T. Sheaves]. if \( 0 \to \mathcal{F}_1 \to \mathcal{F}_2 \to \mathcal{F}_3 \to 0 \) is an exact sequence of \( \mathcal{O} \)-modules and \( \mathcal{F}_1, \mathcal{F}_3 \) are of f.t., then \( \mathcal{F}_2 \) is of f.t..

Proof: For any \( U \in \mathcal{C} \), choose a covering \( \{ U_i \to U \} \) that \( \mathcal{F}_3(U_i) \) is generated by f.m. sections, then by passing to a covering, we may assume these sections come from \( \mathcal{F}_2 \). Pass to another covering that \( \mathcal{F}_1 \) is generated by f.m. sections, then on this covering, \( \mathcal{F}_2 \) is generated by f.m. sections. \( \square \)

Def. (5.2.2.21) [Finite Presentation]. A sheaf of modules \( \mathcal{F} \) is called **of finite presentation** iff locally it is a cokernel of two finite free modules. The pullback of a f.p. sheaf is f.p, by the left adjointness of \( f^* \).

Prop. (5.2.2.22) [FP-FT-FT]. If \( f : \mathcal{G} \to \mathcal{F} \) is a surjection of \( \mathcal{O} \)-modules, \( \mathcal{F} \) is of f.p. and \( \mathcal{G} \) is of f.t., then the kernel is of finite type.
Proof: We first show for $G = \mathcal{O}_n$: By pass to covering, we can construct a diagram

$$
\begin{array}{ccc}
\mathcal{O}^n_{U_{ij}} & \longrightarrow & \mathcal{O}^n_{U_{ij}} \\
& & \downarrow \alpha \\
0 & \longrightarrow & \ker(f)|_{U_{ij}} \\
\end{array}
\quad \Rightarrow 
\begin{array}{ccc}
\mathcal{G}|_{U_{ij}} & \longrightarrow & \mathcal{F}|_{U_{ij}} \\
& & \downarrow \\
0 & \longrightarrow & \mathcal{F}|_{U_{ij}} \\
\end{array}
$$

and then use snake lemma. The image and cokernel of $\alpha$ are all of f.t., then $\ker(f)|_{U_{ij}}$ is of f.t. by (5.2.2.20).

For general $G$, locally choose a surjection $\varphi : \mathcal{O}_n|_{U_t} \rightarrow G|_{U_t}$, then $\ker(f|_{U_t}) = \varphi(\ker(\varphi \circ f|_{U_t}))$, which is of f.t.. $\square$

Prop. (5.2.2.23). Pullbacks of a module of finite type is of finite type. Pullback of a module of finite presentation is of finite presentation.

Finite type and finite presentation are local on the target.

Proof: This is because pullback is a left adjoint thus right exact. They are local on the target because they are defined locally. $\square$

Prop. (5.2.2.24) [Support is Zariski Closed]. If $(X, \mathcal{O}_X)$ is a ringed space and $f : \mathcal{G} \rightarrow \mathcal{F}$ is surjective at a point $x$ and $\mathcal{F}$ is of f.t., then it is surjective on a Zariski nbhd of $x$. Thus the support of a f.t. sheaf is closed (look at $0 \rightarrow \mathcal{F}$).

Proof: Choose a nbhd of $x$ that $\mathcal{F}(U)$ is generated by $s_1, \ldots, s_n \in \mathcal{F}(U)$, because $f$ is surjective at the stalk of $x$, after shrinking $U$, we may assume $s_i = f(t_i)$ for $t_i \in \mathcal{G}(U)$, so $f$ is surjective on $U$. $\square$

(Quasi-)Coherent Sheaves

Def. (5.2.2.25) [Quasi-Coherent Sheaf]. An $\mathcal{O}$-module $\mathcal{F}$ on a ringed site is called quasi-coherent iff locally it is a cokernel of two free modules. A locally f.p. sheaf of modules is $\text{Qco}$.

Prop. (5.2.2.26) [Associated $\text{Qco}$ Sheaves]. And for a ringed space $(X, \mathcal{O}_X)$ and a $R = \Gamma(X, \mathcal{O}_X)$-module $M$, we have a coherent sheaf $\mathcal{F}_M$ on $X$, defined as $\pi^*(M)$, where $M$ is seen as a qco sheaf on $(\text{pt}, R)$. It is the sheaf associated to the presheaf $U \mapsto \mathcal{O}_X(U) \otimes M$.

This construction is a functor from the category of $R$-module to the category of $\text{Qco} \mathcal{O}_X$-modules, and it commutes with colimits because $\pi^*$ does. And it is left adjoint to $\Gamma$ by (5.2.2.9):

$$\text{Hom}_A(M, \Gamma(X, \mathcal{G})) \cong \text{Hom}_{\mathcal{O}_X}(\mathcal{F}_M, \mathcal{G})$$

Def. (5.2.2.27) [Coherent Sheaves]. A coherent sheaf is an $\mathcal{O}$-module $\mathcal{F}$ that is of f.t. and for any object $U$ and for any set of elements of $\Gamma(U, \mathcal{F})$, the kernel of $\oplus \mathcal{O}_U \rightarrow \mathcal{F}|_U$ is of f.t..

A coherent sheaf is of f.p., by base change to a smaller covering, and it is $\text{Qco}$.

Prop. (5.2.2.28) [Properties of Coherent Sheaves]. Any f.t. subsheaf of a coherent sheaf is coherent, by definition. Any kernel of a morphism from a f.t. sheaf to a coherent sheaf is of f.t..

$\text{Coh}(X)$ is a weak Serre subcategory of $\text{Mod}_{\mathcal{O}_X}$. In particular, if $\mathcal{O}_X$ is coherent, then a sheaf is coherent iff it is f.p.
Prop. (5.2.2.29). The pullback of a (quasi-)coherent module is a (quasi-)coherent, because \( f^* \) is a left adjoint.

Prop. (5.2.2.30). (Quasi-)Coherence is local on the target.

Proof: This is because they are defined locally. □

Prop. (5.2.2.31). Let \((X, \mathcal{O}_X)\) be a ringed space and \(x \in X\).

- Let \(f : \mathcal{G} \to \mathcal{F}\) be a map of \(\mathcal{O}_X\)-modules. If \(\mathcal{G}\) is of f.t. and \(\mathcal{F}\) is coherent, and \(f\) is injective at the stalk of \(x\), then there exists a nbhd \(U\) of \(x\) that \(f|_U\) is injective.

- Let \(f : \mathcal{G} \to \mathcal{F}\) be a map of coherent \(\mathcal{O}_X\)-modules that is surjective at the stalk of \(x\), then there exists a nbhd \(U\) of \(x\) that \(f|_U\) is surjective.

- Let \(f : \mathcal{G} \to \mathcal{F}\) be a map of coherent \(\mathcal{O}_X\)-modules that is isomorphism at the stalk of \(x\), then there exists a nbhd \(U\) of \(x\) that \(f|_U\) is an isomorphism.

Proof: 1: Consider the kernel of \(f\), then it is of f.t. by definition (5.2.2.27). Then \(\ker(f)_x = 0\), so there is a nbhd \(U\) of \(x\) that \(\ker(f)|_U = 0\), by (5.2.2.24), which means \(f|_U\) is injective.

2: this is immediate from (5.2.2.24).

3 follows from 1 and 2. □
3 Construction of Sheaves

Internal Hom

Def.(5.2.3.1)[Internal Hom]. Let \(\mathcal{C}\) is a category and \(\mathcal{O}\) is a presheaf of rings, \(\mathcal{F}, \mathcal{G}\) be presheaves of \(\mathcal{O}\)-modules, then \(U \mapsto \text{Hom}_{\mathcal{O}|U}(\mathcal{F}|U, \mathcal{G}|U)\) defines a presheaf \(\text{Hom}(\mathcal{F}, \mathcal{G})\) of \(\mathcal{O}\)-modules, and there is a natural evaluation map

\[
\mathcal{F} \otimes_{\mathcal{O}} \text{Hom}(\mathcal{F}, \mathcal{G}) \to \mathcal{G}.
\]

Now if \(\mathcal{C}\) is a site and \(\mathcal{O}\) is a sheaf of rings, \(\mathcal{F}, \mathcal{G}\) be sheaves of \(\mathcal{O}\)-modules, then \(\text{Hom}_{\mathcal{O}}(\mathcal{F}, \mathcal{G})\) is a sheaf of \(\mathcal{O}\)-modules by (5.1.3.17), called the internal Hom sheaf. Denote \(\text{Hom}(\mathcal{F}, \mathcal{O})\) by \(\mathcal{F}^\vee\).

Prop.(5.2.3.2). Internal Hom sheaf commutes with localization: \(\text{Hom}_{\mathcal{O}|U}(\mathcal{F}|U, \mathcal{G}|U) = \text{Hom}_{\mathcal{O}}(\mathcal{F}, \mathcal{G})|_U\). This follows from the definition.

Prop.(5.2.3.3)[Tensoring and Inner Hom]. If \(\mathcal{C}\) is a site, \(\mathcal{O}\) is a sheaf of rings and \(\mathcal{F}, \mathcal{G}, \mathcal{H}\) are sheaves of \(\mathcal{O}\)-modules, then there is a canonical isomorphism of sheaves:

\[
\text{Hom}_{\mathcal{O}}(\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}, \mathcal{G}) \cong \text{Hom}_{\mathcal{O}}(\mathcal{F}, \text{Hom}_{\mathcal{O}}(\mathcal{H}, \mathcal{G})).
\]

In particular, taking limit over \(\mathcal{C}\), we see \(- \otimes_{\mathcal{O}} \mathcal{H}\) is left adjoint to \(\text{Hom}_{\mathcal{O}}(\mathcal{F}, -)\):

\[
\text{Hom}_{\mathcal{O}}(\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}, \mathcal{G}) \cong \text{Hom}_{\mathcal{O}}(\mathcal{F}, \text{Hom}_{\mathcal{O}}(\mathcal{H}, \mathcal{G})).
\]

In particular, the monoidal category of \(\mathcal{O}_X\)-modules is closed (5.2.2.15).

Proof: Omitted (Recall the definition of tensor product sheaf (5.2.2.7)).

Prop.(5.2.3.4).

\[
\text{Hom}(\lim A_i, B) \cong \lim \text{Hom}(A_i, B) \quad \text{Hom}(A, \lim B_i) \cong \lim \text{Hom}(A, B_i)
\]

Proof: This is immediate from (3.1.4.9).

Prop.(5.2.3.5). \(f^\ast\) is left adjoint to \(f_\ast\) by (5.2.2.9): \(\text{Hom}_{\mathcal{O}_Y}(f^\ast \mathcal{G}, \mathcal{F}) \cong \text{Hom}_{\mathcal{O}_Y}(\mathcal{G}, f_\ast \mathcal{F})\). In fact

\[
f_\ast(\text{Hom}_{\mathcal{O}}(f^\ast \mathcal{G}, \mathcal{F})) \cong \text{Hom}_{\mathcal{O}}(\mathcal{G}, f_\ast \mathcal{F}).
\]

by checking on every open subset \(U \subset Y\).

Prop.(5.2.3.6). Let \(\mathcal{C}\) be a site and \(\mathcal{O} \to \mathcal{O}'\) is a map of sheaves of rings, then for any \(\mathcal{G} \in \text{Mod}(\mathcal{O}')\) and \(\mathcal{F} \in \text{Mod}(\mathcal{O})\), there is a natural isomorphism

\[
\text{Hom}_{\mathcal{O}}(\mathcal{G}, \mathcal{F}) = \text{Hom}_{\mathcal{O}'}(\mathcal{G}, \text{Hom}_{\mathcal{O}}(\mathcal{O}', \mathcal{F})).
\]

by checking on every open subset \(U \subset Y\).

Prop.(5.2.3.7). Let \(f_\ast : (X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)\) be a morphism of ringed spaces, and \(\mathcal{F}, \mathcal{G}\) are \(\mathcal{O}_Y\)-modules. If \(\mathcal{F}\) is f.p. and \(f\) is flat, then the canonical map

\[
f^\ast \text{Hom}_{\mathcal{O}_Y}(\mathcal{F}, \mathcal{G}) \to \text{Hom}_{\mathcal{O}_X}(f^\ast \mathcal{F}, f^\ast \mathcal{G})
\]

is an isomorphism.
5.2. RINGED TOPOI, RINGED SITES, RINGED G-SPACES AND SCHEMES

Proof: 

Prop.(5.2.3.8). Let \((X, \mathcal{O}_X)\) be a ringed space and \(\mathcal{F}, \mathcal{G}\) be \(\mathcal{O}_X\)-modules. If \(\mathcal{F}\) is f.p. or locally free, then the canonical map

\[\text{Hom}(\mathcal{F}, \mathcal{G})_x \to \text{Hom}_{\mathcal{O}_X,x}(\mathcal{F}_x, \mathcal{G}_x)\]

is an isomorphism.

Proof: Choose a presentation of \(\mathcal{F}\). This follows from the exactness of taking stalks and (5.2.3.4).

Prop.(5.2.3.9). Let \((X, \mathcal{O}_X)\) be a ringed site and \(\mathcal{F}, \mathcal{G}\) be \(\mathcal{O}_X\)-modules. If \(\mathcal{F}\) is f.p. and \(\mathcal{G}\) is coherent, then \(\text{Hom}(\mathcal{F}, \mathcal{G})\) is also coherent. In particular, this applies to \(\mathcal{F}, \mathcal{G}\) both coherent.

Proof: This follows from (5.2.3.4) and (5.2.2.28).

Tensor Sheaves

Def.(5.2.3.10)[Tensor Sheaves]. Let \((\mathcal{C}, \mathcal{O})\) be a ringed site and \(\mathcal{F}\) an \(\mathcal{O}\)-module, then we define

- \(T(\mathcal{F})\) to be the sheafification of the presheaf \(U \mapsto T_{\mathcal{O}_X}(\mathcal{F}(U))\) (4.1.1.20).
- \(\wedge \mathcal{F}\) to be the sheafification of the presheaf \(U \mapsto \wedge_{\mathcal{O}_X(U)}(\mathcal{F}(U))\) (4.1.1.20).
- \(\text{Sym}(\mathcal{F})\) to be the sheafification of the presheaf \(U \mapsto \text{Sym}_{\mathcal{O}_X(U)}(\mathcal{F}(U))\) (4.1.1.20).

Cor.(5.2.3.11). Over a ringed space \((X, \mathcal{O}_X)\), the construction of \(T(\mathcal{F}), \wedge(\mathcal{F})\) and \(\text{Sym}(\mathcal{F})\) commutes with taking stalks, because the construction of tensor algebras and sheffification are both left adjoints (4.1.1.21). Also they commutes with pullbacks, because they satisfy the same universal properties.

Prop.(5.2.3.12). let \(\mathcal{F}\) be an \((\mathcal{C}, \mathcal{O})\)-module, then the following properties are preserved under the construction of \(T(\mathcal{F}), \wedge(\mathcal{F})\) and \(\text{Sym}(\mathcal{F})\):

- Locally generated by sections.
- Finite Type.
- Finite Presented.
- Coherent.
- Quasi-coherent.
- Locally free.

Proof: Cf.[Sta]01CL.

4 Sheaf of Differentials

Prop.(5.2.4.1). If \(\mathcal{C}\) is a site and \(\mathcal{O}_1 \to \mathcal{O}_2\) is a homomorphism of sheaves of rings and \(\mathcal{F}\) is a sheaf of \(\mathcal{O}_2\)-modules, then an \(\mathcal{O}_1\)-derivation from \(\mathcal{O}_2\) to \(\mathcal{F}\) is a map that for any \(U \in \mathcal{C}\), the map \(\mathcal{O}_2(U) \to \mathcal{F}(U)\) is a \(\mathcal{O}_1(U)\)-derivation (4.4.3.1).

Prop.(5.2.4.2)[Sheaf of Differentials]. Let \(\mathcal{C}\) be a site and \(\mathcal{O}_1 \to \mathcal{O}_2\) is a homomorphism of sheaves of rings and \(\mathcal{F}\) is a sheaf of \(\mathcal{O}_2\)-modules, then the functor \(\text{Mod}(\mathcal{O}_2) \to \text{Ab}: \mathcal{F} \to \text{Der}_{\mathcal{O}_1}(\mathcal{O}_2, \mathcal{F})\) is representable by a sheaf of modules \(\Omega_{\mathcal{O}_2/\mathcal{O}_1}\), called the sheaf of differentials, and the map \(d: \mathcal{O}_2 \to \Omega_{\mathcal{O}_2/\mathcal{O}_1}\) is called the universal derivation.
Prop. (5.2.4.3)[Localness of Sheaf of Differentials]. If \( \mathcal{O}_1 \to \mathcal{O}_2 \) is a homomorphism of presheaves of rings, then \( \Omega_{\mathcal{O}_2/\mathcal{O}_1} \) is the sheafification of the presheaf \( U \mapsto \Omega_{\mathcal{O}_2(U)/\mathcal{O}_1(U)} \).

Proof: This is because the construction of \( \Omega_{\mathcal{O}_2/\mathcal{O}_1} \) for all \( U \) gives an exact sequence of presheaves, and the sheafification of which is just the construction in (5.2.4.2), so we are done because sheafification is exact (5.1.2.7).

Prop. (5.2.4.4)[Change of Sites]. Let \( f : \text{Sh}(\mathcal{D}) \to \text{Sh}(\mathcal{C}) \) be a morphism of topoi and \( \varphi : \mathcal{O}_1 \to \mathcal{O}_2 \) a homomorphism of rings on \( \mathcal{C} \), then there is a canonical isomorphism \( f^{-1}\Omega_{\mathcal{O}_2/\mathcal{O}_1} \cong \Omega_{f^{-1}\mathcal{O}_2/f^{-1}\mathcal{O}_1} \) compatible with the universal derivations.

Proof: This follows from the construction (5.2.4.2) and the fact \( f^{-1} \) is exact (5.2.4.2).

Prop. (5.2.4.5)[Functoriality of \( \Omega \)]. Let \( \varphi : (\mathcal{O}_1 \to \mathcal{O}_2) \to (\mathcal{O}'_1 \to \mathcal{O}'_2) \) be a commutative diagram of sheaves of rings over a site \( \mathcal{C} \), then the map \( \mathcal{O}'_1 \to \mathcal{O}'_2 \) composed with the derivative \( \mathcal{O}'_2 \to \Omega_{\mathcal{O}'_2/\mathcal{O}'_1} \) is a \( \mathcal{O}'_1 \)-derivative, thus we obtain a map of \( \mathcal{O}_2 \)-modules \( \Omega_{\mathcal{O}_2/\mathcal{O}_1} \to \Omega_{\mathcal{O}'_2/\mathcal{O}'_1} \), or equivalently a map of \( \mathcal{O}'_2 \)-modules \( \Omega_{\mathcal{O}_2/\mathcal{O}_1} \otimes_{\mathcal{O}_2} \mathcal{O}'_2 \to \Omega_{\mathcal{O}'_2/\mathcal{O}'_1} \). Thus \( \Omega_{-/-} \) is a functor of arrows.

Moreover, if \( \mathcal{O}'_2 = \mathcal{O}_2 \otimes_{\mathcal{O}_1} \mathcal{O}'_1 \), then this map is an isomorphism, by (5.2.4.3) and (4.4.3.6).

Prop. (5.2.4.6). Let \( \mathcal{O}_1 \to \mathcal{O}_2 \to \mathcal{O}'_2 \) be a map of sheaves of rings that \( \mathcal{O}_2 \to \mathcal{O}'_2 \) is surjective with kernel \( \mathcal{I} \subset \mathcal{O}_2 \), then there is a canonical exact sequence of \( \mathcal{O}'_2 \)-modules

\[
\mathcal{I}/\mathcal{I}^2 \to \Omega_{\mathcal{O}_2/\mathcal{O}_1} \otimes_{\mathcal{O}_2} \mathcal{O}'_2 \to \Omega_{\mathcal{O}'_2/\mathcal{O}_1} \to 0,
\]

where the first map is characterized by mapping local sections \( f \) of \( \mathcal{I} \) to \( df \otimes 1 \).

Proof: The first map is well-defined if \( d(\mathcal{I}^2) = 0 \). To show the exactness, let \( \mathcal{O}_2'' \subset \mathcal{O}_2 \) be the presheaf of \( \mathcal{O}_1 \)-algebras that \( \mathcal{O}_2''(U) \) the image of \( \mathcal{O}_2(U) \to \mathcal{O}_2''(U) \). Then there is an exact sequence

\[
\mathcal{I}(U)/\mathcal{I}(U)^2 \to \Omega_{\mathcal{O}_2(U)/\mathcal{O}_1(U)} \otimes_{\mathcal{O}_2(U)} \mathcal{O}_2''(U) \to \Omega_{\mathcal{O}'_2''(U)/\mathcal{O}_1(U)} \to 0
\]

by (4.4.3.8). Now sheafification of these presheaves gives use the desired result by (5.2.4.3).

Def. (5.2.4.7)[Sheaf of Differentials]. Let \( (X, \mathcal{O}_X) \to (S, \mathcal{O}_S) \) be a morphism of ringed sites,

- Let \( \mathcal{F} \) be an \( \mathcal{O}_X \)-module, an \( S \)-derivation from \( \mathcal{O}_X \) to \( \mathcal{F} \) is a derivation over \( f^{-1}\mathcal{O}_S \). The set of \( S \)-derivations is denoted by \( \text{Ders}_S(\mathcal{O}_X, \mathcal{F}) \).
- the sheaf of differentials \( \Omega_{X/S} \) is defined to be a sheaf of modules \( \Omega_{\mathcal{O}_X/f^{-1}\mathcal{O}_S} \) (5.2.4.2), with a universal derivation \( d_X/S : \mathcal{O}_X \to \Omega_{X/S} \).
5 Locally Free sheaves

Prop.(5.2.5.1). Pullbacks of (finite)locally free sheaves are (finite)locally free. Sub-$\mathcal{O}_X$-modules of a (finite)locally free sheaf is (finite)locally free, by (2.2.4.21).

Prop.(5.2.5.2) [Finite Locally Free Sheaves and $\mathcal{H}om$]. For any finite locally free sheaf $\mathcal{E}$ on a ringed site $(\mathcal{C}, \mathcal{O})$:
- $\mathcal{E}^\vee \cong \mathcal{E}$.
- $\mathcal{H}om_{\mathcal{O}}(\mathcal{E}, \mathcal{F}) \cong \mathcal{E}^\vee \otimes_{\mathcal{O}} \mathcal{F}$.
- $\mathcal{H}om_{\mathcal{O}}(\mathcal{F}, \mathcal{G}) \otimes_{\mathcal{H}} \mathcal{H} \cong \mathcal{H}om_{\mathcal{O}}(\mathcal{F}, \mathcal{G} \otimes_{\mathcal{O}} \mathcal{H})$ if $\mathcal{F}$ or $\mathcal{H}$ is finite locally free.
- $\mathcal{H}om_{\mathcal{O}}(\mathcal{E} \otimes \mathcal{F}, \mathcal{G}) \cong \mathcal{H}om_{\mathcal{O}}(\mathcal{E}^\vee \otimes \mathcal{G})$, by the first and (5.2.3.3).

Proof: We define the map, and verify locally, which is by 1. □

Prop.(5.2.5.3). $\mathcal{H}om(\mathcal{H}, -)$ is exact for any locally free sheaf $\mathcal{H}$.

Invertible Sheaves

Def.(5.2.5.4) [Invertible Sheaf]. An invertible sheaf $\mathcal{L}$ on a ringed topoi $(\mathcal{Sh}(\mathcal{C}), \mathcal{O})$ is an invertible object in the symmetric monoidal category $\text{Mod}_{\mathcal{O}}$(3.1.4.24).

Prop.(5.2.5.5). Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $\mathcal{L}$ an $\mathcal{O}$-module, the following are equivalent:
- $\mathcal{L}$ is an invertible sheaf.
- there exists some $\mathcal{O}$-module $\mathcal{N}$ that $\mathcal{L} \otimes_{\mathcal{O}} \mathcal{N} \cong \mathcal{O}$.

And in this case, $\mathcal{L}$ is flat and of finite presentation, and $\mathcal{N} \cong \mathcal{H}om_{\mathcal{O}}(\mathcal{L}, \mathcal{O})$.

Proof: $\mathcal{L}$ is flat because tensoring $\mathcal{L}$ is an equivalence thus exact. Let $\psi : \mathcal{L} \otimes_{\mathcal{O}} \mathcal{N} \cong \mathcal{O}$ the isomorphism, $U$ an element of $\mathcal{C}$, then by construction of $\otimes$, after localization, we may assume there exists sections $x_i \in \mathcal{L}(U), y_i \in \mathcal{N}(U)$ that $\psi(x_i \otimes y_i) = 1$. Then there is an automorphism of $\mathcal{L}|_U : x \mapsto \sum \psi(x \otimes y_i)x_i$. This automorphism factors through $\mathcal{L}|_U \to \mathcal{O}^\oplus_{\mathcal{U}} \to \mathcal{L}|_U$,

thus $\mathcal{L}|_U$ is a direct summand of a finite free $\mathcal{O}_U$-module, thus $\mathcal{L}$ is of finite presentation.

Assume $\mathcal{L}$ is invertible, consider the evaluation map $\mathcal{L} \otimes_{\mathcal{O}} \mathcal{H}om(\mathcal{L}, \mathcal{O}) \to \mathcal{O}$,

and by (5.2.3.3),

$$\text{Hom}(\mathcal{O}, \mathcal{O}) = \mathcal{H}om_{\mathcal{O}}(\mathcal{L} \otimes \mathcal{N}, \mathcal{O}) \to \mathcal{H}om_{\mathcal{O}}(\mathcal{N}, \mathcal{H}om_{\mathcal{O}}(\mathcal{L}, \mathcal{O})).$$

The image of 1 gives a morphism $\mathcal{N} \to \mathcal{H}om_{\mathcal{O}}(\mathcal{L}, \mathcal{O})$. Tensoring $\mathcal{L}$ gives the inverse of the evaluation map. □

Cor.(5.2.5.6). The pullback of an invertible sheaf is an invertible sheaf, because tensoring commutes with pullbacks (5.2.2.12).

Def.(5.2.5.7) [Picard Groups]. For any ringed site $(\mathcal{C}, \mathcal{O})$, there is a set of invertible modules over $\mathcal{C}$ that any invertible module is isomorphic to exactly one of them. Then this set forms an Abelian group, called the Picard group $\text{Pic}(\mathcal{O})$. 

For more details on the Picard group, please refer to the corresponding section in the text.
Prop. (5.2.5.8) [Invertible Sheaves and Locally Free Sheaves of Rank 1]. If \((X, \mathcal{O}_X)\) is a ringed space, then any locally free \(\mathcal{O}_X\)-module of rank 1 is invertible. And when \((X, \mathcal{O}_X)\) is a local ringed space, the converse holds as well.

Proof: Assume \(\mathcal{L}\) is locally free of rank 1 and consider the evaluation map (5.2.3.1)

\[
\mathcal{L} \otimes \mathcal{O} \to \mathcal{L}.
\]

This map is an isomorphism when restricting to any trivializing covering of \(\mathcal{L}\), so it is an isomorphism. Thus \(\mathcal{L}\) is invertible by (5.2.5.5).

Assume \((\text{Sh}(\mathcal{C}), \mathcal{O})\) is a local ringed topoi and \(\mathcal{L}\) is invertible, the proof of (5.2.5.5) shows there exists a covering \(\{U_i \to U\}\) that \(\mathcal{L}|_{U_i}\) is a direct summand of a finite free \(\mathcal{O}_{U_i}\)-module. Replacing \(U_i\) by \(U\), let \(\pi\) be the projection of \(\mathcal{O}_U^\ast\) onto \(\mathcal{L}|_U\) which corresponds to a matrix with entries in \(\mathcal{O}(U)\). The image of \(\pi\) acting on \(\mathcal{O}(U)^\ast\) is a finite free \(\mathcal{O}(U)\)-module \(M\), thus there are \(f_1, \ldots, f_t\) generating unit ideal of \(\mathcal{O}(U)\) such that \(M_{f_i}\) is finite free. Now by definition of local ringed topoi (5.2.1.6), after replacing \(U\) by a covering, we may assume \(M\) is finite free, which means \(\mathcal{L}|_U\) is free summand of \(\mathcal{O}_U^\ast\). But \(\mathcal{L}\) is invertible, thus rank of \(\mathcal{L}\) is 1. \(\square\)

Prop. (5.2.5.9). Let \(X\) be a locally ringed space and \(\mathcal{L} \in \text{Pic}(X)\) that is generated by global sections \(s_0, \ldots, s_n\). If \(\mathcal{F}\) is the kernel of the map \(\mathcal{O}_X^\oplus n+1 \to \mathcal{L}\), then \(\mathcal{F} \otimes \mathcal{L}\) is globally generated.

Proof: \(\mathcal{F}\) is finite locally free of rank \(n\) by (5.2.5.1). The elements

\[
s_{ij} = (0, \ldots, 0, s_j, 0, \ldots, 0, s_i, \ldots, 0) \in \Gamma(X, \mathcal{L}^\oplus n+1)
\]

is in \(\Gamma(X, \mathcal{F} \otimes \mathcal{L})\), and it can be verified locally s.t. they generate \(\mathcal{F} \otimes \mathcal{L}\). \(\square\)

6 Sheaves on Spaces

Sheaves on Topological Spaces

Remark (5.2.6.1). A topological space can be regarded as a ringed space by assigning the locally constant sheaf \(\mathbb{Z}\) as the structure sheaf.

Def. (5.2.6.2) [Grothendieck’s Six Operators]. Let \(f: X \to Y\) be a continuous map of topological spaces, then the inverse image defines a continuous map between sites \(Y_{\text{Zar}} \to X_{\text{Zar}}\), so by (5.1.2.9) and (5.1.2.11) we can define

- the pushforward \(f^p \mathcal{F}, f^p \mathcal{F}(U) = \mathcal{F}(f^{-1}(U))\) sends presheaf to presheaf.
- the direct image \(f_* \mathcal{F}, f_* \mathcal{F}(U) = \mathcal{F}(f^{-1}(U))\) sends sheaf to sheaf.
- the inverse image \(f_p \mathcal{G}, f_p \mathcal{G}(U) = \lim_{\substack{\to \mathcal{G}(V) \to \mathcal{G}(V)}} f(U) \cap V\) that sends presheaf to presheaf.
- the inverse image \(f^{-1} \mathcal{G} = f_*(\mathcal{G})\) that sends sheaf to sheaf.
- For a morphism of locally compact spaces, we can define a proper direct image:

\[
f_t(\mathcal{F})(U) = \{ s \in \Gamma(f^{-1}(U), \mathcal{F}) | \text{Supp}(s) \to U \text{ proper} \}
\]

This is a subsheaf of \(f_* \mathcal{F}\) and it is left exact. we denote \(\Gamma_c(X, \mathcal{F})\) as the group \(f_t(\mathcal{F})\) where \(f: X \to \text{pt}\). And the stalk \(f_t(\mathcal{F})_y = \Gamma_c(f^{-1}(y), \mathcal{F}|_{f^{-1}(y)})\) Cf. [Gelfand P224 P225].
5.2. RINGED TOPOI, RINGED SITES, RINGED G-SPACES AND SCHEMES

- the **proper inverse image** (special case) $i^!$ for a closed immersion $Z \subset X$ defined by

$$i^!(\mathcal{F})(U = V \cap Z) = \{ s \in \Gamma(V, \mathcal{F}) | \text{Supp}(s) \in Z \}.$$ 

sends Abelian sheaves to Abelian sheaves.

- the internal tensor product.

- the internal Hom.

**Proof:** Check that $f_!$ is a sheaf: it is separated clearly, it suffices to show that for a covering $\cup U_i = W$ and $\xi_i \in F(f^{-1}(U_i))$, the section $\xi \in F(f^{-1}(W))$ they generated by sheaf property of $F$ is in $f_! F(W)$. For a compact subset $K$, there is a finite cover $\cup_i U_i$ of it, thus $K - \cup_{i \neq j} U_j$ is compact in $U_j$, thus its inverse image is compact in $\text{Supp}(\xi)$. there are f.m. $U_j$, thus the inverse image of $K$ is compact in $\text{Supp}(\xi)$. □

**Def. (5.2.6.3) [Stalks].** The convenience of rings spaces compared to the case of sites is the it has stalk functors: For any presheaf $\mathcal{F}$ on $X$ and a point $i : x \to X$, define the **stalk** $\mathcal{F}_x = i_p(\mathcal{F})$ (5.2.6.2).

**Prop. (5.2.6.4) [Stalks Commutes with Shifification].** Taking stalks commutes with shifification.

**Proof:** Cf. [Sta]007Z. □

**Prop. (5.2.6.5).** If a sheaf on a ringed space has only one non-vanishing stalk, then it is a skyscraper sheaf. (Because the restriction map to that point for every open set is an isomorphism).

**Prop. (5.2.6.6) [Stalks].** Taking stalks is a left adjoint to the skyscraper sheaf from Presheaves to Sets, thus it preserves cokernel. Moreover, for a map of sheaves $\mathcal{F} \to \mathcal{G}$ on $X$,

- $\varphi$ is a monomorphism iff $\varphi_x$ is injective for all $x \in X$.
- $\varphi$ is an epimorphism iff $\varphi_x$ is surjective for all $x \in X$.
- $\varphi$ is an isomorphism iff $\varphi_x$ is surjective for all $x \in X$.

**Proof:** 1: If $\varphi$ is a monomorphism, then $\varphi_x$ is clearly. Conversely, if $\varphi_x$ are all injective, if $s \in \mathcal{F}(U)$ mapsto 0 $\in (U)$, then $s_x$ mapsto 0 $\in \mathcal{G}_x$ for all $x$, thus $s_x = 0$ for all $x$, thus $s = 0$.

2: If $\varphi$ is an epimorphism, then $\varphi_x$ is surjective by definition. The converse is also true.

3: If $\varphi_x$ is isomorphism for all $x$, then $\varphi$ is monomorphism by 1, and for any $t \in \mathcal{G}(U)$, $t$ is locally coming from some section of $s$, and these sections are compatible on their intersections because of monomorphism, so they glue together to a section $s \in \mathcal{F}(U)$ that $\varphi(U)(s) = t$. □

**Prop. (5.2.6.7) [Topological Spaces and Sites].** Let $f : X \to Y$ be a continuous map of topological spaces, then $f$ induces a map of sites $X \to Y$ because $f^{-1}$ is exact (5.1.2.14), thus induces a map of topoi $f : \text{Sh}(X) \to \text{Sh}(Y)$ (5.1.2.19).

**Cor. (5.2.6.8).** Let $f : X \to Y$ be a continuous map of topological spaces,

- Let $\mathcal{G}$ be a presheaf on $Y$, then there is a canonical bijection of stalks $(f_p(\mathcal{G}))_x = \mathcal{G}_{f(x)}$. If $\mathcal{G}$ is a sheaf on $Y$, then there is a canonical bijection of stalks $(f^{-1}(\mathcal{G}))_x = \mathcal{G}_{f(x)}$.
- $f^{-1}$ is left adjoint to $f_!$.
- $f_!$ is left exact when $X, Y$ are locally compact. And $j_!$ is left adjoint to the functor $j^{-1}$ for an inclusion of open subset $j : U \subset X$. 

• $i^!$ is right adjoint to $i_*$ for a closed immersion $i : Z \to X$, in particular $i_*$ is exact when $i$ is a closed immersion.

Proof: 1: This is because $(-)_p$ commutes with composition (5.2.6.3), and also shifification commutes with $(-)_p$ (5.2.6.4).
2: This is immediate.
3: 4: The adjointness follows from the fact that any section under a homomorphism $i_* \mathcal{G} \to \mathcal{F}$ has support contained in $Z$.

Prop. (5.2.6.9). Let $i : Z \to X$ be a closed immersion, then the functor $i_* : \text{Ab}(Z) \to \text{Ab}(X)$ is exact, fully faithful, with the essential image those sheaves with support in $Z$.

Prop. (5.2.6.10) [Canonical Exact Sequences]. We have a canonical exact sequences of sheaves of modules:

$$0 \to j_!(\mathcal{F}|_U) \to \mathcal{F} \to i_*(\mathcal{F}|_Z) \to 0$$

$$0 \to i_* i^! Y \mathcal{F} \to \mathcal{F} \to j_* (\mathcal{F}|_U) \to 0$$

(check on stalks), which is important to use reduction to calculate sheaf cohomology. The latter induces long exact sequences:

$$0 \to H^0_Y(X, \mathcal{F}) \to H^0(X, \mathcal{F}) \to H^0(U, \mathcal{F}|_U) \to H^1_Y(X, \mathcal{F}) \to \cdots$$

Proof: Cf. [Sta]02UT. □

Prop. (5.2.6.11). On a topological space $X$, for a qc open subset $U$, $(\oplus F_i)(U) = \oplus F_i(U)$. This uses the compactness of $U$.

Morphisms of Local Ringed Spaces

Def. (5.2.6.12) [Open Immersion of Ringed Spaces]. A morphism $f : (X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)$ of ringed spaces is called an open immersion if $f$ is a homeomorphism of $X$ onto an open subset of $Y$, and the map $f^\sharp : f^{-1}(\mathcal{O}_Y) \to \mathcal{O}_X$ is an isomorphism.

Prop. (5.2.6.13). Let $(X, \mathcal{O}_X)$ be a ringed space, $U \subset X$ an open subset, and $\mathcal{O}_U = \mathcal{O}_X|_U$ is a sheaf of rings on $U$, then $(U, \mathcal{O}_U) \to (X, \mathcal{O}_X)$ is an open immersion, and $(U, \mathcal{O}_U)$ is called the open subspace associated to $U$.

Prop. (5.2.6.14) [Universal Property of Open Immersions]. Let $f : (X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)$ be an open immersion of ringed spaces, then it has the universal property that any morphism of ringed spaces $(T, \mathcal{O}_T) \to (Y, \mathcal{O}_Y)$ that factors set-theoretically through $f(X)$ factors uniquely through $(X, \mathcal{O}_X)$.

Def. (5.2.6.15) [Closed Immersion]. Let $i : Z \to X$ be a morphism of local ringed spaces, then $i$ is called a closed immersion if:

• $i$ is a homeomorphism of $Z$ onto a closed subspace of $X$.

• the map $\mathcal{O}_X \to i_* \mathcal{O}_Z$ corresponding to $f^\sharp$ is surjective with kernel $\mathcal{I}$.

• the $\mathcal{O}_X$-module $\mathcal{I}$ is locally generated by sections.

And for a closed immersion, $\mathcal{I}$ is called the ideal sheaf of $i$. 
Def. (5.2.6.16) [Closed Immersion Defined by Ideals]. Let \((X, \mathcal{O}_X)\) be a local ringed space, and \(\mathcal{I} \subset \mathcal{O}_X\) a sheaf of ideals on \(X\) locally generated by sections. Let \(Z\) be the support of the sheaf of rings \(\mathcal{O}_X/\mathcal{I}\). \(Z\) is closed in \(X\) because it is the support of \(1\). By (5.2.6.9), there is a unique sheaf of rings \(\mathcal{O}_Z\) on \(Z\) that \(i^* \mathcal{O}_Z = \mathcal{O}_X/\mathcal{I}\). For any \(z \in Z\), the stalk \(\mathcal{O}_z = \mathcal{O}_{X,z}/\mathcal{I}_z\) is a quotient of a local ring and is non-zero, thus a local ring. Then \((Z, \mathcal{O}_Z)\) is a local ringed space and \(i : (Z, \mathcal{O}_Z) \to (X, \mathcal{O}_X)\) is a closed immersion, called the closed immersion defined \(\mathcal{I}\).

Prop. (5.2.6.17) [Closed Immersions are Equivalent to Ideals]. Let \(f : X \to Y\) be a closed immersion of local ringed spaces with ideal sheaf \(\mathcal{I}\). Let \(i : Z \to X\) be the closed immersion defined by \(\mathcal{I}\), then \(f\) is isomorphic to \(i\).

Proof: Because \(f_* \mathcal{O}_Z \cong \mathcal{O}_X/\mathcal{I}\) on \(X\). □

Prop. (5.2.6.18). For a closed immersion of ringed spaces \(f, f_*\) on \(\mathcal{O}_X\)-mod is fully faithful, with image those modules annihilated by \(\mathcal{I}\), where \(\mathcal{I}\) is the structural kernel.

Proof: Cf. [Sta]08KS. □

7 Spec and Schemes

Def. (5.2.7.1) [Spectrum]. Given a commutative ring \(A\), the spectrum of \(A\) \(\text{Spec} A\) is a locally ringed space whose underlying space is the set of primes of \(A\), and the topology is generated by the standard open subsets \(D(f) = \{p \mid f \not\in p\}\).

To define the structure sheaf \(\mathcal{O}_X\), we first define a sheaf on the site of standard open subsets, which takes value \(R_f\) on \(D(f)\). This is truly a sheaf by (4.4.2.3), and then we can use (5.1.2.24) to extend this sheaf to a sheaf on \(\text{Spec} A\), called the structure sheaf \(\mathcal{O}_X\).

A locally ringed space of the form \(\text{Spec} A\) is called an affine scheme. The category of affine schemes is denoted by \(\text{Aff}\).

Def. (5.2.7.2) [Schemes]. The category \(\text{Sch}\) of schemes is a fully faithful category of the category of local ringed spaces (5.2.1.10) consisting of local ringed spaces that are locally isomorphic to \(\text{Spec} A\).

Lemma (5.2.7.3). If \(X\) is a local ringed space, \(x \in X\), and \(Y = \text{Spec} A\) an affine scheme, \(f : X \to Y\) is a morphism, consider the ring map \(\Gamma(X, \mathcal{O}_X) \xrightarrow{f^*} \Gamma(Y, \mathcal{O}_Y) \to \mathcal{O}_{X,x}\), and consider the inverse image \(p\) of \(m_x\), which corresponds to \(y \in Y\), then \(f(x) = y\).

Proof: There are commutative diagrams

\[
\begin{align*}
\Gamma(Y, \mathcal{O}_Y) & \xrightarrow{f^*} \Gamma(Y, \mathcal{O}_Y) \\
\Gamma(X, \mathcal{O}_X) & \xrightarrow{f} \mathcal{O}_{X,x}
\end{align*}
\]

and the map of local rings is a local ring map. So the inverse image of \(m_x\) is just \(m_{f(x)}\), so \(m_{f(x)} = m_y\). □

Prop. (5.2.7.4). Let \(X\) be a local ringed spaces and \(Y = \text{Spec} A\) an affine scheme, then the map \(\text{Hom}(X, \text{Spec} A) \to \text{Hom}(A, \Gamma(X, \mathcal{O}_X))\) is an isomorphism.
The inverse map is constructed as follows: for any \( \varphi : A \to \Gamma(X, \mathcal{O}_X) \) and \( x \in X \), define \( \Phi(x) \) to be the point corresponding to the inverse image of \( m_x \) in \( A \to \Gamma(X, \mathcal{O}_X) \to \mathcal{O}_{X,x} \). In this way, \( \Phi^{-1}(D(f)) \) is just \( D(\varphi(f)) \subset X \) which is open, thus \( \Phi \) is continuous. Now we want to construct a sheaf homomorphism \( f^{-1}(\mathcal{O}_Y) \to \mathcal{O}_X \), and it suffices to construct compatible maps on the affine open basis \( D(f) \), by (5.1.3.17). Now \( \Gamma(D(f), \mathcal{O}_Y) = A_f \), and because \( f \) is invertible on \( D(\varphi(f)) \), there is by universal property a unique map \( A_f \to D(\varphi(f)) \) extending \( \varphi \). Then by universal property these maps are compatible. Notice the construction here also shows the homomorphism is determined by the map set-theoretically.

Finally, we need to show this induces a local ring map on the stalks, and this is quite obvious from the definition.

Then we show these two maps are inverse to each other: It suffices to show any ring map \( A \to \Gamma(X, \mathcal{O}_X) \) comes uniquely from a map \( X \to Y \): the uniqueness is proven by (5.2.7.3), and the sheaf homomorphism is determined by the set-theoretical map by the above argument.

Cor. (5.2.7.5). The \( \text{Spec} \) operator \( \text{Spec} : \text{CAlg}^{op} \to \text{Sch} \) is right adjoint to \( X \to \Gamma(X, \mathcal{O}_X) \):

\[
\text{Hom}_{\text{Sch}}(X, \text{Spec}(A)) \cong \text{Hom}_{\text{CAlg}}(A, \Gamma(X, \mathcal{O}_X)).
\]

Notice the category of schemes is a full subcategory of the category of locally ringed spaces.

Cor. (5.2.7.6). \( \text{Aff} \) is equivalent to \( \text{CAlg}^{op} \).

Prop. (5.2.7.7). Let \( X \) be a scheme and \( R \) a local ring, then there is a natural bijection between morphisms \( \text{Spec} R \to X \) and pairs \( (p, \varphi) \) where \( p \in X \) is a point and \( \varphi : \mathcal{O}_{X,x} \to R \) is a local ring map.

\[
\begin{array}{c}
\mathcal{O}_{Y,y} \rightarrow Y \\
\downarrow \\
\mathcal{O}_{X,x} \rightarrow X
\end{array}
\]

Prop. (5.2.7.10). The closure of a subset \( T \) of \( \text{Spec}(A) \) is \( V(\cap p, p \in T) \).

Prop. (5.2.7.11). The underlying space of a scheme is sober.

\[
\begin{array}{c}
\mathcal{O}_{Y,y} \rightarrow Y \\
\downarrow \\
\mathcal{O}_{X,x} \rightarrow X
\end{array}
\]
Construction of Schemes

**Prop.(5.2.7.12) [Global Spec].** There is an $S$-scheme $f : \text{Spec}_S A \to S$ for every Qco sheaf of $\mathcal{O}_S$-algebras $A$ on $S$ that for any affine open subscheme $U \subset X$, $f^{-1}(U) \cong \text{Spec} \mathcal{A}(U)$ over $U$. This construction is right adjoint to the direct image map:

$$\text{Hom}_{\text{Alg}_{S}}(A, \pi_+ \mathcal{O}_X) \cong \text{Hom}_{\text{Sch}/S}(X, \text{Spec}_S A).$$

and defines an equivalence of affine morphisms over $S$ and Qco $\mathcal{O}_S$-algebras. Moreover, this defines an equivalence of the category of $A$-modules and the category of $\mathcal{O}_{\text{Spec}_A}$-modules.

**Proof:** Choose an affine open covering $\{U_i \to X\}$ of $X$, and consider the schemes $\text{Spec} \mathcal{A}(U_i) \to U_i$ over $U_i$, then their restrictions to $U_{ij}$ are compatible, because this is true after further restriction to an affine open covering of $U_{ij}$, we can use(5.1.5.4). Then we can use(5.1.5.4) to get an $S$-scheme $f : \text{Spec}_S A \to S$ that $f^{-1}(U_i) \cong \text{Spec} \mathcal{A}(U_i)$.

Now we check that for any affine open subset $U \subset X$, $f^{-1}(U) \cong \text{Spec} \mathcal{A}(U)$ over $U$. But this is true after base change to $U \cap U$ for any $i$, so it is true, by(5.1.5.4).

To show the adjointness condition, by(5.1.5.4), it suffices to show canonical(thus compatible) isomorphism for $S$ affine. In this case, this reduces to(5.2.7.5).

**Cor.(5.2.7.13).** Let $S$ be a scheme and $A$ is a Qco sheaf of $\mathcal{O}_S$-algebras, then

- For any morphism $g : S' \to S$, $S' \times_S \text{Spec}_S(A) \cong \text{Spec}_{S'}(g^*A)$.
- The natural map $A \to \pi_+ \mathcal{O}_{\text{Spec}_S(A)}$ is an isomorphism of $\mathcal{O}_S$-algebras.

**Proof:** 1: It can be checked that $S' \times_S \text{Spec}_S(A)$ and $\text{Spec}_{S'}(g^*A)$ satisfy the same universal property.

2: It suffices to check on affine opens, then it is trivial.

**Lemma (5.2.7.14) [Affine Case].** Fiber product of affine schemes is also affine that corresponds to the tensor product of their corresponding rings, by(5.2.7.5).

**Prop.(5.2.7.15) [Finite Limits of Schemes].** Fiber products exist in the category of schemes, and there is a final object Spec $\mathbb{Z}$, so arbitrary limits exist in the category of schemes(3.1.1.47).

In fact, finite limits exists in the category of ringed spaces, and finite limits of schemes coincide with finite limits as ringed spaces.

**Proof:** Let $f : X \to S, g : Y \to S$, and $U_i$ is an affine open covering of $S$, $V_i,j$ is an affine open covering of $f^{-1}(U_i)$ and $W_{ik}$ is an affine open covering of $g^{-1}(U_i)$, then we can check $h_{V_i,j} \times h_{U_i} h_{W_{ik}}$ is a covering of $h_X \times h_Y$ by representable open subfunctors(7.7.1.13), by(5.2.7.14), thus it is representable.

**Cor.(5.2.7.16) [Open Subschemes].** Let $X \to S, Y \to S$, and $V \subset X, W \subset Y$ be open subschemes mapping into open subscheme $U \subset S$, then there is a natural open immersion $V \times_U W \to X \times_S Y$ with image $\pi_1^{-1}V \cap \pi_2^{-1}(W)$.

**Proof:** There is a natural map $V \times_U W \to X \times_S Y$ by Yoneda lemma, and this map has the universal property that any map $f : (T, \mathcal{O}_T) \to X \times_S Y$ that $\pi_1 \circ f$ has image in $V$ and $\pi_2 \circ f$ has image in $W$ factors uniquely through $V \times_U W$. But so does the open immersion $\pi_1^{-1}V \cap \pi_2^{-1}(W) \to X \times_S Y(5.2.6.14)$, so they are equal. □
Cor. (5.2.7.17). Let $f : X \to S, g : Y \to S$, and $U_i$ is an affine open covering of $S$, $V_{ij}$ is an affine open covering of $f^{-1}(U_i)$ and $W_{ik}$ is an affine open covering of $g^{-1}(U_i)$, then

$$X \times_S Y = \bigcup_i \bigcup_{j,k} V_{ij} \times_{U_i} W_{ik}$$

is an affine open covering of $X \times_S Y$.

Also, the structure sheaf of $X \otimes_S Y$ is given by $\mathcal{O}_{X \times_S Y} = \pi_1^{-1}\mathcal{O}_X \otimes_{\mathcal{O}_S} \pi_2^{-1}\mathcal{O}_Y$.

Cor. (5.2.7.18). The equalizer of two morphisms from $X$ to $Y$ exists, it is a locally closed subscheme of $X$, and it is a closed subscheme of $X$ if $Y$ is separated.

Proof: because it is the base change of $\Delta : Y \to Y \times_S Y$ (3.1.1.47), then use (5.4.4.76). □

Remark (5.2.7.19) [Infinite Product of Schemes Doesn’t Exists]. WARNING: infinite products of schemes may not exists, Cf. [Sta]0CNH. Intuitively, if you want to glue affine products together, you will notice you can identify only those products that is equal a.e..

Remark (5.2.7.20). Let $X$ be a scheme over $S$ and $S' \to S$ is a morphism of schemes, then we sometimes denote $X \times_S S'$ by $X_{S'}$, if no confusion is caused.

Def. (5.2.7.21) [Generic Fibers and Special Fibers]. If $X$ is a scheme over an integral ring $A$, then the generic fiber of $X/A$ is the stalk $X_\eta$, where $\eta = (0) \in \text{Spec } A$.

If $X$ is a scheme over a ring $R$, a special fiber is the stalk of $X$ over a maximal ring $m$.

8 Rational Maps

Def. (5.2.8.1) [Rational Maps]. Let $X, Y \in \text{Sch}/S$ and $Y/S$ separated, a rational map over $S$ $f : X \to Y$ is an equivalence class of maps $U \to Y$ over $S$ where $U$ is an open dense subset of $X$. A rational function on $X$ is a rational map $X \to \mathbb{A}^1$. It has a ring structure. The ring of rational functions is denoted by $R(X)$.

Because two rational maps are equivalent iff they are compatible on the intersection of their domain as $Y/S$ is separated, a rational map $\varphi : X \to Y$ has a maximal domain of definition, denoted by $\text{dom}(\varphi)$.

Prop. (5.2.8.2). If $X$ is a scheme with f.m. generic points $\eta_i$, then

$$R(X) = \prod \mathcal{O}_{X, \eta_i}.$$  

Proof: Cf. [Sta]01RV. □

Def. (5.2.8.3) [Birational Maps]. $X, Y \in \text{Sch}/S$ are called birational over $S$ if they are isomorphic in the category of $S$-schemes with dominant rational maps.

Prop. (5.2.8.4). Two schemes $X, Y$ over $S$ are birational over $S$ iff there are nonempty open subschemes $U \subset X, V \subset Y$ that are isomorphic over $S$.

Proof: □

Def. (5.2.8.5) [$S$-Dense Subsets]. Let $X \in \text{Sch}/S$, a subscheme $U \subset X$ is called $S$-dense if $U_s$ is dense in $X_s$ for any $s \in S$. 

Prop.(5.2.8.6). Let $X \in \text{Sch}^{pf}/S$ and $V \subset X$ is a qc open subscheme, then the set of points $s \in S$ s.t. $V_s \subset X_s$ is not dense is locally constructible in $S$. And if $V$ is $S$-dense in $X$, then it is also schematically dense in $X$.

Proof: Cf.[?]P56. □

Prop.(5.2.8.7). If $X \in \text{Sch}_{qc}/S$ and $U \subset X$ is an $S$-dense open subscheme, then $U$ contains an $S$-dense open subscheme of $S$ that is qc.

Proof: Cf.[?]P56. □

Def.(5.2.8.8)[S-Rational Maps]. Let $X,Y \in \text{Sch}_{\text{sep},\text{loc}}^{\text{sep},\text{loc},\text{pf}}/S$ an $S$-rational map $f : X \to Y$ is an equivalence class of maps $U \to Y$ over $S$ where $U$ is an open subset of $X$ that is $S$-dense.

Because two rational maps are equivalent iff they are compatible on the intersection of their domain as $Y/S$ is separated, a rational map $X \to Y$ has a maximal domain of definition.

Def.(5.2.8.9)[S-Birational Maps]. Let $X,Y \in \text{Sch}_{\text{sep},\text{loc}}^{\text{sep},\text{loc},\text{pf}}/S$ are called $S$-birational if they are isomorphic in the category of $S$-schemes with dominant $S$-rational maps.

Prop.(5.2.8.10). The notion of $S$-rational and $S$-birational maps are stable under base change, because a base change of fields is flat locally of f.p. thus open.

Prop.(5.2.8.11)[Faithfully Flat Descent]. Let $X',X,Y \in \text{Sch}_{\text{sep},\text{loc}}^{\text{sep},\text{loc},\text{pf}}/S$ and $\varphi : Y \to S$ an $S$-rational map,

- If $f : X' \to X$ flat, then $\varphi \circ f$ is an $S$-rational map $X' \to Y$, and $\text{dom}(\varphi \circ f) = f^{-1}(\text{dom}(\varphi))$. In particular, if $f$ is f.f. and $\varphi \circ f$ is a morphism, then $\varphi$ is also a morphism.
- If $T \to S$ is flat, then the base change $\varphi_T : X_T \to Y_T$ satisfies $\text{dom}(\varphi_T) = \text{dom}(\varphi) \times_S T$.

Proof: Cf.[BLR90]P58. □

9 Associated Points

Main References are [Sta]Chap30.

Def.(5.2.9.1). For a scheme $X$ and a Qco sheaf $\mathcal{F}$ on $X$, a point is called associated to $\mathcal{F}$ iff $m_x$ is associated to $\mathcal{F}_x$, which is equivalent to $m_x$ are all zero-divisors in $M$ by(4.2.5.18). When $\mathcal{F} = \mathcal{O}_X$, $x$ is called an associated point of $X$.

Prop.(5.2.9.2). If $X$ is locally Noetherian, then an associated prime is equivalent to it is an associated prime of $\Gamma(X,\mathcal{O}_X)$ of $\Gamma(U,\mathcal{F})$ for a nbhd $U$ of $x$.

Proof: Cf.[Sta]02OK. □

Prop.(5.2.9.3). Same results of associated points are parallel to the discussion of associated primes:

- relations of $\text{Ass}(\mathcal{F})$ w.r.t exact sequences(4.2.5.14).
- $\text{Ass}(\mathcal{F}) \subset \text{Supp}(\mathcal{F})(4.2.5.16)$.
- When $X$ is locally Noetherian and $\mathcal{F}$ is coherent, for a quasi-compact open set $U$ of $X$, the number of associated points in $U$ is finite(4.2.5.16).
- When $X$ is locally Noetherian, $\mathcal{F} = 0$ iff $\text{Ass}(\mathcal{F})$ is empty(4.2.5.16).
• When $X$ is locally Noetherian, if $\text{Ass}(\mathcal{F}) \subset$ an open subset $U$, then $\Gamma(X, \mathcal{F}) \to \Gamma(U, \mathcal{F})$ is injective (4.2.5.22).

• If $X$ is locally Noetherian, then the minimal elements (under specialization) of $\text{Supp}(\mathcal{F})$ are associated points of $\mathcal{F}$, in particular, any generic point of an irreducible component of $X$ is an associated points of $X$.

• If $X$ is locally Noetherian, then if a map $\varphi : \mathcal{F} \to \mathcal{G}$ that is injective at all the stalks of $\text{Ass}(\mathcal{F})$, then $\varphi$ is injective.

10 Others

Frobenius

**Def. (5.2.10.1)** [Frobenius]. Let $p \in \mathbb{P}, r \in \mathbb{Z}, q = p^r, k \in \text{Field}, \# k = q, X_0 \in \text{Sch}_k/X, X = X_0 \otimes_k \overline{k},$

- The **absolute Frobenius** for $X$ or $X_0$ is the automorphism $\varphi_{r,X} : X \to X$ that is the $p^r$-th power on $\mathcal{O}_X$.
- $F_X = \text{id}_{X_0} \times_k \varphi_{\overline{k}/k}^{-1}$, called the **arithmetic Frobenius**, which is not $k$-linear!
- $F_{r,X} = \varphi_{X_0} \times_k \text{id}_{\overline{k}} : X \to X$, which is $\overline{k}$-linear, called the **geometric Frobenius**.
- Let $U$ be a $X_0$-scheme, then the **relative Frobenius** $F_{U/X_0,r} : U \to \varphi_{r,X_0}^*(U)$ is defined by the universal property of the base change of $U$ by $\varphi_{X_0}^r$. $F_{U/X_0,1}$ is denoted by $F_{U/X_0}$.

**Prop. (5.2.10.2).** $F_X = \varphi_{r,X} \circ F_X : X \to X$.

*Proof:* Easy. \qed

**Prop. (5.2.10.3).** $F_{U/X_0}$ is a universal homeomorphism. In particular, if $U \to X_0$ is étale, then it is an isomorphism.

*Proof:* Because $U \to X, X \times_{\varphi_{X_0}} U \to X$ are both étale, $F_U/X_0$ is étale. And from the fact both both $\varphi_{X_0}$ and $\varphi_{U_0}$ are universally bijective, we see $F_{U_0/X_0}$ is universally bijective. So it must be an isomorphism? \qed

**Prop. (5.2.10.4).** If $X$ is a scheme over a field $k$ of char $p$, then $X^{(p)}$ is reduced iff $X$ is geometrically reduced. This follows from (5.4.3.2).
5.3 Cohomology on Ringed Sites

Main references are [Sta], [Har77] and [Sheaf Cohomology, Anonymous].

1 Derived Cohomology

Notations(5.3.1.1).
- We use notations defined in Sites, Sheaves and Stacks.

\[ D(\text{Mod}(\mathcal{O})) \]

Def.(5.3.1.2)[Setups]. Let \( (\mathcal{C}, \mathcal{O}) \) be a ringed site, write \( K(\mathcal{O}) = K(\text{Mod}(\mathcal{O})), D(\mathcal{O}) = D(\text{Mod}(\mathcal{O})) \). The Abelian category \( \text{Mod}(\mathcal{O}) \) contains enough injectives by (3.3.2.28) and (3.3.2.24), so we can consider right derived functor for any left exact functor.

1. (Hom) Let \( K \) be a presheaf of sets on \( \mathcal{C} \), then \( \mathcal{F} \mapsto \text{Hom}_{\mathcal{PSh}(\mathcal{C})}(K, \mathcal{F}) \) is a left exact functor \( \text{Mod}(\mathcal{O}) \) to \( \text{Ab} \), thus we denote its derived functors as \( H^i(K, \mathcal{F}) \).

2. (Section) The section functor \( \Gamma(U, \mathcal{F}) \) is the left exact functor \( \text{Mod}(\mathcal{O}) \to \text{Mod}(\mathcal{O}(U)) \) and call the derived functors \( H^i(U, \mathcal{F}) = H^i(R\Gamma(U, \mathcal{F})) \) as the \( i \)-th cohomology of \( \mathcal{F} \) at \( U \). In fact, this functor is just \( \text{Mor}_{\mathcal{PSh}(\mathcal{C})}(h_U, \mathcal{F}) \) defined in (5.3.1.2).

3. (Global Section) Let \( e \) be the final object in \( \mathcal{PSh}(\mathcal{C}) \), then we define the global section functor \( \Gamma(\mathcal{C}, -) \) to be the left exact functor \( \text{Mod}(\mathcal{O}) \to \text{Ab} : \mathcal{F} \mapsto \text{Mor}_{\mathcal{PSh}(\mathcal{C})}(e, \mathcal{F}) = \lim_{\longrightarrow X \in \mathcal{C}_{\text{op}}} \Gamma(X, \mathcal{F}) \), then we define its derived functor \( R\Gamma(\mathcal{C}, \mathcal{F}) \), and call the derived functors \( H^i(\mathcal{C}, \mathcal{F}) = H^i(R\Gamma(\mathcal{C}, \mathcal{F})) \) the \( i \)-th cohomology group of \( \mathcal{F} \) on \( \mathcal{C} \).

4. (Pushforward) Let \( (\mathcal{S}, \mathcal{O}) \to (\mathcal{D}, \mathcal{O}') \) be a morphism of topoi, then \( f_* \) is a left exact functor from \( \text{Mod}(\mathcal{O}) \) to \( \text{Mod}(\mathcal{O}') \)(5.1.2.18), and we call its derived functors \( R^if_* \) the \( i \)-th higher direct images.

5. (Shifification) Let shifification functor \( i : \mathcal{PSh}(\mathcal{C}) \to \mathcal{Sh}(\mathcal{C}) \) is left exact, and we call the derived functors \( H^p(F) \) the sheaf-cohomology presheaves of \( F \).

Def.(5.3.1.3)[G_a, G_m]. Let \( (\mathcal{C}, \mathcal{O}) \) be a ringed site, denote \( G_{a, \mathcal{C}} = \mathcal{O}, G_{m, \mathcal{C}} = \mathcal{O}^* \).

Prop.(5.3.1.4)[Global Section as Pushforward]. For a ringed site \( (\mathcal{C}, \mathcal{O}) \), if we endow \( \mathcal{C} \) with the discrete topology, then there is a functor \( \mathcal{C} \to \text{pt} \) which is cocontinuous, thus induce a morphism of ringed topoi \( \pi : (\mathcal{Sh}(\mathcal{C}), \mathcal{O}) \to (\mathcal{Sh}(\text{pt}) \cong \text{Ab}, \Gamma(\mathcal{C}, \mathcal{O})) \)(5.1.2.20). Then \( \pi_* \) is exactly \( \mathcal{F} \mapsto \Gamma(\mathcal{C}, \mathcal{F}) \), so \( R\pi_* \mathcal{F} = H^i(\mathcal{C}, \mathcal{F}) \).

Prop.(5.3.1.5)[Change of Topologies]. Let \( \mathcal{C}, \mathcal{C}' \) be sites and \( i : \mathcal{C}' \to \mathcal{C} \) is continuous and cocontinuous satisfying the hypothesis of (5.1.2.22), then for \( \mathcal{F} \in \mathcal{Sh}(\mathcal{C}'), \mathcal{G} \in \mathcal{Sh}(\mathcal{C}) \), there are functorial isomorphisms

\[ H^p(\mathcal{C}', U, i^{-1}\mathcal{G}) \cong H^p(\mathcal{C}, U, \mathcal{G}) \]

And if \( i \) satisfies the hypothesis of (5.1.2.24), then moreover there are functorial isomorphisms

\[ H^p(\mathcal{C}', U, F') \cong H^p(\mathcal{C}; U, i_*F') = H^p(\mathcal{C}; i(U), i_*F') \]

Proof: For the first assertion, notice \( g^{-1} \) preserves injectives because it is right adjoint to \( g_! = f^{-1} \) is exact (5.1.2.22).

The second assertion follows immediate from (5.1.2.24).
Calculations

Prop.(5.3.1.6) [Locality of Cohomologies]. Let \((\mathcal{C}, \mathcal{O})\) be a ring site and \(U \in \mathcal{C}\), then for \(\mathcal{F} \in \text{Mod}(\mathcal{O}_X)\), \(H^n(U, \mathcal{F}) = H^n(\mathcal{C}/U, \mathcal{F}|_U)\), by (5.3.1.7) and the composition of derived functors applied to the pullback \(j^* : \mathcal{C}/U \to \mathcal{C}\).

Prop.(5.3.1.7) [Sheaf-Cohomological Presheaves]. The forgetful functor is right adjoint to the exact shiffification functor, the composition of derived functors applied to the functor \(\Gamma(U, -) \circ \iota\) from \(PSh(\mathcal{C})\) to \(Ab\) shows its right derived functor is
\[
\mathcal{H}^p(F) = R^p\iota(F) : U \to H^p(U, F).
\]

Prop.(5.3.1.8) [Higher Direct Image]. For \(f : (\mathcal{C}', \mathcal{O}') \to (\mathcal{C}, \mathcal{O})\) a morphism of ringed topoi and \(\mathcal{F} \in \text{Sh}(\mathcal{C})\), the composition of derived functors applied to the functor \((\mathcal{F} \circ f)^{\text{Sh}} \circ (\mathcal{O})\) (because \(\mathcal{F} \circ f^{\text{Sh}} \circ (\mathcal{O})\) are exact(5.1.2.10)) shows that \(R^p f_* \mathcal{F} = (f_* \mathcal{H}^p(\mathcal{F}))^\#\). So flask sheave thus flabby sheave are right acyclic for \(f_*\).

In particular, \(R^p f_* \mathcal{F}\) can be calculated locally on the base.

Prop.(5.3.1.9) [Relative Leray Spectral Sequence]. Let
\[
(f, f^\sharp) : (\text{Sh}(\mathcal{C}), \mathcal{O}) \to (\text{Sh}(\mathcal{C}'), \mathcal{O}'), \quad (g, g^\sharp) : (\text{Sh}(\mathcal{C}'), \mathcal{O}') \to (\text{Sh}(\mathcal{D}), \mathcal{O}_D)
\]
be morphisms of ringed topoi, then the natural transformation \(R(g \circ f) \to Rg_* \circ Rf_*\) is an isomorphisms, and for any \(\mathcal{F}^\bullet \in K^+(\mathcal{O})\), there is a spectral sequence convergence
\[
E_2^{p,q} = R^p g_* R^q f_* (\mathcal{F}^\bullet) \Rightarrow E^n = R^n (g \circ f)_* (\mathcal{F}^\bullet).
\]

Proof: This is just the Grothendieck spectral sequence(3.4.7.11), where the condition is satisfied by(5.3.1.8) and(5.3.1.12).

Cor.(5.3.1.10) [Leray Spectral Sequence]. Let \(f, f^\sharp) : (\text{Sh}(\mathcal{C}), \mathcal{O}) \to (\text{Sh}(\mathcal{C}'), \mathcal{O}')\) be a morphism of ringed topoi, then for any \(\mathcal{F}^\bullet \in K^+(\mathcal{O})\), then \(R\Gamma(\mathcal{C}, -) \to R\Gamma(\mathcal{C}', -) \circ Rf_*\) is an isomorphism, and there is a spectral sequence convergence
\[
E_2^{p,q} = H^p(\mathcal{C}', R^q f_* (\mathcal{F}^\bullet)) \Rightarrow E^n = H^n(\mathcal{C}, \mathcal{F}^\bullet).
\]

Prop.(5.3.1.11) [Relative Mayer-Vietoris Sequence]. Let \((\mathcal{C}, \mathcal{O})\) be a ringed site and \(U : \{U \to X, V \to X\}\) is a covering s.t. \(U \to X\) is a monomorphism, then for any \(\mathcal{F} \in \text{Sh}(\mathcal{O})\) and any morphism of ringed sites \(f : (\mathcal{C}, \mathcal{O}) \to (\mathcal{O}', \mathcal{O}')\), there is a long exact sequence of sheaves in \(\text{Sh}(\mathcal{O}')\):
\[
0 \to (f|_{X*})(\mathcal{F}|_{X}) \to (f|_{U*})(\mathcal{F}|_{U}) \oplus (f|_{V*})(\mathcal{F}|_{V}) \to (f|_{U \cap V*})(\mathcal{F}|_{U \cap V}) \to R^1(f|_{X*})(\mathcal{F}|_{X}) \to \ldots
\]
that is functorial in \(f\).

Proof: Choose a functorial injection resolution \(\mathcal{F} \to \mathcal{I}^\bullet(3.4.3.9)\), then there is an exact sequence of complexes
\[
0 \to (f|_{X*})(\mathcal{I}^\bullet|_{X}) \to (f|_{U*})(\mathcal{I}^\bullet|_{U}) \oplus (f|_{V*})(\mathcal{I}^\bullet|_{V}) \to (f|_{U \cap V*})(\mathcal{I}^\bullet|_{U \cap V}) \to 0
\]
because injective sheaves are flabby(5.3.4.9) and \((U \times_X V) \times_X f^{-1}W \to V \times_X f^{-1}W\) is a monomorphism for any \(W \in \mathcal{O}'\). Then we take the long exact sequence of cohomology.
Cor. (5.3.1.12) [Mayer-Vietoris Sequence]. Let \((\mathcal{C}, \mathcal{O})\) be a ringed site and \(U : \{U \to X, V \to X\}\) is a covering s.t. \(U \to X\) is a monomorphism, then for any \(\mathcal{F} \in \mathsf{Sh}(\mathcal{O})\), there is a long exact sequence

\[0 \to H^0(X, \mathcal{F}) \to H^0(U, \mathcal{F}) \oplus H^0(V, \mathcal{F}) \to H^0(U \times_X V, \mathcal{F}) \to H^1(X, \mathcal{F}) \to \ldots\]

that is functorial in \(\mathcal{F}\).

Prop. (5.3.1.13) [Compatibility with Algebraic Structures]. Let \((\mathcal{C}, \mathcal{O})\) be a ringed site and \(\mathcal{F} \in \mathsf{Sh}(\mathcal{C})\), \(K \in \mathsf{PSh}(\mathcal{C})\), then \(H^*(K, \mathcal{F})\) is the same calculated as \(\mathcal{O}\)-modules or Abelian sheaves.

Proof: Denote \((C, \mathcal{Z})\) the trivial ringed site and \(ab : (C, \mathcal{O}) \to (C, \mathcal{Z})\) the forgetful functor, then \(ab\) is exact and \(\text{Hom}(K, \mathcal{F}_{ab}) = \text{Hom}(K, \mathcal{F})\), thus we can use the Leray spectral sequence (5.3.1.10). □

Prop. (5.3.1.14) [Direct Products]. Let \((\mathcal{C}, \mathcal{O})\) be a ringed site and \(\mathcal{F}_i\) be a family of sites indexed over a set \(I\), then for any presheaf of sets \(K\) on \(\mathcal{C}\), there is a Leray spectral sequence convergence

\[H^n(K, R^q(\prod_i \mathcal{F}_i)) \to R^n(\prod_i \text{Hom}(K, \mathcal{F}_i))(\mathcal{F}_i) \cong \prod_i H^n(K, \mathcal{F}_i).\]

In particular, \(H^1(K, \prod_i \mathcal{F}_i) \to \prod_i H^1(K, \mathcal{F}_i)\) is injective.

Prop. (5.3.1.15) [Filtered Colimits]. \(H^n(U, -)\) commutes with filtered colimits if \(T\) is a Noetherian topology.

Proof: \(n = 0\) case follows from the fact the colimit presheaf is already a sheaf, because for any finite cover, the Čech complex of the limit sheaf is the filtered colimit of Čech complexes, and filtered colimit is exact.

And a filtered colimits of injective sheaves is flask, because flask need only be checked for finite coverings at this case (because of the fact \(T\) and \(T^f\) have equivalent category of sheaves (5.1.1.3) and definition of flask (5.3.4.8)), and a filtered colimit of exact Čech complexes is exact. So we can choose a functorial injective resolution (3.4.3.9) and use the colimit resolution to calculate the cohomology. □

Prop. (5.3.1.16) [Filtered Colimits]. \(H^1(U, -)\) commutes with direct limits if \(X\) is a qs ringed space and \(U \subset X\) is qc.

Proof: The proof is the same as that of (5.7.1.5). □

Low Dimensions

Prop. (5.3.1.17) [\(H^1\) and Picard Group]. Let \((\mathcal{C}, \mathcal{O})\) be a local ringed site, then there is a canonical isomorphism of Abelian groups

\[H^1(\mathcal{C}, \mathcal{O}^*) = \text{Pic}(\mathcal{O}).\]

Proof: Let \(\mathcal{L}\) be an invertible sheaf, then there exists a subsheaf

\[\mathcal{L}^* : U \mapsto \{s \in \mathcal{L}(U) | s^* : \mathcal{O}(U) \to \mathcal{L}(U)\text{ is an isomorphism}\}.\]
Notice if \( f \in \mathcal{O}^*(U) \) and \( s \in \mathcal{L}^*(U) \), then \( fs \in \mathcal{L}^*(U) \), and any two \( s, s' \in \mathcal{L}^*(U) \) differ by an element of \( \mathcal{O}^*(U) \), so \( \mathcal{L}^* \) is a pseudo-\( \mathcal{O}^* \)-torsor. Moreover, as \( \mathcal{L} \) is locally free of rank 1 by (5.2.5.8), so \( \mathcal{L}^* \) has sections locally, so it is an \( \mathcal{O}^* \)-torsor.

In this way, we get a map
\[
\text{Pic}(\mathcal{O}) \to \text{Tor}(\mathcal{O}_{\mathcal{X}}^*) \cong H^1(X, \mathcal{O}_{\mathcal{X}}^*)(5.3.2.18).
\]
This map is injective: if \( \mathcal{L} \) corresponds to a trivial torsor, then \( \mathcal{L}^* \) has a global section, and then \( \mathcal{L} \) is also trivial. This map is also surjective, because if \( \mathcal{F} \) is an \( \mathcal{O}_{\mathcal{X}}^* \)-torsor, then we can define
\[
\mathcal{L}_1 : U \mapsto [\mathcal{F}(U) \otimes \mathcal{O}(U)]/\mathcal{O}(U)^*,
\]
where the action is given by \( f \cdot (s, g) = (fs, f^{-1}g) \), and \( \mathcal{L}_1 \) is an \( \mathcal{O} \)-module given the addition \( (s, g) + (s', g') = (s, g + \frac{g}{s}g') \), where \( \frac{g}{s} \in \mathcal{O}(U) \) satisfies \( \frac{g}{s} \cdot s = s' \). Then the shifification \( \mathcal{L} \) of \( \mathcal{L} \) is a locally trivial bundle that maps \( \mathcal{F} \).

**Prop. (5.3.1.18) \([H^2 \text{ and Objects of Gerbes}]\)** Let \( \mathcal{C} \) be a site and \( \mathcal{S} \to \mathcal{C} \) be a gerbe whose automorphism sheaves are Abelian. Let \( \mathcal{G} \) be the sheaf defined in (5.1.3.24). If \( U \) is an object of \( \mathcal{C} \) that

- there exists a cofinal system of coverings \( \{U_i \to U\} \) that for any such covering, \( H^1(U_i, \mathcal{G}) = 0 \), \( H^1(U_i \times_U U_j, \mathcal{G}) = 0 \),
- \( H^2(U, \mathcal{G}) = 0 \).

Then \( \mathcal{S}_U \) is non-empty.

**Proof:** By hypothesis, there is a covering \( \{U_i \to U\} \) and \( x_i \) in \( \mathcal{S} \) lying over \( U_i \). By item1, after refining the covering, we may assume \( H^1(U_i, \mathcal{G}) = 0 \) and \( H^1(U_{ij}, \mathcal{G}) = 0 \). Consider the sheaf
\[
\mathcal{F}_{ij} = \text{Isom}(x_i|_{U_{ij}}, x_j|_{U_{ij}})
\]
on \( \mathcal{C}/U_{ij} \), then there is an action \( \mathcal{G}_{U_{ij}} \times \mathcal{F}_{ij} \to \mathcal{F}_{ij} \). Then \( \mathcal{F}_{ij} \) is a pseudo \( \mathcal{G}|_{U_{ij}} \)-torsor and clearly a torsor because any two objects of a gerbe is locally isomorphic.

By (5.3.2.18), these torsors are trivial, thus having a global section. In other words, there are isomorphisms \( \varphi_{ij} : x_i|_{U_{ij}} \to x_j|_{U_{ij}} \). To get an object \( x \) over \( U \), it suffices to manage the choices of \( \varphi_{ij} \) to get a descent datum. For this, use the fact \( H^2(U, \mathcal{G}) = 0 \) and \( H^2(U, \mathcal{G}) \to H^2(U, \mathcal{G}) \) is injective by Cech to Derived spectral sequence (5.3.2.13). \( \square \)

**Others**

**Prop. (5.3.1.19)** Let \( K' \to K \) be a map of presheaves of sets on \( \mathcal{C} \) whose shifification is surjective. Set \( K' = K' \times_K \ldots \times_K K' \), then for any \( \mathcal{F} \in \text{Sh}(\mathcal{C}) \), there is a spectral sequence convergence
\[
E_1^{p,q} = H^q(K'_p, \mathcal{F}) \Rightarrow H^{p+q}(K, \mathcal{F}).
\]

**Proof:** Since shifification is exact, \( (K'_p)^\natural = (K'^\natural)_p \). Then we use (5.1.2.25) to change to a larger site \( \mathcal{C}' \) where the topoi are equivalent and \( K', K \) are objects in \( \mathcal{C}' \) and \( K' \to K \) is a covering, then we use the \( E_1 \) page of the Čech to derived spectral sequence (5.3.2.13). Notice this need modification, the modification goes back to the proof of the Grothendieck spectral sequence, where we choose the natural Čech complex resolution in place of the CE resolution, because we have (5.3.2.3). \( \square \)
Cor. (5.3.1.20)[Čech-Alexander Resolution]. If $C$ is a site with the indiscrete topology, $X$ a weakly final object (3.1.1.20) of $C$, then for any Abelian sheaf $F$ on $C$, the total cohomology $R\Gamma(C, F)$ is represented by the Čech complex

$$F(X) \to F(X \times X) \to F(X \times X \times X) \to \ldots.$$

Proof: By (5.3.4.10), $H^q(X^p, F) = 0$ for $q > 0$. The assumption says $h_X \to \ast$ is surjective, thus the conclusion is a special case of (5.3.1.19).

2 Čech Cohomology

Def. (5.3.2.1)[Čech Complex and Čech Cohomology]. Let $(C, \mathcal{O})$ be a ringed site and $U = \{U \to \ast\}$ be a covering, we have a canonical complex of presheaves $\mathcal{Z}_{U, \bullet}$ defined to be

$$\ldots \to \bigoplus_{i_0, i_1, i_2} j! \mathcal{Z}_{U_{i_0}i_1i_2} \to \bigoplus_{i_0, i_1} j! \mathcal{Z}_{U_{i_0}i_1} \to \bigoplus_{i_0} j! \mathcal{Z}_{U_{i_0}} \to 0.$$

And for any presheaf of $\mathcal{O}_X$-module $F$, the complex

$$\text{Hom}^\bullet_{Psh(C)}(\mathcal{Z}_{U, \bullet} \otimes \mathcal{O}, F) \cong \text{Hom}^\bullet_{P, \text{Ab}}(\mathcal{Z}_{U, \bullet}, F)$$

is called the Čech complex $\check{C}^\bullet(U, F)$ of $F$. The cohomology $\check{H}^\bullet(U, F)$ of $\check{C}^\bullet(U, F)$ is called the Čech cohomology of $F$ w.r.t $U$.

$\mathcal{Z}_{U, \bullet}$ is exact except in degree 0, where the homology is $j! \mathcal{Z}_U$. This is because we have a homotopy: choose a fixed $i_0$, for a $s \in \Gamma(U_{i_1\ldots i_n}, F)$, we map it to $(hs)_{i_1\ldots i_n} = \delta_{i, i_0} s$??. In particular, an injective sheaf is Čech acyclic.

Lemma (5.3.2.2). The Čech complexes $\check{C}^\bullet(U, -)$ induces a functor from $PSh(C)$ to $K^+(\text{Ab})$, which is an exact functor.

Proof: Because in each degree this functor is a sum of functors of the form $F \mapsto F(U)$, which are exact functors on $PSh(C)$.

Prop. (5.3.2.3)[Čech Complex as Derived Functors]. Let $C$ be a site and $U = \{U \to \ast\}$ be a covering, then $\check{H}^0(U, -)$ is left exact, and for $F \in \mathcal{Sh}(C)$, there are functorial quasi-isomorphisms

$$\check{C}^\bullet(U, F) \to R\check{H}^0(U, F)$$

which is functorial in $F$.

Proof: Choose a functorial injective resolution of presheaves $I^\bullet$ of $F$, and consider the double complex $\check{C}(U, I^\bullet)$. There are maps of complexes

$$\check{C}(U, F) \to \text{Tot}(\check{C}(U, I^\bullet)), \quad \check{H}^0(U, I^\bullet) \to \text{Tot}(\check{C}(U, I^\bullet))$$

which are both quasi-isomorphism by an application of spectral sequence and the fact the columns and rows are exact in positive degrees: The columns are exact because of (5.3.2.2) and the rows are exact because $\mathcal{Z}_{U, \bullet}$ is exact in positive degrees (5.3.2.1) and $I^p$ are injective. Then we have the desired quasi-isomorphism, and it is functorial in $F$. 

\[\square\]
Cor. (5.3.2.4) [Čech Cohomologies]. If we take filtered colimit for coverings, \( F \rightarrow \check{H}^0(U, F) = H^0(U, F) \) is a left exact functor from presheaves to sets, the derived complex is just \( \lim_{\rightarrow} \check{\mathcal{C}}^\bullet(U, F) \), and the derived functors are just \( \lim_{\rightarrow} \check{H}^q(U, F) \).

Proof: This is because we can take colimit of the conclusion of (5.3.2.3), because the colimit is filtered by (5.3.2.5) so exact, so the Čech complex also represents the derived complex. \( \square \)

Lemma (5.3.2.5). The refinement morphism of Čech cohomologies of two coverings doesn’t depends on the refinement map chosen.

Proof: For two refinement map, there is a commutative diagram

\[
\begin{array}{ccc}
\prod F(U_i) & \xrightarrow{\delta} & \prod F(U_i \times_U U_j) \\
\downarrow{f-g} & & \downarrow{\Delta^1} \\
\prod F(U'_j) & & 
\end{array}
\]

so it induce the same map on the kernel. \( \square \)

Def. (5.3.2.6) [Alternating Čech Complexes]. Let \((\mathcal{C}, \mathcal{O})\) be a ringed site and \( U : \{U_i \to U\} \in \text{Cov}(\mathcal{C}) \), \( F \in \mathcal{S}_\mathcal{O} \), then the alternating Čech complex \( \check{\mathcal{C}}^\bullet(U, F) \) is defined to be the subcomplex

\[
\check{\mathcal{C}}^\bullet_{\text{alt}}(U, F) = \{ s \in \check{\mathcal{C}}^\bullet(U, F) | s_{i_0, \ldots, i_p} = 0 \text{ if } i_m = i_n, m \neq n, s_{i_{\sigma(0)}, \ldots, i_{\sigma(p)}} = \text{sgn}(\sigma)s_{i_0, \ldots, i_p} \} \subset \check{\mathcal{C}}^\bullet(U, F).
\]

It is truly a subcomplex.

Prop. (5.3.2.7) [Alternating and Usual Complexes]. Let \((\mathcal{X}, \mathcal{O}_X)\) be a ringed space, \( U : \{U_i \to U\} \in \text{Cov}(\mathcal{C}) \), \( F \in \mathcal{S}_\mathcal{O}_X \), then the inclusion \( \check{\mathcal{C}}^\bullet_{\text{alt}}(U, F) \to \check{\mathcal{C}}^\bullet(U, F) \) is a homotopy equivalence.

Proof: Cf.[Sta]01FM. The proof is rather complicated. \( \square \)

Remark (5.3.2.8). WARNING: This is not right for ringed sites, e.g. the étale sites, for example, cf.(6.4.1.23).

Comparison Theorems

Prop. (5.3.2.9). If two coverings are refinements of each other, then their Čech cohomology is isomorphic.

Proof: Because the refinement morphism doesn’t depends on the refinement map(5.3.2.5). \( \square \)

Prop. (5.3.2.10) [Comparison Theorem for Čech Acyclicity]. If there are two coverings \( \mathcal{U}, \mathcal{V} \) and a presheaf \( F \), then we can construct a double Čech complex with the \((p, q)\)-term being \( F(U_{i_1, \ldots, i_p} \cap V_{j_1, \ldots, j_q}) \). Then the vertical and horizontal arrays calculate the Čech cohomology \( \prod_j H^s(U|_{V_{j_1, \ldots, j_q}}, F) \), \( \prod_i H^s(\mathcal{V}|_{U_{i_1, \ldots, i_q}}, F) \) respectively.

So by Spectral sequence(3.4.7.8), if both higher Čech cohomology group \( H^k(U|_{V_{j_1, \ldots, j_q}}, F) \), \( H^k(\mathcal{V}|_{U_{i_1, \ldots, i_q}}, F) \) vanish, i.e., they are both \( F \)-acyclic, then \( H^s(\mathcal{U}, F) \cong H^s(\mathcal{V}, F) \).
Cor. (5.3.2.11). If $\mathfrak{V}$ is a refinement of $\mathfrak{U}$, and $\mathfrak{V}|_{U_{i_1,\ldots,i_p}}$ are all $\mathcal{F}$ acyclic, then $H^*(\mathfrak{U}, \mathcal{F}) \cong H^*(\mathfrak{V}, \mathcal{F}).$

Proof: It suffices to prove $\mathfrak{U}|_{V_{i_1,\ldots,i_q}}$ is $\mathcal{F}$-acyclic. But $\mathfrak{U}|_{V_{i_1,\ldots,i_q}}$ and $\text{id}_{V_{i_1,\ldots,i_q}}$ are refinements of each other, so (5.3.2.9) settles the proof. □

Cor. (5.3.2.12). If $\mathfrak{V}|_{U_{i_1,\ldots,i_p}}$ is $\mathcal{F}$-acyclic, then the covering $H^*(\mathfrak{U} \times \mathfrak{V}, \mathcal{F}) = H^*(\{U_i \cap V_j\}, \mathcal{F}) \cong H^*(\mathfrak{U}, \mathcal{F}).$

Proof: Because $\mathfrak{V}|_{U_{i_1,\ldots,i_p}}$ and $\mathfrak{U} \times \mathfrak{V}|_{U_{i_1,\ldots,i_p}}$ are refinements of each other, so $\mathfrak{U} \times \mathfrak{V}$ refines $\mathfrak{U}$, so (5.3.2.11) can be applied. □

Prop. (5.3.2.13) Čech to Derived. For any $\mathcal{F} \in \text{Sh}(\mathcal{C})$, the Grothendieck spectral sequence applied to $\Gamma(U, -) = H^0(\{U_i \to U\}, -) \circ \iota = \tilde{H}^0(U, -) \circ \iota$ gives us:

$$H^p(\{U_i \to U\}, \mathcal{H}^q(\mathcal{F})) \Rightarrow H^{p+q}(U, \mathcal{F}).$$

$$\tilde{H}^p(U, \mathcal{H}^q(\mathcal{F})) \Rightarrow H^{p+q}(U, \mathcal{F}).$$

Cor. (5.3.2.14) [\tilde{H}^0 of Sheaf-Cohomology Presheaves]. For any $\mathcal{F} \in \text{Sh}(\mathcal{C})$, $\mathcal{H}^p(\mathcal{F})^+ = \mathcal{H}^p(\mathcal{F})^\sharp = 0$ for $p > 0$, so

$$\mathcal{H}^p(\mathcal{F})^+(U) = \tilde{H}^0(U, \mathcal{H}^p(\mathcal{F})) = 0 \quad p > 0.$$  

because $\mathcal{H}^p(\mathcal{F})^+$ is separated by (5.1.2.7). In particular, for any $s \in H^p(U, \mathcal{F})$, $p > 0$, there exists a covering $\mathcal{U}$ of $U$ s.t. $s|_{U_{i_j}} = 0$ for any $i$.

Thus the low degree of Čech to sheaf says (3.4.7.12):

$$0 \to \tilde{H}^1(U, \mathcal{F}) \to H^1(U, \mathcal{F}) \to 0 \to \tilde{H}^2(U, \mathcal{F}) \to H^2(U, \mathcal{F}) \to \tilde{H}^1(U, H^1(\mathcal{F})) \to \tilde{H}^2(U, \mathcal{F}) \to H^3(U, \mathcal{F}).$$

Proof: By Grothendieck spectral sequence applied to forgetful functor and exact $\sharp$ functor, where the condition are satisfied by (5.3.4.3). □

Cor. (5.3.2.15) [Acyclic Covering Calculates Derived Cohomologies]. If we have $H^q(U_{i_1,\ldots,i_p}, \mathcal{F}) = 0, q > 0$, then $H^p(\{U_i \to U\}, \mathcal{F}) = H^p(U, \mathcal{F})$ as $\mathcal{O}_X(U)$-modules.

Proof: Because $H^p(\{U_i \to U\}, \mathcal{H}^q(\mathcal{F}))$ vanish for $q > 0$. □

Prop. (5.3.2.16) Čech Acyclic Čech Comparison. If $\mathcal{C}$ be a ringed site, $\mathfrak{G} \subset \mathcal{C}, \text{Cov} \subset \text{Cov}(\mathcal{C})$ and $\mathcal{F} \in \text{Sh}(\mathcal{C})$ that

- For any $\{U_i \to U\} \in \text{Cov}, U_i, U \in \mathfrak{G}$, and $U_{i_1,\ldots,i_p} \in \mathfrak{G}$.
- $\text{Cov}|_U$ is cofinal in $\text{Cov}(\mathcal{C}/U)$ for any $U \in \mathfrak{G}$.
- $\tilde{H}^q(U, \mathcal{F}) = 0$ for any $U \in \mathfrak{G}$ and $q > 0$.

Then $H^p(X, \mathcal{F}) = \tilde{H}^p(X, \mathcal{F}) = H^p(\{U_i \to X\}, \mathcal{F})$ for any $\{U_i \to X\} \in \text{Cov}$.

Proof: By (5.3.2.15), we only have to show that $H^q(U, \mathcal{F}) = 0$ for $U \in \mathfrak{G}$ and $q > 0$. Use induction on $q$, use Čech to sheaf2: $\tilde{H}^p(U, \mathcal{H}^q(\mathcal{F})) \Rightarrow H^{p+q}(U, \mathcal{F})$. The case $q \neq 0$ is by condition 2, 3, and induction hypothesis. For $p = 0$, use (5.3.2.14). □
Non-Abelian Čech Cohomologies

**Def. (5.3.2.17) [Non-Abelian Cohomology].** Let $\mathcal{C}$ be a site and $\mathcal{G} \in Sh^{sp}(\mathcal{C})$, for any covering $U = \{U_i \to U\} \in Cov(\mathcal{C})$, we can define a non-Abelian Čech cohomology $\check{H}^1(U, \mathcal{G})$ as follows:

Define $Z^1(U, \mathcal{G})=\{\text{sets of families } (c_i) \mid c_i \in \Gamma(U_{ij}, \mathcal{G}) : c_{ijk}c_{ik}^{-1}c_{ij} = 1\}$.

If $c \in Z^1(G, M)$, then for any $g \in \Gamma(U, \mathcal{G})$,

$$c_g = (c_{ij} = g|_{U_i}c_{ij}g|_{U_j})$$

is also in $Z^1(U, \mathcal{G})$. This defines an equivalence relation on $Z^1(U, \mathcal{G})$, the equivalence classes are called $\check{H}^1(G, M)$. This is compatible with the commutative case.

Taking filtered colimit over all coverings of $U$, we can also define $\check{H}^1(U, \mathcal{G})$.

**Prop. (5.3.2.18) [H^1 and Torsors].** Let $\mathcal{C}$ be a site and $\mathcal{H} \in Sh(\mathcal{C})$, then there is a canonical isomorphism of $\mathcal{H}$-torsors(5.1.1.14) and $H^1(\mathcal{C}, \mathcal{H})$.

**Proof:** Cf.[Sta]03AJ. Should have a non-commutative version. \qed

**Prop. (5.3.2.19) [Long Exact Sequence of Non-Abelian Čech Cohomologies].** Let $\mathcal{C}$ be a site and $1 \to A \to B \to C \to 1$ is an exact sequence in $Sh^{sp}(\mathcal{C})$, then for any $U \in \mathcal{C}$, there is a long exact sequence of pointed sets

$$1 \to \Gamma(U, A) \to \Gamma(U, B) \to \Gamma(U, C) \xrightarrow{\delta} \check{H}^1(U, A) \to \check{H}^1(U, B) \to \check{H}^1(U, C) \xrightarrow{\Delta} \check{H}^2(U, A)$$

the last term is defined only when $A$ is in the center of $B$ and $U$ satisfies: For any covering $U$ and a refinement $\mathcal{W} \to U \times U$, there exists a refinement $U' \to U$ s.t. $U' \times U'$ is a refinement of $\mathcal{W}$.

$\delta$ is defined as follows: for $c \in \Gamma(\mathcal{C}, C)$, by taking a covering $\{U_i \to U\}$, we may assume that $c_{ij} = b_i \in \Gamma(U_i, B)$, then $a_{ij} = b_i^{-1}b_j$ is a cocycle, and a different choice differ by a cocycle, so this is well-defined.

$\Delta$ is defined as: for any covering $U$ of $U$ and $c = (c_{ij})$ a cocycle in $\check{H}^1(U, \mathcal{C})$, by passing to a refinement, we may assume that $c_{ij} \in \Gamma(U_{ij}, B)$, then $\delta(c)$ is represented by the 2-cocycle $a_{ijk} = c_{jk}c_{ik}^{-1}c_{ij} \in \Gamma(U, A)$.

**Proof:** The verification of well-definedness of $\Delta$ is checked at [Serre Local Fields P124].

For the exactness at $C^G$, the definition of $\delta$ shows that $\delta(c) = 1$ iff there is an inverse image $b$ that $b^{-1}\sigma(b) = 1$ for all $\sigma$.

For the exactness at $H^1(G, A)$, $a_\sigma = b^{-1}\sigma(b)$ if $a_\sigma$ is in the image of $\delta$. Conversely, the image of $b$ in $C$ is in $C^G$, so it is in the image of $\delta$.

For the exactness at $H^1(G, B)$, one way is clear, and for the other, if $\pi(b_\sigma) = c^{-1}\sigma(c)$, then if $t$ is an inverse image of $c$, then $tb_\sigma\sigma(t)^{-1}$ is a cocycle in $A$ cohomologous to $b_\sigma$.

For the exactness at $H^1(G, C)$, one way is clear, and if $b_\sigma$ is an inverse image of $b_\sigma$ and $a_{\sigma, \tau} = b_\sigma\sigma(b_\tau)b_\sigma^{-1}$ is a coboundary, then it is $a_\sigma\sigma(a_\tau)a_{\sigma, \tau}^{-1}$, so we change $b$ to $a_\sigma^{-1}b_\sigma$, as $A$ is in the center of $B$, this lifts $c$ to a cocycle in $B$. \qed

**Prop. (5.3.2.20) [Hilbert’s Theorem 90].** For $L/K$ a Galois extension, $H^1(\text{Gal}(L/K), GL_n(L)) = 1$, where $L$ is equipped with the discrete topology.
Proof: We prove any cocycle is a coboundary, for this, notice any cocycle factor through a finite quotient, and the images of it is contained in a finite extension of \( K \), hence it reduce to the case of \( L/K \) finite.

By definition, this is equivalent to any \( B \)-semi-linear representation of \( G \) free of finite rank is trivial, which is by(14.2.4.4). \( \square \)

Cor.(5.3.2.21) \[ semi-linear \ representations \]. The proposition implies that any semi-linear \( L \)-representation of \( G_{L/K} \) is trivial.

Cor.(5.3.2.22). \( H^1(G/L/K), SL_n(L) = 1 \). This is seen from the exact sequence 1 → SL\(_n\)(L) → GL\(_n\)(L) → \( L^\times \) → 1.

3 Derived Homology

K-Flat Complexes

Def.(5.3.3.1)[K-flat Complexes]. Let \((\mathcal{C}, \mathcal{O})\) be a ringed site, a complex \( \mathcal{K}^\bullet \) of \( \mathcal{O} \)-modules is called K-flat if for any acyclic complex \( \mathcal{F}^\bullet \) of \( \mathcal{O} \)-modules, the total complex \( \text{Tot}^\oplus(\mathcal{F}^\bullet \otimes_\mathcal{O} \mathcal{K}^\bullet) \) is acyclic, or equivalently, tensoring with \( \mathcal{K}^\bullet \) maps quasi-iso to quasi-iso, by the long exact sequence and the fact tensoring is an exact functor of triangulated categories(3.3.6.4).

Prop.(5.3.3.2). If \( K, K' \) are K-flat complexes of \( \mathcal{O} \)-modules,

\begin{itemize}
  \item \( \text{Tot}^\oplus(\mathcal{K} \otimes_\mathcal{O} \mathcal{K}') \) is K-flat.
  \item If \( (K_1, K_2, K_3) \) is a distinguished triangle in \( K(\mathcal{O}) \), if two of them is K-flat, then the third is also K-flat.
  \item Any bounded above complex of flat \( \mathcal{O} \)-modules is K-flat.
  \item Any filtered colimits of K-flat complexes are K-flat.
\end{itemize}

Proof: 1: This follows from(3.3.6.2).
3: use(3.3.6.4), and the long exact sequence.
4: Cf.[Sta]06YQ.
5: because we are taking termwise-colimit, and Tot and tensor all commute with filtered colimits. \( \square \)

Prop.(5.3.3.3)[K-Flat Resolutions]. Any complex \( \mathcal{P}^\bullet \) of \( \mathcal{O} \)-modules has a K-flat resolution \( \mathcal{K}^\bullet \rightarrow \mathcal{P}^\bullet \), moreover, each term of \( \mathcal{K}^\bullet \) is a flat \( \mathcal{O} \)-module and \( \mathcal{K}^\bullet \rightarrow \mathcal{P}^\bullet \) is termwise surjective.

Proof: Cf.[Sta]06Y4. \( \square \)

Lemma(5.3.3.4). Let \( P \rightarrow Q \) be a quasi-isomorphism of K-flat complexes of \( \mathcal{O} \)-modules, then for any complex \( L \) of \( \mathcal{O} \)-modules, \( \text{Tot}(L \otimes P) \rightarrow \text{Tot}(L \otimes Q) \) is a quasi-isomorphism.

Proof: Choose a K-flat resolution(5.3.3.3) \( K \) of \( L \), then notice

\[
\text{Tot}(L \otimes P) \cong \text{Tot}(K \otimes P) \cong \text{Tot}(K \otimes Q) \cong \text{Tot}(L \otimes Q)
\]

by definition of K-flatness(5.3.3.1). \( \square \)

Prop.(5.3.3.5)[Pullback of K-Flat is K-Flat]. Let \( f : (\text{Sh}(\mathcal{C}'), \mathcal{O}_{\mathcal{C}'}) \rightarrow (\text{Sh}(\mathcal{C}), \mathcal{O}_{\mathcal{C}}) \) be a morphism of ringed topoi, then \( f^* \) maps K-flat complexes to K-flat complexes.

Proof: Cf.[Sta]0G7E. \( \square \)
Derived Tensor Product and Tor

Def. (5.3.3.6) [Derived Tensor Product]. Let \( A \to B \) be a homomorphism of sheaves of rings over a site \( \mathcal{C} \), then the functor \( \text{Tot}^\oplus(- \otimes_{\mathcal{O}} -) \) is a bi-exact bifunctor of triangulated categories \( K(A) \times K(B) \to D(B) \) by (3.6.3.4)(3.4.1.8), and the class of K-flat complexes in \( K(A) \) and K-flat complexes in \( K(B) \) satisfies the condition of (the dual of)?? by (5.3.3.1) and (5.3.3.3), so we get a left derived functor

\[- \otimes^L_A - : D(A) \times D(B) \to D(B),\]

called the derived tensor product. And if any of \( M^\bullet, N^\bullet \in K(A) \) is K-flat, the natural map \( M^\bullet \otimes^L_A N^\bullet \to \text{Tot}^\oplus(M^\bullet \otimes_A N^\bullet) \) is an isomorphism in \( D(B) \).

Prop. (5.3.3.7). Let \( A \to B \) be a homomorphism of sheaves of rings over a site \( \mathcal{C} \). Let \( N^\bullet \) be a \( B \)-module, then for \( M^\bullet \in D(A) \), there are a functorial isomorphisms

\[M^\bullet \otimes^L_A N^\bullet \cong (M^\bullet \otimes^L_A B) \otimes^L_B N^\bullet.\]

Proof: Consider both sides as right derived functors of the multi-exact multifunctor. As this is true for \( \text{Tot}^\oplus \), these follow from the universal property and (3.4.4.14), the conditions are satisfied by (5.3.3.3)(5.3.3.4)(5.3.3.5).

Cor. (5.3.3.8) [Commutative Monoidal Structure]. If \( A = B = \mathcal{C} = \mathcal{O} \) and \( K, L, M \in K(\mathcal{O}) \), there are natural isomorphisms

\[K \otimes^L L \cong L \otimes^L K, \quad (K \otimes^L L) \otimes^L M \cong K \otimes^L (L \otimes^L M).\]

Thus \( D^*(\mathcal{O}) \) has a commutative monoidal structure.

Remark (5.3.3.9) [WARNING]. If \( M, N \) are two \( A \)-modules, then we can define \( M_R \otimes^L_R N \) and \( M \otimes^L_R N_R \), but there are no reason for them to be isomorphic.

Prop. (5.3.3.10). Let \( A \to B \to \mathcal{C} \) be homomorphism of sheaf of rings on a site \( \mathcal{C} \), then for \( M^\bullet \in K(A), N^\bullet \in K(B) \) and \( K^\bullet \in K(C) \), there are functorial isomorphisms

\[(M \otimes^L_A N) \otimes^L_B K = M \otimes^L_A (N \otimes^L_B K) = (M \otimes^L_A C) \otimes^L_C (N \otimes^L_B K)\]

called

\[(M \otimes^L_A N) \otimes^L_B K \cong (M \otimes^L_A K) \otimes^L_B (N \otimes^L_B C)\]

Proof: Consider both sides as right derived functors of the multi-exact multifunctor. As these are true for \( \text{Tot}^\oplus \), these follow from the universal property and (3.4.4.14), the conditions are satisfied by (5.3.3.3)(5.3.3.4)(5.3.3.5).

Def. (5.3.3.11) [Tor Modules]. Let \( \mathcal{F}, \mathcal{G} \) be \( \mathcal{O} \)-modules, then the Tor modules \( \text{Tor}_p^\mathcal{O}(\mathcal{F}, \mathcal{G}) \) is defined to be \( H^{-p}(\mathcal{F} \otimes^L_\mathcal{O} \mathcal{G}) \).

Prop. (5.3.3.12) [Flatness and Tor]. Let \( (\mathcal{C}, \mathcal{O}) \) be a ringed site, and \( \mathcal{F} \) is an \( \mathcal{O} \)-module. Then \( \mathcal{F} \) is a flat \( \mathcal{O} \)-modules iff \( \text{Tor}_1^\mathcal{O}(\mathcal{F}, \mathcal{G}) = 0 \) for any \( \mathcal{O} \)-module \( \mathcal{G} \).

Proof: If \( \mathcal{F} \) is flat, then clearly \( \text{Tor}_1^\mathcal{O}(\mathcal{F}, \mathcal{G}) = 0 \) for any \( \mathcal{O} \)-module \( \mathcal{G} \). Conversely, use the long exact sequence associated to \( \mathcal{F} \otimes^L_\mathcal{O} \) (3.3.6.4).
**Def. (5.3.3.13) [Relative Cup Product].** Let \( f : (\mathcal{Sh}(\mathcal{C}), \mathcal{O}_\mathcal{C}) \to (\mathcal{Sh}(\mathcal{D}), \mathcal{O}_\mathcal{D}) \) be a morphism of ringed topoi, then for any \( K, L \in D(\mathcal{O}_\mathcal{C}) \), there is a canonical functorial **relative cup product**

\[
Rf_*K \otimes^L_{\mathcal{O}_\mathcal{D}} Rf_*L \to Rf_*(K \otimes^L_{\mathcal{O}_\mathcal{C}} L)
\]

in \( D(\mathcal{O}_\mathcal{D}) \) that is the adjunction map of the map

\[
Lf^*(Rf_*K \otimes^L_{\mathcal{O}_\mathcal{D}} Rf_*L) \to Lf^*Rf_*K \otimes^L_{\mathcal{O}_\mathcal{C}} Lf^*Rf_*L \to K \otimes^L_{\mathcal{O}_\mathcal{C}} L
\]

by (5.3.3.15). This map is symmetric and associative.

In particular, if \( (\mathcal{Sh}(\mathcal{D}), \mathcal{O}_\mathcal{D}) = (\mathcal{Sh}(\text{pt}), \Gamma(\mathcal{C}, \mathcal{O}_\mathcal{C}) = A) \) (5.3.1.4), we get a map

\[
R\Gamma(\mathcal{C}, K) \otimes^L_A R\Gamma(\mathcal{C}, L) \to \Gamma(\mathcal{C}, K \otimes^L_{\mathcal{O}_\mathcal{C}} L).
\]

**Derived Pullback**

**Def. (5.3.3.14) [Derived Pullback].** Let \( f : (\mathcal{Sh}(\mathcal{C}'), \mathcal{O}') \to (\mathcal{Sh}(\mathcal{C}), \mathcal{O}) \) be a morphism of ringed site, define the **derived pullback**

\[
Lf^* : D(\mathcal{O}) \to D(\mathcal{O}') : \mathcal{F}^* \mapsto f^{-1}\mathcal{F}^* \otimes^L_{f^{-1}\mathcal{O}} \mathcal{O}'(5.3.3.6).
\]

In particular, if \( \mathcal{F}^* \) is K-flat, then there are natural isomorphisms \( Lf^*\mathcal{F}^* \cong f^*\mathcal{F}^* \).

Moreover, \( Lf^* \) is also naturally isomorphic to the left derived functor of the pullback morphism \( f^* \), by composition of derived functors applied to the \( f^* = \text{Tot}(\cdot \otimes_{f^{-1}\mathcal{O}} \mathcal{O}') \circ f^{-1} \) where \( f^{-1} \) is exact. In particular, \( Lf^* \) only depends on the underlying map \( f^* \) of ringed topoi.

**Prop. (5.3.3.15).** Let \( f : (\mathcal{Sh}(\mathcal{C}), \mathcal{O}_\mathcal{C}) \to (\mathcal{Sh}(\mathcal{D}), \mathcal{O}_\mathcal{D}), \ g : (\mathcal{Sh}(\mathcal{D}), \mathcal{O}_\mathcal{D}) \to (\mathcal{Sh}(\mathcal{E}), \mathcal{O}_\mathcal{E}) \) be a morphism of ringed topoi, then

- There is a natural isomorphism \( L(g \circ f)^* \cong Lf^* \circ Lg^* \). In particular, as localizing map \( j^* \) is exact, \( Lf^* \) can be calculated locally on the base.

- For \( \mathcal{F}^*, \mathcal{G}^* \in \text{Mod}_{\mathcal{O}_\mathcal{D}}, \) there are natural functorial isomorphisms

\[
Lf^*(\mathcal{F}^* \otimes^L_{\mathcal{O}_\mathcal{D}} \mathcal{G}^*) \cong Lf^*\mathcal{F}^* \otimes^L_{\mathcal{O}_\mathcal{C}} Lf^*\mathcal{G}^*.
\]

In particular, as localizing map \( j^* \) is exact, the derived tensor product can be calculated locally on the base.

- For \( \mathcal{F}^* \in \text{Mod}_{\mathcal{O}_\mathcal{C}}, \mathcal{G}^* \in \text{Mod}_{\mathcal{O}_\mathcal{D}}, \) there are natural functorial isomorphisms

\[
\mathcal{F}^* \otimes^L_{\mathcal{O}_\mathcal{C}} Lf^*\mathcal{G}^* \cong \mathcal{F}^* \otimes^L_{f^{-1}\mathcal{O}_\mathcal{D}} f^{-1}\mathcal{G}'
\]

- For \( \mathcal{F}^*, \mathcal{G}^* \in \text{Mod}_{\mathcal{O}_\mathcal{D}}, \) the natural isomorphisms satisfy a commutative diagram

\[
\begin{array}{ccc}
Lf^*(\mathcal{F}^* \otimes^L_{\mathcal{O}_\mathcal{D}} \mathcal{G}^*) & \longrightarrow & Lf^* \text{Tot}^\oplus(\mathcal{F}^* \otimes_{\mathcal{O}_\mathcal{D}} \mathcal{G}^*) \\
\downarrow & & \downarrow \\
Lf^*\mathcal{F}^* \otimes^L_{\mathcal{O}_\mathcal{C}} Lf^*\mathcal{G}^* & \longrightarrow & f^* \text{Tot}^\oplus(f^*\mathcal{F}^* \otimes_{\mathcal{O}_\mathcal{C}} f^*\mathcal{G}^*),
\end{array}
\]
Proof: 1, 2, 3: These follow from (5.3.3.10).

4: By a universal argument, \((\mathcal{F}^\bullet, \mathcal{G}^\bullet) \mapsto LF^*(\mathcal{F}^\bullet \otimes_{\mathcal{O}_D} \mathcal{G}^\bullet)\) is the derived functor of the bi-exact bifunctor

\[ F : K(\mathcal{O}_D) \times K(\mathcal{O}_D) \to D(\mathcal{O}_C) : (\mathcal{F}^\bullet, \mathcal{G}^\bullet) \mapsto f^* \text{Tot}^2(\mathcal{F}^\bullet \otimes_{\mathcal{O}_D} \mathcal{G}^\bullet). \]

Then by the universal property, both natural transformations corresponds to a natural transformation \(\theta_i : LF \to LF\). So it suffices to show that they are isomorphic. But K-flat morphisms are essentially surjective in \(D(\mathcal{O}_D)\), thus it suffices to prove the diagram is commutative for \(\mathcal{F}, \mathcal{G}\) K-flat. But in this case, there are commutative diagrams

\[
\begin{align*}
LF(\mathcal{F}^\bullet, \mathcal{G}^\bullet) & \xrightarrow{\eta(\mathcal{F}, \mathcal{G})} F(\mathcal{F}^\bullet, \mathcal{G}^\bullet) \\
\downarrow \theta_1 & \downarrow \text{id} \\
LF(\mathcal{F}^\bullet, \mathcal{G}^\bullet) & \xrightarrow{\eta(\mathcal{F}, \mathcal{G})} F(\mathcal{F}^\bullet, \mathcal{G}^\bullet)
\end{align*}
\]

and \(\eta(\mathcal{F}, \mathcal{G})\) is an isomorphism, so \(\theta_1 = \theta_2\). \(\square\)

**Prop. (5.3.3.16) [Adjunction].** \(LF^*\) is left adjoint to \(Rf_*\), by (3.4.4.15) and (5.2.2.9).

**Prop. (5.3.3.17) [Base Change Map].** Let

\[
(\text{Sh}(C'), \mathcal{O}_{C'}) \xrightarrow{g'} (\text{Sh}(C), \mathcal{O}_C) \\
\downarrow \mathbb{f}' \quad \downarrow \mathbb{f} \\
(\text{Sh}(D'), \mathcal{O}_{D'}) \xrightarrow{g} (\text{Sh}(D), \mathcal{O}_D)
\]

be a commutative diagram of ringed topoi, then for any \(K \in D(\mathcal{O}_C)\), there is a canonical base change map

\[ LG^*Rf_*K \to R(f')_*L(g')^*K \]

functorial in \(K\), and this map is compatible with composition of diagrams.

**Proof:** By adjunction (5.3.3.16), this follows from the canonical map

\[ Rf_*K \to Rg_*R(f')_*L(g')^*K = Rf_*R(g')_*L(g')^*K, \]

which comes from the adjunction map \(K \to R(g')_*L(g')^*K\). \(\square\)

**Cor. (5.3.3.18) [Flat Base Change Morphism].** Let

\[
(\text{Sh}(C'), \mathcal{O}_{C'}) \xrightarrow{g'} (\text{Sh}(C), \mathcal{O}_C) \\
\downarrow \mathbb{f}' \quad \downarrow \mathbb{f} \\
(\text{Sh}(D'), \mathcal{O}_{D'}) \xrightarrow{g} (\text{Sh}(D), \mathcal{O}_D)
\]

be a commutative diagram of ringed sites. Assume both \(g, g'\) are flat, then for any \(\mathcal{F}^\bullet \in K^+(\mathcal{O}_C)\), there is a canonical base change map

\[ g^*Rf_*\mathcal{F}^\bullet \to Rf'_*(g')^*\mathcal{F}^\bullet. \]

and when \((\text{Sh}(D'), \mathcal{O}_D) = (\text{Sh}(C/U), \mathcal{O}_U)\) is the localizing site, then this map is an isomorphism

\[ (Rf_*\mathcal{F}^\bullet)_U \cong Rf'_*(\mathcal{F}^\bullet)_U. \]
Proof: The last assertion follows from the fact the restriction of a K-injective is also a K-injective \((5.3.4.2)\).

**Def. (5.3.3.19) [Projection Map].** Let \( f : (\mathcal{Sh}(\mathcal{C}), \mathcal{O}_\mathcal{C}) \to (\mathcal{Sh}(\mathcal{D}), \mathcal{O}_\mathcal{D}) \) be a morphism of ringed topoi, then for any \( E \in D(\mathcal{O}_\mathcal{C}) \) and \( K \in D(\mathcal{O}_\mathcal{D}) \), there is a canonical functorial projection map

\[
R f_* E \otimes_{\mathcal{O}_\mathcal{D}} K \to R f_* (E \otimes_{\mathcal{O}_\mathcal{C}} L f^* K)
\]

which is the adjunction of the map

\[
L f^* (R f_* E \otimes_{\mathcal{O}_\mathcal{D}} K) \cong L f^* R f_* E \otimes_{\mathcal{O}_\mathcal{C}} L f^* K \to E \otimes_{\mathcal{O}_\mathcal{C}} L f^* K
\]

by \((5.3.3.15)\).

**Prop. (5.3.3.20) [Projection Formula].** In situation \((5.3.3.19)\), if \( K \) is perfect \((5.3.4.17)\), then the projection map is an isomorphism.

Proof: To check it is an isomorphism, it suffice to find a covering \( \{ U_i \to V \} \) for each \( V \in \mathcal{C} \) that this map is an isomorphism on \( U_i \). (To see this, look at \( H^1 \), and notice \( U \mapsto \text{Mod}(\mathcal{O}_U) \) is a stack.) Then we may assume \( K \) is a finite complex of \( \mathcal{O}_U \)-modules consisting of finite free \( \mathcal{O}_U \)-modules. And then we use truncation to reduce to the case \( K \) is discrete, in which case it is trivial. \( \square \)

**Inner Hom**

**Def. (5.3.3.21) [Sheaf Hom Complexes].** Let \( (\mathcal{C}, \mathcal{O}) \) be a ringed site and \( P^\bullet, Q^\bullet \in K(\mathcal{O}) \), we define the sheaf hom complex \( \mathcal{H}om^\bullet(P^\bullet, Q^\bullet) \) to be

\[
\mathcal{H}om^n(P^\bullet, Q^\bullet) = \prod_i \mathcal{H}om_{\mathcal{O}}(P^i, Q^{n+i})(5.2.3.1),
\]

with the differential giving by \( d(\{ f_k \}_i) = \{ df_i - (-1)^i f_{i+1} d \} \) and suitable signatures.

It is clear that

\[
\Gamma(U, \mathcal{H}om_\mathcal{O}(P^\bullet, Q^\bullet)) = \text{Hom}_{\mathcal{O}_{\mathcal{U}}}(P^\bullet|_U, Q^\bullet|_U), \quad \Gamma(\mathcal{C}, \mathcal{H}om_\mathcal{O}(P^\bullet, Q^\bullet)) = \text{Hom}_{\mathcal{O}}(P^\bullet|_U, Q^\bullet|_U)
\]

and

\[
H^n(\Gamma(\mathcal{C}, \mathcal{H}om^\bullet(P^\bullet, Q^\bullet))) = \text{Hom}_{K(\mathcal{O}_U)}(P^\bullet|_U, Q^\bullet|_U[n]), \quad H^n(\Gamma(\mathcal{C}, \mathcal{H}om^\bullet(P^\bullet, Q^\bullet))) = \text{Hom}_{K(\mathcal{O})}(P^\bullet, Q^\bullet[n]).
\]

**Prop. (5.3.3.22) [Adjunction].** For \( K^\bullet, M^\bullet, L^\bullet \in K(\mathcal{O}) \), there is a canonical functorial isomorphism:

\[
\mathcal{H}om^\bullet(K, \mathcal{H}om^\bullet(L, M)) = \mathcal{H}om^\bullet(\text{Tot}(K \otimes_R L), M).
\]

Proof: Cf. [Sta]0A5Y. \( \square \)

**Prop. (5.3.3.23).** For \( K^\bullet, M^\bullet, L^\bullet \in K(\mathcal{O}) \), there are canonical functorial morphisms:

- \( \text{Tot}(\mathcal{H}om(K^\bullet, L^\bullet) \otimes_{\mathcal{O}} K^\bullet) \to L^\bullet \),
- \( \text{Tot}(\mathcal{H}om^\bullet(L, M) \otimes_{\mathcal{O}} \mathcal{H}om^\bullet(K, L)) \to \mathcal{H}om^\bullet(K, M) \),
- \( \text{Tot}(\mathcal{H}om^\bullet(L, M) \otimes_{\mathcal{O}} K) \to \mathcal{H}om^\bullet(\mathcal{H}om^\bullet(K, L), M) \),
- \( \text{Tot}(K \otimes_{\mathcal{O}} \mathcal{H}om^\bullet(M, L)) \to \mathcal{H}om^\bullet(M, \text{Tot}(K \otimes_{\mathcal{O}} L)) \),
• $\mathcal{K} \to \mathcal{H}om^\bullet(L, \text{Tot}(\mathcal{K} \otimes \mathcal{O} L))$.

**Proof:** All these are consequences of (5.3.3.22). \hfill \Box

**Lemma (5.3.3.24).** Let $(\mathcal{C}, \mathcal{O})$ be a site and $(\mathcal{I}^\bullet)' \to \mathcal{I}^\bullet$ be a quasi-isomorphism of K-injective $\mathcal{O}$-modules and $(\mathcal{L}^\bullet)' \to \mathcal{L}^\bullet$ be a quasi-isomorphism of $\mathcal{O}$-modules, then the natural map

$\mathcal{H}om^\bullet((\mathcal{L}^\bullet)'(\mathcal{I}^\bullet)') \to \mathcal{H}om^\bullet((\mathcal{L}^\bullet)'(\mathcal{I}^\bullet))$

is a quasi-isomorphism.

**Proof:** $H^n(\mathcal{H}om^\bullet((\mathcal{L}^\bullet)'(\mathcal{I}^\bullet)'))$ is the the sheaf $U \to \text{Hom}_{K(\mathcal{O}_U)}((\mathcal{L}^\bullet)'_U,(\mathcal{I}^\bullet)_U^[[n]])$, and $(\mathcal{I}^\bullet)_U^[[n]]$ is K-injective by (5.3.4.2). \hfill \Box

**Def. (5.3.3.25) [Internal Hom].** Let $(\mathcal{C}, \mathcal{O})$ be a ringed site, $K(\mathcal{O})$ has enough K-injectives, thus by (3.4.4.13), we can define the internal Hom

$R\mathcal{H}om : D(\mathcal{O})^{\text{op}} \times D(\mathcal{O}) \to D(\mathcal{O})$

as the right derived functor of the bi-exact bifunctor $\mathcal{H}om^\bullet : K(\mathcal{O})^{\text{op}} \times K(\mathcal{O}) \to D(\mathcal{O})$, where the conditions are satisfied by (5.3.3.24).

**Prop. (5.3.3.26) [Internal Hom and Localization].** Let $(\mathcal{C}, \mathcal{O})$ be a ringed site, for any $\mathcal{G}, \mathcal{F} \in K(\mathcal{O})$ and $U \in \mathcal{C}$, the natural transformation

$R\mathcal{H}om(\mathcal{F}, \mathcal{G}) \mid_U \to R\mathcal{H}om(\mathcal{F} \mid_U, \mathcal{G} \mid_U)$

is an isomorphism. In particular, we can calculate $\mathcal{E}xt$ locally.

**Proof:** This follows from (5.3.3.21)(5.3.4.2) and trivial Grothendieck duality applied to restrictions. \hfill \Box

**Prop. (5.3.3.27) [Derived Hom and Internal Hom].** For a ringed site $(\mathcal{C}, \mathcal{O})$ and $\mathcal{F}, \mathcal{G} \in D(\mathcal{O})$, $U \in \mathcal{C}$,

$$R\Gamma(\mathcal{C}, R\mathcal{H}om(\mathcal{F}, \mathcal{G})) = R\text{Hom}(\mathcal{F}, \mathcal{G}), \quad R\Gamma(U, R\mathcal{H}om(\mathcal{F}, \mathcal{G})) = R\text{Hom}_{\mathcal{O}_U}(\mathcal{F} \mid_U, \mathcal{G} \mid_U).$$

In particular,

$$\Gamma(U, R\mathcal{H}om(\mathcal{F}, \mathcal{G})) = \text{Hom}_{D(\mathcal{O}_U)}(\mathcal{F} \mid_U, \mathcal{G} \mid_U),$$

and

$$H^0(\mathcal{C}, R\mathcal{H}om(\mathcal{F}, \mathcal{G})) = \text{Hom}_{D(\mathcal{O})}(\mathcal{F}, \mathcal{G}), \quad H^p(\mathcal{C}, R\mathcal{H}om(\mathcal{F}, \mathcal{G})) = \text{Ext}^p_{\mathcal{O}}(\mathcal{F}, \mathcal{G})$$

by (5.3.3.21)(5.3.4.2)(5.3.4.13) and the composition of derived functors.

**Prop. (5.3.3.28).** If $\mathcal{K}, \mathcal{L}, \mathcal{M} \in D(\mathcal{O})$, then there is a natural isomorphism

$R\mathcal{H}om_{\mathcal{O}}(\mathcal{K}, R\mathcal{H}om(\mathcal{L}, \mathcal{M})) \cong R\mathcal{H}om_{\mathcal{O}}(\mathcal{K} \otimes_{\mathcal{O}} \mathcal{L}, \mathcal{M}).$

**Proof:** Consider both sides as the derived functor of the triple-exact triple-functor

$$K(\mathcal{O})^{\text{op}} \times K(\mathcal{O})^{\text{op}} \times K(\mathcal{O}) \to D(\mathcal{O}) : (\mathcal{K}^\bullet, \mathcal{L}^\bullet, \mathcal{M}^\bullet) \mapsto \text{Tot}^\oplus(\mathcal{K}^\bullet \otimes_{\mathcal{O}} \text{Tot}^\oplus(\mathcal{L}^\bullet \otimes_{\mathcal{O}} \mathcal{M}^\bullet)),$$

the conditions are satisfied by (5.3.4.13)(5.3.3.3). As this is true for $\text{Tot}$ by (5.3.3.22), this follows from the universal properties and (3.4.4.14). \hfill \Box
5.3. COHOMOLOGY ON RINGED SITES

Cor. (5.3.3.29) [Adjunction]. By (5.3.3.28), taking $H^0(R\Gamma(C, -))$, we get:

$$\text{Hom}_{D(O)}(K, R\text{Hom}(L, M)) = \text{Hom}_{D(O)}(K \otimes L, M).$$

that is, derived tensor is left adjoint to internal hom.

Prop. (5.3.3.30). Given complexes $K, L, M \in D(O)$, there are canonical functorial morphisms:

- $\text{Hom}(K, L) \otimes_M K \to L$,
- $R\text{Hom}(L, M) \otimes_M R\text{Hom}(K, L) \to R\text{Hom}(K, M)$,
- $R\text{Hom}(L, M) \otimes_M K \to R\text{Hom}(R\text{Hom}(K, L), M)$,
- $K \otimes_M R\text{Hom}(M, L) \to R\text{Hom}(M, K \otimes_M L)$,
- $K \to R\text{Hom}(L, K \otimes_M L)$.

Proof: These are direct consequences of (5.3.3.29).

Prop. (5.3.3.31). Let $(\text{Sh}(C), O) \to (\text{Sh}(C'), O')$ be a morphism of ringed site and $K, L \in D(O)$, there is a natural morphism

$$Rf_* R\text{Hom}_O(L, K) \to R\text{Hom}_{O'}(Rf_* L, Rf_* K).$$

Proof: This follows from the adjunction (5.3.3.28) (5.3.3.30) and the relative cup product (5.3.3.13).

Def. (5.3.3.32) [Internal Ext Groups]. For any $G, F \in K(O)$, we define the internal Ext groups

$$\text{Ext}^n_O(G, F) = H^i(R\text{Hom}(G, F)) \in \text{Mod}(O).$$

Prop. (5.3.3.33). For $E, F, L \in \text{Mod}(O_X)$ and $L$ finite locally free,

$$\text{Ext}^i(F \otimes L, G) \cong \text{Ext}^i(F, L^\vee \otimes G) \cong \text{Ext}^i(F, G) \otimes L^\vee$$

because there are maps between them (5.2.5.2), and Ext is local, so check locally. In particular,

$$\text{Ext}^i(F \otimes L, G) = \text{Ext}^i(F, L^\vee \otimes G).$$

Prop. (5.3.3.34) [Spectral Sequences for Internal Ext]. Let $(C, O)$ be a ringed site and $K^\bullet \in K^-(O), F^\bullet \in K^+(O)$, then there are spectral sequence convergence

$$E^{i+j}_2 = \text{Ext}^i_O(H^{-j}(K^\bullet), F^\bullet) \implies \text{Ext}^{i+j}_O(K^\bullet, F^\bullet).$$

$$E^{i+j}_1 = \text{Ext}^i_O(K^{-i}, F^\bullet) \implies \text{Ext}^{i+j}_O(K^\bullet, F^\bullet)$$

$$E^{i+j}_2 = H^i(C, \text{Ext}^j_O(K^\bullet, F^\bullet)) \implies \text{Ext}^{i+j}_O(K^\bullet, F^\bullet)$$

Proof: 1, 2: Choose a (bounded below) injective resolution $I^\bullet$ of $F^\bullet$, and these are the two spectral sequences associated to the double complex $\text{Hom}_{O_X}(K^\bullet, I^\bullet)$.

3: Use Grothendieck spectral sequence on (5.3.3.27).
4 Acyclic Sheaves

Prop. (5.3.4.1) [Pushforward of Injectives]. Let $f : (\text{Sh}(C), O_C) \to (\text{Sh}(D), O_D)$ be a flat map of ringed topoi, then $f$ preserves injectives, as $f^*$ is exact.

Prop. (5.3.4.2) [Restriction of (K-)Injectives]. Let $(C, \mathcal{O})$ be a ringed site, $U \in C$, then
- If $K^\bullet$ be a K-injective complex $\mathcal{O}$-modules, then $(K^\bullet)|_U$ is a K-injective complex of $\mathcal{O}_U$-modules.
- If $\mathcal{I}$ is an injective $\mathcal{O}$-module, then $\mathcal{I}|_U$ is an injective $\mathcal{O}_U$-module.

Proof: Use (3.4.3.6) and the fact $j^*_U$ is right adjoint to the exact shifification functor. □

Prop. (5.3.4.3). If $I \in \text{Sh}(C)$ is injective, then $I$ is also injective in $\text{PSh}(C)$.

Proof: Because restriction is right adjoint to the exact shifification functor. □

Prop. (5.3.4.4). For an injective sheaf $F$ on a site $(C, \mathcal{O})$, $F(U)$ is injective Abelian group for every $U \in C$.

Proof: This is because for the morphism $i : \text{pt} \to C : \text{pt} \mapsto U$, $i_p$ is exact($i_p A(V) = \oplus_{\text{Hom}(V,U)} A$), hence $i^p$ preserves injectives. □

Flask Sheaves

Def. (5.3.4.5) [Totally Acyclic Sheaves]. A totally acyclic sheaf on a ringed site $(C, \mathcal{O})$ is an object in $\text{Sh}(C)$ that is acyclic for any functor $\text{Hom}_{\text{PSh}(C)}(K, -)$.

Prop. (5.3.4.6) [Characterization of Totally Acyclic Sheaves]. Let $\mathcal{C}$ be a site and $F \in \text{Sh}(\mathcal{C})$, then $F$ is totally acyclic iff
- $F$ is acyclic for $\mathcal{I}(U, -)$ for any $U \in \mathcal{C}$.
- For every surjection $K' \to K$ of sheaves of sets the extended Čech complex
  
  $$0 \to H^0(K, F) \to H^0(K', F) \to H^0(K' \times_K K', F) \to \ldots$$

  is exact.

Prop. (5.3.4.7). A totally acyclic sheaf is acyclic for any map of ringed topoi $f : (\text{Sh}(C), O_C) \to (\text{Sh}(D), O_D)$.

Proof: This follows from the description of $R^i f_*$ in (5.3.1.8). □

Def. (5.3.4.8) [Flask Sheaves]. A flask sheaf on a ringed site $(C, \mathcal{O})$ is an object of $\text{Sh}(C)$ that satisfies the following equivalent conditions:
- It is acyclic for $\mathcal{I}$.
- It is acyclic for any $\check{H}^0(\{U_i \to U\}, -)$
- It is acyclic for all $\mathcal{I}(U, -)$.

In particular a totally acyclic sheaf is flask.

A flabby sheaf is an object of $\text{Sh}(C)$ that for any monomorphism $U \to V$, $F(V) \to F(U)$ is surjective;
5.3. COHOMOLOGY ON RINGED SITES

Proof:  1 ⇐⇒ 3 is by (5.3.1.7),
3 → 2: use Čech to sheaf1 (5.3.2.13), notice the \( q > 0 \) terms vanish, thus \( \check{H}^p(\{U_i \to U\}, \mathcal{F}) = H^p(U, \mathcal{F}) = 0. \)
2 → 3 follows from (5.3.2.16).

Prop. (5.3.4.9). Injective sheaves are flabby. Flabby sheaves on a ringed space are flasque.

Proof: For the first assertion, use (5.2.2.9) and the fact \( j_! \mathcal{O}_U \to j_! \mathcal{O}_V \) is a monomorphism for \( V \to U \) a monomorphism by definition (5.2.2.9).
For the last assertion, use (3.4.2.29): Injectives are flabby, so it is sufficiently large. For an exact sequence \( 0 \to \mathcal{F} \to \mathcal{G} \to \mathcal{H} \to 0 \) of sheaves, if \( \mathcal{F} \) is flabby, then \( \mathcal{H} \) is just the presheaf cokernel. (It reduces to \( \check{H}^1(\{U_i \to U\}, \mathcal{F}) = 0 \), and this is done by Zorn’s lemma). Thus if \( \mathcal{F} \) is flabby, \( \mathcal{G} \) is flabby iff \( \mathcal{H} \) is flabby (by five lemma).

Prop. (5.3.4.10). On a discrete site, all sheaves is flasque, because \( \iota \) is the identity functor.

Prop. (5.3.4.11). Filtered colimits of flabby sheaves is flabby. (This is because filtered colimits are exact).
Filtered colimits of injective sheaves over a Noetherian topological space is injective. (Use Baer criterion, then notice every sub-object of \( \mathbb{Z}_U \) is finitely generated because it has only f.m. connected component (3.8.3.4) so it maps to some \( F_\alpha \)).

Prop. (5.3.4.12) [Pushforward of Totally Acyclic/Flask Sheaves]. Let \( f : (\mathcal{S}(\mathcal{C}), \mathcal{O}_C) \to (\mathcal{S}(\mathcal{D}), \mathcal{O}_D) \) be a map of ringed topoi (resp. ringed site), then \( f_* \) maps totally acyclic (resp. flask) sheaves to totally acyclic (resp. flask) sheaves (5.3.4.5)(5.3.4.8). In particular, it maps injectives to totally acyclic sheaves.

Proof: By (5.2.1.3) we may assume \( f \) is a map of ringed sites, and \( K = h_U \) for some \( U \in \mathcal{C} \). Then we notice \( H^i(\{U_i \to U\}, f_* \mathcal{F}) = H^i(\{f^{-1}(U_i) \to f^{-1}(U)\}, \mathcal{F}) \), then we can use (5.3.2.16) to show \( f_* \mathcal{F} \) is totally acyclic.

Prop. (5.3.4.13) [Technical Lemma]. If \( \mathcal{K}^* \) is \( K \)-flat \( \mathcal{O} \)-modules and \( \mathcal{I}^* \) is \( K \)-injective \( \mathcal{O} \)-modules, then \( \mathcal{H}om^*(\mathcal{K}^*, \mathcal{I}^*) \) is \( K \)-injective.

Proof: Use definitions (5.3.3.1)(3.4.3.1) and (5.3.3.22).

Prop. (5.3.4.14). If \( \mathcal{I} \) is an injective \( \mathcal{O}_X \)-module, then for a coherent locally free sheaf \( \mathcal{L} \), \( \mathcal{L} \otimes \mathcal{I} \) is also injective, because tensoring with \( \mathcal{L} \) is adjoint to tensoring with \( \mathcal{L}^\vee \) (5.2.5.2), which is exact.

Pseudo-Coherent Sheaves

Def. (5.3.4.15) [Strictly Perfect Complexes of Modules]. Let \( (\mathcal{C}, \mathcal{O}) \) be a ringed site, a strictly perfect complex of \( \mathcal{O} \)-modules is a finite complex of \( \mathcal{O} \)-modules that each term is a direct summand of a finite free \( \mathcal{O} \)-module.

Def. (5.3.4.16) [Pseudo-Coherent Complexes of Modules]. Let \( (\mathcal{C}, \mathcal{O}) \) be a ringed site, then \( \mathcal{K} \in D(\mathcal{O}_X) \) is called an \( m \)-pseudo-coherent \( \mathcal{O}_X \)-module if for any \( U \in \mathcal{C} \), there exists a covering \( \{U_i \to U\} \) s.t. for any \( i \), there are strictly perfect object \( E_i \in D(\mathcal{O}_{U_i}) \) and a morphism \( E_i \to \mathcal{K}|_{U_i} \) that induces isomorphisms on \( H^i \) for \( i > m \) and surjection on \( H^m \).

\( \mathcal{K} \in D(R) \) is called a pseudo-coherent \( \mathcal{O}_X \)-module if it is \( m \)-pseudo-coherent for any \( m \).
Perfect Sheaves

Def.(5.3.4.17)[Perfect Complexes of Modules]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site, a perfect complex of $\mathcal{O}$-modules is an object $E$ in $D(\mathcal{O})$ that for any $U \in \mathcal{C}$ there is a covering $\{U_i \to U\}$ that $E|_{U_i}$ is can be represented by a strictly perfect complexes (5.3.4.15).

Prop.(5.3.4.18). Every mapping from a strictly perfect complex to an acyclic complex has a cover of open sets that on each open set the map is nullhomotopic.

Proof: This is true for a single direct summand of a finite free sheaf, and we can use induction to prove, Cf.[Sta]08C7.

Cor.(5.3.4.19). The strictly perfect complexes are fake "$K$-projective" objects in $K(\mathcal{O}_X)$. Note it is note technically $K$-projective, but it has all the properties of $K$-projective when proven, noticing the fact it is irrelevant when taken shifification.

Def.(5.3.4.20)[Perfect Sheaves]. Let $(\mathcal{C}, \mathcal{O})$ be a ringed site, an object $K^\bullet$ in $K(\mathcal{O})$ perfect if there is a covering $\mathcal{U}$ that on each $U_i$ there is a quasi-iso $K_i^\bullet \to K^\bullet|_{U_i}$ with $K_i^\bullet$ strictly perfect.

This is equivalent to $K^\bullet$ is locally represented by perfect objects in $D(\mathcal{O})$ by the fact that perfect object is fake $K$-projective.

Prop.(5.3.4.21). When $X$ is local ringed space, perfectness is equivalent to the fact that it is locally a finite free $\mathcal{O}_{U_i}$-module.

Proof: This is because direct summand of a finite free module is free, Cf.[Sta]0BCI.

Prop.(5.3.4.22)[Strictly Perfect Modules are “Acyclic” for $\text{Hom}^\bullet$]. If $(\mathcal{C}, \mathcal{O})$ is a ringed site and $\mathcal{E}^\bullet, \mathcal{F}^\bullet \in K(\mathcal{O})$, then $\mathcal{R}\text{Hom}(\mathcal{E}^\bullet, \mathcal{F}^\bullet)$ can be calculated directly by $\text{Hom}^\bullet(\mathcal{E}, \mathcal{F})$ in the following cases:

• $\mathcal{E}^\bullet$ is strictly perfect.
• $\mathcal{E}^\bullet \in D^-(\mathcal{O}_X), \mathcal{F}^\bullet \in D^+(\mathcal{O}_X)$, and each term $\mathcal{E}^n$ is a direct summand of a finite free $\mathcal{O}_X$-module.

Proof: Cf.[Sta]08I5, 08DM.

Prop.(5.3.4.23)[Duals]. Let $K$ be a perfect object in $D(\mathcal{O})$, then

• $K^\vee = \mathcal{R}\text{Hom}(K, \mathcal{O})$ is also a perfect object, and $(K^\vee)^\vee \cong K$.
• For any $M \in D(\mathcal{O})$, there are functorial isomorphisms

$$M \otimes^L K^\vee \cong \mathcal{R}\text{Hom}(K, M), \quad H^0(\mathcal{C}, M \otimes^L K^\vee) \cong \text{Hom}_{D(\mathcal{O})}(K, M).$$

Proof: Cf.[Sta]08JJ.

Def.(5.3.4.24)[Relative Perfect Modules]. Let $(X, \mathcal{O}_X) \to (S, \mathcal{O}_S)$ be a morphism of ringed sites that is flat and locally of f.p., then $E \in D(\mathcal{O}_X)$ is called a perfect object relative to $S$ if $E$ is pseudo-coherent and $E$ locally has finite tor dimension as an object in $D(f^{-1}\mathcal{O}_S)$. Cf.[Sta]08CG.

5 Topological Sheaves

References are [Sheaf Cohomology, Anonymous].

A topological space can be seen as a ringed site, so the theory of ringed sites applies to topological spaces.
5.3. COHOMOLOGY ON RINGED SITES

**Acyclic sheaves**

**Def. (5.3.5.1).** An Abelian sheaf on a paracompact Hausdorff topological space $X$ is called

- **soft** iff is and $\forall$ closed $V, \mathcal{F}(X) \to \mathcal{F}(V)$ is surjective. A flabby sheaf is soft.
- **fine** iff the sheaf of rings $\text{Hom}(\mathcal{F}, \mathcal{F})$ is soft.

Fine and soft are local properties (Use Zorn’s lemma to construct one-by-one).

**Prop. (5.3.5.2).** For a sheaf of unital rings over a paracompact Hausdorff space $X$, the following are equivalent,

1. it is a soft sheaf.
2. for any disjoint closed sets $V, W$, there is a section of $X$ that is 0 on $V$, and 1 on $W$.
3. it possesses a partition of unity.
4. it is a fine sheaf.

Note any soft sheaf possesses a partition of unity.

**Proof:** $1 \iff 2$ is easy and $1 \to 3$ is the to choose a closed locally finite subcover and use Zorn’s lemma to construct one-by-one. For $3 \to 1$, notice a closed section can extend to a slightly larger nbhd.

Because for a sheaf of rings $\mathcal{F}$, a partition of unity is equivalent to a partition of unity $\text{Hom}(\mathcal{F}, \mathcal{F})$, so $34$ are equivalent because $13$ are equivalent.

**Cor. (5.3.5.3).**

- Note that a fine sheaf possesses a decomposition of section because the previous proposition applies to $\text{Hom}(\mathcal{F}, \mathcal{F})$, and a partition of unity in $\text{Hom}(\mathcal{F}, \mathcal{F})$ yields a decomposition of section in $\mathcal{F}$. Thus a fine sheaf is soft. (extend to a small nbhd and use partition of unity).
- The sheaf of modules over a soft sheaf of rings is soft, by partition of unity.
- The continuous function sheaf on a paracompact Hausdorff space or the smooth function sheaf on a smooth manifold is fine, thus any smooth module is fine (Use bump function).

**Prop. (5.3.5.4).** Soft sheaf, e.g. fine sheaf is adapted to $\Gamma(X, -)$. (Similar as in (5.3.4.9), notice flabby is soft and the others are the same as before).

**Prop. (5.3.5.5).** Let $X$ be a locally compact space of finite compact dimension, when $S$ is a soft sheaf, and one of $S$ and $\mathcal{F}$ is flat, then $S \otimes_k \mathcal{F}$ is soft. Cf.[Cohomology of Sheaves Iversen P319].

**Prop. (5.3.5.6).** Over a locally compact space of finite dimension, any flat sheaf $\mathcal{F}$ on $X$ has a resolution of soft flat sheaves.

**Proof:** Cf.[Gelfand P232].

**Lemma (5.3.5.7).** A constant sheaf on an irreducible topological space is flabby, thus flask.

**Basics**

**Prop. (5.3.5.8).** If $i : Z \to X \in \text{Top}$ is a closed immersion, then for any $\mathcal{F} \in \mathcal{S}h(Z)$, $H^*(Z, \mathcal{F}) = H^*(Z, i_* \mathcal{F})$.

**Proof:** This is because $i_*$ is exact (5.2.6.7), so we can apply the Leray spectral sequence (5.3.1.10).
Comparison Theorems

**Prop. (5.3.5.9) [Singular].** For any locally contractible topological space $X$ and $G \in \mathcal{A}b$, there are canonical isomorphisms

$$H^*_\text{sing}(X, G) \cong H^*(X, G).$$

**Proof:** Shiffification of the singular cochain complex is a flabby presheaf resolution of $G$ because it is locally contractible, check on stalks. Then we only have to prove $C^\bullet(X) \to (C/V)^\bullet(X)$ is quasi-isomorphism, where $V$ is the presheaf of locally vanishing cochain. It suffice to prove $V^\bullet(X)$ is exact.

For any $i$-cocycle $\varphi$, for any $i-1$-complex $\sigma$, use barycentric subdivision, we can construct a $c_\sigma$ whose boundary is $\sigma$ and other simplexes on which $\phi$ vanishes, so we have the coboundary of $\eta : \sigma \to \varphi(c_\sigma)$ is $\varphi$. □

**Lemma (5.3.5.10) [Poincaré].** For a smooth manifold $X$ of dimension $n$, there is an exact sequence

$$0 \to \mathbb{R}^X \xrightarrow{d} \Omega^0 \xrightarrow{d} \Omega^1 \xrightarrow{d} \ldots \xrightarrow{d} \Omega^n \to 0$$

**Proof:** □

**Prop. (5.3.5.11) [DeRham].** For any smooth manifold $X$,

$$H^*_d\text{R}(X, \mathbb{R}^X) \cong H^*(X, \mathbb{R})$$

Where the right is constant sheaf cohomology.

**Proof:** Use the fact that smooth sheaf is fine so adapted to sheaf cohomology (5.3.5.4), and Poincaré lemma (5.3.5.10). □

**Prop. (5.3.5.12) [Period Maps].** For a smooth manifold $X$, by a similar method as (5.3.5.9), we can define a **differentiable singular cohomology** $H^*_{\text{sing,} \infty}(X)$, and prove a canonical isomorphism

$$H^*_{\text{sing,} \infty}(X, \mathbb{R}) \cong H^*(X, \mathbb{R}).$$

Then combining with (5.3.5.11), we get a canonical isomorphism

$$H^*_d\text{R}(X, \mathbb{R}^X) \cong H^*_{\text{sing,} \infty}(X, \mathbb{R})$$

which can be described as follows: there is a map of sheaves

$$\Omega^k \to C^*_\text{sing,} \infty(X)$$

that is locally defined to be $\omega \mapsto \sigma \mapsto \int_\sigma \omega$, then this map gives a map of complexes

$$\Omega^\bullet \to C^*_\text{sing,} \infty(X)$$

that induces the isomorphism.

**Proof:** ? Cf. [Warner, P206]. □

**Lemma (5.3.5.13) [\overline{\partial}-Poincaré Lemma].** If $X$ is a complex manifold of dimension $n$, there is an exact sequences:

$$0 \to \Omega^p_{\text{hol}} \xrightarrow{\overline{\partial}} \Omega^{p,1}_{\text{hol}} \xrightarrow{\overline{\partial}} \ldots \xrightarrow{\overline{\partial}} \Omega^{p,n-p}_{\text{hol}} \to 0$$
5.3. COHOMOLOGY ON RINGED SITES

Proof: Cf.[Sheaf Cohomology P21].

Cor. (5.3.5.14). If $X$ is a complex manifold of dimension $n$, there are exact sequences:

$$0 \to \mathbb{C}_X \xrightarrow{d} \mathcal{O}_X \xrightarrow{d} \Omega^1_{\text{hol}} \xrightarrow{d} \ldots \xrightarrow{d} \Omega^n_{\text{hol}} \to 0$$

Proof: This follows from the Poincare lemma (5.3.5.10) and $\bar{\partial}$-Poincare lemma (5.3.5.13), by applying the spectral sequence (I mean in the category of sheaves).

Prop.(5.3.5.15)[Holomorphic Cohomology]. For a complex manifold $X$,

$$H^p(X, \mathbb{C}) = H^p(X, \Omega^\bullet_{\text{hol}}).$$

Prop.(5.3.5.16)[Dolbeault]. For a complex bundle $\mathcal{E}$ on a complex manifold $X$,

$$H^{p,q}_\bar{\partial}(X, \mathcal{E}) \cong H^q(M, \Omega^p_{\text{hol}} \otimes \mathcal{O}_X \mathcal{E}),$$

where the left is Dolbeault cohomology and the right is sheaf cohomology. (Use the fact that smooth sheaf is fine so adapted to sheaf cohomology (5.3.5.4), and $\bar{\partial}$-Poincare lemma (5.3.5.13)).

Moreover, there is a spectral sequence of

$$E^1_{pq} = H^p_{\bar{\partial}}(X) \Rightarrow E^n = H^n_{\text{dR}}(X, \mathbb{R}) \times \mathbb{R} \mathbb{C}.$$

Prop.(5.3.5.17)[Cartan]. The class of Coh-Acyclic subsets of an analytic space is exactly the class of Stein manifolds.

Proof:

Prop.(5.3.5.18)[Čech and Sheaf Cohomology]. For a paracompact Hausdorff space $X$, there are isomorphisms

$$\check{H}^i(X, \mathbb{Z}) \cong H^i(X, \mathbb{Z}).$$

Proof: Cf.[Godement, Prop5.10.1].

Cohomology with Proper Support

References are [Cohomology of Sheaves Iversen].

Prop.(5.3.5.19). Soft sheaf is adapted to $f_!$ when $X, Y$ are locally compact. Cf.[Gelfand P226]. So we can use soft resolution to define $R^i f_!$, in particular, when $Y = \text{pt}$, we denote it by $H^i_c(X, \mathcal{F})$.

Using (5.2.6.2), we get the stalk of $R^i f_!(\mathcal{F})$ at $y$ is just $H^i_c(f^{-1}(y), \mathcal{F}|_{f^{-1}(y)})$.

Def.(5.3.5.20). The compact dimension of a locally compact topological space is the smallest $n$ that $H^i_c(X, \mathcal{F}) = 0$ for $i > n$. It is also the maximal length of minimal soft resolution.

$
\dim_c \mathbb{R}^n = n$, and when $Y$ is an open or closed subset of $X$, $\dim_c Y \leq \dim_c X$. $\dim_c$ is local in the sense if every point has a nbhd of dimension $\leq n$, then $\dim_c X \leq n$. Cf.[Iversen].

Prop.(5.3.5.21)[Proper Pushforward Commutes with Pullback]. For a pullback diagram

$$
x \times_Y Z \xrightarrow{\tau'} X \xrightarrow{\pi} X$$

we have $\tau^{-1}(\pi_! \mathcal{F}) = \pi'_!(\tau'^{-1} \mathcal{F})$.

Proof:
Cohomology on Noetherian Spaces

There are three basic objects, the derived functor for $f_*$ as an Abelian sheaf, $f_*$ as a $O_X$-module, $\Gamma(U,-)$ as an Abelian sheaf. Notice that an Abelian group is just a $\mathbb{Z}$-module.

**Prop.(5.3.5.22) [Grothendieck Vanishing].** The sheaf cohomology of an Abelian sheaf over a Noetherian topological space of dimension $n$ vanish for $k > n$.

**Proof:** Use (5.2.6.10) and (5.3.5.8) and long exact sequence, we can reduce to the case of $X$ irreducible. Then we induct on dimension. Notice first any sheaf is a filtered colimits of sheaf generated by f.m sections, thus we can use (5.3.1.15) to reduce to f.m sections case. And notice $\mathcal{F}_\alpha' \to \mathcal{F}_\alpha \to \mathcal{G}$, then $\mathcal{G}$ is generated by at most $|\alpha| - |\alpha'|$ elements, so reduce to the one section case.

Now it is a quotient sheaf of $\mathbb{Z}$, look at the kernel $R$. If the kernel is $d\mathbb{Z}$ at the generic pt, then $R|_V \cong \mathbb{Z}$ on some nbhd, and $R|_V/\mathbb{Z}$ supports on a lower dimension set, then we only need to consider the pushout of constant sheaf $\mathbb{Z}_U$.

Now there is an exact sequence $0 \to \mathbb{Z}_U \to \mathbb{Z} \to \mathbb{Z}_Y \to 0$ (5.2.6.10), $\mathbb{Z}$ is flabby (5.3.5.7) so flask, and the conclusion follows by induction.

Cf. [Sta]02UU. \qed

**Prop.(5.3.5.23).** For $f : X \to Y$, if $\mathcal{I}$ is an injective module on $X$, then $\check{H}^p(\{U_i \to U\}, f_*\mathcal{I}) = 0$ for every open cover for an open subset $U$ (5.3.4.8). This is because Čech cohomology is a derived functor. (Notice $f_*\mathcal{I}$ may not be injective when $f$ is not flat).

**Cor.(5.3.5.24) [Mayer-Vietoris].** For $X = U \cup V$, there is a long exact sequence

$$0 \to H^0(X,\mathcal{F}) \to H^0(U,\mathcal{F}) \otimes H^0(V,\mathcal{F}) \to H^0(U \cap V,\mathcal{F}) \to H^1(X,\mathcal{F}) \to \cdots$$

derived from the Čech to sheaf1 because it has only two column, just wrap out the definition.
5.4 Properties of Schemes

Main References are [Har77], [Sta], [?]nd [Tin20].

1 Basic Scheme Properties

Affine Local Properties of Schemes

Lemma (5.4.1.1) [Nike’s Trick]. In a scheme $X$ and $x \subset \text{Spec } A \cap \text{Spec } B$, $x$ has an open nbhd in $\text{Spec } A \cap \text{Spec } B$ that are distinguished in both $\text{Spec } A$ and $\text{Spec } B$.

Proof: Choose a nbhd of $x$ that is distinguished in $\text{Spec } A$ that is contained in $\text{Spec } A \cap \text{Spec } B$, then because distinguished of distinguished is distinguished, we may assume $i : \text{Spec } A \subset \text{Spec } B$. Now let $f \in B$ be an element that $D(f) \subset \text{Spec } A$, then I claim $D(i^\sharp(f)) = D(f)$, this will finish the proof, but this is equivalent to $i^{-1}(\text{Spec } B_f) = \text{Spec } A_{i^\sharp(f)}$, which is true for ideal-theoretical reason. □

Prop. (5.4.1.2) [Affine Communication Theorem]. A property $P$ of affine open subsets is called affine local if: $\text{Spec } (A)$ has $P$ $\Rightarrow$ all $\text{Spec } (A_f)$ has $P$, and any cover of $\text{Spec } (A_f)$ has $P$ $\Rightarrow$ $\text{Spec } (A)$ has $P$. Notice a stalk-wise property is obviously affine-local.

Now if we call $X$ has $\tilde{P}$ if $X = \bigcup_i \text{Spec } A_i$ that $A_i$ has $P$. Then the following is equivalent:

1. any open affine subscheme of $X$ has $P$.
2. any open subscheme of $X$ has $\tilde{P}$.
3. $X$ has a cover of open subschemes that has $\tilde{P}$.
4. $X$ has $\tilde{P}$.

Proof: $1 \rightarrow 2 \rightarrow 3 \rightarrow 4$ is obvious. It suffices to prove $4 \rightarrow 1$: if $X = \bigcup \text{Spec } A$, for any open affine subscheme of $X$, by (5.4.1.1), it can be covered by distinguished opens that are also distinguished in some $\text{Spec } A_i$, so by hypothesis it has $P$. □

Remark (5.4.1.3). When proving locality of morphism properties using affine communication theorem, one usually resort to Local Properties.

Prop. (5.4.1.4) [List of Stalkwise Properties]. All properties defined by a stalkwise ring-theoretic property that is stalkwise. (4.1.4.2)

Prop. (5.4.1.5) [List of properties affine local on the target]. (All the property besides the $H$-projectiveness is local on the target).

1. Because affineness is local on the target (5.1.5.26), all properties defined by a ring-theoretic property local on the target is local on the target (4.1.4.4).
2. All properties that is stalkwise.
3. All properties that satisfies faithfully flat descent (5.1.5.26)
4. Locally projective morphism.

Prop. (5.4.1.6) [List of properties affine local on the source]. (not complete)

1. All properties defined to be local ring map property local on the source (4.1.4.4)
2. Openness.

Proof:
1. Trivial.
2. Trivial.

Irreducible

Def. (5.4.1.7) [Irreducible Schemes]. A scheme is called irreducible if its underlying topological space is irreducible.

Prop. (5.4.1.8) [Nearly Affine Local]. For a scheme, the following are equivalent:
1. It is irreducible.
2. There is an affine cover $U_i$ of $X$ that $U_i$ are all irreducible and $U_i \cap U_j \neq \emptyset$.
3. Every affine open subset of $X$ is irreducible.

Proof: A scheme is sober (5.2.7.11), if $X$ is irreducible, then $X$ has a unique generic pt $\eta$ that $\{\eta\} = X$, then 2, 3 all holds. If 2 holds, then for a decomposition $X = Z_1 \cup Z_2$, any $U_i$ belongs to $Z_1$ or $Z_2$, so it is easy to see $Z_1 = X$ or $Z_2 = X$. If 3 holds, then choose an affine cover $U_i$ of $X$, then $U_i \cap U_j \neq \emptyset$, otherwise $U_i \coprod U_j$ is affine and not irreducible, contradiction, so 2 holds. □

Cor. (5.4.1.9). The fiber product of irreducible schemes is irreducible, because.

Reducedness

Def. (5.4.1.10) [Reduced Schemes]. A scheme is called reduced if $\mathcal{O}_X(U)$ is reduced for every open set $U$. Reduced is a stalk-wise property (5.4.1.5), it suffices to check reducedness at closed pts.

Prop. (5.4.1.11). For a reduced scheme $X$, $\Gamma(X, \mathcal{O}_X) \to \prod_{x \in X} k(x)$ is injective.

Prop. (5.4.1.12). If $X$ is locally Noetherian, the set of points with reduced stalk is open in $X$.

Proof: This set is just the set of points $x$ that $\mathcal{N}_x = 0$, where $\mathcal{N}$ is the sheaf of nilradicals, which is coherent, so it has closed supports (5.5.1.38). □

Prop. (5.4.1.13) [Reduction]. There is a $X_{\text{red}} \to X$ associated tot every scheme, it is $\text{Spec}(\mathcal{O}_X/\mathcal{N})$ where $\mathcal{N}$ is the sheaf of nilpotent elements. This construction is right adjoint to the forgetful functor by the adjoint property of $\text{Spec}(5.2.7.12)$. $X_{\text{red}} \to X$ is an closed immersion.

It’s useful to change to $X_{\text{red}}$ when the proposition only involve topology because $X_{\text{red}}$ has the same topology as $X$. A map can induce a map on their reduced structure.

Prop. (5.4.1.14) [Induced Reduced Scheme Structure]. Let $Z$ be a locally closed subset of a scheme $X$. There is a unique reduced subscheme $Z_{\text{red}}$ of $X$ with underlying topological space $Z$, called the induced reduced scheme structure of $Z$. It has the universal property that any morphism from a reduced scheme $Y$ to $X$ that has image in $Z$ factors through this subscheme (By virtue of reducedness).

In particular, there is a closed subscheme structure $X_{\text{red}}$ of $X$, called the underlying reduced subscheme of $X$.

Proof: The uniqueness is clear by the universal property. The existence is clear when $X$ is affine and $Z$ is closed in $X$. Then we can use the uniqueness to glue them to a global subscheme structure. □
Integral

Def. (5.4.1.15) [Integral Schemes]. A scheme $X$ is called integral if $\mathcal{O}_X(U)$ are all integral. This is equivalent to reduced and irreducible. So a scheme is integral iff there is an integral open affine cover that are pairwise-intersect (5.4.1.7).

The category of integral schemes is denoted by $\text{Sch}^{\text{int}}$.

Proof: If $X$ is irreducible and reduced, then so does any affine subscheme $\text{Spec} R$, so $R$ is integral as $(0)$ is the generic prime, because it has only one minimal prime consisting of nilpotent elements. Conversely, if $X$ is reduced, then any affine subscheme $\text{Spec} R$ is integral so reduced, and is irreducible by the presence of prime $(0)$. □

Cor. (5.4.1.16). The projective space over an integral scheme is integral. (Check the affine covers are dense). The projective space $\mathbb{P}_\mathbb{Z}^n$ is integral.

Prop. (5.4.1.17) [Integral is Almost Stalkwise]. Let $X$ be a non-empty and connected scheme, then $X$ is integral if all the

Def. (5.4.1.18) [Function Field]. Let $X$ be an integral scheme with generic point $\eta$, then $R(X) \cong \mathcal{O}_X,\eta$ is a field (5.2.8.2), called the function field of $X$, denoted by $K(A)$. Then any rational function on $X$ is defined on an open dense subset of $X$.

Prop. (5.4.1.19). If $X$ is an integral scheme and $Z_1, Z_2$ are closed subschemes of $X$ with generic points $\eta_1, \eta_2$, then $\mathcal{O}_{X,\eta_1} \not\subseteq \mathcal{O}_{X,\eta_2}$. In particular, if $Z = \{x\}$ consists of a closed point, then there is a rational function defined near $x$ that is not in $\mathcal{O}_{X,\eta_2}$.

Proof: [Sta]02NF. □

Noetherian

Def. (5.4.1.20) [Noetherian Scheme]. A scheme is called locally Noetherian if it can be covered by open affine schemes of noetherian rings. It is called Noetherian if moreover it is quasi-compact. (Locally)Noetherian is affine local (5.4.1.5).

Prop. (5.4.1.21) [Noetherian Scheme is Noetherian]. The underlying space of a Noetherian scheme is a Noetherian space.

Proof: By (3.8.3.3), we are reduced to the affine case. Now it is clear from the definition. □

Prop. (5.4.1.22). Any locally closed subscheme of a (locally)Noetherian scheme is (locally)Noetherian. In particular, an subset of a Noetherian scheme is quasi-compact.

Proof: This is because any localization and quotients of a Noetherian ring is Noetherian (4.1.1.40), and any subset of a Noetherian space is quasi-compact (3.8.3.2) (5.4.1.21). □

Prop. (5.4.1.23) [Finitely Many Irreducible Components]. For a closed subscheme in a locally Noetherian space, the collection of its irreducible components is locally finite in $X$, because a Noetherian space has f.m. irreducible components (3.8.3.4).

In particular, a locally Noetherian space is locally connected.

Prop. (5.4.1.24). Let $k'/k$ be a f.g. field extension, then a scheme $X$ over $k$ is locally Noetherian iff $X_{k'}$ is locally Noetherian.

Proof: Locally Noetherian is affine local, so the problem is totally ring-theoretic. If $X_{k'}$ is Noetherian, then so does $X$ by ff descent (4.4.2.1). If $X$ is Noetherian, then so does $X_{k'}$ by (4.1.1.44). □
Jacobson

Def. (5.4.1.25). An scheme is called Jacobson iff its underlying topological space is Jacobson (3.8.3.21). In particular, an affine scheme Spec $R$ is Jacobson iff $R$ is Jacobson (4.2.6.5).

So by (3.8.3.22), being Jacobson is a local property.

Prop. (5.4.1.26)[Locally Algebraic Scheme is Jacobson]. For a scheme locally algebraic over a field $k$, the set of closed points $X_0$ is dense in every closed subset of $X$, because it is a Jacobson space by (3.8.3.22) and (4.2.6.10). Equivalently, every locally closed subset of $X$ contains a closed point.

Moreover, the residue field of a closed point is finite over $k$ by (4.2.6.10), and the converse is also true. In particular, by (5.2.7.9), the closed points of $X$ are just the geometric points.

Proof: For the converse, because $k \subset A/p_x \subset k(x)$ are finite hence integral extensions, by (4.2.1.3) $A/p_x$ is a field, thus $x$ is a closed point. □

Cor. (5.4.1.27) [Algebraic Scheme Preserves Closed Points]. A morphism between algebraic schemes over a field $k$ maps closed points to closed points.

Remark (5.4.1.28). When $X$ is geo.reduced, a stronger statement shows the set of separable closed points of $X$ is dense in $X$, Cf. (5.4.3.3).

Cor. (5.4.1.29) [Check Surjectiveness on Closed Points]. If a morphism of locally algebraic schemes over a field $k$ is surjective on closed points, then it is surjective.

Proof: By Chevalley theorem (5.6.1.5), the image is a locally constructible set, thus the supplement set is also locally constructible. Now if it is not surjective, then there is an open closed subset $U \cap Z$ not in the image. But this set contains a closed point by (5.4.1.26), which is a contradiction. □

Cohen-Macaulay

Def. (5.4.1.30) [Cohen-Macaulay Schemes]. A Cohen-Macaulay scheme of a C.M. scheme is a scheme $X \in \text{Sch}$ s.t. all its stalks is C.M. local. Thus being C.M. is a stalkwise property.

Catenary Schemes

Def. (5.4.1.31) [Catenary Schemes]. A catenary scheme is a scheme that its underlying space is catenary. A scheme $S$ is called universally catenary if $S$ is locally Noetherian and every scheme locally of f.t. over $S$ is catenary.

(Universally) catenary is a stalkwise property, by (4.1.4.2).

Prop. (5.4.1.32) [Catenary and Dimension Functions]. Let $X \in \text{Sch}$ be locally Noetherian, then $X$ is catenary iff locally around every point there is a dimension function, by (3.8.3.39).

Example (5.4.1.33) [Universally Catenary Schemes]. The following are some examples of universally catenary schemes, by (4.2.4.7).

- A scheme locally of f.t. over a universally catenary scheme.
- A C.M. scheme.
- Spectrum of a 1-dimensional Noetherian domains,
- Spectrum of a fields.
5.4. PROPERTIES OF SCHEMES

Japanese & Nagata Schemes

Def. (5.4.1.34) [Japanese & Nagata Schemes]. A (universally) Japanese scheme is a scheme that can be covered by open affine spectrum of (universally) Japanese rings (4.3.8.1). A Nagata scheme is a scheme that can be covered by open affine spectrum of Nagata rings (4.3.8.1).

Prop. (5.4.1.35). Being (universally) Japanese or Nagata is a local property, and are stable under taking open subschemes, by (4.3.8.1).

Prop. (5.4.1.36). Let $X$ be a locally Noetherian scheme, then $X$ is Nagata iff every integral closed subscheme $Z$ of $X$ is Japanese.

Proof: One direction is clear. If every integral closed subscheme $Z$ of $X$ is Japanese, let $U = \text{Spec } A \subset X$ be an affine open subscheme and $Z = V(p) \subset U$, we need to show $A/p$ is Japanese. Consider $Z$ with the reduced induced structure is an integral closed subscheme of $X$ and $Z$ is an open subscheme of $Z$, thus $Z$ is Japanese and so is $Z$ by (5.4.1.34). □

2 Normal & Regular

Def. (5.4.2.1) [Normal & Regular Schemes]. A scheme is called normal if all its stalks are normal domains (4.3.5.1), or equivalently all its affine sections are normal rings. In particular, a normal scheme is reduced.

A locally Noetherian scheme is called regular iff all its stalk are regular local rings (4.3.5.17), i.e. all affine opens are regular rings. Regular only have to be checked at close pt by (4.3.5.17).

Def. (5.4.2.2). Let $X$ be a locally Noetherian scheme, the points $x$ that $\mathcal{O}_{X,x}$ is a regular local ring is called the regular locus of $X$, and the complement of the regular locus is called the singular locus of $X$.

Prop. (5.4.2.3) [Noetherian and Integral]. Let $X$ be a locally Noetherian scheme, then $X$ is normal iff it is a disjoint union of integral normal schemes.

Proof: It suffices to show that a connected locally Noetherian scheme is integral. Thus it suffices to show it is irreducible. Suppose there are several irreducible components, and let $p$ be a intersection point, then we may assume $X$ is affine, then this follows from (4.3.5.4). □

Cor. (5.4.2.4). A normal scheme is integral iff it is connected.

Prop. (5.4.2.5). If $X$ is an integral normal scheme, then $\Gamma(X, \mathcal{O}_X)$ is a normal ring.

Proof: If $X$ is integral, then $R = \Gamma(X, \mathcal{O}_X)$ is integral. If $f = a/b \in K(R)$ that is integral over $R$, then for any affine open $U \subset X$, $b|_U$ is non-zero as $X$ is integral, thus $f|_U$ is integral over $\mathcal{O}_X(U)$ thus $f|_U \in \mathcal{O}_X(U)$, thus $f \in R$. □

Prop. (5.4.2.6) [Normalization]. For an integral scheme $X$, there is a $X_{\text{nom}} \rightarrow X$ which is $\text{Spec}(\mathcal{O}_{X,\text{nom}})$, any dominant morphism $f$ from a normal integral scheme to $X$ will factor through $X_{\text{nom}}$. (Use the adjointness for $\text{Spec}$ and notice $f$ maps generic to generic).

Proof: □

Prop. (5.4.2.7) [Normalization is not flat]. Non-trivial normalization is never flat.
Proof: Use (5.6.2.6). □

Prop. (5.4.2.8) [Regular and Normal]. Regular scheme is C.M and locally factorial, hence normal, by (4.3.5.21) and (4.3.5.19). A Normal scheme is regular in codimension 1, by (4.3.5.32).

Cor. (5.4.2.9). A regular connected scheme $X$ is irreducible, by (5.4.2.4).

Prop. (5.4.2.10). For a locally Noetherian scheme of dimension $\leq 1$, normal is equivalent to regular, by (10.3.3.4).

**Factorial Schemes**

Def. (5.4.2.11) [Factorial Schemes]. A factorial scheme is a scheme that all the local rings are UFD.

Prop. (5.4.2.12). If $A$ is a UFD, then $\text{Spec } A$ is factorial.

**Dedekind Scheme**

Def. (5.4.2.13) [Dedekind Scheme]. A Dedekind scheme is an integral Noetherian normal scheme of dimension 1.

Prop. (5.4.2.14). Let $X$ be a Dedekind scheme and $x \in X$ is a closed pt, let $\hat{X} = \text{Spec} (\hat{O}_{X,x}) \rightarrow X$ be the completion of $X$ at $x$, then there is a pullback of categories:

$$
\begin{array}{ccc}
\text{Bun}_X & \rightarrow & \text{Bun}_{X \setminus \{x\}} \\
\downarrow & & \downarrow \\
\text{Bun}_{\hat{X}} & \rightarrow & \text{Bun}_{\hat{X} \setminus \{x\}}
\end{array}
$$

Proof: We may study locally near $x$, then we can assume that $X$ is affine. Now shrink $X$ even more, we can assume that $x$ is defined by a single $f \in A$ (localized at the maximal ideal defined by $x$), then we finish by (4.4.2.12). □

3 Geometrical properties

Def. (5.4.3.1) [Geometric Properties over Fields].

- A scheme $X$ is called geometrically integral/reduced/separated/irreducible... over a field $k$ iff for any field extension $k'/k$, $X_{k'}$ is integral/reduced/separated/....

- A locally Noetherian scheme is called geometrically regular iff for any f.g. field extension $K/k$, $X_K$ is regular. It is stalkwise by (5.4.3.18).

**Geo.reducedness**

Prop. (5.4.3.2) [Geo.Reduced]. For a scheme $X$ over a field $k$, the following are equivalent:

1. $X$ is geometrically reduced.
2. For every reduced $k$-scheme $Y$, the product $X \otimes_k Y$ is reduced.
3. All stalks are geometrically reduced ring.
4. $X$ is reduced and for every maximal point $\eta$ of $X$, the residue field $k(\eta)$ is separable over $k$.
5. $X_{\text{geo}}$ is reduced.
6. $X_K$ is reduced for every finite purely inseparable field extension $K/k$.
7. $X_{K^{1/p}}$ is reduced.

In particular, if $k$ has characteristic 0, then geo.reduced $\iff$ reduced.

Proof: As reduced is local, these all follows from (4.3.6.2).

Prop.(5.4.3.3) [Geo.Reduced and Arithmetic Points]. Let $X$ be a locally algebraic geo.reduced scheme over a field $k$, then the set of closed points with finite separable field extensions $k(x)/k$ is dense in $X$.

Proof: Combine (5.6.4.19) and (5.6.4.21).

Def.(5.4.3.4) [Density of Points]. Let $X$ be an algebraic scheme over a field $k$, and $k'/k$ be a field extension, then a subset $S \subset X(k')$ is said to be schematically dense in $X$ if the only closed subscheme $Z \subset X$ over $k$ that $S \subset Z(k')$ is $X$ itself.

? Should merge with the definition of scheme-theoretical image.

Prop.(5.4.3.5) [Schematically Dense Subset]. Let $X$ be an algebraic scheme over a field $k$, $S \subset X(k)$ be a subset. Then the following are equivalent:
1. $S$ is schematically dense in $X$.
2. $X$ is reduced and $S$ is dense in $|X|$.
3. The family of homomorphisms $O_X \to k : f \mapsto f(s)$ is jointly injective.

Proof: 1 $\to$ 2: Let $\overline{S}$ be the induced reduced structure of the closure $S$ in $X(5.4.1.14)$, then $\overline{S} = X$, so $X$ is reduced with $X = \overline{S}$.

2 $\to$ 3: ? Cf.[Milne Algebraic Groups, P10].

Cor.(5.4.3.6). A schematically dense subset remains schematically dense after field base changes.

Cor.(5.4.3.7). The schematic closure of a subset commutes with base change.

Proof: Use the third definition in (5.4.3.5), notice that the valuation maps are also jointly injective because $k'/k$ is flat.

Cor.(5.4.3.8). If $X$ admits a schematically dense subset $S$, then $X$ is geo.reduced.

Prop.(5.4.3.9). If $X(k')$ is dense in $X$, then $X$ is reduced. Conversely, if $X(k')$ is dense in $|X_{k'}|$ and $X$ is geo.reduced, then $X(k')$ is dense in $X$.

Proof: $X$ is reduced because $X_{\text{red}}(k') = X(k')$. Conversely if $Z \subset X$ is a closed subscheme that $Z(k') = X(k')$, then $|Z_{k'}| = |X_{k'}|$ by condition, and then $Z_{k'} = X_{k'}$ as $X_{k'}$ is reduced. Thus $Z = X$ by flatness.

Cor.(5.4.3.10) [Geometric Points Schematically Dense]. If $X$ is locally algebraic and geo.reduced, then $X(k')$ is schematically dense in $X$ for any separably closed field $k'$ containing $k$. 
Proof: \( X(k') \) is dense in \( |X_{k'}| \) by (5.4.3.3), thus it is schematically dense in \( X \) by the proposition. □

Cor. (5.4.3.11). If \( Z, Z' \) are closed subvarieties of a locally algebraic algebraic scheme \( X \) over \( k \) that \( Z(k') = Z'(k') \subset X(k') \) for some separably closed field \( k' \) containing \( k \), then \( Z = Z' \). In other words, a closed subvariety of \( X \) is determined by the subset \( Z(k^s) \subset X(k^s) \).

\[ \text{Proof:} \quad \text{The closed subscheme } Z \cap Z' \text{ satisfies } Z \cap Z'(k') = Z(k'), \text{ so } Z \cap Z' = Z \text{ by (5.4.3.10).} \]

Similarly, \( Z \cap Z' = Z' \).

Geo. Connected and Geo. Irreducible

Prop. (5.4.3.12)[Geo. Connectedness]. For a scheme \( X \) over a field \( k \), the following are equivalent:

- For every connected \( k \)-scheme \( Y \), the product \( X \otimes_k Y \) is connected.
- \( X \) is geometrically connected.
- \( X_{K^s} \) is connected.
- \( X_K \) is connected for any finite separable extension \( K/k \).

\[ \text{Proof:} \quad \text{Cf. [Sta]0385, 0389.} \]

Prop. (5.4.3.13)[Invariance of Base Change]. Let \( X \) be a scheme over a field \( k \) and \( k'/k \) a field extension, then \( X \) is geo. connected iff \( X_{k'} \) is geo. connected.

\[ \text{Proof:} \quad \text{Cf. [Sta]054N.} \]

Prop. (5.4.3.14). Let \( T \to X \) be a map of schemes over a field \( k \), if \( T \) is geo. connected and \( X \) is connected, then \( X \) is geo. connected.

\[ \text{Proof:} \quad \text{Cf. [Sta]056R.} \]

Cor. (5.4.3.15)[Connected with a Rational Point]. Let \( X \) be a scheme over a field \( k \). Assume \( X \) is connected and has a point \( x \) that \( k \) is alg. closed in \( k(x) \), then \( X \) is geo. connected. In particular, if \( X \) is connected and has a rational point, then \( X \) is geo. connected.

\[ \text{Proof:} \quad \text{Cf. [Sta]04KV.} \]

Prop. (5.4.3.16)[Geometrically Irreducible]. For a scheme \( X \) over a field \( k \), the following are equivalent:

- For every irreducible \( k \)-scheme \( Y \), the product \( X \otimes_k Y \) is irreducible.
- \( X \) is geometrically irreducible.
- \( X_{K^s} \) is irreducible.
- \( X \) is irreducible and if \( \eta \) is the generic pt of \( X \), then \( k \) is separably closed in \( k(\eta) \).
- \( X_K \) is irreducible for any finite separable extension \( K/k \).

\[ \text{Proof:} \quad \text{Cf. [Gortz P136].} \]

□
Geo.Integral

Cor. (5.4.3.17)[geometrically Integral]. For a scheme $X$ over a field $k$, the following are equivalent:

- For every integral $k$-scheme $Y$, the product $X \otimes_k Y$ is integral.
- $X$ is geometrically integral.
- $X_K$ is irreducible for any finite extension $K/k$.
- $X_k$ is integral.
- $X$ is integral and if $\eta$ is the generic pt of $X$, then $k$ is alg. closed in $k(\eta)$ and $k(\eta)/k$ is separable.

Proof: $1 \to 2 \to 3 \to 4$ is easy, Cf.[Gortz P136]. □

Geometrically Regular

Prop. (5.4.3.18). Let $X$ be a locally Noetherian scheme over a field $k$, then $X$ is geometrically regular iff the local ring $\mathcal{O}_{X,x}$ is geometrically regular over $k$. Thus it suffice to check for finite purely inseparable field extensions $k'/k$, by(4.3.6.6).

Proof: For a finite purely inseparable field extension, $\mathcal{O}_{X,x} \otimes_k k'$ is also a local ring because their spectra are the same(4.1.7.26), so $\mathcal{O}_{X,x}$ is geometrically regular by(4.3.6.6).

Conversely, if $\mathcal{O}_{X,x}$ is geo.regular, then for any field extension $k'/k$, stalks of $X_{k'}$ are localization of $\mathcal{O}_{X,x} \otimes_k k'$, so it is regular by(4.3.5.17). □

Cor. (5.4.3.19). A geometrically regular ring is geometrically reduced, by(4.3.5.19) and(5.4.3.2).

Prop. (5.4.3.20)[Partially Invariance Under Base Change]. If $k'/k$ is a f.g. field extension, then $X_{k'}$ is geo.regular over $k'$ iff $X_k$ is geo.regular over $k$.

In fact, this is true for any field extension $k'/k$ if $X$ is locally algebraic over $k$, because in this case geo.regular is equivalent to smoothness.

Proof: One direction is trivial, for the other, Cf.[Sta]038W?. □

4 Basic Morphism Properties

Main references are [Sta]02WE.

Base Change Trick

Prop. (5.4.4.1)[Base Change Trick]. If a property $P$ of morphisms satisfy:

- Closed immersion has $P$.
- Stable under base change and composition.

Then

- it is stable under product.
- $g \circ f : X \to Y \to Z$ has $P$ and $g$ separated implies $f$ has $P$.
- it is stable under $f_{red}$. (Notice $X_{red} \to X$ is closed immersion).
Proof: For the product, we may assume one of them is identity and use composition, but then the product is just base change, so it has \( P \).

For the second, factorize \( f : X \rightarrow X \times_Z Y \rightarrow Y \), the first is base change of \( \Delta : Y \rightarrow Y \times_Z Y \), so it satisfies \( P \) because \( g \) is separable, and the second map is a base change of \( X \rightarrow Z \), so it satisfies \( P \), so \( f \) satisfies \( P \).

\( X_{\text{red}} \rightarrow X \rightarrow Y = X_{\text{red}} \rightarrow Y_{\text{red}} \rightarrow Y \) has \( P \) because \( X_{\text{red}} \rightarrow X \) is closed immersion, and \( Y_{\text{red}} \rightarrow Y \) is separable because closed immersion is separable (checked directly), so by what has been proved, \( X_{\text{red}} \rightarrow Y_{\text{red}} \) has \( P \). \( \square \)

Prop. (5.4.4.2). Lists of properties satisfying the base change trick (5.4.4.1) (not complete):
1. Universal closed/universal injective morphisms.
2. Affineness.
3. Morphisms (locally) of finite type.
4. Finite Morphisms.
5. Integral Morphisms.
6. Morphisms (locally) of finite presentation.
7. Quasi-affine morphisms.
8. Closed Immersions.
10. (Quasi-)Separatedness.
11. Proper.
12. Unramified.
14. (Locally) Quasi-finiteness.
15. H-projectiveness.

Proof:
1. Trivial.
2. Because affineness is local on the target (5.4.1.5), this follows from (5.2.7.17) and (5.2.7.14).
3. Trivial.
4. Trivial.
5. 

6. By (4.3.7.9).
7. Affine morphism is quasi-compact: because quasi-compactness is local on the target, we can reduced to the affine case, thus it is quasi-compact, by (5.4.4.26). To show a base change of quasi-compact morphism is quasi-compact, because quasi-compactness is local on the target (5.4.1.5), then we can choose a cover by affine opens that the image is contained in an affine open, thus it reduces to show a map between affine schemes is quasi-compact, which is (5.4.4.26).
8. For closed immersions, use (5.2.7.16) and check locally, for open immersions, use (5.2.7.16).

9. It suffices to show an affine map is quasi-compact.

10. Closed immersion is separated is checked directly. Composition: For \( X \to Y \to Z \), the diagonal map decomposes as \( X \to X \times_Y X \to X \times_Z X \), the second one is closed immersion (or quasi-compact) by (5.4.4.78), so this follows from that of closed immersion and qc. Base change: The diagonal commutes with base change (3.1.1.48), so this follows from that of closed immersion and qc.

11. Because universally closed, f.t. and separatedness both do (5.4.4.2).

12.

13.

14. □

**Injectivity and Monomorphisms**

**Def.(5.4.4.3)** [Injectivity and Monomorphisms]. A morphism of schemes is called **injective** if it is injective topologically. A morphism of schemes is called a monomorphism if it is a monomorphism in the category of schemes.

**Prop.(5.4.4.4)** [Universally Injective]. For a morphism of schemes \( X \to S \), the following are equivalent:

- It is universally injective.
- It is injective and the residue field extension are all purely inseparable.
- The diagonal map is surjective.
- For any field \( K \), \( \text{Hom}(\text{Spec} \, K, X) \to \text{Hom}(\text{Spec} \, K, S) \) is injective.

In particular, any monomorphism is universally injective.

**Proof:**

1 \to 4: For \( s \in \text{Hom}(\text{Spec} \, K, S) \), a \( x \in \text{Hom}(\text{Spec} \, K, X) \) mapping to \( s \) is a section of the injective map \( X \times_S \text{Spec} \, K \to \text{Spec} \, K \), which is unique if it exists.

4 \to 1: If \( S' \to S \) is a morphism, \( X' = X \times_S S' \), and \( x, x' \in X' \) map to the same point \( s' \in S' \), then we can choose a common field extension \( K/k(s') \) of \( k(x)/k(s) \) and \( k(x')/k(s) \). Then we get two elements in \( \text{Hom}(\text{Spec} \, K, X') \), and the hypothesis says they map to the same element in \( \text{Hom}(\text{Spec} \, K, X) \). Thus they are the same, as \( X' \) is the fiber product.

1 \to 2: It the residue field extension is not purely inseparable, then tensoring with this field extension, we get two points mapping to the same, contradiction.

2 \to 4: It the residue field extension is purely inseparable, then \( k(x) \to K \) is determined by the composition, \( k(s) \to k(x) \to K \), which means 4 is true.

1 \to 3: If \( X \to S \) is universally injective, then \( X \times_S X \to X \) is injective, and \( \Delta_{X/S} \) is a section of this map, thus it must be surjective.

3 \to 1: If \( \Delta_{X/S} \) is surjective, then for any base change \( S' \to S \), \( \Delta_{X'/S'} \) is surjective, thus \( X' \to S' \) is injective, thus 1 holds. □

**Prop.(5.4.4.5)** [Monomorphism and Injectivity]. A morphism of schemes \( j : X \to Y \) is a monomorphism if \( j \) is an injective map and for any \( x \in X \), \( \mathcal{O}_{Y,j(x)} \to \mathcal{O}_{X,x} \) is surjective.
Proof: First check topologically, then check the local ring map. □

Cor. (5.4.4.6). For any scheme $X$ and a point $x$, $\text{Spec} \mathcal{O}_{X,x} \to X$ is a monomorphism.

Closed Map

Prop. (5.4.4.7) [Universal Closed]. Universal closedness is local on the basis and satisfies the base change trick (5.4.4.2).

Prop. (5.4.4.8). If $g$ is surjective, then $f \circ g$ is universally closed iff $f$ is universally closed (because surjective is S.u.B).

Prop. (5.4.4.9) [Closed Map and Specialization]. The image of a quasi-compact morphism is closed iff it is stable under specialization. And it is a closed map iff specializations lift along $f$.

Proof: For the first, the question is local, so reduce to $Y$ affine, and then $X$ is qc $= \bigcup U_i$, then we can replace $X$ by an affine $\bigcap U_i$, then reduce to the affine case (4.1.7.14).

For the second, for any closed subset of $X$ with its induced reduced structure, the restriction to it is still qc and specialization lifts, so we prove the image is closed. Now the image is stable under specialization, so the result follows from the first assertion. □

Affine Map

Prop. (5.4.4.10). $X$ is affine if there is a finite set of elements $f_i \in \Gamma(X, \mathcal{O}_X)$ that generate the unit ideal and $X_{f_i}$ is affine.

Proof: First prove that $X_{f_i} \cap X_{f_j} = X_{f_if_j}$ is affine because affine intersect $X_{f_i}$ is affine. Second, prove $\Gamma(X_f, \mathcal{O}_X) = \Gamma(X, \mathcal{O}_X)_f$, finally glue them to get a map $X \to \text{Spec}(A)$ and use the fact isomorphism is local on the target (5.4.4.5). $X$ is affine scheme if $X \to \text{Spec}(\Gamma(X))$ is affine. □

Cor. (5.4.4.11). Affineness is affine local on the target, and it satisfies the base change trick (5.4.4.2).

Lemma (5.4.4.12) [Serre Criterion of Affineness].

- A qc scheme $X$ is isomorphic to an affine scheme iff $H^1(X, \mathcal{I}) = 0$ for every Qco sheaf of ideals $\mathcal{I}$.

- If $X$ is qcqs, then it suffices to show $H^1(X, \mathcal{I}) = 0$ for every Qco sheaf of ideals $\mathcal{I}$ of f.t..

- If $f : X \to Y$ is a quasi-compact morphism between quasi-separated schemes, then $f$ is affine iff for any Qco sheaf of ideals $\mathcal{I}$ on $X$, $R^1f_*\mathcal{I} = 0$.

Proof: Cf. [Sta]01XF.

The case of affine scheme is proven by (5.7.1.1) and (5.7.1.2). The converse: For every point $p$, choose an open affine nbhd $U$, let $Y = X - U$, by the exact sequence

$$0 \to \mathcal{I}_{Y \cup \{p\}} \to \mathcal{I}_Y \to k(P) \to 0,$$

we have a surjective map $\Gamma(X, \mathcal{I}_Y) \to \Gamma(X, k(P))$ thus there is a $f \in A = \Gamma(X, \mathcal{O}_X)$ that $P \in X_f \subset U$ is affine. So using (5.4.4.10), we only have to show that for f.m $f_i$, they generate $\Gamma(X, \mathcal{O}_X)$. This is by considering the kernel $F$ of $\mathcal{O}_X^* \to \mathcal{O}_X : (a_1, \ldots, a_r) \to \sum f_ia_i$, and there is a filtration on $F$, the quotient of which are all coherent sheaves because kernel and cokernel are Qco, and there by induction and hypothesis, $H^1(X, F) = 0$, thus the result.
2: In the qcqs case, by (5.7.1.5), we can use filtered colimit to show that \( H^1(X, \mathcal{I}) = 0 \) for any Qco sheaf of ideals.

3: For any affine open \( U \) of \( Y \), the inclusion \( U \to Y \) is qc, thus \( f^{-1}(U) \to X \) is also qc. Now any Qco sheaf of ideals \( \mathcal{I} \) on \( U \) extends to a Qco sheaf of ideals on \( X \) by (5.5.1.8), then we can use Leray spectral sequence to conclude that \( H^1(f^{-1}(U), \mathcal{I}) = 0 \), so \( f^{-1}(U) \) is affine.

\[ \square \]

**Cor. (5.4.4.13).** For a Noetherian scheme \( X \), \( X \) is affine iff \( X_{\text{red}} \) is affine.

**Proof:** The canonical exact sequence (5.2.6.10) reads: \( 0 \to N \mathcal{F} \to \mathcal{F} \to i_* i^* \mathcal{F} \to 0 \), so iff \( X_{\text{red}} \) is affine, then we have \( H^i(\mathcal{F}) \cong H^i(N \mathcal{F}) \), and notice \( N^k = 0 \) for some \( k \).

\[ \square \]

**Cor. (5.4.4.14).** For a Noetherian reduced scheme \( X \), \( X \) is affine iff each irreducible component is affine. (The same as the above, notice that \( \prod p_i = 0 \), for the minimal primes of \( A \)). (The reducedness can be dropped by the last proposition).

**Lemma (5.4.4.15).** If a morphism \( X \to Y \) is a homeomorphism onto a closed subset of \( Y \), then \( f \) is affine.

**Proof:** Cf. [Sta]04DE.

**Quasi-affine**

**Def. (5.4.4.16)[Quasi-Affine Morphism].** A scheme is called quasi-affine iff it is isomorphic to a qc open subscheme of an affine scheme. A morphism is called quasi-affine iff the inverse of any affine scheme is quasi-affine.

**Prop. (5.4.4.17).** Quasi-affine is local on the target and satisfies the base change trick.

**Proof:** Cf. [Sta]01SN.

\[ \square \]

**Prop. (5.4.4.18).** Any qc immersion \( i \) of a quasi-affine scheme is quasi-affine.

**Proof:** As \( i \) is qc, \( i \) factors through a map \( Z \to U \to X \), where \( U \) is a quasi-compact open subset of \( X \). Thus it suffices to consider the closed immersion case, which is clear.

\[ \square \]

**Prop. (5.4.4.19).** A morphism \( f : X \to S \) is quasi-affine iff \( \mathcal{O}_X \) is \( f \)-ample. In particular, A scheme is quasi-affine iff \( \mathcal{O}_X \) is ample.

**Proof:** Cf. [Sta]01QE.

\[ \square \]

**Cor. (5.4.4.20).** Let \( X \) be a quasi-affine scheme and \( H^p(X, \mathcal{O}_X) = 0 \) for \( p > 0 \), then \( X \) is affine.

**Proof:** By (5.4.4.19) \( \mathcal{O}_X \) is ample, then by (5.5.4.18), \( X \) is affine.

\[ \square \]

**Prop. (5.4.4.21)[Descent].** Let \( X \) be a scheme over a field \( k \) and \( K/k \) be a field extension, then \( X \) is quasi-affine iff \( X_K \) is quasi-affine.

**Proof:** Cf. [Sta]0BDD.
Dominant

**Prop. (5.4.4.22).** Let \( f : X \to S \) be a map of schemes.
- If every generic point of irreducible components of \( S \) is in the image of \( f \), then \( f \) is dominant.
- If \( f \) is quasi-compact, then the converse is also true. More precisely, if a generic point \( \eta \) is not in the image, then it is not in the closure of the image.
- If \( X \) has only f.m. irreducible component, then the converse is also true.

**Proof:** Cf.[Sta]Chap28.8.

**Prop. (5.4.4.23)[Dominant Map between Integral Schemes].** If \( f : X \to S \) is a map between integral schemes, then the following are equivalent:
- \( f \) is dominant.
- \( f(\eta_X) = \eta_Y \).
- for some(all) affine open subset \( U \subset X, V \subset Y \) with \( f(U) \subset V \), the ring map \( O_Y(V) \to O_X(U) \) is injective.
- for some(all) \( x \in X \), the local ring map \( O_{Y,f(x)} \to O_{X,x} \) is injective.

**Proof:** Cf.[Sta]0CC1.

**Def. (5.4.4.24)[Dominant Rational Maps].** A rational map between irreducible schemes is called a **dominant map** if it maps the generic point to the generic point.

Quasi-Compact

**Prop. (5.4.4.25)[Quasi-Compact Morphism].** A morphism \( f : X \to S \) of schemes is quasi-compact iff the inverse image of any quasi-compact open subsets is quasi-compact, because affine opens form a basis of \( X \).

**Prop. (5.4.4.26).** A map between affine schemes is quasi-compact.

**Proof:** Because quasi-compactness is local on the target(5.4.1.5), it suffices to show the inverse image of a distinguished open subset is quasi-compact, and this is true.

**Prop. (5.4.4.27).** Let \( f : X \to Y, g : Y \to Z \). If \( g \circ f \) is quasi-compact and \( g \) is qs, then \( f \) is qc.

**Proof:** Factor it through \( X \to X \times_Z Y \to Y \). The second map is a base change of \( X \to Z \) hence qc, the first map is a section of \( X \times_Z Y \to X \), which is a base change of \( Y \to Z \), hence qs, so by(14.5.3.19), the first map is also qc.

**Prop. (5.4.4.28).** Any map between Noetherian schemes is quasi-compact, by(5.4.1.22).

Finite Type

**Def. (5.4.4.29)[Morphisms of Finite Type].** A morphism \( f : X \to S \) is called of **locally of finite type** if for there exists an affine open cover \( \{\text{Spec}(B_i)\} \) of \( S \) that \( f^{-1}(U_i) \) has an affine open cover of spec of finite generated \( B_i \)-algebras. It is called **finite type** if moreover it is quasi-compact.
5.4. PROPERTIES OF SCHEMES

Let \( k \in \text{Field} \), then \( S \in \text{Sch} / k \) is called (locally) algebraic iff \( S \) is (locally) of finite type over \( \text{Spec} \ k \).

For \( S \in \text{Sch} \), denote \( \text{Sch}_{\text{loc.ft}} / S(\text{Sch}^{\text{ft}} / S) \) the full subcategory of \( \text{Sch} / S \) consisting of (locally) of finite type schemes over \( S \).

(Locally) Finite type is affine local on the target and on the source, and satisfies the base change trick (5.4.4.2).

Prop. (5.4.4.30) [Closed Subschemes Descending Chain Stablizes]. The closed subschemes of an algebraic scheme \( X \) over a field \( k \) satisfy the descending chain condition.

Proof: As \( X \) is Noetherian, the topological chain \( |Z_1| \supset |Z_2| \supset \ldots \) stabilizes, so we may assume \( |X| = |Z_1| = |Z_2| = \ldots \). Now choose a finite affine cover \( \text{Spec} \ A_i \) of \( X \), then \( Z_i \) corresponds to ideals \( I_i \) of \( A_i \), so they stabilize, as \( A_i \) are Noetherian.

Cor. (5.4.4.31). Arbitrary intersection of closed subschemes of an algebraic scheme \( X \) is well-defined.

Prop. (5.4.4.32) [Algebraic Schemes of Dimension 0]. Let \( X \) be a locally algebraic variety over a field \( k \) of dimension 0, then \( X \) is a disjoint union of f.d. local Artinian \( k \)-algebras.

Proof: Cf. [Sta]06LH.

Prop. (5.4.4.33) [Dimensions for Locally Algebraic \( k \)-Schemes]. Let \( k \) be a field and \( X \) is a locally algebraic \( k \)-scheme.

if \( X \) is irreducible, then \( \dim X = \dim U \) for any nonempty open \( U \subset X \).

Proof: It suffices to show any two affine open subsets \( U, U' \) of \( X \) have the same dimension, then use (3.8.3.26). Now \( U \cap U' \neq \emptyset \) as \( X \) is irreducible, and then it contains a maximal pt \( x \) by Hilbert's Nullstellensatz, and then \( \dim U = \dim(\mathcal{O}_{X,x}) = \dim U' \) because f.g. algebras over a field is catenary.

Integral & Finite Map

Def. (5.4.4.34) [Finite and Integral Map]. A morphism \( f : X \to S \) is called integral if it is affine and there is a affine open covering \( U_i = \text{Spec} \ A_i \) of \( S \) that \( f^{-1}(U_i) = \text{Spec} \ B_i \) and \( A_i \to B_i \) is integral.

A morphism \( f : X \to S \) is called finite if it is affine and there is a affine open covering \( U_i = \text{Spec} \ A_i \) of \( S \) that \( f^{-1}(U_i) = \text{Spec} \ B_i \) and \( B_i \) are finite modules over \( A_i \).

A morphism \( f : X \to S \) is called (locally) quasi-finite if it is (locally) of f.t. and the inverse of a point is a discrete set.

Prop. (5.4.4.35) [Integral Morphism is Closed]. Specialization lifts along an integral morphism. In particular, an integral morphism is closed, by (5.4.4.9).

Proof: If \( f(x) = y, y \to y' \), then we can choose an open affine \( U \) containing \( y' \), which also contains \( y \). So we can choose an open affine containing \( x \) mapping into \( U \), then it reduces to the affine case (4.1.7.13).

Prop. (5.4.4.36) [Chevalley]. If \( f : Y \to X \) is integral surjective, \( Y \) is affine, then \( X \) is affine.
**Proof:** Cf.[Sta]05YU.

**Lemma (5.4.4.37).** If \( f : Y \to X \) is finite surjective, \( Y \) is affine, then \( X \) is affine.

**Proof:**

**Prop. (5.4.4.38) [Finite and Integral].** A morphism is finite iff it is integral of f.t..

**Prop. (5.4.4.39) [Integral and Affine u.c.].** Integral map is equivalent to u.c. and affine.

**Proof:** Integral is stable under base change. And if it is integral, then it is closed by (4.2.1.5).

Conversely, we need to prove if \( \text{Spec } B \to \text{Spec } A \) is u.c., then \( A \to B \) is integral. For any \( a \in B \), let \( J \) be the kernel of \( A[X] \to B[X]/(aX - 1) \), then if \( f \in J \), then \( f(X) = (aX - 1)q(X) \), and \( X^\deg(f) f(\frac{1}{X}) = (a - X)X^\deg(q)q(\frac{1}{X}) \) vanishes at \( a \), so it suffices to find a \( f \in J \) with constant term 1. It suffices to show that \( \text{Spec}(A[X]/J + (x)) \) is empty:

As \( f \) is universally closed, \( \text{Spec } B[X] \to \text{Spec } A[X] \) is closed, thus the image of \( \text{Spec}(B[X]/(aX - 1)) \) is closed in \( \text{Spec } A \), which is the underlying set of \( \text{Spec } A/J \), by (5.4.4.64). Now notice \( T = \text{Spec}(A[X]/J + (x)) \times_{\text{Spec } A[X]/J} \text{Spec}(B[X]/(aX - 1)) \) is empty, because \( (A[X]/J + (x)) \otimes_{A[X]/J} (B[X]/(aX - 1)) = \text{Spec } A \otimes \text{Spec } A/X \text{Spec}(B[X]/(aX - 1)) = 0 \), as \( X \) is invertible in \( B[X]/(aX - 1) \) but vanish in \( A \). But \( T \to \text{Spec}(A[X]/J + (x)) \) is surjective, as a base change of \( \text{Spec}(B[X]/(aX - 1)) \) to \( \text{Spec } A/J \), thus we are done.

**Def. (5.4.4.40) [Degree of Finite Morphisms at a Point].** Suppose \( \pi : X \to Y \) is a finite morphism, then \( \pi_* \mathcal{O}_X \) is a \( \mathcal{O}_Y \)-module of f.t.. Let \( p \in Y \), then the **degree of \( \pi \) at \( p \)** is the rank of this sheaf on \( Y \) (5.5.1.11), which is an upper-semicontinuous function (5.5.1.41).

**Prop. (5.4.4.41).** The degree of a finite morphism \( \pi : X \to Y \) at \( p \) is the dimension over \( k(p) \) of the fiber of \( \pi \) at \( p \). In particular, the degree is zero iff \( \pi^{-1}(p) = 0 \).

**Proof:** Look affine locally.

**Lemma (5.4.4.42).** For \( f : Y \to X \) finite surjective and \( X \) locally Noetherian, for every integral subscheme \( Z \) of \( X \) with generic point \( \xi \), there is a coherent sheaf \( \mathcal{F} \) on \( Y \) that the support of \( f_* \mathcal{F} \) is \( Z \) and \( (f_*Z)_\xi \) is annihilated by \( \mathfrak{m}_\xi \).

**Proof:** Consider an inverse image of \( \xi = \xi' \), and let \( Z' = \frac{\xi}{\mathcal{F}} \) with the induced reduced structure, then let \( \mathcal{F} = i_* \mathcal{O}_{Z'} \) on \( Y \), \( \mathcal{F} \) is coherent, then we need to show that \( (f_* \mathcal{F})_\xi \) is annihilated by \( \mathfrak{m}_\xi \). This is because it factors through \( Z \). Cf.[Sta]01YO.

**Quasi-Finiteness**

**Def. (5.4.4.43) [Quasi-Finite Morphisms].**

(Locally)Quasi-finite morphisms are local on the target and satisfies base change trick.

**Prop. (5.4.4.44) [Characterization of Quasi-Finiteness].** Let \( f : X \to S \) be a morphism, then the following are equivalent:

- \( f \) is quasi-finite.
- \( f \) is locally quasi-finite and quasi-compact.
- \( f \) is locally of f.t., quasi-finite and has finite fibres.
5.4. PROPERTIES OF SCHEMES

Proof: Cf.[Sta]01TJ, 02NH.

Prop.(5.4.4.45). Immersions are locally quasi-finite.

Prop.(5.4.4.46). Let \( f : X \to S \) be a morphism of schemes and \( s \in S \). Assume that \( f \) is locally of f.t. and \( f^{-1}(s) \) is a finite set, then \( X_s \) is a finite discrete topological space, and \( f \) is quasi-finite at every point of \( f^{-1}(s) \).

Proof: Cf.[Sta]02NG.

Prop.(5.4.4.47)[Zariski’s Main Theorem]. Let \( f : Y \to X \) be an affine morphism of f.t.. Let \( Y \xrightarrow{f'} X' \xrightarrow{\nu} X \) where \( X' \) is the normalization of \( X \) in \( Y \), then there exists an open subscheme \( U' \subset X' \) that \( (f')^{-1}(U) \to U \) is an isomorphism and \( (f')^{-1}(U) \) is the set of points at which \( f \) is quasi-finite.

Proof: Cf.[Sta]03GT.

Prop.(5.4.4.48)[Quasi-Finite Locus is Open]. Let \( f : X \to S \) be a morphism of schemes, then the set of points of \( X \) that \( f \) is quasi-finite is an open subset \( U \subset X \), and \( U \to S \) is locally quasi-finite.

Proof: Cf.[Sta]01T1.

Prop.(5.4.4.49)[Zariski’s Main Theorem]. For a morphism \( X \to S \) that is quasi-finite and separated, if \( S \) is qcqs, Then there is a factorization \( X \to T \to S \) that \( X \to T \) is a qc open immersion and \( T \to S \) is finite.

Proof: Cf.[Sta]05K0.

Prop.(5.4.4.50). If \( f : Y \to X \) is a quasi-finite morphism of schemes, and \( T \subset Y \) is nowhere dense, then \( f(T) \subset X \) is also nowhere dense.

Proof: Cf.[Sta]03J2.

Generically Finiteness

Def.(5.4.4.51)[Generically Finite Morphisms]. A generically finite morphism is a morphism \( f : X \to Y \) locally of f.t. and there exists a dense open subset \( U \subset X \) s.t. \( U \to Y \) is locally quasi-finite.

Lemma(5.4.4.52). Let \( R \to S \) be a ring map of f.t., if \( p \subset R \) is a minimal prime that there are f.m. primes in \( S \) lying over \( p \), then there is a \( g \in R \), \( g \notin p \) that \( R_g \to S_g \) is finite.

Proof: The condition means \( S_p/pS_p \) has only f.m. primes and \( pS_p \) is locally nilpotent. Then \( \kappa(p) \to S_p/pS_p \) if finite. Let \( x_i \) generate \( S \) over \( R \), then there are polynomials \( P_i \in R[X] \) that \( P_i(x_i) = 0 \in S_p/pS_p \), and thus \( P_i^e(x_i) = 0 \in S_p \). Now choose \( g \notin p \) that \( g \) divides the common divisors of the coefficients of \( P_i \) and \( P_i^e(x_i) = 0 \in S_p \), then \( R_g \to S_g \) is finite.

Prop.(5.4.4.53)[Generically Finiteness]. Let \( f : X \to Y \) be a morphism of finite type. If \( \eta \in Y \) is a generic point, then:

- \( f^{-1}(\eta) \) is a finite set iff there are affine opens \( U_i \subset X, i = 1, \ldots, n \) and \( V \subset Y \) that \( f(U_i) \subset V, \eta \in V \) and \( f^{-1}(\eta) \subset \cup U_i \) and \( U_i \to V \) are finite.
• If $f$ is qs, then we can further restrict to $n = 1$.
• If $f$ is qcqs, then we can further restrict to $U_1 = f^{-1}(V)$.

Proof: These are local on $Y$, so we can change $Y$ to an affine open subscheme containing $\eta$.

1: If these affine opens exist, then $\# f^{-1}(\eta) < \infty$ because finite maps are quasi-finite (5.4.5.5).

If $f^{-1}(\eta) = \{\xi_1, \ldots, \xi_n\}$, choose affine opens $U_i$ around each $\xi_i$, then we reduce to the affine case (5.4.4.52).

2: Cf. [Sta]02NW.

3: □

Prop. (5.4.4.54) [Extension of Fraction Fields]. Let $f : X \rightarrow Y$ be a dominant morphism locally of f.t. between integral schemes, then the following are equivalent:
• $\text{tr.deg } K(X)/K(Y) = 0$.
• $K(X)/K(Y)$ is finite.
• there exists non-empty affine opens $U \subset X, V \subset Y$ s.t. $f(U) \subset V$ and $U \rightarrow V$ is finite.
• the generic point of $X$ is the only point mapping to the generic point of $Y$.
• If $f$ is qc or qs, we can assume $U = f^{-1}(V)$.

Proof: Cf. [Sta]02NX. □

Def. (5.4.4.55) [Degree Generically Finite Morphisms]. Let $f : X \rightarrow Y$ be a dominant morphism of f.t. between integral schemes, then by (5.4.4.23), $f$ induces an injective map of function fields $K(Y) \rightarrow K(X)$, the degree of $[K(X) : K(Y)]$ is called the degree of $f$, denoted by $\deg(f)$. It is a positive integer or $\infty$.

When $\deg(f)$ is finite (i.e. the conditions of (5.4.4.54) hold), it is called a separable/purely inseparable morphism if the field extension $K(X)/K(Y)$ is separable/purely inseparable. And also we can define the separable, inseparable degree of $f$.

Immersions

Def. (5.4.4.56) [Immersions]. A closed immersion of schemes is a closed immersion of local ringed spaces (5.2.6.15). A closed subscheme of a scheme $X$ is a closed sub-ringed space (5.2.6.15) that is also a scheme.

An open immersion of schemes is an open immersion of local ringed spaces (5.2.6.15). An open subscheme of a scheme $X$ is an open subspace (5.2.6.15) that is also a scheme.

Open and closed immersions are affine local on the target (5.4.1.5).

An immersion is a morphism that is a closed immersion of an open immersion.

Lemma (5.4.4.57) [Closed Immersion for Schemes]. Let $f : Y \rightarrow X$ be a morphism of schemes that induces a homeomorphism of $Y$ onto a closed subset of $X$, and $f^\sharp : \mathcal{O}_X \rightarrow f_\ast \mathcal{O}_Y$ is surjective, then it is a closed immersion (5.2.6.15).

Proof: It suffices to show that the kernel of $f^\sharp$ is Qco. For this, notice that $f$ is quasi-compact, and it is a monomorphism by (5.4.4.5), in particular separated by (5.4.4.86). Then (5.5.1.6) shows $f_\ast \mathcal{O}_Y$ is Qco. Then the kernel is Qco by (5.5.1.3). □

Prop. (5.4.4.58) [Closed Subschemes of Affine Schemes]. The closed sub-ringed spaces of $X = \text{Spec } A$ are all closed subschemes, and they corresponds to ideals $I \subset A$:
5.4. PROPERTIES OF SCHEMES

- If $I \subset A$ is an ideal, then the morphism $Z = \text{Spec } A/I \to \text{Spec } A$ is a homeomorphism of $Z$ onto a closed subspace $V(I)$ of $X$, and also the stalk map at a point $p \subset Z$ is $R_p \to (R/I)_p = R_p / I R_p$, which is surjective. So this is a closed immersion by (5.4.4.57).

- By (5.2.6.17), for any closed subscheme $Z$ of $X$ with sheaf of ideals $\mathcal{I}$, $Z$ is isomorphic to the closed subscheme of $X$ defined by $\mathcal{I}$. Now $\mathcal{I}$ is locally generated by sections, so the quotient sheaf $\mathcal{O}_X / \mathcal{I}$ is a Qco sheaf, so it is of the form $\widetilde{S}$ for some $A$-module $S$, by (5.5.1.2). Then $\mathcal{I}$, as the kernel of $\mathcal{O}_X \to \widetilde{S}$, is also Qco (5.5.1.3), so it equals $\widetilde{I}$ for some ideal $I \subset A$. Thus $S = R \ wedge I$, and we are done.

Prop. (5.4.4.59) [Closed Subscheme of Schemes]. The closed sub-ringed spaces of a scheme $X$ are all closed subschemes, and they correspond to Qco $\mathcal{O}_X$-sheaves of ideals via the ideal sheaf (5.2.6.15):

Proof: Let $i : Y \to X$ be a closed immersion, for any $x \in X$, choose an open affine nbhd $U$ of $x \in X$, then $i : i^{-1}(U) \to U$ is also a closed immersion, so it corresponds to $\text{Spec } A/I \to \text{Spec } A$ for some ideal $I$ by (5.4.4.58). So $Z$ is a scheme, and the ideal sheaf $\mathcal{I}$ is Qco. □

Prop. (5.4.4.60). Closed immersion satisfies the base change trick (5.4.4.2). Open immersion are stable under base change and composition. Immersions are stable under base change and composition.

Proof: For immersion, shrink the open subset. □

Remark (5.4.4.61). A open immersion followed by a closed immersion can be written as a closed immersion followed by an open immersion, but not reversely. The reverse happens if the immersion is quasi-compact or the source is reduced (use the reduced induced structure).

Def. (5.4.4.62) [Scheme-Theoretical Image]. For a morphism $f : X \to Y$, there is a closed scheme called scheme-theoretic image that is the smallest closed subscheme of $Y$ that $f$ factors through $Z$.

For an immersion of schemes, the scheme-theoretic image of the immersion is called the scheme-theoretic closure.

Proof: Consider the kernel of the structural map, and the kernel contains a maximal Qco sheaf of ideals $\mathcal{I}$ by (5.5.1.12). □

Prop. (5.4.4.63). If $X_1 \overset{f_1}{\to} Y_1 \quad \downarrow \quad \downarrow$

be a commutative diagram of schemes and $Z_i \subset Y_i$ be the scheme-theoretic image of $f_i$, then it induces a commutative diagram $X_1 \overset{f_1}{\to} Z_1 \overset{f_1}{\to} Y_1$

$X_2 \overset{f_2}{\to} Z_2 \overset{f_2}{\to} Y_2$

Proof: It suffices to show $Z_1$ factors through the closed subscheme $Z_2 \times_{Y_2} Y_1$ of $Y_1$, which follows from the universal property of $Z_1$. □

Prop. (5.4.4.64). Let $f : X \to Y$ be a qc morphism of schemes and $Z$ be the scheme-theoretical image, then

- the kernel $\mathcal{I} = \ker(\mathcal{O}_Y \to f_* \mathcal{O}_X)$ is Qco, thus $Z$ is the closed subscheme determined by $\mathcal{I}$.

- For any open subscheme $U \subset Y$, the scheme-theoretical image of $f|_{f^{-1}(U)}$ is equal to $Z \cap U$. 

• \( f(X) \) is dense in \( Z \).

**Proof:** 1: As being Qco is local, it suffices to show for \( Y \) affine. Then \( X = \bigcup U_i \) is a finite union of affine schemes. Now take \( X' = \bigsqcup U_i \), then there are maps \( X' \xrightarrow{f'} X \rightarrow Y \). Then \( \mathcal{O}_X \) is a subsheaf of \( f'_*\mathcal{O}_X \). So \( \mathcal{I} = \ker(\mathcal{O}_Y \to f_*f'_*\mathcal{O}_X) \). Now \( f \circ f' \) is qcqs, thus by (5.5.1.6), \( f_*f'_*\mathcal{O}_X \) is Qco, thus also \( \mathcal{I} \) is Qco.

2 follows from 1 as the formation of \( \mathcal{I} \) commutes with restriction to open subschemes.

3 follows from 2 as the scheme-theoretical image of empty set is empty. \( \qed \)

**Prop.(5.4.4.65).** If \( f : X \to Y \) is a morphism and \( X \) is reduced, then the scheme-theoretical image of \( f \) is the induced-reduced structure (5.4.1.14) of \( f(X) \subset Y \).

**Proof:** This is clear. \( \qed \)

**Def.(5.4.4.66) [Scheme-Theoretically Dense].** An open subscheme \( U \subset X \) is called **scheme-theoretically dense** if for any open subscheme \( V \) of \( X \), the scheme-theoretical closure of \( U \cap V \) in \( V \) is equal to \( V \).

**Prop.(5.4.4.67).** If the inclusion \( U \to X \) is qc, then \( U \) is scheme-theoretically dense in \( X \) iff the scheme-theoretical closure of \( U \) is \( X \), by (5.4.4.64).

**Prop.(5.4.4.68).** Let \( j : U \to X \) be an open immersion of schemes, then \( U \) is scheme-theoretically dense in \( X \) iff \( \mathcal{O}_X \to j_*\mathcal{O}_U \) is injective.

**Proof:** If it is not injective, then we can find an open subscheme \( V \) of \( X \) that the kernel is non-zero, thus it contains a non-zero Qco ideal sheaf, which means the scheme-theoretical closure of \( U \cap V \) is not \( V \). \( \qed \)

**Cor.(5.4.4.69).** If \( U, V \) are open subschemes of \( X \) scheme-theoretically dense in \( X \), then \( U \cap V \) is also scheme-theoretically dense in \( X \).

**Proof:** \( \mathcal{O}_X \to \mathcal{O}_X(U) \to \mathcal{O}_X(U \cap V) \) is injective. \( \qed \)

**Prop.(5.4.4.70) [Scheme-Theoretical Image of Immersions].** Let \( f : Z \to X \) be an immersion and either \( f \) is qc or \( Z \) is reduced. Let \( Z \) be the scheme-theoretically image of \( f \), then the morphism \( Z \to Z \) is an open immersion that identifies \( Z \) with a scheme-theoretical dense open subscheme of \( Z \), and also \( Z \) is dense in \( Z \).

**Proof:** Cf. [Sta]01RG. \( \qed \)

**Prop.(5.4.4.71) [Immersion to be Closed].** An immersion \( f \) is a closed immersion iff the image is closed.

**Proof:** Let \( i : Y \to U \) be a closed immersion where \( j : U \subset X \) is an open subscheme, then \( i \) is associated to an ideal sheaf \( \mathcal{I} \) of \( \mathcal{O}_U \). Now because \( \mathcal{I}|_{U \setminus j(Y)} = \mathcal{O}_{U \setminus j(Y)} \), we can glue \( \mathcal{I} \) and \( \mathcal{O}|_{X \setminus j(Y)} \) to a sheaf of ideals \( \mathcal{J} \subset \mathcal{O}_X \). Now \( j^*\mathcal{O}_X/\mathcal{J} = \mathcal{O}_U/\mathcal{I} \cong i_*\mathcal{O}_Y \), thus \( \mathcal{O}_X \to f_*\mathcal{O}_Y = j_*j^*(\mathcal{O}_X/\mathcal{J}) \) is surjective, because \( \mathcal{O}_U/\mathcal{I} \) is supported on a closed subset of \( U \). Thus \( f \) is a closed immersion by (5.4.4.57). \( \qed \)

**Prop.(5.4.4.72) [Immersions are Monomorphisms].** An immersion is a monomorphism.

**Proof:** It is easy to check (5.4.4.5) for both open and closed immersions. \( \qed \)
Prop. (5.4.4.73) [Equivalent Definitions of Closed Immersion]. The following are equivalent for a morphism $f$:

- $f$ is a closed immersion.
- $f$ is a proper monomorphism.
- $f$ is proper, unramified and u.i..
- $f$ is a u.c., unramified monomorphism.
- $f$ is u.c., unramified and u.i..
- $f$ is u.c., locally of f.t. and a monomorphism.
- $f$ is u.c., locally of f.t. and formally unramified.

Proof: $4-7$ are equivalent by (5.6.5.13). For the rest, Cf. [Sta], 04XV.

Universal Homeomorphism

Prop. (5.4.4.74). A morphism is a universally homeomorphism iff it is integral, surjective and universally injective.

Proof: A universally homeomorphism is affine by (5.4.4.15). It is clearly u.c, so it is integral by (5.4.4.39). Conversely, it is integral hence u.c, and universally bijective, so it is universally homeomorphism.

Cor. (5.4.4.75). The reduction $X_{\text{red}} \to X$ is a universal homeomorphism, as closed immersion is u.c.

Separatedness

Def. (5.4.4.76) [Separatedness]. A map $f : X \to Y$ is called separated if the diagonal $\Delta : X \to X \times_Y X$ is a closed immersion. It is called quasi-separated if the diagonal is quasi-compact.

In fact $\Delta$ is always an immersion because maps between affine scheme is separated so $\Delta(X)$ is closed in $\bigcup U_{ij} \otimes_{V_i} U_{ij}$ where $U,V$ are affine open, hence it suffice to check the image is closed.

Prop. (5.4.4.77). (Quasi-)Separatedness is local on the target because closed immersion and quasi-compact is local on the target (5.4.1.5).

(Quasi-)Separatedness satisfies base change trick by (5.4.4.2).

Prop. (5.4.4.78) [Graph]. By (3.1.1.50), for $X \to S$ and $Y \to S$, the map $X = X \times_Y Y \to X \times_S Y$ is an immersion. It is closed immersion if $Y \to S$ is separated, and it is qc if $Y \to S$ is quasi-separated.

Cor. (5.4.4.79). for $X \to Y$ is a morphism of schemes over $S$, the map $X = X \times_Y Y \to X \times_S Y$ is an immersion. It is closed immersion if $Y \to S$ is separated, and it is qc if $Y \to S$ is quasi-separated.

Cor. (5.4.4.80). If $s : S \to X$ is a section of $f : X \to S$, the above proposition applies to this case, because $S = S \times_X X \to S \times_S X = X$.

Prop. (5.4.4.81) [Characterization of Separatedness]. A morphism is quasi-separated iff for any two affine open that mapped into an affine open, their intersection is quasi-compact. This is because quasi-compact is local on the target.

A morphism is separated iff for any two affine open that mapped into an affine open, their intersection is affine and $\mathcal{O}(U) \otimes_{\mathcal{O}(W)} \mathcal{O}(V) \to \mathcal{O}(U \cap V)$ is surjective. This is because closed immersion is local on the target (5.4.1.5).
578  CHAPTER 5. ALGEBRAIC GEOMETRY I: SCHEME THEORY

Cor. (5.4.4.82). A locally Noetherian scheme is quasi-separated.

Cor. (5.4.4.83). If \( g \circ f \) is (quasi-)separated, then so is \( f \).

Cor. (5.4.4.84). If \( X \) is (quasi-)separated, then \( X \to Y \) is (quasi-)separated.

Prop. (5.4.4.85) [Injective Maps are Separated]. Injective maps of schemes are separated.

Proof: Let \( f : X \to Y \) be an injective map. Firstly \( X \times_Y X \) is a union of affine subschemes of the form \( U \times_Y U \) where \( U, V \) are affine and \( f(U) \subset V \); let \( z \in X \times_Y X \), then \( \pi_1(z) = \pi_2(z) \), because they map to the same point in \( Y \), thus we can choose affine nbhds \( U, V \) of \( \pi_1(z) \) and \( f(\pi_1(z)) \). Now for each of these \( U \times_Y U \), \( \Delta : U \to U \times_Y U \) is closed immersion, thus \( \Delta_X \) is also closed immersion (5.4.1.5). \( \square \)

Cor. (5.4.4.86). monomorphisms are separated because they are universal injective (5.4.4.4), and immersions are separated.

Prop. (5.4.4.87). (Quasi-)Affine morphism is separated (Check closed immersion directly).

Prop. (5.4.4.88). if \( f : X \to S \) is affine, \( h : Y \to S \) is separated, and \( g : X \to Y \) is a morphism over \( S \), then \( g \) is affine.

Proof: Decompose \( g \) as \( X \to X \times_S Y \to Y \), where the first map is base change of \( \Delta_Y \) and the second map is base change of \( f \), so they are both affine. \( \square \)

Prop. (5.4.4.89) [Scheme-Theoretic Equalizer]. If \( X, Y \) are schemes over \( S \) and \( a, b : X \to S \) are morphisms, then there is a largest locally closed subscheme \( Z \) of \( X \) that \( a|_Z = b|_Z \). And if \( Y/S \) is separated, \( Z \) is a closed subscheme of \( X \).

Proof: By definition, \( Z \) should be the fibered product:

\[
\begin{align*}
Z & \longrightarrow X \\
\downarrow & \downarrow^{(a,b)} \\
Y & \Delta_Y \times_S Y
\end{align*}
\]

then the theorem follows from the definition and base change trick of locally closed morphisms. \( \square \)

Prop. (5.4.4.90) [Qsqc Lemma]. Let \( X \) be a qcqs scheme and \( s \in \Gamma(X, \mathcal{O}_X) \), then there is a natural isomorphism \( \Gamma(X, \mathcal{O}_X)_s \cong \Gamma(X_s, \mathcal{O}_X) \).

Proof: Firstly this is true for \( X \) affine by definition (5.2.7.1). In general, let \( U_i \) be an affine open cover of \( X \) that \( U_i \cap U_j = \cup_{k=0}^c U_{ijk} \) be a finite cover by affine opens, then there is an exact sequence

\[
\Gamma(X, \mathcal{O}_X) \to \prod_i \Gamma(U_i, \mathcal{O}_X) \to \prod_{ijk} \Gamma(U_{ijk}, \mathcal{O}_X).
\]

Then we can take localization by \( s \) to get an exact sequence

\[
\Gamma(X, \mathcal{O}_X)_s \to \prod_i \Gamma(D(s, U_i), \mathcal{O}_X)_s \to \prod_{ijk} \Gamma(D(s, U_{ijk}), \mathcal{O}_X)_s.
\]

but \( D(s, U_i) \) is an open cover of \( X_s \) with \( D(s, U_i) \cap D(s, U_j) = \cup_k D(s, U_{ijk}) \), thus we get a natural isomorphism \( \Gamma(X, \mathcal{O}_X)_s \cong \Gamma(X_s, \mathcal{O}_X) \). \( \square \)
5 Proper & Projective

Prop.(5.4.5.1)[Proper]. A morphism that is separated, of finite type and universally closed is called proper.

Properness is local on the target, because all these three properties do(5.4.1.5). Properness satisfies the base change trick(5.4.4.2).

Prop.(5.4.5.2). The class of proper morphisms satisfies the base change trick(5.4.4.1), by valuation criterion(5.4.5.13) and fibered products tricks.

Proof: Closed immersion is proper because it is f.t. and is affine so separated(5.4.4.76), and it is universally closed because immersions are stable under base change(5.4.4.60). □

Prop.(5.4.5.3)[Image of Proper Map]. If \( f : X \to Y \) is morphism between separated schemes f.t over \( S \), then if \( X \) is proper, then \( f \) is proper(by base change trick) thus the image is closed, and is proper over \( S \) in its scheme-theoretic structure.

Proof: Notice proper is qc, so by(5.4.4.62), the scheme-theoretic closure has the same underlying space as the image. Then use(5.4.4.8) to show it is u.c.. □

Cor.(5.4.5.4)[Connected Proper to Affine Constant]. A morphism from a connected proper scheme to an Noetherian affine scheme \( \text{Spec} A \) is constant.

Proof: Because the image is proper, by(5.7.4.12), the global section of its image is a finite module over \( k \) thus Artinian(4.1.3.4) so has finitely many points and is discrete. But \( X \) is connected, thus it is constant. □

Prop.(5.4.5.5)[Chevalley]. Let \( f : X \to Y \) be a morphism of schemes, the following are equivalent:

- \( f \) is finite.
- \( f \) is proper and affine.
- \( f \) is proper with finite fibers.
- \( f \) is proper and locally quasi-finite.
- \( f \) is separated, u.c., locally of f.t. and has finite fibres.

Proof: The fiber of \( f : X \to S \) is \( \text{Spec}(k(y) \otimes_A B) \), which is Artinian(4.1.3.4), so it has finitely many primes and they are all closed. Finite morphism is proper because it is integral(5.4.4.39).

The converse follows from Zariski’s main theorem(5.4.4.49).

Cf.[Sta]02LS. □

Cor.(5.4.5.6)[Quasi-Affine+Proper imply Affine]. Let \( f : X \to \text{Spec} A \) be a quasi-affine and proper map, then \( f \) is affine.

Proof: This follows from(5.7.2.8)(5.4.4.20) and the fact \( H^p(X, \mathcal{O}_X) = 0 \) for \( p > 0 \). □

Prop.(5.4.5.7)[Quasi-Finite+Proper Imply Finite]. Let \( f : X \to S \) be a proper morphism of schemes and \( s \in S \) that \( f^{-1}(s) \) is a finite set, then there exists a nbhd \( V \) of \( s \in S \) that \( f^{-1}(V) \to V \) is finite.

Proof: By(5.4.4.46), \( f \) is quasi-finite at the points of \( f^{-1}(s) \). By(5.4.4.48) the set \( U \) of points that \( f \) is quasi-finite is open. Denote \( Z = X \setminus U \), then \( f(Z) \) is closed in \( S \) and doesn’t contain \( s \). Then \( V = S \setminus f(Z) \) satisfies the requirement by(5.4.5.5). □
**Prop. (5.4.5.8) [Generically Finite + Proper Imply Finite]**. Let $f : X \to S$ be a proper morphism of locally Noetherian schemes and $y \in Y$ satisfies $\dim \mathcal{O}_{Y,y} \leq 1$, and if one of the following holds:

- For every generic point $\eta$ of $X$ s.t. $f(\eta)$ generalizes $y$, $k(\eta)/k(f(\eta))$ is algebraic.
- $f$ is quasi-finite at every generic point of $x$.
- $f$ is quasi-finite on a dense subset of $X$.

then there exists an open nbhd $V$ of $y \in Y$ s.t. $f^{-1}(V) \to V$ is finite.

**Proof**: Cf. [Sta]0AB7.

**Prop. (5.4.5.9)**. If $X$ is a separated scheme over a field $k$ of dimension $> 0$ and $x \in X$ is a closed point, then $X \setminus \{x\}$ is not proper over $k$.

**Proof**: Cf. [Sta]0A24.

**Def. (5.4.5.10) [Modification and Alteration]**. A modification of $X \in \text{Sch}$ is a scheme $X'$ together with a proper birational map $X' \to X$.

A alteration of $X$ is a scheme $X'$ together with a proper dominant morphism $f : X' \to X$ that for some non-empty open $U$ of $X$, $f^{-1}(U) \to U$ is finite.

**Prop. (5.4.5.11)**. Let $Y \to X \in \text{Sch}$ be an alteration, then it can be decomposed into $Y \to W \to X$ where $Y \to X$ is a modification and $W \to X$ is finite surjective.

**Proof**: ?

**Valuation Criteria**

**Lemma (5.4.5.12) [Valuation Criteria Lemma]**. If $X$ is a scheme and $x \to y$ is a specialization of pts, then for any field extension $K/k(x)$, there is a valuation ring $A \subset K$ and a morphisms $\text{Spec} A \to X$ that maps the generic pt $\eta$ to $x$ and the unique closed pt to $y$.

Moreover, if $X$ is locally Noetherian, then $A$ can be chosen to be a DVR.

**Proof**: There is a morphism $\mathcal{O}_{X,y} \to k(x) \to K$, so there is a valuation ring $A$ with field of fractions $K$ that dominate the image of $\mathcal{O}_{X,y}$ by (10.3.2.1), which is also a local ring (4.1.1.9). Then this is what we desire.

For the locally Noetherian case, add (10.3.3.7).

**Prop. (5.4.5.13) [Valuation Criteria]**. The valuation criterion for $\text{Spec} K \to \text{Spec} R$ where $R$ is a valuation ring with field of fractions $K$: Given a morphism $f : X \to S$,

1. If it is qc, then it is universally closed iff there is at least one lifting.

2. it is separated iff it is quasi-separated and there is at most one lifting.

3. it is proper iff it is finite type, quasi-separated and lifting exists uniquely.

Moreover, if $S$ is locally Noetherian and $f$ is locally of f.t., then it suffices to check for discrete valuation rings. **Proof**:

1. Firstly, in this case, by (5.4.4.9), it suffices to prove that: specializations lift along any base change of $f$ iff it has at least one lifting. If specializations lift along any base change of $f$, change $S$ to $\text{Spec} A$ and $X$ to $X \times_S \text{Spec} A$. Let $x'$ be the image of $\text{Spec} K \to X$, then by hypothesis there is a specialization $x' \to x$ where $x$ maps to the closed pt of $\text{Spec} A$. Then we
get a map \( A \to \mathcal{O}_{X,x} \to k(x') \to K \), which is exactly the quotient map \( A \to K \). So the image of \( \mathcal{O}_{X,x} \) in \( K \) dominates \( A \), which means it is just \( A \). Thus we get a map \( \mathcal{O}_{X,x} \to A \), which gives a map \( \text{Spec } A \to X \) that commutes \( \text{Spec } K \).

Conversely, if \( f \) has at least one lifting, then any base change of \( f \) also has at least one lifting by categorial reason. Thus it suffices to show specializations lift along \( f \). Let \( s' \to s \) be a specialization in \( S \) and \( x' \in X \) maps to \( s' \), we can apply (5.4.5.12) to \( k(s') \subset k(x') = K \), then we get a lifting diagram, and the image of the closed pt of \( \text{Spec } A \) under the lifting is a point mapping to \( s \).

2. If it is separated, then if there are two lifting, then consider their equalizer, it is a closed subscheme of \( \text{Spec } A \) by (5.2.7.18), and it contains the generic pt, so it equals \( \text{Spec } A \), as desired.

Conversely, if there are at most one lifting, then we want to prove the diagonal is closed. But by (5.4.4.76) and (5.4.4.71) and the valuation criterion for u.c., it suffices to prove the existence of a lifting for the diagonal map (5.4.5.13). But in fact, a valuation digram for the diagonal correspond to two lifting of a valuation criterion for \( X \to S \), then they are the same, and \( \text{Spec } A \to X \times_S X \) lifts along the diagonal.

3. follows from the above two.

\[ \square \]

**Prop. (5.4.5.14) [Extension of Rational Maps]**. Let \( X, Y \) be schemes over \( S \), \( X \) is locally Noetherian and \( Y/S \) is proper. If there is a morphism from an open subset \( U \) of \( X \) to \( Y \), and there is a point \( x \) in the closure of \( U \) with the stalk being a valuation ring, then the morphism can be extended to an open set containing \( x \).

**Proof**: We can replace \( X \) by an affine open nbhd of \( X \). By (4.4.6.1), we assume \( X \) is affine and \( \Gamma(X, \mathcal{O}_X) \subset \mathcal{O}_{X,x} \). In particular \( X \) is integral with generic pt \( \xi \) with residue field \( K \). Then \( U \) contains \( \xi \). By the valuation criterion (5.4.5.13), the morphism \( \text{Spec } K \xrightarrow{\xi} U \to Y \) can be lifted to a morphism \( \text{Spec } \mathcal{O}_{X,x} \to Y \), thus lemma (5.4.6.2) shows there is a morphism on a nbhd \( V \) of \( X \) spreading this morphisms.

Now because \( Y/S \) is separated, the equalizer of this morphism and \( f \) on their intersection is a closed subscheme by (5.4.4.89), but it contains \( \xi \), so they coincide on the intersection, so we are done. \[ \square \]

**Prop. (5.4.5.15) [Singularity in Codimension 1]**. Let \( \varphi : X \to X' \) be a rational map of a locally Noetherian scheme \( X/K \) regular in codimension 1 to a proper scheme \( X'/K \) with maximal domain \( U \), then

\[ \text{codim}(X \setminus U, X) \geq 2. \]

In particular, if \( X \) is non-singular curve, then \( \varphi \) is a morphism.

**Proof**: Use (5.4.5.14), noticing that the stalk at a point of codimention 1 is a DVR (4.3.5.20). \[ \square \]

**Projective Morphism**

**Def. (5.4.5.16) [Projective Morphism]**. A projective morphism \( X \to Y \) is a closed immersion \( X \to \text{Proj}(\mathcal{E}) \) for some \( \mathcal{O}_Y \)-f.t. module \( \mathcal{E} \) over \( Y \).

An \( H \)-projective morphism \( X \to Y \) is a closed immersion \( X \to \mathbb{P}_Y^n \).
An $H$-quasi-projective morphism is a $H$-projective morphism composed with a quasi-compact open immersion.

A locally projective morphism $f : X \to Y$ is a morphism $f$ that there exists a covering $U_i$ of $Y$ that $f^{-1}(U_i) \to U_i$ is projective.

Some proposition about projective is written before the language of Hartshorne so I may not have changed them to the more general notion of projectiveness yet.

**Prop. (5.4.5.17).** For a morphism $f : X \to S$, the following are equivalent:

- $f$ is locally projective.
- There is a covering $U_i$ of $S$ that $f^{-1}(U_i) \to U_i$ is $H$-projective.

**Proof:** Clearly 2 implies 1, and for the converse, it suffices to show that projective morphism is locally $H$-projective. Locally on each affine open nbhd $U = \text{Spec } R$, $X_U$ is isomorphic to a closed subscheme of $P(\mathcal{E})$ for some f.t. $\mathcal{E}$ of $\mathcal{O}_U$-modules. Write $\mathcal{E} = \hat{M}$ for some f.t. $R$-module $M$, which induces a surjection of graded $R$-algebra $R[x_0, \ldots, x_n] \to \text{Sym}_R(M)$, then the corresponding morphism $P(\mathcal{E}) \to \mathbb{P}^n$ is a closed immersion, so $f^{-1}(U)$ is a $H$-projective scheme over $U$. □

**Prop. (5.4.5.18).** $H$-(quasi-)projectiveness is stable under base change and composition. (because Segre embedding is closed). Disjoint union of f.m. projective morphisms is projective (embed into the Segre embedding).

**Proof:** [Sta]01WE. □

**Cor. (5.4.5.19) [Projective Maps are Proper].** Projective morphisms are locally projective and locally projective morphisms are proper. Thus a quasi-projective morphism is locally of f.t. and separated (5.4.4.86).

**Proof:** Because locally projective and proper are both local on the base (5.4.4.2), it suffices to show that $H$-projective morphism is proper by (5.4.5.17).

Because properness satisfies base change trick (5.4.4.2), it suffices to show $\mathbb{P}^n_S \to S$ is proper. Also this is base change of $\mathbb{P}^n_Z \to Z$, it suffices to check this one. $\mathbb{P}^n_Z$ is clearly separated by (14.5.3.20) (looking at the natural affine covering), and qc. Finally we show it is u.c. using valuation criterion (5.4.5.13):

\[
\begin{array}{ccc}
\text{Spec } K & \longrightarrow & X \\
\downarrow & & \downarrow \\
\text{Spec } R & \longrightarrow & \text{Spec } Z \\
\end{array}
\]

Let $\varphi : k(\xi_1) \to K$. Let $f_{ij}$ be the image of $x_i/x_j$ under $\varphi$, and choose $k$ which $f_{k0}$ has the minimal valuation, then $f_{ik} \in R$ for any $i$, which means the there is a map

\[
\mathbb{Z}[x_0/x_k, \ldots, x_n/x_k] \to R
\]

compatible with $\varphi$, or equivalently a map $\text{Spec } R \to D(x_k) \subset X$ commuting the diagram. □

**Prop. (5.4.5.20) [Descent for Projectiveness].** Let $X$ be a scheme over a field $k$, and $K/k$ is a field extension, then $X_K$ is (quasi-)projective iff $X_K$ is (quasi-)projective.

**Proof:** This follows from (5.5.4.19) and f.f. descent. □
Prop. (5.4.5.21). $H$-Projective scheme over Spec $A$ is of the form Proj $S$ where $S_0 = A$ and $S$ is f.g over $S_0$ by $S_1(5.5.2.11)$.

Proof: □

Prop. (5.4.5.22) [Projective Morphisms and Closed Embeddings]. Let $k$ be an alg.closed field and $\pi : X \to Y$ is a projective morphism of algebraic schemes over $k$ that is injective on closed points and injective on tangent vectors at closed points, then $\pi$ is a closed embedding.

Proof: Cf. [Vak17]P506. □

Prop. (5.4.5.23) [Chow’s Lemma]. Let $X \to S$ be separated of f.t over a qcqs $S$, then there is a birational, H-projective map $\pi : X' \to X$ over $S$ that $X'$ is quasi-projective over $S$.

If $X$ is proper, then $X'$ is projective over $S$. And if $X$ is integral/irreducible/reduced over $S$, $X'$ can also be chosen to be so.

Proof: We only prove for $S$ Noetherian, for the general case, Cf. [Sta]0203.

In this case all schemes here are Noetherian. Suppose $X_i, i \le r$ are irreducible components of $X$ with generic points $\eta_i$, by (5.4.6.5) and the fact $X$ is qc we can find a finite affine cover $X = \cup U_i$ that each $U_i$ contains all the generic points of $X$, thus $U = U_1 \cap \ldots \cap U_n$ is dense in $X$. Let $X^*$ be the schematic-closure of $U$ in $X$, and $U_i^* = U_i \cap X^*$, then we may replace $X$ by $X^*$ and assume that $U$ is schematically dense in $X$ by (5.4.4.67) as $X$ is qs. By (5.5.4.22) and (5.4.4.19), there are immersions $U_i \to \mathbb{P}_{S_i}^{n_i}$ together with a closed subscheme $Z_i \subset \mathbb{P}_{S_i}^{n_i}$ that $U_i \to Z$ is a scheme-theoretically dense open immersion (5.4.4.70).

Consider the map $(j_1, \ldots, j_m) : U \to \mathbb{P}_{S_i}^{n_i} \times \ldots \times \mathbb{P}_{S_i}^{n_m}$ with scheme-theoretic image $Z$, and the commutative diagrams

$\begin{array}{c}
\mathbb{P}_{S_i}^{n_i} \times \ldots \times \mathbb{P}_{S_i}^{n_m} \\
\downarrow \pi_i \\
\mathbb{P}_{S_i}^{n_i}
\end{array}$

which induces a map $p_i : Z \to Z_i(5.4.4.63)$ which is proper.

Consider $p_i^{-1}(j_i(U_i)) = V_i$ and $X' = \cup_i V_i$ which is an open subscheme of $Z \subset \mathbb{P}_{S_i}^{n_i} \times \ldots \times \mathbb{P}_{S_i}^{n_m}$ thus quasi-projective over $S$.

Finally, we prove that the morphism $p_i : V_i \to U_i$ glue together to a proper birational morphism $\pi : X' \to X$; this is because they are compatible on $U$, which is scheme-theoretically dense in $V_i$ for each $i$ thus also also scheme-theoretically dense in $V_i$ and $V_j$, thus $p_i$ and $p_j$ are compatible on $V_i \cap V_j$ as the target $X$ is separated over $S$.

To show $\pi$ is proper, firstly notice $\pi^{-1}(U_i) = V_i$; there are decompositions $V_i \to \pi^{-1}(U_i) \to U_i$, where $V_i \to U_i$ is proper, thus $V_i \to \pi^{-1}(U_i)$ is also proper and $V_i$ is schematically dense in $\pi^{-1}(U_i)$ because it contains $U_i$, so it is and isomorphism.

For the same reason $U \to \pi^{-1}(U)$ is an isomorphism. Finally $\pi$ is projective because it factors through some map $X' \to X \times_S \mathbb{P}_S^{n_i} = \mathbb{P}_X^2$ and it is proper.

If $X$ is reduced, then $X'$ is reduced by (5.4.4.65), and if $X$ is irreducible, then $X' = Z$ is the closure of $j(X)$ by (5.4.4.70), which is irreducible. □
6 Technical Lemmas

Lemma (5.4.6.1). Let $X$ be a scheme and $x$ a point, then there exists an open affine nbhd $U$ of $x$ that $\mathcal{O}_X(U) \to \mathcal{O}_{X,x}$ is injective, if any of the follows holds:

- $X$ is integral.
- $X$ is locally Noetherian.
- $X$ is reduced with f.m. irreducible components.

Proof: This problem is clearly local hence follows from the algebra case (4.1.1.34).

Lemma (5.4.6.2) [Spread Out Stalk Morphism]. Let $X, Y$ be schemes over $S$, $s \in S$ and $x, y$ be pts over $S$, then:

- Let $f, g : X \to Y$ be morphisms over $S$ that $f(x) = g(x) = y$ and $f^*_x = g^*_x$, then $f = g$ on a nbhd $U$ of $x$ if any of the following holds:
  - (a) $Y \leftarrow S$ is locally of f.t..
  - (b) $X$ is integral.
  - (c) $X$ is locally Noetherian.
  - (d) $X$ is reduced with f.m. irreducible components.

- Let $\varphi : \mathcal{O}_{Y,y} \to \mathcal{O}_{X,x}$ be a local ring map over $\mathcal{O}_{S,s}$, then there is a morphism $f$ from a nbhd $U$ of $x$ mapping to $Y$ that $f(x) = y$, and $f^*_x = \varphi$, if any of the following holds:
  - (a) $Y \leftarrow S$ is locally of f.p..
  - (b) $Y \leftarrow S$ is locally of f.t. and $X$ is integral.
  - (c) $Y \leftarrow S$ is locally of f.t. and $X$ is locally Noetherian.
  - (d) $Y \leftarrow S$ is local of f.t. and $X$ is reduced with f.m. irreducible components.

Proof: Cf. [[Sta]0BX6].

Prop. (5.4.6.3) [Base Change of Fields is Quotient Map]. For any scheme $X$ over a field $k$ and algebraic extensions $K/k$, $X_K \to X$ is a quotient map, as it is surjective (5.6.2.1), continuous and closed (5.4.4.39).

Lemma (5.4.6.4). Let $X$ be a qs scheme and $Z_i$ be a finite set of irreducible components of $X$. Let $\eta_i$ be the generic point of $Z_i$, then there are open affine subsets $\eta_i \in U_i$ that $U_1, \ldots, U_n$ are pairwise disjoint.

Proof: 

Lemma (5.4.6.5). Let $X$ be a qs scheme and $Z_i$ be a finite set of irreducible components of $X$. Let $\eta_i$ be the generic point of $Z_i$ and $x \in X$, then there is an affine open subset of $X$ containing $x$ and $\eta_i$.

Proof: Let $x \in Z_1, \ldots, Z_r$ but $x \notin Z_{r+1}, \ldots, Z_n$, then we can find an arbitrary affine open nbhd $W$ of $x$ that contains $\eta_1, \ldots, \eta_r$ but not $\eta_{r+1}, \ldots, \eta_n$. By (5.4.6.4), we may choose pairwise disjoint affine open nbhds $\eta_{r+1} \in U_{r+1}, \ldots, \eta_m \in U_n$. Now $U_i \cap W$ is quasi-compact and doesn’t contain $\eta_i$, so we can shrink $U_i$ s.t. $W \cap U_i = \emptyset$ by (4.1.7.24). Then $U = W \coprod (\bigcup U_i)$ satisfies the desired condition.
Main references are [Sta] and [Vak17].

5.5 Quasi-Coherent Sheaves on Schemes

1 (Quasi-)Coherent Sheaves

Lemma (5.5.1.1) [Associated Qco Sheaves on Affine Scheme]. On an affine scheme Spec $A$, there is a sheaf $\tilde{M}$, that is $M_f$ on Spec $A_f$. To check it is a sheaf, we only need to check to affine coverings, and this is by (4.4.2.2).

Prop. (5.5.1.2) [Qco Sheaves on Affine Schemes]. $M \mapsto \tilde{M}$ is an equivalence to the category of quasi-coherent sheaves over Spec $A$. In particular,

$$\text{Hom}_A(M, \Gamma(X, G)) \cong \text{Hom}_{\mathcal{O}_X}(\tilde{M}, G),$$

so $M \mapsto \tilde{M}$ commutes with colimits and is exact, and commutes with pullbacks.

When $A$ is Noetherian, this also induces an equivalence between finite $A$-modules and coherent sheaves over Spec $A$, because finiteness for modules is local (5.4.1.5).

Proof: For any $A$-module $M$, there is a sheaf of modules $\mathcal{F}_M$ on $X = \text{Spec } A$ by (5.2.2.26). This is left adjoint to $\Gamma$ and defines a functor from the category of $A$-modules to the category of $\mathcal{O}_{\text{Spec } A}$-modules.

By universal property of $\mathcal{F}_M$ (5.2.2.26), there is a natural map $\mathcal{F}_M \to \tilde{M}$ corresponding to the ring map $M \to \Gamma(\text{Spec } A, M) = M$. The induced maps on the stalk at a point $x$ is $M \otimes_A \mathcal{O}_{X,x} \to M_x$, which is isomorphism, so $\mathcal{F}_M \cong \tilde{M}$.

From the universal property of $\tilde{M} = \mathcal{F}_M$, $\text{Hom}(\tilde{M}, \tilde{N}) = \text{Hom}(M, N)$, thus $\sim$ is fully faithful, to show it is an equivalence, it suffices to show for any Qco sheaf $\mathcal{F}$ on Spec $A$, the natural map $\Gamma(X, \mathcal{F}) \to \mathcal{F}$ is an isomorphism. Cf. [Sta]01IA.

If $0 \to M_1 \to M \to M_2 \to 0$ is exact, then $0 \to \tilde{M}_1 \to \tilde{M} \to \tilde{M}_2 \to 0$ is exact, because localization is exact. □

Prop. (5.5.1.3) [properties of (Quasi-)Coherent Sheaves on Schemes].

- $\mathcal{QCoh}(X)$ and $\mathcal{Coh}(X)$ are weak Serre subcategories of $\text{Mod}_{\mathcal{O}_X}$, and $\mathcal{Coh}(X)$ is a Serre subcategory of $\mathcal{QCoh}(X)$.
- Colimits in $\text{Mod}(\mathcal{O}_X)$ preserve $\mathcal{QCoh}(X)$, because localization is exact.
- Tensor product of two (Q)co sheaf is (Q)co, and locally free if they are locally free. More explicitly, $\tilde{M} \otimes_A \tilde{N} \cong \tilde{M} \otimes_{\mathcal{O}_X} \tilde{N}$ as tensor product commutes with $\pi^*$.
- If $\mathcal{F}$ is Qco, then so does $T(\mathcal{F}), \text{Sym}(\mathcal{F})$ and $\wedge(\mathcal{F})$, by (5.2.3.12).
- Given $\mathcal{F}, \mathcal{G} \in \mathcal{QCoh}(\mathcal{F})$ that $\mathcal{F}$ is f.p., $\text{Hom}(\mathcal{F}, \mathcal{G}) \in \mathcal{QCoh}(X)$, by (5.2.3.2) and (5.5.1.2). More explicitly, affine locally $\text{Hom}_{\mathcal{O}_X}(\tilde{M}, \tilde{N}) = \text{Hom}_A(M, N)$.
- Pullback preserves $\mathcal{QCoh}(X)$ and $\mathcal{Coh}(X)$, by (5.2.2.29). More explicitly, if $\text{Spec } B \subset Y$ is mapped into $\text{Spec } A \subset X$, then $f^*(\mathcal{F})(\text{Spec } B) = \mathcal{F}(\text{Spec } A) \otimes_A B$, using the fact $\tilde{M} = \mathcal{F}_M = \pi^* M$. \

Cf. [Sta]01IA.
Prop. (5.5.1.4) [Qco Sheaves of F.T./F.P]. Let $X = \text{Spec} \ A$ and $\mathcal{F} = \widetilde{\mathcal{M}}$ a Qco sheaf on $X$, then $\mathcal{F}$ is of f.t./f.p. if $M$ is of f.t./f.p. over $A$.

Proof: These follows from the fact finiteness/f.p. are local properties for modules over a ring (4.1.4.4).

Def. (5.5.1.5) [Locally Projective Qco Sheaves]. Let $X$ be a scheme, then a locally projective Qco sheaf is a Qco sheaf $\mathcal{F}$ on $X$ that is affine locally a locally projective module sheaf.

Proof: The question is local so we let $Y$ be affine, and then $X$ is qcqs, so we cover it with affine opens $U_i$ and their intersections are $U_{ijk}$. Then we see by sheaf property

$$0 \to f_\ast \mathcal{F} \to \bigoplus_i f_\ast (\mathcal{F}|_{U_i}) \to \bigoplus_{ijk} f_\ast (\mathcal{F}|_{U_{ijk}})$$

The last two are Qco because two are maps between affine schemes, so the first is Qco.

Prop. (5.5.1.6) [Qcqs Pushforward]. If $f$ is qcqs, then the pushforward of of a Qco sheaf is Qco. (Used in ??).

Proof: The question is local so we let $Y$ be affine, and then $X$ is qcqs, so we cover it with affine opens $U_i$ and their intersections are $U_{ijk}$. Then we see by sheaf property

$$0 \to f_\ast \mathcal{F} \to \bigoplus_i f_\ast (\mathcal{F}|_{U_i}) \to \bigoplus_{ijk} f_\ast (\mathcal{F}|_{U_{ijk}})$$

The last two are Qco because two are maps between affine schemes, so the first is Qco.

Prop. (5.5.1.7) [Qco Sheaves on Qcqs Schemes]. For a qcqs scheme $X$ and $s \in \Gamma(X, \mathcal{O}_X)$, and a Qco module $\mathcal{F}$, $(\Gamma(X, \mathcal{F}))_s \cong \Gamma(X_s, \mathcal{F})$.

Proof: The canonical map $f : X \to \text{Spec} \Gamma(X, \mathcal{O}_X)$ is qcqs, so $f_\ast \mathcal{F}$ is Qco on Spec $\Gamma(X, \mathcal{O}_X)$ by (5.5.1.6). Then the result follows from the fact $f^{-1}(\text{Spec} \Gamma(X, \mathcal{O}_X)_s) = X_s$ and the definition of $f_\ast$.

Lemma (5.5.1.8) [Extending Qco Sheaves]. Let $i : U \to X$ be a quasi-compact open immersion of schemes, $\mathcal{F}$ a Qco $\mathcal{O}_X$-module and $\mathcal{G} \subset \mathcal{F}|_U$ a Qco $\mathcal{O}_U$-submodule, then there exists a Qco $\mathcal{O}_X$-submodule $\mathcal{G}' \subset \mathcal{F}$ that $\mathcal{G}'|_U = \mathcal{G}$.

Proof: Immersion is separated (5.4.4.86), so $i_\ast \mathcal{G}$ is a Qco $\mathcal{O}_X$-sheaf by (5.5.1.6), and it is a submodule of $i_\ast \mathcal{F}$, so the kernel $\mathcal{H} = \ker(\mathcal{F} \oplus i_\ast \mathcal{G} \to i_\ast \mathcal{F})$ is also Qco by (5.5.1.3), and $\mathcal{H} \subset \mathcal{F}$, $\mathcal{H}|_U = \mathcal{G}$.

Prop. (5.5.1.9) [Extending Qco Sheaves of F.T.]. Let $X$ be a qcqs scheme, and $U \subset X$ a qc open subset, $\mathcal{F}$ a Qco $\mathcal{O}_X$-module and $\mathcal{G} \subset \mathcal{F}|_U$ a Qco $\mathcal{O}_U$-submodule of f.t., then there exists a Qco $\mathcal{O}_X$-submodule $\mathcal{G}' \subset \mathcal{F}$ of finite type that $\mathcal{G}'|_U = \mathcal{G}$.

Proof: Let $n$ be the minimal number of affine open subsets $U_i$ that $X = U \cup \bigcup U_i$, by induction on $n$, it suffices to prove for $n = 1$. Thus we may assume $X = U \cup V$ where $U, V$ are affine opens. Now $U \cap V$ is qc because $X$ is qs. Then we can change $(X, U)$ to $(V, U \cap V)$, because we can glue the resulting sheaf. Then we reduce to the case $X$ is affine.

Let $X = \text{Spec} \ R$ and $\mathcal{F} = \widetilde{\mathcal{M}}$, then by (5.5.1.8), there exists a Qco sheaf $\widetilde{N}$ that $\widetilde{N}|_U = \mathcal{G}$. By hypothesis we can cover $U$ by f.m. open affine $D(f_i)$ that $\mathcal{N}_{f_i}$ is f.g., by element $x_{ij}/f_i^{\alpha_i}$. Let $\mathcal{N}'$ be the submodule of $\mathcal{N}$ generated by these elements $x_{ij}$, then $\widetilde{\mathcal{N}}'$ meets our requirement.
Cor. (5.5.1.10) [Qco Sheaf is a Direct Union of Qco Sheaves of F.T.]. Let $X$ be a qcqs scheme, then any Qco sheaf $\mathcal{F}$ on $X$ is a direct colimit of its Qco subsheaves of f.t..

Proof: It is a direct colimit because the sum of two Qco sheaves of f.t. is also Qco of f.t. Now for any affine open $U \subset X$ and $s \in \mathcal{O}_X(U)$, $s$ generates a Qco $\mathcal{O}_U$-submodule of f.t. of $\mathcal{F}|_U$, and by (5.5.1.9) this extends to a Qco $\mathcal{O}_X$-submodule of $\mathcal{F}$. Then we see that the direct colimit of Qco subsheaves of f.t. of $\mathcal{F}$ contains elements of $\mathcal{F}(U)$ for any affine open subset $U$, thus it is just $\mathcal{F}$. □

Def. (5.5.1.11) [Rank of Sheaves]. Let $X$ be a scheme and $\mathcal{F}$ a Qco sheaf on $X$, then the rank of $\mathcal{F}$ at $p \in X$ is $\text{rank}_p(\mathcal{F}) = \dim_k \mathcal{F}_p/\mathfrak{m}_p \mathcal{F}_p$.

Prop. (5.5.1.12) [Maximal Qco Submodule]. For $X$ a scheme and any $\mathcal{O}_X$-module $\mathcal{F}$, there is a Qco submodule of $\mathcal{F}$ maximal among all Qco submodules of $\mathcal{F}$. This is because a direct colimit of Qco sheaves is Qco (5.5.1.3).

Prop. (5.5.1.13) [Integral and Finite Modules]. Let $X$ be a qcqs scheme and $\mathcal{A}$ an integral Qco $\mathcal{O}_X$-submodule, then
- $\mathcal{A}$ is the directed colimits of its finite Qco $\mathcal{O}_X$-modules.
- $\mathcal{A}$ is a direct colimit of finite and finitely presented Qco $\mathcal{O}_X$-modules.

Proof: Cf. [Sta] 0817. □

Def. (5.5.1.14). ?

Associated Points

Def. (5.5.1.15) [Weakly Associated Points]. Let $X \in \text{Sch}$ and $\mathcal{F} \in \mathcal{QCoh}(X)$, then a weakly associated point of $\mathcal{F}$ is the set of points $x \in X$ that $\mathfrak{m}_x \subset \mathcal{O}_{X,x}$ is weakly associated to the module $\mathcal{F}_x$. The set of w.ass points are denoted by $\text{WeakAsso}(\mathcal{F})$. The weakly associated points of $X$ is the weakly associated points of $\mathcal{O}_X$.

Similarly we can stalkwise define the set of associated points of $X$.

Def. (5.5.1.16) [Embedded Points]. Let $X$ be a scheme and $\mathcal{F}$ a Qco sheaf on $X$, then an embedded point of $\mathcal{F}$ is an associated point that is a specialization of another associated point.

Prop. (5.5.1.17) [Properties of Associated Points]. Let $X$ be a scheme and $\mathcal{F}_i$ be Qco sheaves on $X$, then
1. $\text{Ass}(\mathcal{F}) \subset \text{WeakAsso}(\mathcal{F}) \subset \text{Supp}(\mathcal{F})$.
2. If $0 \to \mathcal{F}_1 \to \mathcal{F}_2 \to \mathcal{F}_3 \to 0$ is an exact sequence, then $\text{WeakAss}(\mathcal{F}_1) \subset \text{WeakAss}(\mathcal{F}_2)$, and $\text{WeakAss}(\mathcal{F}_2) \subset \text{WeakAsso}(\mathcal{F}_1) \cup \text{WeakAsso}(\mathcal{F}_3)$.
3. $\text{WeakAss}(\mathcal{F}) = \emptyset$ iff $\mathcal{F} = 0$. 
4. The generic points of $\text{Supp}(\mathcal{F})$ are in $\text{WeakAsso}(\mathcal{F})$. In particular, generic points of $X$ are in $\text{WeakAss}(X)$.

5. If $X$ is locally Noetherian, then $\text{Ass}(\mathcal{F}) = \text{WeakAsso}(\mathcal{F})$.

6. If $X$ is reduced, then $\text{WeakAsso}(X)$ is just the generic points of $X$. In particular, $X$ has no embedded points.

7. If $X$ is locally Noetherian, then an associated point is an embedded point iff it is not a generic point of $\text{Supp}(\mathcal{F})$.

8. If $X$ is locally Noetherian and $\mathcal{F}$ is coherent, then $\mathcal{F}$ has no embedded points iff it satisfies $(S_1)$.

9. If $X$ is locally Noetherian of dimension $\leq 1$, then $X$ is C.M. iff it has no embedded points.

Proof: By (4.2.5.21), these reduces to the affine case, so they follows from

- (4.2.5.13)(4.2.5.16).
- (4.2.5.14).
- (4.2.5.16).
- (4.2.5.16).
- (4.2.5.21).
- (4.2.5.24).
- (4.2.5.23).
- [Sta]031Q.
- [Sta]0BXG.

Prop. (5.5.1.18). Let $X$ be a scheme and $\mathcal{F} \in \mathcal{Q}\mathcal{Coh}(X)$. If $U$ is an open subset of $X$ that contains $\text{WeakAsso}(\mathcal{F})$, then $\Gamma(X, \mathcal{F}) \to \Gamma(U, \mathcal{F})$ is injective.

Proof: If $s \in \Gamma(X, \mathcal{F})$ be a section that restricts to 0 on $U$, let $\mathcal{F}'$ be the subsheaf generated by $s$, then $\text{WeakAss}(\mathcal{F}') \subset \text{WeakAsso}(\mathcal{F})$, but $\text{Supp}(\mathcal{F}') \subset X \setminus U$, thus $\text{WeakAss}(\mathcal{F}') = 0$, so $\mathcal{F}' = 0$ by (5.5.1.17).

Prop. (5.5.1.19) [Schematically Dense and Associated Points]. Let $X$ be a locally Noetherian scheme and $U \subset X$ an open subset, then the following are equivalent:

- $U$ is schematically dense in $X$.
- $U$ is dense in $X$ and contains all the embedded points of $X$.
- $U$ contains $\text{Ass}(X)$.

Proof: The problem is local, so we assume $X = \text{Spec} A$, then 2, 3 are clearly equivalent.

Let $U = \bigcup_i D(f_i)$, then by (5.4.4.64), $U$ is schematically dense in $A$ iff $A \to \prod A_{f_i}$ is injective. If $p = \text{Ann}(x)$ for some $x \in A$, then $x$ maps to some non-zero element of $A_{f_i}$, then $f_i \notin p$, so $p \subset D(f_i) \subset U$. Conversely, if $\text{Ass}(X) \subset U$, then every map $A \to A_p$ factors through $A \to A_{f_i}$ for some $i$, so injectivity of $A \to \prod_{p \in \text{Ass}(X)} A_p$ implies injectivity of $A \to \prod_{i} A_{f_i}$.

Prop. (5.5.1.20). Let $X$ be a scheme and $\varphi: \mathcal{F} \to \mathcal{G} \in \mathcal{Q}\mathcal{Coh}(X)$ that $\mathcal{F}_x \to \mathcal{G}_x$ is injective for any $x \in \text{WeakAss}(\mathcal{F})$, then $\varphi$ is injective.
Proof: The hypothesis says $\text{WeakAss}(\ker(\varphi)) = 0$, so $\ker(\varphi) = 0$ by (5.5.1.17).

Fitting Ideals

Def. (5.5.1.21) [Fitting Ideals]. Let $X \in \text{Sch}$ and $F \in \mathcal{Q}\text{Coh}^\text{ft}(X)$, the fitting ideal of $F$ is defined to be $\text{fit}$.

Locally Free Sheaves

Prop. (5.5.1.22) [Locally Free is Stalkwise]. $F \in \mathcal{Q}\text{Coh}^\text{pf}(X)$ is locally free iff its stalks are all free, by (4.3.1.7).

Def. (5.5.1.23). Let $X \in \text{Sch}$ and $\delta : X \to \mathbb{N}$ a locally constant function, then the category of locally free sheaves of rank $\delta$ is denoted by $\mathcal{C}oh^\text{free}_\delta(X)$. The category of locally free sheaves is denoted by $\mathcal{C}oh^\text{free}(X)$

Prop. (5.5.1.24) [Locally Free Sheaves]. Suppose $0 \to F' \to F \to F'' \to 0$ is an exact sequence of sheaves on a scheme $X$, then

- If $F', F''$ are both locally free, then so is $F$.
- If $F, F'$ are both locally free of finite rank, then so is $F''$.

Proof: Firstly of all in each case all sheaves are Qco by (5.5.1.3).

1: on an affine open $U = \text{Spec } A \subset X$, the exact sequence is induced by $0 \to A' \to \Gamma(U, F) \to A^J \to 0$, so it splits and $\Gamma(U, F) \cong A^{I+J}$ is free.

2: on an affine open $U = \text{Spec } A \subset X$, the exact sequence is induced by $0 \to \Gamma(U, F') \to A^m \to A^n \to 0$, where the map $A^m \to A^n$ is represented by a $n \times m$ matrix $M$. Then $U$ is covered by open subsets $U_i$ that some $n \times n$ minor of $M$ is invertible. Then after a change of coordinates on each subset, $F(U_i) \cong A^{m-n}$.

Prop. (5.5.1.25). For a exact sequence $0 \to F' \to F \to F'' \to 0$ in $\mathcal{Q}\text{Coh}^\text{free}(X)$, there is a filtration of $\text{Sym}^r F$:

$$0 = G^{r+1} \subset G^r \subset \ldots \subset G^0 = \text{Sym}^r F$$

that

$$G^p / G^{p+1} \cong \text{Sym}^p F' \otimes \text{Sym}^{r-p} F''.$$ 

Proof: On any affine open subset, choose a splitting of the exact sequence, then use coordinates.

Prop. (5.5.1.26). For a exact sequence $0 \to F' \to F \to F'' \to 0$ in $\mathcal{C}oh^\text{free}(X)$, there is a filtration of $\wedge^r F$:

$$0 = G^{r+1} \subset G^r \subset \ldots \subset G^0 = \wedge^r F$$

that

$$G^p / G^{p+1} \cong \wedge^p F' \otimes \wedge^{r-p} F''.$$ 

In particular,

$$\wedge^r F' \otimes \wedge^r F'' \cong \wedge^r F.$$ 

and when $F'' \cong L$ is a line bundle, there is an exact sequence

$$0 \to \wedge^r (F') \to \wedge^r (F) \to \wedge^{r-1} (F') \otimes L \to 0$$
Proof: On any affine open subset, choose a splitting of the exact sequence, then use coordinates.

Prop. (5.5.1.27) [Perfect Pairing Wedge Product Sheaf]. Let $\mathcal{F}$ be a locally free sheaf of rank $n$, then there is a perfect pairing $\wedge^n \mathcal{F} \otimes \wedge^{n-r} \mathcal{F} \to \wedge \mathcal{F}$ which is a perfect pairing, i.e. it induces an isomorphism $\wedge^n \mathcal{F} \cong (\wedge^{n-r} \mathcal{F})^\vee \otimes \wedge \mathcal{F}$.

Proof: The map is natural, and the isomorphism can be seen at the level of stalks, by (5.2.3.11).

Prop. (5.5.1.28). Let $0 \to \mathcal{F} \to \mathcal{G} \to \mathcal{H} \to 0$ is an exact sequence in $\mathcal{QCoh}(X)$ where $\mathcal{H}$ is a locally free sheaf, then for any $\mathcal{Qco}$ sheaf $\mathcal{E}$ of $X$, then for any $\mathcal{Qco}$ sheaf $\mathcal{E}$ on $X$, there is an exact sequence of sheaves

$$0 \to \mathcal{Hom}(\mathcal{H}, \mathcal{E}) \to \mathcal{Hom}(\mathcal{G}, \mathcal{E}) \to \mathcal{Hom}(\mathcal{F}, \mathcal{E}) \to 0.$$  

In particular, $0 \to \mathcal{H}^\vee \to \mathcal{G}^\vee \to \mathcal{F}^\vee \to 0$ is exact.

Proof: As $\mathcal{Hom}(-, \mathcal{E})$ is left exact, it suffices to show the last one is surjective. This is local, so we may assume $0 \to \mathcal{F} \to \mathcal{G} \to \mathcal{H} \to 0$ is $0 \to M \to N \to \mathbb{P}^n \to 0$, so this sequence splits, and the then $\mathcal{Hom}(\mathcal{G}, \mathcal{E}) \to \mathcal{Hom}(\mathcal{F}, \mathcal{E})$ is surjective, by (5.5.1.3).

Prop. (5.5.1.29) [Grothendieck]. Every object in $\mathcal{Coh}^{\text{free},r}(\mathbb{P}^1_k)$ is isomorphic to $\bigoplus_{i=1}^r \mathcal{O}(a_i)$ for a unique non-decreasing sequence of integers $a_1, \ldots, a_r$.

Proof: Use induction on $r$. The $r = 1$ case follows from (5.5.3.16). For a general $r$, let $\mathcal{E} \in \mathcal{Coh}^{\text{free},r}(\mathbb{P}^1_k)$, then $\mathcal{E}(m)$ is generated by global sections for $m$ large as $\mathcal{O}_{\mathbb{P}^1}$ is ample, and $H^0(\mathcal{E}(-m)) = H^1(\mathcal{E}^\vee(m)) = 0$ by Serre duality and (5.7.2.5), so there is a maximal $m$ s.t. there is a non-zero map $\mathcal{O}(m) \to \mathcal{E}$. The image of this map is also locally free and has degree $\geq m$ by (5.11.2.8), so it must have degree $m$ and $\mathcal{O}_X(m) \to \mathcal{E}$ is injective by (5.11.2.8). Now the cokernel $\mathcal{F}$ is also locally free, because otherwise let $\mathcal{F}_{\text{tor}}$ be the torsion part of $\mathcal{F}$ (5.11.2.16), and let $\mathcal{N}$ be the inverse image of $\mathcal{F}_{\text{tor}}$ in $\mathcal{E}$, then it is locally free thus invertible, and $\mathcal{O}(m) \to \mathcal{N}$, so $N = \mathcal{O}(m)$ by (5.11.2.8), and $\mathcal{F}_{\text{tor}} = 0$.

There is an exact sequence

$$0 \to \mathcal{O}(-1) \to \mathcal{E}(-m-1) \to \mathcal{F}(-m-1) \to 0$$

which induces $H^0(\mathcal{E}(-m-1)) = H^0(\mathcal{F}(-m-1)) = 0$ as $H^1(\mathbb{P}_k^1, \mathcal{O}(-1)) = 0$, so by induction hypothesis $\mathcal{F} = \bigoplus_{i=1}^r \mathcal{O}(a_i)$ and $a_i \leq m$. To show this sequence splits, notice $\text{Ext}^1(\mathcal{F}(-m-1), \mathcal{O}(-1)) = \bigoplus_{i=1}^r H^1(\mathcal{O}(m-a_i)) = 0$.

Prop. (5.5.1.30) [Splitting Principal]. Let $X$ be an integral scheme and $\mathcal{E} \in \mathcal{Coh}^{\text{free}}(X)$, then there exists a modification $X' \to X$ s.t. $f^* \mathcal{E}$ has a filtration by invertible sheaves.

Proof: Use induction on rank($\mathcal{E}$). If rank($\mathcal{E}$) $\leq 1$, this is trivial, otherwise let rank($\mathcal{E}$) = $r$, $P = \mathbb{P}(\mathcal{E})$, then $\pi: P \to X$ is proper and there is a canonical surjection $\pi^* \mathcal{E} \to \mathcal{O}_P(1)$, with kernel in $\mathcal{Coh}^{\text{free},r-1}(P)$. Let $U$ be an open subset of $X$ s.t. $E$ is trivial, then $\pi^{-1}(U) \cong \mathbb{P}_U^{r-1}$. Let $s: U \to \mathbb{P}_U^{r-1}$ be a section, and let $X'$ be the scheme-theoretic closure of $U$, which is integral. Then $X' \to X$ is proper and thus a modification. Now $f^* \mathcal{E}$ has an invertible quotient, and we are done by induction hypothesis.
5.5. QUASI-COHERENT SHEAVES ON SCHEMES

Coherent Sheaves

Prop.(5.5.1.31)[Coh(X)]. The category of coherent sheaves on a scheme \( X \) is denoted by \( \text{Coh}(X) \).

When \( \mathcal{O}_X \in \text{Coh}(X) \), \( \text{Coh}(X) = \mathcal{QCo}^\text{ft}(X) \) (5.2.2.28).

In particular when \( X \) is locally Noetherian, \( \text{Coh}(X) = \mathcal{QCo}^\text{ft}(X) \). And the notion of coherence are used usually only when \( X \) is locally Noetherian.

(Quasi-)coherence is an affine local property by (5.2.2.30). \( \mathcal{QCo}(X) \) is an Abelian category, by (5.2.2.28).

Lemma(5.5.1.32). If \( f \) is finite, then \( f_* \) maps coherent sheaves to coherent sheaves.

Proof: This is trivial. \( \square \)

Prop.(5.5.1.33)[Proper Pushforward]. If \( f \) is a proper morphism between locally Noetherian schemes, then \( f_* \) maps coherent sheaves to coherent sheaves.

Proof: Immediate from Grothendieck’s coherence theorem (5.7.4.11). \( \square \)

Prop.(5.5.1.34)[Artin-Rees]. Let \( X \) be a Noetherian scheme, \( \mathcal{F} \) a coherent \( \mathcal{O}_X \)-module, \( \mathcal{G} \) a Qco subsheaf of \( \mathcal{F} \), \( \mathcal{I} \subset \mathcal{O}_X \) a Qco sheaf of ideals, then there exists some \( c > 0 \) that for all \( n \geq c \)

\[ \mathcal{I}^{n-c}(\mathcal{I}^n \mathcal{F} \cap \mathcal{G}) = \mathcal{I}^n \mathcal{F} \cap \mathcal{G}. \]

Proof: Cover \( X \) by f.m. affine open subsets, then this follows from the affine case (4.2.2.13). \( \square \)

Cor.(5.5.1.35)[Vanish Analytically]. Let \( X \) be a Noetherian scheme, \( \mathcal{F} \) a coherent \( \mathcal{O}_X \)-module, for any element \( f \in \bigcap_n \mathfrak{m}_x^n \mathcal{F} \), \( f \) vanishes at a nbhd of \( x \).

Proof: This follows from the intersection theorem (4.2.2.14). \( \square \)

Prop.(5.5.1.36)[Deligne]. On a Noetherian scheme \( X \), let \( \mathcal{F} \) be a Qco sheaf, \( \mathcal{G} \) be a coherent sheaf and \( \mathcal{I} \) be a Qco sheaf of ideals corresponging to \( Z, U = X - Z \), then we have

\[ \lim_{\rightarrow} \text{Hom}_{\mathcal{O}_X}(\mathcal{I}^n \mathcal{G}, \mathcal{F}) \cong \text{Hom}_{\mathcal{O}_U}(\mathcal{G}_|U, \mathcal{F}_|U). \]

In particular,

\[ \lim_{\rightarrow} \text{Hom}_{\mathcal{O}_X}(\mathcal{I}^n, \mathcal{F}) \cong \Gamma(U, \mathcal{F}). \]

Proof: Cf.[Sta]01YB. \( \square \)

Prop.(5.5.1.37)[Kleinmann]. If \( X \) is a Noetherian integral separated locally factorial scheme, then every coherent sheaf on \( X \) is a quotient of a finite locally free sheaf.

Proof: Cf.[Hartshorne P238]. \( ? \)

Prop.(5.5.1.38)[Support of Modules]. For \( X \in \text{Sch} \) and \( \mathcal{F} \in \mathcal{QCo}^\text{ft}(X) \), the support (5.2.2.2) \( \text{Supp}(\mathcal{F}) \) is closed by (5.2.2.24).

For a flat morphism \( f \), \( \text{Supp}(f^*(\mathcal{F})) = f^{-1}(\text{Supp}\mathcal{F}) \), by (5.2.2.18).

Proof: because affine locally, for a set of generators \( x_i \) of \( M \), \( \text{Ann}(\mathcal{F}) = \bigcup \text{Ann}(x_i) \), and \( \text{Ann}(x_i) \) is closed. \( \square \)

Cor.(5.5.1.39). Any coherent sheaf on an integral scheme is locally free over a dense open subset.
Cor. (5.5.1.40) [Geometric Nakayama]. If $\mathcal{F} \in \mathcal{Qcoh}^f(X)$ and for some $p \in U \subset X$ and $a_1, \ldots, a_n \in \mathcal{F}(U)$ generate $\mathcal{F}_p \otimes k(p)$, then there is an affine nbhd $V \subset U$ that $a_1, \ldots, a_n$ generate $\mathcal{F}(V)$.

Cor. (5.5.1.41) [Upper-Semicontinuity of Ranks]. For a Qco sheaf $\mathcal{F}$ of f.t. over $X$, the rank function $p \mapsto \text{rank}_p(\mathcal{F})$ is an upper semicontinuous function on $X$.

**Proof:** By Nakayama, $\varphi(y)$ is equal to the minimal number of generators of the $\mathcal{O}_y$-module $\mathcal{F}_y$. But these generators extends to a nbhd of $y$, so $\varphi \leq n$ on this nbhd. \hfill $\square$

Def. (5.5.1.42) [Schematic Support]. Let $X$ be a scheme and $\mathcal{F}$ a Qco sheaf of f.t. over $X$, then the **annihilating ideal** is the ideal $\mathcal{I} \subset \mathcal{O}_X$ that is affine-locally defined by $\text{Ann}(\mathcal{F}(U)) \subset \mathcal{O}_X(U)$, and the **schematic support** $\text{Supp}(\mathcal{F})$ of $\mathcal{F}$ is the closed subscheme of $X$ corresponding to $\text{Ann}(\mathcal{F})$.

Prop. (5.5.1.43). Let $\mathcal{F}$ be a Qco sheaf of f.t. over a reduced scheme that the rank function $\text{rank}_p(\mathcal{F})$ is locally constant, then it is locally free.

**Proof:** Let $\text{rank}_p(\mathcal{F}) = n$, by (5.5.1.38), for any $x \in X$, there exists an affine nbhd $U = \text{Spec} \ A$ of $x$ and a surjection $f : \mathcal{O}_U^n \to \mathcal{F}_U$. Consider the kernel of $f$. If $(r_1, \ldots, r_n)$ is in the kernel and $r_1 \neq 0$, then $r_1 \notin p$ for some prime $p$ of $A$, as $A$ is reduced. Then $\text{rank}_{x_p}(\mathcal{F}) < n$, contradiction. \hfill $\square$

**Torsion-Free Sheaves**

Def. (5.5.1.44) [Torsion Sheaves]. Let $X$ be an integral scheme, then a **torsion sheaf** is a Qco sheaf that its stalk at the generic point of $X$ vanishes. Equivalently, for any affine open $U \subset X$, $\mathcal{F}(U)$ is a torsion $\mathcal{O}_X(U)$-module.

Prop. (5.5.1.45). Any

Prop. (5.5.1.46). A torsion $\mathcal{O}_X$-module of f.t. on an integral scheme vanish on a dense open subset.

Prop. (5.5.1.47). For $X$ integral, any $\mathcal{F} \in \mathcal{Qcoh}(X)$ factors as $0 \to \mathcal{F}_{\text{tor}} \to \mathcal{F} \to \mathcal{F}_{\text{tf}} \to 0$, where $\mathcal{F}$ is a torsion sheaf (5.5.1.44) and $\mathcal{F}_{\text{tf}}$ is Qco and torsion-free.

Cor. (5.5.1.48). The subpresheaf $U \to \{s \in \mathcal{F}(U) | s_\eta = 0\}$ is a sheaf, and it is also Qco as on an affine open $U \subset X$, it is just $\mathcal{F}(U)_{\text{tor}}$. So the quotient is clearly Qco and torsion-free.

**Devissage of Coherent Sheaves**

Lemma (5.5.1.49). Let $X$ be a Noetherian scheme and $\mathcal{F} \in \mathcal{Coh}(X)$, let $\mathcal{I}$ be a sheaf of ideals that correspond to $Z$, then $\text{Supp}(\mathcal{F}) \subset Z$ iff $\mathcal{I}^n\mathcal{F} = 0$ for some $n$. (This follows easily from Noetherian and (4.2.5.8)).

Lemma (5.5.1.50). Let $X$ be a Noetherian scheme and $\mathcal{F} \in \mathcal{Coh}(X)$ s.t. $\text{Supp}(\mathcal{F}) = Z_1 \cup Z_2$ where $Z_1, Z_2$ are closed, then there is an exact sequence of coherent sheaves $0 \to \mathcal{G}_1 \to \mathcal{F} \to \mathcal{G}_2 \to 0$ that $\text{Supp}(\mathcal{G}_i) \subset Z_i$.

**Proof:** Let $\mathcal{I}$ be the ideal defining the induced reduced structure of $Z_2$, we use the exact sequence $0 \to \mathcal{I}^n\mathcal{F} \to \mathcal{F} \to \text{Coker} \to 0$ and use (5.5.1.49) on $X \setminus Z_2$ to find $n$ large that $\text{Supp}(\mathcal{I}^n\mathcal{F}) \subset Z_1$, and notice Coker has support in $Z_2$. \hfill $\square$
Lemma (5.5.1.51). Let \( X \) be an integral scheme and \( Z \subset X \) an integral closed subscheme with generic point \( \xi \). If \( F \in \text{Coh}(X) \) satisfies \( F_\xi \) is annihilated by \( m_\xi \), then there exists some \( r \geq 0 \) and sheaf of ideals \( I \) on \( Z \) and an injection \( i_*(I^{\oplus r}) \hookrightarrow F \) that is an isomorphism at \( \xi \).

Proof: Cf.[Sta]01YE.

Prop. (5.5.1.52). Let \( X \) be a Noetherian scheme and \( F \in \text{Coh}(X) \), then there is a filtration of coherent sheaves that the quotients are pushforward of ideal sheaves on integral subschemes of \( X \). This is analogous to the filtration in the module case.

Proof: We consider the set of these counterexamples and their \( \text{Supp} \), then use Noetherian induction. The minimal one \( Z \) is irreducible, otherwise from (5.5.1.50) we find a filtration for it. Let the ideal of sheaf of the induced reduced structure of \( Z \) be \( I \), then \( I^nF = 0 \) for some \( n \) by (5.5.1.49), then we may assume \( IF = 0 \). Then we use (5.5.1.51) to finish the proof.

Cor. (5.5.1.53) [Basic Devissage]. Let \( X \) be a Noetherian scheme and \( P \) be a property of coherent sheaves on \( X \) s.t.

1) for an exact sequence of sheaves: \( 0 \to F_1 \to F \to F_2 \to 0 \) if \( F_i \) has \( P \), then \( F \) has \( P \).

2) for any integral closed subscheme \( i : Z \subset X \) and any \( \text{Qco} \) sheaf of ideals \( I \) on \( Z \), \( P \) holds for \( i_*I \).

then \( P \) holds for any coherent sheaf of \( X \).

Lemma (5.5.1.54). Cf.[Sta]01YH.

Prop. (5.5.1.55) [Devissage of Coherent Sheaves I]. Let \( X \) be a Noetherian scheme and \( P \) be a property of coherent sheaves on \( X \) s.t.

1) for an exact sequence \( 0 \to F_1 \to F \to F_2 \to 0 \in \text{Coh}(X) \), if two of them have \( P \), then the third also has \( P \).

2) For every integral closed subscheme \( Z \) of \( X \) with generic point \( \xi \), there is a \( G \in \text{Coh}(X) \) that

(a) \( \text{Supp} G = Z \).
(b) \( G_\xi \cong \mathcal{O}_X/m_\xi \).
(c) \( P \) holds for \( G \).

Then \( P \) holds for every coherent sheaf on \( X \).

Proof: Suppose otherwise, let \( Z \) be the minimal counterexample of item 2 of (5.5.1.55). Then it is easily seen that \( P \) holds for any \( F \) with support strictly contained in \( Z \). Then take \( G \) as in item 2, and let \( 0 \to i_*(I^{\oplus r}) \to G \to \text{Coker} \to 0 \), then \( \text{Supp}(\text{Coker}) \) is strictly contained in \( Z \), and \( r = 1 \) by hypothesis, so \( i_*I \). Then for any other sheaf of ideals \( I' \) on \( Z \), \( I' \) is supported on a smaller subscheme, then it has \( P \), otherwise there are two exact sequences

\[
0 \to i_*I \to i_* (I + I') \to Q \to 0,
\]

\[
0 \to i_*I' \to i_* (I + I') \to Q \to 0,
\]

where \( I, Q \) are supported on smaller subschemes, so \( P \) also holds for \( I' \).

Prop. (5.5.1.56) [Devissage of Coherent Sheaves II]. Let \( X \) be a Noetherian scheme and \( P \) be a property of coherent sheaves on \( X \) s.t.
(1) for an exact sequence of sheaves: \(0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F} \rightarrow \mathcal{F}_2 \rightarrow 0\), if \(\mathcal{F}_i\) has \(P\), then \(\mathcal{F}\) has \(P\).

(2) If \(\mathcal{F}^{\text{tr}}\) has \(P\), then \(\mathcal{F}\) has \(P\).

(3) For every integral closed subscheme \(Z\) of \(X\) with generic point \(\xi\), there is a \(\mathcal{G} \in \text{Coh}(X)\) that

(a) \(\text{Supp}\, \mathcal{G} = Z\).

(b) \(\mathcal{G}_{\xi}\) is annihilated by \(m_{\xi}\).

(c) For every sheaf of ideals \(\mathcal{I}\) on \(X\) that \(\mathcal{I}_{\xi} = \mathcal{O}_{X,\xi}\), there is a Quco subsheaf \(\mathcal{G}' \subset \mathcal{I}\mathcal{G}\) that \(\mathcal{G}'_{\xi} = \mathcal{G}_{\xi}\) and \(P\) holds for \(\mathcal{G}'\).

Then \(P\) holds for every coherent sheaf on \(X\).

Proof: Cf.\([\text{Sta}]01YM\).

\[\square\]

2 Projective Spaces

Prop.(5.5.2.1). For any graded ideal \(I \subset S\), \(V_+(I) = \emptyset\) iff \(S_+ \subset \sqrt{I}\).

Proof: \[\square\]

Def.(5.5.2.2)[Projective Schemes]. For a graded ring \(S\), we have a scheme \(\text{Proj}(S)\) that consists of homogenous primes of \(S\) minus \(S_+\) and the affine cover is \(D(f) = \{p|f \not\in p\}\), and \(\mathcal{O}(D(f)) = \text{Spec}\, S(f)\), where \(S(T)\) is the degree zero part of \(T^{-1}S\). It has \(\mathcal{O}_p = S(p)\).

Proof: Cf.\([\text{Sta}]01M5\)?

\[\square\]

Cor.(5.5.2.3). For any graded ring \(S\), \(\text{Proj}(S)\) is a separated scheme.

Proof: Check that for standard affine opens \(D_+(f)\) and \(D_+(g)\), \(D_+(f) \cap D_+(g) = D_+(fg)\) is affine open, and \(S(f) \otimes \mathbb{Z}\, S(g) \rightarrow S(fg)\) is surjective, which are both clear. \[\square\]

Prop.(5.5.2.4)[Representing Functor of Projective Schemes]. Let \(S\) be a graded ring generated by \(S_1\) over \(S_0\), then \(\text{Proj}(S)\) represents the functor that maps a scheme \(Y\) to the set of pairs \((\mathcal{L}, \psi)\), where \(\mathcal{L}\) is an invertible sheaf on \(Y\), and \(\psi: S \rightarrow \Gamma_+(Y, \mathcal{L})\) is a graded ring homomorphism that \(\mathcal{L}\) is generated by the global sections \(\psi(S_1)\), up to strict equivalences.

Proof: Cf.\([\text{Sta}]01NA\). \[\square\]

Prop.(5.5.2.5)[Associated Quco Sheaves]. Let \(M\) be a graded \(S\)-module, then

- there is a unique Quco sheaf \(\widetilde{M} \in \text{Qcoh}(\text{Proj}(S))\) s.t. \(\Gamma(D_+(f), \widetilde{M}) = M_f\) and the restrictions are compatible with base changes..

- For a point \(x \in \text{Proj}(S)\) corresponding to a homogenous prime not containing \(S_+\), \(\widetilde{M}_x = M_\psi\).

- \(M \mapsto \widetilde{M}\) is an exact functor from the category of graded \(S\)-modules to \(\text{Qcoh}(\text{Proj}(S))\).

- There is a canonical ring map \(S_0 \rightarrow \Gamma(\text{Proj}(S), \mathcal{O}_{\text{Proj}(S)})\) and canonical \(S_0\)-module map \(M_0 \rightarrow \Gamma(\text{Proj}(S), \widetilde{M})\).

Proof: ?

4: This follows from the fact short exact sequences can be checked on stalks, and item2. \[\square\]

Cor.(5.5.2.6). There is a canonical morphism of schemes \(\text{Proj}(S) \rightarrow \text{Spec}\, S_0\).
Prop. (5.5.2.7). If $X \subset \mathbb{P}_k^n$ is a closed subvariety disjoint from a $d$-dimensional subspace $L \subset \mathbb{P}_k^n$, then the projection $\pi : X \to \mathbb{P}^{n-d-1}$ with center $L$ induces a finite map $X \to \pi(X)$.

Proof: Cf.[Shafarovich 1, P63].

Cor. (5.5.2.8). If $F_0, \ldots, F_s$ are forms of degree $m > 0$ on $\mathbb{P}_k^n$ having no common zero on a closed subvariety $X \subset \mathbb{P}^n$, then $\varphi(x) = [F_0(x), \ldots, F_s(x)]$ defines a finite map $\varphi : X \to \varphi(X)$.

Proof: Let $v_m : \mathbb{P}^n \to \mathbb{P}^N$ be the Veronese embedding of degree $m$, then $X \to v_m(X)$ is an isomorphism, and $\varphi$ is a composition of $v_m$ and a projection $\mathbb{P}_k^N \to \mathbb{P}_k^n$, thus it is a finite map, by (5.5.2.7).

Prop. (5.5.2.9) [Tensor and Proj]. For two graded ring with the same $S_0 = A$, Proj($S \times_A T$) $\cong X \times_A Y$, where $(S \times_A T)_n = S_n \times_A T_n$.

Proof:

Def. (5.5.2.10) [Relative Proj]. The relative Proj $S$ over locally Noetherian $Y$ of a Qco graded $\mathcal{O}_Y$-algebra $S$ f.g. over $S_0$ by coherent $S_1$ is the glueing of locally Proj $S$. Proj $S \to Y$ is locally projective thus proper. It is equipped with invertible sheaf $\mathcal{O}(1)$ by glueing.

Prop. (5.5.2.11) [Closed Subscheme of Projective Scheme]. The closed scheme of $X = \mathbb{P}_A^n$ corresponds to the saturated homogenous ideal $I_Y$, (i.e. for any $s$, if there is an $n$ that for any $i, x_i^n s \in I_Y$, then $s \in I_Y$).

So projective scheme over Spec $S_0$ corresponds to Proj $S$, where $S$ are f.g. over $S_0$ by $S_1$ saturated in the sense above.

Proof: A closed immersion is proper, thus the kernel $I_Y$ of the structural map is a Qco (5.5.1.3), so it must be an ideal on every affine open, because Qco is affine local. Then we should use (5.5.3.6), $\Gamma_s(I_Y)$ will suffice. Cf.[Hartshorne Ex2.5.10].

Prop. (5.5.2.12). The global section of a projective space Proj $S \to$ Spec $S_0$ is just $S_0$, this is by (5.5.3.6).

Prop. (5.5.2.13). A quasi-projective scheme $X$ over a field $k$ of dimension $r$ can be covered by $r + 1$ open affine subsets. This is because there are $r$ hyperplane that intersect $X$ non-empty. This can happen by choosing a hyperplane non-intersecting the generic point of $X$, otherwise we choose many hyperplane, then their intersection is empty.

Sheaves on Proj

Def. (5.5.2.14) [Serre Twisting Sheaves]. Let $S$ be a graded ring and $X = \text{Proj}(S)$, there are Qco Serre twisting sheaves $\mathcal{O}_X(n) = \mathcal{S}(n)$. For $\mathcal{F} \in \mathcal{QCoH}(\text{Proj}(S))$, the Serre twisting sheaf of $\mathcal{F}$ is the sheaf $\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{O}_X(n)$.

Prop. (5.5.2.15). Let $S$ be a graded ring and $X = \text{Proj}(S)$,

1. there are canonical maps

$$\mathcal{O}_X(m) \otimes_{\mathcal{O}_X} \mathcal{O}_X(n) \to \mathcal{O}_X(m + n),$$

inducing a map of graded rings $S \to \Gamma_s(X, \mathcal{O}_X) = \oplus_{n \geq 0} \Gamma(X, \mathcal{O}_X(n))$. 
2. For any $\mathcal{F} \in \text{Sh} (\mathcal{O}_X)$, there are canonical maps

$$\mathcal{O}_X (n) \otimes \mathcal{O}_X \mathcal{F} \to \mathcal{F} (n).$$

inducing a map of graded module structure of $\Gamma_*(X, \mathcal{O}_X)$ on $\Gamma_*(X, \mathcal{F}) = \oplus_{n \geq 0} \Gamma_*(X, \mathcal{F} (n))$.

3. There is a canonical map $\Gamma_*(X, \mathcal{F}) \to \mathcal{F}$ that is identity on global sections.

4. For any graded $S$-module $M$, let $M (n) = M \otimes_S S (n)$, there are maps $\tilde{M} (n) \to \tilde{M} (n)$. (Use property of Qco sheaves).

5. For graded rings $M, N$ over $S$, there are canonical maps $\tilde{M} \otimes \mathcal{O}_X \tilde{N} \to \tilde{M} \otimes_S \tilde{N}$.

Proof:

Prop. (5.5.2.16). Let $S$ be a graded ring s.t. $S$ is generated by $S_1$ over $S_0$, then

1. $(M \otimes_S \tilde{N}) (f) \cong M (f) \otimes_{S (f)} \tilde{N} (f)$ for $f \in S_1$.

2. There canonical maps in item 1, 4, 5 of (5.5.2.15) are isomorphisms.

3. For a graded ring map $S \to T$, we have the corresponding Proj map $f : U \to T$ that $f^* (\tilde{M}) \cong (M \otimes_S T) |_U$ and $f^* (\tilde{N}) |_U \cong \tilde{N} |_U$. That’s to say, $f^* (\tilde{M} (n)) = f^* (\tilde{M} (n))$ and $f^* (\tilde{M} (n)) = f^* (\tilde{M} (n))$. □

Proof: 1:

2: By 1 and check locally that tensoring $f^!$ is an isomorphism on $D_+ (f)$. □

Cor. (5.5.2.17). $\mathcal{O}_X (n) \otimes \mathcal{O}_X (m) \cong \mathcal{O}_X (n + m)$ for any scheme $X$ projective over $Y$.

Prop. (5.5.2.18) [Twisting of Proj]. With notation as in (5.5.2.10), Let $S' = S \ast \mathcal{L} ; S'_d = S_d \otimes \mathcal{L}^d$, then $\varphi : \text{Proj} S' \to \text{Proj} S$ is an isomorphism that induces

$$\mathcal{O}' (1) \cong \varphi^* \mathcal{O} (1) \otimes \pi'^* \mathcal{L}.$$

Prop. (5.5.2.19). If $Y$ is Noetherian and admits an ample invertible sheaf, then by definition, we have $S_1 \otimes \mathcal{L}^n$ is base point free for some $n$, thus we have a morphism $\text{Proj} (S \ast \mathcal{L}^n) \to \mathbb{P}_Y^n$, so $P = \text{Proj} S$ is $H$-quasi-projective with $\mathcal{O} (1) = \mathcal{O}_P (1) \otimes \pi^* \mathcal{L}^n$.

Relative Projective Spaces

Def. (5.5.2.20) [Relative Projective Spaces].

Def. (5.5.2.21) [Relative Projective Bundles]. Let $S$ be a scheme, $\pi : V \to S$ is called an Qco vector bundle if it is affine, and $\pi_* \mathcal{O}_V$ endowed with the structure of a graded $\mathcal{O}_S$-algebra structure $\pi_* \mathcal{O}_V = \oplus \mathcal{E}_n$, where $\mathcal{E}_0 = \mathcal{O}_S$, and Sym$^n \mathcal{E}_1 \to \mathcal{E}_n$ is an isomorphism for any $n$. The category of Qco vector bundles on $S$ is denoted by $\text{Vect}^{\text{Qcoh}} (S)$.

A morphism of affine bundles is a map $E' \to E$ over $S$ that the associated map $f_* : \pi_* \mathcal{O}_V \to \pi'_* \mathcal{O}_{V'}$ is compatible with grading.

For $\mathcal{E} \in \text{Qcoh} (X)$, we can define the associated vector bundle $V (\mathcal{E})$ as $\text{Spec}_S \text{Sym} (\mathcal{E}) (5.2.3.10)(5.2.7.12)$. In this way, the category of Qco vector bundles over $S$ is anti-equivalent to the category of Qco $\mathcal{O}_S$-algebras.

For $\mathcal{E} \in \text{Qcoh} (X)$, we can define the associated projective bundle $P (\mathcal{E})$ as $\text{Proj}_S \text{Sym} (\mathcal{E}) (5.2.3.10)(5.2.7.12)$. It is equipped with a Serre twisting sheaf $\mathcal{O} (1)$, which is the glue of locally the Serre sheaf in projective space. There is a surjective morphism $\pi^* (\mathcal{E}) \to \mathcal{O} (1)$ (local check).
Prop. (5.5.2.22). Let \( g : Y \to X \) by a scheme over \( X \), a morphism \( Y \to \mathbb{P}(\mathcal{E}) \) over \( X \) is equivalent to an invertible sheaf \( \mathcal{L} \) on \( Y \) and a surjective map \( g^* \mathcal{E} \to \mathcal{L} \).

In particular, giving a morphism \( X \to \mathbb{P}(\mathcal{E}) \) over \( X \) is equivalent to an invertible sheaf with \( n \) generators.

Proof: If there is a morphism, it will pullback \( \pi^* \mathcal{E} \to \mathcal{O}(1) \) into \( g^* \mathcal{E} \to L \). For the converse, construct locally and glue, we have the natural morphisms \( A[x_1/x_1, \ldots, x_n/x_1] \to \mathcal{O}_{X,s_i} : x_j/x_1 \to s_j/s_i \) in a homogenous sense. It is natural hence glue together. For the module, maps \( x_i \to s_i \). □

Cor. (5.5.2.23). All automorphisms of \( \mathbb{P}^n_k \) is linear.

Proof: The Picard group of \( \mathbb{P}^n_k \) is \( \mathbb{Z} \) and is generated by \( \mathcal{O}(1) \), so the automorphism will map \( \mathcal{O}(1) \) to \( \mathcal{O}(\pm 1) \) and \( \mathcal{O}(-1) \) has no global section. And the globals section is \( n \)-dimensional and determines the morphism by the prop. □

Def. (5.5.2.24)[Projective Space]. Let \( A \) be a ring, the projective space \( \mathbb{P}^n_A \) is defined to be \( \mathbb{P}^n_A = \text{Proj}(A[T_0, \ldots, T_n]) \) with \( \deg(T_i) = 1 \). It represents the functor that maps a scheme \( T \) to the equivalence classes of pairs \( (\mathcal{L}, (s_0, \ldots, s_n)) \), where \( \mathcal{L} \) is an invertible sheaf on \( T \), and \( s_0, \ldots, s_n \in \Gamma(T, \mathcal{L}) \) that generate \( \mathcal{L} \) by (5.5.2.22). For any scheme \( S \), \( \mathbb{P}^n \times Z S \) is called the projective space over \( S \).

Prop. (5.5.2.25). Let \( R \) be a ring and \( X = \mathbb{P}^n_R, F \in \mathcal{QCoh}(X) \), then the canonical map \( \Gamma_s(X, F) \to F \) is an isomorphism.

Proof: Cf.[Sta]03GM. This is a corollary. □

Prop. (5.5.2.26)[Closed Subschemes of \( \mathbb{P}^n_R \)]. Let \( Z \) be a closed subscheme of \( \mathbb{P}^n_R \), then it is of the form

\[ Z = \text{Proj}(R[X_0, \ldots, X_n]/I) \subset \text{Proj}(R[X_0, \ldots, X_n]) \]

where \( I = \oplus I_n \) and \( I_n = \ker(R[X_0, \ldots, X_n]_d \to \Gamma(Z, \mathcal{O}_Z)) \).

Proof: Cf.[Sta]03GI. □

Prop. (5.5.2.27)[Segre Embedding]. Let \( S \) be a scheme, there is a natural closed immersion

\[ \mathbb{P}^n_S \times_S \mathbb{P}^n_S \to \mathbb{P}^{mn+m+n}_S \]

called the Segre embedding.

Proof: It suffices to prove for \( S = Z \), and in this case, it suffices to write down an invertible sheaf on \( \mathbb{P}^n_S \times_S \mathbb{P}^n_S \) with \( (n+1)(n+1) \) global sections that generate it. Then we take the invertible sheaf \( \mathcal{L} = \pi_1^* \mathcal{O}_{\mathbb{P}^m}(1) \oplus \pi_2^* \mathcal{O}_{\mathbb{P}^n}(1) \) and the sections \( X_i Y_j \), where \( (X_0, \ldots, X_m) \) generate \( \mathcal{O}_{\mathbb{P}^m}(1) \) and \( (Y_0, \ldots, Y_n) \) generate \( \mathcal{O}_{\mathbb{P}^n}(1) \).

It is a closed immersion by[Sta]01WD. □

Prop. (5.5.2.28)[Venerose Embedding].
3 Invertible Sheaves

General invertible sheaves on a ringed site is treated in 5.

Prop. (5.5.3.1) [Faithfully Flat Descent]. To show a quasi-coherent sheaf is a line bundle, it suffices to show fpqc-locally, by (4.4.2.1).

Def. (5.5.3.2) [Basepoint-Free Line Bundles]. Let \( \mathcal{L} \) be a line bundle over a scheme \( X \) over a field \( k \), then it is called basepoint free if the intersections \( \{ \text{div}(s) \mid s \in H^0(V) \} \) is empty.

Prop. (5.5.3.3). If \( X \) is qcqs over a field \( k \) and \( K \triangleleft k \) is a field extension, then \( \mathcal{L} \) is basepoint free over \( X_K \).

Proof: By flat base change (5.7.5.1), \( H^0(X_K, \mathcal{L}_K) = H^0(X, \mathcal{L}) \otimes_k K \).

Prop. (5.5.3.4) [Relative Triviality]. Let \( f : X \to Y \) be a finite morphism of schemes and \( \mathcal{L} \in \text{Pic}(X) \), then for any \( y \in Y \), there exists a nbhd \( U \) of \( y \in Y \) s.t. \( \mathcal{L}|_{f^{-1}(U)} \) is trivial.

Proof: Cf. [Sta]0BUT.

Prop. (5.5.3.5) [Global Sections]. Let \( \mathcal{L} \) be an invertible sheaf over qcqs scheme \( X \), for \( F \in \mathcal{QCoh}(X) \), let the global section functor \( \Gamma_* (F) = \oplus \Gamma(X, F \otimes \mathcal{L}^n) \), then

\[ \Gamma_* (F)_{(f)} \cong F(X_f) \]

where \( s \in \Gamma(X, \mathcal{L}) \). In particular that if there is a section \( f \) of \( F \) on \( X_s \), then for some \( n \), \( f \otimes s^n \) is a global section of \( F \otimes \mathcal{L}^n \).

Proof: This is nearly the same as the proof that \( (\text{Spec } A)_f = \text{Spec } A_f \), Cf. [Sta]0PW.

Cor. (5.5.3.6). When \( X = \text{Proj } S \) projective over \( \text{Spec } S_0 \) and \( F \in \mathcal{QCoh}(X) \), \( \Gamma_*(F) \cong F \), where \( \Gamma_*(F) = \oplus_{n \in \mathbb{Z}} \Gamma(X, F(n)) \), which is a graded \( S \)-module. In particular, \( \Gamma_* \) for projective space \( P^n_A \) equals \( A[x_1, \ldots, x_n] \).

Def. (5.5.3.7) [Regular Sections].

Prop. (5.5.3.8) [Complete Series]. Let \( H^0(X, \mathcal{L}) \) be the sections that corresponds to injective maps \( \mathcal{L}^{-1} \to \mathcal{O}_X \), then there is a canonical isomorphism

\[ H^0(X, \mathcal{L})_{\text{reg}}/H^*(X, \mathcal{O}_X^n) \cong |\mathcal{L}|. \]

Notice when \( X \) is not integral, \( H^0(X, \mathcal{L})_{\text{reg}} \) may not equal \( H^0(X, \mathcal{L}) \).

Proof: Cf. [Kle05]P22.

Prop. (5.5.3.9) [Meromorphic Sections]. Let \( X \) be a locally Noetherian scheme having no embedded points, then every invertible sheaf \( \mathcal{L} \in \text{Pic}(X) \) has a meromorphic section. In particular, this applies for \( X \) integral, by (5.5.1.17).

Proof: Cf. [Sta]0EMI.
Picard Groups

Remark (5.5.3.10) [Picard Groups]. The Picard group \( \text{Pic}(X) \) of a local ringed space \((X, \mathcal{O}_X)\) is defined in (5.2.5.7), and it is isomorphic to \( H^1(X, \mathcal{O}_X) \) by (5.3.1.17).

Prop. (5.5.3.11) [Class Group]. If \( X = \text{Spec} \mathcal{O} \) where \( \mathcal{O} \) is a Dedekind domain, then by (4.2.7.8), the isomorphism class of invertible sheaves on \( X \) is equivalent to the isomorphism class of fractional ideals modulo principle ideals. Thus \( \text{Pic}(\mathcal{O}) \) equals the class group of \( \mathcal{O}(4.2.7.9) \). In particular, if \( R \) is a UFD, then \( \text{Pic}(\text{Spec} R) = 0 \).

Def. (5.5.3.12) [Invertible Sheaf Associated to Cartier Divisors]. For a Cartier divisor on a scheme \( X \), we can define \( \mathcal{O}(D) \) the line bundle associated to \( D \) as the sub \( \mathcal{O}_X \)-module of \( K \) locally generated by \((f_i^{-1})\), where \( D = (f_i) \) locally. Equivalently, it is the line bundle \( \mathcal{I}_D^{-1} \).

Def. (5.5.3.13) [Linear Series]. Let \( \mathcal{L} \in \text{Pic}(X) \), then denote \(|\mathcal{L}|\) the complete linear series of effective Cartier divisors \( D \) s.t. \( \mathcal{L}(D) \cong \mathcal{L} \).

Def. (5.5.3.14) [Weil divisor of an invertible Sheaf]. For \( X \) a locally Noetherian integral scheme and \( \mathcal{L} \) an invertible sheaf in \( \mathcal{K} \), if \( s \in \Gamma(X, \mathcal{K} \otimes \mathcal{L}) \) is a meromorphic section of \( \mathcal{L} \) (which exists by (5.5.3.9)), for any prime Weil divisor \( Z \) with generic pt \( \eta \), define \( \text{ord}_Z(s) = \text{ord}_{\mathcal{O}_{Z,\eta}}(s/s_\eta) \) (4.1.2.10), for any \( s_\eta \) a generator of \( \mathcal{L}_\eta \) over \( \mathcal{O}_{X,\eta} \). This is independent of \( s_\eta \) chosen.

The prime Weil divisors that \( \text{ord}_Z(s) \neq 0 \) is locally finite, the same as in (6.1.2.18). And any two different sections \( s_i \) defines Weil divisors up to a difference of \( \text{div}(f)(6.1.2.18) \). So we can define the Weil divisor class associated to \( \mathcal{L} \) as \( \sum \text{ord}_Z(s)[Z] \) for any meromorphic section \( s \) of \( \mathcal{L} \).

It is easy to verify that this induces a homomorphism from \( \text{Pic}(X) \) to \( \text{Cl}(X) \).

Prop. (5.5.3.15) [Cl-Pic]. For a normal integral locally Noetherian scheme, the above map \( \text{Pic}(X) \to \text{Cl}(X)(5.5.3.14) \) is an injection. It is an isomorphism iff all local rings of \( X \) are UFD.

Explicitly, the inverse image of a prime Weil divisor \( D \) is the sheaf \( \mathcal{O}_X(D) = \text{Hom}(\mathcal{I}_D, \mathcal{O}_X) = \mathcal{I}_D^{-1} \), and there is an exact sequence of sheaves on \( X \):

\[ 0 \to \mathcal{O}_X(-D) = \mathcal{I}_D \to \mathcal{O}_X \to i_*\mathcal{O}_D \to 0 \]

In particular, this applies to non-singular prevarieties over a field \( k \), by (5.4.2.8).

Proof: If it is not injective, then some meromorphic section on \( \mathcal{L} \) has no associated Weil divisors, then it suffices to show \( \mathcal{L} \) is trivialized by \( s \). Consider on an affine subscheme Spec \( A \), then \( \text{ord}_{A_p}(s) = 0 \) for each minimal prime \( p \) of \( A \), but \( A_p \) is DVR by (4.3.5.20), so \( s \in A_p^* \) for each minimal prime \( p \), so \( s \in A_*^* \) (4.3.5.11). This shows \( s \) trivialize \( \mathcal{L} \).

To show it is surjective, it suffices to show any Weil divisor \( D \) is in the image: notice \( D \) is an effective Cartier divisor by (5.8.1.4), and by definition (5.8.1.5) the vanishing of the canonical section \( 1_D \in \mathcal{O}_X(D) \) is exactly \( D \).

Prop. (5.5.3.16) [Examples of Picard Groups].

- If \( X \) is a locally Noetherian normal integral separated scheme, then so are \( X \times \text{Spec} \mathbb{Z}[T] \) and \( \mathbb{P}^n_X \), and \( \text{Cl}(X \times \text{Spec} \mathbb{Z}[T]) = \text{Cl}(X) \) and \( \text{Cl}(\mathbb{P}^n_X) = \mathbb{Z} \oplus \text{Cl}(X) \).

- For a UFD \( R \), \( \text{Pic}(\mathbb{A}^n_R) = 0 \).

- For a UFD \( R \), \( \text{Pic}(\mathbb{P}^n_R) \cong \text{Cl}(\mathbb{P}^n_R) \cong \mathbb{Z} \), and it is generated by \( \mathcal{O}_{\mathbb{P}^n_R}(1) \).
• For a UFD $R$, $\text{Pic}(\mathbb{P}^1_R \times \mathbb{P}^1_R) \cong \text{Cl}(\mathbb{P}^1_R \times \mathbb{P}^1_R) \cong \mathbb{Z} \oplus \mathbb{Z}$.

• If $k$ is a field and $Y \subset \mathbb{P}^n_k$ is a hypersurface of degree $d$, then $\text{Pic}(\mathbb{P}^n_k \setminus Y) \cong \text{Cl}(\mathbb{P}^n_k \setminus Y) \cong \mathbb{Z}/d\mathbb{Z}$.

Proof: By $(5.5.3.15)$ and $(6.1.5.7)(6.1.7.10)(6.1.5.8)(6.1.5.9)$. □

Prop. (5.5.3.17). Let $X$ be a complete prevariety over a field $k$ of characteristic $p > 0$, then for any $n$ prime to $p$ and any purely inseparable field extension $k'/k$, the natural map

$$\text{Pic}(X)[n] \to \text{Pic}(X_{k'})[n]$$

is an isomorphism.

Proof: Cf. [Sta]0CD5. □

4 Ample Invertible Sheaves

Prop. (5.5.4.1). Let $X \in \text{Sch}$ and $\mathcal{L} \in \text{Pic}(X)$. Then for any affine open $U \subset X$ and a section $s$ of $\mathcal{L}$, $X_s \cap U$ is affine.

Proof: It suffices to show: If $R$ is a ring, $N$ is an invertible $R$-module and $s \in N$, then $U = \{p|s \notin pN\}$ is an affine open subset of $\text{Spec} R$. For this, let $R' = \lim_{\rightarrow} - \otimes N^{\otimes m}$, then in fact $U = \text{Spec} R'$. Because locally, $R'$ is just $R_s$ via an isomorphism $N_f \cong R_f$. □

Def. (5.5.4.2) [Ample Invertible Sheaves]. On a quasi-compact scheme $X$, an ample invertible sheaf is a line bundle $\mathcal{L} \in \text{Pic}(X)$ s.t. there is some $n \in \mathbb{Z}_+$ and sections $s_i \in \Gamma(X, \mathcal{L}^n)$ that $X_{s_i}$ is an affine cover of $X$. In particular, an ample invertible sheaf is globally generated.

For a qc morphism $f: X \to Y$, an invertible sheaf on $X$ is called $f$-ample iff it is ample restricted to every open subscheme $f^{-1}(V)$, where $V$ is an affine open in $Y$. In particular, an invertible sheaf $\mathcal{L}$ on a quasi-compact scheme $X$ is ample iff it is $f$-ample where $f: X \to \text{Spec} Z$.

Prop. (5.5.4.3). An invertible sheaf $\mathcal{L}$ is $(f)$-ample iff $\mathcal{L}^m$ is $(f)$-ample.

Prop. (5.5.4.4) [Ample Implies Separatedness]. When there is a $f$-ample invertible sheaf for $f: X \to Y$ qc, then $f$ is separated. In particular, if there is an ample line bundle over a qc scheme $X$, then $X$ is separated.

Proof: [Sta]09MP. □

Prop. (5.5.4.5) [Characterizing Ampleness]. Let $X$ be a qc scheme and $\mathcal{L}$ be an invertible sheaf on $X$, $S = \Gamma_*(X, \mathcal{L})$, then the following are equivalent:

1. $\mathcal{L}$ is ample.

2. The open subsets $X_s$, where $s \in \Gamma_*(X, \mathcal{L})$ homogeneous, cover $X$, and the associated morphism $X \to \text{Proj} S$ is an open immersion.

3. The open subsets $X_s$ where $s \in \Gamma_*(X, \mathcal{L})$ homogeneous, form a topological basis for $X$.

4. The open subsets $X_s$ that is affine and where $s \in \Gamma_*(X, \mathcal{L})$ homogeneous, form a topological basis for $X$.

5. For any Qco sheaf $\mathcal{F}$ on $X$, the sum of images of the canonical maps $\Gamma(X, \mathcal{F} \otimes \mathcal{L}^n) \otimes \mathcal{L}^{-n} \to \mathcal{F}$ is surjective.
6. $X$ is quasi-separated, and for any Qco sheaf $\mathcal{F}$ on $X$ of f.t., $\mathcal{F} \otimes \mathcal{L}^\otimes n$ is generated by global sections for $n$ sufficiently large.

7. $X$ is quasi-separated, and for any Qco sheaf $\mathcal{F}$ on $X$ of f.t., there exists an integer $n$ that $\mathcal{F}$ is a quotient of a direct sum of f.m. copies of $\mathcal{L}^\otimes -n$.

Proof: Cf.[Sta]01Q3. □

**Cor.(5.5.4.6).** The pullback of an ample invertible sheaf along a qc immersion is an ample invertible sheaf.

**Cor.(5.5.4.7).** Let $S$ be a quasi-separated scheme and $X, Y$ be schemes over $S$. If $\mathcal{L}$ is an ample invertible sheaf over $X$ and $\mathcal{N}$ an ample invertible sheaf over $Y$, then $\mathcal{M} = \text{pr}_1^* \mathcal{L} \otimes \mathcal{O}_{X \times_S Y} \text{pr}_2^* \mathcal{N}$ is ample over $X \times_S Y$.

Proof: Because $X \times_S Y \to X \times Y$ is a qc immersion, by(5.5.4.6), it suffices to show for $S = \text{Spec } Z$. Then if $X_i$ is an affine nbhd of $x$ and $Y_i$ is an affine nbhd of $y$, then $(X \times Y)_{\pi_i}^* s \otimes s^\mathcal{L}_i$ is an affine nbhd of $x \times y$. □

**Cor.(5.5.4.8) [Tensor Product of Ample Invertible Sheaves is Ample].** If $M$ an invertible sheaf generated by global sections and $\mathcal{L}$ is an ample invertible sheaf, then $\mathcal{L} \otimes M$ is ample. In particular if $\mathcal{L}, \mathcal{M}$ are ample invertible sheaves, then $\mathcal{L} \otimes \mathcal{M}$ is ample.

Proof: For any $x \in X$ and $U$ a nbhd of $x$, choose $s \in \Gamma(X, \mathcal{L}^n)$ that $x \in X_s \subset U$, and choose $t \in \Gamma(X, \mathcal{M})$ that $t_x \neq 0$, then $x \in X_{s \otimes t^\mathcal{M}} \subset U$, thus $X_r$ form a basis for $X$ where $r \in \Gamma(X, (\mathcal{L} \otimes \mathcal{M})^n)$, so $\mathcal{L} \otimes \mathcal{M}$ is ample. □

**Cor.(5.5.4.9).** If $\mathcal{L}$ is ample and $\mathcal{M}$ is an invertible sheaf, then $\mathcal{M} \otimes \mathcal{L}^\otimes n$ is ample for $n$ sufficiently large.

Proof: This is because $\mathcal{L} \otimes \mathcal{M}^n$ is generated by global sections for $n$ sufficiently large, thus $\mathcal{L} \otimes \mathcal{M}^{n+1}$ is ample, by(5.5.4.8). □

**Prop.(5.5.4.10) [Gluing Ample Invertible Sheaves].** Let $X$ be a qc scheme s.t. there is an affine open covering of the form $X_{s_i}$ where $s_i$ are sections of $\mathcal{L}_i$ and $\mathcal{L}_i$ are globally generated line bundles in $\text{Pic}(X)$, then $X$ has an ample line bundle.

Proof: Let $X_{s_i}$ be an affine open covering of $X$ where $s_i$ are sections of globally generated invertible sheaves $\mathcal{L}_i, i = 1, \ldots, r$. As $\mathcal{L}_i$ are globally generated, let $X = \bigcup_j X_{i,j}$ for $j = 0, 1, \ldots, m_i$ where $t_{i0} = s_i$. Then for the line bundle $\otimes_i \mathcal{L}_i$, the sections $t_{1,j_1} \otimes \ldots \otimes t_{r,j_r}$ where at least one of $j_i$ equals 0, covers $X$, and they are all affine by(5.5.4.1). So $\otimes_i \mathcal{L}_i$ is ample. □

**Prop.(5.5.4.11).** $f : X \to Y$, let $\mathcal{L}$ be $f$-ample on $X$ and $\mathcal{M}$ ample on $Y$, then $\mathcal{L} \otimes f^* \mathcal{M}^n$ is ample for $n$ large.

Proof: Cf.[Sta]0892? □

**Cor.(5.5.4.12).** If $f : X \to Y$ is quasi-affine, then the pullback of an ample invertible sheaf is ample, by(5.4.4.19) and(5.5.4.3).

**Prop.(5.5.4.13) [Pullback of Ampleness].** If $f : Y \to X$ is finite and surjective morphism between schemes proper over a Noetherian affine scheme, then for any invertible sheaf $\mathcal{L}$ on $X$, $\mathcal{L}$ is ample iff $f^* \mathcal{L}$ is ample.
Proof: Cf.[Sta]0B5V.

One direction follows from (5.5.4.12). For the other we use Serre criterion (5.7.2.8) and devise-
sage (5.5.1.56). We only verify 3: By (5.4.4.42), there exists such coherent sheaf $f_*\mathcal{F}$ for any integral
subscheme, and for any Qco sheaf of ideals $I$, $I f_*\mathcal{F} = f_*(f^{-1}I \mathcal{F})$ because $f$ is affine, thus

$$H^p(X, I f_*\mathcal{F}) = H^p(X, f_*(f^{-1}I \mathcal{F} \otimes \mathcal{L}^n)) = H^p(Y, f^{-1}I \mathcal{F} \otimes \mathcal{L}^n)$$

by projection formula, and $f$ is affine. This vanish for $n$ large. □

Cor. (5.5.4.14) [Ampleness and Irreducible Components]. Let $X$ be a scheme proper over a
Noetherian affine scheme, then an invertible sheaf $\mathcal{L}$ on $X$ is ample iff it is ample on the induced
reduced structure of irreducible components of $X$.

Proof: This is (5.5.4.13) applied to the case $\coprod X_i \rightarrow X$. □

Prop. (5.5.4.15) [Ampleness Restricted to Reduced Case]. If $i: Z \rightarrow X$ is a closed immersion of
schemes that induce homeomorphism on the underlying topology, then $\mathcal{L}$ is ample iff $i^*\mathcal{L}$ is ample.

In particular, this applies to $X_{\text{red}} \rightarrow X$.

Proof: Cf.[Sta]09MW. □

Prop. (5.5.4.16). Let $f: X \rightarrow Y$ be a proper morphism of schemes and $\mathcal{L}$ an invertible sheaf on $X$.
If $y \in Y$ satisfies $\mathcal{L}_y$ is ample on $X_y$, then there is a nbhd $U$ of $y \in Y$ that $\mathcal{L}|_{f^{-1}(U)}$ is $f$-ample.

Proof: Cf.[Sta]0D2S. □

Prop. (5.5.4.17) [Finite Map and Ample]. Let $\mathcal{L}$ be a basepoint-free line bundle on a proper
scheme $X$, then the associated map $X \rightarrow \text{Proj}(\mathcal{O}_X, \mathcal{L})$ is finite iff $\mathcal{L}$ is ample.

Proof: Cf.[Positivity in Algebraic Geometry, P28]. □

Prop. (5.5.4.18). Let $X$ be a scheme. Let $\mathcal{L}$ be an ample invertible $\mathcal{O}_X$-module. Let $n_0$ be an integer.
If $H^p(X, \mathcal{L}^{-n}) = 0$ for $n \geq n_0$ and $p > 0$, then $X$ is affine.

Proof: Cf.[Sta]0EBD. □

Prop. (5.5.4.19) [Descent of Ample Line Bundles]. Let $K/k$ be a field extension, $X$ a scheme
over $k$ s.t. there exists an ample line bundle on $X_K$, then $X$ also has an ample line bundle.

Proof: Cf.[Sta]0BDC. □

Very Ample Invertible Sheaves

Def. (5.5.4.20) [Very Ampleness]. Let $f: X \rightarrow S$ be a morphism, a $f$-very ample invertible sheaf
on $X$ is the pullback of $\mathcal{O}(1)$ along some immersion $X \rightarrow \text{Proj}(\mathcal{E})$ for some Qco module $\mathcal{E}$ over $Y$,
Cf.(5.5.2.14). It is called H-very ample iff $\mathcal{E}$ is trivial. Notice when $X$ is proper, this immersion
must be closed by (5.4.5.3).

When $S$ is affine and $f: X \rightarrow S$ is of f.t., $f$-very ample is equivalent to H-very ample.

Proof: Cf.[Sta]02NP. □
Prop.(5.5.4.21) [Tensor Product of Very Ample Line Bundles]. Let \( f : X \to \text{Spec } A \) be a morphism. If \( L \) is H-very ample and \( M \) is generated by global sections, then \( L \otimes M \) is H-very ample. In particular, the tensor product of two H-very ample invertible sheaves is H-very ample.

Proof: The hypothesis means \( L = \varphi^*O(1) \), where \( \varphi : X \to P^n_k \) is an immersion, and \( M = \psi^*O(1) \), where \( \psi : X \to P^m_k \) is a morphism. Then the product \( T : X \to P^n_k \times P^m_k \) is also an immersion, by base change trick (5.4.4.2), as \( P^n_k \times P^m_k \to P^n_k \) is separated. Then \( S \circ T : X \to P^{mn+m+n} \), where \( S : P^n_k \times P^m_k \to P^{mn+m+n} \) is the Segre embedding, is also an immersion, and \((ST)^*O(1) \cong L \otimes M \), thus it is H-very ample.

Prop.(5.5.4.22) [Ample and H-Very Ample]. If \( f : X \to S \) is locally of f.t. and \( L \) is an ample invertible sheaf on \( X \), then \( L^{\otimes m} \) is H-very ample for \( m \) sufficiently large.

Proof: Choose an affine open cover \( \{V_i\} \) of \( S \). By (5.5.4.5), there are f.m. affine opens \( X_{s_i} \) that cover \( X \) refining a inverse image of \( \{V_i\} \). Now \( O_X(X_{s_i}) \) is f.g. over \( O_S(V_i) \), so we can find f.m. \( f_{ij} \in O_X(X_{s_i}) \) that generates it over \( O_S(V_i) \). By (5.5.3.5), we can write each \( f_{ij} = s_{ij}/s_{ij}^{e_{ij}} \) for some \( a_{ij} \) homogenous. We can multiply by a factor to make all the \( s_{ij}^{e_{ij}} \) the same degree \( N \), and \( f_{ij} = s_{ij}s_i^{N/\text{deg}(s_i)-e_{ij}} \), then all the elements \( s_i, s_{ij} \) generates the invertible sheaf \( L \), thus inducing a map \( j : X \to P^m_k \). This map is an immersion, because \( j^{-1}(D(T_i)) = X_{s_i} \) and the function \( T_{ij}/T_i \) on \( D(T_i) \) pulls back to \( s_{ij}/s_{ij} \). Thus \( j \) is locally a closed immersion, thus an immersion.

Now \( L^{\otimes d_1} \) is H-very ample for some \( d_1 \), in particular it is separated, and by (5.5.4.5) there is some \( d_2 \) that \( L^{\otimes d} \) is generated by global sections for all \( d \geq d_2 \), then by (5.5.4.21), \( L^{\otimes d} \) is H-very ample for \( d \geq d_1 + d_2 \).

Prop.(5.5.4.23) [f-very Ample Implies f-Ample]. If \( f : X \to S \) is qc, then \( f \)-very ample implies \( f \)-ample.

Proof: Cf.[Sta]01VN. □

Cor.(5.5.4.24) [Serre]. If \( f : X \to S \) is of f.t. and \( S \) is affine, \( L \) is an invertible sheaf on \( X \), then the following are equivalent:

- \( L \) is ample .
- \( L \) is \( f \)-ample.
- \( L^{\otimes n} \) is \( (H-)f \)-very ample for some (all large)\( n \).

Proof: This follows from (5.5.4.20)(5.5.4.22) and (5.5.4.23). □

Cor.(5.5.4.25). If \( f : X \to S \) is of f.t. and \( S \) is quasi-compact, \( L \) is an invertible sheaf on \( X \), then the following are equivalent:

- \( L \) is \( f \)-ample.
- \( L^{\otimes n} \) is \( (H-)f \)-very ample for some (all large)\( n \).

Proof: Cf.[Sta]01VU. □

5 Sheaf of Differentials

Prop.(5.5.5.1) [Differentials on Schemes]. Consider a morphism of schemes \( X \to Y \), we define the sheaf of differentials \( \Omega_{X/Y} \) together with an \( S \)-derivative \( O_X \to \Omega_{X/S} \) as for ringed sites (5.2.4.7).
Then it is a Qco sheaf by \((5.2.4.5)\). In fact, if \(U = \text{Spec } A\) is mapped into \(\text{Spec } B \subset S\), then \(\Omega_{X/S}(U) \cong \Omega_{A/B}\).

In particular, the stalk of \(\Omega_{X/S}\) at a point \(x \in X\) is \(\Omega_{\mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)}}\).

Thus when \(X \to Y\) is locally of f.t.(or locally of f.p.), then \(\Omega_{X/S}\) is an \(\mathcal{O}_X\)-module of f.t.(or of f.p.).

**Prop.(5.5.5.2) [Base change and Differentials].** Let \(\xymatrix{ X' \ar[r]^-f & X \ar[d]^g \cr S' \ar[r]_g & S }\) be a commutative diagram of schemes, then there is a canonical map

\[ f^* \Omega_{X/S} \to \Omega_{X'/S'} \]

which is an isomorphism if the diagram is a fiber product square.

**Proof:** Such a diagram gives a diagram \((f^{-1}g^{-1}\Omega_S \to f^{-1}\Omega_X) \to ((g')^{-1}(\mathcal{O}_{S'}) \to \mathcal{O}_{X'})\) of sheaves of rings on \(X'_{zar}\), thus the conclusion follows from \((5.2.4.5)\) and \((5.2.7.17)\).

**Prop.(5.5.5.3).** Let \(X, Y\) be schemes over another scheme \(S\), then

\[ \pi_1^* \Omega_{X/S} \oplus \pi_2^* \Omega_{Y/S} \cong \Omega_{X \times_S Y/S}, \]

where the maps are given by \((5.5.5.2)\).

**Proof:** It suffices to check on affine subschemes, so we may assume \(X, Y, S\) are affine, thus the map is given by

\[ \Omega_{A/S} \oplus_S B \oplus_{A \otimes_S B} \Omega_{B/S} \otimes_S A \to \Omega_{A \otimes_S B/S} \]

which is an isomorphism by \((4.4.3.6)\).

**Prop.(5.5.5.4).** Let \(X, Y\) be schemes over another scheme \(S\), then \(\Omega_{X \times_S Y/S} \cong \pi_1^* \Omega_{X/S} \oplus \pi_2^* \Omega_{Y/S}\).

**Prop.(5.5.5.5) [Jacobi-Zariski Sequence].** Let \(f : X \to Y\) and \(g : Y \to Z\), then there is an exact sequence of sheaves on \(X\):

\[ f^* \Omega_{Y/Z} \to \Omega_{X/Z} \to \Omega_{X/Y} \to 0. \]

Where the maps come from \((5.5.5.2)\).

**Proof:** Immediate from \((4.4.3.8)\).

**Prop.(5.5.5.6).** The stalk of the differential sheaf \(\Omega_{X/k}\) at a rational point \(x\) of a scheme over a field \(k\) is just the Zariski cotangent space \(m_x/m_x^2\) \((5.6.4.22)\).

**Proof:** Using the Jacobi exact sequence \((4.4.3.8)\) on an affine nbhd \(\text{Spec } A\) of \(x\) for \(A\) and \(m_x\). Then we verified that there is a right inverse of \(A/m^2 \to k(x) = x\), then it follows that \(m_x/m_x^2 \cong \Omega_{A/k} \otimes_A k(x) = \Omega_{A_{m_x}/k}\) which is the stalk of \(\Omega_{X/k}\) by \((5.5.5.1)\).

**Prop.(5.5.5.7) [Euler Exact Sequence].** If \(X = \mathbb{P}^n_A = \text{Proj}(A[x_0, \ldots, x_n])\) over \(Y = \text{Spec } A\), then there is an exact sequence

\[ 0 \to \Omega_{X/A} \to (\mathcal{O}_X(-1))^{n+1} \to \mathcal{O}_X \to 0. \]

\(\Omega_{X/A}\) is locally free by \((5.10.1.16)\), so by taking dual and exterior powers,

\[ 0 \to \mathcal{O}_X \to \mathcal{O}_X(1)^{n+1} \to T_X \to 0, \quad K_X \cong \mathcal{O}_X(-n-1). \]
5.5. QUASI-COHERENT SHEAVES ON SCHEMES 605

Proof: Let \( S = A[x_0, \ldots, x_n] \), \( E = S(-1)^{\oplus n+1} \) with a basis \( e_0, \ldots, e_n \), then there is a map of \( S \)-graded modules \( E \to S \) with kernel \( M \). \( E \to S \) is surjective in all dimension \( \geq 1 \), so we have an exact sequence

\[
0 \to \tilde{M} \to \tilde{E} \to \mathcal{O}_X \to 0.
\]

Notice \( E_{(x_i)} \to S_{(x_i)} \) is given by \( e_j \mapsto x_j/x_i \), so \( \tilde{M}|_{D(x_i)} \) is a free sheaf generated by sections \( 1/x_i e_j - (x_j/x_i^2)e_i, j \neq i \). So we can define \( \varphi_i : \Omega_{X/A}|_{D(x_i)} \to \tilde{M}|_{D(x_i)} : d(x_j/x_i) \mapsto 1/x_i e_j - (x_j/x_i^2)e_i, j \neq i \) mapping isomorphically onto the kernel. It suffices to show this map glue to a map \( \Omega_{X/A} \to \tilde{E} \): On \( D(x_i,x_j) \), \( x_k/x_i = (x_k/x_j) \cdot (x_j/x_i) \), so

\[
d(\frac{x_k}{x_i}) - \frac{x_k}{x_j}d(\frac{x_j}{x_i}) = \frac{x_j}{x_i}d(\frac{x_k}{x_j}).
\]

Applying \( \varphi_i \) to the LHS and \( \varphi_j \) to the RHS gives the same element \( 1/x_i e_k - (x_k/x_i x_j)e_j \), which shows compatibility. \( \square \)

Conormal Sheaves

Def.(5.5.5.8) [Conormal Sheaf of an Immersion]. Let \( i : Z \to X \) be a closed immersion with corresponding sheaf of ideals \( \mathcal{I} \). Consider the Qco sheaf \( \mathcal{I}/\mathcal{I}^2 \), which is annihilated by \( \mathcal{I} \), thus corresponds to a sheaf on \( Z \) by (5.2.6.18), called the conormal sheaf \( \mathcal{C}_{Z/X} \) of \( Z \).

More generally, if \( i \) is any immersion, we can define the conormal sheaf as the conormal sheaf of the closed immersion \( i : Z \to X \setminus \partial Z \). And also the normal sheaf \( \mathcal{N}_{Z/X} \) is defined to be \( \mathcal{N}_{Z/X} = \text{Hom}_{\mathcal{O}_X}(\mathcal{I}/\mathcal{I}^2, \mathcal{O}_Z) \).

Prop.(5.5.5.9) [Pullback of Conormal Sheaf]. Let \( \begin{array}{c} Z' \to X' \to Z \to X \end{array} \) be a fiber product square where \( i, i' \) are immersions, then the canonical map

\[
f^\ast \mathcal{C}_{Z'/X} \to \mathcal{C}_{Z/X}
\]

is surjective, and if \( g \) is flat, it is an isomorphism.

Proof: Change \( X' \to X \setminus \partial Z' \) and \( X \to X \setminus (g^{-1} \partial Z' \cup \partial Z) \), we may assume \( i \) is a closed immersion. Then we may localize to the case \( X' \) and \( X \) is affine. Then we notice if \( R' \to R \) is a ring map and \( I' \subset R' \) is an ideal, with \( I = I'R \), then \( (I'/I')^2 \otimes_{R'} R \to I/I^2 \) is surjective, and if \( R/R' \) is flat, then \( I \cong I' \otimes_{R'} R \), and the map is an isomorphism. \( \square \)

Prop.(5.5.5.10). Let \( Z \to Y \to X \) be immersions of schemes, then there is a canonical exact sequence

\[
i^\ast \mathcal{C}_{Y/X} \to \mathcal{C}_{Z/X} \to \mathcal{C}_{Z/Y} \to 0
\]

Proof: By changing \( Y \to Y \setminus \partial Z \) and \( X \to X \setminus (\partial(Y \setminus Z)) \), we can assume the immersions are closed immersion. Now by restricting to affine subsets, it suffices to show that for surjective ring maps \( C \to B \to A \), if \( I = \ker(B \to A), J = \ker(C \to A), K = \ker(C \to B) \), then there is an exact sequence

\[
K/K^2 \otimes_B A \to J/J^2 \to I/I^2 \to 0.
\]

But this follows from the observation \( K = \ker(J \to I) \). \( \square \)
Prop. (5.5.5.11) [Conormal Sheaf of the Diagonal]. Let \( f : X \to S \) be a morphism, then there is a canonical isomorphism between \( \Omega_{X/S} \) and the conormal sheaf of the diagonal \( \Delta : X \to X \otimes_S X \).

**Proof:** Cf. [Sta]08S2. \( \square \)

Cor. (5.5.5.12). If \( f : X \to S \) is a monomorphism, e.g. an immersion, then \( \Omega_{X/S} = 0 \).

Prop. (5.5.5.13). If \( f : Z \to X \) is an immersion of schemes over \( S \), then there is an exact sequence of sheaves on \( Z \):
\[
\mathcal{C}_{Z/X} \to i^*\Omega_{X/S} \to \Omega_{Z/S} \to 0.
\]

**Proof:** Replace \( X \) be \( X \setminus \partial Z \), we can assume \( f \) is a closed immersion. This follows immediate from (5.2.4.6). \( \square \)

Prop. (5.5.5.14). If \( i : Z \to X \) is an immersion over \( S \) that locally has a left inverse, then the canonical sequence
\[
0 \to \mathcal{C}_{Z/X} \to i^*\Omega_{X/S} \to \Omega_{Z/S} \to 0.
\]
is locally split exact. In particular, if \( s : S \to X \) is a section of the structure morphism \( X \to S \), then the map \( \mathcal{C}_{S/X} \to s^*\Omega_{X/S} \) is an isomorphism.

**Proof:** Cf. [Sta]0474. \( \square \)

Prop. (5.5.5.15). Let \( \begin{array}{ccc}
Z & \xrightarrow{i} & X \\
\downarrow j & & \downarrow \\
Y & \end{array} \) be a commutative diagram where \( i, j \) are immersions, then there is a canonical exact sequence
\[
\mathcal{C}_{Z/Y} \to \mathcal{C}_{Z/X} \to i^*\Omega_{X/Y} \to 0,
\]
where the first arrows comes from (5.5.5.9) and the second map comes from (5.5.13).

**Proof:** By replacing \( Y \) by \( Y \setminus \partial Z \) and \( X \) by \( X \setminus (\partial i(Z) \cup \partial j(Z)) \), then we may assume \( i, j \) are closed immersion. Then we check locally, the exactness follows from (8.2.1.5). \( \square \)
5.6 More Properties of Schemes

Main references are [Sta].

Notations (5.6.0.1). • Use notations defined in Properties of Schemes.

1 Finitely Presentedness

Def. (5.6.1.1) [Locally of Finite Presentation]. A morphism between schemes \( f : Y \to X \) is called of locally finite presentation iff for any point \( x \in X \), there is an open affine mapped into an open affine that the ring map is of finite presentation. It is called of finite presentation iff moreover it is qcqs.

Locally of finite presentation is local on the source and target and it is stable under composition and base change but it doesn’t satisfies the base change trick by (5.4.1.6)(5.4.1.5) and (4.3.7.9).

Prop. (5.6.1.2). Open immersion is locally of finite presentation.

Prop. (5.6.1.3). When the target is locally Noetherian, (locally)finite type and (locally)finite presentation is equivalent.

Prop. (5.6.1.4). For \( f : X \to Y \) over \( S \), if \( X/S \) is locally of f.p. and \( Y/S \) is locally of f.t., then \( f \) is locally of f.p.. If moreover \( X \) is of f.t. and \( Y \) is qs, then \( f \) is of f.t..

Proof: The first follows from (4.3.7.11), the second needs to check qcqs. Qc follows from (5.4.4.27).

□

Prop. (5.6.1.5) [Chevalley]. A qc morphism locally of f.p. maps locally constructible subset to locally constructible subset.

Proof: We prove \( f(E) \cap U_i \) is constructible for every \( U_i \) affine open in \( X \). The inverse image of \( U_i \) is qc, hence a locally constructible set is constructible (3.8.3.10). So we reduce to the affine case (4.1.7.3).

□

Cor. (5.6.1.6). As in the proposition, if \( Y \) is qc, and the image is dense in \( Y \), then it contains an open dense subset of \( Y \), by (3.8.3.17).

2 Flatness

Def. (5.6.2.1) [Flatness for Schemes]. Flat modules and flat morphisms over schemes are defined in the same way as that of ringed spaces (5.2.2.15).

Prop. (5.6.2.2). Flatness is stalkwise by (5.2.2.17), it is stable under base change and compositions.

Thus for \( F \in \Coh(X) \) is flat over \( X \) iff it is locally free, by (4.4.1.10)

For any affine open subsets \( \text{Spec} A \subset X \), \( \Gamma(\text{Spec} A, F) \) is flat over \( A \), because flatness is also stalkwise for modules (4.1.4.2). Similarly, a morphism of schemes \( f : X \to Y \) is flat iff for any affine opens \( \text{Spec} B \subset X, \text{Spec} A \subset Y \) that \( f(\text{Spec} B) \subset \text{Spec} A \) is flat over \( A \).

Prop. (5.6.2.3). For a flat morphism of ringed space, \( f^* \) is exact.

Proof: Because it is \( f^{-1} \) followed by tensoring with \( \mathcal{O}_X \), check on stalks.

□
Prop. (5.6.2.4) [Faithfully Flat Descent for Flat Modules]. Let \( f : X \to Y \) be a morphism of schemes over \( S \) and \( G \in \mathcal{QCoh}(Y) \), then \( G \) is flat over \( S \) iff \( f^*G \) is flat over \( S \). In particular, \( Y \) is flat over \( S \) iff \( X \) is flat over \( S \).

**Proof:** This follows from (4.4.1.6).

Prop. (5.6.2.5). For a Qco sheaf \( F \) on a scheme \( X \), the following are equivalent, by (4.3.1.7).

1. \( F \) is finite projective.
2. \( F \) is f.p. and flat.
3. \( F \) is f.p. and all its localizations at (maximal)primes are free.
4. \( F \) is finite locally free.
5. \( F \) is finite and locally free.
6. \( F \) is finite and all its localizations at primes are free and the function \( p \to \dim_{k(p)} F \otimes_R k(p) \) is a locally constant function on \( \text{Spec} \, R \).

Cor. (5.6.2.6). Let \( f : X \to Y \) be a finite morphism of locally Noetherian schemes and \( Y \) is reduced, the following are equivalent:

- \( f \) is flat.
- \( f_*\mathcal{O}_X \) is locally free.
- \( \dim_{k(x)}(\pi_*\mathcal{O}_X)_x \otimes k(x) \) is a locally constant function for \( x \in Y \).

**Proof:** 3 follows from (5.5.1.43).

Prop. (5.6.2.7) [Going-Down]. Generalizations lift along a flat morphism.

**Proof:** We can find an affine nbhd, then choose a nbhd of the inverse image, then a generalization in an affine open is a true generalization, so it reduce to the affine case. The rest follows from going-down (4.4.1.19).

Cor. (5.6.2.8) [Flat Map and Irreducible Components]. A flat morphism maps generic points to generic points.

Prop. (5.6.2.9) [Flat Map and Associated Points]. Let \( f : X \to S \) be a morphism of schemes that \( S \) is locally Noetherian, and \( F \) a Qco sheaf on \( X \). If \( F \) is flat over \( S \), then \( f \) maps \( \text{WeakAss}(F) \) to \( \text{Ass}(S) \). In particular, if \( X \) is flat over \( S \), then \( f \) maps \( \text{WeakAss}(X) \) to \( \text{Ass}(S) \).

**Proof:** Let \( x \in X, f(x) = s \) that \( s \in \text{Ass}(S) \), then we get a map \( (\mathcal{O}_{S,s}, \mathfrak{m}_s) \to (\mathcal{O}_{X,x}, \mathfrak{m}_x) \). If \( \mathfrak{m}_s \) is not associated point, then by prime avoidance (4.1.1.4), there is some \( m \in \mathfrak{m}_s \) that is not a non-zero divisor, by (4.2.5.17), so \( f^2(m) \) is also a non-zero divisor on \( F_x \), so \( \mathfrak{m}_x \) is not a weakly associated point of \( F \).

Prop. (5.6.2.10) [Flat Map is Open]. A flat morphism locally of f.p. is (universally)open, hence it is qc.

And a qc f.f. morphism of schemes is a quotient map.

**Proof:** It suffices to consider the affine case. Then the assertion follows from (4.4.1.32).

For the second, by (5.6.2.7), a subset whose inverse image is closed is stable under specialization (surjectiveness used), then it is closed by (5.4.4.9).
Prop.(5.6.2.11) [Cartier Divisor and Flat Base Change].
- The flat base change of Cartier divisor is also a Cartier divisor.
- The flat base change of a regular embedding is also a regular embedding.
- The flat base change commutes with blow up, by universal property.

Prop.(5.6.2.12) [Flat Pullback of Closed Subschemes]. Let \( Z \subset X \) be a closed subscheme corresponding to a Qco sheaf of ideals \( I \), and \( f : X' \to X \) be a flat morphism, then the pullback \( Z' \subset X' \) is a closed subscheme that corresponds to the ideal sheaf \( f^*I \).

Proof: This is because \( f^* \) is exact.

Prop.(5.6.2.13) [Pullback of Flat Closed Subschemes]. Let \( X \) be a scheme over \( S \), \( S' \to S \) be a morphism of schemes, and \( Z \subset X \) be a closed subscheme corresponding to a Qco sheaf of ideals \( I \) flat over \( S \), then the pullback \( Z' \subset X' \) is a closed subscheme that corresponds to the ideal sheaf \( f^*I \).

Prop.(5.6.2.14) [Flat Loci is Open]. For a morphism \( f : X \to S \) locally of f.p., and \( F \in \mathcal{Q}\text{coh}^{bf}(X) \), then the set of points of \( X \) that \( F \) is flat over \( S \) is open. In particular, if \( f \) is a closed map, then the set of points of \( Y \) that \( F \) is flat is open.

Proof: Cf.[Sta]00RC. The last assertion follows from the first one.

Prop.(5.6.2.15) [Generic Flatness]. For a morphism \( f : X \to S \) of f.t., if \( S \) is reduced and \( F \) is a Qco f.t. \( \mathcal{O}_X \)-module, then there exists an open dense subset \( U \) of \( S \) that \( X_U \to U \) is flat, of f.p., and \( F|_{X_U} \) is flat over \( U \) and of f.p. over \( \mathcal{O}_U \).

Proof: As flat and f.p. is local on the base, it suffices to show for \( S \) affine. Then this almost immediately reduces to the affine case??y choosing an affine cover of \( X \), except that we need \( X_U \) to be qs over \( U \). To achieve this, it suffices to do it second time and let \( X = \bigcup_{i \leq n} \text{Spec } B_i = \bigcup X_i, \) and \( X_i \cap X_j = D(I_{ij}), M_{ij} = B_i/I_{ij}, \) then choose \( f \) large enough that over \( S_f, \) all \( M_{ij} \) are f.p. over \( B_i, \) then by (4.2.5.9), \( X_{i,f} \cap X_{j,f} \) is qc, thus \( X_f \) is f.p. over \( S_f \).

Prop.(5.6.2.16) [Fibral Criterion of flatness]. Let \( S \in \text{Sch} \) and \( f : X \to Y \in \text{Sch}/S, F \in \mathcal{Q}\text{coh}^{bf}(X) \). Let \( x \in X, y = f(x) \) and \( x \) maps to \( s \in S \). Suppose \( X,Y \) are both locally Noetherian or \( X \) is locally of f.p. over \( S \) and \( Y \) is locally of f.t. over \( S \), then the following are equivalent:
- \( F \) is flat over \( S \) at \( x \) and \( F_s \) is flat over \( Y_s \) at \( x \).
- \( Y \) is flat over \( S \) at \( y \) and \( F \) is flat over \( Y \) at \( x \).

Proof: Cf.[Sta]039B, 039C.

Prop.(5.6.2.17) [Hilbert Polynomial Constant in Flat Family]. For \( X/T \) projective, where \( T \) is an integral Noetherian scheme and \( X \subset \mathbb{P}_T^n \). Then for each point \( T, X_t \) is a closed subscheme of \( \mathbb{P}_k(t)^n \), so we can consider its Hilbert Polynomial \( P_t \). Then \( X/T \) is flat iff \( P_t \) is independent of \( T \).

Needs huge improvement.

Proof: \( P_t(m) = \dim_k H^0(X_t, \mathcal{O}_{X_t}(m)) \) for \( m \) large by (5.7.3.10). And we may let \( X = \mathbb{P}_T^n \) and prove for any coherent sheaf \( F \). Moreover, we may let \( T \) be a affine local Noetherian, because flatness is local and we only need to compare Hilbert polynomial with the generic point. Now we prove a stronger assertion: The following are equivalent:
• \( \mathcal{F} \) is flat over \( T \).
• \( H^0(X, \mathcal{F}(m)) \) is a free \( A \)-module of finite rank, for \( m \) large.
• The Hilbert polynomial \( P_t \) of \( \mathcal{F}_t \) on \( X_t = \mathbb{P}^n_{k(t)} \) is independent of \( t \).

1 \( \rightarrow \) 2: Use the canonical cover and Čech cohomology, then we notice when \( m \) is large, \( H^0(X, \mathcal{F}(m)) \) is a kernel of the Čech resolution, so it is flat. And it is also finite by (5.7.4.12). Then it is free because it is flat by (4.4.1.10).

2 \( \rightarrow \) 1: Let \( M = \oplus_{m \geq m_0} H^0(X, \mathcal{F}(m)) \), then \( \widetilde{M} = \mathcal{F}(5.5.3.6) \), notice that the truncation doesn’t affect.

2 \( \rightarrow \) 3: It suffice to prove that for any \( t \in T \), when \( m \) is large,
\[
H^0(X_t, \mathcal{F}_t(m)) \cong H^0(X, \mathcal{F}(m)) \otimes_A k(t).
\]

For this, we may use (5.7.5.1) to pass to the localization and assume \( t \) is the closed pt of \( T \). Then \( A \rightarrow k(t) \) is surjective and we may let \( A^q \rightarrow A \rightarrow k \rightarrow 0 \), then by (5.7.4.8), we have \( H^0(X_t, \mathcal{F}_t(m)) \) is the cokernel of \( H^0(X, \mathcal{F}(m))^q \rightarrow H^0(X, \mathcal{F}(m)) \), but this cokernel is \( H^0(X, \mathcal{F}(m)) \otimes_k k \) because tensoring is right-adjoint, so we are done.

3 \( \rightarrow \) 2: We have the rank of \( H^0(X, \mathcal{F}(m)) \) at the generic and closed point of \( T \) are the same (still use \( H^0(X_t, \mathcal{F}_t(m)) \cong H^0(X, \mathcal{F}(m)) \otimes_A k(t) \)). Now (4.4.8.1) gives \( H^0(X, \mathcal{F}(m)) \) is free. It is f.g. automatically.

\[\square\]

Cor. (5.6.2.18). For a flat morphism to a connected scheme \( T \), the dimension, degree, and arithmetic genus of the fibers are independent of \( t \).

\[\text{Proof:}\] By (5.7.3.6) and (5.7.3.12). \[\square\]

Def. (5.6.2.19). For a surjective map of varieties \( f : X \rightarrow T \) over an alg.closed field \( k \), its fiberes over closed points with induced reduced structure \( X_t \) is called a \textbf{algebraic family of varieties parametrized by} \( T \) if

1. \( f^{-1}(t) \) is irreducible of dimension \( \dim X - \dim T \) for every closed point \( t \).

2. If \( \zeta \) is the generic point of \( f^{-1}(t) \), then \( F^q m_t \) generates the maximal ideal \( m_\zeta \subset \mathcal{O}_{\zeta, X} \).

Prop. (5.6.2.20). If \( X_t \) is an algebraic family of normal varieties over an alg.closed field \( k \) parametrized by a nonsingular curve \( T \), then it is a flat family of schemes.

\[\text{Proof:}\] By (5.11.1.20), \( X \rightarrow T \) is flat. So what we need to do is to prove \( X_t \) is reduced so \( X_t = X_{(t)} \). Let \( A = \mathcal{O}_{x, X} \), let \( u_t \) be a uniformizer of \( \mathcal{O}_{t, T} \), then \( A/tA \) is the local ring of \( x \) on \( X_t \). By hypothesis \( X_t \) is irreducible so \( tA \) has a unique minimal prime \( p \) in \( A \), and \( t \) generate the maximal ideal of \( A_p \) by hypothesis. The local ring of \( X_{(t)} \) is \( A/p \), so \( A/p \) is normal by hypothesis. Then the result follows from (4.3.5.13). \[\square\]

Cor. (5.6.2.21) [Igusa]. Let \( X_{(t)} \) be an algebraic family of normal varieties in \( \mathbb{P}^n_k \) for \( k \) alg.closed parametrized a variety \( T \), then the Hilbert polynomials of \( X_{(t)} \) are independent of \( t \).

\[\text{Proof:}\] Why is \( X/T \) projective? Cf. [Hartshorne P265]. \[\square\]
Degenerating Techniques

Finite Locally Free Morphism

Def.(5.6.2.22)[Finite Locally Free]. A morphism $f : X \to Y$ is called finite locally free of rank $d$ if it is affine, and $f_*\mathcal{O}_X$ is a finite locally free $\mathcal{O}_Y$-module of rank $d$.

Cor.(5.6.2.23). If $f$ is finite locally free of rank $n$, then for any locally free sheaf $E$ of rank $k$ on $X$, $f_*E$ is locally free of rank $nk$.

Prop.(5.6.2.24). $f$ is finite locally free iff it is finite, flat and of f.p.. In particular, when $Y$ is locally Noetherian, this is equivalent to $f$ is finite flat.

Proof: Both notions are local on the target, so we reduce to the ring case, which is (4.3.1.7). □

Cor.(5.6.2.25). Finite locally freeness is stable under composition and base change, and it is local on the target.

Prop.(5.6.2.26)[Trace and Norm]. Let $f : Y \to X$ be a finite locally free map of constant rank, then there are trace and norm maps $\text{tr} : f_*\mathcal{O}_Y \to \mathcal{O}_X, \text{Nm} : f_*\mathcal{O}_Y \to \mathcal{O}_X$ compatible with arbitrary base change.

Proof: The proof is the same as that of (4.3.1.11). □

Prop.(5.6.2.27). Let $f : Y \to X$ be a finite locally free map of constant rank, and $b \in \Gamma(Y, \mathcal{O}_Y)$, then $f(Z(b)) = Z(\text{Nm}(b))$.

Proof: We can assume $X$ is affine, then we need to show that for a prime $p$ with inverse images $p_i$, $b \in \cup p_i$ iff $\text{Nm}(b) \in p$. We localize at $p$, then $\text{Nm}(b) \in p$ iff $\text{Nm}(b)$ is non-invertible iff multiplication by $b$ is non-invertible iff $b$ is non-invertible iff $b \notin \cup p_i$, because $p_i$ are all the maximal ideals of $B_p$. □

3 Dimensions

Main references are [Mat80] and [Vak17]Chap11.

Prop.(5.6.3.1)[Locally Algebraic Scheme is Catenary]. If $X$ is a locally algebraic scheme over a field $k$ purely of dimension $n$, and $Y$ an irreducible subscheme of $X$, then $\dim Y + \text{codim}(Y, X) = \dim X$.

Proof: Choose an affine open of the generic point of $Y$, then we are reduced to the affine case (4.2.4.3)(4.2.4.7). □

Prop.(5.6.3.2). For any scheme, $\dim \mathcal{O}_x = \text{codim}(\overline{\{x\}}, X)$.

Prop.(5.6.3.3). For an integral scheme algebraic over a field $k$,

$$\dim X = \dim \mathcal{O}_{p,X} = \dim U = \text{tr.deg } K(X)/k$$

for any closed point $p$ and any open subscheme $U$.

Proof: Use closed point are dense (5.4.1.26) and $k$ is universal catenary to prove it is true for some $U$ and all the closed point in it, so other $U$’s because $X$ is irreducible. The last equation follows from (4.2.4.23). □
Prop. (5.6.3.4) [Finite Surjection Preserves Dimension]. Let $X \to Y$ be a surjective finite morphism of algebraic integral schemes over a field $k$, then $\dim X = \dim Y$.

Proof: The hypothesis implies that for any affine open $\text{Spec} \, A \subset Y$, the inverse image is $\text{Spec} \, B$ that $A \to B$ is an injective integral ring extension, so we can use (5.6.3.3) and (4.2.4.14). □

Prop. (5.6.3.5). Let $X$ be a locally Noetherian scheme, if $U \subset X$ is an open subscheme that $U \to X$ is affine, then every irreducible complements of $X - U$ has codimension ≤ 1. And if $U$ is dense, then equality must hold.

Proof: Cf. [Sta]0BCU. □

Prop. (5.6.3.6) [Local Dimensions]. Let $X$ be a locally algebraic scheme over a field $k$ and $x \in X$, then the local dimension $\dim_x(X)$ equals the maximal dimension of irreducible components of $X$ passing through $x$, by (4.2.4.27).

Prop. (5.6.3.7). If $f : X \to Y \in \text{Sch}^{\text{loc}, \text{ft}} / S$, $x \in X$ and $s = f(x)$, then

$$\dim_x(X_s) = \dim O_{X,s,x} + \text{tr.deg}_{k(s)} k(x).$$

Proof: This reduces to the case $Y = \text{Spec} \, k(s)$, and it follows from (4.2.4.28). □

Prop. (5.6.3.8) [Semicontinuity of Dimension]. Let $f : X \to S$ be a morphism of schemes locally of f.t., then the function $x \mapsto \dim_x(X_{f(x)})$ is upper-semicontinuous on $X$.

Moreover, if $f$ is of f.p., then the open subsets $\{x \mid \dim_x(X_{f(x)}) \leq n\}$ is retrocompact.

Proof: This follows directly from (4.2.4.32). □

Prop. (5.6.3.9) [Local Dimension and Base Change]. Let

$$
\begin{array}{ccc}
X' & \xrightarrow{g'} & X \\
\downarrow f' & & \downarrow f \\
S' & \xrightarrow{g} & S
\end{array}
$$

be a fiber product diagram of schemes, and $f$ is locally of f.t.. Suppose $x' \in X'$, $x = g'(x')$, $s = g(s')$. Then

- $\dim_x(X_s) = \dim_{x'}(X_{s'})$.
- $\dim O_{F,x'} = \dim O_{X',x'} - \dim O_{X,x} = \text{tr.deg}_{k(s)}(k(x)) - \text{tr.deg}_{k(s')}(k(x'))$.

where $F$ is the fiber of the morphism $X'_s \to X_s$ over $x$. In particular, $\dim O_{X',x'} \geq \dim O_{X,x}$ and $\text{tr.deg}_{k(s})(k(x')) \leq \text{tr.deg}_{k(s)}(k(x))$.

- Given $s', s$, $x$ that $f(x) = g(s')$, there exists an $x' \in X'$ that $\dim O_{X',x'} = \dim O_{X,x}$ and $\text{tr.deg}_{k(s')}(k(x')) = \text{tr.deg}_{k(s)}(k(x))$.

Proof: It can be reduced to the case that $S = \text{Spec} \, k(s)$, $S' = \text{Spec} \, k(s')$ and $X, X'$ affine. Then 1 follows from (4.2.4.31), and 2, 3 follows from (4.2.4.26). □

Cor. (5.6.3.10) [Dimension and Field Extension]. Let $K/k$ be a field extension, $X$ a locally algebraic scheme over $k$ purely of dimension $n$, then $X_K$ is a scheme purely of dimension $n$. 

Remark (5.6.3.11). This proposition shows in particular local dimension behaves better than the dimension of the stalk.

Def. (5.6.3.12) [Relative Dimensions]. A morphism of schemes which locally of f.t. is called of relative dimension \( n \) iff all fibers \( X_s \) are equidimensional of dimension \( n \).

Prop. (5.6.3.13). Being a morphism of relative dimension \( n \) is stable under field extension, by (5.6.3.10).

Dimension and Flatness

Prop. (5.6.3.14) [Faithfully Flat Morphism]. If \( f : Y \to X \) is a faithfully flat morphism, then \( \dim Y \geq \dim X \).

Proof: This is easy from (5.6.2.7).

Prop. (5.6.3.15) [Integral Flat Morphisms]. If \( f : X' \to X \) is an integral flat morphism of schemes, and \( X \) is pure of dimension \( n \), then so does \( X' \). The converse holds if \( f \) is faithfully flat.

Proof: By (5.6.2.8) and (5.4.4.35), \( f \) maps an irreducible component of \( X' \) onto an irreducible component of \( X \). Then by (3.8.3.26), the proposition reduces to the affine case (4.2.4.15). If \( f \) is faithfully flat, then every irreducible component of \( X \) is in the image.

Cor. (5.6.3.16) [Dimension and Field Extension]. If \( K/k \) is an algebraic extension, \( X \) a scheme over \( k \) purely of dimension \( n \), then \( X_K \) is a scheme purely of dimension \( n \). Compare with (5.6.3.10).

Prop. (5.6.3.17) [Dimension Extension and Flatness]. Let \( f : X \to Y, g : Y \to S \) be locally of f.t., \( x \in X, y = f(x), s = g(y) \), then

\[
\dim_x(X_s) \leq \dim_x(X_y) + \dim_y(Y_s).
\]

Moreover, equality holds if \( \mathcal{O}_{X,x}/\mathcal{O}_{Y,y} \) is flat.

In particular, if \( S = \text{Spec} k \) and \( X, Y \) are irreducible and \( X \) is flat over \( Y \), then \( \dim X_y = \dim X - \dim Y \) for any \( y \in Y \).

Proof: By (5.6.3.7) and the fact transcendental degree is additive, this reduces to

\[
\dim \mathcal{O}_{X,x} \leq \dim \mathcal{O}_{X,y} + \dim \mathcal{O}_{Y,y}.
\]

We can assume \( X, Y \) is affine and \( S = \text{Spec} k(s) \), so the rest follows from (4.2.4.13).

Cor. (5.6.3.18). If \( f : X \to Y, g : Y \to Z \) are of relative dimension \( m \) and \( n \) (5.6.3.12), and \( f \) is flat, then \( g \circ f \) is of relative dimension \( m + n \).

Cor. (5.6.3.19) [Generic Dimension Equation]. If \( f : X \to Y \) is a dominant morphism of irreducible algebraic schemes over \( K \) that \( X \) is reduced, then there is a dense open subset \( U \) of \( Y \) that for any \( y \in Y \),

\[
\dim(Y_y) = \dim X - \dim Y.
\]

Proof: This is a combination of the above proposition and generic flatness (5.6.2.15).
Prop. (5.6.3.20) [Relative Dimension and Base Change]. By (5.6.3.9), the base change of a morphism of locally algebraic schemes over a field \( k \) of relative dimension \( n \) is still of relative dimension \( n \). In particular, for a variety over \( K \) a field, the dimension is invariant under base change of fields.

Cor. (5.6.3.21). Let \( Y, Z \) be irreducible locally algebraic schemes over \( k \), then \( Y \times_k Z \) is pure of dimensional \( \dim(Y) + \dim(Z) \).

Proof: Combine (5.6.3.20) and (5.6.3.17).

Prop. (5.6.3.22). For a morphism \( f : X \to Y \) between locally Noetherian schemes which is flat and locally of f.t and of relative dimension \( n \), then if \( y = f(x) \), we have \( \dim_x(X_y) = \dim_x(X) - \dim_y(Y) \).

Proof: Shrinking the nbhd, we may assume \( \dim_x(X) = \dim X \) and \( \dim_y(Y) = \dim Y \) and \( X, Y \) are affine. Now \( f \) is locally of f.p. and flat, so it is open (5.6.2.10). So we may assume \( f \) is surjective. Then \( \dim \mathcal{O}_{X,a} = \dim \mathcal{O}_{Y,b} + \dim \mathcal{O}_{X,b,a} = \mathcal{O}_{Y,b} + n \) by (4.2.4.13), then taking supremum??, the result follows.

Cor. (5.6.3.23). For a morphism of schemes that is flat and of f.t., if \( Y \) is irreducible, then \( X \) is equidimensional of dimension \( \dim Y + n \) iff \( X_y \) is equidimensional of dimension \( n \) for every \( y \in Y \).

Proof: The proof highly relies on (5.6.3.3).

If \( X \) is equidimensional of dimension \( \dim Y + n \), for \( Z \subset X_y \) an irreducible component, choose a closed pt \( x \) of \( Z \) not contained in any other irreducible component, then
\[
\dim_x Z = \dim_x X - \dim_y Y = \dim X - \dim \{x\} - \dim Y + \dim \{y\}.
\]
The two closures are of the same dimension because by (4.2.6.10), their quotient field extension is finite, and use (4.4.2.14).

Conversely, for an irreducible component of \( X \), choose a closed pt \( x \) of \( Z \) not contained in any other irreducible component, then the image is also closed, by (5.4.1.27), so the result is immediate.

Prop. (5.6.3.24). If \( f : X \to Y \) is a proper flat morphism of schemes of f.p., then the dimension of fibers of \( f \) is a locally constant function.

Proof: Cf. [Sta]04DJ.

4 Smoothness

Def. (5.6.4.1) [Smooth Morphisms]. A \textbf{smooth morphism} \( f : X \to Y \) between schemes is a morphism that there is an open affine cover \( \{U_i\} \) of \( S \) and an open affine cover \( V_{ij} \) of \( f^{-1}(\{U_i\}) \) that the ring map is smooth (4.4.5.12). In particular, it is locally of f.p.. A \textbf{standard smooth morphism} is the Spec map of a standard smooth ring map.

Smoothness is local on the source and target (4.4.5.13). Smoothness is stable under base change and composition (4.4.5.13).

Prop. (5.6.4.2). For a smooth morphism \( X \to S \), the morphism of differential \( \Omega_{X/S} \) is locally free and \( \dim_x \Omega_{X/S} = \dim_x(X_f(x)) \) (local dimension (3.8.3.25)).

Proof: We can assume that \( X \to S \) is standard smooth, so by the proof in (4.4.5.12), \( \Omega_{X/S} \) is free of dimension \( n - c \), and also standard smooth is relative global complete intersection (4.4.5.11), so \( U_f(x) \) is equidimensional of dimension \( n - c \), thus the result.
Cor. (5.6.4.3) [Differential Criterion of Smoothness]. If $X \to S$ is a flat of relative dimension $n$, then $X$ is smooth over $S$ iff it is locally of f.p. and $\Omega_{X/S}$ is locally free of dimension $n$, by (4.4.5.23).

Prop. (5.6.4.4) [Smooth Morphism is Open]. Smooth morphism is syntomic hence flat. Smooth morphism is locally of f.p. Hence smooth morphism is universally open (5.6.2.10).

Smooth morphism is locally standard smooth (4.4.5.12).

Prop. (5.6.4.5) [Fiberwise and Stalkwise]. For a morphism $X \to S$ locally of f.p., the following are equivalent:

- It is smooth at a point $x \in X$ over $s \in S$.
- $O_{X,x}/O_{X,f(x)}$ is flat and $X_{f(x)}/k(f(x))$ is smooth at $x$, by (4.4.5.20).
- $O_{X,x}/O_{S,f(x)}$ is flat and $\Omega_{X/S,x}$ can be generated by $\dim_x(X_{f(x)})$ elements, by (5.6.4.2) and (4.4.5.23).
- $O_{X,x}/O_{S,f(x)}$ is flat and $\Omega_{X/S,x}$ can be generated by $\dim_x(X_{f(x)})$ elements, by Nakayama, because $\Omega_{X/S,x}$ is of f.p. by (4.4.3.9).

In particular, a smooth morphism can be seen as a family of smooth schemes.

Proof:

Cor. (5.6.4.6) [Smoothness over DVR]. Let $R$ be a DVR with fraction field $K$ and residue field $k$, then an integral $R$-scheme $X$ of f.t. is smooth over $R$ iff $X_K \neq \emptyset$ and both $X_K/K$ and $X_k/k$ are smooth.

Proof: Notice that it is flat iff $X_K \neq \emptyset$.

Prop. (5.6.4.7). If $X \to Y$ is a smooth map of schemes over $S$, then by (5.5.5.5)(4.4.5.5), there is an exact sequence of sheaves:

$$0 \to f^*\Omega_{Y/S} \xrightarrow{df^*} \Omega_{X/S} \to \Omega_{X/Y} \to 0$$

Prop. (5.6.4.8). If $Z \to X \to S$, $Z/S$ is smooth and $Z \to X$ is an immersion, then there is an exact sequence of sheaves (5.5.5.13)(4.4.5.6):

$$0 \to C_{Z/X} \to i^*\Omega_{X/S} \to \Omega_{Z/S} \to 0$$

Prop. (5.6.4.9). If $X \to Y \to S$, and $X \to Y$ are faithfully flat and locally of f.p., $X/S$ is smooth, then $Y/S$ is smooth.

Proof: Cf. [Sta] 05B5.

Prop. (5.6.4.10). If $f : X \to S$ is faithfully flat and locally of f.p., then the set of points of $S$ s.t. $f$ is smooth is table under base change.

Proof:

Prop. (5.6.4.11). By (5.6.4.5)(5.6.4.2), A morphism is smooth of relative dimension $n$ is equivalent to fppf+fibers equidimensional of dimension $n$ and $\Omega_{X/S}$ is locally free of dimension $n$.

Prop. (5.6.4.12) [Jacobian Criterion for Projective Schemes]. Let $X$ be a closed subscheme of $\mathbb{P}_R^n$ defined by $r$ polynomials $F_1(X_0, \ldots, X_n), \ldots, F_r(X_1, \ldots, X_n)$, then for $x \in X$, $X$ is smooth at $x$ iff the Jacobian has rank $\geq n - \dim_x X$ at $x$ iff the Jacobian has rank $= n - \dim_x X$ at $x$. 
Proof: Assume that $x$ is in the standard open $X_0 \neq 0$, then we can use Euler’s identity $\sum X_i \partial F_i = \dim(F) F$ to eliminate the first row, then divide by $X_0^{\dim F}$ to get the Jacobian on the affine open $\text{Spec} R[x_0, \ldots, x_n]$, so we finish by $(4.4.5.24)$. □

Prop.(5.6.4.13) [Generic Smoothness on the Source]. Let $\pi : X \to Y$ be a dominant map of integral schemes of f.t. that $K(Y) \to K(X)$ is separable, then there is a non-empty open subscheme $U \subset X$ that $\pi|_U$ is smooth of relative dimension $\dim X - \dim Y$.

Proof: This reduces to the affine case, and follows from $(4.4.5.29)$ and $(5.6.3.17)$. □

Prop.(5.6.4.14) [Generic Smoothness on the Target]. Let $\pi : X \to Y$ be a morphism of $k$-varieties where $\text{char } k = 0$, and $X$ is smooth over $k$, then there is a dense open subset $U \subset Y$ that $\pi^{-1}(U) \to U$ is smooth.

Smooth over Fields

Prop.(5.6.4.15) [Differential Criterion of Smoothness]. Let $X$ be a scheme algebraic over a field $k$.

- If $X$ is equidimensional of dimension $n$, then $X$ is smooth over $k$ iff $\Omega_{X/k}$ is locally free of dimension $n$.
- If $\Omega_{X/k}$ is locally free, and $k$ is of char 0 or $k$ is perfect and $X$ is reduced, then $X$ is smooth over $k$.

Proof: 1: This follows from $(5.6.4.3)$.

2: If $k$ is of characteristic 0, then this follows from $(4.4.5.28)$.

perfect case: [Sta]04QP. ? □

Prop.(5.6.4.16) [Smooth over Field and Geo.Regular]. For a scheme locally algebraic over a field $k$, $X$ is geometrically regular iff it is smooth over $k$. In particular, if $k$ is perfect, then smoothness is equivalent to regularity, by $(5.4.3.18)$.

Proof: The question is local around $x$, so may assume $X$ is affine. Then this follows from $(4.4.5.27)$. □

Cor.(5.6.4.17) [Hartshorne Definition]. By $(5.6.4.5)$ and $(5.6.4.16)$, a morphism between schemes algebraic over a field $k$ is smooth of relative dimension $n$ iff $f$ is flat and every fiber of $f$ is geometrically regular of dimension $n$.

Cor.(5.6.4.18). A smooth scheme over a field $k$ is regular hence normal.

Prop.(5.6.4.19) [Smoothness and Separable Closed Points]. Let $X$ be smooth over a field $k$, then the set of closed points of $X$ with finite separable residue field $k(x)/k$ is dense in $X$.

Proof: It suffices to show there exists one such points. By $(5.6.6.7)$, we can assume $X \xrightarrow{\pi} \mathbb{A}_k^d \to k$, where $\pi$ is étale. Thus $X$ is open in $\mathbb{A}_k^d$ by $(5.6.6.3)$. Then we can choose a closed point of $\pi(X)$ s.t. the residue field is finite separable, as $k^{\text{sep}}$ is infinite. Then choose an inverse image, then the residue if finite étaleover $k$, by $(5.6.6.8)$. This point is clearly closed. □
Prop. (5.6.4.20) [Smoothness at Rational Points]. Let $X$ be a locally algebraic scheme over a field $k$. Let $x \in X$ that $k(x)/k$ is finite separable, then $X$ is smooth at $x$ iff it is $x$ is a regular point, by (4.4.5.26).

Prop. (5.6.4.21) [Geo. Reduced Scheme Generic Smooth]. Let $X$ be a locally algebraic scheme over a field $k$ that is geometrically reduced, then it contains an open dense subset that is smooth over $k$.

Proof: The problem is local, so we may assume $X$ is affine, consider its irreducible components, all their intersections can be removed, because they are nowhere dense, so we may assume $X$ is irreducible. So $X$ is integral, let $\eta$ be the generic pt, then $k(\eta)/k$ is separable, by (5.4.3.2). Then choose an affine subscheme $\text{Spec} A \subset X$, then $A$ is smooth at (0) over $k$, by (4.4.5.29), then by definition, it is smooth on some dense open subscheme of $X$. \qed

Tangent Spaces

Def. (5.6.4.22) [Relative Tangent Spaces]. Let $X$ be a scheme over $S$ and $x \in X$, define $T^*_x/S_x = \Omega_{X/S, x} \otimes_{O_{X, x}} k(x)$, and $T_{x/S} = \text{Hom}_{k(x)}(T^*_x/S_x, k(x)) = \text{Hom}_{O_{X, x}}(\Omega_{X/S, x}, k(x))$, called the relative tangent space of $X$ over $S$ at $x$.

When $x \in X$ mapping to $s \in S$, $T_{x/S} = \text{Hom}_{k(x)}(m_x/m_x^2, k(x))$, where $m_x$ is the maximal ideal of the stalk of $x \in X_s$.

Then it can be verified that for a $k$-scheme and a rational point $x \in X$, $T_{x/S}$ is in bijection with $\text{Mor}_k(\text{Spec} k[\varepsilon], X)$ that maps the closed point to $x$.

Prop. (5.6.4.23) [Tangent Map]. Let $f : X \to Y$ be a morphism of schemes over $S$, $x \in X$, $f(x) = y$. Assume $k(x) = k(y)$, then $f$ defines a natural linear map

$$df : T_{X/S_x} \to T_{Y/S_y} : \text{Hom}_{O_{X, x}}((\Omega_{X/S})_x, k(x)) \to \text{Hom}_{O_{Y, y}}((f^*\Omega_{Y/S})_y, k(x))(5.5.5.5) = \text{Hom}_{O_{X, x}}(\Omega_{Y/S_y} \otimes_{O_{Y, y}} O_{X, x}, k(y)) = \text{Hom}_{O_{Y, y}}(\Omega_{Y/S_y}, k(y))$$

Cor. (5.6.4.24). Via similar argument, if $k(x) = k(s) = k(y)$, there is an isomorphism

$$T_{X/S_x} \oplus T_{Y/S_y} \cong T_{X \times_S Y(x, y)}.$$

Prop. (5.6.4.25). Let $X$ be a scheme over a field $k$ and $x \in X$ with residue field $k(x)$, then the tangent space is canonical isomorphic to $\text{Mor}(k(x)[\varepsilon], X)$ that maps the closed point to $x$. And the vector bundle structure is given by the cogroup structure on $\text{Spec} k[\varepsilon] : \mu : k[\varepsilon] \otimes k[\varepsilon] \to k[\varepsilon]$.

Prop. (5.6.4.26) [Krull’s Principal Tangent Theorem]. Let $Z \subset X$ be a closed subscheme with ideal of definition $I$, $x \in Z$, then $T_{Z, x}$ is the subspace of $T_{X, x}$ cut out by $(I \mod m_x^2)$. In particular, $T_{Y \cap Z, p} = T_{Y, p} \cap T_{Z, p} \subset T_{X, p}$.

Prop. (5.6.4.27) [Tangent Criterion of Smoothness]. By (5.6.4.16)(5.6.4.20) and the definition of regular local ring, if $X$ is a locally algebraic scheme over a field $k$, then $X$ is smooth at a point $x$ with residue field $k(x)/k$ separable iff $\text{dim}_k(T_{X, x}) \leq (\leq)$ the dimension of $O_{X, x}$.
Bertini’s Theorem

Prop.(5.6.4.28)[Bertini]. Let $k$ be a field. For any quasi-projective scheme $X \subset \mathbb{P}^n_k$ smooth away from f.m. points, there is an open dense subset $U$ of the dual projective space $\mathbb{P}^n_k^\vee$ s.t. for any closed point $[H] \subset U$, $H$ doesn’t contain any component of $X$, and the scheme $H \cap X$ is smooth over $k$.

Moreover, if $X$ is a variety and $\dim X \geq 2$, the smooth cut is even a smooth variety by (5.8.6.25) and (5.4.2.9).

Proof: Let $\mathbb{P}^n = \text{Proj } k[x_0, \ldots, x_n], (\mathbb{P}^n)^\vee = \text{Proj } k[a_0, \ldots, a_n]$. Let $\overline{X}$ be cut out by equations $f_1, \ldots, f_r$, we define a projective scheme $Z \subset \mathbb{P}^n \times (\mathbb{P}^n)^\vee$ be cut by the equations

- $f_r$,
- $f_{r+1} = \sum a_i x_i$,
- determinants of $(r + 1) \times (r + 1)$-minors of $(\frac{\partial f_i}{\partial x_j})(r + 1) \times n$.

Now for any $(x, [H]) \in Z$, $x \in X, x \in H$ that $[H]$ is closed in $(\mathbb{P}^n)^\vee$, the last equation means $X \cap H$ is non-smooth at $p$ or contains the irreducible component passing $p$, by Jacobian criterion (5.6.4.12). Now consider the projection $Z \rightarrow X$, for each closed point $p \in X$ that $\dim_p X = d$, the codimension of the fiber of $Z$ over $x$ is of dimension $r - 1 = n - \dim_x X - 1$ (To see this, one way is use regularity and tangent space, another way is to use the fact $(x_i)$ is orthogonal to $(\frac{\partial f_i}{\partial x_j})$ for all $i$ by Euler identity, so the $r+1$ restrictions of $(a_i)$ are linearly independent), then by (5.6.3.17), $\dim Z = \dim \pi_1^{-1}(Z) \leq n - 1$.

Thus the image of $Z$ in $\mathbb{P}^n_k^\vee$ is also a closed subscheme of dimension $\leq n - 1$.

If $X$ has f.m. singular points, we also need to cut out the surfaces $N_{k(x)/k}(\sum x_i^k a_i)$, where $(x'_i)$ are the f.m. closed singular points of $x$. They are also of dimension $n - 1$. $\square$

Cor.(5.6.4.29)[Bertini’s Theorem for Surfaces]. Similarly, for any $d \geq 0$, a generic dimension $d$ surface intersect $X$ at a smooth subscheme, by using Veronese embedding.

Cor.(5.6.4.30). When $X \subset \mathbb{P}^n_k$ is a projective $k$-variety where $k$ has characteristic 0, the scheme $Z$ in $\mathbb{P}^n_k^\vee$ is called the dual variety of $X$. When $X$ is irreducible and smooth, it is of dimension $n - 1$.

Proof: $\square$

Prop.(5.6.4.31). The dual variety of the dual variety is $X$ itself.

Proof: Cf.[Joe Harris, Algebraic Geometry, 15.24]. $\square$

Prop.(5.6.4.32)[Kleinman-Bertini]. Let $X$ be a $k$-variety that is homogenous space for a $k$-variety $G$ over a field $k$, suppose $\alpha : Y \rightarrow X, \beta : Z \rightarrow X$ are morphisms of varieties, then

- There is a non-zero open subset $V \subset G$ that for any closed point $\sigma \in V$, $\dim \sigma(Y) \times_X Z = \dim Y + \dim Z - \dim X$.
- If $Y, Z$ are smooth over $k$ of characteristic 0, then there is a non-empty open subset $V \subset G$ that $(G \times_k Y) \times_X Z \rightarrow G$ is smooth. In particular, for any closed point $\sigma \in V$, $\sigma(Y) \times_X Z$ is smooth over $k(\sigma)$ of dimension $\dim Y + \dim Z - \dim X$.

Proof: Let $\Gamma = (G \times_k Y) \times_X Z$, then there is a map $\Gamma \rightarrow Y \times_k Z$. $Y \times_k Z$ has dimension $\dim Y + \dim Z$ by (5.6.3.21), and there is a base change diagram

\[
\begin{array}{ccc}
(G \times_k Y) \times_X Z & \longrightarrow & Y \times_k Z \\
\downarrow & & \downarrow \\
G \times_k X & \longrightarrow & X \times_k X
\end{array}
\]
and $G \times X \to X \times X$ is flat as it is equivariant under $G \times G$-action, by (5.6.2.15), thus $\Gamma \to Y \times_k Z$ is flat of relative dimension $\dim G - \dim X$, thus it has dimension $\dim Y + \dim Z + \dim G - \dim X$.

1: This follows from (5.6.3.19) applied to the map $G \times_k Y \times_k Z \to G$.

2: As $G \times X \to X \times X$ is flat, and its fiber are isomorphic to $G_x$, which is the fiber of the map $\alpha_x : G \to X$, and this map is smooth by (5.6.4.14), thus $G \times X \to X \times X$ is smooth, and then the assertion follows from (5.6.4.14).

\[ \square \]

Cor. (5.6.4.33). Let $Z$ be a smooth $k$-variety where $\text{char} k = 0$. Let $V$ be a f.d. basepoint-free line series on $Z$, then the section of a general element of $V$ is smooth.

Proof: Apply Kleinman-Bertini to $\varphi_V : Z \to \mathbb{P}V^\vee$, $Y = V(\sum a_i x_i) \in PV \times PV^\vee \to PV^\vee$, $X = PV^\vee$. \[ \square \]

5 Unramified

More advanced materials to learn at [Sta]Chap40.

Def. (5.6.5.1) [Unramified Morphism]. A morphism is called (G-)unramified iff there is an open affine cover $U_i$ and an open affine cover of $f^{-1}(U_i)$ that the induced ring map is (G-)unramified (4.4.6.4). Equivalently, $\Omega_{X/S} = 0$ and it is locally of f.t.(f.p.).

(G-)unramifiedness is local on the source and target (5.4.1.5) (5.4.1.6). (G-)unramifiedness is stable under base change and composition (4.4.6.4). Moreover, unramifiedness satisfies the base change trick.

Prop. (5.6.5.2). An unramified map is locally quasi-finite.

Proof: Cf. [Sta]02V5. \[ \square \]

Prop. (5.6.5.3) [Fiberwise]. A morphism is (G-)unramified iff it is locally of f.t.(f.p.) and all the fibers $X_s$ are disjoint unions of spectra of finite separable extensions of $k(p)$.

Proof: By (4.4.6.7), Notice $pS_q = qS_q$ is equivalent to every $q$ is minimal in $X_p$, which is equivalent to $X_p$ is discrete. \[ \square \]

Cor. (5.6.5.4) [Unramified over Fields]. A scheme over a field $k$ is unramified iff it is a disjoint union of spectra of finite separable extensions of $k$, because locally of f.p. is trivially satisfied.

Prop. (5.6.5.5) [Diagonal is Open]. A morphism $X \to S$ is (G-)unramified iff it is of f.t.(f.p.) and the diagonal is a clopen immersion of $X$, thus all of $X$.

Proof: If it is unramified, then the diagonal is an open immersion by (4.4.6.10). Conversely, $\Omega_{X/S}$ is just the conormal sheaf of the diagonal map, so it is zero. \[ \square \]

Cor. (5.6.5.6) [Sections of Unramified Morphism]. Any section of an unramified morphism is an open immersion. In particular, a section of a separable unramified morphism is a clopen immersion.

Proof: This follows from the proposition and the fact $S \to X$ is a base change of $\Delta_{X/S}$. \[ \square \]

Cor. (5.6.5.7). Let $X, Y$ be schemes over $S$, if $f, g$ are two maps from $X$ to $Y$, then if $Y/S$ is unramified and $f, g$ are equal on a pt $x$ of $X$ (both on image and residue field), then there is a nbhd of $x$ that $f, g$ are equal.
Proof: This follows as $\Delta_{Y/S}$ is open immersion, so the set that $f, g$ are equal is open in $X$. □

Prop. (5.6.5.8) [Fiberwise]. For a morphism $f : X \to S$ locally of f.t.(f.p.), let $x \in X, s = f(x)$, then the following are equivalent:

- It is $(G)$-unramified at $x$.
- The fiber $X_s$ is unramified over $k(s)$ at $x$, by (5.6.5.3).
- $\Omega_{X_s,x} = 0$.
- $\Omega_{X_s/x} \otimes_{O_{X,x}} k(x) = 0$ by (4.4.6.6).
- $m_x O_{X,x} = m_s$ and $k(x)/k(f(x))$ is separable.

Proof: $1 \to 2 \to 3 \to 4$ is clear. $4 \to 1$: Nakayama implies $\Omega_{X_s,x} = 0$, thus $\Omega_{X/S}$ vanishes on a nbhd of $x$ as it is Qco of f.t.

$4 \iff 5$ follows from (4.4.6.7). □

Cor. (5.6.5.9) [Generic Unramifiedness]. Let $f : X \to Y$ be a finite separable dominant morphism of integral schemes, then there exists an open dense nbhd $U$ of $Y$ s.t. $f : f^{-1}(U) \to U$ is unramified.

Prop. (5.6.5.10). If $X \to Y \to S$ is unramified, then $X/Y$ is also unramified. And if $X/S$ is $G$-unramified and $Y/S$ is of f.t., then $X/Y$ is $G$-unramified.

Proof: By (5.6.1.4) and (5.5.5.5). □

Prop. (5.6.5.11) [Unramified Points Base Change]. If $f$ is of f.t.(f.p.), then the set of points of $S$ that $f$ is unramified is stable under base change.

Proof: □

Prop. (5.6.5.12) [Tangent Criterion of unramifiedness]. Let $f : X \to Y$ be a morphism of schemes locally of f.t. over $S, x \in X, y = f(x)$, then the following are equivalent:

- $df : T_{X/S,x} \to T_{Y/S,y}$ is an injection (5.6.4.23).
- $f$ is unramified at $x$.

Proof: It follows from (5.6.4.23) that $df$ is an isomorphism iff $(f^*\Omega_{Y/S})_x \otimes_{O_{X,x}} k(x) \to \Omega_{X/S,x} \otimes_{O_{X,x}} k(x)$ is surjective, which by Jacobi-Zariski (5.5.5.5) is equivalent to $\Omega_{X/Y,x} \otimes_{O_{X,x}} k(x) = 0$, and this is equivalent to $f$ is unramified at $x$ by (5.6.5.8). □

Prop. (5.6.5.13) [Unramified U.i. Morphisms]. For a morphism $f$ of schemes, the following are equivalent:

- $f$ is unramified and a monomorphism.
- $f$ is unramified and universal injective.
- $f$ is locally of f.t., formally unramified and universal injective.
- $f$ is locally of f.t. and a monomorphism.
- $f$ is locally of f.t. and $X_y$ is either empty or $X_y \to y$ is an isomorphism for all $y \in Y$.

Proof: Cf. [Sta], 05VH. □

Prop. (5.6.5.14) [Unramified and Smoothness]. Let $f : X \to Y$ be a morphism of schemes over $S$ s.t. $X/S$ is smooth (of relative dimension $n$) and $Y/S$ is unramified, then $f$ is also smooth (of relative dimension $n$).

Proof: This follows from differential criterion (5.6.4.3) and (5.6.1.4). Notice to show it is flat, use the fact $\Delta_{Y/S}$ and $X \times Y \to Y$ are both flat (5.6.5.5). □
Noetherian Case

Prop. (5.6.5.15). Let $S$ be a Noetherian scheme, $X \to S$ a qc unramified morphism and $Y \to S$ a morphism with $Y$ Noetherian, then $\text{Mor}_S(Y, X)$ is a finite set.

Proof: Cf. [Sta], 0AKI.

Prop. (5.6.5.16) [Unramified Morphisms and DVR]. Let $R_v$ be a DVR with fraction field $K$ and $\varphi : X \to X'$ be a morphisms of schemes of f.t. over $R_v$. Let $Q \in X'(K)$ and $P \in X(K)$ with $\varphi(P) = Q$. Let $w|v$ be a valuation of $K(P)$ extending $v$. If $P$ extends to an $R_w$-valued point $\mathcal{P}$ of $X$, then using the fact $R_w \cap K = R_v$, we see $Q$ also extends to a $R_v$-valued point of $X'$.

Denote the image of the maximal ideal of $R_w$ under $P$ by $P(w)$, then if $\varphi$ is unramified at $P(w)$, then $K(P)/K$ is unramified in $w$.

Proof: Since the unramified point is open, $\varphi$ is also unramified at $P$, thus $K(P)/K$ is separable (5.6.5.8). For the rest, Cf. [Diophantine Geometry, P598].

6 Étale

More advanced materials to learn at [Sta] Chap 40.

Def. (5.6.6.1) [Étale Morphisms]. An étale morphism $f : X \to Y$ of schemes is a morphism s.t there is an open affine cover $\{U_i\}$ of $S$ and an open affine cover $V_{ij}$ of $f^{-1}(\{U_i\})$ that the ring map is étale. A standard étale morphism is the Spec map of a standard étale ring map.

étale is local on the source and target (4.4.7.5). Étale is stable under base change and composition (4.4.7.5).

Prop. (5.6.6.2) [Properties of Étale Morphisms].

- Étale at a point $x$ is equivalent to smooth and unramified at a $x$ (4.4.7.4).
- Étale at a point $x$ is equivalent to flat and $G$-unramified at that point, by (4.4.7.11). So étale over field is equivalent to $G$-unramified, because over a field it is obviously flat.
- Étale at a point $x$ is equivalent to locally standard étale at that point (4.4.7.17).
- A morphism is étale iff it is smooth of relative dimension 0, by definition (5.6.4.11).
- Étale is equivalent to flat, locally of f.p. and formally unramified, by (4.4.7.11).

Cor. (5.6.6.3). Étale map is smooth, hence syntomic, flat.

Étale map is universally open because it is flat and locally of f.p. (5.6.2.10).

Prop. (5.6.6.4). If $X, Y$ are étale over $S$, then any map $X \to Y$ is étale, by (4.4.7.13).

Prop. (5.6.6.5) [Fiberwise]. A morphism of schemes is étale iff it is flat, locally of f.p., and every fiber $X_s$ is a disjoint union of spectra of finite separable field extensions of $k(s)$.

Proof: Follows from (5.6.6.2) (5.6.5.3) and (4.4.7.10).

Cor. (5.6.6.6) [Étale Over Fields]. A scheme is étale over a field $k$ iff it is a disjoint union of spectra of finite separable field extensions. In particular, étaleover fields is equivalent to unramified over fields.
Prop. (5.6.6.7) [Smoothness and Étale]. If \( f : X \to Y \) is smooth at \( x \), then there exist a nbhd \( U \) of \( x \in X \) and nbhd \( V \) of \( f(x) \in Y \) that it factors through \( U \xrightarrow{\pi} \mathbb{A}^d \to V \), where \( \pi \) is étale.

Proof: Any standard smooth morphism can be factorized as an étale map over a polynomial algebra, as easily seen. \( \square \)

Prop. (5.6.6.8) [Stalkwise and Fiberwise]. For a morphism locally of f.p., by (5.6.5.8) and (5.6.4.5), the following are equivalent:

- It is étale at a point \( x \).
- \( \mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)} \) if flat and \( X_{f(x)}/k(x) \) is smooth at \( x \).
- \( \mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)} \) if flat and \( X_{f(x)}/k(x) \) is unramified at \( x \).
- \( \mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)} \) is flat and \( \Omega_{X_{f(x)},x} = 0 \).
- \( \mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)} \) is flat and \( \Omega_{X_{f(x)},x} \otimes_{\mathcal{O}_{X,x}} k(x) = 0 \).
- \( \mathcal{O}_{X,x}/\mathcal{O}_{S,f(x)} \) is flat and \( \mathfrak{m}_{f(x)}/\mathcal{O}_{X,x} = \mathfrak{m}_x \) and \( k(x)/k(s) \) separable.

In particular, an étale morphism can be seen as a family of smooth schemes.

Prop. (5.6.6.9) [Étale Schemes over Field]. Let \( k \) be a field and \( k^s \) its separable closure. Let \( \Gamma = \text{Gal}(k^s/k) \), then the functor \( X \mapsto X(k^s) \) is an equivalence between étale schemes over \( k \) to the category of discrete \( \Gamma \)-sets.

Proof: Cf. [Sta]03QR. \( \square \)

Prop. (5.6.6.10). If \( X \to Y \to S \), and \( X \to Y \) are faithfully flat and locally of f.p., \( X \to S \) is étale, then \( Y \to S \) is also étale.

Proof: Cf. [Sta]05B5. \( \square \)

Cor. (5.6.6.11). If \( f : X \to S \) is faithfully flat and locally of f.p., then the set of points of \( S \) s.t. \( f \) is étale is stable under base change.

Proof: This follows from (5.6.5.11) and (5.6.4.10). \( \square \)

Def. (5.6.6.12) [Étale Neighborhood]. For a point \( s : \text{Spec } k \to X \), an étale nbhd of \( s \) in \( X \) is defined to be an étale map \( U \to X \) that \( s \) factors through \( U \).

Prop. (5.6.6.13). For a morphism \( f : Y \to X \) of schemes étale over field \( k \), then \( f \) is surjective iff \( Y(k_s) \to X(k_s) \) is surjective.

Proof: If \( Y \to X \) is surjective, then? \( \square \)

Étale Connected Components

Def. (5.6.6.14) [Étale Connected Components]. Let \( X \) be a scheme over a field \( k \), let \( \pi_0(X) = \text{Spec}(\pi(X)) \), where \( \pi(X) \) is the largest étale subalgebra of \( \Gamma(X)(4.4.7.23) \).

Prop. (5.6.6.15). Let \( X \) be an algebraic scheme over a field \( k \), then

- for any field extension \( k'/k \), \( \pi_0(X_{k'}) = \pi_0(X)_{k'} \).
- Let \( Y \) be a schemes over a field \( k \), then \( \pi_0(X \times Y) = \pi_0(X) \times \pi_0(Y) \).
Proof:  1: Cf.[Mil17b]P15.
2: There is a map $\pi(X) \times_k \pi(Y) \to \pi(X \times Y)$. Because $\pi$ commutes with base change, we can base change to separable closure. In this case, it suffices to show if $X, Y$ is connected then $X \times Y$ is connected, but this follows from (5.4.3.12).

Prop. (5.6.6.16). Let $X$ be an algebraic scheme over a field $k$, then
- The mapping $\varphi : X \to \pi_0(X)$ induces a 1 to 1 correspondence of points of $\pi_0(X)$ and connected components of $X$.
- For all $x \in \pi_0(X)$, the fiber $\varphi^{-1}(x)$ is geo.connected over $k(x)$.

Proof: $\pi_0(X)$ is discrete, so the inverse image of each point is a sum of connected components of $X$. But this must be connected, because $\pi_0(X_{k(x)}) = \pi_0(X)_{k(x)} = k(x)$. Also, this implies for the alg.closure $\overline{k}$ of $k(x)$, $\pi_0(X_{\overline{k}}) = \pi_0(X_{k(x)})_{\overline{k}} = \overline{k}$, thus $X_{\overline{k}(x)}$ is geo.connected.

Noetherian Case

7 Zariski’s Main Theorem

References are [Sta]Chap36.38.

Prop. (5.6.7.1) [Zariski’s Main Theorem]. For a morphism $X \to S$ that is quasi-finite and separated, if $S$ is qcqs, Then there is a factorization $X \to T \to S$ that $X \to T$ is a qc open immersion and $T \to S$ is finite.

Proof: Cf.[Sta]05K0.

8 Complete Intersection

Should be refreshed with intrinsic definition of locally complete intersection, Cf.[Sta].

Def. (5.6.8.1) [Regular Embedding]. A regular embedding of codimension $r$ is a locally closed embedding $X \to Y$ that for $p \in X$, the ideal of $X$ in the local ring $\mathcal{O}_{Y,p}$ is generated by a regular sequence of length $r$.

Def. (5.6.8.2) [Complete Intersection]. A complete intersection of codimension $r$ in $Y$ is a closed subscheme $X$ that is the intersection of $r$ effective Cartier divisors $D_i$ that at each point $p \in X$, the equations defining $D_i$ form a regular sequence.

Def. (5.6.8.3) [Locally Complete Intersection]. A closed subscheme $Y$ of a nonsingular variety $X$ over a field $k$ is called locally complete intersection iff $Y$ is locally generated by $r = \text{codim}(Y,X)$ elements. By (4.3.4.17) $Y$ is C.M.. In particular, by (5.10.1.16), a regular variety is always a locally complete intersection.

Def. (5.6.8.4) [Syntomic Morphisms]. A standard syntomic morphism is the Spec map of a global complete intersection ring map (4.4.4.11). A syntomic morphism is a morphism that is locally a standard syntomic morphism.

Prop. (5.6.8.5). Syntomic is local on the source and target, stable under base change and composition, by (4.4.4.12).

Prop. (5.6.8.6). Syntomic is equivalent to flat, locally of f.p.+fibers being local complete intersections.
Proof: This follows from (4.4.4.18).

Cor. (5.6.8.7). Syntomic morphisms are universally open.

Prop. (5.6.8.8). An open immersion is syntomic, because localizations are global complete intersections (4.4.4.12).

Prop. (5.6.8.9). If \( f : X \to S \) is a syntomic map, then the function \( x \mapsto \dim_x(X_{f(x)}) \) is locally constant on \( X \). If it is standard syntomic, then it is constant.

Proof: It suffices to prove for syntomic maps, Cf. [Sta] 02K0.

Prop. (5.6.8.10). A local complete intersection has its ideal sheaf \( \mathcal{I} \), then \( \mathcal{I}/\mathcal{I}^2 \) locally free by (4.3.4.16).

Prop. (5.6.8.11). If \( Y \) is a complete intersection in \( \mathbb{P}_k^n \) of hypersurfaces of degree \( d_1, \ldots, d_r \), then \( \omega_Y = \mathcal{O}_Y(\sum_d_i - n - 1) \).

Proof: Use the exact sequence \( 0 \to \mathcal{O}_Z(n - d) \to \mathcal{O}_Z \to i_* \mathcal{O}_Y \to 0 \) and (5.10.1.17).

Prop. (5.6.8.12). For a complete intersection of dimension \( q \), \( H^i(Y, \mathcal{O}_Y(n)) = 0 \) for \( 0 < i < q \). And the natural map \( \Gamma(P, \mathcal{O}_P(n)) \to H^0(Y, \mathcal{O}_Y(n)) \) is a surjection for every \( n \). In particular, \( Y \) is connected, and the arithmetic genus \( p_a(Y) = \dim H^q(Y, \mathcal{O}_Y) \).

Proof: We use induction, the case \( Y = P \) follows from (5.7.2.1), let \( Y = Z \cap H \), where \( H \) has degree \( d \), then

\[
0 \to \mathcal{O}_Z(n - d) \to \mathcal{O}_Z \to i_* \mathcal{O}_Y \to 0
\]

thus use long exact sequence. The rest is easy.
5.7 Cohomology of Schemes

Main references are [Sta]Chap29.

Notations (5.7.0.1).
- Use notations defined in Cohomology on Ringed Sites.

1 Zariski Cohomology

Qco Sheaves

Lemma (5.7.1.1) [Zariski-Poincare]. A Qco sheaf on an affine scheme $X$ is Čech-acyclic.

Proof: Because the principal affine covers are cofinal in the ordering of covers, we only need to consider principal affine covers. Let $R \to A = \prod R_{f_i}$, then it is f.f., so we can use (4.4.2.2), just notice the higher term is $\prod_{i_0, \ldots, i_n} R_{f_{i_0} \cdots f_{i_n}}$. □

Prop (5.7.1.2) [Čech Cohomology on Separated Schemes]. If $X$ is separated and $F \in \mathcal{QCoh}(X)$, $H^p(X, F) = \check{H}^p(X, F) = H^p_{\text{alt}}\left(\{U_i \to X\}, F\right)$ for any open affine covering $\{U_i \to X\}$.

Proof: Use (5.3.2.16) and (5.3.2.6), the family of affine open subsets of $X$ satisfies the requirement because $X$ is separated and (5.7.1.1), thus the result. It can be calculated by alternating complexes by (5.3.2.7). □

Cor (5.7.1.3) [Affine Cohomological Vanishing]. If $X$ is affine and $F \in \mathcal{QCoh}(X)$, $H^i(X, F) = 0$ for $i > 0$.

For a qcqs scheme $X$, choose a finite affine cover $U_1, \ldots, U_t$ of $X$, then for any $F \in \mathcal{QCoh}(X)$, $H^n(X, F) = 0$ for $n \geq d$, where

\[ d = \max_{I \subseteq \{1, \ldots, t\}} (|I| + t(U_I)) \]

and $t(Y)$ is the minimal cardinality of an affine open cover of $Y$.

Proof: The last assertion follows form Čech to sheaf2 (5.3.2.13) and (5.7.1.2), as $U_I$ is separated for any $I \neq \emptyset$. □

Prop (5.7.1.4) [\mathcal{QCoh}(X) vs. \text{Mod}(O_X)]. If $X$ is a Noetherian scheme, then injective objects in $\mathcal{QCoh}(X)$ are all flabby (5.3.4.8), thus nearly calculating all cohomologies are legitimate in the category $\mathcal{QCoh}(X)$.

However, in general, this is not true, as there are examples of injective $A$-module $I$ s.t. $\check{I}$ is not flasque on Spec $A$, by [Sta]0274.

Proof: We use the Deligne formula (5.5.1.36) and the definition of injective, by considering the sheaf of ideals of the corresponding induced reduced structure. □

Prop (5.7.1.5) [Filtered Colimits]. If $X$ is qcqs, then sheaf cohomology on $X$ commutes with filtered colimits.

Proof: This follows from (5.1.4.9) the same way (6.4.1.8) follows from (5.1.4.20). □

Prop (5.7.1.6) [Ext For Coherent Sheaves]. On a locally Noetherian scheme, for $F \in \mathcal{QCoh}(X)$ and $G \in \mathcal{Coh}(X)$, $\mathcal{Ext}^i(F, G) \in \mathcal{QCoh}(X)$, and affine locally are given by $\mathcal{Ext}^i(F(U), G(U))$.

Moreover $G \in \mathcal{Coh}(X)$, then $\mathcal{Ext}^i(F, G) \in \mathcal{Coh}(X)$.
Proof: This follows from (5.8.5.13) and (5.8.5.10). □

Prop. (5.7.1.7). When \( X \) is locally Noetherian and \( \mathcal{F} \in \mathfrak{Coh}(X) \),
\[
\mathcal{E}xt^i(\mathcal{F}, \mathcal{G})_x \cong \text{Ext}^i_{\mathcal{O}_x}(\mathcal{F}_x, \mathcal{G}_x).
\]

Proof: Taking stalk is exact. □

Cor. (5.7.1.8). If \( X \) is locally Noetherian, suppose that every coherent sheaf is a quotient of a locally free sheaf, we can define the **homological dimension** \( \text{hd}(\mathcal{F}) \) of a coherent sheaf \( \mathcal{F} \) as the minimal length of a flat resolution of \( \mathcal{F} \). Then \( \text{hd}(\mathcal{F}) \leq n \iff \mathcal{E}xt^i(\mathcal{F}, \mathcal{G}) = 0 \) for every \( \mathcal{G} \) and every \( i > n \).

And \( \text{hd}(\mathcal{F}) = \sup \text{pd}_{\mathcal{O}_X}(\mathcal{F}_x) \), by (5.7.1.7).

Prop. (5.7.1.9) [Künneth Formula]. If \( X, Y \) are qcqs over a field \( k \) and \( \mathcal{F}, \mathcal{G} \) be \( \text{Qco} \ \mathcal{O}_X, \mathcal{O}_Y \)-modules, then there is a canonical isomorphism:
\[
H^n(X \times_{\text{Spec } k} Y, \text{pr}_1^* \mathcal{F} \otimes_{\mathcal{O}_X \otimes_{\text{Spec } k} Y} \text{pr}_2^* \mathcal{G}) \cong \oplus_{p+q=n} H^p(X, \mathcal{F}) \otimes_k H^q(Y, \mathcal{G}).
\]

Proof: Cf.[Sta]0BEF. □

Prop. (5.7.1.10). On a locally Noetherian scheme \( X \), any \( \text{Qco} \) sheaf \( \mathcal{F} \) admits a resolution of \( \text{Qco} \) sheaves that are flabby.

Proof: Because \( \text{QCoh}(X) \) is Serre subcategory, □

Lemma (5.7.1.11) [Gabber]. Let \( X \) be a scheme, then there exists a cardinal \( \kappa \) that every \( \text{Qco} \) sheaf is a colimit of its \( \kappa \)-generated \( \text{Qco} \) subsheaves.

Proof: Cf.[Sta]077N. □

Prop. (5.7.1.12) [\text{Qco Cohomology Comparison}]. For \( X \in \text{Sch}, \mathcal{F} \in \mathfrak{Coh}(X), \tau \in \{\text{fppf, étale, smooth, syntomic, Zariski}\} \), there are canonical isomorphisms
\[
H^p(X, \mathcal{F}) \cong H^p(\text{Sch}_\tau / X, \mathcal{F}) \cong H^p(X_{\text{Zar}}, \mathcal{F}) \cong H^p(X_{\text{ét}}, \mathcal{F}).
\]

Proof: Let \( \mathcal{C} = \text{Sch}_\tau / X \) or \( X_{\text{ét}}, X_{\text{Zar}} \). We use(5.3.2.16) with \( \mathfrak{G} \) the set of affine schemes and \( \text{Cov} \) the subset of \( \text{Cov}(\mathcal{C}) \) consisting of morphisms between affine schemes. Then Čech vanishing is clear in the affine case by(4.4.2.2). Thus(5.3.2.16) says \( H^p(\mathcal{C}, \mathcal{F}_\mathcal{C}) = 0 \) for \( p > 0 \).

Next, if \( U \subset X \) is an affine open s.t. \( U \to X \) is separated. Let \( \mathcal{U} \) be an affine open covering of \( U \), then all \( U_{i_0, \ldots, i_p} \) are affine, thus
\[
H^p(\mathcal{C}, \mathcal{F}_\mathcal{C}) = \check{H}(\mathcal{U}, \mathcal{F}_\mathcal{C}) = H^p(U, \mathcal{F}|_U)
\]
by(5.3.2.15).

Finally, for \( X \), take an injective resolution \( \mathcal{F} \to \mathcal{I}^* \), and an injective resolution \( \mathcal{F}_\mathcal{C} \to \mathcal{J}^* \). Then the latter restricts to a chain complex \( \mathcal{F} \to \mathcal{J}^*|_X \), which is exact because it is exact on any affine open \( U \subset X \) as \( H^p(\mathcal{C}, \mathcal{F}_\mathcal{C}) = 0 \) for \( p > 0 \). Thus by(3.4.3.5), there is a map \( \mathcal{J}^*|_X \to \mathcal{I}^* \), inducing a map \( H^p(\mathcal{C}, \mathcal{F}_\mathcal{C}) = H^p(X, \mathcal{J}^*) \to H^p(X, \mathcal{I}^*) \cong H^p(X, \mathcal{F}) \).

To show these map are isomorphisms, take an affine open covering \( U \) of \( X \), then there are Čech-to-derived spectral sequences
\[
^\tau E_2^{pq} = \check{H}^p(U, \mathcal{H}^q(\mathcal{F}^a)) \Rightarrow H^{p+q}(\mathcal{C}, \mathcal{F}_\mathcal{C}), \quad E_2^{pq} = \check{H}^p(U, \mathcal{H}^q(\mathcal{F}^a)) \Rightarrow H^{p+q}(\mathcal{C}, \mathcal{F}).
\]
The map \( \mathcal{J}^*|_X \to \mathcal{I}^* \) induces a map \( \check{C}^*(U, \mathcal{J}) \to \check{C}^*(U, \mathcal{I}) \) which induces a map of the spectral sequences. But as each affine open of \( X \) is separated over \( X \), the \( E^2 \)-page is an isomorphism by what we have proved. Thus \( \check{H}^q(\mathcal{F}^a) \to H^{p+q}(\mathcal{C}, \mathcal{F}) \) is an isomorphism. □
Proposition (5.7.1.13). For $X \in \text{Sch}$, $\tau \in \{\text{fpqc, étale, smooth, syntomic, Zariski}\}$,

$$H^1_r(X, \mathbb{G}_m) \cong \text{Pic}(X)(5.5.3.10).$$

Proof: As these $X_\tau$ are all locally ringed sites, by (5.3.1.17), $H^1_r(X, \mathbb{G}_m) \cong \text{Pic}(X_\tau)$. Thus it suffices to prove that

$$\text{Pic}(X_{\text{Zar}}) \to \text{Pic}(X_{\text{ét}}) \to \ldots \to \text{Pic}(X_{\text{fpqc}})$$

are isomorphisms. Then this is because any invertible sheaf is quasi-coherent by (5.2.5.8), so Pic$(X_\tau)$ are in fact the group of invertible objects in $\Omega\text{coh}(X_\tau)$. But $\Omega\text{coh}(X_\tau)$ are all equivalent categories, by fpqc descent for Qco sheaves (5.1.5.12).

2 Proper Schemes

Proposition (5.7.2.1) [Cohomology of Projective Space]. Let $X = \mathbb{P}^r_A$ we have:

(1)

$$H^q(X, \mathcal{O}_X(d)) = \begin{cases} (A[T_0, \ldots, T_r])_d & q = 0 \\ 0 & q \neq 0, r \\ \left(\frac{1}{T_0 \cdots T_r} A[\frac{1}{T_0}, \ldots, \frac{1}{T_r}]\right)_d & q = r \end{cases}$$

(2) The cup product defines a perfect pairing

$$H^0(X, \mathcal{O}_X(n)) \times H^r(X, \mathcal{O}_X(-n - r - 1)) \to H^r(X, \mathcal{O}_X(-r - 1)) \cong A.$$

Proof: $X$ is separated, we use Čech cohomology. Let $\mathcal{F} = \bigoplus_{d \in \mathbb{Z}} \mathcal{O}_X(d)$, then $\mathcal{F}$ is a Qco graded ring. Let $U_{i_0 \ldots i_k}$ be the affine open subset $U(x_{i_0}) \cap \ldots U(x_{i_k})$ of $X$, then $\mathcal{F}(U_{i_0 \ldots i_k}) = A[T_0, \ldots, T_r, T_{i_0}^{-1}, \ldots, T_{i_k}^{-1}]$ as graded rings, and the cohomology $H^\bullet(\mathcal{F})$ is calculated by the Čech complex (5.3.2.1)

$$\check{C}^\bullet = \prod_i A[T_0, \ldots, T_r, T_i^{-1}] \to \prod_{i,j} A[T_0, \ldots, T_r, T_i^{-1}, T_j^{-1}] \to \ldots \to A[T_0, \ldots, T_r, T_1^{-1}, \ldots, T_r^{-1}].$$

This complex has a natural $\mathbb{Z}^r$-grading, and the differential is natural inclusion thus preserves the grading, i.e.

$$\check{C}^\bullet = \bigoplus_{v \in \mathbb{Z}^r} \check{C}^\bullet(v)$$

where if we set $NEG(v) = \{i \in \{0, \ldots, r\} | v_i < 0\}$, then

$$\check{C}^\bullet(v) = \prod_{NEG(v) \subset \{i\}} A T_0^{v_0} \ldots T_r^{v_r} \to \prod_{NEG(v) \subset \{i,j\}} A T_0^{v_0} \ldots T_r^{v_r} \to \ldots \to A T_0^{v_0} \ldots T_r^{v_r}$$

is the subcomplex of $\check{C}^\bullet$. So it suffices to calculate the cohomology of $\check{C}^\bullet(v)$ for each $v$.

If $NEG(v) = \{0, 1, \ldots, n\}$, then there is only one term, so

$$H^\bullet(\check{C}^\bullet(v)) = \begin{cases} A T_0^{v_0} \ldots T_r^{v_r} & q = r \\ 0 & \text{otherwise} \end{cases}$$

The sum of all such $v$ clearly contribute to $\frac{1}{T_0 \cdots T_r} A[\frac{1}{T_0}, \ldots, \frac{1}{T_r}]$ in degree $r$.

If $NEG(v) = 0$, then the complex is isomorphic to the Čech complex calculating cohomology of Spec $A$ using the trivial cover $\{V_i \to \text{Spec} A\}, V_i \cong \text{Spec} A$ times $T_0^{v_0} \ldots T_r^{v_r}$. As Spec is separated,
it is just to the sheaf cohomology of Spec \( A \), which is \( A \) is degree 0 and 0 otherwise by (5.7.1.1). The sum of all such \( v \) clearly contribute to \( A[T_0, \ldots, T_r] \) in degree 0.

Finally, for other \( v \), choose a \( j \in \{0, 1, \ldots, n\} \setminus \mathrm{NEG}(v) \), then the maps

\[
h : \check{C}^{p+1}(v) \to \check{C}^p(v) : h(s)_{i_0 \ldots i_p} = s_{j i_0 i_p}
\]

(where we are using the alternating Čech complex) induces a homotopy between 0 and id, so \( \check{C}^{p+1}(v) \) have trivial cohomologies.

The pairing given by cup product makes \( T_0^{v_0} \ldots T_r^{v_r} \) dual to \( T_0^{-1-v_0} \ldots T_r^{-1-v_r} \), thus it is a perfect pairing.

\[\square\]

**Cor. (5.7.2.2)**. when \( n > 0 \), \( H^r(X, \mathcal{O}_X(n - r - 1)) = 0 \). Notice this an instance of the Kodaira vanishing theorem when \( k \) has characteristic 0 (11.8.8.3).

**Prop. (5.7.2.3)**. Let \( X = \mathbb{P}^n_k \) and \( 0 \leq p, q \leq n \), then \( H^q(X, \mathcal{O}_X^p) = 0 \) for \( p \neq q \) and when \( p = q \), \( H^q(X, \mathcal{O}_X^p) = k \).

**Proof**: By (5.5.1.26) and (5.5.5.7), there is an exact sequence \( 0 \to \Omega^q \to \wedge^q \mathcal{O}(-1) \to \Omega^{q-1} \to 0 \), and the middle has vanishing \( q \)-th cohomology by (5.7.2.1), thus we can induct and (5.7.2.1) gives the result.

**Prop. (5.7.2.4) [Cohomology of Complete Intersections]**. Let \( X \) be a closed subscheme of \( \mathbb{P}^n_k \) defined by a single homogenous equation \( f(x_0, x_1, x_2) \) of degree \( d \), then show that \( \dim H^0(X, \mathcal{O}_X) = 1 \), and if \( n \geq 2 \), \( \dim H^1(X, \mathcal{O}_X) = (d - 1)(d - 2)/2 \).

**Proof**: By (5.5.3.15), there is an exact sequence of sheaves on \( \mathbb{P}^n_k \):

\[
0 \to \mathcal{O}_{\mathbb{P}^n_k}(-d) \cong \mathcal{O}_{\mathbb{P}^n_k}(-X) \to \mathcal{O}_{\mathbb{P}^n_k} \to i_* \mathcal{O}_X \to 0
\]

which induces a long exact sequence (5.7.4.2):

\[
\begin{align*}
H^0(\mathbb{P}^n_k, \mathcal{O}_{\mathbb{P}^n_k}(-d)) & \to H^0(\mathbb{P}^n_k, \mathcal{O}_{\mathbb{P}^n_k}) \to H^0(X, \mathcal{O}_X) \to H^1(\mathbb{P}^n_k, \mathcal{O}_{\mathbb{P}^n_k}(-d)) \\
& \to H^1(\mathbb{P}^n_k, \mathcal{O}_{\mathbb{P}^n_k}) \to H^1(X, \mathcal{O}_X) \to H^2(\mathbb{P}^n_k, \mathcal{O}_{\mathbb{P}^n_k}(-d)) \to H^2(\mathbb{P}^n_k, \mathcal{O}_{\mathbb{P}^n_k})
\end{align*}
\]

By (5.7.2.1), this reads:

\[
0 \to k \to H^0(X, \mathcal{O}_X) \to 0 \to 0 \to H^1(X, \mathcal{O}_X) \to H^2(\mathbb{P}^n_k, \mathcal{O}_{\mathbb{P}^n_k}(-d)) \to 0,
\]

and if \( n = 2 \), \( \dim H^2(\mathbb{P}^2_k, \mathcal{O}_{\mathbb{P}^2_k}(-d)) = (d - 1)(d - 2)/2 \).

\[?\] It is faster using Hilbert Polynomial.

\[\square\]

**Lemma (5.7.2.5) [Cohomology of Projective Space]**. Let \( R \) be a Noetherian ring and \( n \geq 0 \), then for any coherent sheaf \( \mathcal{F} \) on \( \mathbb{P}^n_R \),

- \( H^i(\mathbb{P}^n_R, \mathcal{F}(n)) = 0 \) for \( i > 0 \) and \( n \) large enough.
- For any \( i \), \( H^i(\mathbb{P}^n_R, \mathcal{F}) \) is a finite \( R \)-module.
- For any \( k \in \mathbb{Z} \), \( \bigoplus_{d \geq k} H^0(\mathbb{P}^n_R, \mathcal{F}(d)) \) is a finite \( R[T_0, \ldots, T_n] \)-module.
5.7. COHOMOLOGY OF SCHEMES 629

1: The assertions are true for $\mathcal{O}_X(n)$ by (5.7.2.1), and for general $\mathcal{F}$, we use descending induction on $i$. This is true for $i > n$ by Čech cohomology (5.7.1.2). For general $i > 0$, choose a surjection $\bigoplus \mathcal{O}_X(n_i) \to \mathcal{F}$ with coherent kernel $\mathcal{R}(5.5.4.5)$, then there is an exact sequence

$$H^i(X, \oplus \mathcal{O}_X(n_i + n)) \to H^i(X, \mathcal{F}(n)) \to H^{i+1}(X, \mathcal{R}(n)),$$

and the left term vanish for $n$ large (5.7.2.1), and the right term vanish by induction hypothesis.

2: Notation as above, we use descending induction on $i$. This is true for $i > n$ by Čech cohomology (5.7.1.2). For general $i > 0$, $H^i(X, \oplus \mathcal{O}_X(n_i))$ is finite by (5.7.2.1), and $H^{i+1}(X, \mathcal{R})$ is finite by induction hypothesis, thus $H^i(X, \mathcal{F}(n))$ is also finite.

3: Notation as above, for $n$ large, $H^i(X, \oplus \mathcal{O}_X(n_i + n)) \to H^i(X, \mathcal{F}(n))$ is surjective. Thus $M_k = \bigoplus_{d \geq k} H^0(\mathbb{P}_k^n, \mathcal{F}(d))$ is a quotient of $N_k = \bigoplus_{d \geq k} H^0(\mathbb{P}_k^n, \mathcal{O}_X(d))$ for $k$ large. Notice for $k$ small enough, $N_k \cong \oplus_{i} R[T_0, \ldots, T_n][i]$ is a finite graded $R[T_0, \ldots, T_n]$-module, thus $N_k$ is finite for any $k$ as $R[T_0, \ldots, T_n]$ is Noetherian. Then $M_k$ is finite for $k$ large, and each $H^0(\mathbb{P}_k^n, \mathcal{F}(d))$ is itself finite by item 2, thus $M_k$ is a finite $R[T_0, \ldots, T_n]$-module for any $k$.

**Prop. (5.7.2.6)** [Cohomology of Proper Schemes]. Let $X$ be a proper scheme over a Noetherian ring $A$, $\mathcal{L}$ an ample invertible sheaf on $X$ and $\mathcal{F} \in \text{Coh}(X)$, then

- $H^i(X, \mathcal{F} \otimes \mathcal{L}^\otimes d) = 0$ for $i > 0$ and $d$ large enough.
- The graded ring $A = \bigoplus_{n \geq 0} H^0(X, \mathcal{L}^\otimes n)$ is a f.g. $R$-algebra.
- For any $k \in \mathbb{Z}$, $\bigoplus_{d \geq k} H^0(X, \mathcal{F} \otimes \mathcal{L}^\otimes d)$ is a finite $A$-module.

**Proof:** By (5.5.4.24), there exists a $d > 0$ and some immersion $i : X \to \mathbb{P}_A^n$ that $i^* \mathcal{O}_{\mathbb{P}_A^n}(1) \cong \mathcal{L}^\otimes d$, and $i$ is a closed immersion because $X$ is proper. Let $S = R[T_0, \ldots, T_n]$.

1: By projection formula (5.7.4.6),

$$i_*(\mathcal{F} \otimes \mathcal{O}_X \mathcal{L}^\otimes nd+q) = i_*(\mathcal{F} \otimes \mathcal{O}_X \mathcal{L}^\otimes q)(n).$$

Then by (5.7.4.2) and (5.7.2.5), for $n$ large enough, $H^p(X, \mathcal{F} \otimes \mathcal{L}^\otimes q) = 0$ for any $0 \leq q \leq d - 1$, $p > 0$.

2: By proof of item 1 and (5.7.2.5), we see $\oplus_{n \geq 0} A_{nd+q}$ is a finite graded $S$-module for any $q$, thus $A = \bigoplus_{q=0}^{d-1} \bigoplus_{n \geq 0} A_{nd+q}$ is a f.g. $R$-module.

3: Similarly, we see $\bigoplus_{d \geq k} H^0(X, \mathcal{F} \otimes \mathcal{L}^\otimes d)$ is a finite graded $S$-module, and the $S$-module structure factors through $S \to A$, thus it is a finite $A$-module. □

**Lemma (5.7.2.7).** For an invertible sheaf $\mathcal{L}$ on a qc scheme $X$, if for each Qco sheaf of ideals $\mathcal{I} \in \mathcal{O}_X$, there exists an $n$ that $H^1(X, \mathcal{I} \otimes \mathcal{L}^n) = 0$, then $\mathcal{L}$ is ample.

**Proof:** For any closed pt $P$, choose an open affine nbhd $U$ that $\mathcal{L}$ is trivial, let $Y = X - U$, by the exact sequence $0 \to \mathcal{I}_Y \cup \{p\} \to \mathcal{I}_Y \to k(P) \to 0$, for each $n$,

$$0 \to \mathcal{I}_Y \cup \{p\} \otimes \mathcal{L}^n \to \mathcal{I}_Y \otimes \mathcal{L}^n \to k(P) \otimes \mathcal{L}^n \to 0.$$

Thus by assumption for some $n$ the map $\Gamma(X, \mathcal{I}_Y \otimes \mathcal{L}^n) \to \Gamma(X, k(P) \otimes \mathcal{L}^n)$ is surjective. Now $k(P) \otimes \mathcal{L}^n \cong A/\mathfrak{m}_P$, so we let $s \in \Gamma(X, \mathcal{I}_Y \otimes \mathcal{L}^n)$ maps to a section in $\Gamma(X, k(P) \otimes \mathcal{L}^n)$ that corresponds to $1 \in A/\mathfrak{m}_P$, then $P \in \text{Supp}(s) \subset U$, and $\text{Supp}(s)$ is affine. So we find an affine nbhd $X_s$ for every closed pt of $X$.

Finally these $X_s$ cover $X$, because the complement of $\cup X_s$ is closed in $X$ thus qc, then it contains a closed point by (3.6.6.1). □
Prop. (5.7.2.8) [Serre’s Cohomological Criterion of Ampleness]. If \( X \) is proper over a Noetherian affine scheme, \( \mathcal{L} \) is an invertible sheaf, then the following is equivalent.

- \( \mathcal{L} \) is ample
- For any \( \mathcal{F} \in \text{Coh}(X) \), for \( n \) large enough, \( H^p(X, \mathcal{F} \otimes \mathcal{L}^n) = 0 \) for \( p > 0 \).
- For any \( \mathcal{O}_X \) sheaf of ideals \( \mathcal{I} \in \mathcal{O}_X \), there exists an \( n \geq 1 \) that \( H^1(X, \mathcal{I} \otimes \mathcal{L}^{\otimes n}) = 0 \) (Notice in this case \( H \)-ample \( \iff \) ample).

Proof: 1 \( \rightarrow \) 2: This follows from (5.7.2.6). 2 \( \rightarrow \) 3 is trivial. 3 \( \rightarrow \) 1: (5.7.2.7). \( \square \)

Lichtenbaum’s theorem

Lemma (5.7.2.9). Let \( X \) be a variety and \( \mathcal{F} \in \text{Coh}(\mathcal{O}_X) \). If \( H^d(X, \mathcal{F}) \neq 0 \), then \( \dim X \geq d \), and if equality holds, \( X \) is proper.

Proof: Cf. [Sta]0G1E. \( \square \)

Prop. (5.7.2.10) [Lichtenbaum]. Let \( X \) be a non-empty separated scheme of f.t. over a field \( k \) of dimension \( d \), then the following are equivalent:

- \( H^d(X, \mathcal{F}) = 0 \) for all \( \mathcal{F} \in \text{Coh}(X) \).
- \( H^d(X, \mathcal{F}) = 0 \) for all \( \mathcal{F} \in \text{QCoh}(X) \).
- No irreducible component of \( X \) of dimension \( d \) is proper over \( k \).

Proof: Cf. [Sta]0G1F. \( \square \)

3 Euler Characteristics

Def. (5.7.3.1) [Euler Characteristic]. Let \( X \) be proper over a field \( k \) and \( \mathcal{F} \in \text{Coh}(X) \), then the Euler characteristic of \( \mathcal{F} \) is defined to be:

\[
\chi(\mathcal{F}) = \sum (-1)^i \dim_k H^i(X, \mathcal{F}).
\]

It is definable by Grothendieck vanishing (5.3.5.22) and Grothendieck coherence theorem (5.7.4.12), and it is clearly an additive functor on \( \text{Coh}(X) \).

Prop. (5.7.3.2). For a proper scheme \( X \) over a field \( k \) and \( \mathcal{L}_i \) be invertible sheaves on \( X \). Then for any \( \mathcal{F} \in \text{Coh}(X) \),

\[
\chi(X, \mathcal{F} \otimes \mathcal{L}_1^{n_1} \otimes \cdots \otimes \mathcal{L}_r^{n_r})
\]

is a polynomial in \( (n_1, \ldots, n_r) \) of total degree at most \( \dim \text{Supp} \mathcal{F} \).

Proof: Cf. [Sta]0B1E. \( \square \)

Prop. (5.7.3.3). Let \( f : Y \rightarrow X \) be morphism between schemes proper over field \( k \) and \( \mathcal{F} \in \text{Coh}(X) \),

\[
\chi(Y, \mathcal{F}) = \sum (-1)^i \chi(X, R^if_*\mathcal{F}).
\]

In particular, if \( f \) is affine(finite), then \( \chi(Y, \mathcal{F}) = \chi(X, f_*\mathcal{F}) \).

Prop. (5.7.3.4). This formula makes sense by (5.7.4.4) and (5.7.4.12), and it is true by Leray spectral sequence (5.3.1.10).
Prop.(5.7.3.5). If $X$ is a proper scheme and $F \in \mathcal{Coh}(X)$ with $\dim \text{Supp}(F) = 0$, then $F$ is generated by global sections, $H^i(X,F) = 0$ for $i > 0$, and

$$\chi(X,F \otimes \mathcal{E}) = n\chi(X,F)$$

for any $\mathcal{E} \in \mathcal{V}ect^n(X)$.

Proof: The first two are clear as $F = i_* \mathcal{G}$ where $i : \text{Supp}(F) \to X$. The last assertion follows from the projection formula \(5.7.4.6\) $i_*(\mathcal{G} \otimes i^* \mathcal{E}) \cong F \otimes \mathcal{E}$.

Def.(5.7.3.6)[Arithmetic Genus]. The arithmetic genus of a proper scheme of dimension $r$ over a field is defined to be $p_a(X) = (-1)^r (\chi(\mathcal{O}_X) - 1)$ $(5.7.3.1)$. In particular, when $X$ is a complete curve over a field $k$, then $p_a(X) = \dim_k H^1(X, \mathcal{O}_X)$ $(5.10.1.12)$.

The arithmetic genus is stable under base change of fields, by flat base change theorem.

Prop.(5.7.3.7)[Arithmetic Genus of Product]. By Künneth formula, if $X,Y$ are proper schemes of dimension $r,s$ over a field $k$, then

$$H^n(X \otimes_k Y, \mathcal{O}_{X \otimes_k Y}) \cong \bigoplus_{0 \leq k \leq n} H^k(X, \mathcal{O}_X) \otimes H^{n-k}(Y, \mathcal{O}_Y).$$

Thus $\chi(X \times_k Y) = \chi(X)\chi(Y)$. In particular, we have

$$p_a(X \times Y) = p_a(X)p_a(Y) + (-1)^s p_a(X) + (-1)^r p_a(Y).$$

Prop.(5.7.3.8)[Arithmetic Genus of Complete Intersections]. Let $C$ be a smooth complete intersection of a degree $m$ surface $S_1$ and a degree $n$ surface $S_2$ in $\mathbb{P}_k^3$, then $p_a(C) = \frac{1}{2}(mn(m+n-4) + 2)$.

Proof: There are exact sequences $0 \to \mathcal{O}_{\mathbb{P}_k^3}(-S_1) \to \mathcal{O}_{\mathbb{P}_k^3} \to \mathcal{O}_{S_1} \to 0$, which gives

$$0 \to \mathcal{O}_{\mathbb{P}_k^3}(-S_2)|_{S_1} \to \mathcal{O}_{S_1} \to \mathcal{O}_{S_1 \cap S_2} \to 0.$$ 

So by adjunction formula,

$$K_C = K_{S_1}(S_1 \cap S_2)|_C = K_{\mathbb{P}_k^3}(S_1)(S_2)|_C = \mathcal{O}_C(m+n-4).$$

So $2g - 2 = mn(m+n-4)$.

Prop.(5.7.3.9)[Asymptotic Riemann-Roch]. If $X$ is a proper scheme over a field $k$ of dimension $d$ and $\mathcal{L}$ is an ample invertible sheaf, then $\dim \Gamma(X, \mathcal{L}^n) \sim cn^d$.

Proof: Cf. [Sta]0BJ8.

Hilbert Polynomials

References are [Hartshorne I.7] and [Vak17].

Prop.(5.7.3.10)[Hilbert Polynomial]. For a projective scheme over a field $k$ and a coherent sheaf $F$, there is a polynomial Hilbert polynomial $P \in \mathbb{Q}[\lambda]$ that $\chi(F(n)) = P(n)$, and $\deg P \leq \dim \text{Supp}(F)$.

This Hilbert polynomial is compatible with the definition in $(5.7.3.12)$, because by $(5.7.4.7)$, the higher cohomology group vanishes for $n$ large, so $\chi(F(n)) = \Gamma(F(n)) = \Gamma_*(F)_n$. 

Proof: 

Prop. (5.7.3.11). Let \( X \hookrightarrow Y \hookrightarrow \mathbb{P}^n_k \) be a sequence of closed embeddings, then \( P_X(m) \leq P_Y(m) \) for \( m \) large, and if equality holds for \( m \) large, then \( X = Y \).

Proof: Cf. [Vak17]P490.

Def. (5.7.3.12) [Hilbert Polynomial]. For a scheme projective over a field \( k \) of dimension \( r \), we define the Hilbert polynomial \( P_Y \) as the Hilbert polynomial of its homogenous coordinate ring \( \Gamma_*(Y) \). It has dimension \( r \) by (4.2.2.17).

The degree of \( Y \) is defined as the \( r! \) times the leading coefficients of \( P_Y \).

Prop. (5.7.3.13).
- The degree is a positive integer.
- If \( Y = Y_1 \cup Y_2 \) and \( \dim Y_1 \cap Y_2 < r \), then \( \deg Y = \deg Y_1 + \deg Y_2 \).
- If \( H \) is a hypersurface whose ideal is generated by a homogeneous polynomial of degree \( d \), then \( \deg H = d \).

Proof: Cf. [Hartshorne P52].

Prop. (5.7.3.14). For a variety of degree \( k \) and a general linear space, the intersection has \( k \) points.

Proof: 

4 Relative Cohomology

Prop. (5.7.4.1) [Filtered Colimits]. If \( f : X \to Y \) is qcqs, then \( R^if_* \) commutes with filtered colimits, by (5.3.1.7) and (5.7.1.5).

Prop. (5.7.4.2) [Sheaf Cohomology Commutes with Affine Map]. For \( f : X \to Y \) affine and \( \mathcal{F} \in \mathcal{Q}\text{Coh}(X) \), \( H^n(Y, \mathcal{F}) = H^n(X, f_*\mathcal{F}) \).

Proof: Because \( R^if_*\mathcal{F} = 0 \) by (5.7.1.3) and (5.3.1.8), we can then use (5.3.1.9) to conclude. 

Prop. (5.7.4.3) [Higher Direct Image Preserves Qco Sheaves]. If \( f : X \to S \) is qcqs then \( R^n f_* \) maps \( \mathcal{Q}\text{Coh}(X) \) to \( \mathcal{Q}\text{Coh}(S) \), and for \( U \subset S \) affine open, \( (R^n f_*\mathcal{F})|_U = (H^n(f^{-1}(U), \mathcal{F}))^\wedge \).

Proof: Firstly by (5.3.3.18), \( (R^n f_*\mathcal{F})|_U = R^n f_{U*}(\mathcal{F}|_U) \), so it suffices to prove for \( S \) affine. Then \( R^nf_*\mathcal{F} \) is the sheafification of the presheaf \( G : U \mapsto H^n(f^{-1}(U), \mathcal{F}) \) by (5.3.1.8).

If \( f \) is separated, then we can use Čech cohomology (5.7.1.2) to see that \( H^n(f^{-1}(D(f)), \mathcal{F}) = H^n(X, \mathcal{F})_f \) thus \( G \) is itself a sheaf and the conclusion follows.

In general we can choose a finite affine cover \( U_i \) of \( X \), then every intersection of \( U_i \) is quasi-compact and separated, and there is a spectral sequence convergence \( H^p(\{U_i \to X\}, H^q(\mathcal{F})) \Rightarrow H^{p+q}(X, \mathcal{F}) \), where the left can be calculated using Čech cohomology. Taking localization w.r.t. \( f \), we get the desired isomorphism \( H^n(f^{-1}(D(f)), \mathcal{F}) = H^n(X, \mathcal{F})_f \) also by comparison (3.4.7.5).

Prop. (5.7.4.4) [Cohomological Boundedness of \( Rf_* \)]. For a qcqs morphism \( f : X \to S \), if \( S \) is qc, there is an \( N \) that for every base change \( f' \) of \( f \), we have \( R^n f_*\mathcal{F} = 0 \) for every \( \mathcal{F} \in \mathcal{Q}\text{Coh}(X) \) and \( n \geq N \).

In particular, if \( f \) is affine, then \( R^n f_*\mathcal{F} = 0 \) for \( n > 0 \). And if \( f \) is projective, then \( R^n f_*\mathcal{F} = 0 \) for \( n \) bigger than the maximal dimension of the fiber of \( f \).
Proof: Check affine locally on $S$ and use (5.7.4.3), choose a finite affine cover $U$ of $X$. Then when $n$ is large, $(R^n f_* \mathcal{F})|_U = 0$ by (5.7.4.3) and (5.7.1.3) for any $i$, thus $R^n f_* \mathcal{F} = 0$. For base changes, notice the cardinality of the affine cover are the same.

\[\□\]

Cor. (5.7.4.5). For a qc separated scheme $X$, the cohomology vanish for $n$ large. And when $X$ is separated and can be covered by $r$ affine opens, then $N$ can chosen to be $r$.

Cor. (5.7.4.6) [Projection Formula].
- Let $f : X \to Y$ be a morphism of schemes, and $\mathcal{E}$ a locally free $\mathcal{O}_Y$-module, then for any $\mathcal{F} \in \text{Mod}(\mathcal{O}_X)$ and any $i$, there are natural isomorphisms.
  \[R^i f_*(\mathcal{F} \otimes f^* \mathcal{E}) \cong R^i f_*(\mathcal{F}) \otimes \mathcal{E}.\]
- If $f : X \to Y$ is a qcqs morphism of schemes, then for any $\mathcal{F} \in \text{Coh}(\mathcal{O}_X), \mathcal{E} \in \text{Coh}(\mathcal{O}_Y)$, there is a natural isomorphism
  \[R f_*(\mathcal{F} \otimes ^L f^* \mathcal{E}) \cong R f_*(\mathcal{F}) \otimes ^L \mathcal{E}.\]

Proof: 1 follows from (5.3.3.20) and 2 follows from (5.8.5.8).

Proper Morphism and $\text{Coh}(X)$

Prop. (5.7.4.7) [Relative Serre Vanishing]. If $f : X \to Y$ is a proper morphism of locally Noetherian schemes, $\mathcal{I}$ an invertible sheaf on $X$, then the following are equivalent:
- $\mathcal{L}$ is $f$-ample.
- For any $\mathcal{F} \in \text{Coh}(X)$, for $n$ sufficiently large, $R^i f_*(\mathcal{F} \otimes \mathcal{I}^\otimes n) = 0$ and $i > 0$.
- For any Qco sheaf of ideals $\mathcal{I} \subset \mathcal{O}_X$, there exists an $n \geq 1$ that $R^1 f_*(\mathcal{I} \otimes \mathcal{L}^\otimes n) = 0$.

Proof: 1 $\to$ 2: By (5.7.4.3), this follows from (5.7.2.8). 2 $\to$ 3 is trivial as $X$ is Noetherian. 3 $\to$ 1: Notice for any affine open subset $U$ of $Y$, $U \to Y$ is qc, thus $f^{-1}(U) \to X$ is quasi-compact, thus by (5.5.1.8), a Qco sheaf of ideals $\mathcal{I}$ on $f^{-1}(U)$ can be extended to a Qco sheaf of ideals on $X$. Then we can use (5.7.4.3) and Leray spectral sequence to reduce to (5.7.2.8).

Cor. (5.7.4.8). Let $X$ be proper over a Noetherian affine scheme with an ample invertible sheaf $\mathcal{L}$, then for any finite exact sequence in $\text{Coh}(X)$, if tensoring it with $\mathcal{L}^\otimes n$ for large $n$, the resulting global section is exact.

Cor. (5.7.4.9). Let $X$ be proper over a Noetherian affine scheme with an ample invertible sheaf $\mathcal{L}$, and $\mathcal{F}, \mathcal{G} \in \text{Coh}(X), i \geq 0$, then for $n$ large (depending on $\mathcal{F}, \mathcal{G}, i$),
\[\text{Ext}^i(\mathcal{F}, \mathcal{G}(n)) \cong \Gamma(X, \mathcal{E}xt^i(\mathcal{F}, \mathcal{G}(n))).\]

Proof: By (5.3.3.34)(5.7.1.6), there is a spectral sequence s.t. for $n$ large, all the small terms vanish.

\[\□\]

Lemma (5.7.4.10). If $f : X \to Y$ is projective and $Y$ locally Noetherian, then for any $n \in \mathbb{N}$, $R^n f_*$ maps coherent sheaves to coherent sheaves.

Proof: By (5.7.4.3), this problem is local on the target, so we may assume that $Y = \text{Spec} \ R$ and $X = \mathbb{P}^n_R$, in which case this follows from (5.7.2.5).
Prop. (5.7.4.11) [Grothendieck’s Coherence Theorem]. If \( f : X \to Y \) is proper and \( Y \) locally Noetherian, then for any \( n \in \mathbb{N} \), \( R^n f_* \) maps coherent sheaves to coherent sheaves.

Proof: By (5.7.4.3), this problem is local on the target, so we may assume \( Y \) is Noetherian, and then \( X \) is also Noetherian. We prove by devissage (5.5.1.55): 1 is trivial, for 2, for any closed subscheme \( i : Z \subset X \), denote \( g = f|_Z \), then it suffices to find a coherent sheaf \( \mathcal{G} \) on \( Z \) s.t.

1. \( \mathcal{G}_{\xi} \cong k(\xi) \).
2. \( R^p g_* \mathcal{G} \) are coherent for any \( p \geq 0 \).

Because then \( i_* \mathcal{G} \) is a coherent sheaf on \( X \) (5.5.1.32) that \( R^p f_*(i_* \mathcal{G}) = R^p g_* \mathcal{G} \) for any \( p \) by relative Leray spectral sequence (5.3.1.9) and (5.7.4.4), and also \( (i_* \mathcal{G})_{\xi} = \mathcal{G}_{\xi} \).

As \( g : Z \to Y \) is proper, by Chow’s lemma (5.4.5.23), there is a birational, \( H \)-projective map \( \pi : Z' \to Y \) over \( Y \). Then there is a closed immersion \( j : Z' \to \mathbb{P}^n_Y \) and an induced closed immersion \( j': Z' \to \mathbb{P}^n_Z \). Then \( \mathcal{L} = j^* \mathcal{O}_{\mathbb{P}^n_Y}(1) = (j')^* \mathcal{O}_{\mathbb{P}^n_Z}(1) \) is both \( g \circ \pi \)-relatively ample and \( \pi \)-relatively ample.

Hence by relative Serre vanishing (5.7.4.7) there exists an \( n \) that \( R^p \pi_* \mathcal{L}^\otimes n = 0 \) for any \( p > 0 \). Let \( \mathcal{G} = \pi_* \mathcal{L}^\otimes n \), then this \( \mathcal{G} \) satisfies the conditions: \( \mathcal{G}_{\xi} = \kappa(\xi) \) as \( \pi^{-1}(U) \to U \) is an isomorphism, and from relative Leray spectral sequence

\[
R^p g_* R^q \pi_* \mathcal{L}^\otimes n \implies R^n (g \circ \pi)_* \mathcal{L}^\otimes n,
\]

we see \( R^p g_* \mathcal{G} \cong R^p g'_* \mathcal{L}^\otimes n \), which are coherent by (5.7.4.10). \( \square \)

Cor. (5.7.4.12) [Coherent Cohomology Finite]. If \( \pi : X \to \text{Spec} \, A \) is proper over a Noetherian affine scheme \( A \) and \( \mathcal{F} \) is a coherent sheaf on \( X \), \( H^i(X, \mathcal{F}) \) are finite \( A \)-modules.

Proof: By (5.7.4.3), \( R^p \pi_* \mathcal{F} \) is the Qco sheaf \( H^p(X, \mathcal{F}) \), which is coherent iff \( H^p(X, \mathcal{F}) \) is a finite \( A \)-module. \( \square \)

Prop. (5.7.4.13). Given a proper morphism between locally Noetherian schemes \( f : X \to Y \), a coherent sheaf \( \mathcal{F} \) on \( X \) and a coherent sheaf of ideals \( \mathcal{I} \) of \( \mathcal{O}_Y \). Then \( \mathcal{M} = \bigoplus_{n \geq 0} R^p f_*(\mathcal{I}^n \mathcal{F}) \) is a Qco graded \( A = \bigoplus_{n \geq 0} \mathcal{T}^n \)-module of f.t..

Proof: By (5.7.4.3), this is local on \( Y \), so we may assume \( Y \) is affine, Cf.[Sta]02O8. \( \square \)

Prop. (5.7.4.14). Let \( f : X \to Y \) be a proper morphism between locally Noetherian schemes and \( \mathcal{F} \) a coherent sheaf on \( X \), \( y \in Y \). Consider the infinitesimal nbhds \( X_n = \text{Spec}( \mathcal{O}_{Y, y} / \mathfrak{m}^n_y ) \times_Y X \xrightarrow{i_n} X \) of the fiber \( X_1 = X_y \), and set \( \mathcal{F}_n = i_n^* \mathcal{F} \), then

\[
(R^n f_* \mathcal{F})_y \cong \lim_n H^n(X_n, \mathcal{F}_n)
\]
as \( \mathcal{O}_{Y, y} \)-modules.

Proof: Cf.[Sta]02OD. \( \square \)

Cor. (5.7.4.15) [Support of Higher Direct Images]. Let \( f : X \to Y \) be a proper morphism between locally Noetherian schemes and \( y \in Y \) s.t. \( \dim(X_y) = d \), then for any coherent sheaf \( \mathcal{F} \) on \( X \), \( (R^p f_* \mathcal{F})_y = 0 \) for \( p > d \).

Proof: Cf.[Sta]02V7. \( \square \)
5 Base Change

Prop. (5.7.5.1) [Flat Base Change]. For a Cartesian diagram of schemes

\[
\begin{array}{ccc}
X' & \xrightarrow{g'} & X \\
\downarrow{f'} & & \downarrow{f} \\
S' & \xrightarrow{g} & S
\end{array}
\]

If \(g\) is flat and \(f\) is qcqs, then for every Qco sheaf \(F\) on \(X\) with base change \(F'\) on \(X'\), there is a canonical isomorphism

\[g^* Rf_* F \cong Rf'_* F'.\]

By (5.3.3.18), when \(S, S'\) is affine, this reads:

\[H^i(X, F) \otimes A B \cong H^i(X \otimes A B, (g')^* F).\]

**Proof:** Firstly by (5.3.3.18)(5.7.4.3), it suffices to show for \(S, S'\) affine. If \(X\) is separated, then the then we can use Čech cohomology (5.7.1.2), and the Čech complex of \(K'\) is just the cohomology of the Čech complex tensored with \(B\), so it commutes with taking cohomology because \(B\) is \(A\)-flat.

Now if \(X\) is only qs, then we choose a finite affine open cover \(\{U_i\}\), then every intersection of \(U_i\) is quasi-compact and separated. and there is a spectral sequence convergence \(H^p(\{U_i \to X\}; H^q(F)) \Rightarrow H^{p+q}(X, F)\). Tensoring with \(B\), we also get the desired isomorphism \(H^i(X, F) \otimes A B \cong H^i(X \otimes A B, (g')^* F)\) by comparison (3.4.7.5).

□

Prop. (5.7.5.2) [Finite Locally Free Base Change]. For a Cartesian diagram of schemes

\[
\begin{array}{ccc}
X' & \xrightarrow{g'} & X \\
\downarrow{f'} & & \downarrow{f} \\
S' & \xrightarrow{g} & S
\end{array}
\]

If \(S = \text{Spec } A, S' = \text{Spec } B\) and \(B\) is finite locally free over \(A\), for every Qco sheaf \(F\) on \(X\) with base change \(F'\) on \(X'\), there is a canonical isomorphism

\[H^i(X, F) \otimes A B \cong H^i(X \otimes A B, (g')^* F).\]

**Proof:** If \(X\) is separated, then the then we can use Čech cohomology (5.7.1.2), and the Čech complex of \(K'\) is just the cohomology of the Čech complex tensored with \(B\), so it commutes with taking cohomology because \(B\) is \(A\)-flat and tensoring a f.p. ring map commutes with colimits of rings.

In general we choose an affine open cover \(\{U_i\}\), then every intersection of \(U_i\) is separated. and there is a spectral sequence convergence \(H^p(\{U_i \to X\}; H^q(F)) \Rightarrow H^{p+q}(X, F)\). Tensoring with \(B\), we also get the desired isomorphism \(H^i(X, F) \otimes A B \cong H^i(X \otimes A B, (g')^* F)\) by comparison (3.4.7.5).

□

Prop. (5.7.5.3) [Representing Higher Direct Image]. Let \(f : X \to S\) be a qcqs morphism of schemes. If \(S\) is qc and separated and \(F\) is a Qco sheaf on \(X\), there exists a \(K^\bullet \in K^+(\text{QCoh}(\mathcal{O}_S))\) s.t. for any morphism \(g : S' \to S\), the complex \(g^* K^\bullet\) is a representative for \(Rf'_* F'\), where the notation is as in (5.7.5.1).
Prop. (5.7.5.4) [Proper Flat Base Change]. If $f : X \to S$ is a proper morphism of f.p., then

- If $E$ a perfect object in $D(O_X)$, $\mathcal{G} \in D(O_X)$ is representable by a bounded complex of f.p. $O_X$-modules flat over $S$, then

$$Rf_* (E \otimes_{O_X} ^L \mathcal{G}^*) , \quad Rf_* R\mathcal{H}om (E, \mathcal{G}^*)$$

are perfect complexes in $D(O_S)$, and its formation commutes with base change.

- If $E$ a pseudo-coherent object in $D(O_X)$, $\mathcal{G} \in D(O_X)$ is representable by a bounded above complex of f.p. $O_X$-modules flat over $S$, then $Rf_* (E \otimes_{O_X} ^L \mathcal{G}^*)$ is a pseudo-coherent complex in $D(O_S)$, and its formation commutes with base change.

Proof: Cf. [Sta]0A1H, 0A1J, 0CSC.

Cor. (5.7.5.5). Let $f : X \to S$ be a proper morphism of f.p., then

- If $E \in D(O_X)$ is perfect(pseudo-coherent) and $f$ is flat, then $Rf_* E$ is a perfect(pseudo-coherent) object in $D(O_S)$, and its formation commutes with base change.

- If $\mathcal{G} \in \mathcal{Q}coh^f(O_X)$ and is flat over $S$, then $Rf_* \mathcal{G}$ is a perfect object of $D(O_S)$ and its formation commutes with base change.

Cor. (5.7.5.6). If $A \in \mathcal{C}Alg$, $X$ be a proper scheme of f.p. over $A$, then if $\mathcal{G} \in \mathcal{Q}coh^f(O_X)$ and is flat over $A$, there exists a finite complex of finite projective $A$-modules $L^\bullet$ that for any $A' \in \mathcal{C}Alg_A$, $M \in Mod_A$, by (5.7.5.5) and projection formula (5.7.4.6),

$$H^i(X_{A'}, \mathcal{F}_{A'}) = H^i(L^\bullet \otimes_A A'), \quad H^i(X, \mathcal{F} \otimes_A M) = H^i(L^\bullet \otimes_A M)$$

6 Semicontinuity

Prop. (5.7.6.1). $T^i$ is left exact iff $Coker d^{i-1}$ is a projective $A$-module, iff it is representable by a finite $A$-module.

Proof: Denote $W^i = Coker d^{i-1}$, then $Coker d^{i-1} \otimes_A M = W^i \otimes M$, because tensoring is right exact. Thus $T^i(M) = \ker (W^i \otimes M \to L^{i+1} \otimes M)$. Then for $M' \subset M$, there is a commutative diagram

$$
\begin{array}{cccc}
0 & \to & T^i(M) & \to & W^i \otimes M^' & \to & L^{i+1} \otimes M^' \\
& & \downarrow^{\alpha} & & \downarrow^{\beta} & & \downarrow^{\gamma} \\
0 & \to & T^i(M) & \to & W^i \otimes M & \to & L^{i+1} \otimes M \\
\end{array}
$$
γ is injective, so using spectral sequence, its clear α is injective iff β is injective, i.e. $W^i$ is flat, which is equivalent to finite projective (4.3.1.7).

To prove $T^i$ is representable, let $Q = \text{Coker}(L^{i+1, *} \rightarrow W^{i, *})$, then $Q$ is finite because $W^i$ is finite (4.3.1.18), and $0 \rightarrow \text{Hom}(Q, M) \rightarrow \text{Hom}(W^{i, *}, M) \rightarrow \text{Hom}(L^{i+1, *}, M)$, but by (4.3.1.19), the last two are just $W^i \otimes M$ and $L^{i+1} \otimes M$, $\text{Hom}(Q, M) = T^i(M)$ by what has already been proved. □

**Prop. (5.7.6.2).** $T^i$ is right exact iff the cup product $H^i(X, \mathcal{F}) \otimes_A M \rightarrow H^i(X, \mathcal{F} \otimes_A M)$ is an isomorphism for any $A$-module $M$.

*Proof:* Because $T^i$ and $\otimes$ commutes with direct limit, it suffices to prove for $M$ finite. In this case, choose a finite presentation $A^r \rightarrow A^s \rightarrow M \rightarrow 0$, then there is a diagram

$$
\begin{array}{ccc}
T^i(A) \otimes A^r & \rightarrow & T^i(A) \otimes A^s \\
\downarrow & & \downarrow \\
T^i(A^r) & \rightarrow & T^i(A^s) \\
\end{array}
$$

The first two vertical arrows are isomorphisms, so if $T^i$ is right exact, so does the third vertical arrow. Conversely, if $T^i(A) \otimes_A M \rightarrow T^i(M)$ are all isomorphisms, then by a similar diagram, we can show $T^i(M) \rightarrow T^i(M')$ are surjective for $M \rightarrow M'$ surjective. □

**Cor. (5.7.6.3).** $T^i$ is exact if it is right exact and $T^i(A) = H^i(X, \mathcal{F})$ is a finite projective $A$-modules.

*Proof:* When $T^i$ is right exact, $H^i(X, \mathcal{F} \otimes_A M) \cong H^i(X, \mathcal{F}) \otimes_A M$ by (5.7.6.2), so it is exact iff $H^i(X, \mathcal{F})$ is flat. Because it is in priori finite, this is equivalent to finite projective (4.3.1.7). □

**Def. (5.7.6.4).** For a point $y \in \text{Spec } A$, define $T^i_y(N) = H^i(L^*_y \otimes N)$, then $T^i$ is (left/right)exact at $y$ iff $T^i_y$ are all (left/right)exact (exact sequence is stalkwise (4.1.4.2)).

**Prop. (5.7.6.5).** If $T^i$ is (left/right)exact at a point $y$, then the same is true on a nbhd of $y$.

*Proof:* From (5.7.6.1), $(\text{Coker } d^{i-1})_y$ is a finite projective $A_y$ module, so it is free, and it is a coherent sheaf, so it is free at a nbhd of $y$ by (5.5.1.38), so the same is true on a nbhd of $y$. Now right exactness of $T^i$ is equivalent to left exactness of $T^{i+1}$, and exact is left exact + right exact, so we are done. □

**Prop. (5.7.6.6).** $T^i$ is right exact at $y$ iff $H^i(X, \mathcal{F}) \otimes k(y) \rightarrow H^i(X, \mathcal{F} \otimes_A k(y))$ is surjective.

*Proof:* Cf.[Hartshorne P289]. □

**Prop. (5.7.6.7)[Cohomology and Stalks].** Let $f : X \rightarrow Y$ be a proper morphism of locally Noetherian schemes and $\mathcal{F}$ is a coherent sheaf on $X$ flat over $Y$, $y \in Y$, then

- If the natural map
  $$\varphi^i(y) : R^if_*(\mathcal{F}) \otimes k(y) \rightarrow H^i(X_y, \mathcal{F}_y)$$
  is surjective, then it is an isomorphism, and and the same is true for $y'$ in an open nbhd of $y$.

- Assume $\varphi^i(y)$ is surjective, then $\varphi^{i-1}(y)$ is also surjective iff $R^if_*(\mathcal{F})$ is finite projective in a nbhd of $y$.

*Proof:* 1: This follows from (5.7.6.2) (5.7.6.6) and (5.7.6.5).

2: $\varphi^{i-1}(y), \varphi^i(y)$ are both surjective iff $T^i$ and $T^{i-1}$ are both right exact at $y$ (5.7.6.6), which is equivalent to $T^i$ exact at $y$. Then we finish by (5.7.6.3) □
Remark (5.7.6.8). How’s this related to (5.7.5.5)?

Prop. (5.7.6.9) [Semicontinuity of Cohomology]. Let $X \to Y$ be a projective morphism of locally Noetherian schemes and $\mathcal{F}$ is a coherent sheaf on $X$, flat over $Y$, then for each $i$, $h^i(y, \mathcal{F}) = \dim_{k(y)} H^i(X_y, \mathcal{F}_y)$ is an upper semicontinuous function on $Y$.

Proof: The question is local on $Y$, so we may assume $Y$ is affine Noetherian. By (5.7.5.1), $H^i(y, \mathcal{F}) = \dim_{k(y)} T^i(k(y))$. And as in the proof of (5.7.6.1), $T^i(M) = \ker(W^i \otimes M \to L^{i+1} \otimes M)$, and $W^i \to L^{i+1} \to W^{i+1} \to 0$ is exact, so $0 \to T^i(k(y)) \to W^i \otimes k(y) \to L^{i+1} \otimes k(y) \to W^{i+1} \otimes k(y) \to 0$, and counting dimension, $h^i(y, \mathcal{F}) = \dim W^i \otimes k(y) + \dim W^{i+1} \otimes k(y) - \dim L^{i+1} \otimes k(y)$. Notice the last term is constant as $L^{i+1}$ is free $A$-module and the first two terms are upper semicontinuous by (5.5.1.41), thus $h^i(y, \mathcal{F})$ is upper-semicontinuous. □

Cor. (5.7.6.10) [Grauert]. If $Y$ is integral and $h^i(y, \mathcal{F})$ is constant on $Y$, then $R^i f_*(\mathcal{F})$ is locally free on $Y$ and $R^i f_*(\mathcal{F}) \otimes k(y) \cong H^i(X_y, \mathcal{F}_y)$.

Proof: Cf. [Hartshorne P288]. □
5.8 Topics in Schemes

Main references are [Sta] and [Har77].

1 Cartier Divisors

Def.(5.8.1.1)[Cartier Divisor]. A Cartier divisor on a scheme $X$ is an element in $\Gamma(X, K^*_X/O^*_X)$.

An effective Cartier divisor is a Cartier divisor that is locally defined as $\{(U_i, f_i)\}$ where $f_i \in \Gamma(U_i, O_{U_i})$ are nonzero-divisors, equivalently, it is a closed subscheme whose ideal sheaf is an invertible sheaf. (Notice by definition, $K$ is the localization w.r.t. nonzero-divisors, and $f_i$ is invertible in $K^*$ so $f_i$ must be nonzero-divisors.)

The group of effective Cartier divisors is denoted by $\text{Cart}_{\text{eff}}(X)$.

The Cartier divisor group $\text{CaCl}$ is the quotient of $\Gamma(X, K^*) \to \Gamma(X, K^*/O^*_X)$.

Prop.(5.8.1.2)[Cartier Divisor is Nowhere Dense]. Let $D \subset X$ be an effective Cartier divisor, then it is nowhere dense in $X$, i.e. $X \setminus D \to X$ is scheme-theoretically dense.

Proof: It suffices to check affine-locally, it is qc so the scheme-theoretic closure of $\text{Spec } A_f \to \text{Spec } A$ is $V(\ker(A \to A_f)) = V(0)$ as $f$ is a nonzero-divisor. □

Prop.(5.8.1.3)[Closed Subschemes and Effective Cartier Divisors]. Let $X$ be a locally Noetherian scheme and $D \subset X$ is a closed subscheme corresponding to a Qco sheaf of ideals $\mathcal{I} \subset O_X$. If for any $x \in D$, the ideal $\mathcal{I}_x \subset O_{X,x}$ is generated by a single nonzero-divisor, then $D$ is an effective Cartier divisor.

Proof: Cf.[Sta]0AG8. □

Cor.(5.8.1.4)[Prime Divisor and Effective Cartier Divisor]. Let $X$ be a locally Noetherian scheme and $D$ is a prime Weil divisor on $X$ and $O_{X,x}$ are UFDs for any $x \in D$, then $D$ is an effective Cartier divisor.

Proof: For any $x \in D$, let $A = O_{X,x}$, and $p$ be the prime corresponding to the generic point of $D$, then $\dim A_p = 1$, so $p$ is principle as $A$ is a UFD, so $D$ is an effective Cartier divisor by(5.8.1.3). □

Prop.(5.8.1.5) [Cartier-Pic]. For an integral scheme $X$, the homomorphism $\text{CaCl}(X) \to \text{Pic}(X)(5.8.1.1)(5.5.3.10)$ induced from long exact sequence of $0 \to O^*_X \to K^*_X \to K^*_X/O^*_X \to 0$ is an isomorphism.

Explicitly, for a Cartier divisor $D = \{(U_i, f_i)\}$, the image is the invertible sheaf $O_X(D)(5.5.3.12)$.

Proof: It is clearly injective by definition, so it suffices to show any invertible sheaf can embed into the constant sheaf: for any invertible sheaf $\mathcal{L}$, tensor with $K$ and restrict to the stalk of the generic point, i.e. there is a compatible choice of homomorphisms into $K(X)$. □

Prop.(5.8.1.6). If $X$ is Noetherian and the diagonal map is affine, for a dense affine open $U$, if all the stalk of $X \setminus U$ are UFD, then $U$ is the complement of an effective Cartier divisor.

Proof: The irreducible complements of $X \setminus U$ is finite and has codimension 1 by(5.6.3.5) because $U \to X$ is affine, and it is an effective Cartier divisor by(6.1.5.1), so their sum will suffice. □

Prop.(5.8.1.7) [Pullback of Effective Cartier Divisors]. Let $f : X \to Y \in \text{Sch}$ and $D \in \text{Cart}_{\text{eff}}(Y)$, then the pullback of $D$ via $f$ is an effective Cartier divisor on $X$ in the following cases:
Prop. (5.8.1.10) [Fibral Criterion of Relative Effective Divisor]. If $X$ is a Noetherian scheme with an ample invertible sheaf $L$, then any line bundle in $\text{Pic}(X)$ is isomorphism to $\mathcal{O}_X(D - D')$ for some effective Cartier divisors $D, D'$ on $X$.

Proof: Cf. [Sta] OAYM.

Relative Effective Cartier Divisors

Def. (5.8.1.9) [Relative (Effective) Cartier Divisors]. Let $X$ be a scheme over $S$, then a relative effective (Cartier) divisor on $X/S$ is an effective Cartier divisor $D$ on $X$ that is flat over $S$.

Prop. (5.8.1.10) [Fibral Criterion of Relative Effective Divisor]. Let $f : X \to S$ be a morphism of locally Noetherian schemes locally of f.t., $D \subset X$ be a closed subscheme and $x \in D$, $s = f(x)$, then the following are equivalent:

- $D$ is a relative effective divisor at a nbhd of $x$.
- $X$ and $D$ are flat over $S$ at $x$, and the fiber $D_s$ is a Cartier divisor on $X_s$ at $x$.
- $X$ is flat over $S$ at $x$, and $D$ is cut out by an element that is regular on the fiber $X_s$.

In particular, a relative Cartier divisor pair can be regarded as a family of Cartier divisors pairs.

Proof: 1 $\to$ 2: Let $\mathcal{O}_{D,x} = b\mathcal{O}_{X,x}$, then there is an exact sequence $0 \to \mathcal{O}_{X,x} \xrightarrow{b} \mathcal{O}_{X,x} \to \mathcal{O}_{D,x} \to 0$, which induces a long exact sequence

$$
\text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{X,x}, k(s)) \to \text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{X,x}, k(s)) \to \text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{D,x}, k(s)) \to \mathcal{O}_{X,x} \otimes k(s) \xrightarrow{b} \mathcal{O}_{X,x} \otimes k(s).
$$

Because $D$ is flat over $S$, $\text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{D,x}, k(s)) = 0$, thus $b$ is regular in $\mathcal{O}_{X,x}$ and $D_s$ is an effective divisor on $X_s$ at $x$. Also the map $\text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{X,x}, k(s)) \to \text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{X,x}, k(s))$ is surjective, which is multiplication by $b$, and $b$ is in the maximal ideal, thus by Nakayama lemma, $\text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{X,x}, k(s)) = 0$. Then $\mathcal{O}_{X,x}$ is $\mathcal{O}_{S,s}$-flat by local criterion (4.4.1.16).

2 $\to$ 3: Let $D$ corresponds to an ideal $I$ in $\mathcal{O}_{X,x}$, and because $D_s$ is effective divisor on $X_s$, there exists $b \in I$ s.t. the image of $b$ in $\mathcal{O}_{X,x} \otimes k(s)$ generate the ideal of $D_s$. Then it suffices to show that $b$ generates $I$. Notice there is an exact sequence $0 \to I \to \mathcal{O}_{X,x} \to \mathcal{O}_{D,x} \to 0$, and $\mathcal{O}_{D,x}$ is flat over $\mathcal{O}_{S,s}$, thus $I \otimes k(s) \to \mathcal{O}_{X,x} \otimes k(s)$ is injective, and the image is just the ideal of $D_s$, thus $b$ generates $I \otimes k(s)$. Thus by Nakayama, it also generates $I$.

3 $\to$ 1: The exact sequence $0 \to I \to \mathcal{O}_{X,x} \to \mathcal{O}_{D,x} \to 0$ induces the long exact sequence

$$
\text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{X,x}, k(s)) \to \text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{D,x}, k(s)) \to I \otimes k(s) \to \mathcal{O}_{X,x} \otimes k(s).
$$

$I \otimes k(s) \to \mathcal{O}_{X,x} \otimes k(s)$ is injective because its composition with $\mathcal{O}_{X,x} \otimes k(s) \to I \otimes k(s) \to \mathcal{O}_{X,x} \otimes k(s)$ is multiplication by $b$, thus injective as $b$ is regular on the fiber $X_s$. Thus $\text{Tor}_1^{\mathcal{O}_S,s}(\mathcal{O}_{D,x}, k(s)) = 0$, thus $D$ is flat at $x$ by local criterion (4.4.1.16). And also $I$ is flat over $\mathcal{O}_{S,s}$. Notice $b : \mathcal{O}_{X,x} \to I$ is isomorphism after tensoring $k(x)$ and $I$ is flat, so $\ker(b) = 0$ by Nakayama, and $b$ is regular.
Cor. (5.8.1.11). If \( D, E \) are relative effective Cartier divisors on \( X/S \), then \( D + E \) is also a relative Cartier divisor on \( X/S \).

\[
\text{Proof: } \text{This follows from item 3 of (5.8.1.10).} \quad \square
\]

Prop. (5.8.1.12) [Pullback of Divisors]. For \( S \in \text{Sch}, X \in \text{Sch}/S \) and \( Z \) an relative Cartier divisor on \( X/S \), then for any \( T \in \text{Sch}/S \), \( Z_T \) is a relative Cartier divisor on \( X_T/T \).

And if \( f : X' \to X \) is a flat morphism over \( S \), then \( f^*Z \) is also a relative Cartier divisor on \( X'/S \).

\[
\text{Proof: } \text{If } 0 \to O_X \xrightarrow{\mathcal{I}} O_X \to i_*O_Z \to 0, \text{ then } 0 \to O_{X_T} \xrightarrow{\mathcal{I}_T} O_{X_T} \to i_*O_{Z_T} \to 0 \text{ because } O_Z \text{ is flat over } O_S, \text{ so } \mathcal{I}_T \text{ is also an effective divisor on } X_T/T. \\
\text{The second case is similar.} \quad \square
\]

2 Blowing Up

Blowing-up serves as a way to magnify local properties to global ones.

Def. (5.8.2.1) [Blowing-Up]. Let \( X \) be a scheme and a closed subscheme \( Z \subset X \) defined by \( \mathcal{I} \), the blowing up of \( X \) along \( Z \) \( \text{Bl}_Z X \) is defined as the map \( \beta : \text{Proj}_{X}(\oplus_{d \geq 0} \mathcal{I}^d) \to X \).

The map \( \beta : \text{Bl}_Z X \to X \) pulls back \( Z \) to an effective Cartier divisor \( E_Z X \), called the exceptional divisor, and it has the universal property that any morphism \( Y \to X \) that pulls back \( Z \) to an effective Cartier divisor uniquely factors through \( \text{Bl}_Z X \).

\[
\text{Proof: } \text{Notice first an effective divisor is equivalent to an invertible sheaf of ideal. And any morphism } Z \to X \text{ pulls back } I \text{ to the image of } f^{-1}I \otimes_{O_X} O_Z \to f^{-1}I \cdot O_Z. \text{ This is just } O(1) \text{ on } \text{Bl}_X Z \text{ so invertible.} \\
\text{For the construction, the local uniqueness will implies the existence. Notice locally } \bar{X}_I \text{ is projective over } X. \text{ Now because the } Z \to X \text{ pulls back } I \text{ to an invertible sheaf and it is generated by } f^{-1}(a_i), \text{ we use?? to get another } \text{Proj}_{X}(\oplus_{d \geq 0} \mathcal{I}^d) \text{ and it factors through the closed subscheme } \bar{X}_I. \text{ If there is another morphism } g, \text{ then } f^{-1}I \cdot O_Z = g^{-1}(\pi^{-1}I \cdot O_{\bar{X}_I}) \cdot O_Z = g^{-1}(O_{\bar{X}_I}) \cdot O_Z \text{ surjective, and a surjective morphism between two invertible sheaves is an isomorphism, and they are both ideal sheaves, thus the same, so this morphism is unique as it is determined by the map on } O_X??. \quad \square
\]

Cor. (5.8.2.2). Let \( X \) be a scheme and \( Z \subset X \).

- If \( Z \) is itself an effective Cartier divisor, then the \( \text{Bl}_Z X = X \).
- If \( U \subset X \) is an open subscheme, then \( \text{Bl}_Z(U) = \beta^{-1}(U) \subset \text{Bl}_Z(X) \). In particular, Blowing-up is a local construction.
- If \( Z = X \), then \( \text{Bl}_Z X = \emptyset \).
- \( \beta \) is an isomorphism \( \beta^{-1}(X \setminus Z) \to X \setminus Z \) away from \( Z \).
- If \( X \) is reduced, then \( \text{Bl}_Z X \) is also reduced.
- If \( X \) is irreducible and \( Z \) doesn’t contain the generic point of \( X \), then \( \text{Bl}_Z X \) is irreducible.

\[
\text{Proof: } \text{1: By universal property.} \\
\text{2: This follows from universal property and the fact the restriction of an effective Cartier divisor is an effective Cartier divisor.}
\]
3: By universal property.
4: By item 2 and 3.
5: ?
6: ?

Cor. (5.8.2.3). \( \pi : \tilde{X}_I \to X \) is birational, proper thus surjective. If \( X \) is a (complete) variety, then so does \( \tilde{X}_I \).

Def. (5.8.2.4)[Strict Transform]. Let \( Z \subset X \) is a closed subscheme and \( f : Y \to X \) be a morphism, then \( Y \times_X \text{Bl}_Z X \) is called the total transform of \( Y \), and the strict transform of \( Y \) is the scheme-theoretic closure of \( Y \times_X \text{Bl}_Z X \) \( \setminus Y \times_X E_Z X \) in \( Y \times_X \text{Bl}_Z X \), or equivalently the closed subscheme of \( Y \times_X \text{Bl}_Z X \) cut out by the Qco ideal of sections supported on \( Y \times_X E_Z Y \).

Prop. (5.8.2.5)[Strict Transformation]. Let \( Z \subset X \) is a closed subscheme and \( f : Y \to X \) be a morphism, then the strict transform of \( Y \) is the blowing-up of \( Y \) at the closed subscheme \( f^{-1}Z \).

Proof: Cf.[Sta]080E. (Recall the definition of fiber product, we only need to check for \( Z, X \) affine and glue. For this, check \( B \otimes_A (\oplus I^d) \to \oplus (IB)^d \) defines the fiber map).

Prop. (5.8.2.6). If \( X \) is \( H \)-quasi-projective, then so does \( \tilde{X}_I \) and \( \pi \) is \( H \)-projective(5.5.2.19). And any birational projective morphism from another variety \( Z \) to \( X \) comes from a blowing-up.

Proof: Cf.[Hartshorne]P166.

Prop. (5.8.2.7)[Exceptional Divisor]. Let \( E = \pi^{-1}(x) \) for a blowing-up, called the exceptional divisor. Often the line bundle \( \mathcal{O}_\tilde{X}(E) \) associated with it is called denoted by \( E \).

There are canonical coordinates near \( E \): let \( \tilde{U}_i \) be \( \tilde{U} - \{ (l_i = 0) \} \), then endow \( \tilde{U}_i \) with the coordinate \( z(i) = (l_j/l_i, \ldots, z_i, \ldots, l_n/l_i) \), it is holomorphic to \( \mathbb{C}^n \). \( \pi \) in this coordinate is written as \( (z(1), \ldots, z(n)) \mapsto (z(i)z(z(1)), \ldots, z(i)z(i), \ldots, z(i)z(z(n))) \).

The transition function can be written, it is

\[
\varphi_j \circ \varphi_i^{-1}((z(i)_1, \ldots, z(i)_n)) = \left(\frac{z(i)_1}{z(i)_j}, \ldots, \frac{1}{z(i)_j}, \ldots, \frac{z(i)}{z(i)_j}, \ldots, \frac{z(i)_n}{z(i)_j}\right).
\]

Notice it is somewhat tricky because it has two different coordinates.

The defining function of \( E \) in this coordinate is \( (z(i)) = (z_i) \). So the line bundle \( \mathcal{O}_\tilde{X}(E) \) has transition function \( g_{ij} = z(i)/z(j) \), and it can be thought of as the line bundle that has line \([l] \) at the point \((z, [l]) \in \tilde{U} \). So it is kindof tautological, in fact its restriction on \( E \cong \mathbb{C}P^{n-1} \) is just the tautological line bundle.

Prop. (5.8.2.8). The canonical line bundle \( \mathcal{K}_\tilde{X} = \pi^* \mathcal{K}_X + (n - 1)E \), where \( n \) is the dimension of \( X \).

Proof: Away from \( E \), the \( \pi \) is a holomorphism, so it suffices to compare the two transition function of the two canonical maps near \( E \) using the coordinates in (5.8.2.7), with the local section given by \( dz_1 \wedge \ldots \wedge dz_n \) and \( dz(i)_1 \wedge dz(i)_n \) respectively. On \( \tilde{U}_i \), locally \( dz_1 \wedge \ldots \wedge dz_n \) is pulled by \( \pi^* \) to the trivial bundle on \( U' \), and by calculation, \( dz(j)_1 \wedge dz(j)_n = z(i)^{n-1}dz(i)_1 \wedge dz(i)_n \), so \( \mathcal{K}_\tilde{X} - (n - 2)E \) has a global section \( z(i)^n dz(i)_1 \wedge dz(i)_n \), so it is also trivial on \( \tilde{U} \), so \( \mathcal{K}_\tilde{X} = \pi^* \mathcal{K}_X + (n - 1)E \) is true.
Blowing up along a regular variety

Prop.(5.8.2.9). If $X$ is a regular variety over $k$ and $Y$ is a regular closed subvariety defined by $I$, then the blowing up along $I$ is also regular, and the inverse image $Y' \to Y$ is isomorphic to $P(I/I^2)$, the projective space associated to the locally free bundle $I/I^2$ on $Y$, and the normal sheaf $\mathcal{N}_{Y'/X'} \cong \mathcal{O}_{P(I/I^2)}(-1)$.

Proof: (Imagine the blowing up of $\mathbb{A}^2$ along $\{0\}$). $X' \cong \text{Proj} \oplus I$ and $Y' \cong \text{Proj} \oplus I/I^2$. Then since $Y$ is regular, (4.3.4.17) tells us $I$ is locally generated by a regular sequence and (4.3.4.16) tells $Y' = P(I/I^2)$. $Y'$ is regular by (4.3.5.18), and then (4.3.5.24) shows that $X'$ is regular also. For the normal sheaf, the defining sheaf $I' = \mathcal{O}_{X'}$ and then $I' \cong \mathcal{O}_{Y'} \sim \mathcal{O}_{P(I/I^2)(-1)}$.

□

Prop.(5.8.2.10). In a blowing up along a regular variety of codimension $r \geq 2$, there is an isomorphism $\text{Pic}X' \cong \text{Pic}X \oplus \mathbb{Z}$ induced by the Weil divisor exact sequence of $Y' \subset X'$. This is because $r \geq 2$ and (5.8.2.2).

We also have $\omega_{X'} = f^* \omega_X \otimes \mathcal{L}(r-1)Y'$ because $\mathcal{L}(Y') = \mathcal{O}(-1)$ and $\omega_Y \cong \omega_X \otimes \mathcal{L}(D) \otimes \mathcal{O}_Y$ by (5.10.1.17), so it suffices to prove $\omega_{Y'} \cong f^* \omega_X \otimes \mathcal{O}_{Y'}(-r)$. For this, notice for a closed pt of $Y$, the fiber is a $P^{r-1}$ because $I/I^2$ is locally free of rank $r$ by (5.10.1.16) and the functoriality of $\mathcal{O}(1)$.

3 Compatifications

Def.(5.8.3.1)[Compatifications]. Let $S \in \text{Sch}_{\text{qcqs}}$, $X \in \text{Sch}_{\text{sep}, \text{ft}}/S$, then the category of compatifications of $X/S$ is the category of pairs $(i, X)$, where $i: X \to X$ is an immersion and $X \to S$ is proper.

Thm.(5.8.3.2)[Nagata Compatification]. Situation as in (5.8.3.1), then $X/S$ has a compatification.

Proof: Cf.[Sta]0F41. □

4 Limits of Schemes

Prop.(5.8.4.1)[Noetherian Normalization]. Let $S$ be a qcqs scheme, then there exists a direct system $(S_i, f_{i'i})$ indexed over a set $I$ that

- $f_{i'i}$ are affine.
- $S_i$ are of f.t. over $\mathbb{Z}$.
- $S = \lim_i S_i$.

Proof: Cf.[Sta]01ZA. □

Prop.(5.8.4.2)[Characterizing Morphisms of F.P.]. Let $f : X \to S$ be a morphism of schemes, then the following are equivalent:

- $f$ is locally of finite presentation.
- For any directed inverse system $(T_i, f_{i'i})$ in $\text{Aff}_S$, we have

$$\text{Mor}_S(\lim_i T_i, X) = \lim_i \text{Mor}_S(T_i, X)$$
• For any directed inverse system \((T_i, f_{ii'})\) in \(\text{Sch}_S\) with \(T_i\) qcqs and \(f_{ii'}\) affine, we have

\[
\text{Mor}_S(\lim_{i} T_i, X) = \lim_{i} \text{Mor}_S(T_i, X)
\]

Proof: Cf.\cite[01IZC]{Sta}.

\textbf{Prop. (5.8.4.3) [Reduction to Finite Presented Morphisms].} Let \(f : X \to S\) be a morphism of schemes, if \(X\) is qcqs and \(S\) is qs, then \(X = \lim_{i} X_i\) is a limit of a directed system of schemes \(X_i\) of f.p. over \(S\) with affine morphisms over \(S\).

\[
\text{Mor}_S(\lim_{i} X_i, X) = \lim_{i} \text{Mor}_S(X_i, X)
\]

Proof: Cf.\cite[09MV]{Sta}.

\textbf{Prop. (5.8.4.4) [Integral and Finite].} Let \(f : X \to S\) be an integral morphism of schemes with \(S\) qcqs, then \(X = \lim_{i} X_i\) is a limit of a directed system of schemes \(X_i\) finite of f.p. over \(S\) with affine morphisms over \(S\).

Proof: Consider \(A = f_! \mathcal{O}_X\), which is a Qco sheaf of \(\mathcal{O}_S\)-modules. Then \(A = \lim_{i} A_i\) is a filtered colimit of finite and f.p. \(\mathcal{O}_S\)-modules by (5.5.1.13). Then \(X_i = \text{Spec}_S(A_i)\) satisfies the requirement by (5.2.7.12).

\section{5 \(D_{\mathcal{Q}\text{coh}}(X)\)}

\textbf{Def. (5.8.5.1) [Notations].} For a scheme \(X\),

Denote \(D^*_{\mathcal{Q}\text{coh}}(X) = D^*_{\mathcal{Q}\text{coh}}(X)(\text{Mod}(\mathcal{O}_X))(3.4.2.8)\). There is a natural functor \(D^*(\mathcal{Q}\text{coh}(X)) \to D^*_{\mathcal{Q}\text{coh}}(X)\).

Denote \(D^*_{\text{coh}}(X) = D^*_{\text{coh}}(X)(\text{Mod}(\mathcal{O}_X))(3.4.2.8)\). There is a natural functor \(D^*(\text{coh}(X)) \to D^*_{\text{coh}}(X)\).

By (5.3.1.6), these notions are affine local.

\textbf{Prop. (5.8.5.2) [Direct Sum].} Direct sum exists in \(D_{\mathcal{Q}\text{coh}}(X)\), and equals that in \(D(X)\).

Proof: By (3.4.2.15), direct sum exists in \(D(X)\) and are given by term-wise direct sums. Notice the direct sum of elements in \(D_{\mathcal{Q}\text{coh}}(X)\) is also in \(D_{\mathcal{Q}\text{coh}}(X)\) as direct sums are exact functor and \(\mathcal{Q}\text{coh}(X)\) is stable under direct sums.

\textbf{Prop. (5.8.5.3) [Affine Case].} Let \(X = \text{Spec} A\), there is a natural equivalence \(\sim : D(A) \to D(\mathcal{Q}\text{coh}(X))\). Then the functors \(R\Gamma(X, -) : D_{\mathcal{Q}\text{coh}}(X) \to D(A)\) is quasi-inverse to the inclusion functor \(D^*(\mathcal{Q}\text{coh}(X)) \to D^*_{\mathcal{Q}\text{coh}}(X)(5.8.5.1)\), and they are both isomorphism of triangulated categories.

Proof: Cf.\cite[06Z0]{Sta}.

\textbf{Prop. (5.8.5.4) [Derived Pullbacks].} Let \(f : X \to S\) be a qcqs morphism of schemes, then \(Lf^*\) maps \(D_{\mathcal{Q}\text{coh}}(X)\) into \(D_{\mathcal{Q}\text{coh}}(S)\), and affine locally it is just the derived tensor functor \(\bigotimes_A^L B : D(A) \to D(B)\) via identifications in (5.8.5.3), by (5.3.3.14)(5.3.3.15).

\textbf{Prop. (5.8.5.5) [Derived Products].} For \(X \in \text{Sch} \), \(D_{\mathcal{Q}\text{coh}}(X)\) is stable under derived tensor products, and affine locally it is just the derived tensor product \(\bigotimes^L\) via identifications in (5.8.5.3), by (5.3.3.6)(5.3.3.15).
Prop. (5.8.5.6) [Higher Direct Images]. Let \( f : X \to S \) be a qcqs morphism of schemes, then \( Rf_* \) maps \( D_{\text{QCoh}}(X) \) into \( D_{\text{QCoh}}(S) \). And if \( f \) is affine, affine locally it is just the restriction \( D(B) \to D(A) \) via identifications in (5.8.5.3), by (5.3.1.10).

Moreover, if \( S \) is qc, then there exists a \( N \in \mathbb{Z} \) s.t. \( Rf_*(D_{\text{QCoh}}^m(X)) \subset D_{\text{QCoh}}^{m+N}(S) \), and this \( N \) is invariant under base change.

**Proof:** Cf. [Sta]08D5. \( \square \)

Prop. (5.8.5.7). For \( f : X \to Y \) qcqs, \( Rf_* : D_{\text{QCoh}}(X) \to D_{\text{QCoh}}(Y) \) preserves direct sums.

**Proof:** Cf. [Sta]08DZ. \( \square \)

Prop. (5.8.5.8) [Projection Formula]. Let \( f : X \to Y \) be a qcqs morphism of schemes and \( E \in D_{\text{QCoh}}(X), K \in D_{\text{QCoh}}(Y) \), then the projection map (5.3.3.19)

\[
Rf_*(E) \otimes_{\mathcal{O}_Y} K \to Rf_*(E \otimes_{\mathcal{O}_Y} Lf^* K)
\]

is an isomorphism.

**Proof:** Cf. [Sta]08EU. \( \square \)

**Pseudo-Coherent and Perfect Complexes**

Prop. (5.8.5.9) [Affine Case]. If \( X = \text{Spec} A, M \in D(A) \) and \( E \) is the corresponding element in \( D(X) \), then

- \( E \) is an \((m)\)-pseudo-coherent object in \( D(X) \) iff \( M \) is an \((m)\)-pseudo-coherent object in \( D(A)(4.6.5.9) \).
- \( E \) has Tor-amplitude in \([a, b]\) iff \( M \) has Tor amplitude in \([a, b]\).
- \( E \) is a perfect object in \( D(X) \) iff \( M \) is a perfect object in \( D(A)(4.6.5.3) \).

**Proof:** Cf. [Sta]08E7, 08EB, 08E9,.

Prop. (5.8.5.10) [Noetherian Case]. Let \( X \) be a Noetherian scheme and \( \mathcal{E} \in D_{\text{QCoh}}(X) \), then the following are equivalent:

- \( \mathcal{E} \) is \( m \)-pseudo-coherent.
- \( \mathcal{E} \in D_{\text{QCoh}}^{-m}(X) \) and \( H^i(\mathcal{E}) \in \mathcal{Coh}(X) \) for \( i \geq m \).

In particular, \( E \) is pseudo-coherent iff \( E \in D_{\text{Coh}}^{-m}(X) \).

**Proof:** Cf. [Sta]08E8.

Prop. (5.8.5.11) [\( \mathcal{E} \text{xt} \)]. Let \( X \in \text{sch} \).

1. If \( X = \text{Spec} A \) and \( K, L \in D(A) \), then \( \mathcal{E}xt^n(\widetilde{K}, \widetilde{L}) \) is the sheaf extending the sheaf on the basis \( D(f) \mapsto \text{Ext}^n_A(K_f, L_f) \).
2. If \( X = \text{Spec} A \) and \( K, L \in D(A) \), then \( R\text{Hom}(\widetilde{K}, \widetilde{L}) = (R\text{Hom}_A(K, L))^\sim \) iff \( K \) is pseudo-coherent and \( L \in D_I(A) \), or \( K \) is perfect.
3. If \( \mathcal{L} \in D_{\text{QCoh}}(X) \) and \( K \in D(X) \) perfect, then \( R\text{Hom}(\mathcal{K}, \mathcal{L}) \in D_{\text{QCoh}}(X) \).
4. If \( \mathcal{L} \in D_{\text{QCoh}}^+(X) \) and \( K \in D(X) \) pseudo-coherent, \( R\text{Hom}(\mathcal{K}, \mathcal{L}) \in D_{\text{QCoh}}(X) \) and are locally bounded below.
Prop. (5.8.5.12) [Criterion for Relative Perfectness over Affine Base]. Let \( A \in \mathcal{C}_{\text{Alg}} \) and \( X \) be a separated, flat of f.p. scheme over \( A \), \( K \in D_{\mathcal{Qcoh}}(X) \). If \( R\Gamma(X,E \otimes^L K) \) is perfect in \( D(A) \) for any perfect object \( E \in D(X) \), then \( K \) is perfect over \( A \).

Proof: Cf. [Sta] 0GET.

\[ D_{\mathcal{Coh}}(X) \]

Prop. (5.8.5.13) [\( R\mathcal{H}om \) Preserves \( D_{\mathcal{Coh}}(X) \)]. If \( X \) is a locally Noetherian scheme and \( L \in D^+(\mathcal{Coh}(X)) \) and \( K \in D^-_{\mathcal{Coh}}(X) \), then \( R\mathcal{H}om(K,L) \in D^+_{\mathcal{Coh}}(X) \).

Proof: Cf. [Sta] 0D0C.

Prop. (5.8.5.14). Let \( X \) be a Noetherian scheme, then there are natural equivalences

\[ D^-(\mathcal{Coh}(X)) \cong D^-_{\mathcal{Coh}(X)}(\mathcal{Q}\mathcal{Coh}(X)) \cong D^-_{\mathcal{Coh}}(X), \quad D^b(\mathcal{Coh}(X)) \cong D^b_{\mathcal{Coh}}(X). \]

Proof: Cf. [Sta] 0FDA, 0FDB.

Prop. (5.8.5.15). Let \( S \) be Noetherian and \( f : X \to S \) be a proper morphism, then \( Rf_* \) maps \( D^b_{\mathcal{Coh}}(X) \) to \( D^b_{\mathcal{Coh}}(S) \).

Proof: Cf. [Sta] 08E2.

Prop. (5.8.5.16) [Perfect Complexes for Regular Schemes]. If \( X \) is a Noetherian regular scheme of finite dimension, then \( D^b_{\mathcal{Coh}}(X) \) consists exactly of the perfect objects in \( D(X) \), by (4.6.5.5) and (5.8.5.9).

Def. (5.8.5.17) [K-Groups of Schemes]. Let \( X \in \text{Sch} \), the Grothendieck group of \( X \) is defined to be \( K_0(X) = K_0(D_{\text{perf}}(X)) \). If \( X \) is locally Noetherian, also define the Grothendieck group of coherent sheaves on \( X \) to be \( K'_0(X) = K_0(\mathcal{Coh}(X)) \).

Prop. (5.8.5.18). If \( X \) is Noetherian, then

\[ K'_0(X) = K_0(\mathcal{Coh}(X)) = K_0(D^b(\mathcal{Coh}(X))) = K_0(D^b_{\mathcal{Coh}}(X)). \]

In particular, there is a map \( K_0(X) \to K'_0(X) \).

Proof: This follows from (3.4.2.13) and (5.8.5.14).

Prop. (5.8.5.19) \([K_0 \cong K'_0] \). If \( X \) is a Noetherian regular scheme of finite dimension, then the map \( K_0(X) \to K'_0(X) \) is an isomorphism, by (5.8.5.16).

Prop. (5.8.5.20). For \( X \in \text{Sch} \), \(- \otimes^L -\) defines a ring structure on \( K_0(X) \), by (3.4.1.30) and (3.4.4.12).
Prop. (5.8.5.21). If \( X = \text{Spec} R \), then \( K_0(X) = K_0(R) \). And if \( R \) is Noetherian, then \( K'_0(X) = K'_0(R) \).

Proof: Cf. [Sta] 0FDH.

Prop. (5.8.5.22) [Push and Pull]. Let \( f : X \to Y \) be a proper morphism of locally Noetherian schemes, then there is a map
\[
f_* : K'_0(X) \to K'_0(Y) : [\mathcal{F}] \mapsto \oplus_{i \geq 0} [R^{2i}f_*\mathcal{F}] - \oplus_{i \geq 0} [R^{2i+1}f_*\mathcal{F}],
\]
which is definable by (5.8.5.15). And there is an obvious map \( f^* : K'_0(Y) \to K'_0(X) \). They satisfy
\[
f_*(\alpha \cdot f^*\beta) = f_*\alpha \cdot \beta, \alpha \in K'_0(X), \beta \in K'_0(Y).
\]

Proof: The first assertion follows from long exact sequence for \( Rf_* \). The last assertion follows from projection formula (5.8.5.8).

Prop. (5.8.5.23) [Lambda Operators]. Let \( X \in \mathcal{S}ch \), there are functor \( \lambda^r : K_0(\mathcal{Coh}^{\text{free}}(X)) \to K_0(\mathcal{Coh}^{\text{free}}(X)) \) that sends \( [\mathcal{E}] \) to \( [\wedge^r \mathcal{E}] \).

Proof: Consider a map \( c : \mathcal{Coh}^{\text{free}}(X) \to K_0(\mathcal{Q Coh}^{\text{free}}(X))[t] : [\mathcal{E}] \mapsto \sum_{i=0}^{\infty} [\wedge^i \mathcal{E}] t^i \). It suffices to prove that for any exact sequence \( 0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0 \), \( c(\mathcal{E}) = c(\mathcal{E}') c(\mathcal{E}'') \), and then take \( \lambda^r \) as
\[
c(M) = \sum_{r>0} \lambda^r(M)t^r.
\]

To show this, notice that there is a filtration of \( \wedge^r \mathcal{E} \) with quotients
\[
\wedge^r \mathcal{E}', \wedge^{r-1} \mathcal{E}' \otimes \mathcal{E}'', \ldots, \wedge^r \mathcal{E}'',
\]
by (5.5.1.26).

Prop. (5.8.5.24) [Adam Operators]. Let \( X \in \mathcal{S}ch \), then there is are Adam operators
\[
\psi^{-1}, \psi^1, \psi^2 : K_0(X) \to K_0(X)
\]
s.t. for \( \mathcal{L} \in \text{Pic}(X) \),
\[
\psi^{-1}[\mathcal{L}] = [\mathcal{L}^{-1}], \quad \psi^1[\mathcal{L}] = [\mathcal{L}], \quad \psi^2[\mathcal{L}] = [\mathcal{L} \otimes^2].
\]

Proof: For any \( L \in K_0(X) \), there is an action of \( \{\pm 1\} \) on \( L \otimes^L L \) by switching factors. Denote \( (L \otimes^L L)^+, (L \otimes^L L)^- \) the fixed and anti-fixed parts of \( L \otimes^L L \), and define \( \psi^2[L] = [(L \otimes^L L)^+] - [(L \otimes^L L)^-] \).

Coherator

Prop. (5.8.5.25) [\( \mathcal{RQX} \)].

Prop. (5.8.5.26) [\( \mathcal{DQX} \)]. Let \( X \) be a qcqs scheme, then the inclusion functor \( D_{\mathcal{Q Coh}}(X) \to D(X) \) has a right adjoint, called the coherator, denoted by \( D_{\mathcal{Q} X} \).

Proof: Use (3.4.1.35). The conditions are satisfied as \( D_{\mathcal{Q Coh}}(X) \) is compactly generated and has direct sums that is preserved by inclusion by (5.8.5.30)(5.8.5.2).
Prop. (5.8.5.27). Let $f : X \to Y$ be a morphism of qcqs schemes, then

$$Rf_* \circ DQ_X = DQ_Y \circ Rf_* : D(X) \to D_{QCoh}(Y).$$

Proof: They are both right adjoint to $Lf^* : D_{QCoh}(Y) \to D(X)$, as $Lf^*$ maps $D_{QCoh}(Y)$ into $D_{QCoh}(X)$ (5.8.5.4).

Prop. (5.8.5.28) [Cohomological Boundedness of $DQ_X$]. Let $X$ be a qcqs scheme, then there exists $N \in \mathbb{Z}$ s.t. if $K \in D(X)$ satisfies $K|_U \in D^{[a,b]}(\mathcal{O}_U)$ for any affine open $U \subset X$, then $DQ_X(K) \in D^{[0, b+N]}_{QCoh}(X)$.

Proof: Cf. [Sta]0CSA.

Compact Generators

Prop. (5.8.5.29) [Perfect and Compact Objects]. Let $X$ be a qcqs scheme, then $K \in D(X)$ is perfect iff it is a compact object in $D_{QCoh}(X)$.

Prop. (5.8.5.30) [$D_{QCoh}(X)$ is Compactly Generated]. There is a perfect object $P \subset D_{QCoh}(X)$ that is a generator of $D_{QCoh}(X)$ (3.4.1.31).

Proof: Cf. [Sta]09IS.

Resolution Property

Def. (5.8.5.31) [Resolution Properties]. A scheme $X$ is said to have resolution property iff every $\mathcal{F} \in \mathcal{QCoh}^R(X)$ is a quotient of a locally free sheaf.

Prop. (5.8.5.32). If $X$ has an ample invertible sheaf, then $X$ has the resolution property by (5.5.4.5). In fact, every coherent sheaf is a quotient of a finite direct sum of $\mathcal{O}_X(−n)$.

Prop. (5.8.5.33) [Regular Scheme has Resolution property]. If $X$ is qc regular scheme with an affine diagonal, then $X$ has the resolution property, Cf. [Sta]0F8A? . Conversely, if $X$ is qcqs with the resolution property, then $X$ has affine diagonal. Cf. [Sta]0F8C.

Prop. (5.8.5.34) [Kleiman]. If $X$ is a qc irreducible and locally factorial scheme with affine diagonal map, then $X$ has the resolution property.

Proof: By (5.8.1.6), we have a basis of the form $X_s$ for $s \in \Gamma(X, \mathcal{L})$ for various invertible sheaves, then for any coherent sheaf, it is generated by f.m. sections in $\Gamma(U_i, \mathcal{F})$ and $U_i = X_s$ for $s \in \Gamma(X, \mathcal{L})$, and for each of them, we can use (5.5.3.5), we can extend these to global sections on $\Gamma(\mathcal{F} \otimes \mathcal{L}_s^n)$ for $n_i$ large. Then tensoring $\mathcal{L}_s^{-n_i}$, we find a $\oplus \mathcal{L}_s^{-n_i} \to \mathcal{F}$ surjective.

Prop. (5.8.5.35). When $X$ has the resolution property, $\mathcal{E}xt^*(-, \mathcal{G})$ is an universal $\delta$-functor for every $\mathcal{G} \in \mathcal{QCoh}(X)$, because locally free sheaf is adapted to $\mathcal{E}xt^*(-, \mathcal{G})$ by (5.3.3.25), so we can calculate $\mathcal{E}xt(\mathcal{F}, \mathcal{G})$ using a finite locally free resolution of $\mathcal{F}$.

Prop. (5.8.5.36). If $X$ is a qcqs scheme with the resolution property, then the map $K_0(\text{Vect}(X)) \to K_0(X)$ is an isomorphism.

Proof: Cf. [Sta]0FDJ.
6 Duality for Schemes

Main references are [Hartshorne Residues and Duality, Hartshorne], [Sta] Chap48 and [Grothendieck Duality and Base Change, Conrad]

Right Adjoints of Pushforwards

Prop. (5.8.6.1) [Right Adjoints of Pushforwards Exist]. Let \( f : X \to Y \) be a morphism between qcqs schemes, then the functor \( Rf_* : \mathcal{D}_{\text{qcqs}}(X) \to \mathcal{D}_{\text{qcqs}}(Y) \) has a right adjoint, denoted by \( f^! \).

Proof: Use (3.4.1.35). The conditions are satisfied as \( \mathcal{D}_{\text{qcqs}}(X) \) is compactly generated and has direct sums by (5.8.5.30)(5.8.5.2), and \( Rf_* \) preserves direct limits (5.8.5.7).

Prop. (5.8.6.2). Let \( f : X \to Y \) be a morphism between qcqs schemes, then \( f^! \) maps \( \mathcal{D}_{\text{qcqs}}^+(Y) \) into \( \mathcal{D}_{\text{qcqs}}^+(X) \).

Proof: This follows from the fact \( Rf_* \) has finite cohomological dimension \( N(5.8.5.6) \) and (3.4.2.18).

Prop. (5.8.6.3). Let \( f : X \to Y \) be a morphism of qcqs schemes, then for \( K \in \mathcal{D}_{\text{qcqs}}(X), L \in \mathcal{D}_{\text{qcqs}}(Y) \), there is a canonical map

\[
Rf_* R\mathcal{H}om_{\mathcal{O}_X}(L, f^! K) \to R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* L, Rf_* f^! K) \to R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* L, K),
\]

by (5.3.3.31) and adjunction.

Then this map becomes isomorphism after applying the coherator \( \mathcal{D}Q_X(5.8.5.26) \).

Proof: By Yoneda lemma, it suffices to show that for any \( M \in \mathcal{D}_{\text{qcqs}}(Y) \),

\[
\text{Hom}_Y(M, Rf_* R\mathcal{H}om_{\mathcal{O}_X}(L, f^! K)) \cong \text{Hom}_Y(M, R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* L, K)) :
\]

\[
\text{Hom}_Y(M, Rf_* R\mathcal{H}om_{\mathcal{O}_X}(L, f^! K)) = \text{Hom}_X(Lf^* M, R\mathcal{H}om_{\mathcal{O}_X}(L, f^! K)) = \text{Hom}_X(Lf^* M \otimes L, f^! K)
\]

(by \( Lf^* M \otimes L \in \mathcal{D}_{\text{qcqs}}(X) \) by (5.8.5.4)(5.8.5.5)) = \text{Hom}_Y(Rf_*(Lf^* M \otimes L), K) = \text{Hom}_Y(M \otimes Rf_* L, K) = \text{Hom}_Y(M, R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* L, K))

\( \square \)

Cor. (5.8.6.4). By (5.8.5.6), this adjointness is true without coherator if both \( R\mathcal{H}om_{\mathcal{O}_X}(L, f^! K) \) and \( R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* L, K) \) are in \( \mathcal{D}_{\text{qcqs}}(Y) \). This is the case if \( L, Rf_* L \) are perfect or \( K \in \mathcal{D}_{\text{qcqs}}^+(Y) \) and and \( L, Rf_* L \) are pseudo-coherent, by (5.8.5.11).

In particular, this holds if \( f : X \to Y \) is a proper morphism of Noetherian schemes and \( L \in \mathcal{D}_{\text{qcqs}}^-(X) \) and \( S \in \mathcal{D}_{\text{qcqs}}^+(S) \), by (5.8.5.15) and (5.8.5.10).

Cor. (5.8.6.5) [Global Sections]. Let \( f : X \to Y \) be a morphism of qcqs schemes, then for \( K \in \mathcal{D}_{\text{qcqs}}(X), L \in \mathcal{D}_{\text{qcqs}}(Y) \), there is a canonical isomorphism

\[
R\mathcal{H}om_{\mathcal{O}_X}(L, f^! K) \to R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* L, Rf_* f^! K) \to R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* L, K)
\]
Proof: This is because for any \( E \in D(X) \), \( H^i(X, E) = \text{Ext}^i_{\mathcal{O}_X}(\mathcal{O}_X, E) = \text{Hom}(\mathcal{O}_X[-i], E) = \text{Hom}(\mathcal{O}_X[-i], D\mathcal{O}(E)) \) only depends on \( D\mathcal{O}(E) \).

\[ \square \]

**Prop. (5.8.6.6) [Proper Flat \( f^* \)].** Let \( f : X \to Y \) be a proper flat morphism of f.p. between qcqs schemes, then \( f^* \) is compatible with base change between qcqs schemes.

Proof: Cf. [Sta] 0AAB. \[ \square \]

**Upper Shriek**

**Def. (5.8.6.7) [\( \mathcal{S} \mathcal{C}_{S}^{f.t, \text{sep}} \)].** For a locally Noetherian scheme \( S \), let \( \mathcal{S} \mathcal{C}_{S}^{f.t, \text{sep}} \) be the full subcategory of \( \mathcal{S} \mathcal{C} / S \) consisting of schemes separated of f.t. over \( S \).

**Prop. (5.8.6.8) [Lower Shriek].** Let \( f : X \to Y \in \mathcal{S} \mathcal{C}_{S}^{f.t, \text{sep}} \), take a compactification \( \overline{f} : \overline{X} \to Y \) of \( X/Y \), then we can define the functor

\[
\overline{f}^! : D^+_{\text{QCoh}}(Y) \to D^+_{\text{QCoh}}(X) : f^! K = \overline{f}^!(K)|_X.
\]

and this functor is independent of the compactification chosen.

Proof: Cf. [Sta] 0AA0. \[ \square \]

**Prop. (5.8.6.9).** If \( f : X \to Y, g : Y \to Z \in \mathcal{S} \mathcal{C}_{S}^{f.t, \text{sep}} \), then there is a canonical isomorphism of functors \( (g \circ f)^! \cong f^! \circ g^! \).

Proof: Cf. [Sta] 0ATX. \[ \square \]

**Prop. (5.8.6.10) [Properties of \( f^! \)].** Let \( S \in \mathcal{S} \mathcal{C} \) be Noetherian, then for \( X, Y \in \mathcal{S} \mathcal{C}_{S}^{f.t, \text{sep}} \),

- If \( j : X \to Y \) is an open immersion, then \( j^! = j^* \).
- If \( i : X \to Y \) is a closed immersion, then \( i^! = R\mathcal{H}om(\mathcal{O}_X, -) \).
- \( f^! \) maps \( D^+_{\text{QCoh}}(Y) \) into \( D^+_{\text{QCoh}}(X) \).
- If \( f : X \to Y \) is a local complete intersection morphism, then \( f^! \mathcal{O}_Y \) is an invertible object of \( D(X) \), and \( f^! \) preserves perfect complexes.
- If \( f : X \to Y \) is finite, then \( f_* f^!(-) = R\mathcal{H}om_{\mathcal{O}_Y}(f_* \mathcal{O}_X, -) \).
- If \( f : X \to Y \) is an effective Cartier divisor, then \( f^!(-) = Lf^*(-) \otimes^L \mathcal{O}_X \wedge^c \mathcal{N}[-1] \).
- If \( f : X \to Y \) is a Koszul regular immersion of codimension \( c \), then \( f^!(-) = Lf^*(-) \otimes^L \Omega^d_{X/Y}[d] \).

Proof: Cf. [Sta] 0AU0, 0AA2, 0AU1, 0B6V, 0AU3? \[ \square \]

**Dualizing Complexes**

**Def. (5.8.6.11) [Dualizing Complex].** Let \( X \) be a locally Noetherian scheme, then a complex \( K \in D_{\text{QCoh}}(X) \) is called a **dualizing complex** if it satisfies the following equivalent conditions:

- For any affine open \( U = \text{Spec} \ A \subset X \), \( K|_U \) is a dualizing complex in \( D(A) \).
There exists an affine open covering \( U_i = \text{Spec} \ A_i \) of \( X \) s.t. \( K|U_i \) is a dualizing complex in \( D(A_i) \) for any \( i \).

Proof: This follows from (4.6.8.2).

**Prop. (5.8.6.12) [Dualizing]**. Let \( X \) be a locally Noetherian scheme and \( \omega_X \) be a dualizing complex, then \( D = R\text{Hom}_{\mathcal{O}_X}(-, \omega_X) \) is an anti-equivalence of \( D_{\text{QCoh}}(X) \) with itself, and there is a canonical isomorphism \( \text{id} \cong D^\otimes_2 \).

Moreover, if \( X \) is qc, then \( D \) exchanges \( D^+_{\text{QCoh}}(X) \) and \( D^-_{\text{QCoh}}(X) \), and induces an equivalence \( D : D^b_{\text{QCoh}}(X) \to D^b_{\text{QCoh}}(X) \).

Proof: Cf. [Sta]0A89.

**Thm. (5.8.6.13) [Grothendieck Duality]**. Let \( S \) be a Noetherian scheme, then

- \( f^! \) makes \( D^+_{\text{QCoh}} \) a pseudo-functor on \( \text{Sch}^\text{ft,sept}_S \).
- If \( f : X \to Y \in \text{Sch}^\text{ft,sept}_S \) is proper, then \( f^! \) is the right adjoint of \( Rf_* \), and there is a canonical isomorphism
  \[ Rf_* R\text{Hom}_{\mathcal{O}_X}(K, f^! M) \cong R\text{Hom}_{\mathcal{O}_Y}(Rf_* K, M) \]
  for any \( K \in D^-_{\text{coh}}(X) \) and \( M \in D^+_{\text{QCoh}}(Y) \), by ??
- If \( X \in \text{Sch}^\text{ft,sept}_S \) has a dualizing complex \( \omega_X \), then \( D_X = R\text{Hom}(-, \omega_X) \) defines an involution of \( D^\text{coh}_X \) switching \( D^+_{\text{coh}}(X) \) and \( D^-_{\text{coh}}(X) \) and fixing \( D^b_{\text{coh}}(X) \).
- If \( Y \) has a dualizing complex \( \omega_Y \), then
  
  - \( \omega_X = f^! \omega_Y \) is a dualizing complex for \( X \),
  
  - for \( M \in D^+_{\text{coh}}(Y) \), there is a canonical isomorphism \( D_X(f^! M) \cong Lf^* D_Y(M) \).
  
  - If moreover \( f \) is proper, then \( Rf_* R\text{Hom}_{\mathcal{O}_X}(K, \omega_X) = R\text{Hom}_{\mathcal{O}_Y}(Rf_* K, \omega_Y) \) for \( K \in D^-_{\text{coh}}(X) \).

Proof: Cf. [Sta]0AU3.

**Thm. (5.8.6.14) [Over a Dualizing Basis]**.

Proof: Cf. [Sta]0AUE.

**Dualizing Modules**

**Prop. (5.8.6.15) [Relative Dualizing Modules]**. Let \( f : X \to Y \) be a locally quasi-finite morphism of locally Noetherian schemes, then there exists a unique coherent \( \mathcal{O}_Y \)-module \( \omega_{X/Y} \in \text{Coh}(Y) \) that affine locally is given by the dualizing sheaf \( \omega_{B/A}(4.6.8.4) \).

Proof: Cf. [Sta]0BVG.

**Relative Dualizing Complex**

**Def. (5.8.6.16) [Relative Dualizing Complexes]**. For a separable f.t. morphism of Noetherian schemes \( f : X \to S \), the relative dualizing complex is defined to be \( \omega_{X/S} = f^! \mathcal{O}_S \).

**Prop. (5.8.6.17)**. Let \( Y \) be a qcqs scheme and \( f : X \to Y \) be a proper flat morphism of f.p., then

- \( \omega_{X/Y} \) is perfect over \( Y \).
Prop. (5.8.6.18)[Serre Duality (Proper over Fields case)]. Let \( X \) be a proper scheme over a field \( k \) of dimension \( d \), then there exists a unique dualizing complex \( \omega_X \) with the following properties:

- \( H^i(\omega_X) \neq 0 \) only for \( i \in \{ -\dim(X), 0 \} \).
- \( [\omega_X] = H^{-d}(\omega_X) \) is a coherent \((S_2)\)-module whose support is the irreducible components of \( X \) of dimension \( d \).
- \( \dim \text{Supp}(H^i(\omega_X)) \leq -i \).
- For \( x \in X \) closed, \( H^i(\omega_{X,x}) \oplus \cdots \oplus H^0(\omega_{X,x}) \neq 0 \) iff \( \text{depth}(\mathcal{O}_{X,x}) \leq -i \).
- For \( K \in D_{\text{QCoh}}(X) \), there is a functorial isomorphisms

\[
\text{Ext}^{-i}_X(K, \omega_X) \cong \text{Hom}_k(H^i(X, K), k)
\]

compatible with shifts and distinguished triangles, which characterizes \( \omega_X \) uniquely.

- There are functorial isomorphisms \( \text{Hom}(\mathcal{F}, [\omega_X]) = \text{Hom}_k(H^d(X, \mathcal{F}), k) \) for \( \mathcal{F} \in \text{Coh}(X) \).
- If \( X \) is C.M., equidimensional, then \( \omega_X = [\omega_X][d] \).
- If \( X \) is smooth over \( k \), then \( \omega_X = K_{X/k}[d] \).

**Proof:** As \( f^* \) commutes with base change \((5.8.6.6)\), it suffices to assume that \( Y = \text{Spec} A \).

1. By \((5.8.6.4)(5.3.4.23)\) and \((5.7.5.5)\), for any perfect object \( E \in D(X) \), there are canonical isomorphisms:

\[
Rf_*(E \otimes^L \omega_{X/Y}) = Rf_*R\mathcal{H}om_{\mathcal{O}_X}(E^\vee, \omega_{X/Y}) = R\mathcal{H}om_{\mathcal{O}_Y}(Rf_*E^\vee, \mathcal{O}_Y) = (Rf_*E^\vee)^\vee,
\]

which is perfect. So \( \omega_{X/Y} \) is perfect over \( S \) by \((5.8.5.12)\).

2. By \((5.8.5.8)\),

\[
\mathcal{H}om_Y(\mathcal{O}_Y[-i], Rf_*\omega_{X/Y}) = \mathcal{H}om_Y(Rf_*Lf^*\mathcal{O}_Y[-i], \mathcal{O}_Y) = \mathcal{H}om_Y((Rf_*\mathcal{O}_X)[-i], \mathcal{O}_Y).
\]

By proper flat base change \((5.7.5.5)\), \( Rf_*\mathcal{O}_X \) is perfect in \( Y \), so it can be represented by a finite complex of finite projective \( A \)-modules, so by \((5.3.4.22)\), \( R^if_*\omega_{X/Y} = 0 \) for \( i > 0 \).

3: For any perfect object \( E \in D(X) \), by \((5.8.6.4)(5.3.4.23)(5.7.5.5)(5.3.4.23)\) and \((5.3.1.10)\), there are canonical isomorphisms

\[
\mathcal{H}om_X(E, R\mathcal{H}om_{\mathcal{O}_X}(\omega_{X/Y}, \omega_{X/Y})) = \mathcal{H}om_Y(Rf_*(E \otimes^L \omega_{X/Y}), \mathcal{O}_Y)
\]

\[
= \mathcal{H}om_Y(Rf_*\mathcal{H}om(E^\vee, \omega_{X/Y}), \mathcal{O}_Y)
\]

\[
= \mathcal{H}om_Y(\mathcal{H}om(Rf_*E^\vee, \mathcal{O}_Y), \mathcal{O}_Y)
\]

\[
= R\Gamma(Y, Rf_*E^\vee)
\]

\[
= \mathcal{H}om_X(E, \mathcal{O}_X)
\]

So by \((5.8.5.30)\), perfect objects generate \( D_{\text{QCoh}}(X) \), so \( R\mathcal{H}om_{\mathcal{O}_X}(\omega_{X/Y}, \omega_{X/Y}) \cong \mathcal{O}_X \).

**Prop. (5.8.6.18)[Serre Duality (Proper over Fields case)]** Let \( X \) be a proper scheme over a field \( k \) of dimension \( d \), then there exists a unique dualizing complex \( \omega_X \) with the following properties:

- \( H^i(\omega_X) \neq 0 \) only for \( i \in \{ -\dim(X), 0 \} \).
- \( [\omega_X] = H^{-d}(\omega_X) \) is a coherent \((S_2)\)-module whose support is the irreducible components of \( X \) of dimension \( d \).
- \( \dim \text{Supp}(H^i(\omega_X)) \leq -i \).
- For \( x \in X \) closed, \( H^i(\omega_{X,x}) \oplus \cdots \oplus H^0(\omega_{X,x}) \neq 0 \) iff \( \text{depth}(\mathcal{O}_{X,x}) \leq -i \).
- For \( K \in D_{\text{QCoh}}(X) \), there is a functorial isomorphisms

\[
\text{Ext}^{-i}_X(K, \omega_X) \cong \text{Hom}_k(H^i(X, K), k)
\]

compatible with shifts and distinguished triangles, which characterizes \( \omega_X \) uniquely.

- There are functorial isomorphisms \( \text{Hom}(\mathcal{F}, [\omega_X]) = \text{Hom}_k(H^d(X, \mathcal{F}), k) \) for \( \mathcal{F} \in \text{Coh}(X) \).
- If \( X \) is C.M., equidimensional, then \( \omega_X = [\omega_X][d] \).
- If \( X \) is smooth over \( k \), then \( \omega_X = K_{X/k}[d] \).
Proof: Cf.[Sta]0FVV, 0AWT.? □

Cor. (5.8.6.19) [Serre Duality (Smooth over Fields case)]. If \( k \in \text{Field}, X \in \text{Sch}/k \) is a smooth proper scheme over \( k \) of dimension \( d \), then for any locally free sheaf \( \mathcal{F} \), there is a functorial isomorphism:
\[
H^i(X, \mathcal{F}) \cong (H^{n-i}(X, \mathcal{F}^\vee \otimes \mathcal{K}_{X/k}))^\vee.
\]

Cor. (5.8.6.20). For a smooth proper variety \( X \) over a field \( k \) of dimension \( n \), \( H^n(X, \mathcal{K}_X) = k \), by (5.10.1.12).

Cor. (5.8.6.21). For a smooth proper variety \( X \) over a field \( k \) of dimension \( n \), \( \Omega_{X/k}^n \) is locally free by (5.6.4.15), thus by (5.5.1.25), \( \Omega_{X/k}^{n-p} \cong (\Omega_{X/k}^p)^\vee \otimes \mathcal{K}_X \). So by (5.8.6.19):
\[
H^q(X, \Omega_{X/k}^p) \cong (H^{n-q}(X, \Omega_{X/k}^{n-p}))^\vee.
\]

Cor. (5.8.6.22). If \( X \) is a closed subscheme of \( P^n_k \) of codimension \( r \), then \( X \) has a dualizing sheaf \([\omega_X] = \text{Ext}^r_p(i_*\mathcal{O}_X, \mathcal{K}_{P^n/k}), \) and \( \text{Ext}^i(i_*\mathcal{O}_X, \mathcal{K}_{P^n/k}) = 0 \) for \( i < r \).

Proof: This follows from (5.8.6.18) and (5.8.6.13). □

Prop. (5.8.6.23) [Characterizing Cohen-Macaulay Schemes]. Let \( X \) be projective of dimension \( n \) over a field \( k \) and \([\omega_X]\) be the dualizing sheaf, then for \( \mathcal{F} \in \text{Coh}(X) \), there is a natural map
\[
\text{Ext}^i(\mathcal{F}, [\omega_X]) \to (H^{n-i}(X, \mathcal{F}))^\vee
\]
And the following are equivalent:
- For any \( \mathcal{F} \) locally free on \( X \), \( H^i(X, \mathcal{F}(-q)) = 0 \) for \( i < n \) and \( q \) large.
- \( H^i(X, \mathcal{O}_X(-q)) = 0 \) for \( i < n \) and \( q \) large.
- This is an isomorphism of \( \delta \)-functors.
- \( X \) is C.M. and equidimensional.

Proof: Notice the left side is an universal \( \delta \)-functor in \( \mathcal{F} \) by (5.8.5.35), so the map exist, and
2 \( \Rightarrow 3 \): This implies that the right is also universal by (5.8.5.32).
3 \( \Rightarrow 1 \): For \( \mathcal{F} \) locally free, by (5.3.3.33),
\[
H^i(X, \mathcal{F}(-q)) = (\text{Ext}^{n-i}(\mathcal{F}(-q), \omega_X)) = (H^{n-i}(X, \mathcal{F}^\vee \otimes \omega_X(q)))^\vee
\]
which is 0 for \( q \) large.
4 \( \Rightarrow 1 \): Embed \( X \) in \( P = P^N_k \), for \( \mathcal{F} \) locally free, since \( X \) is catenary, equidimensional is equivalent to \( \dim \mathcal{F}_x = n \) for all closed pt \( x \), and C.M. says depth \( \mathcal{F}_x = n \). Thus by (4.3.5.26), \( pd_{\mathcal{O}_{P,x}} \mathcal{F}_{x} = N - n \). Thus \( \text{Ext}^k_p(\mathcal{F}, -) \) vanish for \( k > N - n \) checked on stalks.
Now \( H^i(X, \mathcal{F}(-q)) \) is dual to \( \text{Ext}^{N-i}_p(\mathcal{F}, \omega_p(q)) \) by the proof of (5.8.6.22), which is isomorphic to \( \Gamma(P, \text{Ext}^{N-i}_p(\mathcal{F}(-q), \omega_p(q))) \) for \( q \) large by (5.7.4.9), so it vanish when \( i < n \) by what we proved.
1 \( \Rightarrow 4 \): The same as the proof of 4 \( \Rightarrow 1 \), then for \( i < n \),
\[
\Gamma(P, \text{Ext}^{N-i}_p(\mathcal{F}, \omega_p(q))) = 0 = \Gamma(P, \text{Ext}^{N-i}_p(\mathcal{F}, \omega_p)(q))
\]
for \( q \) large, so \( \text{Ext}^{N-i}_p(\mathcal{F}, \omega_p) = 0 \) as it is coherent. Then the stalk is \( \text{Ext}^{N-i}_{\mathcal{O}_{P,x}}(\mathcal{O}_{X,x}, \mathcal{O}_{P,x}) \), so \( pd_{\mathcal{O}_{P,x}} \mathcal{F}_{x} \leq N - n \) by (4.3.5.27), so depth \( \mathcal{O}_{X,x} \geq n \), we must have equality, thus \( X \) is C.M. and equidimensional, as it suffice to check at closed pts. □
Cor. (5.8.6.24) [Enriques-Severi-Zariski]. Let $X$ be a normal projective scheme that every irreducible component has dimension $\geq 2$, then for any $\mathcal{F} \in \text{Vect}(X)$, $H^1(X, \mathcal{F}(-q)) = 0$ for $q$ large. 

Proof: Just notice that $\dim \mathcal{F}_x \geq 2$, and Serre criterion shows depth $\mathcal{F}_x \geq 2$, the rest is the same as $4 \to 1$ in the proof of (5.8.6.23).

Prop. (5.8.6.25) [Ample Effective Divisor Connected]. Let $X$ be a proper connected CM. equidimensional scheme over $k$ of dimension at least 2 and $D$ is an ample effective Cartier divisor, then $D$ is connected.

In particular, if $X$ is a smooth complete variety of dimension $\geq 2$, $D$ is also a complete variety. 

Proof: Let $D = V(s)$, where $s$ is a section of an ample invertible sheaf, then there is an exact sequence 

$$0 \to \mathcal{O}_X(-nD) \to \mathcal{O}_X \to i_*\mathcal{O}_{V(s^n)} \to 0,$$

which gives a long exact sequence 

$$0 \to H^0(X, \mathcal{O}_X(-nD)) \to H^0(X, \mathcal{O}_X) \to H^0(V(s^n), \mathcal{O}_{V(s^n)}) \to H^1(X, \mathcal{O}_X(-nD)).$$

But by Serre duality (5.8.6.19) and (5.7.2.6), $H^0(X, \mathcal{O}_X(-nD)) = H^{\dim X}(X, [\omega_X] \otimes \mathcal{O}_X(nD)) = 0$ for $n$ sufficiently large, and $H^1(X, \mathcal{O}_X(-nD)) = H^{\dim X-1}(X, [\omega_X] \otimes \mathcal{O}_X(nD)) = 0$ for $n$ sufficiently large, so $H^0(V(s^n), \mathcal{O}_{V(s^n)}) \cong H^0(X, \mathcal{O}_X)$ has no idempotents for $n$ sufficiently large, so $V(s^n)$ is connected, and $D$ is also connected. 

Cor. (5.8.6.26). Any global complete intersection in $\mathbb{P}^n$ is connected.

Topological Sheaves

Prop. (5.8.6.27) [Global Verdier Duality]. If $f : X \to Y$ is a map between locally compact spaces with finite dimension, then there exists a functor $f^! : D^+(S\text{Ab}_Y) \to D^+(S\text{Ab}_X)$ that 

$$R\text{Hom}(Rf_*\mathcal{F}^*, G^*) \cong R\text{Hom}(\mathcal{F}, f^!G^*).$$

In particular, $f^!$ is right adjoint to $Rf_!$. Cf. [Gelfand P228].

There is also a local form of Verdier duality, which implies the global version by taking global section, Cf. [Cohomology of Sheaves Iversen P330].

Prop. (5.8.6.28). When $X \to Y$ is an inclusion of open subset, $f_!$ is just $j_!$ defined in (5.2.6.2) and $f^!$ is the restriction. When it is an inclusion of closed subset of locally compact spaces, it is the direct image $f_*$ and $f^!$ is the $j^!$ previously defined in (5.2.6.2). They are not barely defined on $D^+(S\text{Ab})$ but on $S\text{Ab}$.

Prop. (5.8.6.29). We consider the case where $f : X \to \text{pt}$, and let $G = \mathbb{Z}$, denote $f^!(\mathbb{Z})$ by $\mathcal{D}^X_\bullet$, called the dualizing complex, then there is a duality: 

$$R\text{Hom}(R\Gamma_c(X, \mathcal{F}^*), \mathbb{Z}) \cong R\text{Hom}(\mathcal{F}^*, \mathcal{D}^X_\bullet).$$

for $\mathcal{F}^* \in D^+(\text{Sh}(X))$. 
Prop. (5.8.6.30). When $X$ is a $n$ dimensional topological manifold with boundary, then $D^n_X = \omega_X[n]$, where the sheaf $\omega_X$ is defined by
$$\Gamma(U, \omega_X) = \text{Hom}_{\text{Ab}}(H^n_c(U, \mathbb{Z}), \mathbb{Z}).$$

Cf.[Gelfand P234]. If we replace $\mathbb{Z}$ by a field $k$, then $w_X$ is the sheaf of $k$-orientations of $\text{int}(X)$, thus the constant sheaf when $X$ is oriented or $\text{char} k = 2$.

In particular, place $k$ in dimension $i$ then we get an isomorphism
$$\text{Hom}_k(H^i_c(X, \mathcal{F}), k) = \text{Ext}^{n-i}(\mathcal{F}, \omega_X)$$
(because $k$ is a field thus injective). Gelfand even gives an interpretation of this pair in [Gelfand P236].

And if $\mathcal{F} = \omega_X$ and $X$ oriented or $\text{char} k = 2$, we have $\text{Ext}^{n-i}(k_X, k_X[n]) = H^{n-i}(X, k_X)$ using the adjointness of constant sheaf, so we get the Poincare duality:
$$H^i_c(X, k_X)^\vee \cong H^{n-i}(X, k_X).$$

Prop. (5.8.6.31). Compact cohomology commute with colimits, Cf.[Cohomology of Sheaves Iversen P173].

7 Discriminant and Different

Trace Elements

Def. (5.8.7.1) [Traces]. Let $f : X \to Y$ be a finite locally free morphism, the trace of $f$ is defined to be
$$\text{tr}_f : f_* \mathcal{O}_X \to \mathcal{O}_Y.$$

Then $\text{tr}_f \circ f^\# = [\text{deg}(f)] : \mathcal{O}_Y \to \mathcal{O}_Y$. Let the trace pairing be
$$Q_f : f_* \mathcal{O}_X \otimes f_* \mathcal{O}_X \to \mathcal{O}_Y : (s, t) \mapsto \text{tr}_f(st)$$
which is equivalent to a map $Q_f : f_* \mathcal{O}_X \to f_* \mathcal{O}_X^\vee$, so the determinant of which is
$$\det(Q_f) : \wedge(f_* \mathcal{O}_X) \to \wedge(f_* \mathcal{O}_X)^{-1},$$
a section of the line bundle $\wedge(f_* \mathcal{O}_X)^{-2}$. Then the discriminant of $f$ is defined to be the closed subscheme $D_f$ of $Y$ cut out by this section $\det(Q_f)$.

Def. (5.8.7.2) [Trace Element of Rings]. Let $A \to B$ be a flat quasi-finite map of Noetherian rings, $[\omega_B/A]$ the dualizing module (4.6.8.4), then there exists a unique element $\tau_{A/B} \in \omega_B/A$ s.t. for any Noetherian $A$-algebra $A_1$ s.t. $B \otimes_A A_1 = C \times D$ with $C$ finite over $A_1$, the image of $\tau_{B/A}$ in $[\omega_{C/A_1}]$ is $\text{tr}_{C/A}$, called the trace element.

Def. (5.8.7.3) [Trace Element of Morphisms]. Let $f : X \to Y$ be a flat quasi-finite morphism of locally Noetherian schemes, then denote $\tau_{X/Y} \in \Gamma(X, [\omega_{X/Y}])$ the trace element of $f$ affine locally given by the trace element $\tau_{B/A}(5.8.7.2)$.

Prop. (5.8.7.4) [Discriminant and ÉtaleLocus]. If $f : X \to Y$ is finite locally free, then $f$ is étale iff $D_f = \emptyset$.

Proof: $f$ is flat, so it suffices to check fiberwise. Then this follows from (4.4.7.21). □
**Differents**

**Def.(5.8.7.5) [Kähler Different].** Let \( f : X \to Y \) be a morphism of schemes locally of f.t., the **Kähler different** of \( f \) is the 0-th fitting ideal \( \text{Fit}_0(\Omega_{X/Y}) \in \mathcal{O}_{\text{Coh}}(X) \).

**Prop.(5.8.7.6).** Let \( f : X \to Y \) be a morphism of schemes locally of f.t., then the closed subscheme cut out by the Kähler different is stable under base change.

**Proof:** Cf.[Sta]0BVX.

**Prop.(5.8.7.7).** If \( X = \text{Spec } A[X_1,\ldots,X_n]/(f_1,\ldots,f_m) \), then the Kähler different of \( X \to \text{Spec } A \) is just the ideal generated by the Jacobians \( \det(\frac{\partial f_i(j)}{\partial X_j})_{0 \leq j \leq n} \).

**Proof:** Because \( \Omega_{X/A} \) has a presentation

\[
0 \to \bigoplus_{0 \leq i \leq m} f_i \overset{d}{\to} \bigoplus_{0 \leq j \leq n} dX_j \to \Omega_{X/A} \to 0.
\]

**Prop.(5.8.7.8) [Kähler Different and Unramified Locus].** Let \( f : X \to Y \) be a morphism of schemes locally of f.t., then the closed subscheme cut out by the Kähler different contains exactly the points that \( f \) is not unramified.

**Proof:** Cf.[Sta]0C3J.

**Def.(5.8.7.9)[Differents].** Let \( f : X \to Y \) be a flat quasi-finite morphism between locally Noetherian schemes, define the **different** of \( f \) to be the annihilator of \( [\omega_{X/Y}]/\tau_{X/Y} \), which is a coherent ideal \( \mathcal{D}_f \subset \mathcal{O}_X \).

**Prop.(5.8.7.10)[Differents and Étale(Unramified) Locus].** Let \( f : X \to Y \) be a flat quasi-finite morphism between locally Noetherian schemes, then the closed subscheme of \( X \) cut out by the different \( \mathcal{D}_f \) contains exactly the set of points that \( f \) is not étale(unramified).

**Proof:** Cf.[Sta]0BW9.

**Prop.(5.8.7.11).** If \( f : X \to Y \) is a quasi-finite syntomic morphism between locally Noetherian schemes, then the different \( \mathcal{D}_f \) equals the Kähler different of \( f \).

**Proof:** Cf.[Sta]0BWG.

**Prop.(5.8.7.12) [Differents for Smooth Schemes].** Let \( S \) be a locally Noetherian scheme and \( X,Y \) be smooth scheme of relative dimension \( n \) over \( S \), and \( f : X \to Y \) is a quasi-finite morphism, then \( f \) is syntomic, and the closed subscheme \( R \) cut out by the different \( \mathcal{D}_f \) of \( f \) is the locally principal vanishing locus of

\[
\wedge^n(df^*) \in \text{Hom}(f^*\Omega^n_{Y/S},\Omega^n_{X/S}) = \Gamma(Y, (f^*\Omega^n_{Y/S})^{-1} \otimes \Omega^n_{X/S}).
\]

And if \( f \) is étale at the associated points of \( X \), then \( R \) is an effective Cartier divisor, and

\[
f^*\Omega^n_{Y/S} \otimes \mathcal{O}(R) \cong \Omega^n_{X/S}.
\]

**Proof:** Cf.[Sta]0BWJ.
8 Fourier-Mukai Transform

Cf. [Sta] Chap 56.

9 Deformation Theory

Basic references are [Sta] Chap 36.

Def. (5.8.9.1) [Thickenings]. We call $X'$ a thickening of a $X$ iff $X$ is a closed subscheme of $X'$ that their underlying topological space are the same. Morphisms of thickenings are defined routinely.

A thickening is said to have order $n$ iff the ideal sheaf $\mathcal{I}$ satisfies $\mathcal{I}^{n+1} = 0$.

Base change and composition of a (order $n$)thickening is also a (order $n$)thickening, because closed immersion and surjective do.

Prop. (5.8.9.2). Any thickening of an affine scheme is also affine.

Proof: This is a special case of (5.4.4.36).

Prop. (5.8.9.3) [Picard Group of Thickenings]. Let $X \subset X'$ be a first order thickening with ideal sheaf $\mathcal{I}$, then there is a canonical long exact sequence of Abelian groups:

\[
0 \to H^0(X, \mathcal{I}) \to H^0(X', \mathcal{O}_{X'}) \to H^0(X, \mathcal{O}_X^*) \to H^1(X, \mathcal{I}) \to \text{Pic}(X') \to \text{Pic}(X) \to H^2(X, \mathcal{I}) \to \ldots
\]

Proof: This follows from taking cohomology of the exact sequence $0 \to \mathcal{I} \to \mathcal{O}_{X'} \to i_*\mathcal{O}_X \to 0$, where $\mathcal{I} \to \mathcal{O}_{X'}$ is given by $a \mapsto 1 + a$. \hfill $\square$

Prop. (5.8.9.4). Let $X \subset X'$ be a thickening with ideal sheaf $\mathcal{I}$ and $n$ is invertible in $\mathcal{O}_X$, then $\text{Pic}(X)[n] \to \text{Pic}(X')[n]$ is an isomorphism.

Proof: By taking cohomology of the exact sequence $0 \to (1 + \mathcal{I})^* \to \mathcal{O}_{X'} \to i_*\mathcal{O}_X \to 0$, it suffices to show that $n : (1 + \mathcal{I})^* \to (1 + \mathcal{I})^*$ is an isomorphism, which is true by (4.1.1.17). \hfill $\square$

Def. (5.8.9.5) [Infinitesimal Neighbourhood]. Let $Z \subset U \subset X$ be a closed immersion of the open subscheme $U$ that $Z$ corresponds to the ideal $\mathcal{I}$ on $U$, then a $n$-th infinitesimal neighbourhood of $Z$ in $X$ is the closed subscheme of $U$ corresponding to $\mathcal{I}^n$.

The infinitesimal neighbourhood of $Z$ in $X$ has the universal property s.t. for any infinitesimal thickening $T \subset T'$ of order $n$ over $X$ and a map $T \to Z \in \text{Sch}_X$ extension to a morphism of infinitesimal thickenings ($T \subset T'$) \to ($Z \to Z'$) over $X$.

Def. (5.8.9.6) [Infinitesimal Extension]. Let $X$ be a scheme algebraic over a field $k$ and $\mathcal{F}$ is a coherent sheaf on $X$, then a infinitesimal extension of $X$ by the sheaf $\mathcal{F}$ is a scheme $X'$ over $k$ that has a sheaf of ideals $\mathcal{I}$ that $\mathcal{I}^2 = 0$ and $(X', \mathcal{O}_{X'}/\mathcal{I}) \cong (X, \mathcal{O}_X)$, and moreover, $\mathcal{I}$ with the $\mathcal{O}_X$-structure is isomorphic to $\mathcal{F}$.

There is a trivial extension, that is $(X', \mathcal{O}_{X'}) \cong (X, \mathcal{O}_X \oplus \mathcal{F})$, where the multiplication is $(a, f)(a', f') = (aa', af' + a'f)$.

Def. (5.8.9.7) [Deformation]. Let $X$ be a scheme algebraic over a field $k$, an infinitesimal deformation of $X$ is a scheme $X'$ flat over $D = k[t]/(t^2)$ that $X' \otimes_D k = X$. An infinitesimal deformation is a first order thickening, by (5.8.9.1).

If $Y$ is a closed subscheme of $X$, then we define the infinitesimal deformation of $Y$ in $X$ to be a closed subscheme $Y' \subset X \otimes_D D$ which is flat over $D$ and $Y' \otimes_D k = Y$.

A scheme algebraic over a field $k$ is called rigid if it has no infinitesimal deformations.
Prop.(5.8.9.8) [Affine Case]. Any thickening of an affine scheme is affine. (Immediate from (5.4.4.36)).

Prop.(5.8.9.9). Let $X$ be a nonsingular variety over an alg.closed field $k$, infinitesimal deformation of $X$ is the same as an infinitesimal extension of $X$ by the sheaf $\mathcal{O}_X$. Thus we get the set of infinitesimal deformations of $X$ is parametrized by $H^1(X, T_X)$, by (5.8.9.11) below.

Proof: For an infinitesimal deformation, tensoring $\mathcal{O}_X'$ with the exact sequence $0 \to k \xrightarrow{\iota} D \to k \to 0$, we get (by flatness)

$0 \to \mathcal{O}_X \xrightarrow{\iota} \mathcal{O}_X' \to \mathcal{O}_X \to 0$,

and conversely, an extension is locally free (because it is f.g. so flat over $D$ is equivalent to free).

Prop.(5.8.9.10). If $X$ is an affine regular scheme algebraic over an alg.closed field $k$, then any extension by coherent sheaf is trivial.

Proof: For any infinitesimal extension, the morphism $X \to X'$ is a closed immersion and surjection, so $X'$ is also affine by (5.8.9.8), = Spec $A'$. Now the rest follows from??.

Cor.(5.8.9.11) [Infinitesimal Extension and Cohomology]. Let $X$ be a nonsingular variety over an alg.closed field $k$, then the set of infinitesimal extensions by a coherent sheaf $F$ is parametrized by $H^1(X, F \otimes T_X)$.

If $Y$ is a closed subscheme of $X$, then the set of infinitesimal deformation of $Y$ in $X$ is parametrized by $H^0(Y, N_{Y/X})$.

Proof: By the proposition, we know that an infinitesimal extension is locally isomorphic to $(U, \mathcal{O}_X(U) \otimes F(U))$, by a section $F(U) \to \mathcal{O}_X(U)$.

But there is a twist, because there can because different sections. But the different sections different at a $\text{Hom}_{\mathcal{O}_X(U)}(\Omega_{\mathcal{O}_X(U)/k}, F(U)) = (T \otimes F)(U)$. These forms a Čech cocycle for $F \otimes T_X$, and the converse is also true. Finally, use the fact that $X$ is separated so Čech and sheaf cohomology coincide.

For the subscheme, ?

Formal Properties

Def.(5.8.9.12) [Formal Properties]. Let $f : X \to S$ be a morphism of schemes, then $f$ is called a formally unramified/smooth/étale if for any first order thickening of affine schemes $T \to T'$ and a morphism $(T \to T') \to (X \to S)$, there exists at most one/exists one/exists exactly one lifting $T' \to X$.

Formally unramified/smooth/étale morphisms are stable under base change and compositions.

Prop.(5.8.9.13).  
- A morphism is (G-)unramified iff it is formally unramified and locally of f.t.(f.p.).
- A morphism is étaleiff it is formally étale and locally of f.p.
- A morphism is smooth it is formally smooth and locally of f.p.

Proof: [Sta]
5.9 Resolution of Singularities

References are [K-M85].

Def. (5.9.0.1) [Desingularizations]. Let $X \in \text{Sch}$ be reduced and locally Noetherian, then a desingularization of $X$ is a modification (5.4.5.10) $Z \to X$ s.t. $Z$ is regular. A strong desingularization is a desingularization $\pi : Z \to X$ that $\pi$ is an isomorphism over any regular point $x \in X$.

Thm. (5.9.0.2) [Hironaka]. Let $X$ be a reduced scheme locally of f.t. over an excellent, reduced, locally Noetherian scheme of characteristic 0 (i.e. $\text{char} \kappa(x) = 0$ for any $x \in X$), then $X$ admits a strong desingularization over $S$.

Thm. (5.9.0.3) [de Jong]. Let $R$ be a CDVR or a field, $X \in \text{Sch}_{\text{int}}^{\text{ft,sep}} / R$, then $X$ admits an alteration $Y \to X$ over $R$ s.t. $Y$ is integral.

5.10 Varieties

Basic references are [Sta] and [Har77].

The materials distinguishes here in the fact that most schemes considered have geo.reduced, geo.connected or geo.integral properties in nature.

1 Varieties

Classical varieties

Prop. (5.10.1.1) [Soberization Functor]. For a sep.closed field \( k \), the soberization functor \( t \) induce a fully faithful functor from classical varieties over \( k \) to quasi-projective integral schemes over \( k \). It maps projective varieties to projective integral schemes and preserves fiber products ?.

Proof: We assign the irreducible closed subsets space \( t(X) \) and show that this embeds \( X \) in \( t(X) \), and for an affine variety \( (V, \mathcal{O}_V) \), the regular function sheaf is isomorphic to the pullback sheaf on \( t(V) = \text{Spec}(A) \).

By definition \( t(X) \) is quasi-projective, which is separated, the set of geometric pts of any closed variety is dense so \( t(V) \) is homeomorphic to \( X \). And because they are both reduced, they are isomorphic. So it is essentially surjective.

It is fully faithful by (5.10.1.11).

Prop. (5.10.1.2). The soberization of a classical variety \( X \) is regular at a closed point iff the local defining functions has rank \( n - \dim X \).

Proof: Consider the space of closed point of \( X \), they correspond to classical points because \( k \) is alg.closed. Let \( a_p = (x_1 - a_1, \ldots, x_n - a_n) \) and \( b \) be the locally defining ideal. Then the differential defines an isomorphism of vector space \( a_p/a_p^2 \cong k^n \), and the local ring at \( p \) is \( m/m^2 \cong (a_p/b)/(a_p/b)^2 \cong a_p/(b + a_p^2) \). The rank of the defining functions is \( b + a_p^2/a_p^2 \). Counting dimension gives us the result. (Use (5.6.3.3) also).

Varieties

Def. (5.10.1.3) [Varieties]. A variety is a geo.integral separated scheme algebraic over a field \( k \). An prevariety is an integral separated scheme algebraic over a field \( k \). A complete variety is a variety that is also proper(i.e. universally closed). The category of varieties over \( k \) is denoted by \( \mathcal{V} \text{ar}_k \).

A classical variety is an abstract variety because quasi-projective is f.t. and separated (5.4.5.19).

A non-singular variety is a regular variety.

A curve over \( k \) is a variety of dimension 1.

If \( X \) is a (complete)variety over \( k \) and \( K/k \) is a field extension, then \( A_K \) is a (complete)variety over \( K \), by (5.4.3.17).

Remark (5.10.1.4). Notice the prevariety is the same as the variety defined in [Sta].

Cor. (5.10.1.5). Any variety is birational to an integral H-quasi-projective scheme. A complete variety is birational to an integral projective scheme by Chow’s lemma (5.4.5.23)(5.4.5.3).
**Prop. (5.10.1.6).** By valuation criterion, for a complete variety, every valuation of the function fields of $K/k$ dominate a unique point of $X$. So the points of $X$ correspond to valuations of $K$ containing $k$.

**Prop. (5.10.1.7) [Generically Smoothness].** A variety is generically smooth, by (5.6.4.21).

**Prop. (5.10.1.8) [Nagata].** By Nagata compactification (5.8.3.2), any variety can be embedded as an open subset of a complete variety.

**Proof:**

**Prop. (5.10.1.9) [Product of Varieties].** The product of two (complete) varieties over $k$ is also a (complete) variety.

**Proof:** It is geometrically integral by (5.4.3.17), it is separated because separatedness is stable under composition and base change (5.4.4.2). So does properness.

**Def. (5.10.1.10) [Arithmetic Points].** An arithmetic point of a scheme $X$ over a field $k$ is an element of $X(k_s)$. When $X$ is a variety, the arithmetic points of $X$ is dense in $X$, by (5.4.3.3).

An geometric point of a scheme $X$ is an element of $X(k)$.

**Prop. (5.10.1.11).** To verify two morphisms $f, g$ between two varieties $X$ and $Y$ are equal, it suffices to prove that they are equal on the set of arithmetic points of an open subscheme $U$ (5.10.1.10).

**Proof:** Because the equalizer is a closed subscheme of $X$ (5.2.7.18), and it contains all geometric pts of an open subset of $X$, so it must by $X$, as the geometric-points are dense in $U$ (5.10.1.10), and $X$ is reduced and irreducible.

**Prop. (5.10.1.12) [Global Sections].** Let $X$ be a proper scheme over a field $k$, then

- $A = H^0(X, \mathcal{O}_X)$ is a finite $k$-algebra hence is a finite product of Artinian local $k$-algebras, one for each connected component of $X$.
- If $X$ is reduced, then $A = \prod k_i$ is a finite product of finite field extensions of $k$.
- If $X$ is geo.reduced, then $k_i$ are all separable over $k$.
- If $X$ is geo.connected, then $A$ is geo.irreducible over $k$ (4.3.6.1).
- If $X$ is geo.integral (i.e. a complete variety), then $\Gamma(X, \mathcal{O}_X) = k$.

**Proof:**

1: $H^0(X, \mathcal{O}_X)$ is finite $k$-algebra by (5.7.4.11), thus it is Artinian (4.1.3.4). The connected components of $X$ clearly corresponds to idempotents of $A$, which corresponds to Artinian local $k$-algebras, as a local ring is connected.

2: This follows from (4.1.3.5).

3: $A \otimes_k \overline{k} = H^0(X_{\overline{k}}, \mathcal{O}_{X_{\overline{k}}})$ is also reduced by flat base change (5.7.5.1), so each $k'/k$ is geo.reduced (4.3.6.2), thus separable by (4.3.9.4).

4: By hypothesis $A \otimes_k \overline{k} = H^0(X_{\overline{k}}, \mathcal{O}_{X_{\overline{k}}})$ is an Artinian local ring, thus it has only one point, so irreducible, so it is geo.irreducible (4.3.6.3).

5: By item3, 4, $A = k'$ is a finite separable field extension of $k$ that $\text{Spec}(k' \otimes_k \overline{k})$ is irreducible, but $k' \otimes_k \overline{k}$ is a finite product of $\overline{k}$, thus $k' = k$. 

□
Prop.(5.10.1.13) [Check Properties on Geometric/Closed Points]. A nice property of varieties is that identity of two morphisms of products of varieties can be checked at the geometric pts(5.10.1.10), by(5.10.1.11) and(5.10.1.9).

Surjectiveness of a map between varieties can be checked on closed points, by(5.4.1.29).

Also surjective and injective of Qco sheaves need only be checked at closed pts by(5.5.1.38)(5.4.1.26).

Canonical Sheaves

Prop.(5.10.1.14)[Canonical Sheaves]. For a smooth variety $X$ over a field $k$ and $Y$ a local complete intersection of $X$ of codimension $r$, by(5.6.4.2) and(5.6.4.16) and(5.6.8.10), $\mathcal{K}_{X/k}$ and $I/I^2$ is locally free, so we can define the following locally free sheaves:

- The canonical sheaf $\mathcal{K}_{X/k} = \wedge^n \Omega_{X/k}$ on $X$.
- The tangent sheaf $\mathcal{T}_X = (\mathcal{K}_{X/k})^{-1}$ on $X$.
- The conormal sheaf $\mathcal{C}_{Y/X} = I/I^2$ on $Y$.
- The normal sheaf $\mathcal{N}_{Y/X} = \mathcal{C}_{Y/X}^{-1}$ on $Y$.

Prop.(5.10.1.15) [Kodaira-Spencer map]. There is another characterization of tangent vector fields. (Note: this should be a special case of Prop8.5.9 in [FGA]). Let $X$ be a variety over $k$ and $S = k[\varepsilon]$ the dual numbers. Then $H^0(X, \mathcal{T}_X) \cong \text{Aut}^{(1)}(X_S/S)$, where $\text{Aut}^{(1)}(X_S/S)$ means that the automorphisms of $X_S$ over $S$ that is identity on $X$ (inclusion to $X_S$ induced by $\text{Spec} k \subset \text{Spec} S$).

Proof: First the case $X = \text{Spec} A$ is affine, then because $H^0(X, \mathcal{T}_X) = \text{Hom}_k(\mathcal{K}_{A/k}, A) = \text{Der}(A, A)$, so this is equivalent to $\text{Der}(A, A) \cong \text{automorphisms of } A[\varepsilon]$ that is identity under pass to quotients to $A$. For this, a $d \in \text{Der}(A, A)$ is mapped to $a + b\varepsilon \mapsto a + b\varepsilon + d(a)\varepsilon$. This is checked to be a ring morphism, and any desired morphism are like these.

The above construction is natural and functorial in $A$, so it glue together to give the global case.

□

Prop.(5.10.1.16) [Smoothness and Conormal Sheaves]. Let $X$ be a smooth variety over a field $k$, then an irreducible closed subscheme $Y$ of codimension $r$ in $X$ is smooth iff $\mathcal{K}_{Y/k}$ is locally free and(5.5.5.13) is exact on the left.

In this case, $I$ is locally generated by $r$ elements and $\mathcal{C}_{Y/X}$ is a locally free sheaf of rank $r$ on $Y$ by(5.6.8.10).

Proof: Cf.[Hartshorne P178]. Should has something to do with(5.6.4.2),(5.6.4.16) and(5.6.4.15).

□

Prop.(5.10.1.17) [Adjunction Formulas]. For a smooth variety $X$ over a field $k$ and $Y$ a smooth subvariety of codimension $r$. There is an exact sequence

$$0 \to I/I^2 \to \mathcal{K}_{X/k} \otimes \mathcal{O}_Y \to \mathcal{K}_{Y/k} \to 0$$

by(5.5.5.14). Taking the highest exterior power(5.5.1.25), we get:

$$\mathcal{K}_Y = \mathcal{K}_X \otimes \wedge^r \mathcal{N}_{Y/X} = \mathcal{K}_X \otimes (\wedge I/I^2)^{-1}$$
In particular, if \( r = 1 \) then \( Y \) is a divisor \( D \) in \( X \), the canonical sheaf

\[
\mathcal{K}_Y \cong (\mathcal{K}_X \otimes \mathcal{L}(D))_Y, \quad \mathcal{K}_{\mathbb{P}_k^n/k} = \mathcal{O}(-n - 1)(5.5.5.7).
\]

because \( \mathcal{I}_Y \cong \mathcal{L}(-Y) \) in this case so \( \mathcal{I}_Y/\mathcal{I}_Y^2 = \mathcal{L}(-Y) \otimes \mathcal{O}_Y \).

Taking dual, we get:

\[
0 \to \mathcal{T}_Y \to \mathcal{T}_X \otimes \mathcal{O}_Y \to \mathcal{N}_{Y/X} \to 0
\]

Prop. (5.10.1.18)[Geometric Genus]. For a smooth proper variety over a field \( k \), the geometric genus \( p_g \) is defined as the rank of the global section of the invertible canonical sheaf \( \mathcal{K}_X = \Lambda^n\mathcal{K}_{X/k} \).

It is a birational invariance. With the same methods, we can prove the rank of global sections of any other functorially defined bundles of \( \mathcal{K}_X \) is birational invariance, e.g. Hodge numbers.

**Proof:** For any rational map \( U \to Y \), there is a subset \( V \subset U \) and a local isomorphism \( V \to f(V) \), that will define an isomorphism of global sections. Because a nonzero section of an invertible sheaf cannot vanish on a dense open set \( f(V) \), the morphism of global sections is injective into \( \Gamma(U, \mathcal{O}_U) \).

Now we find a \( U \) that \( \text{codim}(X - U) > 1 \), then we can use(4.3.5.11) to get \( \Gamma(U) = \Gamma(X) \), then \( p_g(X) \geq p_g(X') \), and the converse is also true. For this, we use valuation criterion of properness, then for any codimension 1 point, the stalk is a DVR, thus we find a Spec\( \mathcal{O}_p \to X' \), this extends to a nbhd of \( p \) because \( X' \) is of f.t.

\[
\mathcal{K}_{\mathbb{P}_k^n} \cong \mathcal{O}(-n - 1), \quad \text{so it has no global section by(5.7.2.1),} \quad p_g(\mathbb{P}_k^n) = 0.
\]

Hence every rational variety over a field \( k \), i.e. one that is birational to \( \mathbb{P}_k^n \), has geometric genus 0.

**Complete Varieties**

Lemma (5.10.1.20)[Rigidity Lemma]. Let \( X, Y \) be varieties over a field \( k \) and \( f : X \times Y \to Z \) a morphism of schemes over \( k \) s.t. \( Z \) is separated. If \( X \) is complete with a rational point \( p \) and \( y \) is a rational point of \( Y \) s.t. \( f(\cdot, y) : X \to Z \) is constant, then \( f \) factors through the projection \( \text{pr}_Y : X \times Y \to Y \).

**Proof:** The equalizer is a closed subscheme of \( X \times Y \) as \( Z \) is separated(5.4.4.89), and \( X \times Y \) is a variety(5.10.1.9), thus we can check on closed points. Let \( g(y) = f(p, y) : Y \to Z \), then we want to show \( f = g \circ \text{pr}_Y \).

Let \( U \) be affine open in \( Z \), then because \( X \) is universally closed, \( \text{pr}_Y \) is closed, so \( V = \text{pr}_Y(f^{-1}(Z \setminus U)) \) is closed in \( Y \). But if \( y \notin V(\mathbb{F}) \), then \( f(X, y) \subset U \), and \( X \) is complete and connected, so \( f(\cdot, y) \) is constant(5.4.5.4), and \( f(x, y) = f(p, y) \). Thus \( f = g \circ \text{pr}_Y \) on a non-empty open subset of \( X \times Y \), which is a variety, so this is true on all of \( X \times Y \) by(5.10.1.11).

Prop. (5.10.1.21)[See-Saw Principle]. Let \( X \) be a complete variety over a field \( k \) and \( Y \) a \( k \)-scheme, then for any line bundle \( \mathcal{L} \) on \( X \times Y \), there is a closed subscheme \( Y_1 \subset Y \) s.t. for any morphism \( f : S \to Y \), \( (1 \times f)^*\mathcal{L} \) is trivial on \( X \times S \) iff \( f \) factors through \( Y_1 \).

**Proof:** This \( \mathcal{L} \) corresponds to a morphism \( Y \to \text{Pic}_X/k \), and clearly \( Y_1 \) is the fiber of \( Y \) over \( e \in \text{Pic}_X/k \).

Cor. (5.10.1.22). Let \( X \) be a complete variety over a field \( k \) and \( Y \) a reduced locally algebraic \( k \)-scheme, if \( \mathcal{L}, \mathcal{M} \) are two line bundles on \( X \times Y \) s.t. \( \mathcal{L}_y \cong \mathcal{M}_y \) for all closed points \( y \in Y \), and for some \( x \in X(k) \), \( \mathcal{L}_x \cong \mathcal{M}_x \), then \( \mathcal{L} \cong \mathcal{M} \).
Prop. (5.10.1.23) [Theorem of the Cube]. If $X, Y$ are complete varieties over a field $k$, and $Z$ is a connected, locally Noetherian $k$-scheme, if $x, y$ are rational points of $X, Y$ resp. and $z \in Z$. Supposed $\mathcal{L} \in \text{Pic}(X \times Y \times Z)$ that is trivial on $x \times Y \times z, X \times y \times Z, X \times Y \times z$, then $\mathcal{L}$ is trivial.

Proof: Let $Z'$ be the maximal closed subscheme of $Z$ given by (5.10.1.21). We show that $Z'$ is open, thus it is all of $Z$. If $\zeta \in Z'$, let $I \subset \mathcal{O}_{Z,\zeta}$ be the ideal defining $Z'$, we show $I = (0)$, which is equivalent to $Z'$ containing a nbhd of $\zeta$ (locally Noetherian used). If not, then because $\cap \mathfrak{m}^n = 0$ by Krull’s theorem (locally Noetherian used), there is an $n \geq 1$ that $I \subset \mathfrak{m}^n, I \not\subset \mathfrak{m}^{n+1}$. Let $a_1 = (I, \mathfrak{m}^{n+1})$, and $\mathfrak{m}^{n+1} \subset a_2 \subset a_1$ that $\dim_{k(\zeta)}(a_1/a_2) = 1$ (so $a_1 = a_2 + k(\zeta)a$ for some $a \in a_2$), and let $Z_i \subset \text{Spec} \mathcal{O}_{Z,\zeta}$ be the closed subscheme defined by $a_i$. Let $\mathcal{L}_i$ be the restriction of $L$ on $X \times Y \times Z_2$. If we show that $\mathcal{L}_2$ is trivial, then $Z_2$ is contained in $Z'$, which is contradiction because $I \not\subset a_2$.

For this, notice that $\mathcal{L}_1$ is trivial, and to show that $\mathcal{L}_2$ is trivial, it suffices to lift a non-vanishing global section $s$ of $\mathcal{L}_1$ to $\mathcal{L}_2$, because $Z_1, Z_2$ has the same underlying set.

For this, notice there is an exact sequence $0 \to k(\zeta) \xrightarrow{\Delta} \mathcal{O}_Z \to \mathcal{O}_{Z_2} \to 0$, where $k(\zeta)$ is the skyscraper sheaf at $\zeta$. So the obstruction of the lifting is an element $\xi \in H^1((X \times Y)_{k(\zeta)}, \mathcal{O}_{(X \times Y)_{k(\zeta)}})$. But now the conditions show that $\xi$ is zero under the pullback along $x \times Y \hookrightarrow X \times Y$ and $X \times y \hookrightarrow X \times Y$. So by Kunneth formula (5.7.1.9) and (5.10.1.12), $\xi$ vanishes.

2 Projective Varieties

Example (5.10.2.1) [Non-Projective Smooth Proper Varieties]. There are proper smooth complex varieties that are not projective. Examples are given in [Har77]?.

Prop. (5.10.2.2) [Affine Dimension Theorem]. Suppose $X, Y$ are subschemes of $\mathbb{A}^n_k$ of codimensions $d$ and $e$ resp., and $d + e \leq n$, then every non-empty irreducible component of $X \cap Y$ has dimension $\geq n - d - e$.

Proof: If $Y$ is an intersection of $e$ hypersurfaces, then this follows from Krull’s height theorem (4.2.4.18). In general, notice the diagonal map $\Delta : \mathbb{A}^n_k \to \mathbb{A}^n_k \times \mathbb{A}^n_k$ is an isomorphism onto the diagonal $T$ defined by $\{X_i = Y_i\}_{i=1,\ldots,n}$, thus it is a complete intersection in $\mathbb{A}^n_k \to \mathbb{A}^n_k \times \mathbb{A}^n_k$, and $\Delta$ induces an isomorphism $X \cap Y \cong X \times Y \cap T$, so we are done.

Cor. (5.10.2.3) [Projective Dimension Theorem]. Suppose $X, Y$ are subvarieties of $\mathbb{P}^n_k$ of codimensions $d$ and $e$ resp., and $d + e \leq n$, then $X$ and $Y$ intersect.

Proof: Take the affine cone, then item2 shows any irreducible component of $X \cap Y$ containing the origin has dimension $\geq 1$, which means $X \cap Y \neq \emptyset$.

Prop. (5.10.2.4) [Transversal Intersection]. Show that if $X$ is a closed subscheme of $\mathbb{P}^n_k$ of dimension $r$, then there is an intersection of $r + 1$ non-empty hypersurfaces missing $X$. And if $k$ is infinite, these hypersurfaces can be chosen to be hyperplanes.

If $k$ is infinite, there is an intersection of $r$ non-empty hypersurfaces intersecting $X$ at f.m. points.

Proof: Let $\eta_1, \ldots, \eta_n$ be the generic points of $X$, we want to find a hypersurface $F$ that doesn’t contain any of these generic points. We use induction on $n$. If $n = 1$, then there is clearly a hyperplane missing $\eta_1$. If we find a hypersurface missing $\eta_1, \ldots, \eta_{n-1}$, if it also misses $\eta_n$, we are done, if it contains $\eta_n$, we can change $\eta_n$ to $\eta_i$ and consider again. If we find polynomials...
Prop. (5.10.4.3). Let \( \varphi : X \to X' \) be a birational map of \( K \)-varieties with \( X \) smooth. If the base change \( \varphi_K \) extends to a morphism \( X_K \to X'_K \), then \( \varphi \) extends to a morphism \( X \to X' \).

Proof: Let \( U \) be an open dense subset that \( \varphi \) is defined. For a point \( x \), let \( x' = \varphi_K(x) \), then \( x' \) is in the closure of \( \varphi(U) \). By (5.4.6.2), it suffices to construct a morphism \( \mathcal{O}_{X',x'} \to \mathcal{O}_{X,x} \), i.e., to prove for any rational function \( f \) regular at \( x' \), \( \varphi \circ f \) is regular at \( x \). The argument is the same as that of (5.4.5.14).

For any such \( f \), \( f_K \circ \varphi_K \) is regular at \( x \), thus no pole of \( \text{div}(f_K \circ \varphi_K) \) passes through \( x \). For the rest, Cf. [Diophantine Geometry, P576].

Prop. (5.10.4.4)[Generic Separable Degree]. Let \( \varphi : X \to X' \) be a dominant morphism of varieties over a field \( k \) of the same dimension, then there exists an open dense subscheme \( U' \) of \( X' \) s.t. \( \varphi^{-1}(U') \to U' \) is finite and the fibers all have cardinality \( \deg_s(\varphi) \).

Proof: By (5.10.3.2), we can decompose \( \varphi \) and assume it is either separable or purely inseparable, and also primitive. If it is separable, let it be generated by \( t \). After shrinking (and cutting closure of images), we may assume the coefficients of \( t \) are regular functions, and \( \Gamma(X) = \Gamma(X')[t]/(q(t)) \). As \( q \) is separable, there exists \( a, b \in K(X') \) s.t. \( aq + bq' = 1 \). We may shrink \( X' \) and assume \( a, b \in \Gamma(X') \), so \( q \) is also separable over any fiber of \( X \), which means the fibers all have cardinality \( \deg_s(\varphi) \).

If it is purely inseparable, let \( q(t) = t^q - h \) be the minimal polynomial of \( t \) over \( K(X') \), \( h \in K(X') \). Then after shrinking, we may assume \( h \in \Gamma(X') \), thus \( q(t) \) is purely inseparable over any fiber of \( X \), which means  

4 Others

Prop. (5.10.4.1). Varieties are triangulable.

Proof: Cf. [Triangulation of Algebraic Sets, Hironaka].
Fano Varieties

Def. (5.10.4.2) [Fano Varieties]. A Fano variety is a complete smooth variety $X$ over a field $K$ s.t. $\mathcal{K}_X$ is ample.

Prop. (5.10.4.3). a smooth complete intersection of hypersurfaces in $\mathbb{P}^n_K$ is Fano if and only if the sum of their degrees is at most $n$.

Prop. (5.10.4.4) [Kollár-Miyaoka-Mori]. Fano varieties over an alg.closed field are rationally chain connected.

Proof: Cf. [Rational connectedness and boundedness of Fano manifolds, Kollár]. □

Rationally Connected Varieties

Def. (5.10.4.5) [Rationally Connected Varieties]. A variety $X$ over $K$ is called rationally connected if any two points of $X(\overline{K})$ can be connected by a rational curve (5.11.1.1) over $\overline{K}$.

5 Relative Varieties

Def. (5.10.5.1) [Varieties over Schemes]. Let $S \in \text{Sch}$, a (proper/smooth) variety over $S$ is a (proper/smooth) flat morphism $f : X \to S$ s.t. all the geometric fibers of $f$ are geo.integral over the resp. residue field $k(s)$. It can be regarded as a family of (proper/smooth)varieties parametrized by $S$.

Being a (proper/smooth) variety is stable under base change.

Prop. (5.10.5.2) [Global Sections]. Let $S \in \text{Sch}$ be locally Noetherian and $X$ a proper variety over $S$, then $\mathcal{O}_S \to f_*\mathcal{O}_X$ is an isomorphism.

Proof: For any closed point $s \in S$, $k(s) \to H^0(X_s, \mathcal{O}_{X_s})$ is an isomorphism by (5.10.1.12), and this isomorphism factors through $k(s) \to f_*(\mathcal{O}_X) \otimes k(s) \to H^0(X_s, \mathcal{O}_{X_s})$. So $f_*(\mathcal{O}_X) \otimes k(s) \to H^0(X_s, \mathcal{O}_{X_s})$ is surjective, thus it is an isomorphism by item 4 → 3 of (7.7.3.16). Thus the first map is also an isomorphism.

Now $\mathcal{O}_S \to f_*(\mathcal{O}_X)$ is a surjection at $s$ by Nakayama. Let $\mathcal{Q}$ be the coherent sheaf on $S$ associated to $\mathcal{F}$, then by (7.7.3.16), it is free at $s$, and $\mathcal{Q}_s = H^0(X_s, \mathcal{O}_{X_s})$ is of rank 1, but also $\mathcal{Q}^\vee \cong f_*(\mathcal{O}_X)$, so $\mathcal{O}_S \to f_*(\mathcal{O}_X)$ is in fact a surjection at $s$. Now $s$ is arbitrary, so $\mathcal{O}_S \to f_*(\mathcal{O}_X)$ is an isomorphism. □

Prop. (5.10.5.3). Let $(R, K, k)$ be a DVR and $X$ is a smooth $R$-scheme s.t. $X_K$ is geo.integral and $X_k$ is proper, then $X$ is a proper smooth variety over $R$.

Proof: Cf. [Good Reduction of Abelian Varieties, P495] □
5.11 Curves

Main references are [黎曼曲面, 伍鸿熙], [Vak17]Chap19, [G-H78], [Har77]Chap4 and [Sta]Chap53.

In this section, properties to morphisms of relative dimension \( \leq 1 \) are studied.

Notations (5.11.0.1).
- Use notations defined in Cohomology of Schemes.
- Use notations defined in Varieties.

1 Basics

Def. (5.11.1.1) [Rational Curve]. A rational curve over a field \( k \) is a curve that is birational to \( \mathbb{P}^1_k \).

Lemma (5.11.1.2). If \( X \) is an integral separated scheme and \( U \subset X \) is an non-empty affine open that \( X \setminus U \) is a finite set of points with \( O_{X,x} \) Noetherian of dimension 1, then there exists a base-point free invertible sheaf \( \mathcal{L} \in \text{Pic}(X) \) and a section \( s \) s.t. \( U = X_s \).

Proof: Cf. [Sta]09NB. \( \square \)

Prop. (5.11.1.3). A Noetherian separated scheme of dimension \( \leq 1 \) has an ample invertible sheaf.

Proof: First reduce to the case when \( X_{\text{red}} \), because (5.11.2.19) shows any invertible sheaf on \( X_{\text{red}} \) is a pullback of a sheaf of \( X \) and (5.5.4.15) shows this sheaf is ample.

Second we reduce to the case \( X \) is integral. Let \( X_i \) are the integral irreducible components of \( Z \), Cf. [Sta]09NX?

Finally, for \( X \) integral, the assertion follows from (5.11.1.2) and (5.5.4.10). \( \square \)

Cor. (5.11.1.4) [Complete Precurves are Projective]. A separated algebraic scheme \( X \) of dimension 1 over a field \( k \) is \( H \)-(quasi)projective, by (5.11.1.3) and (5.5.4.22). If \( X \) is proper, then it is projective.

Prop. (5.11.1.5) [Completion of Curves]. For a separated algebraic \( k \)-scheme \( X \) of dimension \( \leq 1 \), there is an open immersion \( j : X \to \overline{X} \) that

- \( \overline{X} \) is \( H \)-projective over \( k \).
- \( j(X) \subset \overline{X} \) is dense and schematically dense open subscheme.
- \( \overline{X} \setminus X \) consists of f.m. closed points \( \{x_i\} \) of \( \overline{X} \), called the completion curve of \( X \). And when \( X \) is reduced, the stalk at \( x_i \) are DVRs. In particular, It is non-singular if \( X \) is non-singular.

Proof: By (5.11.1.3), we can assume \( X \) is a locally closed subscheme of \( \mathbb{P}^n_k \). Let \( \overline{X} \) be the scheme theoretic image (5.4.4.62) of the inclusion, then 1,2 holds by (5.4.4.70). 3 holds because \( \overline{X} \setminus X \) is Noetherian of dimension 0.

For the last assertion, Cf. [Sta]0BXW. \( \square \)

Cor. (5.11.1.6). A morphism of prevarieties \( X \to Y \) with \( X \) a precurve (thus reduced) and \( Y \) proper over a field \( k \) factors through the completion \( \overline{X} \) of \( X \) by (5.4.5.14).

Prop. (5.11.1.7) [Affine or Projective]. A precurve over a field \( k \) is either affine (not proper) or \( H \)-projective (proper).
Cor. (5.11.1.8). Let $X$ be a separated scheme algebraic over a field $k$. If $\dim X \leq 1$ and no irreducible component of $X$ is proper of dimension 1, then $X$ is affine.

Proof: Let $X_i$ be f.m. irreducible components of $X$, then they are precurves in the induced reduced structure, so they are affine by (5.11.1.7). Now $\coprod X_i \to X$ is a finite surjective morphism, so $X$ is affine by (5.4.4.36).

Prop. (5.11.1.9). A map from a proper connected scheme to a precurve is either constant or surjective.

Proof: Because the closed subset of a precurve is either itself or f.m. closed points.

Prop. (5.11.1.10) [Constant or Finite]. Let $f : X \to Y$ be a morphism of schemes over a field $k$ that $Y$ is separated and $X$ is proper of dimension $\leq 1$. If the image of every irreducible component of $X$ is not a pt, then $f$ is finite. If $Y$ is a precurve, then it is moreover surjective.

Proof: Cf. [Sta] 0CCL.

Def. (5.11.1.11) [Separable Morphisms]. Let $f : X \to Y$ be a non-constant morphism of precurves, then $f$ is finite surjective by (5.11.1.10). so $\deg(f)$ is finite (5.4.4.55), and we can define separable/purely separable morphisms as in (5.4.4.55).

Non-Singular Curves

Def. (5.11.1.12) [Uniformizer]. Let $C$ be a precurve over a field $k$, then the local rings of $C$ at a non-singular closed point $p$ is a DVR by (10.3.3.4). Then an element $t \in K(C)$ with valuation 1 is called a uniformizer at $p$.

Prop. (5.11.1.13). Let $C$ be a precurve over a field $K$, and $t \in K(C)$ is a uniformizer at some non-singular point, then $K(C)$ is a finite separable extension of the subfield generated by $t$.

Proof: $K(C)$ is a finite extension of $K(t)$, because $\tr \deg(K(C)/K) = 1$ and $t$ is not algebraic over $K$ by valuation reasons. Then it suffices to show for any $x \in K(C)$, $x$ is separable over $K(t)$. Let $\Phi(X, T) = \sum a_{ij} T^i X^j$ be a minimal polynomial of $x$ over $K(T)$. It is separable iff for some $(j, p) = 1$ and some $i$, $a_{ij} \neq 0$. If it is not separable then we can write $\Phi(X, T) = \sum_{k=0}^{p-1} \varphi_k(X, T) T^k$. But each $\varphi_k(x, t)^{p^k}$ has distinct valuations, unless they are all zero, contradicting the fact $\Phi$ is a minimal polynomial.

Prop. (5.11.1.14) [Non-singular Complete Precurves and DVRs]. Let $C$ be a non-singular complete precurve, then all valuation rings of $K(C)$ containing $k$ are DVRs, and the set of closed points of $C$ correspond to the set of DVRs in $K(C)$ containing $k$, which is denoted by $\Sigma^0_{K(C)}$.

Proof: This is a consequence of the valuation criterion (5.4.5.13). Notice that the local rings of $C$ at closed points are all DVRs (10.3.3.4), thus they must equal to the valuation ring given.

Prop. (5.11.1.15) [Extension of Rational Maps]. Rational map from a non-singular precurve to a complete prevariety is the same as a morphism, by (5.4.5.15).

Cor. (5.11.1.16). Two birationally equivalent normal proper precurves over a field is isomorphic.

Thus if a normal precurve is birationally equivalent to another normal complete curve, then it is an open immersion, by (5.11.1.5).
Prop. (5.11.1.17) [Category of Non-singular Projective Precurves]. Let \( k \) be a field, the following categories are equivalent:

1. The opposite category of f.g. field extensions of \( k \) of trans.deg 1 with injective \( k \)-homomorphisms.

2. The category of precurves and dominant rational maps.

3. The category of normal complete precurves over \( k \) with non-constant morphisms.

4. The category of nonsingular projective precurves over \( k \) with non-constant morphisms.

Proof: 1 and 2 are equivalent by (5.10.3.2).

3 and 4 are equivalent by (5.11.1.7) and the fact normal and regular are the same (5.4.2.10).

For the rest, Cf. [Sta]0BY1. \( \square \)

Cor. (5.11.1.18) [Non-singular Projective Model]. Comparing this and (5.10.3.2), we see that every precurve over \( k \) is birational to a unique non-singular proper precurve over \( k \) with the same function field, which is called the non-singular projective model.

Prop. (5.11.1.19) [Flatness and Associated Points]. \( f : X \to Y \) with \( Y \) integral and regular of dimension 1. Then \( f \) is flat iff every associated prime of \( X \) is mapped to the generic point of \( Y \).

In particular when \( X \) is reduced, this is equivalent to every irreducible component of \( X \) dominants \( Y \), by (4.2.5.25).

Proof: If \( x \) is mapped to a closed pt of \( Y \), then \( O_{y,Y} \) is a DVR, let \( t \) be a uniformizer, then \( t \) is not a zero-divisor, and \( f^\sharp(t) \in \mathfrak{m}_x \) is also not a zero-divisor. So \( x \) is not an associated point.

Conversely, to show \( f \) is flat, if \( y \) is the generic point, then \( O_{y,Y} \) is a field, so it is flat. When \( y \) is a closed pt, \( O_{y,Y} \) is a DVR, so by (4.4.1.11), we need to show that it is torsion free. If it is not, then \( f^\sharp(t) \) must be a zero-divisor for a uniformizer \( t \) of \( O_{y,Y} \). But then it is contained in some associated prime \( p \) of \( O_{x,X} \) (4.2.5.17). Now \( p \) is mapped to \( y \), which is a contradiction. \( \square \)

Cor. (5.11.1.20) [Morphism to a Non-singular Curve is Flat]. If \( f : X \to Y \) is a dominant morphism from a prevariety to a non-singular curve over \( k \), then \( f \) is flat.

Cor. (5.11.1.21) [Flat Specializations along Curves]. Let \( Y \) be integral and regular of dimension 1 and \( P \) a closed pt. \( X \) is a closed subscheme in \( \mathbb{P}^n_Y - P \) that is flat over \( Y - P \), then there is a unique closed subscheme \( \overline{X} \) closed in \( \mathbb{P}^n_Y \) that is flat over \( Y \) and restrict to \( X \) on \( \mathbb{P}^n_Y - P \).

Proof: Choose the scheme-theoretic closure of \( X \) in \( \mathbb{P}^n_Y \). Cf. [Hartshorne P258]. \( \square \)

Cor. (5.11.1.22) [Finite Flatness]. Any non-constant morphism from a precurve to a nonsingular precurve is finite locally free, by (5.11.1.19) and (5.11.1.10).

Prop. (5.11.1.23). A projective non-degenerate non-singular curve of degree \( d \) in \( \mathbb{P}^n_k \) is isomorphic to the \( n \)-tuple embedding, and \( d = n \).

This has easy generalizations to surfaces and higher dimensions.

Proof: (5.5.3.16) shows \( O_X(1) \cong O(d) \) over \( \mathbb{P}^1_k \), and the restriction of global sections is injective. So the global section is an isomorphism, and it defines the embedding up to a linear automorphism. \( \square \)
Prop. (5.11.1.24) [Genera Equal]. For a complete smooth curve $X$ over a field $k$,

$$p_a(X) = p_g(X) = \dim_k H^1(X, \mathcal{O}_X)$$

by Serre duality (5.8.6.19) and (5.10.1.18) (5.7.3.6). So from now on we use genus to denote the arithmetic genus.

Cor. (5.11.1.25) [Topological Genus]. By GAGA, for a complex complete smooth curve, the genus also equals the topological genus.

Morphisms Between Non-singular Curves

Prop. (5.11.1.26) [Degree and Analytic Degree]. Let $f : C \to C'$ be a non-constant morphism between smooth complex curves, then the degree defined in (5.4.4.55) is the same as the degree as map of Riemann surfaces.

Proof: This is because the map is finite locally free (5.11.1.22), thus for an affine open subset $U = \text{Spec} A$ of $C'$, the $f^{-1}(U) = \text{Spec} B$ where $B \cong A^\otimes n$ as $A$-modules, where $n$ is the degree. Then clearly for most $x \in U$, $\sharp f^{-1}(x) = n$ (look at the minimal polynomial of a family of generators for $B$ over $A$).

Def. (5.11.1.27) [Ramification Degrees]. Let $f : X \to Y$ be a morphism of non-singular precurves over a field $k$, let $P \in X$ be a closed point and $f(P) = Q$. Because the local rings are DVRs, we define the ramification degree $e_P(f)$ where $f^\sharp(m_Q)\mathcal{O}_{X,P} = n_P^e(f)$.

$f$ is called weakly unramified at $P$ if $e_P(f) = 1$, and it is called unramified at $P$ if moreover $\kappa(P)/\kappa(f(P))$ is separable. $f$ is called tamely unramified at $P$ if $e_P(f) = 1$.

Notice that unramifiedness just means the morphism is unramified, by (5.6.5.8) and (5.11.1.22).

Prop. (5.11.1.28). Let $f : X \to Y$ be a non-constant morphism of non-singular precurves over a field $k$, then

- If $g : Y \to X$ be another morphism of non-singular precurves, then for any $P_1 \in X$, $e_{P_1}(g \circ f) = e_P(g \circ f)(g)$.
- for any closed point $Q \in C_2$, $\sum_{P \in f^{-1}(Q)} e_P(f)[k(P) : k(Q)] = \deg(f)$.
- If $k$ is alg.closed, then for a.e. closed point $Q \in C_2$, $\# f^{-1}(Q) = \deg_s(f)$.

Proof: 1: Trivial.
2: This follows from (5.11.1.44).
3: This follows from (5.10.3.4).

Prop. (5.11.1.29). If $f : X \to Y$ is a non-constant morphism of percurves over a field $k$ s.t. $X$ is smooth and $Y$ is non-singular, then $Y$ is also smooth, by (5.1.5.28).

Prop. (5.11.1.30). Let $X$ be a smooth curve over a field $k$, $x \in X$ and $\mathfrak{p} \in X_k$ is a point mapping to $x$, then the ramification degree of $\mathcal{O}_{X,x} \subset \mathcal{O}_{X_\mathfrak{p}}$ equals the inseparable degree of $k(x)/k$.

Proof: By (5.6.6.7), we can find a étalemap $X \to \mathbb{A}^1_k$, which has ramification degree 1 and separable, so we may assume $X = \mathbb{A}^1_k$. Then the assertion is clear.

Prop. (5.11.1.31) [Separable Morphisms]. Let $f : X \to Y$ be a morphism of smooth curves over $k$, then the following are equivalent:
1. $f$ is finite separable.
2. $df^* : f^*\Omega_{Y/k} \to \Omega_{X/k}$ is non-zero.
3. $\Omega_{X/Y}$ is supported on a proper closed subscheme of $X$.
4. There exists a non-empty open subset $U \subset X$ s.t. $f$ is unramified.
5. There exists a non-empty open subset $U \subset X$ s.t. $f$ is étale.

**Proof:** As $X, Y$ are smooth, $\Omega_{X/k}, \Omega_{Y/k}$ are invertible sheaves, and the exact sequence

$$f^*\Omega_{Y/k} \to \Omega_{X/k} \to \Omega_{X/Y} \to 0$$

shows 2, 3 are both equivalent to $\Omega_{X/Y} = 0$.

3, 4, 5 are equivalent as $f$ is automatically flat (5.11.1.20).

1, 5 are equivalent by (5.6.5.9). $\square$

**Prop. (5.11.1.32) [Riemann-Hurewitz for Separable Maps].** If $f : X \to Y$ is a non-constant separable map between two complete smooth curves over a field $k$, then

$$2g_X - 2 = \deg(f)(2g_Y - 2) + \sum_{x \in X} d_x[\kappa(x) : k],$$

where $d_x = \text{length}_{\mathcal{O}_{X,x}}(\Omega_{X/Y,x}) \geq 0$ satisfies $d_x \geq e_x(f) - 1$, and equality holds iff $f$ is tamely unramified at $P$.

**Proof:** By (5.8.7.12), in this case the vanishing locus $R$ of $df^*$ is an effective Cartier divisor, and $f^*K_{Y/k} \otimes \mathcal{O}(R) \cong K_{X/k}$, so by (5.11.2.10)(5.11.2.3)(5.11.2.7),

$$2g_X - 2 = \deg(K_{X/k}) = \deg(f^*K_{Y/k} \otimes \mathcal{O}(R)) = \deg(f) \deg(K_{Y/k}) + \deg(R) = \deg(f)(2g_Y - 2) + \deg(R).$$

For analysis of $d_x$, Cf. [Sta]0C1F. $\square$

**Cor. (5.11.1.33).** The only geo.integral unramified finite covering of $\mathbb{P}^1_k$ is itself.

**Thm. (5.11.1.34) [De Franchis].** Let $k \in \text{Field}$ and $C, C'$ are two complete smooth curves over $k$. Then if $g(C) \geq 2$, there are only f.m. non-constant maps $C' \to C$.

In particular, $\# \text{Aut}(C) < \infty$.

**Proof:** We prove for $k = \mathbb{C}$? Cf. [Mil08]P146.

Any automorphism of $C$ fixes its set of Weierstrass sets, which is finite, so we only need to consider the case that it fixes all Weierstrass points.

If $C$ is hyperelliptic, consider a hyperelliptic map, this covering has an involution of $C$, and this is just $C \mapsto C/\tau$. So modulo $\tau$, it suffices to show $\mathbb{P}^1$ has f.m. automorphisms fixing the branch points. But this is true, as $2g + 2 > 3$.

If $C$ is non-hyperelliptic, then there are more than $2g + 2$ Weierstrass points. But we can find a function $f$ on $C$ with $g + 1$ zeros and poles, by Riemann-Roch, then for an automorphism $\varphi$ of $C$, $f - \varphi^*f$ has no more than $2g + 2$ poles, so also has no more than $2g + 2$ zeros. But $\varphi$ fixes all Weierstrass points, so it has more than $2g + 2$ zeros, contradiction. $\square$

**Prop. (5.11.1.35) [Hurewitz’s Automorphism Theorem].** If $C$ is a complete smooth curve of genus $g \geq 2$ over a field of characteristic 0, then $\# \text{Aut}(C) \leq 84(g - 1)$. 
Proof: We may pass to the alg. closure. By (5.11.1.34), \( \# \text{Aut}(C) < \infty \). In fact, let \( G \) be a finite group acting on \( C \), let \( C' \) be the non-singular precurve corresponding to \( C' \), then by (2.2.7.4), \( C \to C' \) is a Galois cover with Galois group \( G \). Now by Dedekind extension theory, \( G \) acts transitively on the preimage of a given point. Suppose there are \( n \) branched points with ramification degrees \( r_i \), then by Riemann-Hurwitz (5.11.1.32) (notice in this case it is tamely unramified):

\[
(2g - 2) = |G|(2g(C') - 2 + \sum_{i=1}^{n} \frac{r_i - 1}{r_i}).
\]

Then a combinatorial argument shows the maximal possible \(|G|\) is obtained when \( g(C') = 0, n = 3 \) and \((r_1, r_2, r_3) = (2, 3, 7)\).

Remark (5.11.1.36). In the case char \( k \neq 0 \), there may be more automorphisms. For example, if \( p \in \mathbb{P} \setminus \{2\} \), the completion of the affine curve \( y^{p^n} = x + x^{p^n+1} \) has genus \( g = p^3(p^n - 1)/12 \) and \( \# \text{Aut}(C) = p^{3n}(p^{3n} + 1)(p^{2n} - 1) \), Cf.[H.Stichtenoth,UberdieAutomorphismengruppeeinesalgebraischenFunktionenkoerpersvonPrimzahlcharakteristik. I. Eine Abschatzung der Ordnung der Automorphismengruppe, Arch. Math. (Basel) 24 (1973), 527–544.].

Prop. (5.11.1.37) [Frobenius Map]. Let \( C \) be a smooth curve over a field \( k \) of characteristic \( p \), and \( C \xrightarrow{F_{X/k,r}} C^{(r)} \) be the Frobenius, where \( C^{(r)} = C \otimes_{k,Frob^e} k \), then \( F_{X/k,r} \) is purely inseparable, and \( \deg(F_{X/k,r}) = p^r \). And it is a topological homeomorphism by (4.1.7.26).

Proof: To show inseparability, we can base change to \( \overline{k} \), then the field map is \( f/g \mapsto f(X^{p^r})/g(X^{p^r}) \), which is just \( K(C_{\overline{k}})^{p^r} \), so purely inseparable of degree \( p^r \).

Prop. (5.11.1.38) [Inseparable Decomposition]. Let \( k \) be a field of characteristic \( p > 0 \). If \( C_1 \) is a smooth complete precurve, then any map of non-singular complete precurves \( f : C_1 \to C_2 \) over \( k \) factors as

\[
C_1 \xrightarrow{F_{X/k,r}} C_1^{(r)} \xrightarrow{\lambda} C_2
\]

where \( C_1^{(r)} = C_1 \otimes_{k,Frob^e} k \), and \( \lambda \) is separable.

Proof: By (5.11.1.17), it suffices to show any inseparable morphism is a Frobenius. It suffices to show that any subfield of \( K(X) \) of index \( p \) equals \( K(X^{(1)}) = kK(X)^p \). For this, Cf.[Sta]0CCY?

Cor. (5.11.1.39). If \( C \to C' \) is a non-constant separable map between complete smooth curves, then \( g(C) \geq g(C') \).

Proof: This follows from (5.11.1.38)(5.11.1.32) and the fact \( C_1^{(r)} \) is smooth and have the same genus as \( C_1 \) by flat base change.

Divisors on Curves

Def. (5.11.1.40) [Divisors on Curves]. If \( X \) is a locally algebraic integral scheme of dimension 1 over an alg. closed field, then a Weil divisor on \( X \) are just a locally finite formal sum of closed pts.

If \( X \) is integral algebraic over a field \( k \) of dimension 1, then the sum is in fact finite, we can define the degree of a Weil divisor \( D = \sum n_PP \) as \( \deg(D) = \sum n_P[k(P) : k] \).

Similarly, for a Cartier divisor \( D \) on \( X \), the degree of \( D \) is defined to be \( \dim_k \Gamma(D, \mathcal{O}_D) \).

By (6.1.5.1), a Cartier Divisor on \( X \) is equivalent to an effective Weil divisor, and the definition of degrees are compatible.
Cor. (5.11.1.41) [Non-singular Case]. As a nonsingular precurve $C$ is locally factorial, (5.5.3.15) shows in this case a line bundles on $C$ is equivalent to a Weil divisor on $C$.

Prop. (5.11.1.42) [Pullback of Divisor]. For a non-constant morphism $f$ between two non-singular curves over alg.closed field, e.g. dominant morphism between complete non-singular curves, $\deg f^*D = \deg f \cdot \deg D$. This is because $f$ is finite locally free (5.11.1.22), thus this follows from [Sta]02RH?

Prop. (5.11.1.43). An element $\xi \in k$ in the function fields of a projective non-singular curve over an alg.closed $k$ defines an inclusion $k(f) \subset K(X)$ thus a morphism from $X$ to $P^1_k$ (5.10.3.2), and $(f) = \varphi^*([0] - \{\infty\})$.

Prop. (5.11.1.44). Let $\pi : C \to C'$ be a non-constant separable morphism of precurves over a field $k$ that $C'$ is nonsingular, $p \in C'$ is a closed point, then $\pi$ is finite locally free by (5.11.1.22), and

- $\dim_k(\Gamma(\pi^{-1}(p))) = (\deg \pi)(\deg p)$.
- Let $\varpi$ be a uniformizer of the DVR $\mathcal{O}_{C',p}$, then $\deg \pi = \sum_{x \in \pi^{-1}(p)} [k(x) : k(p)] \text{ord}_{\mathcal{O}_{C,x}}(f^*\varpi)$.

Proof: Look affine locally, then these follow from the fundamental identity (4.2.7.18).
