Proof: Cf.[Sta]0A89. □

Thm. (5.8.6.13) [Grothendieck Duality]. Let S be a Noetherian scheme, then

- $f^!$ makes $D^+_{\mathcal{QC}oh}$ a pseudo-functor on $\mathcal{S}ch_S^{\mathrm{ft,sep}}$.
- If $f : X \to Y \in \mathcal{S}ch_S^{\mathrm{ft,sep}}$ is proper, then $f^!$ is the right adjoint of Rf_*, and there is a canonical isomorphism
$$Rf_* R\mathcal{H}om_{\mathcal{O}_X}(K, f^! M) \cong R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* K, M)$$
for any $K \in D^-_{\mathcal{C}oh}(X)$ and $M \in D^+_{\mathcal{QC}oh}(Y)$, by**??**
- If $X \in \mathcal{S}ch_S^{\mathrm{ft,sep}}$ has a dualizing complex ω_X, then $D_X = R\mathcal{H}om(-, \omega_X)$ defines an involution of $D_{\mathcal{C}oh}(X)$ switching $D^+_{\mathcal{C}oh}(X)$ and $D^-_{\mathcal{C}oh}(X)$ and fixing $D^b_{\mathcal{C}oh}(X)$.
- If Y has a dualizing complex ω_Y, then
  - $\omega_X = f^! \omega_Y$ is a dualizing complex for X,
  - for $M \in D^+_{\mathcal{C}oh}(Y)$, there is a canonical isomorphism $D_X(f^! M) \cong Lf^* D_Y(M)$.
  - If moreover f is proper, then $Rf_* R\mathcal{H}om_{\mathcal{O}_X}(K, \omega_X) = R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* K, \omega_Y)$ for $K \in D^-_{\mathcal{C}oh}(X)$.

Proof: Cf.[Sta]0AU3. □

Thm. (5.8.6.14) [Over a Dualizing Basis].

Proof: Cf.[Sta]0AUE. □

Dualizing Modules

Prop. (5.8.6.15) [Relative Dualizing Modules]. Let $f : X \to Y$ be a locally quasi-finite morphism of locally Noetherian schemes, then there exists a unique coherent $\mathcal{O}_Y$-module $\omega_{X/Y} \in \mathcal{C}oh(Y)$ that affine locally is given by the dualizing sheaf $\omega_{B/A}$(4.9.8.4).

Proof: Cf.[Sta]0BVG. □

Relative Dualizing Complex

Def. (5.8.6.16) [Relative Dualizing Complexes]. For a separable f.t. morphism of Noetherian schemes $f : X \to S$, the **relative dualizing complex** is defined to be $\omega_{X/S} = f^! \mathcal{O}_S$.

Prop. (5.8.6.17). Let Y be a qcqs scheme and $f : X \to Y$ be a proper flat morphism of f.p., then

- $\omega_{X/Y}$ is perfect over Y.
- $R^i f_* \omega_{X/Y} = 0$ for $i > 0$.
- $\mathcal{O}_X \to \mathcal{H}om_{\mathcal{O}_X}(\omega_{X/S}, \omega_{X/S})$ is an isomorphism.

Proof: As $f^\times$ commutes with base change(5.8.6.6), it suffices to assume that $Y = \operatorname{Spec} A$.

1: By(5.8.6.4)(5.3.4.23) and(5.7.5.5), for any perfect object $E \in D(X)$, there are canonical isomorphisms:

$$Rf_*(E \otimes^L \omega_{X/Y}) = Rf_* R\mathcal{H}om_{\mathcal{O}_X}(E^\vee, \omega_{X/Y}) = R\mathcal{H}om_{\mathcal{O}_Y}(Rf_* E^\vee, \mathcal{O}_Y) = (Rf_* E^\vee)^\vee,$$

which is perfect. So $\omega_{X/Y}$ is perfect over S by(5.8.5.12).

2: By(5.8.5.8),

$$\mathcal{H}om_Y(\mathcal{O}_Y[-i], Rf_*\omega_{X/Y}) = \mathrm{Hom}_Y(Rf_*Lf^*\mathcal{O}_Y[-i], \mathcal{O}_Y) = \mathrm{Hom}_Y((Rf_*\mathcal{O}_X)[-i], \mathcal{O}_Y).$$

By proper flat base change(5.7.5.5), $Rf_*\mathcal{O}_X$ is perfect in Y, so it can be represented by a finite complex of finite projective A-modules, so by(5.3.4.22), $R^if_*\omega_{X/Y} = 0$ for $i > 0$.

3: For any perfect object $E \in D(X)$, by(5.8.6.4)(5.3.4.23)(5.7.5.5)(5.3.4.23) and(5.3.1.9), there are canonical isomorphisms

$$\begin{aligned}\mathrm{Hom}_X(E, R\mathcal{H}om_{\mathcal{O}_X}(\omega_{X/Y}, \omega_{X/Y})) &= \mathrm{Hom}_Y(Rf_*(E \otimes^L \omega_{X/Y}), \mathcal{O}_Y)\\ &= \mathrm{Hom}_Y(Rf_*\mathcal{H}om(E^\vee, \omega_{X/Y}), \mathcal{O}_Y)\\ &= \mathrm{Hom}_Y(\mathcal{H}om(Rf_*E^\vee, \mathcal{O}_Y), \mathcal{O}_Y)\\ &= R\Gamma(Y, Rf_*E^\vee)\\ &= \mathrm{Hom}_X(E, \mathcal{O}_X)\end{aligned}$$

So by(5.8.5.30), perfect objects generate $D_{\mathfrak{QCoh}}(X)$, so $R\mathcal{H}om_{\mathcal{O}_X}(\omega_{X/Y}, \omega_{X/Y}) \cong \mathcal{O}_X$. □

Proper over Field case

Prop. (5.8.6.18) [Serre Duality(Proper over Fields case)]. Let X be a proper scheme over a field k of dimension d, then there exists a unique dualizing complex ω_X with the following properties:

- $H^i(\omega_X) \neq 0$ only for $i \in [-\dim(X), 0]$.
- $[\omega_X] = H^{-d}(\omega_X)$ is a coherent (S_2)-module whose support is the irreducible components of X of dimension d.
- $\dim \mathrm{Supp}(H^i(\omega_X)) \leq -i$.
- For $x \in X$ closed, $H^i(\omega_{X,x}) \oplus \ldots \oplus H^0(\omega_{X,x}) \neq 0$ iff $\mathrm{depth}(\mathcal{O}_{X,x}) \leq -i$.
- For $K \in D_{\mathfrak{QCoh}}(X)$, there is a functorial isomorphisms

  $$\mathrm{Ext}_X^{-i}(K, \omega_X) \cong \mathrm{Hom}_k(H^i(X, K), k)$$

  compatible with shifts and distinguished triangles, which characterizes ω_X uniquely.
- There are functorial isomorphisms $\mathrm{Hom}(\mathcal{F}, [\omega_X]) = \mathrm{Hom}_k(H^d(X, \mathcal{F}), k)$ for $\mathcal{F} \in \mathfrak{Coh}(X)$.
- If X is C.M., equidimensional, then $\omega_X = [\omega_X][d]$.
- If X is smooth over k, then $\omega_X = \mathcal{K}_{X/k}[d]$.

Proof: Cf.[Sta]0FVV, 0AWT.? □

Cor. (5.8.6.19) [Serre Duality(Smooth over Fields case)]. If $k \in \mathtt{Field}$, $X \in \mathcal{S}ch/k$ is a smooth proper scheme over k of dimension d, then for any locally free sheaf $\mathcal{F}$, there is a functorial isomorphism:

$$H^i(X, \mathcal{F}) \cong (H^{n-i}(X, \mathcal{F}^\vee \otimes \mathcal{K}_{X/k}))^\vee.$$

Cor. (5.8.6.20). For a smooth proper variety X over a field k of dimension n, $H^n(X, \mathcal{K}_X) = k$, by(5.10.1.12).

Cor. (5.8.6.21). For a smooth proper variety X over a field k of dimension n, $\Omega_{X/k}$ is locally free by(5.6.4.15), thus by(5.5.1.25), $\Omega^{n-p}_{X/k} \cong (\Omega^p_{X/k})^\vee \otimes \mathcal{K}_X$. So by(5.8.6.19):

$$H^q(X, \Omega^p_{X/k}) \cong (H^{n-q}(X, \Omega^{n-p}_{X/k}))^\vee.$$

Cor. (5.8.6.22). If X is a closed subscheme of $\mathbb{P}^n_k$ of codimension r, then X has a dualizing sheaf $[\omega_X] = \mathcal{E}xt^r_P(i_*\mathcal{O}_X, \mathcal{K}_{\mathbb{P}^n_k/k})$, and $\mathcal{E}xt^i(i_*\mathcal{O}_X, \mathcal{K}_{\mathbb{P}^n/k}) = 0$ for $i < r$

Proof: This follows from(5.8.6.18) and(5.8.6.13). □

Prop. (5.8.6.23) [Characterizing Cohen-Macauley Schemes]. Let X be projective of dimension n over a field k and $[\omega_X]$ be the dualizing sheaf, then for $\mathcal{F} \in \mathfrak{Coh}(X)$, there is a natural map

$$\mathrm{Ext}^i(\mathcal{F}, [\omega_X]) \to (H^{n-i}(X, \mathcal{F}))^\vee$$

And the following are equivalent:

- For any $\mathcal{F}$ locally free on X, $H^i(X, \mathcal{F}(-q)) = 0$ for $i < n$ and q large.
- $H^i(X, \mathcal{O}_X(-q)) = 0$ for $i < n$ and q large.
- This is an isomorphism of δ-functors.
- X is C.M. and equidimensional.

Proof: Notice the left side is an universal δ-functor in $\mathcal{F}$ by(5.8.5.35), so the map exist, and

$2 \to 3$: This implies that the right is also universal by(5.8.5.32).

$3 \to 1$: For $\mathcal{F}$ locally free, by(5.3.3.33),

$$H^i(X, \mathcal{F}(-q)) = (\mathrm{Ext}^{n-i}(\mathcal{F}(-q), \omega_X))^\vee = (H^{n-i}(X, \mathcal{F}^\vee \otimes \omega_X(q)))^\vee$$

which is 0 for q large.

$4 \to 1$: Embed X in $P = \mathbb{P}^N_k$, for $\mathcal{F}$ locally free, since X is catenary, equidimensional is equivalent to $\dim \mathcal{F}_x = n$ for all closed pt x, and C.M. says depth $\mathcal{F}_x = n$. Thus by(4.3.5.26), $pd_{\mathcal{O}_{P,x}} \mathcal{F}_x = N - n$. Thus $\mathcal{E}xt^k_P(\mathcal{F}, -)$ vanish for $k > N - n$ checked on stalks.

Now $H^i(X, \mathcal{F}(-q))$ is dual to $\mathrm{Ext}^{N-i}_P(\mathcal{F}, \omega_P(q))$ by the proof of(5.8.6.22), which is isomorphic to $\Gamma(P, \mathcal{E}xt^{N-i}_P(\mathcal{F}, \omega_P(q)))$ for q large by(5.7.4.9), so it vanish when $i < n$ by what we proved.

$1 \to 4$: The same as the proof of $4 \to 1$, then for $i < n$,

$$\Gamma(P, \mathcal{E}xt^{N-i}_P(\mathcal{F}, \omega_P(q))) = 0 = \Gamma(P, \mathcal{E}xt^{N-i}_P(\mathcal{F}, \omega_P)(q))$$

for q large, so $\mathcal{E}xt^{N-i}_P(\mathcal{F}, \omega_P) = 0$ as it is coherent. Then the stalk is $\mathrm{Ext}^{N-i}_{\mathcal{O}_{P,x}}(\mathcal{O}_{X,x}, \mathcal{O}_{P,x})$, so $pd_{\mathcal{O}_{P,x}} \mathcal{F}_x \leq N - n$ by(4.3.5.27), so depth $\mathcal{O}_{X,x} \geq n$, we must have equality, thus X is C.M. and equidimensional, as it suffice to check at closed pts. □

Cor. (5.8.6.24) [Enriques-Severi-Zariski]. Let X be a normal projective scheme that every irreducible component has dimension≥ 2, then for any $\mathcal{F} \in \mathcal{V}\mathrm{ect}(X)$, $H^1(X, \mathcal{F}(-q)) = 0$ for q large.

Proof: Just notice that $\dim \mathcal{F}_x \geq 2$, and Serre criterion shows depth $\mathcal{F}_x \geq 2$, the rest is the same as $4 \to 1$ in the proof of(5.8.6.23). □

Prop. (5.8.6.25) [Ample Effective Divisor Connected]. Let X be a proper connected CM. equidimensional scheme over k of dimension at least 2 and D is an ample effective Cartier divisor, then D is connected.

In particular, if X is a smooth complete variety of dimension≥ 2, D is also a complete variety.

Proof: Let $D = V(s)$, where s is a section of an ample invertible sheaf, then there is an exact sequence

$$0 \to \mathcal{O}_X(-nD) \to \mathcal{O}_X \to i_*\mathcal{O}_{V(s^n)} \to 0,$$

which gives a long exact sequence

$$0 \to H^0(X, \mathcal{O}_X(-nD)) \to H^0(X, \mathcal{O}_X) \to H^0(V(s^n), \mathcal{O}_{V(s^n)}) \to H^1(X, \mathcal{O}_X(-nD)).$$

But by Serre duality(5.8.6.19) and(5.7.2.6), $H^0(X, \mathcal{O}_X(-nD)) = H^{\dim X}(X, [\omega_X] \otimes \mathcal{O}_X(nD)) = 0$ for n sufficiently large, and $H^1(X, \mathcal{O}_X(-nD)) = H^{\dim X - 1}(X, [\omega_X] \otimes \mathcal{O}_X(nD)) = 0$ for n sufficiently large, so $H^0(V(s^n), \mathcal{O}_{V(s^n)}) \cong H^0(X, \mathcal{O}_X)$ has no idempotents for n sufficiently large, so $V(s^n)$ is connected, and D is also connected. □

Cor. (5.8.6.26). Any global complete intersection in $\mathbb{P}^n$ is connected.

Topological Sheaves

Prop. (5.8.6.27) [Global Verdier Duality]. If $f : X \to Y$ is a map between locally compact spaces with finite dimension, then there exists a functor $f^! : D^+(SAb_Y) \to D^+(SAb_X)$ that

$$R\operatorname{Hom}(Rf_!\mathcal{F}^\bullet, \mathcal{G}^\bullet) \cong R\operatorname{Hom}(\mathcal{F}, f^!\mathcal{G}^\bullet).$$

In particular, $f^!$ is right adjoint to $Rf_!$. Cf.[Gelfand P228].

There is also a local form of Verdier duality, which implies the global version by taking global section, Cf.[Cohomology of Sheaves Iversen P330].

Prop. (5.8.6.28). When $X \to Y$ is an inclusion of open subset, $f_!$ is just $j_!$ defined in(5.2.6.2) and $f^!$ is the restriction. When it is an inclusion of closed subset of locally compact spaces, it is the direct image f_* and $f^!$ is the $j^!$ previously defined in(5.2.6.2). They are not barely defined on $D^+(SAb)$ but on SAb.

Prop. (5.8.6.29). We consider the case where $f : X \to \mathrm{pt}$, and let $G = \mathbb{Z}$, denote $f^!(\mathbb{Z})$ by $\mathcal{D}_X^\bullet$, called the **dualizing complex**, then there is a duality:

$$R\operatorname{Hom}(R\Gamma_c(X, \mathcal{F}^\bullet), \mathbb{Z}) \cong R\operatorname{Hom}(\mathcal{F}^\bullet, \mathcal{D}_X^\bullet).$$

for $\mathcal{F}^\bullet \in D^+(\mathcal{S}\mathrm{h}(X))$.

Prop. (5.8.6.30). When X is a n dimensional topological manifold with boundary, then $\mathcal{D}_X^\bullet = \omega_X[n]$, where the sheaf ω_X is defined by

$$\Gamma(U, \omega_X) = \operatorname{Hom}_{\mathcal{A}\mathrm{b}}(H_c^n(U, \mathbb{Z}), \mathbb{Z}).$$

Cf.[Gelfand P234]. If we replace $\mathbb{Z}$ by a field k, then w_X is the sheaf of k-orientations of $\operatorname{int}(X)$, thus the constant sheaf when X is oriented or char $k = 2$**?**.

In particular, place k in dimension i then we get an isomorphism

$$\operatorname{Hom}_k(H_c^i(X, \mathcal{F}), k) = \operatorname{Ext}^{n-i}(\mathcal{F}, \omega_X)$$

(because k is a field thus injective). Gelfand even gives an interpretation of this pair in [Gelfand P236].

And if $\mathcal{F} = \omega_X$ and X oriented or char$k = 2$, we have $\operatorname{Ext}^{n-i}(k_X, k_X[n]) = H^{n-i}(X, k_X)$ using the adjointness of constant sheaf, so we get the Poincare duality:

$$H_c^i(X, k_X)^\vee \cong H^{n-i}(X, k_X).$$

Prop. (5.8.6.31). Compact cohomology commute with colimits, Cf.[Cohomology of Sheaves Iversen P173].

7 Discriminant and Different

Trace Elements

Def. (5.8.7.1) [Traces]. Let $f : X \to Y$ be a finite locally free morphism, the **trace of** f is defined to be

$$\mathrm{tr}_f : f_*\mathcal{O}_X \to \mathcal{O}_Y.$$

Then $\mathrm{tr}_f \circ f^\# = [\deg(f)] : \mathcal{O}_Y \to \mathcal{O}_Y$. Let the **trace pairing** be

$$Q_f : f_*\mathcal{O}_X \otimes f_*\mathcal{O}_X \to \mathcal{O}_Y : (s,t) \mapsto \mathrm{tr}_f(st)$$

which is equivalent to a map $Q_f : f_*\mathcal{O}_X \to f_*\mathcal{O}_X^\vee$, so the determinant of which is

$$\det(Q_f) : \wedge(f_*\mathcal{O}_X) \to \wedge(f_*\mathcal{O}_X)^{-1},$$

a section of the line bundle $\wedge(f_*\mathcal{O}_X)^{-2}$. Then the **discriminant of** f is defined to be the closed subscheme D_f of Y cut out by this section $\det(Q_f)$.

Def. (5.8.7.2) [Trace Element of Rings]. Let $A \to B$ be a flat quasi-finite map of Noetherian rings, $[\omega_{B/A}]$ the dualizing module(4.9.8.4), then there exists a unique element $\tau_{A/B} \in \omega_{B/A}$ s.t. for any Noetherian A-algebra A_1 s.t. $B \otimes_A A_1 = C \times D$ with C finite over A_1, the image of $\tau_{B/A}$ in $[\omega_{C/A_1}]$ is $\mathrm{tr}_{C/A}$, called the **trace element**.

Def. (5.8.7.3) [Trace Element of Morphisms]. Let $f : X \to Y$ be a flat quasi-finite morphism of locally Noetherian schemes, then denote $\tau_{X/Y} \in \Gamma(X, [\omega_{X/Y}])$ the **trace element of** f affine locally given by the trace element $\tau_{B/A}$(5.8.7.2).

Prop. (5.8.7.4) [Discriminant and ÉtaleLocus]. If $f : X \to Y$ is finite locally free, then f is étaleiff $D_f = \varnothing$.

Proof: f is flat, so it suffices to check fiberwise. Then this follows from(4.4.7.21). □

Differents

Def. (5.8.7.5) [Kähler Different]. Let $f : X \to Y$ be a morphism of schemes locally of f.t., the **Kähler different** of f is the 0-th fitting ideal $\mathrm{Fit}_0(\Omega_{X/Y}) \in \mathfrak{QCoh}(X)$(5.5.1.21).

Prop. (5.8.7.6). Let $f : X \to Y$ be a morphism of schemes locally of f.t., then the closed subscheme cut out by the Kähler different is stable under base change.

Proof: Cf.[Sta]0BVX. □

Prop. (5.8.7.7). If $X = \mathrm{Spec}\, A[X_1, \ldots, X_n]/(f_1, \ldots, f_m)$, then the Kähler different of $X \to \mathrm{Spec}\, A$ is just the ideal generated by the Jacobians $\det(\frac{\partial f_{i(j)}}{\partial X_j})_{0 \le j \le n}$.

Proof: Because $\Omega_{X/A}$ has a presentation

$$0 \to \bigoplus_{0 \le i \le m} f_i \xrightarrow{d} \bigoplus_{0 \le j \le n} dX_j \to \Omega_{X/A} \to 0.$$

□

Prop. (5.8.7.8) [Kähler Different and Unramified Locus]. Let $f : X \to Y$ be a morphism of schemes locally of f.t., then the closed subscheme cut out by the Kähler different contains exactly the points that f is not unramified.

Proof: Cf.[Sta]0C3J. □

Def. (5.8.7.9) [Differents]. Let $f : X \to Y$ be a flat quasi-finite morphism between locally Noetherian schemes, define the **different of** f to be the annihilator of $[\omega_{X/Y}]/\tau_{X/Y}$, which is a coherent ideal $\mathfrak{D}_f \subset \mathcal{O}_X$.

Prop. (5.8.7.10) [Differents and Étale(Unramified) Locus]. Let $f : X \to Y$ be a flat quasi-finite morphism between locally Noetherian schemes, then the closed subscheme of X cut out by the different $\mathfrak{D}_f$ contains exactly the set of points that f is not étale(unramified).

Proof: Cf.[Sta]0BW9. □

Prop. (5.8.7.11). If $f : X \to Y$ is a quasi-finite syntomic morphism between locally Noetherian schemes, then the different $\mathfrak{D}_f$ equals the Kähler different of f(5.8.7.5).

Proof: Cf.[Sta]0BWG. □

Prop. (5.8.7.12) [Differents for Smooth Schemes]. Let S be a locally Noetherian scheme and X, Y be smooth scheme of relative dimension n over S, and $f : X \to Y$ is a quasi-finite morphism, then f is syntomic, and the closed subscheme R cut out by the different $\mathfrak{D}_f$ of f is the locally principal vanishing locus of

$$\wedge^n(df^*) \in \mathrm{Hom}(f^*\Omega^n_{Y/S}, \Omega^n_{X/S}) = \Gamma(Y, (f^*\Omega^n_{Y/S})^{-1} \otimes \Omega^n_{X/S}).$$

And if f is étaleat the associated points of X, then R is an effective Cartier divisor, and

$$f^*\Omega^n_{Y/S} \otimes \mathcal{O}(R) \cong \Omega^n_{X/S}.$$

Proof: Cf.[Sta]0BWJ. □

8 Fourier-Mukai Transform

Cf.[Sta]Chap56.

9 Deformation Theory

Basic references are [Sta]Chap36.

Def. (5.8.9.1) [Thickenings]. We call X' a **thickening** of a X iff X is a closed subscheme of X' that their underlying topological space are the same. Morphisms of thickenings are defined routinely.

A thickening is said to **have order** n iff the ideal sheaf $\mathcal{I}$ satisfies $\mathcal{I}^{n+1} = 0$.

Base change and composition of a (order n)thickening is also a (order n)thickening, because closed immersion and surjective do.

Prop. (5.8.9.2). Any thickening of an affine scheme is also affine.

Proof: This is a special case of(5.4.4.36). □

Prop. (5.8.9.3) [Picard Group of Thickenings]. Let $X \subset X'$ be a first order thickening with ideal sheaf $\mathcal{I}$, then there is a canonical long exact sequence of Abelian groups:

$$0 \to H^0(X, \mathcal{I}) \to H^0(X', \mathcal{O}_{X'}^*) \to H^0(X, \mathcal{O}_X^*) \to H^1(X, \mathcal{I}) \to \mathrm{Pic}(X') \to \mathrm{Pic}(X) \to H^2(X, \mathcal{I}) \to \ldots$$

Proof: This follows from taking cohomology of the exact sequence $0 \to \mathcal{I} \to \mathcal{O}_{X'} \to i_*\mathcal{O}_X \to 0$, where $\mathcal{I} \to \mathcal{O}_{X'}$ is given by $a \mapsto 1 + a$. □

Prop. (5.8.9.4). Let $X \subset X'$ be a thickening with ideal sheaf $\mathcal{I}$ and n is invertible in $\mathcal{O}_X$, then $\mathrm{Pic}(X)[n] \to \mathrm{Pic}(X')[n]$ is an isomorphism.

Proof: By taking cohomology of the exact sequence $0 \to (1 + \mathcal{I})^* \to \mathcal{O}_{X'} \to i_*\mathcal{O}_X \to 0$, it suffices to show that $n : (1 + \mathcal{I})^* \to (1 + \mathcal{I})^*$ is an isomorphism, which is true by(4.1.1.17). □

Def. (5.8.9.5) [Infinitesimal Neighbourhood]. Let $Z \subset U \subset X$ be a closed immersion of the open subscheme U that Z corresponds to the ideal $\mathcal{I}$ on U, then a **n-th infinitesimal neighbourhood** of Z in X is the closed subscheme of U corresponding to $\mathcal{I}^n$.

The infinitesimal neighbourhood of Z in X has the universal property s.t. for any infinitesimal thickening $T \subset T'$ of order n over X and a map $T \to Z \in \mathcal{S}\mathrm{ch}_X$ extension to a morphism of infinitesimal thickenings $(T \subset T') \to (Z \to Z')$ over X.

Def. (5.8.9.6) [Infinitesimal Extension]. Let X be a scheme algebraic over a field k and $\mathcal{F}$ is a coherent sheaf on X, then a **infinitesimal extension** of X by the sheaf $\mathcal{F}$ is a scheme X' over k that has a sheaf of ideals $\mathcal{I}$ that $\mathcal{I}^2 = 0$ and $(X', \mathcal{O}_{X'}/\mathcal{I}) \cong (X, \mathcal{O}_X)$, and moreover, $\mathcal{I}$ with the $\mathcal{O}_X$-structure is isomorphic to $\mathcal{F}$.

There is a trivial extension, that is $(X', \mathcal{O}_{X'}) \cong (X, \mathcal{O}_X \oplus \mathcal{F})$, where the multiplication is $(a, f)(a', f') = (aa', af' + a'f)$.

Def. (5.8.9.7) [Deformation]. Let X be a scheme algebraic over a field k, an **infinitesimal deformation** of X is a scheme X' flat over $D = k[t]/(t^2)$ that $X' \otimes_D k = X$. A infinitesimal deformation is a first order thickening, by(5.8.9.1).

If Y is a closed subscheme of X, then we define the **infinitesimal deformation of Y in X** to be a closed subscheme $Y' \subset X \otimes_k D$ which is flat over D and $Y' \otimes_D k = Y$.

A scheme algebraic over a field k is called **rigid** if it has no infinitesimal deformations.

Prop. (5.8.9.8) [Affine Case]. Any thickening of an affine scheme is affine. (Immediate from(5.4.4.36)).

Prop. (5.8.9.9). Let X be a nonsingular variety over an alg.closed field k, infinitesimal deformation of X is the same as an infinitesimal extension of X by the sheaf $\mathcal{O}_X$. Thus we get the set of infinitesimal deformations of X is parametrized by $H^1(X, \mathcal{T}_X)$, by(5.8.9.11)below.

Proof: For an infinitesimal deformation, tensoring $\mathcal{O}_{X'}$ with the exact sequence $0 \to k \xrightarrow{t} D \to k \to 0$, we get(by flatness)

$$0 \to \mathcal{O}_X \xrightarrow{t} \mathcal{O}_{X'} \to \mathcal{O}_X \to 0,$$

, and conversely, an extension is locally free(because it is f.g. so flat over D is equivalent to free). □

Prop. (5.8.9.10). If X is an affine regular scheme algebraic over an alg.closed field k, then any extension by coherent sheave is trivial.

Proof: For any infinitesimal extension, the morphism $X \to X'$ is a closed immersion and surjection, so X' is also affine by(5.8.9.8), $=\operatorname{Spec} A'$. Now the rest follows from**??**. □

Cor. (5.8.9.11) [Infinitesimal Extension and Cohomology]. Let X be a nonsingular variety over an alg.closed field k, then the set of infinitesimal extensions by a coherent sheaf $\mathcal{F}$ is parametrized by $H^1(X, \mathcal{F} \otimes \mathcal{T}_X)$.

If Y is a closed subscheme of X, then the set of infinitesimal deformation of Y in X is parametrized by $H^0(Y, \mathcal{N}_{Y/X})$.

Proof: By the proposition, we know that an infinitesimal extension s locally isomorphic to $(U, \mathcal{O}_X(U) \otimes \mathcal{F}(U))$, by a section $\mathcal{F}(U) \to \mathcal{O}_{X'}(U)$.

But there is a twist, because there can because different sections. But the different sections different at a $\operatorname{Hom}_{\mathcal{O}_X(U)}(\Omega_{\mathcal{O}_X(U)/k}, \mathcal{F}(U)) = (\mathcal{T} \otimes \mathcal{F})(U)$. These forms a Čech cocycle for $\mathcal{F} \otimes \mathcal{T}_X$, and the converse is also true. Finally, use the fact that X is separated so Čech and sheaf cohomology coincide.

For the subscheme,**?** □

Formal Properties

Def. (5.8.9.12) [Formal Properties]. Let $f : X \to S$ be a morphism of schemes, then f is called a **formally unramified/smooth/étale** if for any first order thickening of affine schemes $T \to T'$ and a morphism $(T \to T') \to (X \to S)$, there exists at most one/exists one/exists exactly one lifting $T' \to X$.

Formally unramified/smooth/etale morphisms are stable under base change and compositions.

Prop. (5.8.9.13).

- A morphism is (G-)unramified iff it is formally unramified and locally of f.t.(f.p.).
- A morphism is étaleiff it is formally étaleand locally of f.p.
- A morphism is smooth it is formally smooth and locally of f.p.

Proof: [Sta] □

5.9 Resolution of Singularities

References are[K-M85].

Def. (5.9.0.1)[Desingularizations]. Let $X \in \mathcal{S}\mathrm{ch}$ be reduced and locally Noetherian, then a **desingularization** of X is a modification(5.4.5.10) $Z \to X$ s.t. Z is regular. A **strong desingularization** is a desingularization $\pi : Z \to X$ that π is an isomorphism over any regular point $x \in X$.

Thm. (5.9.0.2) [Hironaka]. Let X be a reduced scheme locally of f.t. over an excellent, reduced, locally Noetherian scheme S of characteristic 0(i.e. $\mathrm{char}\,\kappa(x) = 0$ for any $x \in X$), then X admits a strong desingularization over S.

Proof: [Hironaka, Resolution of singularities of an algebraic variety over a field of characteristic zero. I, II, Ann. Math. 79 (1964), 109 – 203; 205 – 326.] or [Resolution of Singularities, Hauser, Lipman, Oort, Quiros]. □

Thm. (5.9.0.3) [de Jong]. Let R be a CDVR or a field, $X \in \mathcal{S}\mathrm{ch}^{\mathrm{ft,sep}}_{\mathrm{int}}/R$, then X admits an alteration(5.4.5.10) $Y \to X$ over R s.t. Y is regular.

Proof: [de Jong, Smoothness, Semi-stability and Alterations, Publ. Math. IHES 83 (1996), 51–93.] □

5.10 Varieties

Basic references are [Sta]and [Har77].

The materials distinguishes here in the fact that most schemes considered have geo.reduced, geo.connected or geo.integral properties in nature.

1 Varieties

Classical varieties

Prop. (5.10.1.1) [Soberization Functor]. For a sep.closed field k, the soberization functor t induce a fully faithful functor from classical varieties over k to quasi-projective integral schemes over k. It maps projective varieties to projective integral schemes and preserves fiber products **?**.

Proof: We assign the irreducible closed subsets space $t(X)$ and show that this embeds X in $t(X)$, and for an affine variety $(V, \mathcal{O}_V)$, the regular function sheaf is isomorphic to the pullback sheaf on $t(V) = \mathrm{Spec}(A)$.

By definition $t(X)$ is quasi-projective, which is separated, the set of geometric pts of any closed variety is dense so $t(V)$ is homeomorphic to X. And because they are both reduced, they are isomorphic. So it is essentially surjective.

It is fully faithful by(5.10.1.11). □

Prop. (5.10.1.2). The soberization of a classical variety X is regular at a closed point iff the local defining functions has rank $n - \dim X$.

Proof: Consider the space of closed point of X, they correspond to classical points because k is alg.closed. Let $a_p = (x_1 - a_1, \ldots, x_n - a_n)$ and b be the locally defining ideal. Then the differential defines an isomorphism of vector space $a_p/a_p^2 \cong k^n$, and the local ring at p is $m/m^2 \cong (a_p/b)/(a_p/b)^2 \cong a_p/(b + a_p^2)$. The rank of the defining functions is $b + a_p^2/a_p^2$. Counting dimension gives us the result. (Use (5.6.3.3) also). □

Varieties

Def. (5.10.1.3) [Varieties]. Given $k \in \mathtt{Field}$,

- A **variety** over k is a geo.integral separated scheme algebraic over k.
- An **prevariety** over k is an integral separated scheme algebraic over k.
- A **complete variety** over k is a variety over k that is also proper(i.e. universally closed) over k.
- A classical variety over k is an abstract variety over k because quasi-projective is f.t. and separated(5.4.5.19).
- A **non-singular variety** over k is a regular variety over k.
- A **curve** over k is a variety of dimension 1 over k.

The category of varieties over k is denoted by $\mathcal{V}\mathrm{ar}_k$.

If X/k is a (complete)variety and K/k is a field extension, then X_K is a (complete)variety over K, by(5.4.3.17).

Remark (5.10.1.4). Notice the prevariety is the same as the variety defined in [Sta].

Cor. (5.10.1.5). Any variety is birational to an integral H-quasi-projective scheme. A complete variety is birational to an integral projective scheme by Chow's lemma(5.4.5.23)(5.4.5.3).

Prop. (5.10.1.6). By valuation criterion, for a complete variety, every valuation of the function fields of K/k dominate a unique point of X. So the points of X correspond to valuations of K containing k

Prop. (5.10.1.7) [Generically Smoothness]. A variety is generically smooth, by(5.6.4.21).

Prop. (5.10.1.8) [Nagata]. By Nagata compactification(5.8.3.2), any variety can be embedded as an open subset of a complete variety.

Proof: □

Prop. (5.10.1.9) [Product of Varieties]. The product of two (complete)varieties over k is also a (complete)variety.

Proof: It is geometrically integral by(5.4.3.17), it is separated because separatedness is stable under composition and base change(5.4.4.2). So does properness. □

Def. (5.10.1.10) [Arithmetic Points]. An **arithmetic point** of a scheme X over a field k is an element of $X(k^s)$. When X is a variety, the arithmetic points of X is dense in X, by(5.4.3.3).

An **geometric point** of a scheme X is an element of $X(\overline{k})$.

Prop. (5.10.1.11). To verify two morphisms f, g between two varieties X and Y are equal, it suffices to prove that they are equal on the set of arithmetic points of an open subscheme U(5.10.1.10).

Proof: Because the equalizer is a closed subscheme of X(5.2.7.18), and it contains all geometric pts of an open subset of X, so it must by X, as the geometric-points are dense in U(5.10.1.10), and X is reduced and irreducible. □

Prop. (5.10.1.12) [Global Sections]. Let $k \in \mathtt{Field}$ and $X \in \mathcal{S}\mathrm{ch}^{proper}/k$, then

- $A = \Gamma(X, \mathcal{O}_X)$ is a finite k-algebra hence is a finite product of Artinian local k-algebras, one for each connected component of X.
- If X is reduced, then $A = \prod k_i$ is a finite product of finite field extensions of k.
- If X is geo.reduced, then k_i are all separable over k.
- If X is geo.connected, then A is geo.irreducible over k(4.3.6.1).
- If X is geo.integral(i.e. a complete variety), then $\Gamma(X, \mathcal{O}_X) = k$.

Proof: 1: $H^0(X, \mathcal{O}_X)$ is finite k-algebra by(5.7.4.11), thus it is Artinian(4.1.3.4). The connected components of X clearly corresponds to idempotents of A, which corresponds to Artinian local k-algebras, as a local ring is connected.

2: This follows from(4.1.3.5).

3: $A \otimes_k \overline{k} = H^0(X_{\overline{k}}, \mathcal{O}_{X_{\overline{k}}})$ is also reduced by flat base change(5.7.5.1), so each k'/k is geo.reduced(4.3.6.2), thus separable by(4.3.9.4).

4: By hypothesis $A \otimes_k \overline{k} = H^0(X_{\overline{k}}, \mathcal{O}_{X_{\overline{k}}})$ is an Artinian local ring, thus it has only one point, so irreducible, so it is geo.irreducible(4.3.6.3).

5: By item3, 4, $A = k'$ is a finite separable field extension of k that $\mathrm{Spec}(k' \otimes_k \overline{k})$ is irreducible, but $k' \otimes_k \overline{k}$ is a finite product of $\overline{k}$, thus $k' = k$. □

Prop. (5.10.1.13)[Check Properties on Geometric/Closed Points]. A nice property of varieties is that identity of two morphisms of products of varieties can be checked at the geometric pts(5.10.1.10), by(5.10.1.11) and(5.10.1.9).

Surjectiveness of a map between varieties can be checked on closed points, by(5.4.1.29).

Also surjective and injective of Qco sheaves need only be checked at closed pts by(5.5.1.38)(5.4.1.26).

Canonical Sheaves

Prop. (5.10.1.14)[Canonical Sheaves]. For a smooth variety X over a field k and Y a local complete intersection of X of codimension r, by(5.6.4.2) and(5.6.4.16) and(5.6.8.10), $\mathcal{K}_{X/k}$ and $\mathcal{I}/\mathcal{I}^2$ is locally free, so we can define the following locally free sheaves:

- The **canonical sheaf** $\mathcal{K}_{X/k} = \wedge^n \Omega_{X/k}$ on X.
- The **tangent sheaf** $\mathcal{T}_X = (\mathcal{K}_{X/k})^{-1}$ on X.
- The conormal sheaf $\mathcal{C}_{Y/X} = \mathcal{I}/\mathcal{I}^2$ on Y.
- The normal sheaf $\mathcal{N}_{Y/X} = \mathcal{C}_{Y/X}^{-1}$ on Y.

Prop. (5.10.1.15)[Kodaira-Spencer map]. There is another characterization of tangent vector fields. (Note: this should be a special case of Prop8.5.9 in [FGA]).

Let X be a variety over k and $S = k[\varepsilon]$ the dual numbers. Then $H^0(X, \mathcal{T}_X) \cong \mathrm{Aut}^{(1)}(X_S/S)$, where $\mathrm{Aut}^{(1)}(X_S/S)$ means that the automorphisms of X_S over S that is identity on X(inclusion to X_S induced by $\mathrm{Spec}\, k \subset \mathrm{Spec}\, S$).

Proof: First the case $X = \mathrm{Spec}\, A$ is affine, then because $H^0(X, \mathcal{T}_X) = \mathrm{Hom}_k(\mathcal{K}_{A/k}, A) = \mathrm{Der}(A, A)$, so this is equivalent to $\mathrm{Der}(A, A) \cong$ automorphisms of $A[\varepsilon]$ that is identity under pass to quotients to A. For this, a $d \in \mathrm{Der}(A, A)$ is mapped to $a + b\varepsilon \mapsto a + b\varepsilon + d(a)\varepsilon$. This is checked to be a ring morphism, and any desired morphism are like these.

The above construction is natural and functorial in A, so it glue together to give the global case. □

Prop. (5.10.1.16)[Smoothness and Conormal Sheaves]. ? Let X be a smooth variety over a field k, then an irreducible closed subscheme Y of codimension r in X is smooth iff $\mathcal{K}_{Y/k}$ is locally free and(5.5.5.13) is exact on the left.

In this case, $\mathcal{I}$ is locally generated by r elements and $\mathcal{C}_{Y/X}$ is a locally free sheaf of rank r on Y by(5.6.8.10).

Proof: Cf.[Hartshorne P178]. Should has something to do with(5.6.4.2),(5.6.4.16) and(5.6.4.15). □

Prop. (5.10.1.17) [Adjunction Formulas]. For a smooth variety X over a field k and Y a smooth subvariety of codimension r. There is an exact sequence

$$0 \to \mathcal{I}/\mathcal{I}^2 \to \mathcal{K}_{X/k} \otimes \mathcal{O}_Y \to \mathcal{K}_{Y/k} \to 0$$

by(5.5.5.14). Taking the highest exterior power(5.5.1.25), we get:

$$\mathcal{K}_Y = \mathcal{K}_X \otimes \wedge^r \mathcal{N}_{Y/X} = \mathcal{K}_X \otimes (\wedge \mathcal{I}/\mathcal{I}^2)^{-1}$$

In particular, if $r = 1$ then Y is a divisor D in X, the canonical sheaf

$$\mathcal{K}_Y \cong (\mathcal{K}_X \otimes \mathcal{L}(D))_Y, \quad \mathcal{K}_{\mathbb{P}^n_k/k} = \mathcal{O}(-n-1)(5.5.5.7).$$

because $\mathcal{I}_Y \cong \mathcal{L}(-Y)$ in this case so $\mathcal{I}_Y/\mathcal{I}_Y^2 = L(-Y) \otimes \mathcal{O}_Y$.

Taking dual, we get:

$$0 \to \mathcal{T}_Y \to \mathcal{T}_X \otimes \mathcal{O}_Y \to \mathcal{N}_{Y/X} \to 0$$

Prop. (5.10.1.18) [Geometric Genus]. For a smooth proper variety over a field k, the **geometric genus** p_g is defined as the rank of the global section of the invertible canonical sheaf $\mathcal{K}_X = \wedge^n \mathcal{K}_{X/k}$. It is a birational invariance. With the same methods, we can prove the rank of global sections of any other functorially defined bundles of $\mathcal{K}_X$ is birational invariance, e.g. Hodge numbers.

Proof: For any rational map $U \to Y$, there is a subset $V \in U$ and a local isomorphism V and $f(V)$, that will define an isomorphism of global sections. Because a nonzero section of an invertible sheaf cannot vanish on a dense open set $f(V)$, the morphism of global sections is injective into $\Gamma(U, \mathcal{O}_U)$. Now we find a U that $\mathrm{codim}(X - U) > 1$, then we can use(4.3.5.11) to get $\Gamma(U) = \Gamma(X)$, then $p_g(X) \geq p_g(X')$, and the converse is also true. For this, we use valuation criterion of properness, then for any codimension 1 point, the stalk is a DVR, thus we find a $\mathrm{Spec}\, \mathcal{O}_p \to X'$, this extends to a nbhd of p because X' is of f.t.. □

Cor. (5.10.1.19). By(5.5.5.7), $\mathcal{K}_{\mathbf{P}^n_k} \cong \mathcal{O}(-n-1)$, so it has no global section by(5.7.2.1), $p_g(\mathbb{P}^n_k) = 0$. Hence every rational variety over a field k, i.e. one that is birational to $\mathbb{P}^n_k$, has geometric genus 0.

Complete Variaties

Lemma (5.10.1.20) [Rigidity Lemma]. Let X, Y be varieties over a field k and $f : X \times Y \to Z$ a morphism of schemes over k s.t. Z is separated. If X is complete with a rational point p and y is a rational point of Y s.t. $f(\cdot, y) : X \to Z$ is constant, then f factors through the projection $\mathrm{pr}_Y : X \times Y \to Y$.

Proof: The equalizer is a closed subscheme of $X \times Y$ as Z is separated(5.4.4.89), and $X \times Y$ is a variety(5.10.1.9), thus we can check on closed points. Let $g(y) = f(p, y) : Y \to Z$, then we want to show $f = g \circ \mathrm{pr}_Y$.

Let U be affine open in Z, then because X is universally closed, pr_Y is closed, so $V = \mathrm{pr}_Y(f^{-1}(Z \backslash U))$ is closed in Y. But if $y \notin V(\overline{k})$, then $f(X, y) \subset U$, and X is complete and connected, so $f(\cdot, y)$ is constant(5.4.5.4), and $f(x, y) = f(p, y)$. Thus $f = g \circ \mathrm{pr}_Y$ on a non-empty open subset of $X \times Y$, which is a variety, so this is true on all of $X \times Y$ by(5.10.1.11). □

Prop. (5.10.1.21)[See-Saw Principle]. Let X be a complete variety over a field k and Y a k-scheme, then for any line bundle $\mathcal{L}$ on $X \times Y$, there is a closed subscheme $Y_1 \subset Y$ s.t. for any morphism $f : S \to Y$, $(1 \times f)^*\mathcal{L}$ is trivial on $X \times S$ iff f factors through Y_1.

Proof: This $\mathcal{L}$ corresponds to a morphism $Y \to \underline{\mathrm{Pic}}_{X/k}$, and clearly Y_1 is the fiber of Y over $e \in \underline{\mathrm{Pic}}_{X/k}$. □

Cor. (5.10.1.22). Let X be a complete variety over a field k and Y a reduced locally algebraic k-scheme, if $\mathcal{L}, \mathcal{M}$ are two line bundles on $X \times Y$ s.t. $\mathcal{L}_y \cong \mathcal{M}_y$ for all closed points $y \in Y$, and for some $x \in X(k)$, $\mathcal{L}_x \cong \mathcal{M}_x$, then $\mathcal{L} \cong \mathcal{M}$.

Prop. (5.10.1.23) [Theorem of the Cube]. If X, Y are complete varieties over a field k, and Z is a connected, locally Noetherian k-scheme, if x, y are rational points of X, Y resp. and $z \in Z$. Supposed $\mathcal{L} \in \mathrm{Pic}(X \times Y \times Z)$ that is trivial on $x \times Y \times Z, X \times y \times Z, X \times Y \times z$, then $\mathcal{L}$ is trivial.

Proof: Let Z' be the maximal closed subscheme of Z given by(5.10.1.21). We show that Z' is open, thus it is all of Z: If $\zeta \in Z'$, let $I \subset \mathcal{O}_{Z,\zeta}$ be the ideal defining Z', we show $I = (0)$, which is equivalent to Z' containing a nbhd of ζ(locally Noetherian used). If not, then because $\cap \mathfrak{m}^n = 0$ by Krull's theorem(locally Noetherian used), there is an $n \geq 1$ that $I \subset \mathfrak{m}^n, I \not\subseteq \mathfrak{m}^{n+1}$. Let $\mathfrak{a}_1 = (I, \mathfrak{m}^{n+1})$, and $\mathfrak{m}^{n+1} \subset \mathfrak{a}_2 \subset \mathfrak{a}_1$ that $\dim_{k(\zeta)}(\mathfrak{a}_1/\mathfrak{a}_2) = 1$(so $\mathfrak{a}_1 = \mathfrak{a}_2 + k(\xi)a$ for some $a \in \mathfrak{a}_2$), and let $Z_i \subset \mathrm{Spec}\, \mathcal{O}_{Z,\xi}$ be the closed subscheme defined by a_i. Let $\mathcal{L}_i$ be the restriction of L on $X \times Y \times Z_2$. If we show that $\mathcal{L}_2$ is trivial, then Z_2 is contained in Z', which is contradiction because $I \not\subseteq \mathfrak{a}_2$.

For this, notice that $\mathcal{L}_1$ is trivial, and to show that $\mathcal{L}_2$ is trivial, it suffices to lift a non-vanishing global section s of $\mathcal{L}_1$ to $\mathcal{L}_2$, because Z_1, Z_2 has the same underlying set.

For this, notice there is an exact sequence $0 \to k(\xi) \xrightarrow{a} \mathcal{O}_{Z_2} \to \mathcal{O}_{Z_1} \to 0$, where $k(\xi)$ is the skyscraper sheaf at ξ. So the obstruction of the lifting is an element $\xi \in H^1((X \times Y)_{k(\xi)}, \mathcal{O}_{(X \times Y)_{k(\xi)}})$. But now the conditions show that ξ is zero under the pullback along $x \times Y \hookrightarrow X \times Y$ and $X \times y \hookrightarrow X \times Y$. So by Kunneth formula(5.7.1.10) and(5.10.1.12), ξ vanishes. □

2 Projective Varieties

Example (5.10.2.1) [Non-Projective Smooth Proper Varieties]. There are proper smooth complex varieties that are not projective. Examples are given in [Har77]P443**?**.

Prop. (5.10.2.2)[Affine Dimension Theorem]. Suppose X, Y are subschemes of $\mathbb{A}^n_k$ of codimensions d and e resp., and $d + e \leq n$, then every non-empty irreducible component of $X \cap Y$ has dimension $\geq n - d - e$.

Proof: If Y is an intersection of e hypersurfaces, then this follows from Krull's height theorem(4.2.4.18). In general, notice the diagonal map $\Delta : \mathbb{A}^n_k \to \mathbb{A}^n_k \times \mathbb{A}^n_k$ is an isomorphism onto the diagonal T defined by $\{X_i = Y_i\}_{i=1,\ldots,n}$, thus it is a complete intersection in $\mathbb{A}^n_k \to \mathbb{A}^n_k \times \mathbb{A}^n_k$, and Δ induces an isomorphism $X \cap Y \cong X \times Y \cap T$, so we are done. □

Cor. (5.10.2.3) [Projective Dimension Theorem]. Suppose X, Y are subvarieties of $\mathbb{P}^n_k$ of codimensions d and e resp., and $d + e \leq n$, then X and Y intersect.

Proof: Take the affine cone, then item2 shows any irreducible component of $\overline{X} \cap \overline{Y}$ containing the origin has dimension≥ 1, which means $X \cap Y \neq 0$. □

Prop. (5.10.2.4)[Transversal Intersection]. Show that if X is a closed subscheme of $\mathbb{P}^n_k$ of dimension r, then there is an intersection of $r + 1$ non-empty hypersurfaces missing X. And if k is infinite, these hypersurfaces can be chosen to be hyperplanes.

If k is infinite, there is an intersection of r non-empty hypersurfaces intersecting X at f.m. points.

Proof: Let $\eta_1, \ldots, \eta_n$ be the generic points of X, we want to find a hypersurface F that doesn't contain any of these generic points. We use induction on n. If $n = 1$, then there is clearly a hyperplane missing η_1. If we find a hypersurface missing $\eta_1, \ldots, \eta_{n-1}$, if it also misses η_n, we are done, if it contains η_n, we can change η_n to η_i and consider again. If we find polynomials $F_1, \ldots, F_n$ that $F_i(\eta_i) = 0, F_i(\eta_j) \neq 0$, we may assume $\deg(F_i)$ are the same, so $\sum_i F_1 \ldots \widehat{F_i} \ldots F_n$ is a polynomial non-zero on each of η_i. If moreover k is infinite, then we want to find a hyperplane missing every generic point of X. But each generic point corresponds to a graded ideal I_i of $k[T_0,\ldots,T_n]$, and $(I_i)_1 \neq k\{T_0,\ldots,T_n\}$ are proper linear subspaces. As k is infinite, we can choose a $a_0T_0+\ldots+a_nT_n$ not in these subspaces, thus non-zero on any generaic point of X.

Now $X\cap F$ is a closed subscheme of $\mathbb{P}^n_k$ of dimension $r-1$, thus we can use conduction on r to finish. □

3 Birational Geometry

Prop. (5.10.3.1). Any variety over K is birational to a hypersurface in $\mathbb{A}^n_K$ for some n.

Proof: Cf.[Diophantine Geometry, P575]. □

Prop. (5.10.3.2) [Prevarieties and Function Fields]. The following categories are equivalent.

- The category of prevarieties over k with dominant rational morphisms.
- The dual category of f.g. field extensions over k.

Proof: Cf.[Sta]0BXN.**?** □

Prop. (5.10.3.3). Let $\varphi: X\to X'$ be a rational map of K-varieties with X smooth. If the base change $\varphi_{\overline{K}}$ extends to a morphism $X_{\overline{K}}\to X'_{\overline{K}}$, then φ extends to a morphism $X\to X'$.

Proof: Let U be an open dense subset that φ is defined. For a point x, let $x'=\varphi_{\overline{K}}(x)$, then x' is in the closure of $\varphi(U)$. By(5.4.6.2), it suffices to construct a morphism $\mathcal{O}_{X',x'}\to\mathcal{O}_{X,x}$, i.e., to prove for any rational function f regular at x', $\varphi\circ f$ is regular at x. The argument is the same as that of(5.4.5.14).

For any such f, $f_{\overline{K}}\circ\varphi_{\overline{K}}$ is regular at x, thus no pole of $\mathrm{div}(f_{\overline{K}}\circ\varphi_{\overline{K}})$ passes through x. For the rest, Cf.[Diophantine Geometry, P576].**?** □

Prop. (5.10.3.4) [Generic Separable Degree]. Let $\varphi: X\to X'$ be a dominant morphism of varieties over a field k of the same dimension, then there exists an open dense subscheme U' of X' s.t. $\varphi^{-1}(U')\to U'$ is finite and the fibers all have cardinality $\deg_s(\varphi)$.

Proof: By(5.10.3.2), we can decompose φ and assume it is either separable or purely inseparable, and also primitive. If it is separable, let it be generated by t. After shrinking(and cutting closure of images), we may assume the coefficients of t are regular functions, and $\Gamma(X)=\Gamma(X')[t]/(q(t))$. As q is separable, there exists $a,b\in K(X')$ s.t. $aq+bq'=1$. We may shrink X' and assume $a,b\in\Gamma(X')$, so q is also separable over any fiber of X, which means the fibers all have cardinality $\deg_s(\varphi)$.

If it is purely inseparable, let $q(t)=t^{p^k}-h$ be the minimal polynomial of t over $K(X')$, h$\in K(X')$. Then after shrinking, we may assume $h\in\Gamma(X')$, thus $q(t)$ is purely inseparable over any fiber of X, which means □

4 Others

Prop. (5.10.4.1). Varieties are triangulable.

Proof: Cf.[Triangulation of Algebraic Sets, Hironaka]. □

Fano Varieties

Def. (5.10.4.2) [Fano Varieties]. A **Fano variety** is a complete smooth variety X over a field K s.t. $\mathcal{K}_X^*$ is ample.

Prop. (5.10.4.3). a smooth complete intersection of hypersurfaces in $\mathbb{P}^n_K$ is Fano if and only if the sum of their degrees is at most n.

Prop. (5.10.4.4) [Kollár-Miyaoka-Mori]. Fano varieties over an alg.closed field are rationally chain connected.

Proof: Cf.[Rational connectedness and boundedness of Fano manifolds, Kollar]. □

Rationally Connected Varieties

Def. (5.10.4.5) [Rationally Connected Varieties]. A variety X over K is called **rationally connected** if any two points of $X(\overline{K})$ can be connected by a rational curve(5.11.1.1) over $\overline{K}$.

5 Relative Varieties

Def. (5.10.5.1) [Varieties over Schemes]. Let $S \in \mathcal{S}ch$, a (proper/smooth)**variety over** S is a (proper/smooth) flat morphism $f : X \to S$ s.t. all the geometric fibers of f are geo.integral over the resp. residue field $k(s)$. It can be regarded as a family of (proper/smooth)varieties parametrized by S.

Being a (proper/smooth) variety is stable under base change.

Prop. (5.10.5.2) [Global Sections]. Let $S \in \mathcal{S}ch$ be locally Noetherian and X a proper variety over S, then $\mathcal{O}_S \to f_*\mathcal{O}_X$ is an isomorphism.

Proof: For any closed point $s \in S$, $k(s) \to H^0(X_s, \mathcal{O}_{X_s})$ is an isomorphism by(5.10.1.12), and this isomorphism factors through $k(s) \to f_*(\mathcal{O}_X) \otimes k(s) \to H^0(X_s, \mathcal{O}_{X_s})$. So $f_*(\mathcal{O}_X) \otimes k(s) \to H^0(X_s, \mathcal{O}_{X_s})$ is surjective, thus it is an isomorphism by item4 → 3 of (8.7.3.16). Thus the first map is also an isomorphism.

Now $\mathcal{O}_S \to f_*(\mathcal{O}_X)$ is a surjection at s by Nakayama. Let $\mathcal{Q}$ be the coherent sheaf on S associated to $\mathcal{F}$, then by(8.7.3.16), it is free at s, and $\mathcal{Q}_s = H^0(X_s, \mathcal{O}_{X_s})$ is of rank 1, but also $\mathcal{Q}^\vee \cong f_*(\mathcal{O}_X)$, so $\mathcal{O}_S \to f_*(\mathcal{O}_X)$ is in fact a surjection at s. Now s is arbitrary, so $\mathcal{O}_S \to f_*(\mathcal{O}_X)$ is an isomorphism. □

Prop. (5.10.5.3). Let (R, K, k) be a DVR and X is a smooth R-scheme s.t. X_K is geo.integral and X_k is proper, then X is a proper smooth variety over R.

Proof: Cf.[Good Reduction of Abelian Varieties, P495]**?** □

5.11 Curves

Main references are [黎曼曲面, 伍鸿熙], [Vak17]Chap19, [G-H78], [Har77]Chap4 and [Sta]Chap53. In this section, properties to morphisms of relative dimension≤ 1 are studied.

Notation (5.11.0.1).

- Use notations defined in Cohomology of Schemes.
- Use notations defined in Varieties.

1 Basics

Def. (5.11.1.1) [Rational Curve]. A **rational curve** over a field k is a curve that is birational to $\mathbb{P}^1_k$.

Lemma (5.11.1.2). If X is an integral separated scheme and $U\subset X$ is an non-empty affine open that $X\backslash U$ is a finite set of points with $\mathcal{O}_{X,x_i}$ Noetherian of dimension 1, then there exists a base-point free invertible sheaf $\mathcal{L}\in\mathrm{Pic}(X)$ and a section s s.t. $U=X_s$.

Proof: Cf.[Sta]09NB. □

Prop. (5.11.1.3). A Noetherian separated scheme of dimension≤ 1 has an ample invertible sheaf.

Proof: First reduce to the case when X_{red}, because(5.11.2.19) shows any invertible sheaf on X_{red} is a pullback of a sheaf of X and(5.5.4.15) shows this sheaf is ample.

Second we reduce to the case X is integral. Let X_i are the integral irreducible components of Z, Cf.[Sta]09NX**?**

Finally, for X integral, the assertion follows from(5.11.1.2) and(5.5.4.10). □

Cor. (5.11.1.4) [Complete Precurves are Projective]. A separated algebraic scheme X of dimension 1 over a field k is H-(quasi)projective, by(5.11.1.3) and(5.5.4.22). If X is proper, then it is projective.

Prop. (5.11.1.5) [Completion of Curves]. For a separated algebraic k-scheme X of dimension≤ 1, there is an open immersion $j:X\to\overline{X}$ that

- $\overline{X}$ is projective over k.
- $j(X)\subset\overline{X}$ is dense and schematically dense open subscheme.
- $\overline{X}\backslash X$ consists of f.m. closed points $\{x_i\}$ of $\overline{X}$.

This $\underline{X}$ is called a **completion curve** of X. And when X is reduced, the stalk at x_i are DVRs. In particular, it is non-singular if X is non-singular.

Proof: By(5.11.1.3), we can assume X is a locally closed subscheme of $\mathbb{P}^n_k$. Let $\overline{X}$ be the scheme theoretic image(5.4.4.62) of the inclusion, then $1,2$ holds by(5.4.4.70). 3 holds because $\overline{X}\backslash X$ is Noetherian of dimension 0.

For the last assertion, Cf.[Sta]0BXW. □

Cor. (5.11.1.6). A morphism of prevarieties $X\to Y$ with X a precurve(thus reduced) and Y proper over a field k factors through the completion $\overline{X}$ of X by(5.4.5.14). In particular, the completion curves of X are unique.

Prop. (5.11.1.7) [Affine or Projective]. A precurve over a field k is either affine(not proper) or H-projective(proper).

Proof: Cf.[Sta]0A27**?**, (Hard). ☐

Cor. (5.11.1.8). Let X be a separated scheme algebraic over a field k. If $\dim X \leq 1$ and no irreducible component of X is proper of dimension 1, then X is affine.

Proof: Let X_i be f.m. irreducible components of X, then they are precurves in the induced reduced structure, so they are affine by(5.11.1.7). Now $\coprod X_i \to X$ is a finite surjective morphism, so X is affine by(5.4.4.36). ☐

Prop. (5.11.1.9). A map from a proper connected scheme to a precurve is either constant or surjective.

Proof: Because the closed subset of a precurve is either itself or f.m. closed points. ☐

Prop. (5.11.1.10)[Constant or Finite]. Let $f : X \to Y$ be a morphism of schemes over a field k that Y is separated and X is proper of dimension ≤ 1. If the image of every irreducible component of X is not a pt, then f is finite. If Y is a precurve, then it is moreover surjective.

Proof: Cf.[Sta]0CCL.**?** ☐

Def. (5.11.1.11)[Separable Morphisms]. Let $f : X \to Y$ be a non-constant morphism of precurves, then f is finite surjective by(5.11.1.10). so $\deg(f)$ is finite(5.4.4.55), and we can define separable/purely separable morphisms as in(5.4.4.55).

Non-Singular Curves

Def. (5.11.1.12) [Uniformizer]. Let C be a precurve over a field k, then the local rings of C at a non-singular closed point p is a DVR by(10.3.3.4). Then an element $t \in K(C)$ with valuation 1 is called a **uniformizer at** p.

Prop. (5.11.1.13). Let C be a precurve over a field K, and $t \in K(C)$ is a uniformizer at some non-singular point, then $K(C)$ is a finite separable extension of the subfield generated by t.

Proof: $K(C)$ is a finite extension of $K(t)$, because $\operatorname{tr.deg}(K(C)/K) = 1$ and t is not algebraic over K by valuation reasons. Then it suffices to show for any $x \in K(C)$, x is separable over $K(t)$. Let $\Phi(X,T) = \sum a_{ij}T^iX^j$ be a minimal polynomial of x over $K(T)$. It is separable iff for some $(j,p) = 1$ and some i, $a_{ij} \neq 0$. If it is not separable then we can write $\Phi(X,T) = \sum_{k=0}^{p-1}\varphi_k(X,T)^pT^k$. But each $\varphi_k(x,t)^pt^k$ has distinct valuations, unless they are all zero, contradicting the fact Φ is a minimal polynomial. ☐

Prop. (5.11.1.14)[Non-singular Complete Precurves and DVRs]. Let C be a non-singular complete precurve, then all valuation rings of $K(C)$ containing k are DVRs, and the set of closed points of C correspond to the set of DVRs in $K(C)$ containing k, which is denoted by $\Sigma^0_{K(C)}$.

Proof: This is a consequence of the valuation criterion(5.4.5.13). Notice that the local rings of C at closed points are all DVRs(10.3.3.4), thus they must equal to the valuation ring given. ☐

Prop. (5.11.1.15)[Extension of Rational Maps]. Rational map from a non-singular precurve to a complete prevariety is the same as a morphism, by(5.4.5.15).

Cor. (5.11.1.16). Two birationally equivalent normal proper precurves over a field is isomorphic.

Thus if a normal precurve is birationally equivalent to another normal complete curve, then it is an open immersion, by(5.11.1.5).

Prop. (5.11.1.17) [Category of Non-singular Projective Precurves]. Let k be a field, the following categories are equivalent:

1. The opposite category of f.g. field extensions of k of trans.deg 1 with injective k-homomorphisms.
2. The category of precurves and dominant rational maps.
3. The category of normal complete precurves over k with non-constant morphisms.
4. The category of non-singular projective precurves over k with non-constant morphisms.

Proof: 1 and 2 are equivalent by(5.10.3.2).

3 and 4 are equivalent by(5.11.1.7) and the fact normal and regular are the same(5.4.2.11).

For the rest, Cf.[Sta]0BY1.**?** □

Cor. (5.11.1.18) [Non-singular Projective Model]. Comparing this and(5.10.3.2), we see that every precurve over k is birational to a unique non-singular proper precurve over k with the same function field, which is called the **non-singular projective model**.

Prop. (5.11.1.19) [Flatness and Associated Points]. $f : X \to Y$ with Y integral and regular of dimension 1. Then f is flat iff every associated prime of X is mapped to the generic point of Y.

In particular when X is reduced, this is equivalent to every irreducible component of X dominants Y, by(4.2.5.25).

Proof: If x is mapped to a closed pt of Y, then $\mathcal{O}_{y,Y}$ is a DVR, let t be a uniformizer, then t is not a zero-divisor, and $f^\sharp(t) \in \mathfrak{m}_x$ is also not a zero-divisor. So x is not an associated point.

Conversely, to show f is flat, if y is the generic point, then $\mathcal{O}_{y,Y}$ is a field, so it is flat. When y is a closed pt, $\mathcal{O}_{y,Y}$ is a DVR, so by(4.4.1.11), we need to show that it is torsion free. If it is not, then $f^\sharp(t)$ must be a zero-divisor for a uniformizer t of $\mathcal{O}_{y,Y}$. But then it is contained in some associated prime p of $\mathcal{O}_{x,X}$(4.2.5.17). Now p is mapped to y, which is a contradiction. □

Cor. (5.11.1.20) [Morphism to a Non-singular Curve is Flat]. If $f : X \to Y$ is a dominant morphism from a prevariety to a non-singular curve over k, then f is flat.

Cor. (5.11.1.21) [Flat Specializations along Curves]. Let Y be integral and regular of dimension 1 and P a closed pt. X is a closed subscheme in $\mathbb{P}^n_{Y-P}$ that is flat over $Y - P$, then there is a unique closed subscheme $\overline{X}$ closed in $\mathbb{P}^n_Y$ that is flat over Y and restrict to X on $\mathbb{P}^n_{Y-P}$.

Proof: Choose the scheme-theoretic closure of X in $\mathbb{P}^n_Y$. Cf.[Hartshorne P258]. □

Cor. (5.11.1.22) [Finite Flatness]. Any non-constant morphism from a precurve to a nonsingular precurve is finite locally free, by(5.11.1.19) and(5.11.1.10).

Prop. (5.11.1.23). A projective non-degenerate non-singular curve of degree d in $\mathbb{P}^n_k$ is isomorphic to the n-tuple embedding, and $d = n$.

This has easy generalizations to surfaces and higher dimensions.

Proof: (5.5.3.16)shows $\mathcal{O}_X(1) \cong \mathcal{O}(d)$ over $\mathbb{P}^1_k$, and the restriction of global sections is injective. So the global section is an isomorphism, and it defines the embedding up to a linear automorphism. □

Prop. (5.11.1.24) [Genera Equal]. For a complete smooth curve X over a field k,

$$p_a(X) = p_g(X) = \dim_k H^1(X, \mathcal{O}_X)$$

by Serre duality(5.8.6.19) and(5.10.1.18)(5.7.3.6).

So from now on we use genus to denote the arithmetic genus.

Cor. (5.11.1.25) [Topological Genus]. By GAGA, for a complex complete smooth curve, the genus also equals the topological genus.

Morphisms Between Non-singular Curves

Prop. (5.11.1.26) [Degree and Analytic Degree]. Let $f : C \to C'$ be a non-constant morphism between smooth complex curves, then the degree defined in(5.4.4.55) is the same as the degree as map of Riemann surfaces.

Proof: This is because the map is finite locally free(5.11.1.22), thus for an affine open subset $U = \operatorname{Spec} A$ of C', the $f^{-1}(U) = \operatorname{Spec} B$ where $B \cong A^{\otimes n}$ as A-modules, where n is the degree. Then clearly for most $x \in U$, $\sharp f^{-1}(x) = n$(look at the minimal polynomial of a family of generators for B over A). □

Def. (5.11.1.27) [Ramification Degrees]. Let $f : X \to Y$ be a morphism of non-singular precurves over a field k, let $P \in X$ be a closed point and $f(P) = Q$. Because the local rings are DVRs, we define the **ramification degree** $e_P(f)$ where $f^\sharp(\mathfrak{m}_Q)\mathcal{O}_{X,P} = \mathfrak{m}_P^{e_P(f)}$.

f is called **weakly unramified at** P if $e_P(f) = 1$, and it is called **unramified at** P if moreover $\kappa(P)/\kappa(f(P))$ is separable. f is called **tamely unramified at** P if**?**

Notice that unramifiedness just means the morphism is unramified, by(5.6.5.8) and(5.11.1.22).

Prop. (5.11.1.28). Let $f : X \to Y$ be a non-constant morphism of non-singular precurves over a field k, then

- If $g : Y \to X$ be another morphism of non-singular precurves, then for any $P_1 \in X$, $e_P(g \circ f) = e_P(f)e_{f(P)}(g)$.
- for any closed point $Q \in C_2$, $\sum_{P \in f^{-1}(Q)} e_P(f)[k(P) : k(Q)] = \deg(f)$.
- If k is alg.closed, then for a.e. closed point $Q \in C_2$, $\# f^{-1}(Q) = \deg_s(f)$.

Proof: 1: Trivial.

2: This follows from(5.11.1.44).

3: This follows from(5.10.3.4). □

Prop. (5.11.1.29). If $f : X \to Y$ is a non-constant morphism of percurves over a field k s.t. X is smooth and Y is non-singular, then Y is also smooth, by(5.1.5.28).

Prop. (5.11.1.30). Let X be a smooth curve over a field k, $x \in X$ and $\overline{x} \in X_{\overline{k}}$ is a point mapping to x, then the ramification degree of $\mathcal{O}_{X,x} \subset \mathcal{O}_{X_{\overline{k}},\overline{x}}$ equals the inseparable degree of $k(x)/k$.

Proof: By(5.6.6.7), we can find a étalemap $X \to \mathbb{A}^1_k$, which has ramification degree 1 and separable, so we may assume $X = \mathbb{A}^1_k$. Then the assertion is clear. □

Prop. (5.11.1.31) [Separable Morphisms]. Let $f : X \to Y$ be a morphism of smooth curves over k, then the following are equivalent:

1. f is finite separable.
2. $df^*: f^*\Omega_{Y/k} \to \Omega_{X/k}$ is non-zero.
3. $\Omega_{X/Y}$ is supported on a proper closed subscheme of X.
4. There exists a non-empty open subset $U \subset X$ s.t. f is unramified.
5. There exists a non-empty open subset $U \subset X$ s.t. f is étale.

Proof: As X, Y are smooth, $\Omega_{X/k}, \Omega_{Y/k}$ are invertible sheaves, and the exact sequence

$$f^*\Omega_{Y/k} \to \Omega_{X/k} \to \Omega_{X/Y} \to 0$$

shows 2, 3 are both equivalent to $\Omega_{X/Y,\xi} = 0$.

3, 4, 5 are equivalent as f is automatically flat(5.11.1.20).

1, 5 are equivalent by(5.6.5.9). □

Prop. (5.11.1.32) [Riemann-Hurewitz for Separable Maps]. If $f : X \to Y$ is a non-constant separable map between two complete smooth curves over a field k, then

$$2g_X - 2 = \deg(f)(2g_Y - 2) + \sum_{x\in X} d_x[\kappa(x) : k],$$

where $d_x = \mathrm{length}_{\mathcal{O}_{X,x}}(\Omega_{X/Y,x}) \geq 0$ satisfies $d_x \geq e_x(f) - 1$, and equality holds iff f is tamely unramified at P.

Proof: By(5.8.7.12), in this case the vanishing locus R of df^* is an effective Cartier divisor, and $f^*\mathcal{K}_{Y/k} \otimes \mathcal{O}(R) \cong \mathcal{K}_{X/k}$, so by(5.11.2.10)(5.11.2.3)(5.11.2.7),

$$2g_X - 2 = \deg(\mathcal{K}_{X/k}) = \deg(f^*\mathcal{K}_{Y/k} \otimes \mathcal{O}(R)) = \deg(f)\deg(\mathcal{K}_{Y/k}) + \deg(R) = \deg(f)(2g_Y - 2) + \deg(R).$$

For analysis of d_x, Cf.[Sta]0C1F.**?** □

Cor. (5.11.1.33). The only geo.integral unramified finite covering of $\mathbb{P}^1_k$ is itself.

Thm. (5.11.1.34) [De Franchis]. Let $k \in$ `Field` and C, C' are two complete smooth curves over k. Then if $g(C) \geq 2$, there are only f.m. non-constant maps $C' \to C$.

In particular, $\# \mathrm{Aut}(C) < \infty$.

Proof: We prove for $k = \mathbb{C}$**?** Cf.[Mil08]P146.

Any automorphism of C fixes its set of Weierstrass sets, which is finite, so we only need to consider the case that it fixes all Weierstrass points.

If C is hyperelliptic, consider a hyperelliptic map, this covering has an involution of C, and this is just $C \mapsto C/\tau$. So modulo τ, it suffices to show $\mathbb{P}^1$ has f.m. automorphisms fixing the branch points. But this is true, as $2g + 2 > 3$.

If C is non-hyperelliptic, then there are more than $2g + 2$ Weierstrass points. But we can find a function f on C with $g + 1$ zeros and poles, by Riemann-Roch, then for an automorphism φ of C, $f - \varphi^* f$ has no more than $2g + 2$ poles, so also has no more than $2g + 2$ zeros. But φ fixes all Weierstrass points, so it has more than $2g + 2$ zeros, contradiction. □

Prop. (5.11.1.35)[Hurewitz's Automorphism Theorem]. If C is a complete smooth curve of genus $g \geq 2$ over a field of characteristic 0, then $\# \mathrm{Aut}(C) \leq 84(g - 1)$.

Proof: We may pass to the alg.closure. By(5.11.1.34), $\#\operatorname{Aut}(C)<\infty$. In fact, let G be a finite group acting on C, let C' be the non-singular precurve corresponding to C', then by(2.2.7.5), $C\to C'$ is a Galois cover with Galois group G. Now by Dedekind extension theory, G acts transitively on the preimage of a given point. Suppose there are n branched points with ramification degrees r_i, then by Riemann-Hurewitz(5.11.1.32)(notice in this case it is tamely unramified):

$$(2g-2)=|G|(2g(C')-2+\sum_{i=1}^n\frac{r_i-1}{r_i}).$$

Then a combinatorial argument shows the maximal possible $|G|$ is obtained when $g(C')=0,n=3$ and $(r_1,r_2,r_3)=(2,3,7)$. □

Remark (5.11.1.36). In the case $\operatorname{char}k\neq 0$, there may be more automorphisms. For example, if $p\in\mathbf{P}\backslash\{2\}$, the completion of the affine curve $y^{p^n}=x+x^{p^n+1}$ has genus $g=p^n(p^n-1)/12$ and $\#\operatorname{Aut}(C)=p^{3n}(p^{3n}+1)(p^{2n}-1)$, Cf.[H.Stichtenoth,U¨berdieAutomorphismengruppeeinesal-gebraischenFunktionenko¨rpersvon Primzahlcharakteristik. I. Eine Abscha¨tzung der Ordnung der Automorphismengruppe, Arch. Math. (Basel) 24 (1973), 527–544.].

Prop. (5.11.1.37) [Frobenius Map]. Let C be a smooth curve over a field k of characteristic p, and $C\xrightarrow{F_{X/k,r}}C^{(r)}$ be the Frobenius, where $C^{(r)}=C\otimes_{k,\mathrm{Frob}^r}k$, then $F_{X/k,r}$ is purely inseparable, and $\deg(F_{X/k,r})=p^r$. And it is a topological homeomorphism by(4.1.7.26).

Proof: To show inseparability, we can base change to $\overline{k}$, then the field map is $f/g\mapsto f(\underline{X}^{p^r})/g(\underline{X}^{p^r})$, which is just $K(C_{\overline{k}})^{p^r}$, so purely inseparable of degree p^r. □

Prop. (5.11.1.38) [Inseparable Decomposition]. Let k be a field of characteristic $p>0$. If C_1 is a smooth complete precurve, then any map of non-singular complete precurves $f:C_1\to C_2$ over k factors as

$$C_1\xrightarrow{F_{X/k,r}}C_1^{(r)}\xrightarrow{\lambda}C_2$$

where $C_1^{(r)}=C_1\otimes_{k,\mathrm{Frob}^r}k$, and λ is separable.

Proof: By(5.11.1.17), it suffices to show any inseparable morphism is a Frobenius. It suffices to show that any subfield of $K(X)$ of index p equals $K(X^{(1)})=kK(X)^p$. For this, Cf.[Sta]0CCY**?**. □

Cor. (5.11.1.39). If $C\to C'$ is a non-constant separable map between complete smooth curves, then $g(C)\geq g(C')$.

Proof: This follows from(5.11.1.38)(5.11.1.32) and the fact $C_1^{(r)}$ is smooth and have the same genus as C_1 by flat base change. □

Divisors on Curves

Def. (5.11.1.40)[Divisors on Curves]. If X is a locally algebraic integral scheme of dimension 1 over an alg.closed field, then a Weil divisor on X are just a locally finite formal sum of closed pts.

If X is integral algebraic over a field k of dimension 1, then the sum is in fact finite, we we can define the **degree** of a Weil divisor $D=\sum n_PP$ as $\deg(D)=\sum n_P[k(P):k]$.

Similarly, for a Cartier divisor D on X, the **degree of** D is defined to be $\dim_k\Gamma(D,\mathcal{O}_D)$. By(7.1.5.1), a Cartier Divisor on X is equivalent to an effective Weil divisor, and the definition of degrees are compatible.

Cor. (5.11.1.41) [Non-singular Case]. As a nonsingular precurve C is locally factorial, (5.5.3.15) shows in this case a line bundles on $\mathcal{C}$ is equivalent to a Weil divisor on C.

Prop. (5.11.1.42) [Pullback of Divisor]. For a non-constant morphism f between two non-singular curves over alg.closed field, e.g. dominant morphism between complete non-singular curves, $\deg f^*D = \deg f \cdot \deg D$. This is because f is finite locally free(5.11.1.22), thus this follows from [Sta]02RH**?**.

Prop. (5.11.1.43). An element $\notin k$ in the function fields of a projective non-singular curve over an alg.closed k defines a inclusion $k(f) \subset K(X)$ thus a morphism from X to P^1_k(5.10.3.2), and $(f) = \varphi^*(\{0\} - \{\infty\})$.

Prop. (5.11.1.44). Let $\pi : C \to C'$ be a non-constant separable morphism of precurves over a field k that C' is nonsingular, $p \in C'$ is a closed point, then π is finite locally free by(5.11.1.22), and

- $\pi^{-1}(p) \subset C$ is a dimension 0 scheme.
- $\dim_k(\Gamma(\pi^{-1}(p))) = (\deg \pi)(\deg p)$.
- Let ϖ be a uniformizer of the DVR $\mathcal{O}_{C',p}$, then

$$\deg \pi = \sum_{x\in\pi^{-1}(p)} [k(x) : k(p)] \operatorname{ord}_{\mathcal{O}_{C,x}}(f^*\varpi).$$

Proof: Look affine locally, then these follow from the fundamental identity(4.2.7.21). □

Prop. (5.11.1.45). For a 1-dimensional integral scheme $c : X \to k$ proper over a field k and a function $f \in K(X)^*$,

$$\sum_{x \text{ closed}} [k(x) : k]\operatorname{ord}_{\mathcal{O}_{X,x}}(f) = 0.$$

In other words, the number of zeros of f equals the number of poles of f.

Proof: It suffices to show that the pushforward $c_* \operatorname{div}(f) = 0 \in \mathrm{CH}_0(\operatorname{Spec} k)$. consider Y the closure of the graph of f in $X \times \mathbb{P}^1_k$, then there is a commutative diagram

$$\begin{array}{ccc} Y & \xrightarrow{\mathrm{pr}_1} & X \\ \downarrow{\scriptstyle \mathrm{pr}_2} & & \downarrow{\scriptstyle c} \\ \mathbb{P}^1_k & \xrightarrow{c'} & \operatorname{Spec} k \end{array},$$

and $\operatorname{div}_X(f) = \mathrm{pr}_{1*} \operatorname{div}_Y(f)$ by(7.1.2.22). We may assume f is not constant, then pr_2 is finite locally free of degree d, and $\operatorname{div}_Y(f) = \mathrm{pr}_2^*([(0)] - [(\infty)])$, so $\mathrm{pr}_{2*} \operatorname{div}_Y(f) = d([(0)] - [(\infty)])$ is mapped to $0 \in \mathrm{CH}_0(\operatorname{Spec} k)$. □

2 Vector Bundles

Degrees and Riemann-Roch

Def. (5.11.2.1) [Degrees]. The **degree of a locally free sheaf** $\mathcal{E}$ of rank n on a proper scheme X of dimension≤ 1 over a field k is defined to be $\deg(\mathcal{E}) = \chi(X, \mathcal{E}) - n\chi(\mathcal{O}_X)$(5.7.3.1).

If X is integral(e.g. a complete precurve), this definition can extends to any coherent sheaves $\mathcal{F}$, if we define $\operatorname{rank}(\mathcal{F}) = \dim_{k(\eta)} \mathcal{F}_\eta$.

Prop. (5.11.2.2). The degree function is additive, stable under base change of fields, and stable under birational equivalence of proper scheme X of dimension 1 over a field k.

Proof: The base change follows from flat base change(5.7.5.1), the additivity follows from the additivity of rank and Euler characteristic(5.7.3.1).

For the birational equivalence, If $f: X \to Y$ is a birational map between proper schemes of dimension≤ 1 over k, then f is proper with finite fibres, so f is finite(5.4.5.5), thus for any $\mathcal{E} \in \mathfrak{QCoh}^{\mathrm{free},n}(Y)$, $f_*f^*\mathcal{E} = \mathcal{E} \otimes_{\mathcal{O}_Y} f_*\mathcal{O}_X$, and there is an exact sequence

$$0 \to \mathcal{K} \to \mathcal{O}_Y \to f_*\mathcal{O}_X \to \mathcal{Q} \to 0$$

where $\mathcal{K}, \mathcal{Q}$ are coherent sheaves on Y with supported dimension0. Then by(5.7.3.5) and(5.7.3.3),

$$\begin{aligned}\chi(Y,\mathcal{E}) - \chi(X, f^*\mathcal{E}) &= \chi(Y,\mathcal{E}) - \chi(Y, f_*f^*\mathcal{E})\\ &= \chi(Y, \mathcal{K}\otimes\mathcal{E}) - \chi(Y,\mathcal{Q}\otimes E)\\ &= n\chi(Y,\mathcal{K}) - n\chi(Y,\mathcal{Q})\\ &= n\chi(Y,\mathcal{O}_Y) - n\chi(X,\mathcal{O}_X)\end{aligned}$$

□

Prop. (5.11.2.3) [Non-reduced Riemann-Roch]. If X is a proper scheme over a field k of dimension≤ 1 with integral components C_i of X of dimension1 with generic points $\eta_1, \ldots, \eta_r$ and multiplicity m_i, and $\mathcal{E} \in \mathcal{V}\mathrm{ect}^n(C), \mathcal{F} \in \mathfrak{Coh}(C)$, then

$$\chi(\mathcal{E}\otimes\mathcal{F}) = \sum_i (\mathrm{length}_{\mathcal{O}_{X,\eta_i}} \mathcal{F}_{\eta_i}) \deg(\mathcal{E}|_{C_i}) + n\chi(\mathcal{F}).$$

Proof: We use dévissage(5.5.1.55), the condition1 are true by additivity of χ, and for condition2, take $\mathcal{G} = i_*\mathcal{O}_Z$, the equation holds by(5.7.3.5) and projection formula. □

Cor. (5.11.2.4). Let X be a proper scheme of dimension≤ 1 over a field k, and C_i are the irreducible components of X of dimension1 with the induced reduced structure and multiplicity m_i, then for $\mathcal{E} \in \mathfrak{Coh}^{\mathrm{free}}(X)$,

$$\deg(\mathcal{E}) = \sum m_i \deg(\mathcal{E}|_{C_i}).$$

Cor. (5.11.2.5). Let X be a proper scheme of dimension≤ 1 over a field k, then

- If $\mathcal{E} \in \mathfrak{Coh}^{\mathrm{free},m}(X), \mathcal{F} \in \mathfrak{Coh}^{\mathrm{free},n}(X)$, then $\deg(\mathcal{E}\otimes\mathcal{F}) = m\deg(\mathcal{F}) + n\deg(\mathcal{E})$.
- If $\mathcal{L}, \mathcal{M} \in \mathrm{Pic}(X)$, then $\deg(\mathcal{L}\otimes\mathcal{M}) = \deg(\mathcal{L}) + \deg(\mathcal{M})$.
- If $\mathcal{L} \in \mathrm{Pic}(X)$, $\deg(\mathcal{L}) = -\deg(\mathcal{L}^{-1})$.
- If $\mathcal{E} \in \mathfrak{Coh}^{\mathrm{free}}(X)$, $\deg(\mathcal{E}) = \deg(\wedge\mathcal{E})$.

Proof: By(5.11.2.4), we can assume X is integral. Then $1, 2$ follow from(5.11.2.3), and 3 follows from the fact there is a modification $X' \to X$ s.t. $f^*\mathcal{E}$ has a filtration with invertible sheaves $\mathcal{L}_i$ as quotients(5.5.1.30). Then by(5.11.2.2), we can work on X'. Then $\deg(\mathcal{E}) = \otimes_i\mathcal{L}_i$, and the assertion follows from additivity and(5.11.2.3). □

Prop. (5.11.2.6). If D is an effective Cartier divisor on a proper scheme of dimension≤ 1 on a field k, then for $\mathcal{E} \in \mathfrak{Coh}^{\mathrm{free},n}(X)$,

$$\deg(\mathcal{E}(D)) = n\dim_k\deg(D) + \deg(\mathcal{E})$$

In particular, $\deg(\mathcal{L}(D)) = \deg(D)$.

Proof: By(5.8.1.2), D is nowhere dense in X, thus D is finite over k, and there is an exact sequence

$$0 \to \mathcal{E} \to \mathcal{E}(D) \to \mathcal{E}(D)|_D \to 0.$$

So the assertion follows from(5.7.3.5). □

Prop. (5.11.2.7). Let $f : X \to Y$ be a non-constant map of complete precurves over a field k and $\mathcal{E} \in \mathfrak{Coh}^{\mathrm{free}}(Y)$, then $\deg(f^*\mathcal{E}) = \deg(f)\deg(\mathcal{E})$.

Proof: By(5.11.1.10) and(5.11.2.3),

$$\chi(X, f^*\mathcal{E}) = \chi(Y, \mathcal{E} \otimes f_*\mathcal{O}_X) = \deg(f)\deg(\mathcal{E}) + \mathrm{rank}(\mathcal{E})\chi(X, \mathcal{O}_X).$$

□

Prop. (5.11.2.8)[Degree and Sections]. Let C be a complete precurve over a field k and $\mathcal{L} \in \mathrm{Pic}(C)$, then

- If $\mathcal{L}$ has a non-zero section, then $\deg(\mathcal{L}) \geq 0$.
- If $\mathcal{L}$ has a non-zero section that vanishes at some point, then $\deg(\mathcal{L}) \geq 1$.
- If both $\mathcal{L}, \mathcal{L}^{-1}$ have non-zero sections, then $\mathcal{L} \cong \mathcal{O}_X$.
- If $\deg(\mathcal{L}) \leq 0$ and $\mathcal{L}$ has a non-zero section, then $\mathcal{L} \cong \mathcal{O}_X$.
- If $\mathcal{N} \to \mathcal{L}$ is a non-zero map of invertible sheaves, then $\deg(\mathcal{L}) \geq \deg(\mathcal{N})$, with equality iff this is an isomorphism.

Proof: If s is a section of $\mathcal{L}$ with vanishing locus D, then D is an effective Cartier divisor and $\mathcal{L} \cong \mathcal{L}(D)$, so $\deg(\mathcal{L}) = \deg(D)$ by(5.11.2.6), so these are all simple now. □

Prop. (5.11.2.9) [Riemann-Roch]. Let D be a Weil divisor on a complete non-singular precurve X of genus g, then

- If $l(D) = \dim_k H^0(X, \mathcal{L}(D))$, $l(D)$ is finite by(5.7.4.11).
- $[\omega_X]$ is an invertible sheaf by [Sta]0BFQ**?**.
- $l(D) - l([\omega_X] - D) = \deg D + 1 - g$.
- $\deg(D) = \deg(\mathcal{L}(D))$

Notice when X is smooth, $[\omega_X]$ is just $\mathcal{K}_X$(5.8.6.18).

Proof: 4 is equivalent to 3 by Serre duality(5.8.6.18), and 3 follows from(5.11.2.6). □

Cor. (5.11.2.10). $\deg([\omega_C]) = 2g - 2$.

Proof: By(5.11.2.9) and Serre-duality(5.8.6.18),

$$\deg([\omega_C]) = h^0(X, [\omega_X]) - h^0(X, \mathcal{O}_X) + g - 1 = h^1(X, \mathcal{O}_X) - h^0(X, \mathcal{O}_X) + g - 1 = 2g - 2.$$

□

Prop. (5.11.2.11)[Twisting Sheaves]. Let $\mathcal{L}$ be a line bundle on a complete nonsingular precurve C, and $p \in C$ is a closed point of degree d, then $0 \leq h^0(\mathcal{L}) - h^0(\mathcal{L}(-p)) \leq d$ for any $\mathcal{L} \in \mathrm{Pic}(C)$.

In particular, by(5.11.2.8), if C is a complete non-singular curve, then $h^0(\mathcal{L}) \leq \deg L + 1$ for any $\mathcal{L} \in \mathrm{Pic}(C)$.

Proof: There is an exact sequence $0 \to \mathcal{O}_C(-p) \to \mathcal{O}_C \to \mathcal{O}_C|_p \to 0$, tensoring with $\mathcal{L}$ and take the cohomology, we get an exact sequence $0 \to h^0(\mathcal{L}, \mathcal{L}(-p)) \to h^0(\mathcal{L}, \mathcal{L}) \to H^0(C, \mathcal{L}|_p)$, and notice that $h^0(C, \mathcal{L}|_p) = d$. □

Prop. (5.11.2.12)[Riemann-Roch for High Degree D]. If $\deg(D) \geq 2g-1$, then $\deg([\omega_X]-D) < 0$, so by(5.11.2.8), $l([\omega_X] - D) = 0$, thus $l(D) = d - g + 1$.

Cor. (5.11.2.13) [Characterizing $[\omega_C]$]. Any degree $2g-2$ divisor D satisfies $l(D) = g-1$ or g, and the latter case happens iff $D = [\omega_C]$.

Proof: $l([\omega_C] - D) = 1$ iff $[\omega_C] = D$ by(5.11.2.8). □

Def. (5.11.2.14) [Special Divisors]. A **special divisor** on a complete non-singular curve is a divisor D that $h^0([\omega_C] - D) > 0$.

Prop. (5.11.2.15). For any complete smooth curve C of genus $g > 1$ over a field k, there is a closed point on C of degree$\leq 2g-2$. And if $g \geq 2$, we can assume this point is a geometric point.

Proof: The canonical sheaf $\mathcal{K}_C$ is a line bundle of degree $2g-2$ and $h^0(\mathcal{K}_C) = g \geq 1$, so we can assume $\mathcal{K}_C$ is an effective divisor, then one of its support point has degree$\leq 2g-2$.

For the last assertion, Cf.[Sta]0CD4. □

Vector Bundles

Prop. (5.11.2.16) [Torsion-Free Sheaves]. Let C be a non-singular precurves over a field k, then

- Any torsion-free coherent sheaf $\mathcal{F}$ on C is locally free.
- Any $\mathcal{F} \in \mathfrak{Coh}(X)$ factors as $0 \to \mathcal{F}_{\text{tor}} \to \mathcal{F} \to \mathcal{F}_{\text{lf}} \to 0$, where $\mathcal{F}$ is a torsion sheaf(5.5.1.44) and $\mathcal{F}_{\text{lf}}$ is Qco and locally free, by(5.5.1.47)

Proof: □

Prop. (5.11.2.17)[$\mathrm{Pic}^0(C)$]. For a smooth complete curve C over a field k with a rational point, $\mathrm{Pic}^0(C)$ are exactly the set of line bundles of degree 0, by(13.5.13.1). In particular, there is an exact sequence

$$0 \to \mathrm{Pic}^0(C) \to \mathrm{Pic}(C) \to \mathbb{Z} \to 0.$$

Prop. (5.11.2.18)[Torsion Elements]. Let C be a smooth complete curve of genus g over an alg.closed field, then for $m \in \mathbb{Z} \cap k^*$, $\mathrm{Pic}(C)[m] = \mathrm{Pic}^0(C) \cong (\mathbb{Z}/(m))^{2g}$.

Proof: This follows from(13.5.13.1)(5.11.2.17) and(13.5.6.14). □

Prop. (5.11.2.19). If $Z \to X$ is a closed immersion and $\dim X \leq 1$, then $\mathrm{Pic}\, X \to \mathrm{Pic}\, Z$ is a surjection.

Proof: Use the exact sequence $0 \to (1 + \mathcal{I}) \cap \mathcal{O}_X^* \to \mathcal{O}_X^* \to i_*\mathcal{O}_Z^* \to 0$, $\dim X \leq 1$ and the Grothendieck vanishing theorem gives the desired result, also notice i is affine. □

Ample Line Bundles

Prop. (5.11.2.20). A line bundle $\mathcal{L}$ over a complete precurve C over a field k is ample iff $\deg(\mathcal{L}) > 0$.

Proof: If C is non-singular, the proof is easy: $\mathcal{L}$ is ample iff $\mathcal{L}^{\otimes n}$ is very ample for n large(5.5.4.22). If $\deg(\mathcal{L}) < 0$, this cannot happen, by(5.11.2.8). For $\deg L \geq 0$, $\mathcal{L}^{\otimes n}$ is very ample for n large by(5.11.2.26).

In general, Cf.[Sta]0B5X**?** □

Cor. (5.11.2.21) [Ample and Nef Line Bundles]. Let $\mathcal{L}$ be an invertible $\mathcal{O}_X$-module over a proper scheme of dimension≤ 1 over k, let C_i be the integral components of X of dimension 1, then $\mathcal{L}$ is a ample iff $\deg(\mathcal{L}|_{C_i}) > 0$ for all i.

Proof: This follows from(5.5.4.14) applied to the reduced structure of the irreducible components of X, together with the fact a line bundle on an irreducible component $\operatorname{Spec} k(x)$ of dimension 0 is obviously ample. □

Prop. (5.11.2.22). Let $\mathcal{L}$ be a line bundle on a complete non-singular precurve C of degree d that is basepoint-free, then it determines a morphism $\pi : C \to \mathbb{P}^1_k$ of degree d.

Proof: This follows from(5.11.1.44). □

Prop. (5.11.2.23). Let C be a complete precurve over a field k with genus $g > 0$, and p, q are rational points on C, then $\mathcal{O}_C(p) \cong \mathcal{O}_C(q)$ iff $p = q$, and $h^0(C, \mathcal{O}_C(p)) = 1$.

Proof: The hypothesis shows $\mathcal{L} = \mathcal{O}_C(p)$ has degree 1 and is basepoint-free, thus defines a degree 1 map $C \to \mathbb{P}^1_k$, which is an isomorphism, by(5.11.1.15) and(5.11.1.17), contradiction.

If $h^0(C, \mathcal{O}_C(p)) \geq 2$, then for any section s, $\operatorname{div}(s) = q$ for some rational point q, so by the above argument, $q = p$, so any two such f is proportional. □

Prop. (5.11.2.24). Let C be a complete curve over a field k with genus $g > 0$, and $\mathcal{L}$ is a line bundle of degree 2, then $h^0(C, \mathcal{L}) \leq 2$, and if the equality holds, then it is basepoint-free.

Proof: We can base change to $\overline{k}$. $h^0(C, \mathcal{L}) \leq 3$ by(5.11.2.11). If equality holds, then then $h^0(C, \mathcal{L}(-p)) = 2$ for some p, contradiction by(5.11.2.23). If $h^0(C, \mathcal{L}) = 2$, then $h^0(C, \mathcal{L}(-p)) < 2$ for any p, so it is basepoint-free. Conversely, if it is basepoint free, then $\mathcal{L} \cong \mathcal{O}(p)$ for some rational point p, and $h^0(C, \mathcal{L}) = h^0(C, \mathcal{O}_C) + 1 = 2$. □

Prop. (5.11.2.25) [Criterion of Very Ampleness]. Let $\mathcal{L}$ be a line bundle on a curve over an alg.closed field k, then

- $\mathcal{L}$ is basepoint-free iff $h^0(\mathcal{L}) - h^0(\mathcal{L} - p) = 1$ for any closed point $p \in \mathcal{L}$.
- $\mathcal{L}$ is very ample iff $h^0(\mathcal{L}) - h^0(\mathcal{L} - p - q) = 2$ for any closed points $p, q \in \mathcal{L}$.

Proof: Cf.[Vakil, P509].**?** □

Cor. (5.11.2.26). Any line bundle $\mathcal{L}$ on a complete non-singular curve of genus g that $\deg(\mathcal{L}) \geq 2g$ is basepoint-free, and if $\deg(\mathcal{L}) \geq 2g + 1$, then it is very ample.

Proof: When $k = \overline{k}$, this follows from(5.11.2.25) and Riemann-Roch(5.11.2.9). For general k, use the fact being basepoint-free, closed embedding and degree are all stable and reflective under base change of fields(5.11.2.2)(5.5.3.3)(5.1.5.26). □

Prop. (5.11.2.27) [Very Ample Line Bundles]. Let X be a complete curve over a field k, then

- If $\mathcal{L}$ is effective and $H^1(X,\mathcal{L})=0$, then $\mathcal{L}^{\oplus 6}$ is very ample.
- If $\mathcal{L}$ is globally generated and $H^1(X,\mathcal{L})=0$, then $\mathcal{L}^{\oplus 2}$ is very ample.

Proof: Cf.[Sta]0E8V, 0E8W.**?** □

Curves in Low Dimension

Prop. (5.11.2.28) [Projection Along a Point]. Let $C\subset\mathbb{P}^n_k$ be a non-singular precurve, then for any rational point $p\in C$, there is a **projection along** p map $v_p: C\to\mathbb{P}^{n-1}_k$ that is the projection along p for $q\in C\backslash\{p\}$, and extend to whole C by(5.11.1.15), which corresponds to the line bundle $\mathcal{O}_C(1)(-p)$.

Prop. (5.11.2.29). Let C be a smooth plane precurve of degree $e>2$ and D_1,D_2 are two polynomials of degree d not vanishing on C. Suppose there is a divisor E on C of degree $de-1$ and rational points p_i on C that $D_i|_C=E+p_i$, then $\mathcal{O}_C(-E)$ is not base-free.

Proof: Notice by genus formula $g>0$, and $\mathcal{O}_C(-E)\cong\mathcal{O}_C(p_i)$ has degree 1, then $p_1=p_2$ by(5.11.2.23). □

Prop. (5.11.2.30). Let C be a smooth conic plane curve over a field of characteristic$\neq 2$, show the dual variety of C is also a smooth conic. In particular, for a general point in the plane, there are two tangents to C.(This can be also proved using Riemann-Hurewitz by projection through this point).

Proof: □

Prop. (5.11.2.31). The number of plane conics containing i generally chosen points and $5-i$ generally chosen lines is $1,2,4,4,2,1$ resp. for $i=0,1,\ldots,4,5$. (The duality comes from the duality between the conic and the dual conic(5.11.2.30)).

Proof: □

Prop. (5.11.2.32) [Curves in $\mathbb{P}^1\times\mathbb{P}^1$]. Let C be a curve in $\mathbb{P}^1\times\mathbb{P}^1$ given by a bi-homogenous polynomial of type (a,b). Then $g(C)=(a-1)(b-1)$.

Proof: We have $\mathcal{K}_C=(\mathcal{K}_{\mathbb{P}^1\times\mathbb{P}^1}+C)|_C$(5.10.1.17). We have $\mathrm{Pic}(\mathbb{P}^1\times\mathbb{P}^1)\cong\mathbb{Z}H_1\oplus\mathbb{Z}H_2$, thus

$$\begin{aligned}\deg(\mathcal{K}_C)&=\deg((\mathcal{K}_{\mathbb{P}^1\times\mathbb{P}^1}+C)_C)\\&=\deg((-2H_1-2H_2+aH_1+bH_2)|_C)\\&=\deg(((a-2)H_1+(b-2)H_2)|_C)\\&=(a-2)b+(b-2)a=2ab-2a-2b\\&=2g-2.\end{aligned}$$

Thus $g=(a-1)(b-1)$.

? For non-smooth case, see AG psets. □

Prop. (5.11.2.33) [Genus Formula]. Let C be a closed subscheme of $\mathbb{P}^2_k$ defined by a homogenous polynomial $f(x_0,x_1,x_2)$ of degree d, then it has arithmetic genus $p_a(C)=(d-1)(d-2)/2$.

Proof: This follows from(5.7.2.4). ☐

Cor. (5.11.2.34). Let C be a complete smooth plane curve of degree d, then it has genus $g = (d-1)(d-2)/2$.

Proof: Alternative proof: By adjunction formula, $\mathcal{K}_C = \mathcal{K}_{\mathbb{P}^2}(C)|_C = \mathcal{O}_C(d-3)$ which has degree $d(d-3)$. But this also equals $2g-2$(5.11.2.10), thus $g = (d-1)(d-2)/2$. ☐

Prop. (5.11.2.35)[Cubic Curves in $\mathbb{P}^3$]. A twisted cubic(rational) C in $\mathbb{P}^3$ is contained in a quadric.

Proof: Calculate that $h^0(\mathcal{O}_{\mathbb{P}^3}(2)) = C_5^2 = 10$ and $\deg(\mathcal{O}_C(2)) = 6$, thus $h^0(\mathcal{O}_C(2)) = 6+1 = 7$ by Riemann-Roch. Then C is contained in 3 quadrics. ☐

3 Singularities and δ-Invariants

Def. (5.11.3.1) [Different Kinds of Singularities]. Let X be a curve over an alg.closed field k, a point $p \in X$ is called a

- **node** if the completion of $\mathcal{O}_{X,p}$ at $\mathfrak{m}_{X,p}$ is isomorphic to $k[[x,y]]/(xy)$ as topological local rings.
- **cusp** if the completion of $\mathcal{O}_{X,p}$ at $\mathfrak{m}_{X,p}$ is isomorphic to the completion of $k[x,y]/(x^2-y^3)$ at (x,y).
- **tacnode** if the completion of $\mathcal{O}_{X,p}$ at $\mathfrak{m}_{X,p}$ is isomorphic to the completion of $k[x,y]/(x^2-y^4)$ at (x,y).
- **triple point** if the completion of $\mathcal{O}_{X,p}$ at $\mathfrak{m}_{X,p}$ is isomorphic to the completion of $k[x,y]/(x^3-y^3)$ at (x,y).

Def. (5.11.3.2) [δ-Invariants].

4 Linear Series

Def. (5.11.4.1) [Moduli Spaces]. Define the **Hilbert scheme** $\mathcal{H}_{d,g,r} = \{$Curves C of degree d and genus $g\}$.

Define the **moduli space of curves** $\mathcal{M}_g = \{$isomorphism classes of smooth projective curves of genus $g\}$.

Define $W_d^r(C) = \{L \in \mathrm{Pic}^d(C), h^0(L) \geq r+1\}$.

Def. (5.11.4.2) [Linear Series]. A **linear series** is a line bundle L together with a vector space $V \subset H^0(L)$.

A $\mathfrak{g}_d^r$ is a line bundle L together with a vector space $V \subset H^0(L)$ of dimension $r+1$.

For a line bundle $\mathcal{L}$, denote by $|L|$ the linear series $(L, H^0(L))$.

Cor. (5.11.4.3) [$r \leq d$]. If $\mathfrak{g}_d^r$ exists on a complete curve C, then $r \leq d$. And if $r = d$, then $g(C) = 0$.

Proof: Let s be a section of $\mathcal{L}$, then the vanishing locus of s is an effective Cartier divisor D, $\mathcal{L} \cong \mathcal{L}(D)$, and there is an exact sequence

$$0 \to \mathcal{O}_X \to \mathcal{L} \to \mathcal{L}|_D \to 0.$$

As D is an Artinian scheme, $\mathcal{L}|_D$ is trivial as D is discrete, so by(5.11.2.6), $h^0(\mathcal{L}|_D) = \deg(D)$, and $h^0(X, \mathcal{O}_X) = 1$, so $r = h^0(X, \mathcal{L}) \leq d$.

If the equality holds, then $H^0(X,\mathcal{L})\to H^0(X,\mathcal{L}|_D)$ is surjective, so to show $g(C)=0$, it suffices to show that $h^0(X,\mathcal{L})=0$. As $\mathcal{L}|_D$ is trivial, there is a section t of $\mathcal{L}$ that generate $\mathcal{L}|_D$. Consider the exact sequence

$$0\to\mathcal{L}\to\mathcal{L}^2\to\mathcal{L}^2|_D\to 0,$$

$H^0(X,\mathcal{L}^2)\to H^0(X,\mathcal{L}|_D)$ is surjective because $\sigma\otimes t$ is mapped to σ. Then by(5.11.2.5),

$$h^0(X,\mathcal{L}^2)=2r+1=\deg(\mathcal{L}^2)+1.$$

So we may replace $\mathcal{L}$ by arbitrarily large powers of $\mathcal{L}$. Now $\mathcal{L}$ is ample by(5.11.2.20), so for r large, $H^1(X,\mathcal{L}^r)=0$. □

Prop. (5.11.4.4) [Linear Series and Maps]. For any $\mathfrak{g}^r_d\ (L,V)$ on a non-singular precurve C, there is a map $\varphi:C\to\mathbb{P}^r$ and a map $\varphi^*\mathcal{O}_{\mathbb{P}^r}(1)\to\mathcal{L}$ s.t. the coordinates $T_0,\ldots,T_r$ are mapped to a basis of V.

This map is injective iff for any $p\neq q$, V_{p+q} has codimension 2. This map is an immersion iff for all p, V_{2p} has codimension 2. So in particular, this map is an embedding iff for any effective divisor D of degree 2, V_D has codimension 2.

Proof: Take a basis $s_0,s_1,\ldots,s_r\in V$, as C is non-singular, the image of the map $(s_0,\ldots,s_r):\mathcal{O}_X^{r+1}\to\mathcal{L}$ is an invertible sheaf as it is torsion-free. Then take the corresponding embedding induced by(5.5.2.4). □

Cor. (5.11.4.5). If $\mathcal{L}$ is a very ample line bundle of degree d on a curve C, then $\varphi_{|\mathcal{L}|}$ embeds C as a closed subscheme of degree d.

Proof: Use(5.11.4.4), The pullback of $\mathcal{O}_{\mathbb{P}^r}(1)$ under φ is just $\mathcal{L}$, so the assertion follows from(5.11.2.7). □

Lemma (5.11.4.6). Let $\mathcal{L}\in\mathrm{Pic}^d(C)$ be general, then $h^0(\mathcal{L})=\max\{1,d-g+1\}$.

Proof: If $D=\sum p_i$ is a general effective divisor, notice $h^0(K)=g$, $h^0(K-p_1)=g-1$, $h^0(K-p_1-p_2)=g-2$, and repeating this, we get $h^0(K-D)=\max\{0,g-d\}$, when we choose p_i that are as independent as possible(any section has f.m. zeros). Then by Riemann-Roch, $l(D)=d-g+1+\max\{0,g-d\}=\max\{1,d-g+1\}$. As every divisor of degree $d\geq g$ is effective, this settles the $d\geq g$ case.

If D is non-effective and $d\leq g-1$, we need to show W^0_d is not dominant in Pic^d. But J has dimension g by**??**nd W^0_d has dimension at most d, so this is true. □

Prop. (5.11.4.7). Suppose D is a divisor of degree $g+3$, then for D general, $\varphi_D=\varphi_{|\mathcal{L}(D)|}$ is an embedding.

Proof: By(5.11.4.6), for a general D, $l(D)=4$. Thus φ_D being not an embedding is equivalent to the existence of a divisor $D_0=p+q$ that $l(D-D_0)\geq 3$. This means $D-D_0\in W^2_{g+1}=K-W^0_{g-3}$. So the divisor $D=D_0+(D-D_0)\in W^0_2+(K-W^0_{g-3})$ which has dimension at most $2+(g-3)=g-1$. But a general divisor D doesn't lie on this $g-1$-dimensional subvariety by(13.5.13.10), so a general D defines an embedding φ_D. □

Def. (5.11.4.8) [Canonical Map]. For a smooth curve C of degree g over a field k of genus $g\geq 1$, the canonical divisor $\mathcal{K}_C$ is basepoint-free, and defines a **canonical map** to $\mathbb{P}^{g-1}_k$.

Proof: By(5.11.2.2)(5.5.3.3)(5.1.5.26), it suffices to prove for $\overline{k}$, thus for any closed point p, $h^0(\mathcal{K}_C - p) = 2g-3-g+1+h^0(\mathcal{O}_C(p)) \leq g-1 < h^0(\mathcal{K}_C) = g$ by(5.11.2.23), so it is basepoint-free. □

Prop. (5.11.4.9) [Base-Free Pencil Trick]. Let $\mathcal{L}, \mathcal{M}$ be line bundles on C. Let s_1, s_2 be sections of $H^0(\mathcal{L})$ without common zero, then the kernel of the map

$$s_1 H^0(\mathcal{M}) \oplus s_2 H^0(\mathcal{M}) \to H^0(\mathcal{L}\otimes\mathcal{M})$$

is $H^0(\mathcal{M}\otimes\mathcal{L}^{-1})$.

Proof: Indeed, there is an exact sequence of sheaves:

$$\mathcal{M}\otimes\mathcal{L}^{-1} \to \mathcal{M}\oplus\mathcal{M} \xrightarrow{(s_1,s_2)} \mathcal{M}\otimes\mathcal{L} \to 0.$$

Where the first map maps a section t to the pair $(ts_2, -ts_1)$. This is a Koszul regular sequence(on a common trivialization U of $\mathcal{M}, \mathcal{L}$, $s_1, s_2 \in C(U)$, thus this is just $0 \to A \to A\oplus A \xrightarrow{s_1,s_2} A \to 0$). Taking the global section functor gives the desired result. □

Prop. (5.11.4.10) [Geometric Riemann-Roch]. Let C be a non-hyperelliptic curve of genus $g \geq 2$. Then the canonical map φ_K is an embedding, so we can assume $C \subset \mathbb{P}^{g-1}$. Then for a divisor $D = \sum p_i$,

$$r(D) = d - 1 - \dim \overline{D},$$

where $\overline{D}$ is the linear subspace generated by p_i. Thus $r(D)$ can be interpreted as the number of linear relations between p_i.

Proof: By the definition of the canonical embedding, $l(K-D)$ is just the dimension of hypersurfaces containing p_i, thus it is equal to $g-1-\dim\overline{D}$. Now by Riemann-Roch, $r(D) = d-g+l(K-D) = d-g+g-1-\dim\overline{D} = d-1-\dim\overline{D}$. □

Prop. (5.11.4.11).

Cor. (5.11.4.12) [Special Divisors]. Let $U^{(g)}$ be the open subscheme of $C^{(g)}$ corresponding to the set of non-special divisors of degree g.?

Proof:

□

Prop. (5.11.4.13) [Clifford Theorem]. For a divisor D of degree $0 \leq d \leq 2g-2$ on a curve of genus g,

$$r(D) \leq \frac{d}{2}.$$

with equality iff one of the following holds:

- $r = d = 0, D = 0$.
- $d = 2g-2, r = g-1, D = \mathcal{K}_C$.
- C is hyperelliptic and $D = mg^1_2$.

Proof: Cf.[Algebraic Curves, Harris, P32].? □

5 Hyperelliptic Curves

Def. (5.11.5.1) [Hyperelliptic Curves]. A **hyperelliptic curve** over k is a complete non-singular curve C together with a finite degree 2 map $C \to \mathbb{P}^1_k$. Such a map is called a **hyperelliptic map**. For $g > 0$, this is equivalen to the existence of a g^1_2 on C(such a linear series must be basepoint-free, by(5.11.2.24).

Cor. (5.11.5.2) [Genus 2 Curves are Hyperelliptic]. Any complete nonsingular curve of genus 2 is hyperelliptic, because $\mathcal{K}_C$ has degree 2 and $h^0(\mathcal{K}_C) = 2$(5.11.2.10).

Prop. (5.11.5.3) [Equation of Hyperelliptic Curves]. Any image of a hyperelliptic map from a hyperelliptic curve of genus g over an alg.closed field k of characteristic $k \neq 2$ is isomorphic to the projective curve that is the completion(5.11.1.18) of the affine curve in $\mathbb{A}^2$ defined in an affine chart by $y^2 = \prod_{i=0}^{2g+2}(x - \alpha_i)$ or $y^2 = \prod_{i=0}^{2g+1}(x - \alpha_i)$, depending on whether the ∞ is branched or not. And given $2g + 2$ points in $\mathbb{P}^1_k$, there is exactly one degree 2 covering of $\mathbb{P}^1$ branched over these points.

Proof: Given any r points of $\mathbb{P}^1_k$, we can use a transformation of $\mathbb{P}^1$ to assume that all branch points are finite, denoted by $\alpha_1, \ldots, \alpha_r$. Consider the curve C' defined by $y^2 = \prod_{i=0}^{2g+2}(x - \alpha_i)$, then it is a smooth curve by Jacobian criterion. Now let C be the smooth model of C', and consider $\pi : C \to \mathbb{P}^1$ by projecting to the x-coordinates and extend to the whole C by(5.11.1.15). This is finite separable of degree 2, and π is simply branched at the points α_i, and simply branched over ∞ if r is odd, thus it has genus $\lfloor \frac{r-1}{2} \rfloor$ by Riemann-Hurwitz(5.11.1.32).

Conversely, by Riemann-Hurwitz(5.11.1.32), any degree 2 covering of $\mathbb{P}^1$ has $2g+2$ branch points, because the branch points must be simply branched. The map $k(x) \to k(C)$ is Galois of degree 2, take a $y \in k(C)$ that $\sigma(y) = -y$, then $y^2 = g \in k(x)$. We can modify y s.t. g is a monic polynomial with no repeated factors. Then it is of the form $g(x) = \prod_{i=1}^{r}(x - x_i)$. Then it is isomorphic to the curve constructed above, and branched over $x_1, \ldots, x_r$ and possibly ∞. In particular, it is determined by the set of branched points, so we get the desired assertion. □

Remark (5.11.5.4). The completion of C can be explicitly constructed, by gluing another affine chart defined by $(\frac{y}{x^{g+1}})^2 = \prod_{i=0}^{2g+2}(1 - \alpha_i \frac{1}{x})$ or $(\frac{y}{x^{g+1}})^2 = \frac{1}{x}\prod_{i=0}^{2g+1}(1 - \alpha_i \frac{1}{x})$.

Prop. (5.11.5.5). If C is a nonsingular complete curve of genus $g \geq 2$ over k and $\mathcal{L}$ is a line bundle that corresponds to a hyperelliptic map $C \to \mathbb{P}^1_k$, then $\mathcal{L}^{\otimes(g-1)} \cong \mathcal{K}_C$.

In particular, the image of C under the canonical map is the rational curve in $\mathbb{P}^{g-1}_k$.

Proof: Consider the composition of the hyperelliptic map and the Veronese map

$$C \xrightarrow{|\mathcal{L}|} \mathbb{P}^1_k \xrightarrow{v_{g-1}} \mathbb{P}^{g-1}_k,$$

which corresponds to the line bundle $|\mathcal{L}^{\otimes(g-1)}|$. This line bundle has degree $2g - 2$, and the map $H^0(\mathbb{P}^{g-1}, \mathcal{O}(1)) \to H^0(C, \mathcal{L}^{\otimes(g-1)})$ is injective, because the Veronese map is non-degenerate. Thus $h^0(\mathcal{L}^{\otimes(g-1)}) \geq g$, thus isomorphic to $\mathcal{K}_C$, by(5.11.2.13). Hence this map is just the canonical map. □

Cor. (5.11.5.6). For a hyperelliptic curve, the smallest degree of an embedding $C \to \mathbb{P}^r$ is $g + r$. Note that hyperelliptic curves cannot be embedded into $\mathbb{P}^2$, i.e. smooth plane curves are non-hyperelliptic.

Proof: Firstly we show a special divisor cannot induce an embedding: A special divisor is a divisor that is contained in a hypersurface intersection of C under the canonical map, thus by geometric Riemann-Roch(5.11.4.10), $r(D)$ is just the number of points of D mapped to the same point under the canonical map, because intersection with the rational normal curve are all linearly independent. Now this means D contains g^1_2, so φ_D factors through π, thus not an embedding.**?** Cf.[Algebraic Curves, Harris, P21]. □

Prop. (5.11.5.7) [Hyperelliptic and Canonical Map]. A complete smooth curve of genus $g \geq 1$ is hyperelliptic iff the canonical map(5.11.4.8) is not a closed embedding.

Proof: The canonical map is not an embedding iff there exists an effective divisor D of degree 2 that $l(K-D) > l(K) - 2$. Now $l(K-D) = 2g - 4 - g + 1 + l(D)$, so this is equivalent to $l(D) > 1$, which is equivalent to a g_2^1, which is equivalent to hyperelliptic(5.11.5.1). □

Prop. (5.11.5.8) [Uniqueness of Hyperelliptic Maps]. For a hyperelliptic curve of genus $g \geq 2$, up to automorphic of $\mathbb{P}^1$, there are at most one hyperelliptic map, or equivalently there is exactly one g_2^1 on C.

But for (hyperelliptic)curve of genus 1, thus is not unique: any divisor of degree 2 is effective, but they are not unique, because $\mathrm{Pic}^2(C) \cong J(C)$(13.5.13.10).

Proof: If $\mathcal{L} \neq \mathcal{M}$ are two line bundles on C with $h^0 = 2$, then $h^0(\mathcal{L} \otimes \mathcal{M}) \geq 4$ by base-free pencil trick(5.11.4.9), and in fact $h^0(\mathcal{L} \otimes \mathcal{M}) = 4$ by(5.11.4.3). Now we can tun the same argument again to $\mathcal{L}$ and $\mathcal{L} \otimes \mathcal{M}$, to show that $h^0(\mathcal{L}^2 \otimes \mathcal{M}) = 6$. And inductively $h^0(\mathcal{L}^n \otimes \mathcal{M}) = 2n+2$. But then for n large, Riemann-Roch shows $2n+2 = 2n+2-g+1$, thus $g = 1$, contradiction. □

Gonal Curves

Def. (5.11.5.9) [Gonal Curves]. A **trigonal curve** is a complete non-singular curve C with a degree 3 map $C \to \mathbb{P}^1$. Similarly, a k-**gonal curve** is a complete non-singular curve C with a degree k map $C \to \mathbb{P}^1_k$. Being k-gonal is equivalent to having a basepoint-free g_k^1.

Notice also for non-hyperelliptic curves, any g_3^1 must be basepoint-free.

Def. (5.11.5.10) [Hurewitz Spaces]. Let the **Hurewitz space** be

$$\mathcal{H}_{d,g} = \{(C, f) | C \in \mathcal{M}_g, f : C \to \mathbb{P}^1 \text{ of degree } d \text{ with simple branching}\}.$$

In particular, $\mathcal{H}_{2,g}$ is just the space of hyperelliptic curves together with a hyperelliptic map.

Prop. (5.11.5.11) [Dimension of Hurewitz Spaces]. $\dim \mathcal{H}_{d,g} = 2d + 2g - 2$.

Proof: Let $b = 2d + 2g - 2$, then the branch divisor will consist of an unordered b-tuple of distinct points. Then we obtain a map $\mathcal{H}_{d,g} \to \mathbb{P}^b \backslash \Delta$, where we regard $\mathbb{P}^b$ as the set of polynomials of degree b and Δ the determinant, and the fiber is finite by cut-paste technique. □

Cor. (5.11.5.12) [Dimension of Moduli Space of Curves]. $\dim \mathcal{M}_g = 3g - 3$.

Proof: There is a map $\mathcal{H}_{d,g} \to \mathcal{M}_g$. When d is large, we can analyze the fiber of this map, that is, given a curve of genus g, how many simply branched maps $C \to \mathbb{P}^1$ of degree d are there? Such a map is equivalent to a line bundle of degree d and a pair of base free sections $\sigma_0, \sigma_1 \in H^0(L)$. The base-free condition is an open condition, thus the dimension of the fiber is $g + 2(d-g-1) - 1 = 2d + g - 1$. Thus the dimension of $\mathcal{M}_g = 2d + 2g - 2 - (2d - g + 1) = 3g - 3$. □

Cor. (5.11.5.13). The space of hyperelliptic curves has dimension $2g - 1$.

Proof: $\mathcal{H}_{2,g}$ has dimension $2g+2$, and for any hyperelliptic curve, there is exactly one hyperelliptic map up to automorphism of $\mathbb{P}^1$, by(5.11.5.8), thus the space of hyperelliptic curves has dimension $2g + 2 - 3 = 2g - 1$. □

Cor. (5.11.5.14). If $g \geq 3$, then not all curves of genus g is hyperelliptic.

Proof: Because when $g \geq 3$, $2g-1 < 3g-3$. □

Lemma (5.11.5.15). For a line bundle of degree 3 on a curve of genus $g \geq 3$, $h^0(L) \leq 2$, by Clifford's theorem(5.11.4.13). Thus a trigonal map must be associated to a complete linear series g_3^1.

Prop. (5.11.5.16) [Hyperelliptic are not Trigonal]. A curve of genus $g \geq 3$ cannot be both hyperelliptic and trigonal.

Proof: Suppose there are two basepoint-free line bundles $\mathcal{L}, \mathcal{M}$ of degree 2 and 3 on C that $h^0(\mathcal{L}) = h^0(\mathcal{M}) = 2$(5.11.5.15), then the base-free pencil trick(5.11.4.9) implies that $h^0(\mathcal{M}\otimes\mathcal{L}) \geq 4$. If $g = 3$, then this contradicts Riemann-Roch. If $g \geq 4$, then this contradicts Clifford's theorem(5.11.4.13). □

Prop. (5.11.5.17) [Genus 3 Curves are Hyperelliptic or Trigonal]. Any genus 3 non-hyperelliptic complete smooth curve C with a rational point is trigonal.

Proof: If C is non-hyperelliptic, then the canonical map realizes C as a plane curve of degree 4(5.11.8.6), thus the projection of C along a point on C induces a map $C \to \mathbb{P}^1$. This map is finite of degree 3 because it is non-constant as C is non-degenerate, and has degree 3, by(5.11.2.28). □

Prop. (5.11.5.18) [Uniqueness of Trigonal Divisors]. There exists at most one g_3^1 on a curve of genus $g \geq 5$.

Proof: If $\mathcal{L} \neq \mathcal{M}$ are two base free line bundles of degree 3 that $h^0 = 2$, then we can use base-free trick to show that $h^0(\mathcal{L}\otimes\mathcal{M}) = 4$. But this contradicts Clifford's theorem(5.11.4.13). Notice the equality cannot hold, because the degree is too low to be the canonical bundle, and also C cannot be both hyperelliptic and trigonal(5.11.5.16). □

6 Castelnuovo's Theory

Lemma (5.11.6.1) [Castelnuovo's Lemma]. Let $\Gamma \in \mathbb{P}^n$ be a configuration of $d \geq 2n+3$ points in linear general position, and if $h_\Gamma(2) = 2n+1$, then Γ lies in a rational normal curve.

7 Plucker Formulas

Def. (5.11.7.1) [Weierstrass Group]. Let C be a smooth of genus $g \geq 2$, $p \in C$, then $S_p = \{-\operatorname{ord}_p(f) | f \in H^0(\mathcal{O}_C(-p))\}$ is a semigroup, called the **Weierstrass semigroup** of $p \in C$. And the **gap sequence** is $\mathbb{N}\backslash S_p$, which is the set of orders of pole of p that doesn't occur.

Lemma (5.11.7.2). We have $|G_p| = g$.

Proof: Notice that

$$G_p = \{m : h^0(mp) = h^0((m-1)p)\}, \quad S_p = \{m : h^0(mp) = h^0((m-1)p) + 1\}$$

and we know by(5.11.2.12) that $h^p(mp) = m - g + 1$ for m large, thus there are exactly g jumps, which shows $|G_p| = g$. □

Def. (5.11.7.3) [Weierstrass Points]. A point $p \in C$ is called **Weierstrass point** if the gap sequence is not $\{1, 2, \ldots, g\}$. It is called a **hyperelliptic Weierstrass point** if $G_p = \{1, 3, \ldots, 2g-1\}$, and is called a **normal Weierstrass point** if $G_p = \{1, 2, 3, \ldots, g-1, g+1\}$.

Define the **weight** of the $p \in C$ to be the sum $w(p) = \sum_{i \leq g}(a_i - i)$, where the gap sequence is numbered $\{a_1, \ldots, a_g\}$.

Prop. (5.11.7.4). For any compact Riemann surface C, $\sum_{p\in C} w(p) = g(g-1)(g+1)$.

Proof: Cf.[G-H78], P274. □

Cor. (5.11.7.5). For general $p \in C$, $G_p = \{1, 2, \ldots, g\}$.

Prop. (5.11.7.6)[Hyperelliptic Weierstrass Points]. If C is hyperelliptic defined by $y^2 = \prod_{i=0}^{2g+1}(x-\alpha_i)$, then there are $2g+2$ branching point of x, where $S_p = \{0, 2, 4, \ldots, 2g, 2g+1, \ldots\}$. In this way, $w(p) = g(g-1)/2$. Thus there are $2g+2$ Weierstrass points, and these are all of them.

If C is non-hyperelliptic, then by Clifford's theorem(5.11.4.13),

$$h^0(kp) < \frac{k}{2} + 1, k = 1, \ldots, g$$

Thus $h^0((a_i-1)p) < \frac{a_i-1}{2} + 1$, and $h^0((a_i-1)p) = 1 + (a_i-1) - (i-1)$. Thus we get

$$a_i \leq 2i - 2, i = 2, \ldots, g.$$

Then $w(p) \leq \sum_{i=2}^{g}(i-2) = \frac{(g-1)(g-2)}{2}$. Thus there are at least

$$\frac{2g(g-1)(g+1)}{(g-1)(g-2)} \geq 2g + 6$$

Weierstrass points.

To sum up, there are no less than $2g+2$ Weierstrass points, and there are exactly $2g+2$ Weierstrass points iff C is hyperelliptic.

Prop. (5.11.7.7). A generic Riemann surface of genus $g \geq 3$ has no automorphisms.

8 Curves of Low Genus

In this subsection complete smooth curves of low genus are considered.

Prop. (5.11.8.1) [Genus 0 Curve]. All smooth complete curve C of genus 0 is isomorphic to a plane conic.

Proof: The curve has a degree 2 line bundle $\mathcal{K}_C^\vee$, thus by Riemann-Roch $h^0(\mathcal{O}(p)) = 3$ and by(5.11.2.26) it induces a closed embedding of C into $\mathbb{P}^2$ of degree 2, thus it is a plane conic. □

Prop. (5.11.8.2). A nonsingular curve C of genus 0 with a k-rational point p is isomorphic to $\mathbb{P}^1_k$:

Proof: By Riemann-Roch, $h^0(\mathcal{O}(p)) = 2$ and $\deg \mathcal{O}(p) = 1$, thus by(5.11.2.26), $\mathcal{O}(p)$ defines a closed embedding of C into $\mathbb{P}^1$, which must be an isomorphism. □

Prop. (5.11.8.3) [Genus 1 Curve]. By(5.11.2.26), an effective divisor of degree 3 induces an embedding of $\mathbb{C}$ into $\mathbb{P}^2$, So it is a smooth plane cubic by genus formula(5.11.2.33). Conversely, any smooth plane cubic has genus 1.

Similarly, if we take an effective divisor of degree 4, then it gives an embedding $C \to \mathbb{P}^3$. We know that $h^0(\mathcal{O}_{\mathbb{P}^3}(2)) = 10$ and $h^0(\mathcal{O}_C(2)) = 8$, thus C is contained in 2 quadrics. Then C is the intersection of these two quadrics, by Bezout's theorem.

Prop. (5.11.8.4) [Genus 2 Curves and Degree 4 Divisors]. Let C be a curve of genus 2, and D a divisor of degree 4. Then $l(D-K_C)=1+l(2K_C-D)\geq 1$, thus $D-K_C$ is effective. Let $D-K_C=p+q$. Then φ_D maps p,q to the same point.

There are two situations, firstly if $D\neq 2K_C$, then $D-K_C$ can be written uniquely as $p+q$. Then the image of φ_D is a degree 4 curve with a node(if $p=q$) or a cusp(if $p=q$). Counting genus, this has exactly arithmetic genus 2.

If $D=2K_C$. Then notice φ_{2K_C} is equal to φ_K followed by the normal curve map $\mathbb{P}^1\to\mathbb{P}^2$. This is because if ω_1,ω_2 are a basis of $H^0(K_C)$, then $\omega_1^2,\omega_1\omega_2,\omega_2^2$ is a basis of $H^0(K_C^2)$. So φ_D is a 2 to 1 map to a rational normal curve in $\mathbb{P}^2$.

Prop. (5.11.8.5) [Genus 2 Curve and degree 5 Divisors]. Let C be a curve of genus 2 and D a divisor of degree 5, then $\varphi_D: C\to\mathbb{P}^3$ embeds C as a degree 5 curve, by(5.11.2.26).

Notice $h^0(\mathcal{O}_{\mathbb{P}^3}(2))=10$ and $h^0(\mathcal{O}_C(2))=10-2+1=9$, thus C lies on at least one quadric Q. And it can in fact lie on only one quadric, because if it lies on two quadrics, then C is the intersection, and can have degree at most 4.

Next, notice $h^0(\mathcal{O}_{\mathbb{P}^3}(3))=20$ and $h^0(\mathcal{O}_C(3))=15-2+1=14$, so C lies on at least 6 cubics. Without the 4 cubics containing the quadric, there are still at least 2 new cubics. Let S be such a cubic, then $S\cap Q$ is a curve of degree 6, so $S\cap Q=C\cup L$, where $L\cong\mathbb{P}^1$.

Prop. (5.11.8.6) [Genus 3 Non-Hyperelliptic Curve]. For any non-hyperelliptic smooth curve C of genus 3 over a field k, the canonical map(5.11.4.8) embeds C as a smooth quartic curve in $\mathbb{P}^2$. This induces an isomorphism of smooth quartic plane curves up to automorphism of $\mathbb{P}^2$.

Proof: The canonical embedding is a closed embedding by(5.11.5.7). For the last assertion, any plane curve of degree 4 has genus 3 by(5.11.2.33), and the sheaf $\mathcal{O}_C(1)$ has degree 4 and 3 sections, thus by(5.11.2.13), so this comes from a canonical embedding. In particular, any such curve can be embedded in $\mathbb{P}^2$ in a unique way. □

Prop. (5.11.8.7). Any hyperelliptic smooth curve of genus 3 is a flat limit of non-hyperelliptic smooth curves of genus 3.

Proof: Cf.[Vak17]P520. □

Prop. (5.11.8.8) [Genus 4 Non-Hyperelliptic Curves]. Any non-hyperelliptic smooth complete canonical curve C of genus 4 is a complete intersection of a quadric surface and a cubic surface. Conversely, any regular complete intersection of a quadric surface and a cubic surface is a canonically embedded non-hyperelliptic curve of genus 4.

Proof: Looking at the map $H^0(\mathcal{O}_{\mathbb{P}^3}(2))\to H^0(\mathcal{O}_C(2))$, we see C lies on a unique quadric Q(uniqueness follows from Bezout's theorem and(5.7.3.11), by the same reason as(5.11.8.5)).

Next looking at the map $H^0(\mathcal{O}_{\mathbb{P}^3}(3))\to H^0(\mathcal{O}_C(3))$, then the kernel has dimension at least 5, thus there is a cubic containing C but not Q. Then $S\cap Q$ is a complete intersection of degree 6 containing C, also it has the same arithmetic genus as C(5.7.3.8), thus the same Hilbert polynomial(linear function), so $C=S\cap Q$ by(5.7.3.11)s. Conversely, any smooth curve of the form $S\cap Q$ is a canonical curve of genus 4, by adjunction formula($\mathcal{K}_C=\mathcal{O}_C(1)$ has degree 6).

Conversely, for any smooth complete intersection of a quadric surface and a cubic surface has arithmetic genus 4 by(5.7.3.8), $\mathcal{O}_C(1)$ has degree 6 and $h^0(\mathcal{O}_C(1))\geq 4$ because C is non-degenerate: there are no smooth plane curve of genus 4.

Now if Q is non-singular, then C is of type $(3,3)$ in Q, thus the two projections are two trigonal map from C to $\mathbb{P}^1$, and if Q is a cone, the projection from the vertex is a trigonal map from C to $\mathbb{P}^1$. □

Prop. (5.11.8.9) [Non-Hyperelliptic Curve of Genus $\geq$ 5]. For a non-hyperelliptic curve C of genus 5, we have a canonical map $\varphi : C \to \mathbb{P}^4$. Firstly we consider what quadrics C lies on: $h^0(\mathcal{O}_{\mathbb{P}^4}(2)) = 15$ and $h^0(\mathcal{O}_C(2)) = 12$, so C lies on at least 3 quadrics. There are two cases:

1. $C = \cap Q_i$ where Q_i are the quadrics containing C.
2. C is a strict subset of $\cap Q_i$.

which corresponds to non-trigonal and trigonal curves.

Proof: The case 1 does occur, because by Bertini's theorem(5.6.4.29), for general three quadrics Q_i, $\cap Q_i$ is a smooth curve, and thus $\mathcal{K}_C = (\mathcal{K}_{\mathbb{P}^4}(-5+2+2+2))|_C = \mathcal{O}_C(1)$. So $d = 8, g(C) = 5$.

In this case, C is not trigonal, because if C is trigonal, then C has a g^1_3, which means C has three colinear point. Then all the quadrics Q_i must contain this line, contradiction.

The case 2: Cf.[Algebraic Curves, Harris, P24].**?** This case corresponds to trigonal curves. □

Prop. (5.11.8.10) [Non-Hyperelliptic Curve of Genus 5 is Tetragonal]. Let C be a canonical embedded curve which is not trigonal admits a map of degree 4 to $\mathbb{P}^1$.

Proof: Let $\mathbb{P}^2 = \{Q | C \subset Q\}$. We can ask there are singular quadrics in this set. Inside $\mathbb{P}^{14}$ which is the space of all quadrics in $\mathbb{P}^4$, there is a quintic hypersurface of singular quadrics. **?** For the rest, Cf.[Algebraic Curves, Harris, P25]. □

Prop. (5.11.8.11). If $C \subset \mathbb{P}^{g-1}_k$ is a canonical smooth curve of genus $g \geq 6$, then C is not a complete intersection.

Proof:

□

11 Relative Curves

Def. (5.11.11.1) [Relative Curves]. Let $S \in \mathcal{S}ch$, a **smooth curve** over S is a smooth morphism $C \to S$ of relative dimension 1 that is separated and of f.p..

Prop. (5.11.11.2). Let $S \in \mathcal{S}ch$ and C a smooth curve over S, then

12 Riemann Surfaces

Prop. (5.11.12.1) [Genus].

Thm. (5.11.12.2)[Uniformization Theorem, Poincaré-Klein-Koebe]. Any simply-connected Riemann surface is analytically isomorphic to one of the following:

$$\mathcal{H}, \mathbb{C}, \overline{\mathbb{C}}.$$

Proof: □

Cor. (5.11.12.3) [Classifying Riemann Surfaces]. For any Riemann surface S with universal covering space $\widetilde{S}$,

- If $\widetilde{S} \cong \overline{\mathbb{C}}$, then S is compact, so by(5.11.12.5) and Riemann-Hurewitz(5.11.1.32), $\widetilde{S} \to S$ is an isomorphism. So in this case $S \cong \overline{\mathbb{C}}$.
- If $\widetilde{S} \cong \mathbb{C}$, then $\pi_1(S) \subset \mathrm{Aut}(\widetilde{S}) = \mathbb{C} \ltimes \mathbb{C}^\times$ by(10.5.7.8). But $\pi_1(S)$ can have no fixed point, so they are all of the form $\tau : z \mapsto z + b$. So it is a lattice of $\mathbb{C}$, thus isomorphic to $\mathbb{1}, \mathbb{Z}$ or $\mathbb{Z}^2$. The corresponding S is $\mathbb{C}, \mathbb{C}^\times$ or $\mathbb{C}/\Lambda$ a torus.
- If $\widetilde{S} \cong \mathscr{H}$, then $S = \mathscr{H}/\Gamma$ where $\Gamma \subset \mathrm{PSL}(2, \mathbb{R})$ is a Fuchs group**?**. Such S are called a t**hyperbolic Riemann surface.**

Prop. (5.11.12.4) [Metrics on Riemann Surfaces]. For a Riemann surface S,

- If $S = \overline{\mathbb{C}}$, then S has a natural Fubini-Study metric
$$\mathrm{d}s^2 = \frac{4|\mathrm{d}z|^2}{(1+|z|^2)^2}.$$
with curvature 1.
- If $\widetilde{S} = \mathbb{C}$, then $\pi_1(S) \subset \mathrm{Aut}(\mathbb{C})$ are all translations so preserves the Euclidean metric $\mathrm{d}s^2 = |\mathrm{d}z|^2$, thus S has a flat metric.
- If $\widetilde{S} = \mathscr{H}$, then $\pi_1(S) \subset \mathrm{Aut}(\mathbb{C}) \cong \mathrm{PSL}(\mathbb{R})$ preserves the hyperbolic metric $\mathrm{d}s^2 = y^{-2}\mathrm{d}x\mathrm{d}y$ by(11.7.4.5), thus inducing a hyperbolic metric on S with curvature -1.

Compact Riemann Surfaces

References are [李 04].

Prop. (5.11.12.5) [Riemann Existence Theorem]. Any compact Riemann Surface is a Hodge manifold, thus projective algebraic, by(11.9.8.6) and Chow's lemma**??**. And the category of compact Riemann surfaces is equivalent to the category of compact algebraic curves, by GAGA(11.8.7.17).

Proof: Because $H^{1,1}(X) = H^2(X, \mathbb{Z})$, so it clearly contains integral classes. And it is positive because there is a basis generated by any Hermitian metric on X. So the theorem follows from(11.9.8.6). □

Remark (5.11.12.6). In fact the same argument shows that any Kähler manifold with $H^{0,2}(X) = 0$ is projective.

Cor. (5.11.12.7). Any compact Riemann surface of genus 0 is analytically isomorphic to $\overline{\mathbb{C}}$.

Prop. (5.11.12.8).

- For any meromorphic function f on a compact Riemann surface, $(f) = (f)_0 - (f)_\infty$ has degree 0.
- Let ω be a differential form on a compact Riemann surface, then the sum of residues of ω at its poles is zero.

Proof: 2: Choose a triangularization of the Riemann surface, then use the fact for any simple region Ω be boundary C,
$$\int_C \omega = 2\pi\,\mathrm{i}(\sum_{\text{poles}} \mathrm{res}_p\,\omega).$$
And the integrals cancel out.

1: This is a direct consequence of 2 applied to the differential form $\omega = df/f$. □

Abel's Theorem and Reciprocity Law

Prop. (5.11.12.9) [Reciprocity Law I]. Cf.[Griffith/Harris P230].

Prop. (5.11.12.10) [Weil]. f, g are meromorphic functions on a compact Riemann surface that $(f), (g)$ are disjoint, then

$$\prod f(p)^{v_p(g)} = \prod g(p)^{v_p(f)}.$$

Proof: Cf.[Griffith/Harris, P242]. □

Prop. (5.11.12.11) [Differentials on Plane Curves].

6 Algebraic Geometry II: Spectral Algebraic Geometry

6.1 Andre-Quillen-Cohomology

Basic references are [Andre-Quillen Cohomology of Commutative Algebras Iyenger]. See also [Quillen Cohomology of Commutative Rings] and [Quillen On the (Co-)homology of Commutative Rings]. [Smoothness, Regularity and Complete Intersections] is a must read.

1 Naive Cotangent Complex

This subsection is obsolete.

Prop. (6.1.1.1) [Polynomial Replacement]. For a morphism of ring morphisms $(R \to S) \to (R' \to S')$, let α, α' be two presentations, then there exists morphism of presentations, and different morphisms induce homotopic maps $NL_{S/R} \to NL_{S'/R'}$.

Proof: Cf.[[Sta]00S1]. In fact, any surjective formally smooth representation will give the naive cotangent complex, up to quasi-isomorphism(6.1.1.4). □

Cor. (6.1.1.2). If $A = R[X_i]$ be a polynomial algebras, then $NL_{A/R}$ is homotopic to $(0 \to \Omega_{B/A})$ because $A \to A$ is a presentation with zero kernel.

If $R \to A$ is surjective with kernel I, then $NL_{A/R}$ is homotopic to $(I/I^2 \to 0)$.

Lemma (6.1.1.3) [Formally Smooth Replacement 1]. If $A \to B$ is a ring map that has two surjective presentations $C \to B, D \to B$ with kernels I, J. If there is a map $C \to D$ commutating these two presentation, D formally smooth, and $C \to D$ is surjective or C is formally smooth, then their corresponding naive cotangent complexes are quasi isomorphic.

Proof: Cf.[Foundations of Perfectoid Geometry P123]. □

Prop. (6.1.1.4) [Formally Smooth Replacement 2]. If B is an A-algebra that has two formally smooth presentation $C \to B, D \to B$ with kernels I, J. then their corresponding naive cotangent complexes are quasi isomorphic.

Proof: It suffices to prove they are both quasi isomorphic to the canonical cotangent complex. For this, we first consider the diagram $\begin{array}{ccc} D & \longrightarrow & C \\ \downarrow & & \downarrow \\ A[B] & \longrightarrow & B \end{array}$, where $D = A[S]$ and $S = C \coprod A[B]$ as sets. The two map $D \to A[B]$ and $D \to A[B]$ can be chosen because $C \to B$ is surjective. So the results follows from(6.1.1.3). □

Prop. (6.1.1.5) [Jacobi-Zariski Sequence]. Let $A \to B \to C$ be a ring map. Choose a presentation $\alpha : P \to B$ for B/A with kernel I, a presentation $\beta : Q \to C$ for C/B with kernel J, a presentation $\gamma : R \to C$ for the induced representation C/A with kernel K, then there is an exact sequence of complexes:

$$\begin{array}{ccccccccc} & & I/I^2 \otimes_B C & \longrightarrow & K/K^2 & \longrightarrow & J/J^2 & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \Omega_{P/A} \otimes_B C & \longrightarrow & \Omega_{R/A} \otimes C & \longrightarrow & \Omega_{Q/B} \otimes C & \longrightarrow & 0 \end{array}$$

Applying snake lemma, we get

$$H_1(NL_{B/A} \otimes_B C) \to H_1(L_{C/A}) \to H_1(L_{C/B}) \to C \otimes_B \Omega_{B/A} \to \Omega_{C/A} \to \Omega_{C/B} \to 0.$$

Proof: Cf.[[Sta]00S2]. □

Prop. (6.1.1.6) [Localization]. Let $A \to B$ be a ring map, for a multiplicative set S of B, we have $NL_{B/A} \otimes_B S^{-1}B$ is quasi-isomorphic to $NL_{S^{-1}B/A}$.

Proof: Because it commutes with colimit, it suffice to prove for $S = f$, and this is the content of lemma(6.1.1.7) below. □

Lemma (6.1.1.7). If $A \to B$ is a ring map and $\alpha : P \to B$ is a presentation of B with kernel I, then $\beta : P[X] \to B_g : X \to 1/g$ is a presentation of B_g with kernel $J = I + (gX - 1)$. Then we have

- $J/J^2 = (I/I^2)_g \oplus B_g(fX - 1)$.
- $\Omega_{P[X]/A} \otimes_{P[X]} B_g = \Omega_{P/A} \otimes_P B_g \oplus B_g dX$.
- $NL(\beta) \cong NL(\alpha) \otimes_B B_g \oplus (B_g \xrightarrow{g} B_g)$.

Hence $NL_{B/A} \otimes_B B_g \to NL_{B_g/A}$ is a homotopy equivalence.

Proof: Cf.[[Sta]08JZ]. □

2 Cotangent Complex

Def. (6.1.2.1) [Cotangent Complex]. The adjunction of $A \ltimes -$ and $A \otimes_{-} \Omega_{-/R}$(4.4.3.5) extends to an adjunction between $(sCAlg_R)_{/A}$ and $s\mathcal{M}od_A$. Theses categories are model categories by(4.8.2.11)(4.8.2.14) and(3.4.4.1), and $A \ltimes -$ preserves all weak equivalences and fibrations, so it is a Quillen adjunction(3.4.2.1). Then the **cotangent complex** $L_{A/R}$ as a simplicial A-module is defined to be the total left derived functor applied to the trivial simplicial algebra A. Equivalently, it is

$$L_{A/R} = A \otimes_X \Omega_{X/R}$$

where X is a cofibrant replacement(3.4.1.12) of A.

Because of the Dold-Kan equivalence, we sometimes also call $NL_{A/R}$ the cotangent complex.

Def. (6.1.2.2) [André-Quillen Homology and Cohomology]. The **André-Quillen homology** is defined to be

$$D_q(A/R) = \pi_q(L_{A/R}) = H_q N(L_{A/R})\text{(4.8.2.2)}.$$

More generally, if M is an A-module, then let

$$D_q(A/R, M) = \pi_q(L_{A/R} \otimes_A M).$$

The **André-Quillen cohomology** is defined to be

$$D^q(A/R, M) = \mathrm{Ext}^n(NL_{A/R}, M).$$

Prop. (6.1.2.3) [Functoriality]. The cotangent complex is functorial in arrows $R \to A$: If there is a commutative diagram

$$\begin{array}{ccc} R & \longrightarrow & S \\ \downarrow & & \downarrow \\ A & \longrightarrow & B \end{array}$$

then there is a natural morphism $L_{A/S} \otimes_A B \to L_{B/R}$. This is because if X is a cofibrant replacement for A, then $X \otimes_R S$ is also cofibrant object, because $B \otimes_A -$ is a Quillen adjunction, by(4.8.2.15), then it factors through $X \otimes_R S \to Y \to B$ where Y is a cofibrant replacement of B, thus Y is also cofibrant. Then the functor $L_{A/S} \otimes_A B \to L_{B/R}$ is induced by

$$B \otimes_A (A \otimes_X \Omega_{X/R}) \to B \otimes_Y \Omega_{Y/S}.$$

The formation of Kähler differential commutes with arbitrary colimit as it is a left adjoint, so the formation of cotangent complex commutes with filtered colimits, both in A and B. Especially, it commutes with taking stalks, hence the sheaf of cotangent complexes of a map between schemes can be constructed as in the case of Kähler differentials, and it is a Qco sheaf.

Def. (6.1.2.4) [Canonical Resolution]. By the Dold-Kan correspondence, we will say that two simplicial A-modules are quasi-isomorphic iff their normalized nerves are quasi-isomorphic. Then $P_A(B) \to B$ is a quasi-isomorphic resolution of B, where B is the trivial complex.

Proof: There is a homotopy d between id and 0 for $n \leq 0$, where

$$d_n : F(GF)^n G(B) \to F(FG)^n \circ GFG(B)$$

using counit map, and on degree $0, -1$, it is $A[A[B]] \xrightarrow{\partial_1 - \partial_2} A[B] \to B \to 0$, which is clearly 0, so this is a zero map.

Thus $Tot(P_A(B)) \cong B$, and $N_*(A) \cong Tot(A)$ by Dold-Kan correspondence, so we are done. □

Cor. (6.1.2.5).

$$D_0(L_{B/A}, M) = \Omega_{B/A} \otimes M, \quad D^0(A/R, M) = \mathrm{Der}_R(A, M)$$

by the generator-relation definition of Kähler differential.

Prop. (6.1.2.6) [The fundamental Distinguished Triangle]. If $\mathcal{T}$ is a site and $A \to B \to C$ are morphisms of sheaves of rings over $\mathcal{T}$, then there is a morphism of simplicial A-modules that corresponds to distinguished triangles in $D^{\leq 0}(C)$ via Dold-Kan correspondence:

$$L_{B/A} \otimes^L_B C \to L_{C/A} \to L_{C/B}.$$

In particular, if M is a B-module, then there are long exact sequences

$$\ldots \to D_1(A/R, M) \to D_1(B/R, M) \to D_1(B/A, M) \to M \otimes_A \Omega_{A/R} \to M \otimes_A \Omega_{B/A} \to M \otimes_B \Omega_{B/A} \to 0$$

$$\ldots \to D^1(A/R, M) \to D^1(B/R, M) \to D^1(B/A, M) \to \mathrm{Der}_R(A, M) \to \mathrm{Der}_A(B, M) \to \mathrm{Der}_A(B, M) \to 0$$

Proof: Choose a simplicial resolution $X \to A$ where X is free, then we factor the morphism $X \to A \to B$ to get a commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{i} & Y \\ \downarrow & & \downarrow \\ A & \longrightarrow & B \end{array}$$

where i is free, then we have an exact sequence(in $Ch_{\geq 0}(R)$ via Dold-Kan) of simplicial modules

$$0 \to B \otimes_X \Omega_{X/R} \to B \otimes_Y \Omega_{Y/R} \to B \otimes_Y \Omega_{Y/X} \to 0$$

because each $X_n \to Y_n = X_n \otimes \bigoplus_{\varphi:[n]\twoheadrightarrow[k]} \varphi^* P_k$ has a retraction, and use(4.4.3.7).

Notice we have a simplicial map $A \otimes_X Y \to B$ which is a weak equivalence and $A \otimes_X Y$ is a free simplicial A-algebra. Then it suffices to note that $X_n \to Y_n = X_n \otimes \bigoplus_{\varphi:[n]\twoheadrightarrow[k]} \varphi^* P_k$ is projective implies

$$B \otimes_Y \Omega_{Y/X} \cong B \otimes_{A\otimes_X Y} \Omega_{A\otimes_X Y/A}$$

, and $\Omega_{X/R}$ is termwise projective. □

Prop. (6.1.2.7) [Properties of Cotangent Complexes].

- If $B = s(P)$ where P is a projective A-module, then $L_{B/A}$ is weakly equivalent to $\Omega^1_{P/A}[0]$.
- (Kunneth Formula) If B, C are Tor independent over A, then
$$L_{B\otimes C/A} \cong (L_{B/A} \otimes_A C) \oplus (L_{C/A} \otimes_A B).$$
- (Flat Base Change)If B, C are Tor independent over A, $L_{B/A} \otimes_A C \cong L_{B\otimes_A C/C}$.

Proof:

- $S_R(P)$ is already cofibrant in $(sCAlg_R)_{/A}$.
- Let $X \to B, Y \to C$ be cofibrant replacement of A, B respectively, then $X \otimes_R Y \to B \otimes_A C$ is a cofibrant replacement, as $X \otimes_A Y$ is cofibrant, and Tor independence shows
$$\pi_*(X \otimes_A Y) = \pi_*(X) \otimes_A \pi_*(Y) = B \otimes_A C.$$
thus the result follows from(4.4.3.6).
- The same as Künneth formula, noticing that $X \otimes_A C \to B \otimes_A C$ is a weak equivalence by Tor independence, and $X \otimes_A C$ is cofibrant.

□

3 Relations with Algebraic Properties

Cf.[Andre-Quillen Homology].

Prop. (6.1.3.1) [Acyclicity for Smooth Algebras]. If $A \to B$ is smooth, then $L_{B/A} \cong \Omega^1_{B/A}[0]$. In particular, if $A \to B$ is étale, then $L_{B/A} = 0$, and $L_{C/A} \cong L_{B/A} \otimes_B C$, by distinguished triangle(6.1.2.6).

Proof: The cotangent complex is local, so we may assume it is standard smooth, so it factors as $A \to A[X_1, \ldots, X_k] \xrightarrow{g} B$, where g is étale, so using the distinguished triangle and polynomial case, the result follows. □

Prop. (6.1.3.2) [Compatibility with p-adic Completion]. If A is a p-adically complete commutative ring with bounded p-torsion and B is a flat A-module, then B also has bounded p^∞-torsion by(4.9.2.4), let $\widehat{B}$ be the p-adic completion of B, then the cotangent complex $L_{\widehat{B}/B}$ vanishes after derived p-completion.

In particular, by the distinguished triangle(6.1.2.6), if B is a smooth algebra, then $L_{\widehat{B}/A} \cong \Omega^1_{\widehat{B}/A}$ is a finite projective $\widehat{B}$-module.

Proof: This is true after base change $- \otimes^L_A A/p$ by flat base change(6.1.2.7),(4.9.7.4) and derived Nakayama(4.9.6.10). □

4 Deformations

Prop. (6.1.4.1) [Topological Invariance of Étale Site]. Let A be a ring, consider the following category: $\mathcal{C}_A$ of flat A-algebras B that $L_{B/A}=0$, then if $\widetilde{A}\to A$ is surjective with locally nilpotent kernel, then the base change defines an isomorphism of categories $\mathcal{C}_{\widetilde{A}}\cong\mathcal{C}_A$.

By(6.1.2.7), $L_{B/A}$ vanish is equivalent to being étale, thus the properties characterize the invariance of étale site under infinitesimal thickening.

Proof: ? □

Prop. (6.1.4.2) [Relative Perfect Case]. If A is a ring of char$p$ and B is an A-algebra which is relatively perfect, i.e. $B^{(1)}=B\otimes_{A,\mathrm{Frob}}A\to B$ is an isomorphism, then $L_{B/A}=0$.

Proof: Notice for any A-algebra C, the relative Frobenius induces zero map $L_{C^{(1)}/A}\to L_{C/A}$, because by using the canonical polynomial resolution, $d(x^p)=px^{p-1}xs=0$. Now the relative Frobenius is an isomorphism $B^{(1)}\to B$, thus induces an isomorphism $L_{B^{(1)}/A}\to L_{B/A}$ by Functoriality, thus $L_{B/A}=0$. □

Cor. (6.1.4.3) [Witt Vector Construction]. There is an equivalence of categories of $\mathcal{C}_n=$ flat $\mathbb{Z}/p^n$-algebras that A/p is perfect and $\mathcal{C}_1=$ perfect rings over $\mathbb{Z}/p$.

moreover, taking limit, this is even equivalent to the category of flat p-adically complete $\mathbb{Z}_p$ algebras that A/p is perfect. Which is just the construction of Witt vectors.

Proof: It suffices to show that $\mathcal{C}_n\subset\mathcal{C}_{\mathbb{Z}/p^n}$: By(6.1.4.2) and flat base change(6.1.2.7), $L_{A/(\mathbb{Z}/p^n)}\otimes_{\mathbb{Z}/p^n}\mathbb{Z}/p\cong L_{(A/p)/(\mathbb{Z}/p)}=0$, so $L_{A/(\mathbb{Z}/p^n)}\otimes_{\mathbb{Z}/p^n}\mathbb{Z}/p^k\cong 0$ by induction, and so $L_{A/(\mathbb{Z}/p^n)}\cong 0$.

For the last assertion, it is flat because it is torsion-free, which is because if $p(x_n)=0$, then by $0\to p^n\mathbb{Z}/p^{n+1}\to\mathbb{Z}/p^{n+1}\xrightarrow{p}\mathbb{Z}/p^n\to 0$ and the flatness of A_{n+1}, $x_{n+1}\in p^nA_{n+1}$, thus $x_n=0$, and $x=0$. □

Prop. (6.1.4.4) [Adjointness of Witt Vectors]. Using a more careful analysis of cotangent complex(embedded deformation), we can show that if $A\to B\in\mathcal{C}_A$ and there is a infinitesimal deformation $C\to C'$ of A-algebra, then a map $B\to C'$ can be lifted to an A-algebra map $A\to C$.

In particular, taking inverse image, we get that

$$\mathrm{Hom}_{\mathbb{F}_p}(A,B/p)\cong\mathrm{Hom}_{\mathcal{CR}\mathrm{ing}_{\mathbb{Z}_p}}(W(A),B).$$

which is the usual adjointness of the Witt vector construction.

5 Algebra Extension

Cf.[Perfectoid Geometry Appendix B].

Def. (6.1.5.1) [Algebra Extensions]. Let $A\to B$ be a ring map and M be a B-module, then an **A-algebra extension** of B by M is a short exact sequence of A-modules $0\to M\to B'\to B\to 0$ that B' is an A-algebra with M being an ideal of it.

The set of such extensions are denoted by $\mathrm{Exal}_A(B,M)$.

Prop. (6.1.5.2). $\mathrm{Exal}_A(B,M)$ is a group under Baer sum, where the sum of two extension is the extension given by pushout, i.e. $(B_1\oplus B_2)/\{(m,-m)|m\in M\}$. Moreover, it is a B-module, where the multiplication is the pushout along multiplication of b on M.

Prop. (6.1.5.3). There is a trivial extension given by $D_B(M) = B \oplus M$(4.4.3.5), and the automorphism of $D_B(M)$ is isomorphic to $\mathrm{Der}_A(B, M)$ via $d \mapsto \mathrm{id} \oplus d$.

Proof: Cf.[Foundations of Perfectoid Spaces Masullo P118]. □

Prop. (6.1.5.4). Let $A \to B \to C$ be ring maps, then for any C-module M, there is an exact sequence

$$0 \to \mathrm{Der}_B(C, M) \to \mathrm{Der}_A(C, M) \to \mathrm{Der}_A(B, M) \xrightarrow{\partial} \mathrm{Exal}_B(C, M) \to \mathrm{Exal}_A(C, M) \to \mathrm{Exal}_A(B, M)$$

functorial in M. Where ∂ is given by(6.1.5.3).

Proof: Cf.[Foundations of Perfectoid Spaces Masullo P119]. □

Prop. (6.1.5.5). Let $A \to B$ be a ring map or a map of sheaves of rings, and let M be a B-module, then there is an isomorphism of B-modules that is natural in M:

$$\mathrm{Exal}_A(B, M) = \mathrm{Ext}^1_B(NL_{B/A}, M).$$

Proof: Cf.[Foundations of Perfectoid Spaces, P127]. □

Infinitesimal Deformation

Def. (6.1.5.6). An **infinitesimal deformation** of a f.g. k-algebra is defined as a algebra A' flat over $D = k[t]/(t^2)$ that $A' \otimes_D k = A$.

A f.g. k-algebra is called **rigid** if it has no infinitesimal deformations.

Prop. (6.1.5.7). Let A be a f.g. k-algebra, write A as a quotient of a polynomial ring over k with kernel J, then there is an exact sequence $J/J^2 \to \Omega_{P/k} \otimes_P A \to \Omega_{A/k} \to 0$ by(4.4.3.7), then we apply $\mathrm{Hom}_A(-, A)$ and let $T^1(A) = \mathrm{Coker}(\mathrm{Hom}_A(\Omega_{P/k} \otimes_A A, A) \to \mathrm{Hom}_A(J/J^2, A))$. Then $T^1(A)$ parametrize infinitesimal deformations of A.

6.2 Spectral Algebraic Geometry(Lurie)

Main references are Lurie's work, [Derived Algebraic Geometry, Thesis, Lurie].

Notation (6.2.0.1).

- Use notations from Derived Commutative Algebras.

Prop. (6.2.0.2) [$\mathcal{D}_{\mathcal{QC}oh}(\operatorname{Spec} R)$]. For $R \in \mathcal{CR}ing$, there exists a unique sheaf of ∞-categories $\mathcal{D}_{\mathcal{QC}oh}$ on $\operatorname{Spec} R$ s.t. for any affine open subset U,

$$\mathcal{D}_{\mathcal{QC}oh}(U) = \mathcal{D}(\mathcal{O}(U)).$$

Proof: Cf.[Clausen, deRham Cohomology]L8P3. □

Cor. (6.2.0.3). For $R \in \mathcal{CR}ing$ and any $M \in \mathcal{M}od(R)$, there exists an associated sheaf of derived modules $M^\sharp$ on $\operatorname{Spec} R$ s.t. for any affine open $U \subset \operatorname{Spec} R$, $M^\sharp(U) = M \otimes_R \mathcal{O}_{\operatorname{Spec} R}(U)$. (I think this sheaf is just the derived shifification of the associated sheaf $\widetilde{M}$ on $\operatorname{Spec} R$ defined in(5.5.1.1).)

Proof: Cf.[Clausen, deRham Cohomology]L8P3. □

Cor. (6.2.0.4). Let $X \in \mathcal{A}ff$ and $\mathcal{F} \in \mathcal{QC}oh(X)$, then $H^q(X;\mathcal{F}) = 0$ for $q > 0$.

Proof: This is because the sheaf cohomology is the global section of the derived shifification, and the derived shifification of $\mathcal{F}(X)^\sharp$ equals $\widetilde{\mathcal{F}(X)}$ on any affine opens by(6.2.0.3). Thus $H^*(X;\mathcal{F}) = \mathcal{F}(X) \in D(\mathcal{O}_X(X))$. □

Cor. (6.2.0.5). For $R \in \mathcal{CR}ing$, there is a sheaf of Abelian categories on $X = \operatorname{Spec} R$ with assigns $\mathcal{M}od_{\mathcal{O}_X(U)}$ for any affine open subset $U \subset X$.

Proof: It suffices to show the discrete elements in $\mathcal{D}_{\mathcal{QC}oh}(\operatorname{Spec} R)$ form a sheaf, i.e. if $M \in \mathcal{D}_{\mathcal{O}_X(U)}$ is locally discrete, then it is discrete. And this is because the ring extensions are flat. □

Def. (6.2.0.6) [$\mathcal{D}(X)$]. Let $X \in \mathcal{S}ch$, then $\mathcal{D}(X) = \mathcal{M}od_{\mathcal{O}_X}(\mathcal{S}h(X;\mathcal{D}(Z)))$ is an ∞-category, and the assignment $\mathcal{D}_X : U \mapsto \mathcal{D}(U)$ is a sheaf of ∞-categories on X.

Proof: **?** □

Def. (6.2.0.7) [$\mathcal{D}_{\mathcal{QC}oh}(\operatorname{Spec} R)$]. Let $X \in \mathcal{S}ch$, then there is a sub-∞-category

$$\mathcal{D}_{\mathcal{QC}oh}(X) \subset \mathcal{D}(X)$$

consisting of elements $\mathcal{M}$ s.t. for any inclusion of affine opens $U \subset V$, there is a natural isomorphism

$$\mathcal{M}(V) \otimes_{\mathcal{O}_X(V)} \mathcal{O}_X(U) \cong \mathcal{M}(U).$$

And the assignment $\mathcal{D}_{\mathcal{QC}oh,X} : U \mapsto \mathcal{D}_{\mathcal{QC}oh}(X)$ is a sheaf of ∞-categories on X.

Moreover, when X is affine, the global section functor defines an equivalence $\mathcal{D}(X) \cong D(\mathcal{O}_X(X))$.

Proof: **?**

This follows from(6.2.0.6) and the fact that the Qco requirement is local:.

The last assertion is trivial. □

Prop. (6.2.0.8) [Compact Objects in $\mathcal{D}(R)$]. For $R \in \mathcal{CR}\mathrm{ing}$ and $M \in \mathcal{D}(R)$, the following are equivalent:

- M is a compact object.
- M lies in the thick (stable-∞)subcategory generated by R.
- M is dualizable w.r.t. the tensor product.
- M can be represented by a bounded chain of finite projective R-modules.

In particular, there is a full sub-∞-category of $D_{\mathcal{QC}\mathrm{oh}}(R)$ consisting of perfect objects, denoted by $\mathcal{P}\mathrm{erf}(R)$.

Proof: Cf.[Clausen, deRham Cohomology]L8P8. □

Cor. (6.2.0.9). For $R \in \mathcal{CR}\mathrm{ing}$, $X = \operatorname{Spec} R$, the assignment $\mathcal{P}\mathrm{erf} : U \mapsto \mathcal{P}\mathrm{erf}(\mathcal{O}_X(U))$ on affine opens is a subsheaf of $D_{\mathcal{QC}\mathrm{oh},X}$ on affine opens.

Proof: Cf.[Clausen, deRham Cohomology]L8P9. □

Def. (6.2.0.10)[Perfect Objects]. For $X \in \mathcal{S}\mathrm{ch}$, a **perfect quasi-coherent sheaf** on X is an object $\mathcal{F} \in \mathcal{D}_{\mathcal{QC}\mathrm{oh}}(X)$ s.t. for any affine open $U \subset X$, $\mathcal{F}|_U \in \mathcal{D}(U)$ is a compact object(**?** i.e. $\mathrm{Hom}(\mathcal{M}, -) : \mathcal{D}_{\mathcal{QC}\mathrm{oh}}(X) \to s\,\mathcal{S}\mathrm{et}$ commutes with filtered colimits).

Prop. (6.2.0.11)[Pull and Push]. For $f : X \to Y \in \mathcal{S}\mathrm{ch}$, there is a pushforward functor $f_* : \mathcal{D}(X) \to \mathcal{D}(Y)$ s.t.

- $f_*\mathcal{D}_{\mathcal{QC}\mathrm{oh}}(X) \subset \mathcal{D}_{\mathcal{QC}\mathrm{oh}}(Y)$.
- $f_* : \mathcal{D}_{\mathcal{QC}\mathrm{oh}}(X) \to \mathcal{D}_{\mathcal{QC}\mathrm{oh}}(Y)$ preserves colimits and limits.

And it has a left adjoint $f^* : \mathcal{D}(Y) \to \mathcal{D}(X)$ s.t.

- $f^*\mathcal{D}_{\mathcal{QC}\mathrm{oh}}(Y) \subset \mathcal{D}_{\mathcal{QC}\mathrm{oh}}(X)$.
- If $X, Y \in \mathcal{A}\mathrm{ff}$, then f^* is just the derived base change functor.
- f_* commutes with base change**?**.
- f_* satisfies projection formula**?**.

Proof: Cf.[Clausen, deRham Cohomology]L8P7. □

Prop. (6.2.0.12). If f is smooth and proper, $f_* : \mathcal{D}_{\mathcal{QC}\mathrm{oh}}(X) \to \mathcal{D}_{\mathcal{QC}\mathrm{oh}}(Y)$ preserves perfect objects.

Proof: Cf.[Clausen, deRham Cohomology]L8P8. □

Prop. (6.2.0.13)[Grothendieck Duality]. If $f : X \to Y \in \mathcal{S}\mathrm{ch}$ is proper and smooth, then there is a right adjoint $f^!$ to $f_* : \mathcal{D}(X) \to \mathcal{D}(Y)$, and it satisfies

- There is a natural isomorphism of functors: $f^* \otimes f^!(\mathcal{O}_Y) \cong f^!$.
- If f has relative dimension d, then there is a natural isomorphism $f^!(\mathcal{O}_Y) \cong \Omega^d_{X/Y}[d]$.

Proof: **?** □

7.1 Intersection Theory

Main references are [Sta]Chap43, 44 and [Ful98].

1 Setups

Def. (7.1.1.1) [Setups]. The setup is a universally catenary(hence locally Noetherian) scheme S(5.4.1.31) endowed with a dimension function δ(3.11.3.36), which will be fixed.

Example (7.1.1.2). There are some examples of (S,δ) in(7.1.1.1):

- $k\in \texttt{Field}, S=\operatorname{Spec} k$ and $\delta(|S|)=0$.
- A is a Noetherian domain of dimension 1, $\delta(\mathfrak{p})=0$ if $\mathfrak{p}$ is a maximal ideal and $\delta(\eta)=1$ for the generic point η.
- S is a C.M. scheme and let $\delta(s)=-\dim(\mathcal{O}_{S,s})$.

Proof: These follow from(5.4.1.33). □

Prop. (7.1.1.3). Let (S,δ) be in(7.1.1.1), S Jacobian and $\delta(s)=0$ for any closed point $s\in S$. If $Z\subset S$ is an integral closed subscheme with generic point ξ, then

$$\delta(\xi)=\dim(Z)=\dim(\mathcal{O}_{Z,z})$$

where $z\in Z$ is a closed point.

Proof: Cf.[Sta]02QO. □

Prop. (7.1.1.4) [δ-Dimension]. For $f:X\to S$ locally of f.t., the function

$$\delta(x)=\delta(f(x))+\operatorname{tr.deg}_{k(f(x))}k(x)$$

is a dimension function on X. In particular, this equation is satisfied for any morphisms between schemes of f.t. over S.

For a closed subscheme Z of X, define $\dim_\delta(Z)=\sup\dim_\delta(\eta)$ where η are generic pts of irreducible components of Z.

Proof: Cf.[Sta]02JW.**?** □

2 Chow Homologies

Cycles

Def. (7.1.2.1) [Cycles]. An **algebraic cycle** on a scheme $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ is a formal sum of integral closed subschemes of X with integer coefficients that is locally finite. A k-cycle is a cycle that is a sum of integral closed subschemes of dimension k that is locally finite. The group of k-cycles over X is denoted by $Z_k(X)$.

If $\dim_\delta(X) = d$, then we also denote $Z^k(X) = Z_{d-k}(X)$.

Prop. (7.1.2.2). Let X be a scheme locally of f.t. over S, and $X = X_1 \cup X_2$ is a decomposition as closed subschemes, then there are exact sequences

$$Z_k(X_1 \cap X_2) \to Z_k(X_1) \oplus Z_k(X_2) \to Z_k(X) \to 0$$

Prop. (7.1.2.3) [Cycle associated to a Closed Subscheme]. For a closed subscheme Z of a scheme $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, if $\dim_\delta(Z) \leq k$ and $\eta \in Z$ has dimension k, then η is a generic pt of an irreducible component Z' of Z, and $m_{Z,Z'} = \mathrm{length}_{\mathcal{O}_{X,\eta}} \mathcal{O}_{Z,\eta}$ is finite.

So we may define the **k-cycle associated to** Z as: $[Z]_k = \sum_{Z' \subset Z} m_{Z,Z'}[Z']$, where the sum is over all integral components of Z of δ-dimension k.

Proof: $m_{Z,Z'}$ is finite because $\mathrm{length}_{\mathcal{O}_{Z,\eta}} \mathcal{O}_{Z,\eta} = \mathrm{length}_{\mathcal{O}_{X,\eta}} \mathcal{O}_{Z,\eta} < \infty$ because it is Noetherian and have 0 dimension(4.1.3.4). The sum is locally finite by(5.4.1.23). □

Prop. (7.1.2.4) [Cycle associated to a Coherent Sheaf]. For $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{F} \in \mathcal{C}\mathrm{oh}(X)$, if $\dim_\delta \mathrm{Supp}(\mathcal{F}) \leq k$ and $\eta \in \mathrm{Supp}(\mathcal{F})$ has dimension k, then η is a generic pt of an irreducible component Z' of Z, and $m_{Z,\mathcal{F}} = \mathrm{length}_{\mathcal{O}_{X,\eta}} \mathcal{F}_\eta < \infty$.

So we may define the **k-cycle associated to** $\mathcal{F}$ as: $[\mathcal{F}]_k = \sum_{Z \subset X} m_{Z,\mathcal{F}}[Z]$, where the sum is over all integral components of $\mathrm{Supp}\,\mathcal{F}$ of δ-dimension k.

Proof: $\mathrm{length}_{\mathcal{O}_{X,\eta}} \mathcal{F}_\xi < \infty$ by(4.2.5.7). □

Prop. (7.1.2.5). Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $Z \subset X$ a closed subscheme with $\dim_\delta(Z) \leq k$, then $[Z]_k = [\mathcal{O}_Z]_k$.

Prop. (7.1.2.6). Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, the cycle map from $\mathcal{C}\mathrm{oh}^{\leq k}(X)$ to $Z_k(X)$ is additive.

Pushforward and Pullback

Lemma (7.1.2.7) [Degree of Maps]. Let $f : X \to Y$ be a map between schemes integral and locally of f.t. over S, if $\dim_\delta X = \dim_\delta Y$, then either $f(X)$ not dominant or the function field extension is finite. If f is dominant, the the degree of f(5.4.4.55) is a finite number.

Proof: Because X is irreducible, so does $f(X)$ and $\overline{f(X)}$. If $f(X)$ is dominant, then f maps the generic point of X to that of Y. Now $\deg_{K(Y)}(K(X)) = 0$ and $K(X)/K(Y)$ is f.g., thus it is a finite extension. □

Lemma (7.1.2.8). Let $f : X \to Y$ be a qc map between schemes integral and locally of f.t. over S, and $\{Z_i\}$ is a locally finite collection of closed subschemes of X, then $\{\overline{f(Z)}\}$ is also a locally finite collection of closed subschemes of X.

Proof: This is a simple topological proof and omitted. □

Def. (7.1.2.9) [Proper Pushforward]. Let $f: X \to Y$ be a proper morphism in $\mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, we define a map

$$p_*: Z_k(X) \to \mathrm{CH}_k(X)$$

as follows: If $Z \subset X$ is an integral closed subscheme of X that $\dim_\delta(Z) = k$, then we define

$$f_*[Z] = \begin{cases} 0 & \dim_\delta(f(Z)) \le k \\ \deg(Z/f(Z))[f(Z)](7.1.2.7) & \dim_\delta(f(Z)) = k \end{cases}.$$

where we regard $f(Z)$ as an integral closed subscheme of Y using its scheme-theoretical image. In general

$$f_*(\sum n_Z[Z]) = \sum n_Z f_*([Z]).$$

The sum is locally finite by(7.1.2.8).

It can be easily verified that $f_* \circ g_* = (f \circ g)_*$.

Prop. (7.1.2.10) [Pushforward of Coherent Sheaves]. Let $f: X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, then

- If $Z \subset X$ is an integral closed subscheme of X that $\dim_\delta(Z) \le k$, then

$$f_*[Z]_k = [\mathcal{O}_Z]_k.$$

- If $\mathcal{F} \in \mathcal{C}\mathrm{oh}^{\le k}(X)$, then

$$f_*[\mathcal{F}]_k = [f_*\mathcal{F}]_k.$$

Proof: 1 follows from 2 and(7.1.2.5). To show 2, by restricting to $\mathrm{Supp}(\mathcal{F})$ and taking the scheme-theoretic image, it suffices to show for both closed immersions and proper dominant maps. The closed immersions case are easy. For the proper dominant case, it suffices to show $f_*[\mathcal{F}]_k$ and $[f_*\mathcal{F}]_k$ have the same coefficients in each integral subscheme $Z \subset X$ of dimension k. By looking at the inverse image of the generic point of Z, we may assume that f is finite by(5.4.4.53). Thus we can assume f is finite. Then it reduces to the affine case, which follows from(4.1.2.7). □

Lemma (7.1.2.11). Let $f: X \to Y$ be a flat morphism of relative dimension r in $\mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, then for any closed subscheme $Z \subset Y$, $\dim_\delta(f^{-1}(Z)) = \dim_\delta(Z) + r$ if $f^{-1}(Z) \neq \varnothing$. If Z is irreducible and $Z' \subset f^{-1}(Z)$ is an irreducible component, then Z' dominants Z and $\dim_\delta(Z') = \dim_\delta(Z) + r$.

Proof: By passing to the integral components, we may assume $Z = Y$ is integral and $X \to Y$ is surjective, then notice f is open, and use(7.1.1.4) and(5.6.3.7). □

Def. (7.1.2.12) [Flat Pullbacks]. Let $f: X \to Y$ be a flat morphism of relative dimension r in $\mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, for $Z \subset X$ an integral closed subscheme that $\dim_\delta(Z) \le k$, define

$$f^*: Z_k(Y) \to Z_{k+r}(X): f^*([Z]) = [f^{-1}(Z)]_{k+r}$$

which is definable by(7.1.2.11). In general, define $f^*(\sum n_Z[Z]) = \sum n_Z f^*([Z])$, which is locally finite.

Prop. (7.1.2.13). If $f: X \to Y, g: Y \to Z \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ is flat of relative dimensions r and s, then $f^* \circ g^* = (g \circ f)^*$.

Proof: Firstly $g \circ f$ is flat of relative dimension $r + s$ by(5.6.3.18). And the assertion follows from(4.1.2.9). □

Prop. (7.1.2.14). Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $i : Y \to X$ a reduced closed subscheme of X, $j : U = X \backslash Z \to X$, then for any $k \in \mathbb{Z}$, there is an exact sequence

$$Z_k(Y) \xrightarrow{i_*} Z_k(X) \xrightarrow{j^*} Z_k(U) \to 0.$$

Prop. (7.1.2.15) [Pullback of Coherent Sheaves]. If $f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ is flat of relative dimensions r, $\mathcal{F} \in \mathcal{C}\mathrm{oh}^{\leq k}(\mathcal{O}_Y)$, then $f^*\mathcal{F} \in \mathcal{C}\mathrm{oh}^{\leq k+r}(\mathcal{O}_X)$, and

$$f^*[\mathcal{F}] = [f^*\mathcal{F}]_{k+r}.$$

In particular, for a closed subscheme $Z \subset X$ with $\dim_\delta(Z) \leq k$, $f^*[Z]_k = [f^{-1}Z]_{k+r}$, by(4.1.2.8).

Proof: This follows from(4.1.2.9). □

Prop. (7.1.2.16) [Push and Pull].

- Let

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

be a diagram in $\mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ where f is proper and g is flat of relative dimension r, then

$$g^*f_* = (g')^*f'_* : Z_k(X) \to Z_{k+r}(Y').$$

- Let $f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ be a finite locally free morphism of degree d, then it it both proper and flat of relative dimension 0, and $f_*f^* = [d] : Z_k(Y) \to Z_k(Y)$.

Proof: 1: It suffices to prove for a closed subscheme $W \subset X$ of δ-dimension k. Then $[W] = [\mathcal{O}_W]$(7.1.2.5). Then by(7.1.2.10) and(7.1.2.15), the assertion follows from flat base change.

2: Similarly this follows from the fact $f_*f^*\mathcal{O}_Z$ is a finite locally free $\mathcal{O}_Z$-sheaf of rank d. □

Rational Equivalences and Chow Groups

Def. (7.1.2.17)[Prime Weil Divisors]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft,int}}/S$, then an integral closed scheme $W \subset X$ of δ-codimension 1 is called a **prime Weil divisor**.

Prop. (7.1.2.18)[Principal Weil Divisor]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft,int}}/S$, $f \in \mathcal{K}$, for any prime Weil divisor Z with generic pt η, we can define $\mathrm{ord}_Z(f) = \mathrm{ord}_{\mathcal{O}_{X,\eta}}(f)$(4.1.2.10). It is multiplicative, and the closed integral subschemes Z that $\mathrm{ord}_Z(f) \neq 0$ is locally finite.

So, we can define the **principle Weil divisor** $\mathrm{div}(f) = \sum_Z \mathrm{ord}_Z(f)[Z]$.

Proof: There is an open subset U that $f \in \Gamma(U, \mathcal{O}_X^*)$, so all Z are irreducible components of $X - U$, which is locally finite because X is locally Noetherian and(5.4.1.23). □

Def. (7.1.2.19)[Principle Divisors]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $f \in K(X)^*$, then the **principle divisor associated to** f is defined to be

$$\mathrm{div}(f) = \sum \mathrm{ord}_Z(f)[Z] \in Z^1(X)$$

as defined in(7.1.2.18). This is truly a k-cycle.

Def. (7.1.2.20)[Rational Equivalence]. Let $X \in \mathcal{S}\mathrm{ch}^{\text{loc.ft}}/S$ has δ-dimension $k+1$. Given any locally finite collection of integrally closed subschemes $W_i \subset X$ of δ-dimension $k+1$ and rational functions f_i on W_i, we can consider the k-cycle $\sum (i_j)_*(\mathrm{div}(f_i))$ on X. This is a cycle because $\coprod W_i \to X$ is proper. Two k-cycles are called **rational equivalent** if they differ by a k-cycle of the this form.

Define the **Chow group of k-cycles** $\mathrm{CH}_k(X)$ to be $Z_k(X)$ modulo the rational equivalence relation. $\mathrm{CH}_k(X)$ is also denoted by $\mathrm{Cl}(X)$.

Lemma (7.1.2.21) [Push and Pull of Principle Divisors].

- If $f: X \to Y \in \mathcal{S}\mathrm{ch}^{\text{loc.ft,int}}/S$ is flat of relative dimension r, and $g \in K(Y)^*$, then $f^* \mathrm{div}(f) = \mathrm{div}(f)$.
- If $\varphi: X \to Y \in \mathcal{S}\mathrm{ch}^{\text{loc.ft,int},\delta=d}/S$ is a dominant proper morphism, $f \in K(X)^*$, and $g = \mathrm{Nm}_{K(X)/K(Y)}(f) \in K(Y)^*$, then $f_* \mathrm{div}(f) = \mathrm{div}(g)$.

Proof: 1: Cf.[Sta]0EPH**?**.
2: Cf.[Sta]02RT**?**. □

Lemma (7.1.2.22). If $X \in \mathcal{S}\mathrm{ch}^{\text{loc.ft,int},\delta=n}/S$ $U \subset X$ be an open subscheme and $f \in \Gamma(U, \mathcal{O}_X)^* \subset K(X)^*$, let Y be the graph of f in $X \times_S \mathbb{P}^1_S$, then

- the projection $\mathrm{pr}_1 : Y \to X$ is an isomorphism $\mathrm{pr}^{-1}(U) \to U$, thus $\dim_\delta(Y) = n$.
- the closed subschemes $Y_0 = \mathrm{pr}_2^{-1}(\{0\})$ and $Y_\infty = \mathrm{pr}_2^{-1}(\{\infty\})$ of Y are effective Cartier divisors. In particular, they have δ-dimension $n-1$ by(7.1.5.2).
- $\mathrm{div}_Y(f) = [Y_0] - [Y_\infty]$.
- $\mathrm{div}_X(f) = \mathrm{pr}_{1*} \mathrm{div}_Y(f) = [Y_0] - [Y_\infty]$.

Proof: 1 is clear.
2 follows from(5.8.1.7) as $\mathrm{pr}_2 : Y \to \mathbb{P}^1$ is dominant.
3 is clear.
4 follows from item1 and(7.1.2.21). □

Prop. (7.1.2.23) [Rational Equivalence via Rational Functions]. Let $X \in \mathcal{S}\mathrm{ch}^{\text{loc.ft}}/S$, then $\alpha \in Z_k(X)$ is rationally trivial iff

$$\alpha = \sum ([(W_i)_0]_k - [(W_i)_1]_k) = j_0^*(\sum [W_i]) - j_\infty^*(\sum [W_i])$$

where $\{W_i\}$ is a locally finite family of integral closed subschemes of $X \times_S \mathbb{P}^1_S$ of δ-dimension k.(j_0^*, j_∞^* are the Gysin maps, which will be defined in(7.1.4.2))

Proof: Firstly such a $\sum([(W_i)_0]_k - [(W_i)_\infty]_k)$ is locally finite, and each $[(W_i)_0]_k - [(W_i)_\infty]_k$ is rationally trivial: Similar as in(7.1.2.22), $[(W_i)_0] - [(W_i)_\infty]$ is rationally trivial on W_i, and then it pushforward via pr_1 is also rationally trivial, by(7.1.2.21).

Conversely, if $\alpha = \sum (V_i \to X)_* \mathrm{div}(f_i)$, where $\{V_i\}$ is a locally finite family of integral closed subschemes of X of δ-dimension $k+1$ and $f_i \in K(V_i)^*$. Let $W_i \subset V_i \times \mathbb{P}^1_k \subset X_i \times \mathbb{P}^1_k$ be the the graph of f, then $(V_i \to X)_* \mathrm{div}(f_i)$ equals $[(W_i)_0]_k - [(W_i)_1]_k$ by(7.1.2.22) again.(We are secretly using the fact Gysin map commutes with pushforwards(7.1.6.9), but in this case it is trivial trough). □

Prop. (7.1.2.24) [Push and Pull for Chow Groups].

- If $f: X \to Y \in \mathcal{S}\mathrm{ch}^{\text{loc.ft}}/S$ is flat of relative dimension r, then f^* induces a map $\mathrm{CH}_k(Y) \to \mathrm{CH}_{k+r}(X)$ for each $k \in \mathbb{N}$.

- If $f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ is proper, then f_* induces a map $\mathrm{CH}_k(X) \to \mathrm{CH}_k(X)$ for each $k \in \mathbb{N}$.

Proof: Cf.[Sta]02S2, 02S1. □

Prop. (7.1.2.25) [Restriction of Divisors]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $i : Y \to X$ a reduced closed subscheme of X, $j : U = X\backslash Z \to X$, then for any $k \in \mathbb{Z}$, there is an exact sequence

$$\mathrm{CH}_k(Y) \xrightarrow{i_*} \mathrm{CH}_k(X) \xrightarrow{j^*} \mathrm{CH}_k(U) \to 0.$$

Proof: Cf.[Sta]02RX?. □

Prop. (7.1.2.26)[Excision]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and X_1, X_2 be closed subschemes of X s.t. $X_1 \cup X_2 = X$ as sets, then for any $k \in \mathbb{Z}$, there is an exact sequence

$$\mathrm{CH}_k(X_1 \cap X_2) \to \mathrm{CH}_k(X_1) \oplus \mathrm{CH}_k(X_2) \to \mathrm{CH}_k(X) \to 0.$$

Proof: Cf.[Sta]0F94. □

Def. (7.1.2.27)[Degree of 0-Cycles]. Let X be a proper scheme over a field k, the **degree of a zero cycle** is given by the proper pushforward

$$p_* : \mathrm{CH}_0(X) \to \mathrm{CH}_0(\operatorname{Spec} k) \cong \mathbb{Z}.$$

Equivalently, if $\alpha = \sum n_i[Z_i] \in Z_0(X)$, $\deg(\alpha) = \sum n_i \deg(Z_i)$. deg is also denoted by $\int_X$.

Def. (7.1.2.28) [Stratification by Dimension]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, then the following are equivalent:

- There exists a decomposition $X = \coprod_n X_n$ where X_n is pure of δ-dimension n.
- For any $x \in X$, there exist s nbhd $x \in U$ s.t. U is pure of δ-dimension n.
- For an $x \in X$, the irreducible components of X containing x are all of the same δ-dimension n_x.

These conditions are satisfied if X is normal or Cohen-Macaulay.

Proof: $1 \to 2 \to 3$ is trivial. $3 \to 1$ follows from the fact $x \mapsto n_x$ is continuous.

If X is normal, it is a disjoint union of integral schemes by(5.4.2.3). For X Cohen-Macaulay, Cf.[Sta]0FE3.? □

Def. (7.1.2.29)[Cohomological Chow Groups]. If X satisfies(7.1.2.28), we define

$$Z^p(X) = \prod_n Z_{n-p}(X_n), \quad Z^*(X) = \bigoplus_p Z^p(X)$$

and the **Chow group of codimension p cycle**

$$\mathrm{CH}^p(X) = \prod_n \mathrm{CH}_{n-p}(X_n), \quad \mathrm{CH}^*(X) = \bigoplus_p \mathrm{CH}^p(X).$$

Def. (7.1.2.30)[Fundamental Class]. If X satisfies(7.1.2.28), define

$$[X] = \prod [X_n]_n \in \mathrm{CH}^0(X)$$

to be the **fundamental class of X**.

3 Chow Groups and K-Groups

Cf.[Sta]42.22, 42.56 and42.68.

4 Gysin Maps

Def. (7.1.4.1) [Gysin Maps for Virtual Divisors]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S, \mathcal{L} \in \mathrm{Pic}(X), s \in H^0(X,\mathcal{L})$, denote $D = Z(s)$, and $i : D \to X$ the closed immersion. Then for any $k \in \mathbb{Z}$, there is a **Gysin homomorphism**

$$i^* : Z_{k+1}(X) \to \mathrm{CH}_k(D)$$

that for an integral closed subscheme $Z \subset X$ with $\dim_\delta(Z) = k+1$,

$$i^*([Z]) = \begin{cases} [D \cap Z]_k & , Z \not\subset D \\ i'_*(c_1(\mathcal{L}|_Z) \cap [Z]) & , Z \subset D \text{ via } i' : Z \to D \end{cases}$$

and extends linearly to $Z_{k+1}(X)$, which is also locally finite.

We will see this is map i^* in fact factor through rational equivalence relations in(7.1.6.9).

Proof: To show this is well defined, Cf.[Sta]02TO.? □

Remark (7.1.4.2). If $\mathcal{L}|_D \cong \mathcal{O}_D$, the $c_1(\mathcal{L}|_Z)$ term is trivial, so the Gysin homomorphism factors through $Z_k(D) \to \mathrm{CH}_k(D)$.

Cor. (7.1.4.3). Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S, (\mathcal{L}, s, i : D \to X)$ as in(7.1.4.1), then for any $\alpha \in \mathrm{CH}_*(X)$,

$$i_* i^* \alpha = c_1(\mathcal{L}) \cap \alpha$$

Def. (7.1.4.4) [Intersection with Cartier Divisors]. If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S, D \in \mathrm{Cart}^{\mathrm{eff}}(X)$, denote $D \cap \alpha = c_1(\mathcal{O}_X(D)) \cap \alpha$ for $\alpha \in Z_*(X)$.?

Def. (7.1.4.5) [Gysin Map for Local Complete Intersection Maps]. Let $f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ be a local complete intersection map s.t. $f = g \circ i$ where g is smooth and i is a regular immersion, then we define the **Gyin map** for f to be $f^! = i^! \circ g^* \in A^*(X \to Y)$. This is independent of the decomposition $f = g \circ i$ chosen. In this case, we say the Gysin map for f exists.

Proof: Cf.[Sta]0FF2.? □

Prop. (7.1.4.6) [$f^!$ and f^*]. Let $f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ be a local complete intersection map, then if the Gysin map $f^!$ exists and f is flat, then f^* can be defined and $f^! = f^* \in A^*(X \to Y)$.

Proof: Cf.[Sta]0FF4.? □

5 Weil Divisors

Prop. (7.1.5.1) [Weil-Cartier]. For $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, there is a map from Cartier divisors on X to Weil divisors mapping (D, s_D) to $[Z(s_D)]_k$. Notice this is defined because a Cartier divisor is locally defined by a regular element and Krull's principal ideal theorem.

Moreover, if X is locally factorial, this map is an isomorphism $\mathrm{CaCl}(X) \to \mathrm{Cl}(X)$ by(5.8.1.4), and (effective)Cartier divisors correspond (effective)Weil divisors.

This in particular applies to non-singular varieties over a field, by(4.3.5.19).

Prop. (7.1.5.2). Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $Z \subset X$ be an integral closed subscheme, then Z is a Weil divisor iff $\dim_\delta(Z) = \dim_\delta(X) - 1$. In particular, this holds for any irreducible component of a Cartier divisor by(7.1.5.1).

Def. (7.1.5.3) [$\mathbb{Q}$-Cartier Divisors]. A **$\mathbb{Q}$-Cartier divisor** on a locally Noetherian integral scheme is a Weil divisor that some multiply of it is the image of a Cartier divisor.

Example (7.1.5.4)[Non-$\mathbb{Q}$-Cartier Divisors]. It is easy to show some Weil divisor is not an $\mathbb{Q}$-Cartier divisor (on a singular variety), by showing its complement is not affine(5.8.1.1). For example, on $X = \operatorname{Spec} k[x, y, z, w]/(xy - zw)$, the Weil divisor cut out by (z, w) is not $\mathbb{Q}$-Cartier, as the closed subscheme $y = w = 0$ of its complement is isomorphic to $\mathbb{A}^2_k \backslash \{(0, 0)\}$, which is not affine by calculating Čech cohomology.

In particular, $k[x, y, z, w]/(xy - zw)$ is normal but not a UFD.

Prop. (7.1.5.5) [Rational Functions and Poles]. If X is an integral locally Noetherian normal scheme and $f \in K(X)$ has no poles, then $f \in \Gamma(X)$, by(4.3.5.11).

Prop. (7.1.5.6) [UFD and Class Groups]. For A a Noetherian normal domain, it is a UFD iff $\mathrm{Cl}(\operatorname{Spec} A) = 0$.

Proof: It suffices to show minimal primes of A is principal iff minimal primes of A are principal divisors. This is done by(4.3.5.11) and(2.2.3.6). □

Prop. (7.1.5.7) [Picard Group of Projective Spaces]. Let R be a UFD, then $\mathrm{Cl}(\mathbb{P}^n_R) = \mathbb{Z}$, and it is generated by $[H]$ where H is any hyperplane of $\mathbb{P}^n_R$. And a hypersurface Y of degree d is mapped to d.

Proof: These follow from(7.1.7.10) and(7.1.5.6). The last assertion follows from the fact $[Y] \sim d[H]$ by direct verification. □

Cor. (7.1.5.8). If $Y \subset \mathbb{P}^n_k$ is a hypersurface of degree d, then $\mathrm{Cl}(\mathbb{P}^2 \backslash Y) = \mathbb{Z}/d\mathbb{Z}$.

Proof: This follows form(7.1.2.25) and(7.1.5.7). □

Cor. (7.1.5.9). If $k \in \mathtt{Field}$, $\mathrm{Cl}(\mathbb{P}^1_k \times \mathbb{P}^1_k) = \mathbb{Z} \oplus \mathbb{Z}$, by(7.1.7.10).

Prop. (7.1.5.10). If X is a non-singular cubic surface in $\mathbb{P}^3_k$, then $\mathrm{Cl}(X) \cong \mathbb{Z}^7$.

Proof: Cf.[Har77]Chap5.4.8. □

6 Bivariant Classes

Def. (7.1.6.1) [Bivariant Classes]. Let $f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $p \in \mathbb{Z}$, a **bivariant class** c of degree p for f is a class of maps

$$c \cap - : \mathrm{CH}_k(Y') \to \mathrm{CH}_{k-p}(Y' \times_Y X)$$

for any $Y' \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/Y$ and $k \in \mathbb{Z}_+$ that satisfies

- If $Y'' \to Y' \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/Y$ is proper, $c \cap -$ commutes with proper pushforwards.
- If $Y'' \to Y' \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/Y$ is flat of relative dimension $r \in \mathbb{Z}$, $c \cap -$ commutes with flat pullbacks.
- Let $(\mathcal{L}, s, i : D \to Y')$ be a triple on Y' as in(7.1.4.1), then $c \cap -$ commutes with Gysin homomorphisms i^*.

The set of bivariant classes of degree p for f is denoted by $A^p(X \to Y)$. And denote $A^*(X \to Y) = \oplus_{p\in\mathbb{Z}} A^p(X \to Y)$.

Prop. (7.1.6.2). For any $f : X \to Y, g : Y \to X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, $p, q \in \mathbb{Z}$, $A^p(X \to Y)$ is an Abelian group, and the composition defines a bilinear map

$$A^q(Y \to Z) \times A^p(X \to Y) \to A^{p+q}(X \to Z)$$

that is associative w.r.t. compositions in $\mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$.

Def. (7.1.6.3) [Chow Cohomologies]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, denote $A^p(X) = A^p(\mathrm{id}_X)$, and $A^*(X) = \oplus_{p\in\mathbb{Z}} A^p(X)$ the graded ring, called the **Chow cohomology group** of X.

Prop. (7.1.6.4) [Restriction of Classes]. Let $X \to Y, f : Y' \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $X' = X \times_Y Y'$, then obviously there is a map $f^* : A^p(X \to Y) \to A^p(X' \to Y')$. In particular, if $Z \subset X$ is a closed subscheme, then $f^*(c) \cap \alpha = c \cap f_*(\alpha)$ for $c \in A^p(Z \to X), \alpha \in A^p(Z)$ by proper pushforward(7.1.6.1).

Cor. (7.1.6.5) [Product of Classes]. Let $X \to Y, X' \to Y' \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, $c \in A^p(X \to Y), c' \in A^q(X' \to Y')$, then the product $c \circ c'$ is defined to be the element in $A^{p+q}(X \times_S X' \to Y \times_S Y')$ defined by the map

$$\mathrm{CH}_*(Y \times_S Y') \xrightarrow{c' \cap -} \mathrm{CH}_{*+q}(Y \times_S X') \xrightarrow{c \cap -} \mathrm{CH}_{*+p+q}(X \times_S X')$$

and all base change variants of this.

Notice $c' \circ c$ is also in $A^{p+q}(X \times_S X' \to Y \times_S Y')$, so it makes sense to talk about when two classes commute. Maybe $c' \circ c$ can be defined on smaller base changes, but to say c, c' commute always means $c \circ c' = c' \circ c \in A^{p+q}(X \times_S X' \to Y \times_S Y')$.

Lemma (7.1.6.6) [Gysin Factors Through Rational Equivalences]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, Gysin homomorphism for a triple $(\mathcal{L}, s, j : D \to X)$ on X that are base change of $(\mathcal{O}(1), x, j : S \times (0) \to \mathbb{P}^1_S)$ factors through rational equivalences.

Proof: This follows from the characterization of rational equivalences in(7.1.2.23) and the fact in this case Gysin maps are easy to describe: They are just k-parts of the inverse images. □

Prop. (7.1.6.7) [Weakening Bivariant Conditions]. Let $f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and c is a class of maps

$$c \cap - : Z_k(Y') \to \mathrm{CH}_{k-p}(Y' \times_Y X)$$

for any $Y' \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/Y$ that is compatible with Gysin homomorphism for triples $(\mathcal{L}, s, j : D \to Y')$ that are base change of $(\mathcal{O}(1), x, j : S \times (0) \to \mathbb{P}^1_S)$, then c factors through rational equivalences

And if moreover c commutes with proper pushforwards and flat pullbacks(up to rational homotopy), then it induces a bivariant class $c \in A^p(X \to Y)$.

Proof: For the first assertion: As $\mathcal{L}|_D = \mathcal{O}_D$, the Gysin homomorphism is defined on the level of cycles by(7.1.4.2) and pass to CH_*(7.1.6.6), so compositions with Gysin homomorphisms are well-defined. Then c factors through rational equivalence by the characterization of rational equivalences in(7.1.2.23).

For the last assertion, Cf.[Ful98]P321 or [Sta]0F9A.**?** □

Prop. (7.1.6.8). Let $f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $X = \coprod_I X_i, Y = \coprod_J Y_j$ be clopen subschemes and $\alpha : I \to J$ is a map of sets s.t. $f(X_i) \subset Y_{\alpha(i)}$, then for any $p \in \mathbb{Z}_+$,

$$A^p(X \to Y) = \prod_I A^p(X_i \to Y_{\alpha(i)}).$$

Proof: Cf.[Sta]0FDZ?. □

Prop. (7.1.6.9)[Gysin Homomorphisms are Bivariant]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $(\mathcal{L}, s, i : D \to X)$ be a triple on X as in(7.1.4.1), then the Gysin homomorphism $(i')^*$ associated to the base changes of i form a bivariant class in $A^1(D \to X)$.

Proof: Cf.[Sta]02TA, 0B71, 0B73.? and(7.1.6.7).

Let $f : X' \to X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $(\mathcal{L}, s, i : D \to X)$ be a triple on X as in(7.1.4.1), we can define the pullback triple $f^*(\mathcal{L}, s, i) = (\mathcal{L}', s', i' : D' \to X')$, and then

- If f is proper, then Gysin maps commute with proper pushforwards.
- If f is flat of relative dimension r, then the Gysin maps commute with flat pullbacks.
- If $(\mathcal{M}, t, f : X' \to X)$ is a triple on X as in(7.1.4.1), then the different Gysin maps are compatible.

□

Prop. (7.1.6.10) [Flat Pullbacks are Bivariant]. Let $f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ be flat of relative dimension r, then the flat pullbacks along base changes of f form a bivariant class of degree $-r$.

Proof: This follows from(7.1.2.13)(7.1.2.16)(7.1.6.9) and(7.1.6.7). □

Prop. (7.1.6.11)[Proper Pushforwards are Bivariant]. Let $f : X \to Y, g : Y \to Z \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, f is proper, and $c \in A^p(X \to Z)$, then the base change of $f_* \circ c$ form a bivariant class in $A^p(Y \to Z)$.

Proof: This reduces to the fact proper pushforwards commutes with flat pullbacks, proper pushforwards and Gysin maps, by(7.1.6.10)(7.1.6.9)(7.1.2.9) and(7.1.6.7). □

7 Chern Classes

Invertible Sheaves

Prop. (7.1.7.1) [First Chern Classes]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{L} \in \mathrm{Pic}(X)$, then for any $k \in \mathbb{Z}$, there is a map

$$c_1(\mathcal{L}) \cap - : Z_{k+1}(X) \to \mathrm{CH}_k(X)$$

called intersection with the **first Chern class** of $\mathcal{L}$(the name will be made clear from(7.1.7.5)), defined as follows: If $i : Z \to X$ is an integral subscheme of X with $\dim_\delta(Z) = k+1$, then $c_1(\mathcal{L}) \cap [Z]$ is the the pushforward of the image of $i^*\mathcal{L}$ under the map $\mathrm{Pic}(Z) \to \mathrm{Cl}(Z) \cong \mathrm{CH}_k(Z)$(5.5.3.14), i.e.

$$c_1(\mathcal{L}) \cap [Z] = i_*(c_1(i^*\mathcal{L}) \cap [W]).$$

In general, define $c_1(\mathcal{L}) \cap (\sum n_Z[Z]) = \sum n_Z c_1(\mathcal{L}) \cap [Z]$. We will see the first Chern class factors through rational equivalence relations in(7.1.7.5).

Lemma (7.1.7.2) [The first Chern Class is Multiplicative]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{L}, \mathcal{N} \in \mathrm{Pic}(X)$, then

$$c_1(\mathcal{L}) + c_1(\mathcal{N}) = c_1(\mathcal{L} \otimes \mathcal{N}) : \mathrm{CH}_*(X) \to \mathrm{CH}_*(X).$$

In particular, $c_1(\mathcal{L}) = -c_1(\mathcal{L}^{-1})$, and $c_1(\mathcal{O}_X) = 0$.

Prop. (7.1.7.3) [Chern Classes and Zero Cycles]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{L} \in \mathrm{Pic}(X)$, $Y \subset X$ a closed subscheme. If $s \in \Gamma(Y, \mathcal{L}|_Y)$ satisfies

- $\dim_\delta(Y) \leq k+1$.
- $\dim_\delta(Z(s)) \leq k$.
- For any generic point ξ of irreducible components of $Z(s)$ of δ-dimension k, multiplying by s induces an injection $\mathcal{O}_{Y,\xi} \to (\mathcal{L}|_Y)_\xi$.

Then $c_1(\mathcal{L}) \cap [Y]_{k+1} = [Z(s)]_k$.

Proof: Cf.[Sta]02SQ.**?** □

Prop. (7.1.7.4) [First Chern Classes Factor Through $\mathrm{CH}_*(X)$]. Situation in(7.1.7.1), then the map $c_1(\mathcal{L}) \cap - : Z_{k+1}(X) \to \mathrm{CH}_k(X)$ factors through $Z_{k+1}(X) \to \mathrm{CH}_{k+1}(X)$.

Proof: Cf.[Sta]02TI. □

Prop. (7.1.7.5) [First Chern Classes Form Bivariant Classes]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/X$ and $\mathcal{L} \in \mathrm{Pic}(X)$, then the maps $c_1(f^*\mathcal{L}) \cap - : Z_*(X') \to \mathrm{CH}_{*-1}(X')$ factor through rational equivalences for each $f : X' \to X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/X$, and form a bivariant class in $A^1(X)$, called the **first Chern class** $c_1(\mathcal{L})$.

Proof: Cf.[Sta]02SU, 02SS, 0B72. and(7.1.6.7).
To show it commutes with pullbacks, □

Prop. (7.1.7.6) [First Chern Classes Commute with Bivariant Classes]. Let $f : X' \to X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{L} \in \mathrm{Pic}(X)$, then $c_1(\mathcal{L})$ commutes with every element of $A^*(X' \to X)$.
In particular, $c_1(\mathcal{L})$ is in the center of $A^*(X)$.

Proof: Cf.[Sta]0B7B.**?** □

Prop. (7.1.7.7). Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{L} \in \mathrm{Pic}(X)$ be an ample invertible sheaf. Assume $d = \dim(X) < \infty$, then for any $\mathcal{L}_1, \ldots, \mathcal{L}_{d+1} \in \mathrm{Pic}(X)$, $c_1(\mathcal{L}_1) \circ \ldots c_1(\mathcal{L}_{d+1}) = 0 \in A^{d+1}(X)$.

Proof: Use induction on d: $d = 0$ case is trivial as X is discrete thus any invertible sheaf is trivial. In general, by(5.8.1.8) and(7.1.7.2), it suffices to prove for $\mathcal{L}_i = \mathcal{O}_X(D_i)$ being Cartier divisors. If $i : D_{d+1} \to X$, then $c_1(\mathcal{L}_{d+1}) = i_* \circ i^*$ by(7.1.4.3), and $c_1(\mathcal{L}_i)$ commutes with both i_* and i^*, so we can replace X by D and then use induction hypothesis. □

Lemma (7.1.7.8). If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $0 \to \mathcal{L}_1 \to \mathcal{E} \to \mathcal{L}_2 \to 0$ is an exact sequence with $\mathcal{L}_1, \mathcal{L}_2 \in \mathrm{Pic}(X)$, and there is a non-vanishing section s of $\mathcal{E}$, then $c_1(\mathcal{L}_1) \cap c_1(\mathcal{L}_2) = 0 \in A^2(X)$.

Proof: Consider the image $\overline{s}$ of s in $\Gamma(X, \mathcal{L}_2)$, then we can consider the Gysin map associated to $(\mathcal{L}_2, \overline{s}, j)$. Then

$$c_1(\mathcal{L}_1) \cap c_1(\mathcal{L}_2) \cap \alpha = j_*(c_1(j^*\mathcal{L}_1) \cap j^*\alpha).$$

$j^*\mathcal{L}_1$ is trivialized by s now, so this one is vanishes. □

Lemma (7.1.7.9). If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S, r \in \mathbb{Z}_+, \mathcal{L} \in \mathcal{V}\mathrm{ect}^r(X)$, let $\pi : \mathbf{P}(\mathcal{E}) \to X$ be the projective space of $\mathcal{E}$, then for any $k \in \mathbb{Z}$ and $\alpha \in \mathrm{CH}_k(X)$,

$$\pi_*(c_1(\mathcal{O}_{\mathbf{P}(\mathcal{E})}(1))^s \cap \pi^*\alpha) = \begin{cases} 0 & , s < r-1 \\ \alpha & , s = r-1 \end{cases} \in \mathrm{CH}_{k+r-1-s}(X).$$

Proof: Cf.[Sta]02TW. □

Prop. (7.1.7.10) [Projective Bundles Formula]. If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S, r \in \mathbb{Z}_+, \mathcal{L} \in \mathcal{V}\mathrm{ect}^r(X)$, let $\pi : \mathbf{P}(\mathcal{E}) \to X$ be the projective space of $\mathcal{E}$, then for any $k \in \mathbb{Z}$, the map

$$\mathrm{CH}_{k+r-1}(\mathbf{P}(\mathcal{E})) = \bigoplus_{i=0}^{r} c_i(\mathcal{O}_{\mathbf{P}(\mathcal{E})}(1))^i \cap \pi^* \mathrm{CH}_{k+i}(X).$$

is an isomorphism.

In particular, if X is integral, then

$$\mathrm{Cl}(\mathbf{P}(\mathcal{E})) = \pi^*(\mathrm{Cl}(X)) \oplus [c_1(\mathcal{O}_{\mathbf{P}(\mathcal{E})}(1))].$$

Proof: Cf.[Sta]02TX.**?** □

Prop. (7.1.7.11) [Vector Bundles]. If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S, r \in \mathbb{Z}_+, \mathcal{L} \in \mathcal{V}\mathrm{ect}^r(X)$, let $\pi : \mathbf{E} = \mathbf{Spec}(\mathrm{Sym}(\mathcal{E})) \to X$ be the vector bundle of $\mathcal{E}$, then for any $k \in \mathbb{Z}$, $p^* : \mathrm{CH}_k(X) \to \mathrm{CH}_{k+r}(X)$ is an isomorphism.

Proof: Cf.[Sta]02TY. □

Vector Bundles

Prop. (7.1.7.12) [Splitting Principle]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, $\mathcal{E}_i \subset \mathcal{V}\mathrm{ect}(X)$ be a finite set of finite locally free sheaves, there exists a projective flat morphism $\pi : P \to X$ of relative dimension d s.t.

- For any $Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/X$, the map $\pi_Y^* : \mathrm{CH}^*(Y) \to \mathrm{CH}^*(Y \times_X P)$ is injective.
- Each $\pi^*\mathcal{E}_i$ has a filtration with invertible quotient sheaves.

This is useful in the way that when proving functorial properties of Chern classes of vector bundles, we can reduce to invertible sheaves.

Proof: Cf.[Sta]02UL. □

Prop. (7.1.7.13) [Chern Classes of Vector Bundles]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, $r \in \mathbb{Z}_+, \mathcal{E} \subset \mathcal{V}\mathrm{ect}^r(X)$ with projective bundle $\pi : \mathbf{P}(\mathcal{E}) \to X$, then for any $k, p \in \mathbb{N}$, there is a map

$$c_p(\mathcal{E}) \cap - : \mathrm{CH}_k(X) \to \mathrm{CH}_{k-p}(X)$$

called **intersection with Chern classes** as follows(the name will be made clear in(7.1.7.14)): Let $\alpha \in \mathrm{CH}_k(X)$, by(7.1.7.10) there are unique elements $c_p \in \mathrm{CH}_{k-p}(X)$ s.t. $c_0 = \alpha$ and

$$\sum_{p=0}^{r}(-1)^p c_1(\mathcal{O}_{\mathbf{P}(\mathcal{E})})^p \cap \pi^* c_{r-p} = 0 \in \mathrm{CH}_{k-1}(\mathbf{P}(i^*\mathcal{E})).$$

Then define $c_p(\mathcal{E}) \cap \alpha = c_p$.

In particular, if $\mathcal{E}$ is an invertible sheaf, $c_1(\mathcal{E})\cap$ is just the intersection with the first Chern class $c_1(\mathcal{E}) \cap \alpha$(7.1.7.1)(7.1.7.6).

Prop. (7.1.7.14) [Chern Classes Form Bivariant Classes]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/X, r \in \mathbb{Z}_+, \mathcal{E} \in \mathcal{V}\mathrm{ect}^r(X)$, then the maps $c_p(f^*\mathcal{E})\cap - : \mathrm{CH}_k(X') \to \mathrm{CH}_{k-p}(X')$ for each $f : X' \to X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/X, k \in \mathbb{Z}_+$ form a bivariant class in $A^p(X)$, called the **Chern classes** $c_p(\mathcal{E})$. By convention, set $c_p(\mathcal{E}) = 0$ for $p > r$.

And $c(\mathcal{E}) = \sum_{i=0}^r c_i(\mathcal{E}) \in A^*(X)$ are called the **total Chern class** of $\mathcal{E}$.

Proof: For commuting with proper pushforward, use the definition(7.1.7.13) and(7.1.2.24)(7.1.7.5), and push and pull(7.1.2.16).

For commuting with flat pullback, use the definition(7.1.7.13) and(7.1.2.24)(7.1.7.5) and properties of flat pullbacks(7.1.2.13).

For commuting with Gysin map, use the definition(7.1.7.13) and(7.1.2.24)(7.1.7.5) and properties of Gysin maps(7.1.6.9). □

Prop. (7.1.7.15) [Chern Classes Commute with Bivariant Classes]. Let $f : X' \to X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{E} \in \mathcal{V}\mathrm{ect}^r(X)$, then for any $p \in \mathbb{Z}_+$, $c_p(\mathcal{E})$ commutes with every element of $A^*(X' \to X)$.

In particular, $c_p(\mathcal{E})$ are in the center of $A^*(X)$, and for $\mathcal{E} \in \mathcal{V}\mathrm{ect}^r(X), \mathcal{F} \in \mathcal{V}\mathrm{ect}^s(X), p, q \in \mathbb{Z}_+$, $c_p(\mathcal{E}), c_q(\mathcal{F})$ commute.

Proof: Reduce to c_1 and(7.1.7.6) as we did in(7.1.7.14). □

Prop. (7.1.7.16) [Chern Classes for Arbitrary Vector Bundles]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/X, \mathcal{E} \in \mathcal{V}\mathrm{ect}^\delta(X)$, then constancy of r induces a clopen partition of $X = \coprod_{i=0}^\infty X_i$, where X_i are the clopen subscheme s.t. $\delta = i$. Then by(7.1.6.8), $A^p(X) = \prod_{i=0}^\infty A^p(X_i)$, so we can define the Chern class $c_p(\mathcal{E})$ to be the product of $c_p(\mathcal{E}|_{X_i})$. Also we can define a **rank class** $r(\mathcal{E}) \in A^0(X) = \prod_{i=0}^\infty A^0(X_i)$ that is product of $[i] \in A^0(X_i)$.

Prop. (7.1.7.17) [Additivity]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $0 \to \mathcal{E}_1 \to \mathcal{E} \to \mathcal{E}_2 \to 0 \in \mathcal{V}\mathrm{ect}(X)$, then

$$c(\mathcal{E}) = c(\mathcal{E}_1)c(\mathcal{E}_2).$$

Proof: It suffices to check this by their action on $[X]$ where $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft,int}}/S$. Using splitting principle(7.1.7.12), we can easily reduce to the case $\mathcal{E}_1, \mathcal{E}_2 \in \mathrm{Pic}(X)$ by induction on $\mathrm{rank}(\mathcal{E}_1)$ and $\mathrm{rank}(\mathcal{E}_2)$. In this case, let $\mathbf{P}$ be the projective bundle of $\mathcal{E}$ with $\mathcal{O}(1) = \mathcal{O}_{\mathbf{P}}(1)$. By tag02U6, it suffices to show that

$$c_1(\mathcal{O}(1))^2 \cap \pi^*\alpha - c_1(\mathcal{O}(1)) \cap \pi^*(c_1(\mathcal{E}_1) \cap \alpha + c_1(\mathcal{E}_2) \cap \alpha) + \pi^*(c_1(\mathcal{E}_1) \cap c_1(\mathcal{E}_2) \cap \alpha).$$

for which it suffices to show that

$$(c_1(\mathcal{O}(1)) - c_1(\pi^*\mathcal{E}_1)) \cap (c_1(\mathcal{O}(1)) - c_1(\pi^*\mathcal{E}_2)) = c_1(\pi^*\mathcal{E}_1^\vee(1)) \cap c_1(\pi^*\mathcal{E}_2^\vee(1)) = 0$$

There is a surjection $\mathcal{E} \to \mathcal{O}(1)$, which corresponds to a non-zero section of $\mathcal{E}^\vee(1)$. Notice there is an exact sequence

$$0 \to \mathcal{E}_2^\vee \to \mathcal{E}^\vee(1) \to \mathcal{E}_1^\vee \to 0,$$

so the assertion follows from(7.1.7.8). □

Prop. (7.1.7.18). Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{E} \in \mathcal{V}\mathrm{ect}^r(X)$, then $c_1(\wedge\mathcal{E}) = c_1(\mathcal{E})$, and

$$\prod_{p=0}^r c(\wedge^p\mathcal{E})^{(-1)^n} = 1 - (r-1)!c_r(\mathcal{E}) + \dots.$$

Proof: Use splitting principle and Cf.[Sta]0FEE. □

Prop. (7.1.7.19) [Degrees and First Chern Classes]. Let X be a proper scheme over a field k, then

- Let $\mathcal{L}_1,\ldots,\mathcal{L}_d$ be invertible sheaves on X and $Z\subset X$ a closed subscheme of dimension d, then

$$(\mathcal{L}_1\cdot\ldots\cdot\mathcal{L}_d;Z)=\deg(c_1(\mathcal{L}_1)\cap\ldots\cap c_1(\mathcal{L}_d)\cap[Z]_d).$$

  In particular, if $\mathcal{L}$ is an ample invertible sheaf,

$$\deg_{\mathcal{L}}(Z)=\deg(c_1(\mathcal{L})^d\cdot[Z]_d).$$

- If $\dim X\leq 1$, for $\mathcal{E}\in\mathcal{C}\mathrm{oh}^{\mathrm{free}}(X)$,

$$\deg(\mathcal{E})=\deg(c_1(\mathcal{E})\cdot[X]_1).$$

Proof: Cf.[Sta]0AZ3, 0BFI.**?** □

Prop. (7.1.7.20) [Chern Characters]. Let $X\in\mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, r a locally constant $\mathbb{Z}$-valued functions on X and $\mathcal{E}\in\mathcal{V}\mathrm{ect}^r(X)$, define the **Chern character** of $\mathcal{E}$ to be

$$\begin{aligned}\mathrm{ch}(\mathcal{E})&=\mathrm{rank}(\mathcal{E})+\sum_{p\geq 0}\frac{P_p(c_1(\mathcal{E}),\ldots,c_n(\mathcal{E}))}{p!}\in\prod_{i\geq 0}A^i(X)_{\mathbb{Q}}\\&=\mathrm{rank}(\mathcal{E})+c_1(\mathcal{E})+\frac{1}{2}(c_1(\mathcal{E})^2-2c_2(\mathcal{E}))+\frac{1}{6}(c_1(\mathcal{E})^3-3c_1(\mathcal{E})c_2(\mathcal{E})3c_3(\mathcal{E}))\\&+\frac{1}{24}(c_1(\mathcal{E})^4-4c_1(\mathcal{E})^2c_2(\mathcal{E})+4c_1(\mathcal{E})c_3(\mathcal{E})+2c_2(\mathcal{E})^2-4c_4(\mathcal{E}))+\ldots\end{aligned}$$

where P_p are Chern polynomials(2.2.2.27).

Prop. (7.1.7.21) [Tensor Products]. If $X\in\mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, r,s,t are locally constant $\mathbb{Z}$-valued functions on X and $\mathcal{E}\in\mathcal{V}\mathrm{ect}(X),\mathcal{F}\in\mathcal{V}\mathrm{ect}(X),\mathcal{G}\in\mathcal{V}\mathrm{ect}(X)$, then

- If there is an exact sequence $0\to\mathcal{E}\to\mathcal{G}\to\mathcal{F}\to 0$, then $\mathrm{ch}(\mathcal{E})+\mathrm{ch}(\mathcal{F})=\mathrm{ch}(\mathcal{G})$.
- $\mathrm{ch}(\mathcal{E}\otimes_{\mathcal{O}_X}\mathcal{F})=\mathrm{ch}(\mathcal{E})\,\mathrm{ch}(\mathcal{F})$.
- $\mathrm{ch}_i(\mathcal{E}^\vee)=(-1)^i\,\mathrm{ch}_i(\mathcal{E})$.

In particular, ch defines a ring homomorphism $\mathrm{ch}:K_0(\mathcal{V}\mathrm{ect}(X))\to\prod_{i\geq 0}A^i(X)_{\mathbb{Q}}$.

Proof: It suffices to prove for X connected, and then by(7.1.7.12), we can assume $\mathcal{E},\mathcal{F}$ have filtrations with invertible quotient sheaves $\mathcal{E}_1,\ldots,\mathcal{E}_r$ and $\mathcal{F}_1,\ldots,\mathcal{F}_s$ with first Chern characters $a_1,\ldots,a_r$ and $b_1,\ldots,b_s$, then by additivity(7.1.7.17) and the definition of Chern polynomials(2.2.2.27), we see

$$\mathrm{ch}(\mathcal{E})=\sum_{i=1}^r\exp(a_i),\quad\mathrm{ch}(\mathcal{F})=\sum_{j=1}^s\exp(b_j),$$

and $\mathcal{E}\otimes\mathcal{F}$ has a filtration with quotient sheaves $\mathcal{E}_i\otimes\mathcal{F}_j$ with first Chern characters a_i+b_j by(7.1.7.2), so the assertions are now clear. □

Cor. (7.1.7.22) [Chern Classes of Tensor Products]. If $X\in\mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, r,s are locally constant $\mathbb{Z}$-valued functions on X and $\mathcal{E}\in\mathcal{V}\mathrm{ect}^r(X),\mathcal{F}\in\mathcal{V}\mathrm{ect}^s(X)$, then

$$c_i(\mathcal{E}^\vee)=(-1)^ic_i(\mathcal{E})\in A^i(X),$$

$$c_1(\mathcal{E}\otimes\mathcal{F}) = rc_1(\mathcal{E}) + sc_1(\mathcal{F}) \in A^1(X),$$
$$c_2(\mathcal{E}\otimes\mathcal{F}) = rc_2(\mathcal{F}) + sc_2(\mathcal{E}) + \binom{r}{2}c_1(\mathcal{F})^2 + (rs-1)c_1(\mathcal{E})c_1(\mathcal{F}) + \binom{s}{2}c_1(\mathcal{E})^2 \in A^2(X),$$
$$c_2(\mathcal{H}om(\mathcal{E},\mathcal{E})) = 2rc_2(\mathcal{E}) - (r-1)c_1(\mathcal{E})^2 \in A^2(X).$$

Prop. (7.1.7.23) [Todd Classes]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{E} \in \mathcal{V}\mathrm{ect}(X)$, define the **Todd class** $\mathrm{Todd}(\mathcal{E})$ of $\mathcal{E}$ to be

$$\mathrm{Todd}(\mathcal{E}) = \mathrm{Todd}(c_1(\mathcal{E}), c_2(\mathcal{E}), \ldots)(2.2.2.28) = 1 + \frac{1}{2}c_1(\mathcal{E}) + \frac{1}{12}(c_1(\mathcal{E})^2 + c_2(\mathcal{E}))$$
$$+\frac{1}{24}c_1(\mathcal{E})c_2(\mathcal{E}) + \frac{1}{720}(-c_1^4(\mathcal{E}) + 4c_1^2(\mathcal{E})c_2(\mathcal{E}) + 3c_2^2(\mathcal{E}) + c_1(\mathcal{E})c_3(\mathcal{E}) - c_4(\mathcal{E})) + \ldots.$$

Then if $0 \to \mathcal{E}' \to \mathcal{E} \to \mathcal{E}'' \to 0 \in \mathcal{V}\mathrm{ect}(X)$ be an exact sequence, then $\mathrm{Todd}(\mathcal{E})\,\mathrm{Todd}(\mathcal{E}'') = \mathrm{Todd}(\mathcal{E})$.

Proof: The proof is the same as that of(7.1.7.21). □

Prop. (7.1.7.24) [Borel-Serre]. Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{E} \in \mathcal{V}\mathrm{ect}^r(X)$, then

$$\sum_{p=0}^{r}(-1)^p\,\mathrm{ch}(\wedge^p\mathcal{E}^\vee) = c_r(\mathcal{E})\,\mathrm{Todd}(\mathcal{E})^{-1}.$$

Proof: ? □

Prop. (7.1.7.25) [Chern Classes of K-Groups]. $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, by additivity and multiplicativeness(7.1.7.17)(7.1.7.21), we can extend Chern classes and Chern characters to the K-group $K_0(\mathcal{V}\mathrm{ect}(X))$:

$$c : K_0(\mathcal{V}\mathrm{ect}(X)) \to \prod_{p\geq 0} A^p(X), \quad \mathrm{ch} : K_0(\mathcal{V}\mathrm{ect}(X)) \to \prod_{p\geq 0} A^p(X)_{\mathbb{Q}}$$

where c is a group homomorphism and ch is a ring homomorphism.

Prop. (7.1.7.26) [Adam Operators and Chern Characters]. $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\alpha \in K_0(\mathcal{V}\mathrm{ect}(X))$, then $c_i(\psi^k(\alpha)) = 2^{ki}c_i(\alpha)$ and $\mathrm{ch}_i(\psi^k(\alpha)) = 2^{ki}\,\mathrm{ch}_i(\alpha)$.

Proof: It suffices to prove for $\alpha = [\mathcal{E}]$ where $\mathcal{E} \in \mathcal{V}\mathrm{ect}(X)$, then by splitting principle it suffices to prove for line bundles, and this is clear from(7.1.7.22) and the definition(7.1.7.20)t. □

Perfect Complexes

Lemma (7.1.7.27). Let $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, then for each perfect complex $\mathcal{E}$ in $D(\mathcal{O}_X)$, we can define the Chern classes, Chern characters and ranks of $\mathcal{E}$. But we only define fora subset of E here?Cf.[Sta]0F9E: If $\mathcal{E}$ is represented by a finite complex $\mathcal{E}^\bullet$ of vector bundles on X, define

$$c(\mathcal{E}) = \prod_i c(\mathcal{E}^i)^{(-1)^i} \in \prod_{i\geq 0} A^i(X), \quad \mathrm{ch}(\mathcal{E}) = \sum_i (-1)^i\,\mathrm{ch}(\mathcal{E}^i) \in \prod_{i\geq 0} A^i(X)_{\mathbb{Q}}, \quad r(\mathcal{E}) = \sum_i (-1)^i r(\mathcal{E}^i).$$

Proof: To show this well defined, □

Prop. (7.1.7.28) [Chern Classes via Envelopes]. Let $Y \to X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ be an envolope**?**, $\mathcal{E}$ perfect in $D(\mathcal{O}_X)$ s.t. $Lf^*\mathcal{E}$ is representable by a finite complex of vector bundles on Y, then there are unique bivariant classes $c(\mathcal{E}) \in \prod_{i\geq 0} A^i(X), \mathrm{ch}(\mathcal{E}) \in \prod_{i\geq 0} A^i(X)_{\mathbb{Q}}, \quad r(\mathcal{E})$ s.t. their restrictions to Y are of the form defined in(7.1.7.27).

Moreover, these bivariant classes are invariant of the envelope chosen. In this case, we say the Chern classes of $\mathcal{E}$ are defined.

Proof: Cf.[Sta]0GUD. □

Prop. (7.1.7.29). If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and each irreducible components of X are qc, then X has an envelope. In particular, this applies to X qc.

Proof: Cf.[Sta]0GUE**?**. □

Prop. (7.1.7.30)[Additivity]. If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{E}_1 \to \mathcal{E}_2 \to \mathcal{E}_3 \to \mathcal{E}_1[1]$ is a distinguished triangle of perfect complexes in $D(\mathcal{O}_X)$, and one of the following holds:

- There exists an envelope $f : Y \to X$ s.t. $Lf^*\mathcal{E}_1 \to Lf^*\mathcal{E}_2$ is representable by a map of finite complexes of vector bundles on Y.
- Each irreducible components of X is irreducible.

Then Chern classes of $\mathcal{E}_i$ are defined, and

$$c(\mathcal{E}_2) = c(\mathcal{E}_1)c(\mathcal{E}_3), \quad \mathrm{ch}(\mathcal{E}_2) = \mathrm{ch}(\mathcal{E}_1) + \mathrm{ch}(\mathcal{E}_3).$$

Proof: Cf.[Sta]0F9F**?**. □

Se

Prop. (7.1.7.31). If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and $\mathcal{E}$ be a perfect object in $D(\mathcal{O}_X)$ whose Chern classes are defined, then

- Let $f : X' \to X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$, $p \in \mathbb{Z}_+$, then $c_p(\mathcal{E})$ commutes with every element of $A^*(X' \to X)$, i.e. $c \cdot c_p(\mathcal{E}) = c_p(Lf^*\mathcal{E}) \cdot c$.
  In particular, $c_p(\mathcal{E})$ are in the center of $A^*(X)$, and for $\mathcal{E}, \mathcal{F}$ perfect in $D(\mathcal{O}_X)$ whose Chern classes are defined, $p, q \in \mathbb{Z}_+, c_p(\mathcal{E}), c_q(\mathcal{F})$ commute.
- $\log(c(\mathcal{E})) = \sum_{p\geq 0} \frac{P_p(c_1(\mathcal{E}),\ldots,c_n(\mathcal{E}))}{p}$ also holds, where P_p are Chern polynomials(2.2.2.27). Similarly for Chern character $\mathrm{ch}(\mathcal{E})$.
- $c_i(\mathcal{E}^\vee) = (-1)^i c_i(\mathcal{E}), \mathrm{ch}_i(\mathcal{E}^\vee) = (-1)^i \mathrm{ch}_i(\mathcal{E})$.

Proof: These follow from the splitting principle and the definition(7.1.7.28). □

Prop. (7.1.7.32) [Tensor Products]. If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ and E, F perfect in $D(\mathcal{O}_X)$ whose Chern classes are defined, then

$$\mathrm{ch}(\mathcal{E} \otimes^L_{\mathcal{O}_X} \mathcal{F}) = \mathrm{ch}(\mathcal{E})\,\mathrm{ch}(\mathcal{F}),$$

in particular, formulas in(7.1.7.22) hold.

Proof: This follows from the splitting principle and the definition(7.1.7.28). □

8 Non-Singular Intersection Theory

Lemma (7.1.8.1). If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{ft,sep}}_{\mathrm{reg},qc}/S$ with bounded δ-dimension, then the composition

$$K_0(\mathcal{V}\mathrm{ect}(X)) \otimes \mathbb{Q} \xrightarrow{\mathrm{ch}} \prod_{p\geq 0} A^p(X) \xrightarrow{-\cap[X]} \mathrm{CH}^*(X) \otimes \mathbb{Q}$$

is an isomorphism.

Proof: Firstly $K_0(X) = K_0'(X) = K_0(\mathcal{V}\mathrm{ect}(X))$ by(5.8.5.33) and(5.8.5.36).

The rest follows from[Sta]0FEY.**?** ☐

Prop. (7.1.8.2)[$\mathbb{Q}$-Intersection Products on Regular Schemes]. If $X \in \mathcal{S}\mathrm{ch}^{\mathrm{ft,sep}}_{\mathrm{reg},qc}/S$ with bounded δ-dimension, then the isomorphism $K_0(\mathcal{V}\mathrm{ect}(X)) \otimes \mathbb{Q} \cong \mathrm{CH}^*(X) \otimes \mathbb{Q}$ endows $\mathrm{CH}^*(X)_{\mathbb{Q}}$ with a commutative associative ring structure: If $\alpha = \mathrm{ch}(\alpha') \cap [X], \beta = \mathrm{ch}(\beta') \cap [X]$, then

$$\alpha \cdot \beta = \mathrm{ch}(\alpha) \cap \mathrm{ch}(\beta) \cap [X] = \mathrm{ch}(\alpha') \cap \beta = \mathrm{ch}(\beta') \cap \alpha.$$

And this ring structure preserves the gradation on $\mathrm{CH}^*(X)_{\mathbb{Q}}$. Also it is preserved under morphism in $\mathcal{S}\mathrm{ch}^{\mathrm{ft,sep}}_{\mathrm{reg},qc}$ flat of relative dimension r.

Proof: To prove it preserves gradation, suppose $\alpha \in \mathrm{CH}^i(X), \beta \in \mathrm{CH}^j(X)$, then α' and $2^{-i}\psi^2(\alpha')$(7.1.7.26) are both inverse images of α, so they are equal. Then $\mathrm{ch}(\alpha') = \mathrm{ch}(2^{-i}\psi^2(\alpha'))$, which means $\mathrm{ch}(\alpha') \in A^i(X)_{\mathbb{Q}}$, and then $\mathrm{ch}(\alpha') \cap \beta \in \mathrm{CH}^{i+j}(X)_{\mathbb{Q}}$. ☐

Smooth over Dedekind Schemes Case

Smooth over Fields Case

Prop. (7.1.8.3)[Exterior Products]. If $k \in \mathtt{Field}$, $S = \mathrm{Spec}\, k$, $X, Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/k$, there is a **exterior product map**

$$\mathrm{CH}_n(X) \otimes \mathrm{CH}_m(Y) \to \mathrm{CH}_{n+m}(X \times_S Y)$$

defined by sending $[X'] \otimes [Y']$ to $[X' \times_S Y']_{n+m}$, where $X' \subset X, Y' \subset Y$ are integral closed subschemes of dimension n and m resp.

Proof: To show this is well defined, consider $i : X' \to X, c : X \to \mathrm{Spec}\, k$, then by(7.1.6.11), $c_* \circ (c \circ i)^* \in A^{-n}(X \to \mathrm{Spec}\, k)$, which sends $[Y']$ to $[X' \times_k Y']_{n+m}$, so this map factors through rational equivalences on Y, and similarly it factors through rational equivalences on X. ☐

Prop. (7.1.8.4). If $k \in \mathtt{Field}$, $S = \mathrm{Spec}\, k$ and $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/k$, there is a natural isomorphism $A^p(X \to \mathrm{Spec}\, k) \cong \mathrm{CH}_{-p}(X)$ for any $p \in \mathbb{Z}$.

Proof: The map $A^p(X \to \mathrm{Spec}\, k) \to \mathrm{CH}_{-p}(X)$ is given by $c \mapsto c \cap [\mathrm{Spec}\, k]$. Conversely, for any $\alpha \in \mathrm{CH}_{-p}(X)$, we can define for any $X' \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/k$ a map

$$\mathrm{CH}_n(X') \to \mathrm{CH}_{n-p}(X \times_k X') : \beta \mapsto \alpha \times \beta(7.1.8.3).$$

Then this is a bivariant class in $A^p(X \to \mathrm{Spec}\, k)$: Let $\alpha = \sum n_i[X_i]$, and let $g : \coprod_i X_i \to X$, $f : \coprod_i X_i \to \mathrm{Spec}\, k$. Denote $\nu^* \in A^0(\coprod_i X_i)$ the bivariant class that multiplies by n_i at each component X_i, then $g_* \circ \nu \circ f^* \in A^p(X \to \mathrm{Spec}\, k)$ by(7.1.6.10)(7.1.6.11), and this is just the map we defined above.

To show these two maps are inverse to each other, one direction is clear. To show $c(\beta) = (c \cap [\mathrm{Spec}\, k]) \times \beta$, it suffices to show for $\beta = [X']$ is integral, then $\beta = (X' \to \mathrm{Spec}\, k)^*[\mathrm{Spec}\, k]$, then it is easy to see they are equal because c commutes with flat pullbacks $(X' \to \mathrm{Spec}\, k)^*$. ☐

Cor. (7.1.8.5) [Commutativity and Associativity]. If $k \in \texttt{Field}, S = \operatorname{Spec} k$ and $X \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/k$, then $c \in A^p(X \to \operatorname{Spec}(k))$ commutes with any $c' \in A^q(Y \to Z)$ for any $f : Y \to Z \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/k$. In other words, for any $\alpha \in \mathrm{CH}_*(X), \beta \in \mathrm{CH}_*(Z)$ and $c \in A^*(Y \to Z)$,

$$\alpha \times (c \cap \beta) = c \cap (\alpha \times \beta) \in \mathrm{CH}_*(X \times_k Y).$$

In particular, if $\gamma \in \mathrm{CH}_*(Y)$, then

$$(\alpha \times \beta) \times \gamma = \alpha \times (\beta \times \gamma) \in \mathrm{CH}_*(X \times_k Y \times_k Z).$$

Proof: This is because $c = g_* \circ \nu \circ f^*$ as in the proof of(7.1.8.4). □

Prop. (7.1.8.6) [Perturbation and Chow Rings]. Any two algebraic cycles $\gamma_1, \gamma_2 \in Z_*(X)$ are rationally equivalent to cycles γ_1', γ_2' s.t. γ_1', γ_2' intersect properly. And the rational class of resulting intersection cycle is well-defined. So there is an intersection on $\mathrm{CH}^*(X)$ making it a commutative ring, called the **Chow ring of** X.

Proof:

□

Prop. (7.1.8.7) [Bezout]. The Chow ring of $\mathbb{P}^n_k$ is isomorphic to $\mathbb{Z}[x]/(x^{n+1})$. The degree of an irreducible closed variety corresponds to the coefficient of it.

Proof:

□

Def. (7.1.8.8) [Euler Characteristic]. If X is a smooth scheme over a field k of dimension d with tangent bundle $\mathcal{T}_{X/k}$, the **Euler characteristic** of X is defined to $\deg(c_d(\mathcal{T}_{X/k}) \cap [X])$, and the **Todd characteristic** of X is defined to $\deg(\mathrm{Todd}_d(\mathcal{T}_{X/k}) \cap [X])$.

Prop. (7.1.8.9). If X is a smooth scheme over a field k and $i : Y \to X$ is a regular closed immersion and Y is equidimensional of dimension e, then

$$[Y]_e \cdot \alpha = i_*(i^!(\alpha)).$$

Proof: Cf.[Sta]0FFE**?**. □

<u>**Serre's Approach**</u>

Prop. (7.1.8.10). If X is a integral scheme smooth over a field k, and W, V be two integral closed subschemes of X, then $\operatorname{codim}(W \cap V) \le \operatorname{codim}(W) + \operatorname{codim}(V)$.

Proof: Cf.[Sta]0AZP. □

Def. (7.1.8.11) [Proper Intersections]. Let X be a integral scheme smooth over a field k, then two cycles $\alpha = \sum n_i[W_i]$ and $\beta = \sum m_j[V_j]$ are said to intersect properly iff

$$\operatorname{codim}(W_i \cap V_j) \ge \operatorname{codim}(W_i) + \operatorname{codim}(V_j).$$

And in fact equality holds, by(7.1.8.10).

Lemma (7.1.8.12) [Tor Sheaves]. Let X be a integral scheme smooth over a field k and $\mathcal{F},\mathcal{G}\in\mathfrak{Coh}(X)$, then $\mathrm{Tor}_p^{\mathcal{O}_X}(\mathcal{F},\mathcal{G})\in\mathfrak{Coh}(X)$, with stalk at $x\in X$ being $\mathrm{Tor}_p^{\mathcal{O}_{X,x}}(\mathcal{F}_x,\mathcal{G}_x)$, and is supported on $\mathrm{Supp}(\mathcal{F})\cap\mathrm{Supp}(\mathcal{G})$, and nonzero only for $0\le p\le\dim X$.

Proof: Cf.[Sta]0AZT. ☐

Def. (7.1.8.13) [Intersection via Tor]. Let X be a regular scheme and $W,V\subset X$ be integral closed subschemes intersecting properly, by(7.1.8.12) we can define the **intersection product**

$$W\cdot V=\sum_i[\mathrm{Tor}_i^{\mathcal{O}_X}(\mathcal{O}_W,\mathcal{O}_V)]_{r+s-\dim X},$$

and for any irreducible component Z of $W\cap V$ the **intersection multiplicities**

$$e(X,W\cdot V,Z)=\sum_i(-1)^i\,\mathrm{length}_{\mathcal{O}_{X,Z}}\mathrm{Tor}_i^{\mathcal{O}_{X,Z}}(\mathcal{O}_{W,Z},\mathcal{O}_{V,Z}).$$

Proof: Why is this compatible with the definition given before**?**. Why the multiplicity is given by this form**?** ☐

Remark (7.1.8.14) [Serre Conjecture]. Serre conjectured that in(7.1.8.13), even if W,V doesn't intersect properly, for an irreducible component $Z\subset W\cap V$ of dimension$\ge\dim W+\dim V-\dim X$, we have $e(X,W\cdot V,P)=0$.

Prop. (7.1.8.15) [Discrete Case]. Let X be a integral scheme smooth over k and $W,V\subset X$ be closed subvarieties that intersect properly. Let Z be an irreducible component of $V\cap W$ with generic point ξ and $\mathcal{O}_{W,\xi},\mathcal{O}_{V,\xi}$ are both C.M., then

$$e(X,W\cdot V,Z)=\mathrm{length}_{\mathcal{O}_{X,\xi}}(\mathcal{O}_{V\cap W,\xi}).$$

Proof: Cf.[Sta]0B02**?**. ☐

Prop. (7.1.8.16) [Exterior Product of Subvarieties]. Let X,Y be integral schemes smooth over k and $W\subset X,V\subset Y$ be subvarieties, then $[W]\times[V]=([W]\times[Y])\cdot([X]\times[V])\in Z_*(X\times Y)$.

Proof: As $W\times V$ is a variety with generic point ξ, and X is smooth over k, $X\times V$ is smooth over V, thus $\mathcal{O}_{X\times V,\xi}$ is regular, hence C.M., and similarly is $\mathcal{O}_{W\times Y,\xi}$, thus(7.1.8.15) applies to show that $([W]\times[Y])\cdot([X]\times[V])=[W]\times[V]$. ☐

Prop. (7.1.8.17) [Serre]. If X is a integral scheme smooth over a field k, $\mathcal{F}\in\mathfrak{Coh}_{\le r}(X),\mathcal{G}\in\mathfrak{Coh}_{\le s}(X)$, and $\dim(\mathrm{Supp}(\mathcal{F})\cap\mathrm{Supp}(\mathcal{G}))\le r+s-\dim X$. Then $[\mathcal{F}]_r$ and $[\mathcal{G}]_s$ intersect properly, and

$$[\mathcal{F}]_r\cdot[\mathcal{G}]_s=\sum_p(-1)^p[\mathrm{Tor}_p^{\mathcal{O}_X}(\mathcal{F},\mathcal{G})]_{r+s-\dim X}$$

Proof: Cf.[Sta]0B0W. ☐

Cor. (7.1.8.18). If X is a smooth integral scheme over a field k, the intersection product on $\mathrm{CH}^*(X)$ makes it a commutative graded (associative, unital)ring.

Proof: To show the intersection is associative, let U,V,W be closed subvarieties of X s.t. $\mathrm{codim}(U\cap V\cap W,X)=\mathrm{codim}(U,X)+\mathrm{codim}(V,X)+\mathrm{codim}(W,X)=p$, then it suffices to show that

$$\sum_i(-1)^{i+j}[\mathrm{Tor}_j(\mathcal{O}_U,\mathrm{Tor}_i(\mathcal{O}_V,\mathcal{O}_W))]_{\dim X-p}=\sum_i(-1)^{i+j}[\mathrm{Tor}_j(\mathrm{Tor}_i(\mathcal{O}_U,\mathcal{O}_V),\mathcal{O}_W)]_{\dim X-p}.$$

This is true because they are both equal to

$$\sum_k(-1)^k[H^k(\mathcal{O}_U\otimes^L\mathcal{O}_V\otimes^L\mathcal{O}_W)]_{\dim X-p}$$

which is because there is an spectral sequence convergence

$$E_2^{p,q}=\mathrm{Tor}_{-p}(\mathcal{O}_U,\mathrm{Tor}_{-q}(\mathcal{O}_V,\mathcal{O}_W))\Rightarrow H^{p+q}(\mathcal{O}_U\otimes^L\mathcal{O}_V\otimes^L\mathcal{O}_W)$$

and use the fact length functions are additive. □

10 Riemann-Roch

Main references are[Ful98]Chap15, 18.

Prop. (7.1.10.1)[Grothendieck-Riemann-Roch]. Let $f: X, Y \in \mathcal{S}\mathrm{ch}^{\mathrm{loc.ft}}/S$ be proper smooth, and $\mathcal{E} \in \mathcal{C}\mathrm{oh}^{\mathrm{free}}(X)$, $\mathcal{T}_{X/Y}$ the locally free relative tangent bundle, then

$$f_*(\mathrm{Todd}(\mathcal{T}_{X/Y})\,\mathrm{ch}(\mathcal{E})) = \sum_i (-1)^i \,\mathrm{ch}(R^i f_* \mathcal{E}).$$

Remark (7.1.10.2). This theorem also has an Arithmetic version.

Proof: □

Cor. (7.1.10.3) [Hirzebruch-Riemann-Roch]. If X is a smooth complete variety over a field k, $\mathcal{E} \in \mathcal{C}\mathrm{oh}^{\mathrm{free}}(X)$, then

$$\chi(X, \mathcal{E}) = \int_X \mathrm{Todd}(\mathcal{T}_{X/k})\,\mathrm{ch}(\mathcal{E})$$

Cor. (7.1.10.4). If X is a smooth complete variety over a field k, then

$$\chi(X, \mathcal{O}_X) = \int_X \mathrm{Todd}(\mathcal{T}_{X/k}).$$

<u>**Singular Case**</u>

11 Numerical Equivalences

Def. (7.1.11.1) [Numerical Equivalences]. Two cycles $\gamma, \gamma' \in \mathrm{CH}^k(X)$ are called **numerically equivalent** if for any $\delta \in Z_k(X)$, $\gamma \cdot \delta = \gamma' \cdot \delta$. And we can define $GH_k(X)$ the **Grothendieck group of k-cycles** to be $Z_k(X)$ modulo the numerical equivalence relation.

Prop. (7.1.11.2) [Grothendieck Rings]. There is a group homomorphism $\mathrm{CH}^*(X) \to GH^*(X)$ and the ring structure on $\mathrm{CH}^*(X)$ descends to $GH^*(X)$, making it a ring, called the **Grothendieck ring of X**.

12 Intersection for Line Bundles

Main references are [FGA, Appendix B].

<u>**Algebraic Equivalence**</u>

Def. (7.1.12.1) [Algebraically Equivalent Line Bundles]. Let X be a scheme over a field k, then $\mathcal{L}_1, \mathcal{L}_2 \in \mathrm{Pic}(X)$ are called **algebraically equivalent** if they are equivalent in the equivalence relation $\mathcal{M} \sim \mathcal{N}$ iff there is a connected scheme T and a line bundle $\mathcal{L} \in \underline{\mathrm{Pic}}_{X/k}(T)$ s.t. $\mathcal{N}_{k(t_1)} = \mathcal{L}_{t_1}$ and $\mathcal{M}_{k(t_2)} = \mathcal{L}_{t_2}$ where $t_1, t_2 \in T$.

Cor. (7.1.12.2)[$\mathrm{Pic}^0(X)$]**.** The elements in $\mathrm{Pic}(X)$ algebraically equivalent to 0 is a subgroup of $\mathrm{Pic}(X)$, denoted by $\underline{\mathrm{Pic}}^0(X)$. In(7.1.12.4), we will see when X has a rational point and $\underline{\mathrm{Pic}}_{X/k}$ is representable, this is just $\underline{\mathrm{Pic}}^0_{X/k}(k)$, by(8.7.3.7).

Prop. (7.1.12.3) [Algebraically Equivalent Divisors]. If X be a regular K-prevariety, then $\mathrm{Pic}(X) \cong \mathrm{CH}^1(X)$(5.5.3.15). We call two divisors D_1, D_2 on X **algebraically equivalent** if $\mathcal{O}(D_1)$ and $\mathcal{O}(D_2)$ are algebraically equivalent.

Proof: Cf.[Diophantine Geometry, P563]. □

Prop. (7.1.12.4) [Moduli Characterization]. If X is a scheme over a field k s.t. $\underline{\mathrm{Pic}}_{X/k}$ is representable, then two line bundles are algebraically equivalent iff they corresponds to points of $\underline{\mathrm{Pic}}_{X/k}$ in the same connected component.

Proof: By(8.7.3.20), $\underline{\mathrm{Pic}}_{X/k}$ is a locally algebraic group scheme over k, so by(8.1.4.13), every connected components of it is irreducible. Clearly two algebraically equivalent line bundles are in the same connected component of $\underline{\mathrm{Pic}}_{X/k}$. Conversely, the inclusion of their common connected component P corresponds to a line bundle on some fppf covering $T \to P$. Then use the fact fppf covering is open map, and the fact P is irreducible to get an algebraic equivalence chain. □

Prop. (7.1.12.5) [Algebraic Equivalence for Curves]. If C is a smooth complete curve over a field k, then two line bundles $\mathcal{L}_1, \mathcal{L}_2 \in \mathrm{Pic}(C)$ are algebraically equivalent iff they have the same degree.

Proof: It suffices to show after base change to $\overline{k}$. Then it suffices to show for any two closed points $x_1, x_2 \in C$, $\mathcal{L}(x_1) \sim \mathcal{L}(x_2)$. Consider the diagonal of $C \times C$ is a Cartier divisor, and its restriction to $C \times \{x_i\}$ is $\mathcal{L}(x_i)$. □

<u>Numerical Intersections</u>

Def. (7.1.12.6). Let X be a proper scheme and $\mathcal{F}$ be a coherent sheaf with $\dim \mathrm{Supp}\, \mathcal{F} \le n$, and $\mathcal{L}_1, \ldots, \mathcal{L}_n$ are invertible sheaves on X, then we define $(\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_n; \mathcal{F})$ to be

$$\sum_{\{i_1,\ldots,i_m\}\subset\{1,\ldots,n\}} (-1)^m \chi(X, \mathcal{L}_{i_1}^\vee \otimes \ldots \otimes \mathcal{L}_{i_m}^\vee \otimes \mathcal{F}).$$

When $\mathcal{F}$ is the structure sheaf of a closed subscheme Y, then denote $(\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_n; \mathcal{F})$ by $(\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_n; \mathcal{Y})$. This intersection is stable under base change of fields.

Prop. (7.1.12.7). If X is a complete curve and $\mathcal{L}$ an invertible sheaf on X, then $(\mathcal{L}; X) = \deg(\mathcal{L})$.

Proof: □

Prop. (7.1.12.8). If k is an infinite field and $X = \mathbb{P}^n_k$, and Y is a dimension n subvariety of X. If $H_1, \ldots, H_n$ are generic chosen hypersurfaces of degree $d_1, \ldots, d_n$ resp., then

$$(\mathcal{O}_X(H_1) \cdot \ldots \cdot \mathcal{O}_X(H_n); Y) = d_1 \ldots d_n \deg(Y).$$

Proof: □

Prop. (7.1.12.9). If D is an effective Cartier divisor on X that doesn't contain any associated point of $\mathcal{F}$, then

$$(\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_n \cdot \mathcal{O}(D); \mathcal{F}) = (\mathcal{L}_1|_Y \cdot \ldots \cdot \mathcal{L}_n|_Y; \mathcal{F}|_D)$$

Proof: □

Prop. (7.1.12.10). For a fixed $\mathcal{F}$, $(\mathcal{L}_1 \cdot \ldots \mathcal{L}_n; \mathcal{F})$ is a symmetric multilinear function of $\mathcal{L}_1, \ldots, \mathcal{L}_n$, where the addition is tensor production. Moreover, if $\mathcal{F}$ is a coherent sheaf with support dimension n, then $(\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_{n+1}; \mathcal{F}) = 0$.

Proof: Cf.[Rising Sea, P544]. □

Prop. (7.1.12.11). The numerical intersection $(\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_n; \mathcal{F})$ only depends on the numerical classes of $\mathcal{L}_i$.

Prop. (7.1.12.12) [Projection Formula]. Let $\pi : X_1 \to X_2$ be a proper morphism of proper schemes, then

$$(\pi^*\mathcal{L}_1 \cdot \ldots \cdot \pi^*\mathcal{L}_n; \mathcal{F}) = (\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_n; \pi_*\mathcal{F}).$$

In particular, when X_1, X_2 are integral with the same dimensions and π is a finite map,

$$(\pi^*\mathcal{L}_1 \cdot \ldots \cdot \pi^*\mathcal{L}_n) = \deg(\pi)(\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_n).$$

Proof:

For the last assertion, notice $\pi_*\mathcal{O}_{X_1} = \deg(\pi)\mathcal{O}_{X_2}+$ coherent sheaves with smaller supper dimensions. □

Prop. (7.1.12.13). Let k be a field and X a proper scheme over k, and $Z \subset X$ a closed subscheme of dimension d. If $\mathcal{L}_1, \ldots, \mathcal{L}_d$ are ample invertible sheaves on X, then $(\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_d; Z)$ is positive.

Proof: □

Prop. (7.1.12.14). Let X be a complex projective scheme, then $(\mathcal{L}_1 \cdot \ldots \cdot \mathcal{L}_n; Z)$ equals

$$(c_1((\mathcal{L}_1)_{an}) \cup \ldots c_1((\mathcal{L}_n)_{an}), Z)$$

where c_1 is the complex Chern class.

Proof: Cf.[Rising Sea, P547]. □

Def. (7.1.12.15) [First Chern Class]. Let X be a proper scheme and K be the Grothendieck group of $\mathcal{C}\mathrm{oh}(X)$. For $\mathcal{L} \in \mathrm{Pic}(X)$, define $c_1(\mathcal{L})$ to be the endomorphism of K defined by

$$c_1(\mathcal{L})\mathcal{F} = \mathcal{F} - \mathcal{L}^{-1} \otimes \mathcal{F}.$$

Prop. (7.1.12.16). If $\mathcal{L}, \mathcal{M} \in \mathrm{Pic}(X)$, then

- $c_1(\mathcal{L})c_1(\mathcal{M}) = c_1(\mathcal{L}) + c_1(\mathcal{M}) - c_1(\mathcal{L} \otimes \mathcal{M})$.
- $c_1(\mathcal{O}_X) = 0$.
- $c_1(\mathcal{L})c_1(\mathcal{L}^{-1}) = c_1(\mathcal{L}) + c_1(\mathcal{L}^{-1})$.

In particular, $c_1(\mathcal{L})$ and $c_2(\mathcal{M})$ commutes.

Prop. (7.1.12.17). If X is a proper scheme over a field k and let K^d be the subgroup generated by coherent sheaves over X with support dimension $\leq d$, then if $\mathcal{F} \in K^d$, then $c_1(\mathcal{L})\mathcal{F} \in K^{d-1}$.

Proof:

□

Prop. (7.1.12.18). If $Y \subset X$ is a closed subscheme, and $\mathcal{L} \in \mathrm{Pic}(X)$ satisfy $\mathcal{L}_Y$ is an effective Cartier divisor D, then $c_1(L)[Y] = [D]$.

Proof: There is an exact sequence $0 \to \mathcal{O}_Y(-D) \to \mathcal{O}_Y \to \mathcal{O}_D$, and $\mathcal{O}_Y(-D) \cong \mathcal{L}^{-1} \otimes \mathcal{O}_Y$. □

τ-Equivalences

Def. (7.1.12.19) [τ-Equivalence]. Let X be a scheme over a field k, then two line bundles $\mathcal{L}_1, \mathcal{L}_2$ are called **τ-equivalent** if there are some $m \in \mathbb{Z}_+$ s.t. $\mathcal{L}_1^{\otimes m} \sim \mathcal{L}_2^{\otimes m}$.

Prop. (7.1.12.20) [Moduli Characterization]. Let X be a scheme over a field k and $\underline{\mathrm{Pic}}_{X/k}$ is representable, then $\mathcal{L} \in \mathrm{Pic}(X)$ is τ-equivalent to $\mathcal{O}_X$ iff its corresponding point $\lambda \in \underline{\mathrm{Pic}}_{X/k}$ is in $\underline{\mathrm{Pic}}^\tau_{X/k}$.

Proof: Clear from the definition of $\underline{\mathrm{Pic}}^\tau_{X/k}$. □

Def. (7.1.12.21) [Numerically Equivalence]. Tow line bundles L_1, L_2 on a complete prevariety over a field K is called **numerically equivalent** if $c_1(L_1).\alpha = c_1(L_2).\alpha$ for any complete precurve $C \subset X$. Two divisors on X is called **numerically equivalent** if their corresponding line bundle do.

Numerically trivial line bundles form a group, and are stable under proper pullbacks, by(5.11.2.7)(5.11.2.5).

Prop. (7.1.12.22) [Algebraic and Numerical Equivalences]. Let $\mathcal{L}_1, \mathcal{L}_2$ be algebraically equivalent line bundles on a proper scheme X/k, then $\deg_{\mathcal{L}_1}(X) = \deg_{\mathcal{L}_2}(X)$. In particular, algebraically equivalent divisors are numerically equivalent.

Proof: This is because in this case $\mathcal{L}_1, \mathcal{L}_2$ are in the same connected component of $\underline{\mathrm{Pic}}_{X/k}$. □

Cor. (7.1.12.23). Let X be a complete prevariety over K and L_i be line bundles and $Z \in Z_r(X)$, then $\deg(c_1(L_1).c_1(L_2).\ldots.c_r(L_r).Z)$ only depends on algebraic equivalence classes of L_i.

Proof: Cf.[Diophantine Geometry, P562]. □

Def. (7.1.12.24) [Bounded Set of Line Bundles]. Let X be a scheme over S, then a set $\Lambda \subset \mathrm{Pic}(X_k)$ where $\mathrm{Spec}\, k \to S$ are points are called **bounded** if there is a $T \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}}/S$ and a line bundle $\mathcal{M}$ on X_T s.t. for any $\mathcal{L} \in \Lambda$, there is some schematic point $\mathrm{Spec}\, k \to T$ s.t. $\mathcal{L} \cong \mathcal{M}_k$.

Prop. (7.1.12.25) [Numerical and τ-Equivalence]. If X is proper over an alg.closed field k and $\mathcal{L} \in \mathrm{Pic}(X)$, then the following are equivalent:

- $\mathcal{L}$ is τ-equivalent to $\mathcal{O}_X$.
- $\mathcal{L}$ is numerically equivalent to $\mathcal{O}_X$.
- The family $\{\mathcal{L}^{\oplus p} | p \in \mathbb{Z}\}$ is bounded.
- For any $\mathcal{F} \in \mathcal{C}\mathrm{oh}(X)$, $\chi(\mathcal{F} \otimes \mathcal{L}) = \chi(\mathcal{F})$.
- For any $p \in \mathbb{Z}$, $\mathcal{L}^{\oplus p}(1)$ is ample.
-

Proof: Cf.[Kle05]P52, 57. is this true for k separably closed**?** □

Prop. (7.1.12.26). If X is projective over an alg.closed field k, then the set of line bundles numerically equivalent to $\mathcal{O}_X$ is bounded.

Proof: See the proof of [Kle05]P52. □

Prop. (7.1.12.27). If X is projective over an alg.closed field k, then there exists an $m \in \mathbb{Z}$ s.t. for any $\mathcal{L} \in \mathrm{Pic}(X)$ numerically equivalent to $\mathcal{O}_X$, $\mathcal{L}$ is m-regular and $\chi(\mathcal{L}(n)) = \chi(\mathcal{O}_X(n))$ for any $n \in \mathbb{Z}$.

Proof: Cf.[Kle05]P55. □

Nef Line Bundles

Def. (7.1.12.28) [Nef Line Bundles]. A **nef line bundle** or **numerically effective line bundle** on a complete prevariety over a field k is a line bundle $\mathcal{L}$ s.t. $c_1(\mathcal{L}).C \geq 0$ for any complete precurve $C \subset X$.

Nef line bundles form a semigroup, and are stable under proper pullbacks, by(5.11.2.7)(5.11.2.5).

Prop. (7.1.12.29). Ample line bundles are nef, by(5.11.2.20).

Surface Case

Def. (7.1.12.30) [(-1)-Curves]. Let X be a complete curve over a field k, then a (-1)**-curve** on X is a curve C consisting of smooth points, $C \cong \mathbb{P}^1_k$ and $C \cdot C = -1$.

Prop. (7.1.12.31) [Hodge Index Theorem]. Let X is a smooth surface over a field k and $\mathcal{L}, \mathcal{H} \in \mathrm{Pic}(X)$ with $\mathcal{H} \cdot \mathcal{H} > 0$ and $\mathcal{L} \cdot \mathcal{H} = 0$, then $\mathcal{L} \cdot \mathcal{L} = 0$, and the equality holds iff $\mathcal{L}$ is numerically trivial.

Proof: Cf.[Rising Sea, P552]. □

Prop. (7.1.12.32) [$\mathbb{P}^1 \times \mathbb{P}^1$]. Let $X = \mathbb{P}^1 \times \mathbb{P}^1$, $l = \mathbb{P}^1 \times \{0\}$ and $m = \{0\} \times \mathbb{P}^1$, then $l \cdot l = m \cdot m = 0$, and $l \cdot m = 1$.

7.2 Algebraic de Rham Cohomology

Main references are [algebraic de Rham Cohomology, Clausen] and [Gro15].

Notation (7.2.0.1).

- Use notations from Spectral Algebraic Geometry(Lurie).

1 de Rham Complexes

Def. (7.2.1.1) [Absolute de Rham Complex]. Let B be a ring, let $\Omega_B = \Omega_{B/\mathbb{Z}}$, and $\Omega^i_B = \wedge^i \Omega_B$, then there is a **total de Rham complex** of B:

$$B \to \Omega^1_B \to \Omega^2_B \to \dots$$

as B-modules, which is a complex, where $d(b_0 db_1 \wedge \dots \wedge db_p) = db_0 \wedge db_1 \dots db_p$.

Proof: d is well-defined on Ω^1_B because it vanishes on the element $d(a+b) - da - db$ and $d(ab) - ad(b) - bd(a)$ by Leibniz rule, and the we get a map

$$\bigotimes_1^p \Omega_B \to \Omega^{p+1}_B : \omega_1 \otimes \dots \omega_p \mapsto \sum (-1)^{i+1} w_1 \wedge \dots \wedge d(\omega_i) \wedge \dots \wedge \omega_p.$$

We want to descend this to a map on Ω^p_B using(4.1.1.20): it is clearly alternating, and it suffices to show it is f-linear, and this is clear by direct calculation.

Finally $d^2 = 0$. □

Prop. (7.2.1.2)[Quotient of de Rham Complexes]. Let B be a ring and $\pi : \Omega_B \to \Omega$ be a surjective map of B-modules. Denote $d : B \to \Omega_B \to \Omega$, and $\Omega^i = \wedge^i \Omega$. Assume that the kernel of π is generated as a B-module by elements ω that $\wedge^2(\pi)(d_B(\omega)) = 0$ in Ω^2, then there is a de Rham complex

$$B \to \Omega^1 \to \Omega^2 \to \dots$$

whose differential is defined by the rules similar to that of(7.2.1.1).

Proof: Because π is surjective, so do $\wedge^i \pi$, and it suffices to show $\wedge \pi$ gives a connnecting morphism between $\Omega^\bullet_B$ and $\Omega^\bullet$, then the well-definedness of d is automatic. Cf.[[Sta]07HY]. □

Cor. (7.2.1.3) [Relative de Rham Complex]. If B is an A-algebra, the surjection $\Omega_B \to \Omega_{B/A}$ satisfies the condition of(7.2.1.2) thus we can define the **relative de Rham complex** $\Omega^\bullet_{B/A}$.

Proof: The verification of the condition is routine. □

Prop. (7.2.1.4) [Universality of de Rham Complexes]. Let C be a B-algebra and $(E^\bullet, d)$ a non-negatively graded commutative B-dga and we are given a B-algebra map $\eta : C \to E^0$ that for every $x \in C$, the element $d(\eta(x)) \in E^1$ satisfies $d^2 = 0$, then the map $C \to E^0$ extends uniquely to a map $\Omega^\bullet_{C/B} \to E^\bullet$ of B-dga.

Proof: One direction is trivial as $\Omega^\bullet_{C/B}$ is strict by construction. Conversely, the composite map $C \to E^0 \to E^1$ is a B-derivation thus extends to a map $\eta^1 : \Omega^1_{C/B} \to E^1$, then the universal property of the exterior product(4.1.1.20) gives maps $\eta^i : \Omega^i_{C/B} \to E^i$, and this gives the desired extension. □

Def. (7.2.1.5) [Connection]. Let B be a ring and $\Omega_B \to \Omega$ be a quotient satisfying the condition of(7.2.1.2), then a **connection** on M is an additive map

$$\nabla : M \mapsto M \otimes_B \Omega : \quad \nabla(b \otimes m) = b\nabla(m) + m \otimes db$$

Given a connection on M, we can define maps

$$\nabla : M \otimes_B \Omega^i \to M \otimes_B \Omega^{i+1}, \quad \nabla(b \otimes \omega) = \nabla(b) \wedge \omega + m \wedge d\omega$$

This is well defined because it commutes it commutes with B-action. The connection is called **integrable** if $\nabla^2 = 0$.

Prop. (7.2.1.6) [Algebraic de Rham Cohomology]. Let $X \to S$ be a morphism of rings, then we define the **algebraic de Rham cohomology** of X over S as the image of the de Rham complex $\Omega^\bullet_{X/S}$ in $D(\mathcal{M}\mathrm{od}(\mathcal{O}_S))$.

Prop. (7.2.1.7). There is a similar construction of connections on a f.g. projective R-module M and Weil-Chern theory parallel to that of 9 and 3.

But in this case, the trace map is defined only when M is f.g. projective, which is called the **Hattoris-Stallings trace**: If A is f.g. projective, the natural map $\mathrm{Hom}_R(A, R) \otimes_R A \to \mathrm{End}_A(P)$ is an isomorphism (Because locally it is an isomorphism**??**), and the inverse composed with $\mathrm{Hom}_R(A, R) \otimes_R A \to A$, we get the desired map.

Also, when M is f.g. projective, there is a **Levi-Cevita connection** induced by the $A \to \Omega^1_{A/R}$ because M is a direct summand of some A^n. This is verified to be independent of n, or one can more algeeoly use the fact that projective module is locally free.

The Chern character is important, it defines a ring map from $K_0(R)$ to $H^{ev}_{dR}(A)$. In fact, this can be lifted to a morphism $K_0(A) \to HC_0^{\mathrm{perf}}(A) \to H^{ev}_{\mathrm{dR}}(A)$, Cf.[阳恩林 循环同调 Dennis trace].

Prop. (7.2.1.8) [Grothendieck]. For $X \in \mathcal{S}\mathrm{ch}^{\mathrm{sm}}/\mathbb{C}$, there is a functorial equivalence

$$R\Gamma(X; \Omega^\bullet_{X/\mathbb{C}}) \cong R\Gamma(X^{\mathrm{an}}; \Omega^{\mathrm{an},\bullet}_{X^{\mathrm{an}}/\mathbb{C}}).$$

Proof: □

Remark (7.2.1.9). Notice if X is smooth and proper, then this follows from GAGA.

2 Infinitesimal Sites

3 Cup Products

Def. (7.2.3.1) [Hodge Cohomologies]. For a morphism $f : X \to S$, define the **Hodge cohomology** to be the graded $H^0(S, \mathcal{O}_S)$-algebra

$$H^*_{\mathrm{Hdg}}(X/S) = \bigoplus_{n \geq 0} H^n_{\mathrm{Hdg}}(X/S) = \bigoplus_{n \geq 0} \bigoplus_{p+q=n} H^p(X, \Omega^q_{X/S})$$

with cup product given by**?**. It is associative and graded commutative. And $S \mapsto H^*_{\mathrm{Hdg}}(X/S)$ is compatible with base change.

Proof: Cf.[Sta]0FM5. □

Prop. (7.2.3.2) [Hodge-to-deRham Spectral Sequence]. There is a spectral sequence convergence

$$E_1^{p,q} = H^q(X; \Omega^q) \implies H^n_{\mathrm{dR}}(X/\mathbb{C}).$$

And its E_2-page is given by $H^q(X; R^p\Omega)$.

Proof: **?** □

4 Poincaré Duality

Def. (7.2.4.1) [Situation]. Let S be a qcqs scheme and $f : X \to S$ is a proper smooth morphism of schemes whose fiber are all equidimensional of dimension d.

Prop. (7.2.4.2) [Relative Poincaré duality]. In situation(7.2.4.1) there is a canonical $\mathcal{O}_S$-module map

$$t : Rf_*\Omega^d_{X/S}[d] \to \mathcal{O}_S$$

s.t. for any p, the pairing

$$Rf_*\Omega^p_{X/S} \otimes^L_{\mathcal{O}_S} Rf_*\Omega^{n-p}_{X/S} \to \mathcal{O}_S$$

induced from relative cup product and t is a perfect pairing of perfect complexes in $D(\mathcal{O}_S)$ that is compatible perfect under base change. And it also induces a perfect $\mathcal{O}_S$-bilinear pairing

$$f_*\mathcal{O}_X \otimes R^d f_*\Omega^d_{X/S} \to \mathcal{O}_S$$

compatible with base change.

Proof: Cf.[Sta]0G8I. □

Cor. (7.2.4.3). If S is Noetherian and X is a proper smooth variety over S, then there is an isomorphism $R^d f_*\Omega^d_{X/S} \cong \mathcal{O}_S$ that is compatible with base change.

7.3 Étale Fundamental Groups

References are[K-M85].

1 Étale Connected Components

Def. (7.3.1.1) [Étale Connected Components]. Let X be a scheme over a field k, let $\pi_0(X) = \mathrm{Spec}(\pi(X))$, where $\pi(X)$ is the largest étale subalgebra of $\Gamma(X, \mathcal{O}_X)$(4.4.7.23).

Prop. (7.3.1.2). Let X be a locally algebraic scheme over a field k, then

- for any field extension k'/k, $\pi_0(X_{k'}) = \pi_0(X)_{k'}$.
- Let Y be a schemes over a field k, then $\pi_0(X \times Y) = \pi_0(X) \times \pi_0(Y)$.

Proof: 1: Cf.[Mil17b]P15.

2: There is a map $\pi(X) \times_k \pi(Y) \to \pi(X \times Y)$. Because π commutes with base change, we can base change to separable closure. In this case, it suffices to show if X, Y is connected then $X \times Y$ is connected, but this follows from(5.4.3.12). □

Prop. (7.3.1.3). Let X be a locally algebraic scheme over a field k, then

- The mapping $\varphi : X \to \pi_0(X)$ induces a 1 to 1 correspondence of points of $\pi_0(X)$ and connected components of X.
- For all $x \in \pi_0(X)$, the fiber $\varphi^{-1}(x)$ is geo.connected over $k(x)$.
- $X \to \pi_0(X)$ is faithfully flat.

Proof: $\pi_0(X)$ is discrete, so the inverse image of each point is a sum of connected components of X. But this must be connected, because $\pi_0(X_{k(x)}) = \pi_0(X)_{k(x)} = k(x)$. Also, this implies for the alg.closure $\overline{k}$ of $k(x)$, $\pi_0(X_{\overline{k}}) = \pi_0(X_{k(x)})_{\overline{k}} = \overline{k}$, thus $X_{\overline{k(x)}}$ is geo.connected. □

2 Étale Fundamental Groups

Main references are [Sta]Chap53 and [Fu11]Chap3.

Lemma (7.3.2.1) [Rigidity Lemma]. If $f, g : S' \to S''$ are two S-morphisms where S'' is a separated étale S-scheme and $(S', \overline{s}')$ is a pointed scheme that $f(\overline{s}') = g(\overline{s}')$, then $f = g$.

Proof: The diagonal $S'' \to S'' \otimes_S S''$ is a closed immersion and also étale hence open(5.6.6.3), so the diagonal is an clopen subset. And now $f \times g : S' \to S'' \otimes_S S''$ intersects the diagonal, and S' is connected, so f, g are identical on the diagonal. □

Def. (7.3.2.2) [Galois Cover]. If $(S, \overline{s})$ is a pointed connected scheme, $S' \to S$ is a finite étale cover of degree n, then there are at most n point over $\overline{s}$, so by(7.3.2.1), $|\mathrm{Aut}(S'/S)| \leq n$. If the equality holds, then we call S'/S a **Galois cover** and define $\mathrm{Gal}(S'/S) = \mathrm{Aut}(S'/S)^{op}$.

Prop. (7.3.2.3). If $S' \to S$ is a connected finite étale cover, then there is a finite étale cover $S'' \to S'$ that $S'' \to S$ is Galois.

Proof: Cf.[SGA1, Exp.V, §2 − §4]. □

Def. (7.3.2.4)[Étale Fundamental Group]. For any two finite Galois étale cover $S'/S, S''/S$, if there is a S-morphism $S'' \to S'$, then it induces a morphism of Galois groups because the Galois group of S' acts transitively on the fiber over a closed point. And it is surjective by the same reason for S''.

Then we define the **étale cohomology group**

$$\pi_1(S, x) = \varprojlim_{(S', \overline{x}')} \operatorname{Gal}(S'/S)$$

Prop. (7.3.2.5)[Fundamental Group and Covers]. For X connected smooth scheme and $\overline{x} \to X$ a geometric point, there is a profinite group $\pi_1(X, \overline{x})$ that there is a correspondence:

$$\{\text{finite étale covers } Y \to X\} \leftrightarrow \{\text{Finite sets with a continuous action of } \pi_1(X, x)\}$$

Such a group $\pi_1(X, \overline{x})$ is called the **étale fundamental group** of X w.r.t $\overline{x}$.

Proof: □

Prop. (7.3.2.6). Let (S, s) be a connected scheme, then the functor $S' \mapsto S'_{\overline{s}}$ induces an equivalence of categories between the finite étale covers $S' \to S$ with the category of finite discrete $\pi_1(X, x)$-sets.

Proof: We may assume S' is connected, then use(7.3.2.3) to find a Galois cover $S'' \to S'$ that S''/S is Galois, then clearly there is a bijection

$$\operatorname{Gal}(S''/S)/\operatorname{Gal}(S''/S') \cong S'(s')$$

And any transitive discrete $\pi_1(X, x)$-sets arise this way.

To prove the essentially surjectivity and fully faithfulness, ? □

Cor. (7.3.2.7). The étale fundamental group is independent of the base point $\overline{s}$ chosen.

Proof: This is because for two profinite groups, if the categories of their finite sets are equivalent, then they are isomorphic?. □

Cor. (7.3.2.8) [Locally Constant Sheaves and Fundamental Group]. By(7.4.2.19), if X is a connected scheme and $\overline{x}$ be a geometric point of X, then there is an equivalence of categories between finite locally constant Abelian sheaves on X and finite $\pi_1(X, \overline{x})$-modules.

Prop. (7.3.2.9). For k alg.closed, $\pi_1(\mathbb{P}^1_k) = 0$.

Proof: □

Prop. (7.3.2.10)[Arithmetic Geometric Exact Sequence]. If X_0 is a variety over $\mathbb{F}_q$, then there is an exact sequence

$$1 \to \pi_1(X, \overline{x}) \to \pi_1(X_0, \overline{x}) \to G(\overline{k}/k) \to 1.$$

7.4 Étale Cohomology Theory

Basic references are [Fu11], [Sta], [Étale Cohomology, Tamme], [Mil13b], [Con15] and [Notes on étale cohomology of number fields,. Ann. Sci. Éc. Norm. Super. (4) 6, 521–552 (1973), Mazur].

Notation (7.4.0.1).

- Use notations defined in Cohomology of Schemes.
- Use notations defined in More Properties of Schemes.

1 Basics

Prop. (7.4.1.1). For $X \in \mathcal{S}\mathrm{ch}$, the étale site $X_{\text{ét}}$ is a ringed site, $\mathcal{S}\mathrm{h}(X_{\text{ét}})$ is a Grothendieck Abelian category, and we can define right derived functors of any left exact functor, by(5.3.1.1).

Étale Topoi

Prop. (7.4.1.2) [Zariski-Étale Comparison]. For $X \in \mathcal{S}\mathrm{ch}$, the inclusion $X_{\mathrm{Zar}} \to X_{\text{ét}}$ of topologies which is a morphism of sites $\varepsilon : X_{\text{ét}} \to X_{\mathrm{Zar}}$, for any $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, there is a Leray spectral sequence(5.3.1.8)

$$E_2^{pq} = H^p_{\mathrm{Zar}}(X, R^q\varepsilon_*(\mathcal{F})) \Rightarrow \mathrm{H}^{p+q}_{\text{ét}}(X, \mathcal{F}).$$

Def. (7.4.1.3)[Pushforward & Pullback]. For a morphism of schemes $X \to Y$, there is a continuous functor between sites $f_{\text{ét}} : Y_{\text{ét}} \to X_{\text{ét}}$, which preserves final objects and finite fiber products, so by(5.1.2.14), it induces a morphism of sites(5.1.1.5) $f_{\text{ét}} : X_{\text{ét}} \to Y_{\text{ét}}$, which induces a morphism of topoi

$$f_{\text{ét}} : \mathcal{S}\mathrm{h}(X_{\text{ét}}) \to \mathcal{S}\mathrm{h}(Y_{\text{ét}}).$$

$f^*_{\text{ét}}$ is called the inverse image, it is exact. By definition(5.1.2.11), for $\mathcal{F} \in \mathcal{S}\mathrm{h}(Y_{\text{ét}})$ and $X \in X_{\text{ét}}$, $f^*\mathcal{F}(X')$ equals the colimit over all pairs (Y', φ) where $Y' \in Y_{\text{ét}}$ and $\varphi : X' \to Y' \times_Y X$, equivalently, all $X' \to Y'$ over Y.

Cor. (7.4.1.4) [Localizations]. By(5.1.2.25), an object $i : X' \to X \in X_{\text{ét}}$ induce a morphism $({}_si, i^s)$ of topoi $X'_{\text{ét}} \to X_{\text{ét}}$.

Denote $i^s\mathcal{F} = F/X'$, then for $Z' \in X'_{\text{ét}}$, by(5.3.1.4) and(5.1.2.25)

$$F/X'(Z') = F(Z'), \quad H^q(X_{\text{ét}}; Z', F) \cong H^q(X'_{\text{ét}}; Z', F/X').$$

In particular,

$$H^q(X_{\text{ét}}; X', \mathcal{F}) = H^q(X'_{\text{ét}}; X', \mathcal{F}|_{X'}),$$

thus we will omit the ambient sites and the restriction of sheaves, which should cause no confusion.

Prop. (7.4.1.5). If Z is étale over X, then the canonical morphism

$$f^* \operatorname{Hom}_X(-, Z) \to \operatorname{Hom}_Y(-, Z \times_X Y)$$

is an isomorphism.

Proof: By definition, $f^* \operatorname{Hom}_X(-, Z)$ is the sheaf associated to the presheaf $f_p \operatorname{Hom}_X(-, Z)$(5.1.2.11), which is identical to the presheaf $\operatorname{Hom}_Y(-, Z)$ on $Y_{\text{ét}}$, but it is already a sheaf(5.1.4.34). □

Prop. (7.4.1.6) [Relative Leray Spectral Sequence]. If $f : X \to Y, g : Y \to Z \in \mathcal{S}\mathrm{ch}$, then for any $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, there is a relative Leray spectral sequence(5.3.1.8)

$$E_2^{pq} = R^p g_*(R^q f_*(\mathcal{F})) \Rightarrow R^{p+q}(gf)_*(\mathcal{F}).$$

Cor. (7.4.1.7) [Leray Spectral Sequence]. For a morphism of schemes $f : X \to Y$ and $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, $Y' \in Y_{\text{ét}}$, there is a Leray spectral sequence**??**:

$$E_2^p = \mathrm{H}^p(Y', R^q f_*(\mathcal{F})) \Rightarrow \mathrm{H}^{p+q}(Y' \times_Y X, \mathcal{F})$$

Prop. (7.4.1.8) [Commutes with Colimits]. For $X \in \mathcal{S}\mathrm{ch}^{\mathrm{qcqs}}$, by(5.1.4.17)(5.1.4.20) and(5.3.1.14), $\mathrm{H}^q_{\text{ét}}(X, -)$ commutes with filtered colimits.

Prop. (7.4.1.9). Let $X, Y \in \mathcal{A}\mathrm{ff}$, then for any morphism of ringed sites $(g, g^\sharp) : (X_{\text{ét}}, \mathcal{O}_X) \to (Y_{\text{ét}}, \mathcal{O}_Y)$, there exists a unique morphism of schemes $f : X \to Y \in \mathcal{S}\mathrm{ch}$ s.t. $(g, g^\sharp)$ is 2-isomorphic to $(f, f^\sharp)$.

Proof: Cf.[Sta]04I6. □

Field Case

Prop. (7.4.1.10) [Etále Site over Fields]. The functor $f : X' \to X'(k_s)$ is an equivalence of topologies from the small étale site $(\mathrm{Spec}(k))_{\text{ét}}$ to the canonnical topology T_G on the category of G-sets, where $G = G(k_s/k)$.

In particular, any Abelian sheaf on $\mathrm{Spec}(k)_{\text{ét}}$ is representable by**?**.

Proof: First f maps a family of morphisms of schemes to a covering iff this family is a covering itself. This is because both are defined by set-theoretical surjectivity, and this is by(5.6.6.13).

Next we need to show this is an equivalence of categories. f has a left adjoint g because $X' \to \mathrm{Hom}_G(U, X'(k_s))$ is representable for any G-set U, because any G-set is equivalent to disjoint sums of G/H, and both category has arbitrary sums, so it suffice to prove for G/H, but this is represented by $\mathrm{Spec}\, k'$, where k' is the fixed field of H.

To prove $fg \cong \mathrm{id}$ and $gf \cong \mathrm{id}$, they commutes with direct sums, so the first one is true because $G/H \to fg(G/H) = \mathrm{Spec}(k_s)(k)$ is an isomorphism, and the second follows from(5.6.6.6) as all étale schemes over field k is a disjoint union of spectra of finite separable field extensions of k. □

Cor. (7.4.1.11) [Étale and Galois Cohomologies]. By(10.1.2.1),

$$\mathcal{S}\mathrm{h}((\mathrm{Spec}\, k)_{\text{ét}}) \to \mathcal{M}\mathrm{od}_G : \mathcal{F} \to \varinjlim_{k \subset k' \subset k^s} \mathcal{F}(\mathrm{Spec}\, k')$$

is an equivalence of categories, so

$$\mathrm{H}_{\text{ét}}{}^q(\mathrm{Spec}\, k, \mathcal{F}) \cong \mathrm{H}^q(G, \varinjlim_{k \subset k' \subset k^s} \mathcal{F}(\mathrm{Spec}\, k_s)).$$

In particular, if $k = k^s$, then $(\mathrm{Spec}\, k)_{\text{ét}}$ is equivalent to $\mathcal{A}\mathrm{b}$, and $\mathrm{H}^p_{\text{ét}}(\mathrm{Spec}(k), \mathcal{F}) = 0$ for $p > 0$.

Stalks

Def. (7.4.1.12) [Stalk]. By(7.4.1.10), for any scheme X and an arithmetic point $x : \operatorname{Spec} k \to X$, the section functor $F \to F(x)$ is an equivalence of categories from $(\operatorname{Spec} k)_{\text{ét}}$ to $\mathcal{A}\mathrm{b}$. Thus for any $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, we can define the **stalk map**

$$\mathcal{S}\mathrm{h}(X_{\text{ét}}) \to \mathcal{A}\mathrm{b} : \mathcal{F} \mapsto (x^*\mathcal{F})(x).$$

Prop. (7.4.1.13). For any geometric point P of X,

- the stalk map is exact and commutes with colimits.
- For any morphism $u : P' \to P$ of geometric points over X, $\mathcal{F}_P \cong F_{P'}$.
- If $X \to Y$ is a morphism, then $(f^*F)_P \cong F_P$.

Proof: 1: taking stalk is a composition of f^* and taking section over P(which is an equivalence), so it is exact and commutes with colimits(7.4.1.3).

2, 3: Trivial. □

Prop. (7.4.1.14) [Stalk is Defined Naturally]. By the definition of f^*(5.1.2.11), if X' be an étale nbhd of P in X, i.e. $P \to X' \to X$, then

$$(f_{\text{ét}})_p(\mathcal{F}(P)) = \varinjlim_{X'} \mathcal{F}(X')$$

and $F_P = f^*F(P)$, thus there is a natural map $\varinjlim_{X'} F(X') \to F_P$.

Then we have:

$$\varinjlim_{X'} G(X') \to (G^\sharp)_P$$

for any presheaf G on $X_{\text{ét}}$.

Proof: Firstly $(f^\cdot)^\sharp(G) \cong (f^*G)^\sharp$ by(5.1.2.12). Then it suffices to prove that $G(P) \to G^\sharp(P)$ is an isomorphism for any presheaf G on $P_{\text{ét}}$. But this is because $P_{\text{ét}}$ is just $\mathcal{A}b$(7.4.1.10), and $P \xrightarrow{\text{id}} P$ is cofinal in the category of coverings of P. □

Cor. (7.4.1.15). For a morphism of schemes $X \to Y$ and P is a geometric point of Y, then

$$R^p f_*(F)_P \cong \varinjlim_{P \in Y'} H^p(X \times_Y Y', F).$$

Cor. (7.4.1.16). For $X = \operatorname{Spec} k$, the equivalence(7.4.1.10) of $X_{\text{ét}}$ with continuous G-modules are just induced by taking the stalk at $\operatorname{Spec} k_s$.

Prop. (7.4.1.17) [Exactness and Stalks]. The exactness, injectivity and surjectivity of maps of sheaves $F' \to F$ on $X_{\text{ét}}$ can be checked on stalks(7.4.1.12).

Proof: It suffices to prove the isomorphism case, because taking stalks are exact(7.4.1.13) and other maps can be characterized by isomorphisms.

Monomorphism: suppose not, if $s \in F'(X')$ is mapped to 0, by taking base change, we can assume $X' = X$, and then $0 = v(s)_{\overline{x}} = v_{\overline{x}}(s_{\overline{x}})$, thus $s_{\overline{x}} = 0$ by assumption. Now by(7.4.1.14), for any x there is an étale nbhd of x that s vanishes on it. So we find an étale covering of X that s vanishes, thus $s = 0$ because F' is a sheaf.

Epimorphism: Similarly, for any $v \in F(X')$, we can pass to the base change and assume $X' = X$, then find for each x a nbhd that comes from some $v(s_x)$, and they glue together to be a global section of $F'(X)$. □

Prop. (7.4.1.18) [Finite Morphism is Exact]. For a finite morphism f, f_* are exact on étale topos.

Proof: Check on stalks, □

Properties of Étale Cohomologies

Prop. (7.4.1.19) [Restriction to Small Sites]. If $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\text{ét}}/S$, then the cohomology groups of $\mathcal{F}$ on S agrees with the cohomology of its restriction on $\mathcal{S}\mathrm{h}(S_{\text{ét}})$, by(5.3.1.4).

Prop. (7.4.1.20) [Čech Comparison, Arin]. If $X \in \mathcal{S}\mathrm{ch}$ is compact and any finite subset of X is contained in an open affine(e.g. X is quasi-projective), then for any covering $\mathcal{U} \in \mathrm{Cov}(\mathcal{S}\mathrm{ch}_{\text{ét}}/X)$ of X, $\check{H}(\mathcal{U}, -)$ is exact.

In particular, by(5.3.2.16), in this case, we can use Čech cohomology to calculate the étale cohomologies.

Proof: Cf.[Milne, Étale Cohomologies, Prop3.2.17]. □

Prop. (7.4.1.21) [Inverse Limits]. Let $(X_i)_I$ be a projective system in $\mathcal{S}\mathrm{ch}_{qc}$ with affine morphisms, $X_\infty = \varprojlim_{i\in I} X_i$. For any projective system of sheaves $(\mathcal{F}_i)_I, \mathcal{F}_i \in \mathcal{S}\mathrm{h}((X_i)_{\text{ét}})$, let $\mathcal{F}_\infty = \varprojlim_{i\in I} \mathcal{F}_i$, then there are isomorphisms

$$\varinjlim_{i\in I} \mathrm{H}^p_{\text{ét}}(X_i, \mathcal{F}_i) \cong \mathrm{H}^p_{\text{ét}}(X_\infty, \mathcal{F}_\infty).$$

Proof: Cf. SGA4, Prop7.5.8, or Artin 1962, Chap3.3.? □

Prop. (7.4.1.22) [Étale-Zariski Comparison for Qco Sheaves]. Recall by(5.1.4.36) if $M \in \mathcal{Q}\mathcal{C}\mathrm{oh}(X)$ then $\widetilde{M}$ is a fpqc sheaf on X, in particular an étale sheaf on X. Now the edge map of the Zariski-étale comparison for $\widetilde{M}$ is an isomorphism:

$$H^p_{\mathrm{Zar}}(X, M) \cong \mathrm{H}^p_{\text{ét}}(X, \widetilde{M})$$

In particular, $\mathrm{H}^p_{\text{ét}}(X, \mathbb{G}_a) \cong H^p(X, \mathcal{O}_X)$, and the étale cohomology for Qco sheaves vanishes on affine schemes.

Proof: Cf.[Sta].

We show that $R^p\varepsilon^s(\widetilde{M}) = 0$ for $p > 0$, Cf.[Tamme P109]. Not hard. □

Prop. (7.4.1.23) [Galois Covering and Group Cohomology]. If $\mathcal{U} = \{Y \to X\}$ is a single Galois covering with Galois group G, $\mathcal{P}$ is a presheaf on $\mathcal{S}\mathrm{ch}/X$ s.t. then $\check{H}^r(\mathcal{U}, \mathcal{P}) = H^r(G, \mathcal{P}(Y))$.

In particular, we may not use alternating complex to calculate the étale cohomologies.

Proof: □

Prop. (7.4.1.24) [Hochschild-Serre Spectral Sequences]. Let $X \in \mathcal{S}\mathrm{ch}$ and $Y \in X_{\text{ét}}$ be a Galois covering with Galois group Γ, then for any $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, there is a spectral sequence

Prop. (7.4.1.25) [Mayer-Vietoris Sequences]. Let $X \in \mathcal{S}\mathrm{ch}$ and $f : Y \to X \in X_{\text{ét}}, U \subset X$ s.t. $f(Y) \cup U = X$, then for any $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, there is a long exact sequence

$$0 \to \mathrm{H}^0_{\text{ét}}(X, \mathcal{F}) \to \mathrm{H}^0_{\text{ét}}(U, \mathcal{F}) \oplus \mathrm{H}^0_{\text{ét}}(Y, \mathcal{F}) \to \mathrm{H}^0_{\text{ét}}(f^{-1}(U), \mathcal{F}) \to \mathrm{H}^1_{\text{ét}}(X, \mathcal{F}) \to \ldots$$

that is functorial in $\mathcal{F}$, by(5.3.1.11).

Def. (7.4.1.26) [Restricted Cohomologies]. Let $X \in \mathcal{S}\mathrm{ch}$, $Z \subset X$ be a closed subscheme, $U = X \backslash Z$, then there is a functor

$$\Gamma_Z(X, -) : \mathcal{S}\mathrm{h}(X_{\text{ét}}) \to \mathcal{A}\mathrm{b} : \mathcal{F} \mapsto \ker(\Gamma(X, \mathcal{F}) \to \Gamma(U, \mathcal{F})),$$

which is left exact as both $\Gamma(X, -)$ and $\Gamma(U, -)$ are.

The right derived cohomology of $H^r_Z(X, -)$, called the **cohomology of $\mathcal{F}$ with supports in Z**.

Prop. (7.4.1.27) [Long Exact Sequences]. Situation as in(7.4.1.26), for any $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, there is a functorial long exact sequence

$$\cdots \to H^r_Z(X, \mathcal{F}) \to \mathrm{H}^r_{\text{ét}}(X, \mathcal{F}) \to \mathrm{H}^r_{\text{ét}}(U, \mathcal{F}) \to H^{r+1}_Z(X, \mathcal{F}) \to \cdots.$$

Proof: Choose a functorial injective resolution(3.9.2.9), and this follows from the fact an injective sheaf is flabby(5.3.4.9). □

Prop. (7.4.1.28) [Excisions]. Let $X \in \mathcal{S}\mathrm{ch}$, $f : X' \to X \in X_{\text{ét}}$, $Z \subset X$ be a closed subset s.t. $Z' = f^{-1}(Z) \to Z$ is an isomorphism, and $f^{-1}(X \backslash Z, \mathcal{F}) \to X \backslash Z$ is an open immersion, then for $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, the canonical maps

$$H^r_Z(X, \mathcal{F}) \to H^r_{Z'}(X', \mathcal{F})$$

are isomorphisms.

Proof: As f^* is exact and preserves injectives by(5.3.4.2), it suffices to prove for $r = 0$. Let $U = X \backslash Z, U' = X' \backslash Z'$. If $s \in \Gamma_Z(X, \mathcal{F})$ restricts to $0 \in \Gamma_{Z'}(X', \mathcal{F})$, then s restricts to 0 in both X' and U. But $\{X', U\}$ is an étale covering of X, so $s = 0$.

Conversely, if $s' \in \Gamma_{Z'}(X', \mathcal{F})$, to show it comes from some $s \in \Gamma_Z(X, \mathcal{F})$, it suffices to show s' and $0 \in \Gamma(U, \mathcal{F})$ defines a cocycle in the Čech complex $\check{C}(\{X', U\}, \mathcal{F})$: They both restrict to $0 \in X' \cap U = U'$, and for $X' \times_X X'$, we can check on stalks: s' restrict to 0 on $U' \times_X U'$ from both sides, and on $Z' \times_X Z' \cong Z'$, the maps $Z' \times_X Z' \to Z$ are equal isomorphisms. □

Cor. (7.4.1.29) [Restricted Cohomology at a point]. Let $x \in X$ be a closed point, then for any $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, there is an isomorphism

$$H^p_x(X, \mathcal{F}) \cong \mathrm{H}^r_{\text{ét}}(\mathrm{Spec}\, \mathcal{O}^h_{X,x}, j^*\mathcal{F}).$$

Proof: Take limits over the affine étale nbhds of $x \in X$ and use(7.4.1.21). □

Artin-Schreier Theory and Kummer Theory

Prop. (7.4.1.30) [Artin-Schreier Sequence]. Let X be a scheme that has char p, let $F : (\mathbb{G}_a)_X \to (\mathbb{G}_a)_X$ be the Frobenius map, and let $P = \mathrm{id} - F$, then there is an **Artin-Schreier exact sequence**

$$0 \to (\underline{\mathbb{Z}/(p)})_X \to (\mathbb{G}_a)_X \xrightarrow{P} (\mathbb{G}_a)_X \to 0$$

Proof: If $s \in \mathcal{O}_{X'}$ is in the kernel, then $s = s^p$, so it is locally constant and comes from the map $\mathbb{Z}/p\mathbb{Z} \to \mathcal{O}_{X'}$. Conversely, for any $s \in \mathcal{O}_{X'}$, it suffices to find an étale cover that s is a p-th power in $\mathcal{O}_{X'_i}$. For this, it suffices to notice that for any p-ring A, $A[t]/(t^p - t - s)$ is free of rank p and étale over A. □

Cor. (7.4.1.31). If X has char p, then by the long exact sequence and(7.4.1.22), there is an exact sequence

$$0 \to H^0(X, \mathcal{O}_X)/P(H^0(X, \mathcal{O}_X)) \to H^1(X, (\mathbb{Z}/p\mathbb{Z})) \to H^1(X, \mathcal{O}_X)^F \to 0$$

where the last one is the fixed elements.

Cor. (7.4.1.32). If $X = \operatorname{Spec} A$ and $pA = 0$, then $H^q(X, (\mathbb{Z}/p\mathbb{Z})_X) = A/P(A)$ for $p = 0$ and vanish for $p > 0$.

Cor. (7.4.1.33). If k is separably closed field of char$p$ and X is a reduced proper k-scheme, then $H^1(X, (\mathbb{Z}/p\mathbb{Z})_X) = (H^1(X, \mathcal{O}_X))^F$.

Prop. (7.4.1.34) [Kummer Sequence]. If n is invertible on X, then there is an exact sequence in $\mathcal{S}\mathrm{h}(X_{\text{ét}})$:

$$0 \to \mu_{n,X} \to \mathbb{G}_{m,X} \xrightarrow{n} \mathbb{G}_{m,X} \to 0$$

Proof: The proof is similar to that of Artin-Schreier sequence(7.4.1.30), noticing that $A \to A[T]/(T^n - s)$ is an étale map. □

Cor. (7.4.1.35). If n is invertible on X,then by(5.7.1.14), there is an exact sequence

$$0 \to H^0(X, \mathcal{O}_X^*)/nH^0(X, \mathcal{O}_X^*) \to H^1(X, \mu_n) \to \operatorname{Pic}(X)[n] \to 0$$

Cor. (7.4.1.36). If $X = \operatorname{Spec} A$ where A is a local ring and n is invertible in A, then $H^1(X, \mu_n) \cong A^*/(A^*)^n$.?

Proof: Cf.[Tamme, P110]. □

Cor. (7.4.1.37). If $k \in \texttt{Field}, k = k^s, X \in \mathcal{S}\mathrm{ch}/k$ is reduced and proper, and $n \in \mathbb{Z} \cap k^\times$, then $H^1(X, \mu_n) \cong \operatorname{Pic}(X)[n]$, by(5.10.1.12).

Strict Henselization

Def. (7.4.1.38).

2 Constructible Sheaves

Torsion Sheaves

Def. (7.4.2.1) [Torsion Sheaves]. For $\mathcal{C} \in \mathcal{S}\mathrm{ite}$, $\mathcal{F} \in \mathcal{S}\mathrm{h}(\mathcal{C}; \mathcal{S}\mathrm{et})$ is called a **torsion sheaf** iff it is associated to a presheaf of torsion Abelian groups. Equivalently, the canonical morphism $\varinjlim_n \mathcal{F}[n] \to F$ is an isomorphism. The category of torsion sheaves on $\mathcal{C}$ is denoted by $\mathcal{S}\mathrm{h}_{\mathrm{tor}}(\mathcal{C})$.

Proof: It $\mathcal{F} = P^\sharp$, then consider $0 \to P[n] \to P \xrightarrow{n} P \to 0$. Because $\sharp$ is exact, $\mathcal{F}[n] = (P[n])^\sharp$. Then because $\sharp$ commutes with inductive limits and $P = \varinjlim_n P[n]$, it follows $\mathcal{F} = \varinjlim_n \mathcal{F}[n]$.

Conversely, if $\mathcal{F} = \varinjlim_n \mathcal{F}[n]$, then $\mathcal{F} = \varinjlim_n (\mathcal{F}^{\mathcal{P}\mathcal{S}\mathrm{h}}[n])^\sharp = (\varinjlim_n \mathcal{F}[n])^\sharp$, and $\varinjlim_n \mathcal{F}^{\mathcal{P}\mathcal{S}\mathrm{h}}[n]$ is presheaf of torsion Abelian groups. □

Remark (7.4.2.2). WARNING: For a torsion sheaf, $\mathcal{F}(U)$ need not be torsion Abelian, but this is the case if U is quasi-compact, Cf.[Tamme P146].

Prop. (7.4.2.3) [Being Torsion is Local]. $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$ is a torsion sheaf iff all stalks $\mathcal{F}_x$ are torsion.

Proof: By definition $\mathcal{F}$ is torsion iff $\varinjlim_n \mathcal{F}[n] \to \mathcal{F}$ is an isomorphism. Then use the fact isomorphisms are checked on stalks(7.4.1.17) and stalk maps are exact(7.4.1.13). □

Prop. (7.4.2.4).

- If $X \to Y$ is a morphism of schemes and F is a torsion sheaf on Y, then f^*F is torsion sheaf on X.
- If $X \to Y$ is a qcqs morphism of schemes and F is a torsion sheaf on X, then $R^q f_* F$ are torsion sheaves on Y.
- In particular, if X is qcqs and F is a torsion sheaf on X, then $\mathrm{H}^q_{\text{ét}}(X, F)$ are torsion for all q.

Proof: 1: This follows immediately from(7.4.2.3) and(7.4.1.13).

2: For any $y \in Y$, $(R^q f_* F)_{\overline{y}} \cong H^q(\overline{X}, \overline{F})$, where $\overline{X} = X \otimes_Y \overline{Y}$ and $\overline{Y}$ is the strict localization of Y in $\overline{y}$ by**?**. Now $\overline{F}$ is torsion sheaf by item1, and $\overline{X} \to \overline{Y}$ is also qcqs with $\overline{Y}$ being affine, so $H^q(\overline{X}, \overline{F})$ is torsion by item3, so $R^q f_* F$ is torsion by(7.4.2.3).

3: By(7.4.1.8), in this case, $\mathrm{H}^p_{\text{ét}}(X, -)$ commutes with filtered colimits, so we can replace F by ${}_nF$. Then multiplying by n is zero on F, so also it is zero on $\mathrm{H}^p_{\text{ét}}(X, F)$, so $\mathrm{H}^p_{\text{ét}}(X, F)$ is torsion. □

Prop. (7.4.2.5). If X is Noetherian scheme and x is a point of X, let $i : \mathrm{Spec}(k(x)) \to X$ be the structure map, then

- for any Abelian sheaf F on $\mathrm{Spec}(k(x))_{\text{ét}}$, the sheaves $R^p i_* F$ are torsion sheaf for $p > 0$.
- $\mathrm{H}^p_{\text{ét}}(X, i_* F)$ are torsion for all $p > 0$.

Proof: 1: Cf.[Tamme P148]. Uses strict Henselization.

2: Consider the Leray spectral sequence $\mathrm{H}^p_{\text{ét}}(X, R^q i_* F) \Longrightarrow H^{p+q}_{\text{ét}}(\mathrm{Spec}(k(x)), F)$, the left term vanishes for $p \geq 0, q > 0$ by item1 and(7.4.2.4), and the right hand side vanish for $p + q > 0$ by(7.4.2.4), then it can be checked that $\mathrm{H}^p_{\text{ét}}(X, i_* F)$ are torsion for $p > 0$. □

Prop. (7.4.2.6). For a closed subscheme $i : Y \subset X$, $R^p i^!$ preserves torsion sheaves.

Proof: Cf.[Tamme P148]. □

Prop. (7.4.2.7). For a regular Noetherian scheme X, $\mathrm{H}^q_{\text{ét}}(X, (\mathbb{G}_m)_X)$ are torsion for $q \geq 2$.

Proof: Cf.[Tamme P149]. □

Prop. (7.4.2.8). For a torsion sheaf F, define $F(\ell) = \varinjlim_n F[\ell^n]$, so it is an ℓ-torsion sheaf, and in fact

$$\oplus_{\ell \in \mathbf{P}} F(\ell) = F$$

this is because this is true at the stalks, because stalks is exact and commutes with colimits(7.4.1.13).

So if X is qcqs, then $H^p(X, F) \cong H^p(X, F(l))$, which is the primary decomposition of $H^p(X, F)$.

Proof: □

Def. (7.4.2.9)[Cohomological Dimension]. If $X \in \mathcal{S}\mathrm{ch}_{\mathrm{qcqs}}/k$, $\ell \in \mathbf{P}$, define the **ℓ-adic cohomological dimension** of X as the smallest number $\mathrm{cd}_\ell(X) = n$ that $H^p(X, \mathcal{F})[\frac{1}{\ell}] = 0$ for all $p > n$ and $\mathcal{F} \in \mathcal{S}\mathrm{h}^{\mathrm{tor}}(X_{\text{ét}})$, and define the **cohomological dimension** $\mathrm{cd}(X)$ of X as the smallest number n that $H^p(X, F) = 0$ for all $p > n$ and $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\mathrm{tor}}(X_{\text{ét}})$. Equivalently, $\mathrm{cd}(X) = \sup_{\ell \in \mathbf{P}} \{\mathrm{cd}_\ell(X)\}$.

Prop. (7.4.2.10). If $k \in \texttt{Field}$ and $X \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}}/k$, then

$$\mathrm{cd}_\ell(X) \leq \begin{cases} 2\dim X + \mathrm{cd}_\ell(k) & \ell \neq \mathrm{char}\, k \\ \dim X + 1 & \ell = \mathrm{char}\, k \end{cases}.$$

Proof: □

Cor. (7.4.2.11). If $k \in \texttt{Field}, k = k^s$, then $\mathrm{cd}(X) \leq 2\dim X$.

Proof: □

Thm. (7.4.2.12) [Artin Vanishing]. If $k \in \texttt{Field}, k = k^s$ and $X \in \mathcal{A}\mathrm{ff}^{\mathrm{ft}}/k$, then $\mathrm{cd}(X) \leq \dim X$.

Proof: Cf.[Mil13b]P105.**?** □

Prop. (7.4.2.13) [Arc Descent for Étale Cohomology]. Let R be a ring and $\mathcal{G} \in \mathcal{S}\mathrm{h}^{\mathrm{tor}}_{\mathrm{\acute{e}t}}(\mathrm{Spec}\, R)$, and $\mathcal{F} : (\mathcal{S}\mathrm{ch}_{\mathrm{qcqs}}/R)^{\mathrm{op}} \to D^{\geq 0}(\Lambda)$ be the functor $(f : X \to \mathrm{Spec}\, R) \mapsto R\Gamma(X_{\mathrm{\acute{e}t}}, f^*\mathcal{G})$, then $\mathcal{F}$ satisfies arc-descent.

Proof: Cf.[Arc Topology, Bhatt, 5.4.] □

Constructible Sheaves

References are [Conrad notes, L3].

Prop. (7.4.2.14). If G is a commutative, finite and étale group scheme on X, the sheaf G_X represented by G is locally finite on $X_{\mathrm{\acute{e}t}}$.

Conversely, any locally constant sheaf on $X_{\mathrm{\acute{e}t}}$ is represented by a unique commutative étale group scheme over X, and it is finite if F has finite stalks.

Proof: Cf.[Tamme P152]. □

Def. (7.4.2.15) [Finite étale Sheaves]. For $X \in \mathcal{S}\mathrm{ch}$, a **finite étale sheaf** is a sheaf $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\mathrm{\acute{e}t}}; \mathcal{S}\mathrm{et})$ s.t. all its stalks are finite.

Def. (7.4.2.16) [Constructible étale Sheaves]. For $X \in \mathrm{N}\mathcal{S}\mathrm{ch}$, a **constructible étale sheaf** is a sheaf $\mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\mathrm{\acute{e}t}}; \mathcal{S}\mathrm{et})$ s.t. there is a stratification $\{X_i\}$ of X that $\mathcal{F}_{X_i}$ are all locally constant and finite(7.4.2.15). The category of constructible sheaves on X is denoted by $\mathcal{S}\mathrm{h}_{\mathrm{const}}(X_{\mathrm{\acute{e}t}}; \mathcal{S}\mathrm{et})$.

If moreover $\mathcal{F}$ is locally constant, i.e. $\mathcal{F}$ is locally constant and finite, then it is called a **lcc étale sheaf**. The category of lcc étale sheaves are denoted by $\mathcal{S}\mathrm{h}_{\mathrm{lcc}}(X_{\mathrm{\acute{e}t}}; \mathcal{S}\mathrm{et})$.

Prop. (7.4.2.17). $\mu_{n,X}$ is étale over X iff n is prime to the characteristic of all local residue fields of X. (Only unramifiedness is concerned, and it is fiberwise(4.4.6.6)). And we can compute the Kahler differential of $k[T]/(T^n - 1)$ vanish iff $n \neq 0$ in k.

In this case, μ_n is locally isomorphic to $(\mathbb{Z}/n\mathbb{Z})_X$, because for any affine open $U = \mathrm{Spec}\, A$, $U' = \mathrm{Spec}\, A[t]/(t^n - 1) \to U$ is étale and surjective(4.4.1.22) and U' has all n-th roots of unity, so $(\mu_n)_{\mathrm{Spec}\, U'} \cong (\mathbb{Z}/n\mathbb{Z})_{\mathrm{Spec}\, U'}$.

Example (7.4.2.18). For $n \in \mathbb{Z}_+$, $\mu_n \in \mathcal{S}\mathrm{h}_{\mathrm{const}}(\mathbb{Z}[\frac{1}{n}])$ but $\mu_n \notin \mathcal{S}\mathrm{h}_{\mathrm{lcc}}(\mathbb{Z}[\frac{1}{n}])$.

Proof: It is locally constant after the étale base change $\mathbb{Z}[\frac{1}{n}] \to \mathbb{Z}[\frac{1}{n}][\zeta_n]$. □

Prop. (7.4.2.19) [Properties of Constructible Sheaves].

- If $F \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$ and X has a finite decomposition into constructible reduced subschemes X_i that F/X_i are locally constant, then F is constructible. The converse is also true if X is qcqs.
- Constructibility is a local property.
- Constructibility is stable under pullback, pushout and finite direct limits.
- Constructibility is stable $j_!$ for j qc étale.
- Subsheaves of a constructible sheaf are constructible.

Proof: Cf.[Tamme P155]. [Conrad L3 P2], [Étale Cohomology and Weil Conjecture P42]**?** □

Prop. (7.4.2.20) [Lcc Sheaves and Finite Étale Schemes]. The functor $X \mapsto \mathrm{Hom}_S(-, X)$ defines an equivalence of categories

$$\mathcal{S}\mathrm{ch}^{\text{fét}}/S \cong \mathcal{S}\mathrm{h}_{\text{lcc}}(S_{\text{ét}}; \mathcal{S}\mathrm{et}).$$

Proof: The Yoneda functor is fully faithful, thus we need to show the essentially surjectivity. Notice first $\mathrm{Hom}_S(-, X)$ is locally constant finite: we can restrict to an open subset of S that the fiber are of fixed order n, and $X \to X \times_S X$ is étale and a closed immersion, thus $X \times_S X = X \coprod Y$, and Y is finite étale over X through π_1. Now by induction on the order of the fiber, $Y = X \otimes \Sigma'$ locally. So $X = S \times \Sigma$ locally, which means X represents the constant sheaf $\underline{\Sigma}$ locally.

To show that every locally constant finite étale sheaf is represented by a finite étale scheme, Cf.[Conrad Etale coh, P19]**?**. □

Prop. (7.4.2.21). If G is a commutative étale group scheme over X, then the sheaf G_X represented by G is constructible iff G is f.p. over X.

Proof: □

Prop. (7.4.2.22) [Locally Constancy and Specializations]. For $S \in \mathcal{N}\mathcal{S}\mathrm{ch}$ and $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\text{const}}(S_{\text{ét}})$, $\mathcal{F}$ is locally constant iff all the specialization maps for geometric points $\mathcal{F}_{\overline{s}} \to \mathcal{F}_{\overline{\eta}}$ are bijective.

Proof: If $\mathcal{F}$ is locally constant, because the conclusion is local, we may assume $\mathcal{F}$ is constant, then $\mathcal{F}_{\overline{s}} \to \mathcal{F}_{\eta}$ are all identities.

Conversely, for any geometric point s, $\Sigma = \mathcal{F}_s$ is finite by definition, thus there is an étale nbhd U of s that the map $\underline{\Sigma} \to \mathcal{F}$ induces an isomorphism on s-stalks, so this is an isomorphism for any geometric point linked to s by specialization, in particular the generic point of the irreducible component containing s and all the points in this irreducible component, thus $\mathcal{F}$ is constant on an open nbhd of s(because X is Noetherian thus has f.m. irreducible components), so $\mathcal{F}$ is locally constant because X is Noetherian. □

Prop. (7.4.2.23) [Constructible Sheaves are Noetherian]. $\mathcal{S}\mathrm{h}_{\text{const}}(X_{\text{ét}})$ are exactly the Noetherian objects in $\mathcal{S}\mathrm{h}_{\text{tor}}(X_{\text{ét}})$.

Proof: □

Frobenius Actions

Prop. (7.4.2.24) [Frobenius action on Étale Sheaves]. Let $k \in \mathtt{Field}^p, k \cong \mathbb{F}_{p^r}$ and $X \in \mathcal{S}\mathrm{ch}\,\mathrm{sep}, \mathrm{ft}/k, \mathcal{F} \in \mathcal{S}\mathrm{ch}(X_{\text{ét}})$, we have an isomorphism $\mathcal{F} \cong (\varphi_{r,X})_* \mathcal{F}$ which is the inverse of the isomorphisms

$$(\varphi_{r,X})_*(\mathcal{F})(U) = \mathcal{F}(\varphi_{r,X}^{-1}(U)) \xrightarrow{F_{U/X}^*} \mathcal{F}(U),$$

and its adjoint $\varphi_{r,X}^*\mathcal{F}\to\mathcal{F}$ is denoted by $\varphi_{\mathcal{F}}$.

Then $\varphi_{\mathcal{F}}$ commutes with tensor product and it is an isomorphism.

Proof: The adjoint is an isomorphism because φ induces equivalence of categories of étale site of $X_{\text{ét}}$ with itself by(5.1.4.22). □

Prop. (7.4.2.25) [Compatibility of φ_F wit Pullbacks]. Let $k\in\texttt{Field}^p, k\cong\mathbb{F}_{p^r}$ and $f:Y\to X\in\mathcal{S}\text{ch}\,\text{sep},\text{ft}/k$ be separated, $\mathcal{F}\in\mathcal{S}\text{ch}(X_{\text{ét}})$, then the morphism $\varphi_Y^*f^*\mathcal{F}\cong f^*\varphi_{r,X}^*\mathcal{F}\xrightarrow{f^*\varphi_{\mathcal{F}}}f^*\mathcal{F}$ is just $\varphi_{f^*\mathcal{F}}$.

Proof: Cf.[Fu11]P586. □

Prop. (7.4.2.26) [Compatibility of $\varphi_{\mathcal{F}}$ with Higher Direct Image]. Let $k\in\texttt{Field}^p, k\cong\mathbb{F}_{p^r}$ and $f:X\to Y\in\mathcal{S}\text{ch}\,\text{sep},\text{ft}/k$ be separated, $\mathcal{F}\in\mathcal{S}\text{ch}(X_{\text{ét}})$, so we have a Cartesian diagram about $\varphi_{r,X}$ and φ_Y. Then the composition

$$\varphi_S^*R^if_*\mathcal{F}\to R^if_*\varphi_{r,X}^*\mathcal{F}\xrightarrow{R^if_*(\varphi_{\mathcal{F}})}R^if_*\mathcal{F}$$

is just $\varphi_{R^if_*\mathcal{F}}$.

Proof: Cf.[Conrad L18 P4].? □

Cor. (7.4.2.27) [Compatibility of $\varphi_{\mathcal{F}}$ with Proper Pushforward]. If $X\to S$ is a separated morphism of f.t. between k-schemes and $\mathcal{F}$ is a torsion Abelian sheaf on $X_{\text{ét}}$, then the morphism

$$\varphi_{r,S}^*R^if_!\mathcal{F}\to R^if_!\varphi_{r,X}^*\mathcal{F}\xrightarrow{R^if_!(\varphi_{\mathcal{F}})}R^if_!\mathcal{F}$$

is just $\varphi_{R^if_!\mathcal{F}}$.

Proof: Choose a compactification, the $j_!$ doesn't matter, so we finish by(7.4.2.26). □

Def. (7.4.2.28) [Frobenius Action on Compact Cohomology]. Let $k\in\texttt{Field}^p, k\cong\mathbb{F}_{p^r}, X_0\in\mathcal{S}\text{ch}\,\text{sep},\text{ft}/k, \mathcal{F}_0\in\mathcal{S}\text{h}((X_0)_{\text{ét}}),\ X=X_0\times_k\overline{k},\ \mathcal{F}=\mathcal{F}_0\times_k\overline{k}$,

- As Fr_X is finite, by(7.4.5.4) it induces a pullback map $H^i_{\text{ét},c}(X,\mathcal{F})\to H^i_{\text{ét},c}(X,\text{Fr}_X^*\mathcal{F})$, which by composing with the natural isomorphism

$$\text{Fr}_{\mathcal{F}}:\text{Fr}_X^*\mathcal{F}=\text{Fr}^*(X\to X_0)^*\mathcal{F}_0=(X\to X_0)^*(\varphi_{r,X})^*\mathcal{F}_0\overset{\varphi_{\mathcal{F}_0}(7.4.2.24)}{\cong}(X\to X_0)^*\mathcal{F}_0=\mathcal{F}$$

  gives an endomorphism $\text{Fr}_{\mathcal{F}}^*:H^i_{\text{ét},c}(X,\mathcal{F})\to H^i_{\text{ét},c}(X,\mathcal{F})$, called the **geometric Frobenius action on the étale cohomology**.

- Similarly, there are natural isomorphisms

$$F_{\mathcal{F}}:F_X^*\mathcal{F}=F_X^*(X\to X_0)^*\mathcal{F}_0\cong((X\to X_0)\circ F_X)^*\mathcal{F}_0=\mathcal{F},$$

  so we can define the action F_X^* on $H^i_{\text{ét},c}(X,\mathcal{F})$, called the **arithmetic Frobenius action on the étale cohomology**.

- Similarly, the natural isomorphisms $\varphi_{\mathcal{F}}:\varphi_{r,X}^*\mathcal{F}\cong\mathcal{F}$(7.4.2.24) defines an action $\varphi_{r,X}^*$ on $H^i_{\text{ét},c}(X,\mathcal{F})$, called the **absolute Frobenius action on the étale cohomology**.

Lemma (7.4.2.29). Situation as in(7.4.2.28), $\mathrm{Fr}_X^*\mathcal{F} = \varphi_{r,X}^* F_X^*\mathcal{F} \cong \varphi_{r,X}^*\mathcal{F} \xrightarrow{\varphi_{\mathcal{F}}} \mathcal{F}$ is just $\mathrm{Fr}_{\mathcal{F}}$, by(5.2.10.2).

Prop. (7.4.2.30) [Frobenius Actions are Compatible]. Situation as in(7.4.2.28), $\varphi_{r,X}^* = \mathrm{id}$ on $H^i_{\text{ét},c}(X,\mathcal{F})$.

In particular, (7.4.2.29) shows $\mathrm{Fr}_X^* = \varphi_{r,X}^* \circ F_X^*$ on $H^i_{\text{ét},c}(X,\mathcal{G})$, so F_X^* agrees with Fr_X^* on $H^i_{\text{ét},c}(X,\mathcal{F})$, which is $\overline{k}$-linear. We can calculate with either one of them, and denote it by $F_X^*\cdot$, called the **Frobenius action on compact étale cohomologies**.

Proof: Choose an injective resolution $\mathcal{F} \to \mathcal{I}^\bullet$, it suffices to show that

$$\Gamma(X,\mathcal{I}^\bullet) \to \Gamma(X,\varphi_*\varphi^*\mathcal{I}^\bullet) \xrightarrow{\varphi_{\mathcal{F}}} \Gamma(X,\varphi_*\mathcal{I}^\bullet)$$

is the identity. But notice by definition $\mathcal{I}^\bullet \to \varphi_*\varphi^*\mathcal{I}^\bullet \xrightarrow{\varphi_{\mathcal{F}}} \varphi_*\mathcal{I}^\bullet$ is the inverse of the isomorphism in(7.4.2.24). □

3 Base Changes

Prop. (7.4.3.1) [Proper Base Change]. If there is a Cartesian diagram

$$\begin{array}{ccc} X' & \xrightarrow{g'} & Y' \\ \downarrow{f'} & & \downarrow{f} \\ X & \xrightarrow{g} & Y \end{array}$$

that f is proper, then for any torsion sheaf $\mathcal{F}$ on Y', the base change maps(5.3.3.18)

$$g^*R^qf_*\mathcal{F} \to R^qf'_*(g'^*\mathcal{F})$$

are isomorphisms.

Proof: Cf.[Conrad L6]. □

Prop. (7.4.3.2) [Smooth Base Change]. If there is a Cartesian diagram

$$\begin{array}{ccc} X' & \xrightarrow{g'} & Y' \\ \downarrow{f'} & & \downarrow{f} \\ X & \xrightarrow{g} & Y \end{array}$$

that f is smooth, then for any $\mathcal{K}^\bullet \in D^+(X,\mathbb{Z}/(n))$, the base change map(5.3.3.18)

$$f^*Rg_*\mathcal{K}^\bullet \to Rg'_*f'^*\mathcal{K}^\bullet$$

is an isomorphism.

Proof: Cf.[Lei Fu, P391]. □

4 Lower Shriek Functor

5 Cohomology with Compact Support

Cf.[Weil1, P18].

Lemma (7.4.5.1). Extension by 0 commutes with pullback Cf.[KF Lemma4.9].

Def. (7.4.5.2) [Higher Direct Images with Compact Support]. Let $Y \in \mathcal{S}\mathrm{ch}_{\mathrm{qcqs}}, f : X \to Y \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,ft}}/Y, \mathcal{F} \in \mathcal{S}\mathrm{h}(X_{\text{ét}})$, then f factors as $f : X \xhookrightarrow{j} \overline{X} \xrightarrow{\overline{f}} Y$ where $j : X \to \overline{X}$ is an open dense subscheme and $\overline{f}$ is proper, by Nagata compactification(5.8.3.2), then we define the **higher direct image with compact support** as

$$Rf_! = R\overline{f}_* j_! : D^+(X, \mathrm{tor}) \to D^+(Y, \mathrm{tor}).$$

Then this notion is well-defined.

And if $Y = \operatorname{Spec} k$, define $H^i_{\text{ét},c}(X, \mathcal{F}) = H^i(\operatorname{Spec} k, Rf_!\mathcal{F})$, called the **étale cohomology with compact support**.

Proof: To show it is well-defined, notice for any two compactification, we can find a common compactification that dominates them both**?**, so using lemma(7.4.5.3), we easily show they are isomorphic. □

Lemma (7.4.5.3) [$i_!$ and Higher Pushforward]. If there is a commutative diagram

$$\begin{array}{ccc} X & \xhookrightarrow{i} & \overline{X} \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle \overline{f}} \\ Y & \xhookrightarrow{j} & \overline{Y} \end{array}$$

where i, j are open immersion and $f, \overline{f}$ are proper, then there is a natural transformation $j_! f_* \to \overline{f}_* i_!$ that induces a natural transformation

$$j_! Rf_* \to R\overline{f}_* i_!,$$

which is an isomorphism iff $\overline{f}$ is proper.

Proof: If this is a Cartesian diagram, then the natural transformation is give by

$$j_! f_* \to \overline{f}_* \overline{f}^* j_! f_* \cong \overline{f}_* i_! f^* f_* \to \overline{f}_* i_!.$$

(the second isomorphism is by(7.4.5.1)). The rest is by proper base change Cf.[KF P88].

The general case is also easily reduced to the Cartesian case.**?** □

Prop. (7.4.5.4) [Proper Map Induces Map on Proper Pushforward]. If $g : Y \to X, f : X \to S$ is a proper morphism between schemes separated of f.t. over a Noetherian scheme S, then for any étale Abelian sheaf $\mathcal{F}$ on X, there is a canonical mop

$$g : Rf_!(\mathcal{F}) \to R(f \circ g)_!(\mathcal{F})$$

Proof: Choose a compactification $X_2 \xrightarrow{j} \overline{X}_2$, then choose a compactification $X_1 \xrightarrow{i} \overline{X}_1$ of $i \circ g$, now Cf.https://math.stackexchange.com/questions/3120833/proper-morphism-induces-a-map-between-co

?. □

Prop. (7.4.5.5) [Properties of Compact Pushforwards].

- (Base Change) If there is a Cartesian diagram

$$\begin{array}{ccc} X' & \xrightarrow{h} & X \\ \downarrow{f'} & & \downarrow{f} \\ S' & \xrightarrow{g} & S \end{array}$$

  that f is separated of f.t., then there is a natural isomorphism

$$g^*Rf_! \cong Rf'_!h^*$$

- (Composition) For two separated morphisms of f.t, $R(f_1\circ f_2)_! = R(f_1)_!R(f_2)_!$, which induces a Leray spectral sequence.
- (Excision) Let $f: X\to S$ be a separated morphism of f.t, and $\mathcal{F}\in D^+_{\text{tor}}(X)$. Let $Z\subset X$ be a closed subscheme and $U = X\backslash Z$, then there is a long exact sequence

$$\cdots\to R^p(f_U)_!(\mathcal{F}|_U)\to R^pf_!\mathcal{F}\to R^p(f_Z)_!(\mathcal{F}|_Z)\to R^{p+1}(f_U)_!(\mathcal{F}|_U)\to\cdots$$

Proof: 1: Choose a compactification of f, then it suffices to show Rf^c_* and $j_!$ both commutes with base change, which is by proper base change(7.4.3.1) and(7.4.5.1).

2: Two compactification can be splinted, and use(7.4.5.3).

3: Use the long exact sequence applied to the exact sequence(checked on stalks(7.4.1.17))

$$0\to j_!j^*F\to\mathcal{F}\to i_*i^*\mathcal{F}\to 0$$

□

Prop. (7.4.5.6) [Proper Pushforward to Direct Image]. There is a natural map from $R^if_!\to R^if_*$, which is induced by

$$R^if_! = R^i\overline{f}_*j_!\to R^i\overline{f}_*j_*\to R^if_*$$

where the second one is edge map of Leray spectral sequence.

In particular, there is a map $H^i_{\text{ét},c}(X,\mathcal{F})\to \mathrm{H}^i_{\text{ét}}(X,\mathcal{F})$.

Prop. (7.4.5.7) [Vanishing Result]. If $f: X\to S$ is separated of f.t. and let $d = \sup_{s\in S}\dim X_s$, then if $\mathcal{F}\in D(X,\text{tor})$ satisfies $H^p(\mathcal{F})[p] = 0$ for $p\geq r$, then

$$R^pf_!\mathcal{F} = 0,\quad p\geq r+2d.$$

Proof: Cf.[Conrad L10 P4]. □

Prop. (7.4.5.8) [Projection Formula]. If $X\to S$ is a quasi-projective morphism, $\mathcal{F}\in D^-(S)$ and $\mathcal{G}\in D(X)$, then we have a natural isomorphism

$$\mathcal{F}\otimes^L_S Rf_!\mathcal{G}\cong Rf_!(f^*\mathcal{F}\otimes^L_X\mathcal{G})$$

Proof: We may pass to the compactification, as $j_!$ commutes with f^***?**. □

6 Torsion Cohomology

Finiteness Theorems

Prop. (7.4.6.1). If $S \in \mathcal{S}\mathrm{ch}$ is Noetherian, $f : X \to S \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,ft}}/S$, and $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\mathrm{const}}(X_{\text{ét}})$ whose torsion order is invertible in S, then $R^p f_! \mathcal{F}$ are all constructible on Y.

Proof: Cf.[Conrad L10 P5]. □

Cor. (7.4.6.2). If X is a proper scheme over a separably closed field k and $\mathcal{F}$ is a constructible sheaf on $X_{\text{ét}}$, then $\mathrm{H}^p_{\text{ét}}(X, \mathcal{F})$ are finite for all $p \geq 0$.

Proof: □

Lemma (7.4.6.3). If $X \to S$ is smooth and proper, and F is a locally constant finite Abelian sheaf with torsion order invertible on S, suppose S is Noetherian, then all specialization maps for $R^p f_* \mathcal{F}$ are isomorphisms.

Proof: Cf.[Conrad L10 P5]. □

Prop. (7.4.6.4) [Proper Smooth Higher Direct Image of Lcc Sheaves]. If $X \to S$ is smooth and proper, and F is a lcc Abelian sheaf(7.4.2.15) with torsion order invertible on S, then $R^p f_* \mathcal{F}$ are locally constant finite sheaves for any $p \geq 0$.

Proof: By(7.4.2.20), we may assume $\mathcal{F} = \underline{X'}$ for some finite étale scheme $X' \to X$. By Noetherian descent? together with proper base change, we may reduce to the case S is Noetherian. Thus by(7.4.6.1), $R^p f_* \mathcal{F} = R^p f_! \mathcal{F}$ are constructible, and(7.4.6.3) shows that the stalk maps are isomorphisms. So(7.4.2.22) shows that $R^p f_* \mathcal{F}$ are locally constant finite. □

7 ℓ-adic Étale Cohomologies

Notation (7.4.7.1).

- Fix a CDVR $(\Lambda, \mathfrak{m}, K, \kappa)$ of mixed characteristic $(0, p)$ and suppose $\#\kappa < \infty$.
- Fix $S \in \mathcal{S}\mathrm{ch}$.
- Let $\Lambda_n = \Lambda/\mathfrak{m}^n$.

Artin-Rees Formalism

Def. (7.4.7.2). The **pre Artin-Rees category** of A-modules has objects $M_\bullet = (M_n)_{n \in \mathbb{Z}}$ which are projective systems of A-modules with $M_n = 0$ for $n << 0$, and the morphisms in this category are the elements of the set

$$\mathrm{Hom}_{\text{A-R}}(M_\bullet, N_\bullet) = \varinjlim \mathrm{Hom}(M_\bullet[d], N_\bullet)$$

An object $M^\bullet$ in the Artin-Rees category is called a **null system** if for some ≥ 0 the map $M_{n+} \to M_n$ vanishes for all n.

Prop. (7.4.7.3) [Artin-Rees Category]. The pre Artin-Rees category is an Abelian category, and the null systems form a Weak Serre subcategory. Then we define the **Arin-Rees category** as the quotient category.

Proof: □

Prop. (7.4.7.4). If the kernel and cokernel of two systems are all null systems, then they induce isomorphism on inverse limit.

Proof: Cf.[Conrad L15, P5]. □

Def. (7.4.7.5). An object $M^\bullet$ in the A-R category is called **Artin-Rees I-adic** if it is represented by a system M_n that $M_n = 0$ for $n < 0$ and M_n is finite over A_n, $M_{n+1} \otimes_{A_{n+1}} A_n \to M_n$ is an isomorphism for $n \geq 0$.

Prop. (7.4.7.6). The full subcategory of Artin-Rees I-adic modules is an Abelian category, and it is equivalent to the category of finite A-modules by the stalk functor.

Prop. (7.4.7.7). The category $\mathcal{S}\mathrm{h}_{\Lambda\text{-lcc}}(S_{\text{ét}})$ is equivalent to the full subcategory of $\mathcal{S}\mathrm{h}_{\mathfrak{m}}(S_{\text{ét}})$ consisting of objects with Artin-Rees property and that the terminal stable image is constructible.

Proof: □

Def. (7.4.7.8) [Strictly $\mathfrak{m}$-adic Sheaves]. The category $\mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-strict}}(S_{\text{ét}})$ of **strict $\mathfrak{m}$-adic sheaves** are defined as before.

Prop. (7.4.7.9). We can strictify any $\mathfrak{m}$-adic sheaf, Cf.[Conrad, Etale Coh].

Constructible and Lisse $\mathfrak{m}$-adic Sheaves

Def. (7.4.7.10) [Lisse Adic Sheaves]. For $S \in \mathcal{S}\mathrm{ch}$, $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\mathfrak{m}}(S)$ is called **constructible $\mathfrak{m}$-adic sheaf** if it is isomorphic to a strict system $\{\mathcal{F}_n\}$ that $\mathcal{F}_n \in \mathcal{S}\mathrm{h}_{\Lambda_n\text{-const}}(S_{\text{ét}})$. The subcategory of constructible $\mathfrak{m}$-adic sheaves is denoted by $\mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-const}}(S)$.

$\mathcal{F} \in \mathcal{S}\mathrm{h}_{\mathfrak{m}}(S)$ is called a **lisse $\mathfrak{m}$-adic sheaf** if it is isomorphic to a strict system $\{\mathcal{F}_n\}$ s.t. $\mathcal{F}_n \in \mathcal{S}\mathrm{h}_{\Lambda_n\text{-lcc}}(S_{\text{ét}})$.

Def. (7.4.7.11) [Tate Twist Sheaves]. The **Tate twist sheaf** $\Lambda(1)$ is defined to be. It is invertible, thus we denote its dual by $\Lambda(-1)$. Then $\Lambda(r) \in \mathcal{S}\mathrm{h}_{\Lambda\text{-lcc}}(X_{\text{ét}})$ if p is invertible on X.

For any $\mathfrak{m}$-adic sheaf $\mathcal{F}$, denote $\mathcal{F}(1)$ to be the sheaf $\mathcal{F} \otimes \Lambda(1)$. Also denote $\Lambda(r) = \Lambda(1)^{\otimes r}$.

Def. (7.4.7.12) [Stalk Maps]. Let $s \to S$ be a arithmetic point, then there is a **stalk map**

$$\mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-const}}(S) \to \mathcal{M}\mathrm{od}_\Lambda^{\mathrm{fin}} : \mathcal{F}_\bullet \mapsto \varprojlim_n (\mathcal{F}_n)_s.$$

It is well-defined by [Conrad, Etale Coh]P72.

Prop. (7.4.7.13). Constructibility/lisse are étale-local and stratification-local properties for $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\mathfrak{m}}(S_{\text{ét}})$.

Proof: Cf.[Conrad, Etale Coh]P71. □

Prop. (7.4.7.14). The full subcategory $\mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-lcc}}(S_{\text{ét}}) \subset \mathcal{S}\mathrm{h}_{\mathfrak{m}}(S_{\text{ét}})$ is stable under taking kernels and cokernels.

Prop. (7.4.7.15) [Constructible and Lisse $\mathfrak{m}$-adic Sheaves]. Let $S \in \mathrm{N}\mathcal{S}\mathrm{ch}$ and $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-const}}(S_{\text{ét}})$, then there is a stratification of X that $\mathcal{F}$ is locally constant finite on each stratum.

Proof: Cf.[Conrad, Etale Coh]P73**?**.

By the stalk criterion of locally constant finite(7.4.2.22), a constructible extension of locally constant finite sheaves is also locally constant finite. So by the exact sequence $1 \to \ell^{n-1}\mathcal{F}_n \to \mathcal{F}_n \to \mathcal{F}_{n-1} \to 1$, iff we show there is a stratification that all $\ell^{n-1}\mathcal{F}_n$ are locally constant finite, then by induction all $\mathcal{F}_n$ are locally constant finite. But then $\ell^{n-1}\mathcal{F}_n$ is a descending chain of quotients of $\mathcal{F}_1$, thus the kernel is ascending thus stablizes because $\mathcal{F}_1$ is constructible(7.4.2.23), so there are only f.m. such $l^n\mathcal{F}_n$, so there is a common stratification. □

Cor. (7.4.7.16). Exactness/Isomorphism between constructible sheaves can be checked at stalks.

Def. (7.4.7.17) [Constructible K-Sheaves]. The category $\mathcal{S}\mathrm{h}_{K\text{-const}}(X_{\text{ét}})$ of **constructible K-sheaves** has the same object as $\mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-const}}(X_{\text{ét}})$ but with the homomorphism groups

$$\mathrm{Hom}_{\mathcal{S}\mathrm{h}_{K\text{-const}}(S_{\text{ét}})}(\mathcal{F},\mathcal{G}) = \mathrm{Hom}_{\mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-const}}(S_{\text{ét}})}(\mathcal{F},\mathcal{G}) \otimes_\Lambda K.$$

And there is a natural functor

$$K \otimes - : \mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-const}}(X_{\text{ét}}) \to \mathcal{S}\mathrm{h}_{K\text{-const}}(X_{\text{ét}}).$$

Then a **lisse K-sheaf** is the image of a lisse $\mathfrak{m}$-adic sheaf.

Def. (7.4.7.18) [Tate Twist Sheaves]. Denote $K(r) = \Lambda(r) \otimes_\Lambda K$, also called the **Tate twist sheaf**.

Prop. (7.4.7.19) [Lisse K-Sheaves and $\pi_1(S,\overline{x})$-Representations]. Assume S is connected, then for an arithmetic point $\overline{s}$ of S, the stalk map $\mathcal{F} \to \mathcal{F}_{\overline{x}}$ induces equivalences:

$$\mathcal{S}\mathrm{h}_{\Lambda\text{-const}}(X_{\text{ét}}) \cong \mathrm{Rep}_\Lambda(\pi_1(S,\overline{s})), \quad \mathcal{S}\mathrm{h}_{K\text{-const}}(X_{\text{ét}}) \cong \mathrm{Rep}_K^{\mathrm{fd}}(\pi_1(S,\overline{s})).$$

Proof: The point is that by(15.3.1.3), any representation of $\pi_1(S,\overline{s})$ stabilizes some Λ-lattice. So by the equivalence(7.3.2.5)(7.4.2.20) and taking limit using(7.4.7.6), we get the result about $\mathcal{O}_E$-sheaves and representations of $\pi_1(X_0,\overline{s})$ over $\mathcal{O}_E$. □

Prop. (7.4.7.20) [Lisse and Specializations]. For $S \in \mathcal{N}\mathcal{S}\mathrm{ch}$ and $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-const}}(S_{\text{ét}})$, then $\mathcal{F}$ is lisse iff all the specialization maps for geometric points $\mathcal{F}_{\overline{s}} \to \mathcal{F}_{\overline{\eta}}$ are bijective.

And if S is moreover normal, then the same holds for $\mathcal{F} \in \mathcal{S}\mathrm{h}_{K\text{-const}}(S_{\text{ét}})$.

Proof: We can assume $\mathcal{F}$ is strictly $\mathfrak{m}$-adic(7.4.7.10) and then use(7.4.2.22) on each $\mathcal{F}_n$.

For the second assertion, Cf.[Conrad, Etale Coh]P77. □

Cor. (7.4.7.21) [Étale Descent for Lisse K-Sheaves]. If S is Noetherian and normal, then étale descent holds for lisse K-sheaves.

Proof: **?** □

Prop. (7.4.7.22). Constructible $\mathfrak{m}$-adic sheaves are Noetherian: Ascending chain of subsheaves stablizes.

Proof: Cf.[Conrad L16 P3]. □

Prop. (7.4.7.23). For any $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\mathfrak{m}\text{-const}}(S_{\text{ét}})$, there exists some $\mathcal{G} \in \mathcal{S}\mathrm{h}_{\Lambda\text{-const}}(S_{\text{ét}})$ s.t. $\mathcal{G} \subset \mathcal{F}$ and $\mathcal{F}/\mathcal{G}$ has Λ-flat stalks.

In particular, any $\mathcal{F} \in \mathcal{S}\mathrm{h}_{K\text{-const}}(S_{\text{ét}})$ is K-isomorphic to some $K \otimes \mathcal{F}'$ where $\mathcal{F}'$ has Λ-flat stalks.

Proof: Cf.[Conrad Etale Coh]P75.**?** □

Def. (7.4.7.24) [Extensions]. Let Λ'/Λ be an extension, then we can define extension functors

$$\Lambda' \otimes_\Lambda - : \mathcal{S}\mathrm{h}_{\Lambda\text{-const}}(X_{\text{ét}}) \to \mathcal{S}\mathrm{h}_{\Lambda'\text{-const}}(X_{\text{ét}}), \quad K' \otimes_K - : \mathcal{S}\mathrm{h}_{K\text{-const}}(X_{\text{ét}}) \to \mathcal{S}\mathrm{h}_{K'\text{-const}}(X_{\text{ét}}).$$

?

$\mathfrak{m}$-adic Cohomologies

Prop. (7.4.7.25) [Direct Pushforward of $\mathfrak{m}$-adic Sheaves]. For a constructible $\mathfrak{m}$-adic sheaf $\mathcal{F}$ and a compatifiable morphism $X_0 \to S_0$, we can define $R^i f_*$ and $R^i f_!$ termwisely, and we have $R^i f_* \mathcal{F}$ is a constructible sheaf, hence so is $R^i f_!$.

Proof: Cf.[Weil Conjecture and Étale sheaves, P128]. □

Constructible and Lisse $\overline{\mathbb{Q}}_\ell$-Sheaves

Def. (7.4.7.26) [E-Sheaves]. The category $\mathcal{S}\mathrm{h}_{\overline{\mathbb{Q}}_\ell\text{-const}}(X_{\text{ét}})$ of **constructible $\overline{\mathbb{Q}}_\ell$-sheaves** are the direct limit of categories of $\mathcal{S}\mathrm{h}_{E\text{-const}}(X_{\text{ét}})$ for $E \in p$-`NField`.

The category $\mathcal{S}\mathrm{h}_{\overline{\mathbb{Q}}_\ell\text{-lcc}}(X_{\text{ét}})$ of **lisse $\overline{\mathbb{Q}}_\ell$-sheaves** are the direct limit of categories of $\mathcal{S}\mathrm{h}_{E\text{-lcc}}(X_{\text{ét}})$ for $E \in p$-`NField`.

Prop. (7.4.7.27) [Lisse $\overline{\mathbb{Q}}_\ell$-Sheaves and $\pi_1(S, \overline{x})$-Representations]. Assume S is connected, then for an arithmetic point $\overline{s}$ of S, the stalk map $\mathcal{F} \to \mathcal{F}_{\overline{x}}$ induces equivalences:

$$\mathcal{S}\mathrm{h}_{\overline{\mathbb{Q}}_\ell\text{-const}}(X_{\text{ét}}) \cong \mathrm{Rep}_\Lambda(\pi_1(S, \overline{s})), \quad \mathcal{S}\mathrm{h}_{\Lambda\text{-const}}(X_{\text{ét}}) \cong \mathrm{Rep}^{\mathrm{fd}}_{\overline{\mathbb{Q}}_\ell}(\pi_1(S, \overline{s}))$$

Proof: This follows from(7.4.7.19) and(15.3.1.3) by taking direct limit. □

Cor. (7.4.7.28) [Irreducible/Semisimple Lisse Sheaves]. $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\overline{\mathbb{Q}}_\ell-\mathrm{lcc}}(S_{\text{ét}})$ is called an **irreducible/semisimple lisse sheaf** if its corresponding representation(7.4.7.27) is. It is called **geometrically irreducible/semisimple** if $\mathcal{F}_{k^s} \in \mathcal{S}\mathrm{h}_{\overline{\mathbb{Q}}_\ell\text{-lcc}}((S_{k^s})_{\text{ét}})$ is irreducible/semisimple, or equivalently, its corresponding representation is irreducible/semisimple as a $\pi_1(S_{k^s}, \overline{x})$-representation.

Def. (7.4.7.29) [p-adic étale Cohomologies]. For $X \in \mathcal{S}\mathrm{ch}$, $p \in \mathbf{P}$, define

$$\mathrm{H}^i_{\text{ét}}(X, \mathbb{Q}_p) = (\varprojlim_n H^i(X, \mathbb{Z}/(p^n)))[\frac{1}{p}].$$

Analytification

Comparison Theorems

Thm. (7.4.7.30) [Topological Comparison, Artin]. Let $f : X \to S \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}}/\mathbb{C}$ be separable of f.t., then

- If $\mathcal{F} \in \mathcal{S}\mathrm{ch}_{\mathrm{tor}}(S_{\text{ét}})$, then the comparison morphism for $R^\bullet f_!$ is an isomorphism.
- If $\mathcal{C} \in \mathcal{S}\mathrm{ch}_{\mathrm{const}}(S_{\text{ét}})$, then the comparison morphism for $R^\bullet f_*$ is an isomorphism.

Proof: [Conrad, Etale Coh]? □

Cor. (7.4.7.31) [Comparison with Betti Cohomology]. For $X \in \mathcal{S}\mathrm{ch}^{\mathrm{ft,sep}}/\mathbb{C}$, $A \in \mathcal{A}\mathrm{b}^{\mathrm{fin}}$, there is a canonical isomorphism

$$\mathrm{H}^q_{\text{ét}}(X, \underline{A}_X) \cong H^q_{\mathrm{Betti}}(X; A).$$

Cor. (7.4.7.32). Let $F \in$ `NField`, $p \in \mathbf{P}$ and $v \in \Sigma^p_F$. For $\mathcal{X} \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{rpr}/\mathcal{O}_{F_v}$, let $X = \mathcal{X}_{\kappa(v)}$ and $\overline{X} = X_{\overline{\kappa(v)}}$, then for $\ell \neq p$, then

$$\mathrm{H}^i_{\text{ét}}(\overline{X}; \mathbb{Q}_\ell) \cong H^i(\mathcal{X}_{\overline{\eta}}; \mathbb{Q}_\ell) \cong H^i_{\mathrm{Betti}}(\mathcal{X}_\mathbb{C})_{\mathbb{Q}_\ell}.$$

Proof: Let $\operatorname{Spec}\mathcal{O}_{F_v} = \{s, \eta\}$, where s is the special point and η the generic point. Let $\overline{\eta}, \overline{s}$ be arithmetic points mapping to η, s resp. By proper base change(7.4.3.1), The stalk of higher direct image of $X \to \mathcal{O}_{F_v}$ along $\overline{s}, \overline{\eta}$ are $\mathrm{H}^i_{\text{ét}}(\overline{X}, \mathbb{Q}_\ell)$ and $H^i(\mathcal{X}_{\overline{\eta}}, \mathbb{Q}_\ell)$ resp., and they are the same by(7.4.6.4). And $H^i(\mathcal{X}_{\overline{\eta}}, \mathbb{Q}_\ell) \cong H^i_{\text{Betti}}(X, \mathbb{Q}_\ell)$ by(7.4.7.31) and the fact $\overline{\mathbb{Q}}_\ell$ is isomorphic to $\mathbb{C}$. □

Cor. (7.4.7.33) [Good Reduction implies Unramifiedness]. If $K \in p\text{-}\mathtt{LField}$ and X is a scheme over K with good reduction, then $\mathrm{H}^i_{\text{ét}}(X, G)$ is an unramified representation of Gal_K.

Prop. (7.4.7.34) [Étale and Fppf Comparison]. Let $X \in \mathcal{S}\mathrm{ch}$ and G a smooth commutative group scheme over X, then there are natural isomorphisms

$$\mathrm{H}^*_{\text{ét}}(X; G) \cong H^*_{\text{fppf}}(X; G).$$

Proof: Cf.[Mil80Etale Cohomologies, Prop. III.3]. □

$\mathbf{A}^f$-Cohomologies

Def. (7.4.7.35) [$\mathbf{A}^f$-Cohomologies]. For $X \in \mathcal{S}\mathrm{ch}$, define

$$\mathrm{H}^n_{\text{ét}}(X; \mathbf{A}^f) = (\varprojlim_m \mathrm{H}^n_{\text{ét}}(X, \mathbb{Z}/(m))) \otimes \mathbb{Q}.$$

Then if X is a smooth complete variety over $\mathbb{C}$, then by(7.4.7.31), there is a canonical isomorphism

$$H^n_{\text{Betti}}(X) \otimes \mathbf{A}^f \cong H^n_{\mathbf{A}^f}(X).$$

Thus $H^n_{\text{Betti}}(X) \otimes \mathbf{A}^f$ is intrinsic in X and $H^n_{\mathbf{A}^f}(X)$ free over $\mathbf{A}^f$.

Conjectures

Conj. (7.4.7.36) [Grothenfieck-Serre]. For $F \in \mathtt{NField}$ and $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{rpr}/F$, the representation $\mathrm{H}^i_{\text{ét}}(X, \mathbb{Q}_p)$ of Gal_F is semistable.

Conj. (7.4.7.37) [Semisimplicity of Frobenius]. For X

8 Curves

Prop. (7.4.8.1). If $k \in \mathtt{Field}, k = k^s, X \in \mathcal{S}\mathrm{ch}^{\text{sep,ft,dim=1}}/k$, and $\mathcal{F} \in \mathcal{S}\mathrm{h}^{\text{tor}}(X_{\text{ét}})$, then $\mathrm{H}^i_{\text{ét}}(X, \mathcal{F}) = 0$ for $i > 2$, and if $\mathcal{F}$ is constructible, then $\mathrm{H}^i_{\text{ét}}(X, \mathcal{F})$ are finite.

Moreover if X is affine and $\mathcal{F}$ is locally killed by n not divisible by $\operatorname{char} k$ or X is proper and sections of $\mathcal{F}$ are locally p-torsions with $p = \operatorname{char} k > 0$, then $H^2_{\text{ét}}(X, \mathcal{F}) = 0$.

Proof: Cf.[Conrad L4 P4] and [Tamme]. □

Lemma (7.4.8.2) [Smooth Complete Curves]. If $k \in \mathtt{Field}, k = k^s$, X is a smooth complete curve of genus g and $n \in \mathbb{Z} \cap k^*$, then there are canonical identifications

$$\mathrm{H}^q_{\text{ét}}(X, \mu_n) = \begin{cases} \mu_n(k) & , q = 0 \\ \mathrm{Pic}^0(X)[n] & , q = 1 \\ \mathbb{Z}/n\mathbb{Z} & , q = 2 \\ 0 & , q \geq 3 \end{cases}, \quad \#\mathrm{H}^q_{\text{ét}}(X, \mu_n) = \begin{cases} n & , q = 0 \\ n^{2g} & , q = 1 \\ n & , q = 2 \\ 0 & , q \geq 3 \end{cases}$$

In particular, because $\underline{\mathbb{Z}/(n)} \cong \mu_n$, we can get the corresponding cohomologies.

Proof: Cf.[Sta]03RQ. □

Prop. (7.4.8.3) [Torsion-Freeness]. Let $k \in \texttt{Field}$, $L \in \ell\text{-}\texttt{NField}$, X a smooth curve over k, then $H^i_{\text{ét},c}(X, \mathcal{O}_L)$ are torsion-free.

Proof: Cf. [SGA4$\frac{1}{2}$, Chap3.3].**?** □

Prop. (7.4.8.4) [Curve and Jacobians]. For a smooth complete curve C, its first ℓ-adic étale cohomology group equals that of its Jacobian variety.

Proof: □

Prop. (7.4.8.5) [Non-Complete Curves]. If $k \in \texttt{Field}, k = k^s, \ell \in \mathbf{P} \backslash \operatorname{char} k$, then

$$H^i_{\text{ét},c}(\mathbb{A}^1_k, \mathbb{Q}_\ell) = \begin{cases} \mathbb{Q}_\ell & , i = 2 \\ 0 & , \text{otherwise} \end{cases}, \quad H^i_{\text{ét},c}(\mathbb{A}^1_k \backslash \{0\}, \mathbb{Q}_\ell) = \begin{cases} \mathbb{Q}_\ell & , i = 1, 2 \\ 0 & , \text{otherwise} \end{cases}$$

Proof: These follow from(7.4.8.2) by excision and(7.4.2.12). □

Weil Axioms

Prop. (7.4.8.6) [Compact ℓ-adic Étale Cohomologies]. Let $k \in \texttt{Field}, k = k^s, X \in \mathcal{S}\text{ch}^{\text{sep,ft,dim}=d}/k$, $\Lambda \in \mathcal{A}\text{b}^{\text{tor}}$ with torsion orders prime to $\operatorname{char} k$, then

1. $H^i_{\text{ét},c}(X, \underline{\Lambda})$ are finite Λ-modules.
2. $H^i_{\text{ét},c}(X, \underline{\Lambda}) = 0$ if $i < 0$ or $i > 2d$. And if X is affine, then $H^i_{\text{ét},c}(X, \underline{\Lambda}) = 0$ if $i < 0$ or $i > d$.
3. There is a natural isomorphism $H^{2d}_{\text{ét},c}(X, \underline{\Lambda}) \cong \Lambda[S]$, where S is the set of irreducible components of X of dimension d.
4. there is a long exact sequence
$$\cdots \to H^p_{\text{ét},c}(U, \underline{\Lambda}) \to H^p_{\text{ét},c}(X, \underline{\Lambda}) \to H^p_{\text{ét},c}(Z, \underline{\Lambda}) \to H^{p+1}_{\text{ét},c}(U, \underline{\Lambda}) \to \cdots$$
5. $H^i_{\text{ét},c}(\mathbb{A}^d_k, \underline{\Lambda}) = \begin{cases} \Lambda & i = 2d \\ 0 & \text{otherwise} \end{cases}$.
6. If G is a connected algebraic scheme over k acting regularly on X, then $G(k)$ acts trivially on $H^i_{\text{ét},c}(X, \underline{\Lambda})$.

Proof: 1 follows from(7.4.6.1). 4 follows from excision(7.4.5.5).
2 follows from(7.4.2.11) and(7.4.2.12).
3: By item2 and item4, it suffices to show for X irreducible.**?**
5: This follows from Künneth formula(7.4.8.9) and(7.4.8.5).
6: Cf.[Deligne-Lustig]Prop6.4**?**. □

Def. (7.4.8.7) [Cup Product].

Cor. (7.4.8.8) [Homotopy Axiom]. Two maps $\varphi, \varphi' : X \to Y \in \mathcal{S}\text{ch}$ induce the same map on the ℓ-adic cohomology if their graphs are rationally equivalent.

Proof: This is because the maps on cohomology depends only on the rational equivalence classes of the graph.**?** □

Prop. (7.4.8.9) [Künneth Formula]. Let X, Y be complete varieties over k, then there is a natural isomorphism
$$\mathrm{H}^*_{\text{ét}}(X, \mathbb{Q}_\ell) \otimes \mathrm{H}^*_{\text{ét}}(Y, \mathbb{Q}_\ell) \cong \mathrm{H}^*_{\text{ét}}(X \times Y, \mathbb{Q}_\ell).$$

Proof: ? □

Lemma (7.4.8.10) [Torsion Poincaré Duality].

Prop. (7.4.8.11) [Poincaré Duality]. If $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k, d = \dim X$, $\mathcal{F}$ is a lisse sheaf on X, then there is a natural isomorphism $H^{2d}_{\text{ét},c}(X_{k^s}, \mathbb{Q}_\ell(d)) \xrightarrow{\mathrm{tr}_X} \mathbb{Q}_\ell$ and a perfect pairing
$$\mathrm{H}^n_{\text{ét}}(X_{k^s}, \mathcal{F}) \times H^{2d-n}_{\text{ét},c}(X_{k^s}, \mathcal{F}^\vee(d)) \xrightarrow{\cup} H^{2d}_{\text{ét},c}(X_{k^s}, \mathbb{Q}_\ell(d)) \xrightarrow{\mathrm{tr}_X} \mathbb{Q}_\ell$$
compatible with action of Gal_k.

Proof: Cf.[Conrad L12-13], [Weil 2Bhatt P5].?. □

Def. (7.4.8.12) [Cycle Maps]. For $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{rpr}/k$, there exists a **cycle map**
$$\mathrm{cyl}_\ell : \mathrm{CH}^j(X) \to \mathrm{H}^{2j}_{\text{ét}}(X_{k^s}, \mathbb{Q}_\ell)(j)$$
s.t.
$$x \cdot y = \mathrm{tr}_X(\mathrm{cyl}_\ell(x) \cup \mathrm{cyl}_\ell(y)).$$

Proof: □

Trace Formulae

Def. (7.4.8.13) [Lefschetz Numbers]. Let $k \in \mathtt{Field}, k = k^s$, $X \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,ft}}/k$, $\mathcal{F}$ a constructible $\mathbb{Q}_\ell$-sheaf on X, then for any $g \in \mathrm{Aut}(X)$, define the **alternating cohomology group**
$$H_{\text{ét},c}(X, \mathcal{F}) = \sum_{i \geq 0} (-1)^i H^i_{\text{ét},c}(X, \mathcal{F}).$$
and the **Lefschetz number** to be
$$\mathrm{tr}(g, X, \mathcal{F}) = \mathrm{tr}(g | H_{\text{ét},c}(X, \mathcal{F})) = \sum_{i \geq 0} (-1)^i \,\mathrm{tr}(g | H^i_{\text{ét},c}(X, \mathcal{F})).$$

Prop. (7.4.8.14). Let $k \in \mathtt{Field}, k = k^s$, $X, C' \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,ft}}/k, g, h \in \mathrm{Aut}(X), g' \in \mathrm{Aut}(X')$, then

1. $\mathrm{tr}(g, X, \cdot)$ is additive.
2. If $Z \subset X$ is a closed subscheme and $U = X \backslash Z$, then $\mathrm{tr}(g, X, \mathcal{F}) = \mathrm{tr}(g, U, \mathcal{F}) + \mathrm{tr}(g, Z, \mathcal{F})$.
3. $\mathrm{tr}(g \times g, X \times X', \mathcal{F} \times \mathcal{F}') = \mathrm{tr}(g, X, \mathcal{F})\,\mathrm{tr}(g', X', \mathcal{F}')$.
4. If g, h commute, then $\mathrm{tr}(gh, X, \mathcal{F}) = \mathrm{tr}(g, X^h, \mathcal{F})$.
5. If T is a tori acting on X, then $\mathrm{tr}(g, X, \mathcal{F}) = \mathrm{tr}(g, X^S, \mathcal{F})$.

Proof: $1, 2, 3$ follow from(7.4.8.6).
$4, 5$: [Deligne-Lustig, Thm3.2] and [Digne and Michel, Prop10.15].? □

Prop. (7.4.8.15). Cf.[Representations of Finite Groups of Lie type, Digne and Michel].

Cor. (7.4.8.16). The Lefschetz number is independent of ℓ.

7.5 Pro-Étale Cohomology

Main references are [B-S14] and [Sta]Chap56.

1 Introduction

In his second paper on the Weil conjectures ([Del80]), Deligne introduced a derived category of l-adic sheaves as a certain 2-limit of categories of complexes of sheaves of $\mathbb{Z}/l^n\mathbb{Z}$-modules on the étalesite of a scheme X. This approach is used in the paper by Beilinson, Bernstein, and Deligne ([BBD82]) as the basis for their beautiful theory of perverse sheaves. In a paper entitled "Continuous ÉtaleCohomology"([Jan88]) Uwe Jannsen discusses an important variant of the cohomology of a l-adic sheaf on a variety over a field. His paper is followed up by a paper of Torsten Ekedahl ([Eke90]) who discusses the adic formalism needed to work comfortably with derived categories defined as limits.

2 Ring-Theoretical Stuff

Def. (7.5.2.1) [étaleLocal Isomorphism]. A ring map $A\to B$ is called a **local isomorphism** if for every prime $\mathfrak{q}\in\operatorname{Spec}B$, there is a nbhd $\operatorname{Spec}B_g$ that $\operatorname{Spec}B_g\to\operatorname{Spec}A$ is an open immersion.

Prop. (7.5.2.2). The class of local isomorphisms is stable under base change and compositions. (This follows from(5.4.4.60)).

Moreover, if $A\to B\to C$ are ring maps that $A\to B, A\to C$ are both local isomorphisms, then $B\to C$ is also a local isomorphism.

Def. (7.5.2.3) [w-Local Rings]. A ring A is called **w-local** if $\operatorname{Spec}A$ is w-local(3.11.4.17). it is called **strictly w-local** if it is w-local and every f.f. étale map $A\to B$ has a section. A map of rings is called **w-local** if it induces a w-local map(3.11.4.17) on the Spec.

Prop. (7.5.2.4). A w-local ring A is strictly w-local iff all local rings of A at closed pts are strictly Henselian.

Proof: Cf.[Pro-Etale Cohomology, Scholze, P10]. □

<u>**Ind-Zariski Algebra**</u>

Def. (7.5.2.5) [Ind-Zariski Algebra]. A ring map $A\to B$ is called **ind-Zariski/smooth/étale** if B is a filtered colimit of local isomorphisms/smooth ring maps/étale ring maps $A\to B_i$.

Prop. (7.5.2.6) [Properties of Ind-Zariski Algebras]. Ind-Zariski ring maps are stable under base change and composition, by(7.5.2.2).?

If $A\to B\to C$ are ring maps that $A\to B, A\to C$ are both ind-Zariski, then $B\to C$ is also ind-Zariski.

$A\to B$ be ind-Zariski, then it identifies local rings.

Proof: □

Def. (7.5.2.7) [Ind-(Zariski Localization)]. A ring map $A\to B$ is called a **Zariski localization** if $B=\prod_i^n A_{f_i}$. An **ind-(Zariski localization)** of A is a colimit of Zariski localizations of A.

7.6 Crystalline Cohomology

Main references are [Sta]and [Berthelot-Ogus, Notes on Crystalline Cohomology. Princeton University Press, 1978.]

1 PD-Schemes

Def. (7.6.1.1)[PD-Schemes]. A **pd-scheme** is a triple $(S, \mathcal{I}, \gamma)$ where S is a scheme, $\mathcal{I}$ is a Qco sheaf of ideals, and γ is a pd-structure on $\mathcal{I}$(4.6.0.1). A morphism of pd-schemes is a morphism that all the structure morphisms are morphisms of pd-structures.

Def. (7.6.1.2)[PD-Thickening]. A **pd-thickening** is a (U, T, δ) where T is a thickening of U(5.8.9.1) with sheaf of ideals $\mathcal{I}$(i.e. $U = \mathbf{Spec}(\mathcal{I})$) that $(T, \mathcal{I}, \delta)$ is a pd-structure.

Prop. (7.6.1.3). The fibered product of two morphisms in the category of pd-schemes exists if one of them is a pd-thickening.

Proof: Cf.[Sta]07ME. □

2 Crystalline Site

Def. (7.6.2.1)[Coverings]. A family of morphisms $\{(U_i, T_i, \delta_i) \to (U, T, \delta)\}$ of pd-thickenings is called a Zariski/smooth/étale/syntomic/fppf... iff

- $U_i = U \otimes_T T_i$,
- $\{T_i \to T\}$ is a Zariski/smooth/étale/syntomic/fppf... covering of T.

Def. (7.6.2.2)[Crystalline Sites]. Let p be a prime and $(S, \mathcal{I}, \gamma)$ be a pd-scheme over $\mathbb{Z}_{(p)}$, let $S_0 = V(\mathcal{I}) \subset S$, and $X \to S_0$ a morphism of schemes that p is nilpotent on X, then the **big-crystalline site** $(X/S)_{\mathrm{Crys}}$ consists of pd-thickenings(7.6.1.2) (U, T, δ) over $(S, \mathcal{I}, \delta)$ and a morphism of schemes $U \to X$, and the topology is the Zariski topology(7.6.2.1). In fact for any $(U, T, \delta) \in (X/S)_{\mathrm{Crys}}$, p is locally nilpotent in T, by(4.6.0.5).

The **crystalline site** $(X/S)_{\mathrm{crys}}$ is the strictly full subcategory consisting of objects that $U \to X$ is an open immersion.

Notice the structure sheaf that maps (U, T, δ) to $\Gamma(\mathcal{O}_U, U)$ is a sheaf of rings on $(X/S)_{\mathrm{crys}}$, called the **structure sheaf** $\mathcal{O}_{X/S}$.

Prop. (7.6.2.3)[Comparing with Zariski Site]. The functor

$$u_{X/S} : (X/S)_{\mathrm{crys}} \to X_{\mathrm{Zar}} : (U, T, \delta) \to U$$

is cocontinuous(easy to verify), thus defines a morphism of topoi $Sh((X/S)_{\mathrm{crys}}) \to Sh(X_{\mathrm{Zar}})$ by(5.1.2.21), which is functorial in X and S.

Prop. (7.6.2.4)[Finite Limits]. The category $(S/X)_{\mathrm{Crys}}$ has all finite limits, and the forgetful functor $(U, T, \delta) \to U$ preserves finite limits.

Proof: Cf.[[Sta]07I9].**?** □

Def. (7.6.2.5)[Affine Crystalline Site]. Let (A, I, γ) be a pd-structure that A is a $\mathbb{Z}_{(p)}$-algebra, and C is an A/I-algebra that p is nilpotent in C, then the crystalline site(7.6.2.2) $(C/A)_{\mathrm{Crys}}$ is the site whose object are pd-structures (B, J, δ) over (A, I, γ) that p is nilpotent in B(4.6.0.5), together with a map of rings $C \to B/J$ over A/I, and $(C/A)_{\mathrm{crys}}$ the full subcategory of objects B that $C \to B/J$ is an isomorphism.

Notice for any object (B, J, δ) in $(C/A)_{\mathrm{Crys}}$, J is nilpotent, by(4.6.0.5).

Sheaf of Differentials

Def. (7.6.2.6)[S-Derivations]. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_{X/S}$-modules on $(X/S)_{\text{crys}}$, then an S-derivation $D : \mathcal{O}_{X/S} \to \mathcal{F}$ is a map of sheaves that for any object (U, T, δ) of $(X/S)_{\text{crys}}$, the map $D : \Gamma(T, \mathcal{O}_T) \to \Gamma(T, \mathcal{F})$ is a pd-derivation over $\Gamma(V, \mathcal{O}_V)$ for any open subset $V \subset S$ that $T \to S$ factors through V.

Prop. (7.6.2.7) [Sheaf of PD-Differentials]. Similar to the construction of sheaf of differentials(5.2.4.2), we can construct of sheaf of pd-differentials $\Omega_{X/S,\delta}$ on $(X/S)_{\text{crys}}$, which is a quotient of the sheaf of differentials $\Omega_{X/S}$. And similar to(5.2.4.3), for any $(U, T, \delta) \in (X/S)_{\text{crys}}$, $\Omega_{X/S,\delta}|_{(T/S)_{\text{crys}}} = \Omega_{T/S,\delta}$.

Prop. (7.6.2.8)[A First Order PD-Thickening]. Let $(U, T, \delta) \in (X/S)_{\text{crys}}$, $\mathcal{J}$ the ideal sheaf of U, we define a first order thickening T' of T: let $\mathcal{O}_{T'} = \mathcal{O}_T \oplus \Omega_{T/S,\delta}$ with the algebraic structure that $\Omega^2_{T/S,\delta} = 0$, and let $\mathcal{J}' = \mathcal{J} \otimes \Omega_{T/S,\delta}$, and define the pd-structure as

$$\delta'_n(f, \omega) = (\delta_n(f), \delta_{n-1}(f)\omega).$$

Then (U, T, δ') is a pd-thickening and $(U, T, \delta) \to (U, T', \delta')$ is a morphism in $(X/S)_{\text{crys}}$. Moreover, there are two ring maps

$$p_0, p_1 : \mathcal{O}_T \to \mathcal{O}_{T'} : p_0(f) = (f, 0), \quad p_1(f) = (f, d_{T/S,\delta}(f))$$

Then we get two contraction of the morphism $T \to T'$, and $p_0^* - p_1^*$ is the universal derivation $d_{T/S,\delta}$ included in $\mathcal{O}_{T'}$.

This construction is functorial in T/S by(7.6.2.7) and hence gives a functor of sites $(X/S)_{\text{crys}} \to (X/S)_{\text{crys}}$.

Proof: The verification of the pd-axioms in in [Sta]07HH. □

Prop. (7.6.2.9)[Second Order PD-Thickening]. There is a further thickening T'' of T', which is a second order thickening of T:

$$\Omega_{T''} = \mathcal{O}_T \oplus \Omega_{T/S,\delta} \oplus \Omega_{T/S,\delta} \oplus \Omega^2_{T/S,\delta}$$

with the algebra structure given by

$$(f, \omega_1, \omega_2, \eta)(f', \omega'_1, \omega'_2, \eta') = (ff', f\omega'_1 + f'\omega_1, f\omega'_2 + f'\omega_2, f\eta' + f'\eta + \omega_1 \wedge \omega'_2 + \omega'_1 \wedge \omega_2)$$

Let $\mathcal{J}'' = \mathcal{J} \oplus \Omega_{T/S,\delta} \oplus \Omega_{T/S,\delta} \oplus \Omega^2_{T/S,\delta}$, then there is a PD-structure on $\mathcal{J}''$ given by

$$\delta''_n(f, \omega_1, \omega_2, \eta)) = (\delta_n(f), \delta_{n-1}(f)\omega_1, \delta_{n-1}(f)\omega_2, \delta_{n-1}(f)\eta + \delta_{n-1}(f)\omega_1 \wedge \omega_2)$$

This construction is functorial in T/S by(7.6.2.7) and hence gives a functor of sites $(X/S)_{\text{crys}} \to (X/S)_{\text{crys}}$.

Proof: For the details, Cf.[Sta]07J3. □

3 Crystals

Def. (7.6.3.1) [Crystals]. In situation(7.6.2.2), for $\mathcal{F} \in \mathfrak{Mod}(X/S)_{\text{crys}}$, it restricts to a sheaf f_T on T for every object $(U, T, \delta) \in (X/S)_{\text{crys}}$. And it is functorial. Then $\mathcal{F}$ is called

- an $\mathcal{O}_{X/S}$-crystal if for any morphism $u : (U', T', \delta') \to (U, T, \delta)$ in $(X/S)_{\text{crys}}$, the morphism of $\mathcal{O}_{T'}$-modules $u^*\mathcal{F}_T \to F_{T'}$ is an isomorphism.
- **locally Qco** if $\mathcal{F}_T \in \mathfrak{QCoh}(\mathcal{O}_T)$ for any $(U, T, \delta) \in (X/S)_{\text{crys}}$.
- **Qco** as defined in(5.2.2.25).

In particular, $\mathcal{O}_{X/S}$ is a crystal in $\mathcal{O}_{X/S}$-modules.

Def. (7.6.3.2). Is it true that if $X = S = \operatorname{Spec} R$ where R is a perfect ring, then a crystal is simply a module over $W(R)$**??**

Connections

Def. (7.6.3.3) [deRham Complexes for $(X/S)_{\text{crys}}$]. On a crystalline site $(X/S)_{\text{crys}}$, if we define $\Omega^i_{X/S,\delta} = \wedge^i \Omega_{X/S,\delta}$(7.6.2.7), then by(7.2.1.2), the universal S-derivative $d_{X/S}$ give rises to the **deRham complex**

$$\mathcal{O}_{X/S} \to \Omega^1_{X/S,\delta} \to \Omega^2_{X/S,\delta} \to \dots$$

as $\mathcal{O}_{X/S}$-modules on $(X/S)_{\text{crys}}$.

Proof: The verification of the condition for the quotient $\Omega_X \to \Omega_{X/S,\delta}$ is routine. □

Def. (7.6.3.4) [Connections on $(X/S)_{\text{crys}}$]. we define the notion of connection on $(X/S)_{\text{crys}}$ of an $\mathcal{O}_{X/S}$-module $\mathcal{F}$ on $(X/S)_{\text{crys}}$ w.r.t. the differential $\Omega_{X/S,\delta}$, as in(7.2.1.5).

Prop. (7.6.3.5) [Connections of Crystals]. Any $\mathcal{O}_{X/S}$-crystal $\mathcal{F}$ is equipped with a canonical integrable connection.

Proof: For any $(U, T, \delta) \in (X/S)_{\text{crys}}$, consider the first order thickening (U, T', δ') given in(7.6.2.8), then there are two projections $p_0, p_1 : T' \to T$ and a inclusion $i : T \to T'$, then by the property of crystals we get isomorphisms

$$p_0^*\mathcal{F}_T \xrightarrow{c_0} \mathcal{F}_{T'} \xleftarrow{c_1} p_1^*\mathcal{F}_T$$

then $\nabla(s) = p_1^*(s) - c_1^{-1}c_0(p_0^*(s))$ vanishes after pulling back to T via i^*, so it is in the kernel of i^*, which is

$$\mathcal{F}_T \otimes_{\mathcal{O}_T} \Omega_{T/S}$$

by the construction of T'(7.6.2.8). This ∇ is functorial in T as everything is functorial, hence gives a connection on $\mathcal{F}$.

For the integrability, Cf.[Sta]07J6.**?** □

Cor. (7.6.3.6). If $\mathcal{F}$ is a crystal in in Qco modules, then we can define a de Rham complex

$$\mathcal{F} \to \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega_{X/S,\delta} \to \mathcal{F} \otimes_{\mathcal{O}_{X/S,\delta}} \Omega^2_{X/S,\delta} \to \dots$$

Crystals in Qco modules

Def. (7.6.3.7) [Quasi-Coherent Crystals]. An $\mathcal{O}_X$-module $\mathcal{F}$ on $(X/S)_{\mathrm{crys}}$ is called a **quasi-coherent crystal** if it satisfies the following equivalent conditions:

- $\mathcal{F} \in \mathfrak{QCoh}(X/S)_{\mathrm{crys}}$.
- $\mathcal{F}$ is locally Qco(7.6.3.1) and it is a crystal in $\mathcal{O}_{X/S}$-modules.

Moreover, $\mathcal{F}$ is called a **crystal in finite locally free modules** if $\mathcal{F}$ is finite locally free.

Proof: Cf.[[Sta]07IT]. □

Def. (7.6.3.8)[Notations in Polynomial case]. If in situation(7.6.2.5), $S = \operatorname{Spec} A, X = \operatorname{Spec} C$, we let $P \to C$ be a surjection of A-algebras with $P = A[X_i]$, and the kernel is J. Set $D = D_{P,\gamma}(J)^\wedge$ be the p-adically completed pd-envelope, then $(D, \widehat{J}, \widehat{\gamma})$ admits a natural pd-structure, by(4.6.0.12). Let $D_e = D/p^e$ and J_e the image of $\widehat{J}$ in D_e. Denote

$$\Omega_D = (\Omega_{D/A,\gamma})^\wedge = (\Omega_{D_{P,\gamma}(J)/A,\overline{\gamma}})^\wedge = \lim_e \Omega_{D(n)_e/A,\overline{\gamma}}(4.6.1.4).$$

By(4.6.1.4), $\Omega_{D_{P,\gamma}(J)/A,\overline{\gamma}} = \Omega_{P/A} \otimes_P D_{P,\gamma}(J)$ which is free over $D_{P,\gamma}(J)$ on dx_i, so Ω_D is topologically free over D on dx_i, and there is a universal derivation $d : D \to \Omega_D$.

Now let $J(n) = \ker(P \otimes_A \otimes_A \ldots \otimes_A P \to C)$ where the tensor has $n+1$ factors, and

$$D(n) = (D_{P\otimes_A \otimes_A \ldots \otimes_A P/A,\gamma}(J(n)))^\wedge$$

with divided ideals $\widehat{J}(n)$, and also $D(n)_e = D(n)/p^e$, $T(n)_e = \operatorname{Spec} D(n)_e$, then $(X, T(n)_e, \overline{\gamma}(n))$ is a pd-thickening by(4.6.0.5) for e large(4.6.0.12), by(4.6.0.5) as p is nilpotent in X. And

$$\Omega_{D(n)} = (\Omega_{D(n)/A,\overline{\gamma}(n)})^\wedge.$$

Then $D(0) = D, D(1), \ldots$ form a cosimplicial pd-structures.

Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_{X/S}$-modules, denote

$$M(n) = \lim_e (\Gamma((X, T(n)_e, \overline{\gamma}(n)), \mathcal{F})).$$

Prop. (7.6.3.9). Notation as in(7.6.3.8), there is an isomorphism

$$D(n) \cong (D\langle \xi_i(j) \rangle)^\wedge$$

where $\xi_i(j) = X_i \otimes 1 \otimes \ldots 1 - 1 \otimes 1 \ldots X_i \otimes 1 \otimes \ldots 1$.

Proof: There is an isomorphism $P \otimes_A \ldots \otimes_A P \cong P[\xi_i(j)]$, and $J(n)$ is just generated by $JP \otimes_A \ldots \otimes_A P + (\xi_i(j))$, so this theorem follows from(4.6.0.17). □

Crystals and Connections

Lemma (7.6.3.10) [Crystals and Connections]. Notation as in(7.6.3.8), there is a functor from the category of crystals in Qco $\mathcal{O}_{X/S}$-modules to the category of pairs (M, ∇) that

- M is a p-adically complete D-module.
- $\nabla : M \to M \widehat{\otimes}_D \Omega_D$ is an integrable connection.
- ∇ is topological quasi-nilpotent: for any $m \in M$, there are only f.m. pairs (i, k) that $\nabla^k_{\partial/\partial x_i}(m) \in pM$.

Proof: For a crystal, we associate to it $M = M(0)$ defined in(7.6.3.8). let $\Gamma((X, T(0)_e, \overline{\gamma}(0)), \mathcal{F}) = M_e$, then because $\mathcal{F}$ is a crystal in qco sheaves, $\mathcal{F}_{T(0)_e} = \widetilde{M_e}$, and $M_e = M_{e+1}/p^e M_{e+1}$, thus $M_e = M/p^e M$ and M is p-adically complete by(4.2.3.6). By evaluating the natural connection defined in(7.6.3.6) on T_e and take limit, then we get an integral connection $\nabla : M \to M\widehat{\otimes}_D\Omega_D$.

To show this integral is topologically quasi-nilpotent, we can do the same thing for $M = M(n)$ for any n, and using the crystal property of $\mathcal{F}$ and take limits, we get isomorphisms

$$M\widehat{\otimes}_{D,p_0}D(1) \to M(1) \to M\widehat{\otimes}_{D,p_1}D(1)$$

For the rest, Cf.[[Sta]07JG]. □

Prop. (7.6.3.11). The functor defined in(7.6.3.10) is an equivalence of categories.

Proof: Cf.[[Sta]07JH]. □

Def. (7.6.3.12) [Notations in Smooth Case]. Situation as in(7.6.3.8), but this time we choose a smooth A-algebra P' and $A \to P' \to C$ with $\ker(P' \to C) = J'$ and do the same as(7.6.3.8) again, to get

$$D' = D_{P',\gamma}(J')^\wedge$$

and

$$\Omega_{D'} = (\Omega_{D'/A,\gamma})^\wedge = (\Omega_{D_{P',\gamma}(J)/A,\overline{\gamma}})^\wedge = \lim_e \Omega_{D'(n)_e/A,\overline{\gamma}}$$

Prop. (7.6.3.13)[Crystals and Connections in Smooth case]. Situation as in(7.6.3.8) and(7.6.3.8), then we can find a $P = A[X_i]$ that there are maps $a : D \to D', b : D' \to D$ between the completed pd-envelope of P, P' that $a \circ b = \mathrm{id}$ and compatible with the maps $D \to C$ and $D' \to C$, such that the base change along a, b induces an equivalence of categories between the categories of modules with an integrable connection over D as in(7.6.3.10) and the category of modules over D' with an integrable connection.

Proof: We con find P that $P \to C$ factors through a surjection $P \to P'$, hence we get a surjection $a : D \to D'$ the left adjointness of pd-envelope. Let e large that D'_e is a pd-thickening of C over A by(4.6.0.12)(4.6.0.5), then the kernel of $D_e \to D'_e$ is nilpotent by(4.6.0.5), hence by the strongly lifting property(4.4.5.16) of the smooth ring map $P \to P'$(4.4.5.21) w.r.t. the thickening $D_e \to D'_e$, we find a lift $P' \to D_e$.

Notice $D_{e+i+1} \to D_{e+i} \times_{D'_{e+i}} D'_{e+i+1}$ is surjective with nilpotent kernels(because $p^{e+i}D \to p^{e+i}D'$ is surjective), we can use the smooth of $A \to P$ to lift inductively the map $P' \to D_e$ to a map $P' \to D$, thus by universal property of completed pd-envelope extends to a map $b : D' \to D$. It is clear that $a \circ b = \mathrm{id}$.

For the equivalence of categories, Cf.[[Sta]07L5].**?** □

Remark (7.6.3.14). In fact this proposition holds with P' being any ring that $A \to P'$ satisfies the strong lifting property(4.4.5.16). In particular, this holds for ind-smooth A-algebras(7.5.2.5).

4 (F-)Isocrystals

References are [Slope Filtrations of F-Crystals, Katz].

Notation (7.6.4.1).

- Let $R \in \mathcal{CR}\mathrm{ing}/\mathbb{F}_p, S = \operatorname{Spec} R$.

Def. (7.6.4.2) [Crystals and Isocrystals]. A **locally free crystal over** S is simply a module over $W(R)$.

An **isocrystal on** S is an object in the category of locally free crystals on S up to isogeny, i.e. a module over $W(R)[\frac{1}{p}]$.

An **F-isocrystal on** S is a pair (M,φ) where M is an isocrystal over S and $\varphi : M^{(p)} \cong M$ is an isomorphism of isocrystals over S. The category of F-isocrystals over S is denoted by F-Isoc(S).

Over Perfect Fields

Notation (7.6.4.3).

- Let $k \in \mathtt{Field}^p$ be a perfect field.
- $K_0 = W(k)[\frac{1}{p}]$ its maximal unramified subextension.
- The Frobenius action on K_0 is denoted by σ.
- We abbreviate F-isocrystals to isocrystals.

Def. (7.6.4.4) [Isocrystals and φ-Modules]. An isocrystal over k is the same thing as a φ-module over (K_0,σ)(15.4.6.1).

Def. (7.6.4.5) [Hodge-Tate Weight]. For any complete $W(k)$-lattice M of D, let a_n be the maximum integer that $\varphi^n(M) \subset p^{a_n}M$, then we have $a_{m+n} \geq a_m + a_n$, thus by(24.1.1.1), we have a_n/n converges to $\sup a_n/n = \lambda$. λ doesn't depend on M because of the cofinality of lattices, and it is called the **Hodge-Tate weight** of D.

Lemma (7.6.4.6). Let M be a lattice of D that $\varphi^{h+1}(M) \subset p^{-1}M$, where h is the dimension of D, then D is effective.

Proof: Let $M_j = M + \varphi(M) + \ldots + \varphi^j(M)$, then $M_j/M \subset p^{-1}M/M$, which is a k-vector space of dimension h, then $M_j = M_{j+1}$ for some j, hence M_j is stable under φ. □

Prop. (7.6.4.7). $\lambda \geq 0$ iff D is effective(15.4.6.11). And $\lambda = s/r$, where $1 \leq r \leq h$.

Proof: If D is effective, then $a_n \geq 0$, conversely, if $a_n \geq 1$, then $M' = M + \varphi(M) + \ldots + \varphi^{n-1}(M)$ is stable under φ, so D is effective.

For the second assertion, we first notice, if $\lambda > 0$, then φ is nilpotent on M/pM, which is a k-vector space of dimension h, then $\varphi^h = 0$ on M/pM, so $\lambda \geq 1/h$.

Now we find s, r that $|r\lambda - s| \leq 1/(h+1)$, and $\widetilde{\varphi} = p^{-s}\varphi^r$ has $|\widetilde{\lambda}| \leq 1/(h+1)$, so(7.6.4.6) shows that $\widetilde{\varphi}$ is effective, hence $\widetilde{\varphi} \geq 0$, and by what we have proved, $\widetilde{\varphi} = 0$, hence it is $\lambda = s/r$. □

Lemma (7.6.4.8). For a φ-stable $W(k)$-lattice M of D, one has $M = M_0 \oplus M_{>0}$, where φ is bijection on M_0 and topologically nilpotent on $M_{>0}$.

Proof: We consider M/p^nM, then by(2.2.4.5) under slight modification, we have a decomposition for M/p^nM. This decompositions for different n are compatible, so taking an inverse limit gives a decomposition of M it self. □

Def. (7.6.4.9) [Isotypical φ-Modules]. $V \in \varphi\mathfrak{Mod}(K_0)$ is called **pure(isotypical) of slope** $\lambda = s/r \in \mathbb{Q}$ if V admits a lattice M on which $p^{-s}\varphi^r$ is a bijection. This is independent of V because λ is independent of V.

Prop. (7.6.4.10) [Dieudonné-Manin]. Any $V \in \varphi\text{-}\mathcal{M}\mathrm{od}(K_0)$ is a finite sum of modules pure of slopes λ_i. This is called the **isocrystal decomposition** of V.

Proof: We use the $\widetilde{\varphi}$ as in the proof of(7.6.4.7), we see that M has a decomposition $M_0 \oplus M_{>0}$ by(7.6.4.8), and $M_0 \neq 0$ by definition. Then we use induction to get the result. □

Lemma (7.6.4.11). If k is a separably closed field and V is a φ-module with $a \geq 1$ of slope 0, then V has a basis of elements fixed by φ, and $1-\varphi$ is a surjection.

If $A = W(k)$ is a ring with k a separably close field and V is a φ-module over A with $a \geq 1$ and slope 0, then V has a basis of elements fixed by φ, and $1-\varphi$ is a surjection.

Proof: We choose a $e_0 \in V$, and set $e_i = \varphi^i(e_0)$, and suppose $e_d = a_0 e_0 + \ldots + a_{d-1}e_{d-1}$, then if we consider the equation $\varphi(b_0e_0 + \ldots + b_{d-1}e_{d-1}) = b_0e_0 + \ldots + b_{d-1}e_{d-1}$, then we need to assure b_{d-1} is a zero of

$$x = a_0^{q^{d-1}} x^{q^d} + a_1^{q^{d-2}} x^{q^{d-1}} + \ldots + a_{d-1}x^q$$

which is separable, so it has a non-zero solution in k, so φ has a fixed point v. By induction, we have $V/k\cdot v$ admits a basis fixed by φ. We know that $1-\varphi : k\cdot v \to k\cdot v : x \mapsto (x - x^q)$ is surjective, so we can adjust the coefficient of v to get a basis of V fixed by φ. And meanwhile we proved $1-\varphi$ is surjective.

The second assertion follows from successive approximation, as $x^p - x - a$ always has a root in k. □

Def. (7.6.4.12). When k is alg.closed, for $\lambda = s/r$, we define a φ-module over $K = W(k)[1/p]$ $E_\lambda = \oplus_{i+0}^{r-1} K e_i$ that $\varphi(e_i) = e_{i+1}$, and $\varphi(e_{r+1}) = p^s e_0$. In this case, E_λ is irreducible.

Proof: If D is a $W(k)$-lattice stable under φ, then we may assume it is pure of slope d/h by(7.6.4.10), and then we find an element $y = \sum y_i e_i$ fixed by $p^{-d}\varphi^h$, then $p^{sh}\varphi^{rh}(y_i) = p^{rd}y_i$, which by valuation is only possible when $sh = rd$, so $h \geq r$, so D generate E_λ. □

Thm. (7.6.4.13) [Dieudonné-Manin]. If $k = \overline{k}$, then any $V \in \varphi\text{-}\mathcal{M}\mathrm{od}(K_0)$ has a unique decomposition as sums of E_{λ_i}(7.6.4.12).

Proof: By(7.6.4.10) we assume D is pure, then by(7.6.4.11) we find a basis y_i that $\varphi^r(y_i) = p^s y_i$, then there is a map $E_\lambda \to D$. Since E_λ is irreducible, this is injective, and we consider all y_i until $E_\lambda^m \to V$ is surjective, then it is an isomorphism(this is like the case of simple modules). □

Def. (7.6.4.14) [Tate Twists]. The Tate object $\mathbb{1}(n), n \in \mathbb{Z}$ is the 1-dimensional isocrystal over K_0 that $\varphi = p^n\sigma$, so it is of slope n. And the **Tate twist isocrystal** is tensoring by $\mathbb{1}(n)$. It preserves rank and shifts Hodge-Tate weight by n.

5 Properties

Cf.[Sta]Chap55.24.

Def. (7.6.5.1) [Higher Direct Images]. Let p be a prime number, $(S, \mathcal{I}, \gamma) \to (S', \mathcal{I}', \gamma')$ be a morphism of PD-schemes over $\mathbb{Z}_{(p)}$ and $f : X/S_0 \to X'/S'_0$ be a morphism of schemes that p is locally nilpotent on X and X'. For the rest, Cf.[Sta]07MJ.

Def. (7.6.5.2) [F-Crystals]. In situation(7.6.2.2), let $S = \operatorname{Spec} A$ where (A, I, γ) is a divided power algebra with $p \in I$, and there is a Frobenius σ on A extending that of A/I. Since the absolute Frobenius on X and S_0 are compatible, thus there is a morphism of crystalline site $(F_X)_{\text{crys}} : (X/S)_{\text{crys}} \to (X/S)_{\text{crys}}$.

Then an F**-crystal** on X/S relative to σ is a pair $(\mathcal{E}, F_{\mathcal{E}})$ given by a crystal in finite locally free $\mathcal{O}_{X/S}$-modules(7.6.3.7) together with a map

$$F_{\mathcal{E}} : (F_X)^*_{\text{crys}}\mathcal{E} \to \mathcal{E}.$$

A **non-degenerate** F**-crystal** is an F-crystal that there exists a map $V : \mathcal{E} \to (F_X)^*_{\text{crys}}\mathcal{E}$ that $V \circ F_{\mathcal{E}} = p^i \operatorname{id}$ for $i \geq 0$.

6 Computations

Prop. (7.6.6.1)[Affine Thickening is Acyclic]. If T is a locally Qco sheaf of $\mathcal{O}_X$-modules on (X/S), then $H^p((U, T, \delta), \mathcal{F}) = 0$ for any $p > 0$ and U or T affine.

Proof: Firstly notice U is affine iff T is affine, by(5.8.9.2), then we use(5.3.2.16) with $\mathfrak{G}$ being the affine thickenings and Cov the affine coverings of affine thickenings, then Cov is cofinal, and it suffices to check that $\check{H}^q(T, \mathcal{F}) = 0$ for an affine thickening T and $q > 0$, and this is just the usual cohomology for Qco sheaves as the affine covering is cofinal, and it follows from(5.7.1.1). □

Lemma (7.6.6.2). Situation as in(7.6.3.8), then the morphism

$$(\operatorname{colim}_e h_{(X, T_e, \overline{\delta})})^\sharp \to *$$

of sheaves on $(X/S)_{\text{crys}}$ is surjective.

Proof: We need to show that for any $(U, B, \delta) \in (X/A)_{Crys}$, there is an Zariski covering (U_i, B_i, δ) of it that there are maps $(U_i, B_i, \delta) \to (X, T_{e_i}, \overline{\delta})$ that are compatible, But this is in fact equivalent to the existence of a morphism $(U, B, \delta) \to (X, \operatorname{Spec} D, \delta)$ of pd-structures. For this, notice the morphism $U \to X$ can be extended to a morphism $X \to \operatorname{Spec} P$ by strong lifting property(4.4.5.16) of smooth morphism(4.4.5.21), and this extends to the desired morphism by the universal property of pd-envelope and the fact p is locally nilpotent on B(7.6.2.2) thus B is locally p-complete. □

Lemma (7.6.6.3). Let $K' = (\operatorname{colim}_e h_{(X, T_e, \overline{\delta})})^\sharp$, then the product sheaf $(K')^n$ is in fact isomorphic to $(\operatorname{colim}_e h_{(X, T(n)_e, \overline{\delta})})^\sharp$ on $(X/S)_{\text{crys}}$.

Proof: This follows from the definition and the universal properties of completion, pd-envelope and $P \otimes_A \otimes_A \ldots \otimes_A P$ is a coproduct. Compare with the proof of(7.6.6.2). □

Prop. (7.6.6.4). Situation as in(7.6.3.8), if $\mathcal{F}$ is locally Qco and satisfies: for any morphism $f : (U, T, \delta) \to (U', T', \delta') \in (X/S)_{\text{crys}}$ that $f : T \to T'$ is a closed immersion the map $f^*\mathcal{F}_{T'} \to \mathcal{F}_T$ is surjective, then the complex

$$M(0) \to M(1) \to \ldots$$

computes $R\Gamma((X/S)_{\text{crys}}, \mathcal{F})$. Moreover,

$$R\Gamma((X/S)_{\text{crys}}, \mathcal{F} \otimes_{\mathcal{O}_{X/S}} \Omega^i_{X/S,\delta}) = 0$$

for $i > 0$.

Proof: We use(5.3.1.19) for the presheaf $K' = \mathrm{colim}_e\, h_{(X,T_e,\overline{\delta})}$ and $K = *$, which satisfies the condition by(7.6.6.2). Then we get a spectral sequence

$$E_1^{p,q} = H^q(K'_p, \mathcal{F}) \Rightarrow H^{p+q}(K, \mathcal{F}).$$

Notice $K'_n = (\mathrm{colim}_e\, h_{(X,T(n)_e,\overline{\delta})})^\sharp$ by(7.6.6.3), so the cohomology

$$R\Gamma(K'_n, \mathcal{F}) = R\lim_e(\Gamma((X, T(n)_e, \overline{\gamma}(n)), \mathcal{F}))$$

Now the surjectivity $f^*\mathcal{F}_{T'} \to \mathcal{F}_T$ is equivalent to the surjectivity $\mathcal{F}_{T'} \to f_*\mathcal{F}_T$, so there is an exact sequence of Qco $\mathcal{T}'$-sheaves

$$0 \to \mathcal{K} \to \mathcal{F}_{T'} \to f_*\mathcal{F}_T \to 0$$

which implies that $\mathcal{F}((U', T', \delta')) \to \mathcal{F}((U, T, \delta))$ is surjective, by(5.7.4.2) and(5.7.1.3).

Then by(4.9.3.3),

$$R\Gamma(K'_n, \mathcal{F}) = R\lim_e(\Gamma((X, T(n)_e, \overline{\gamma}(n)), \mathcal{F})) = M(n)$$

thus we are done. □

Lemma (7.6.6.5). Situation as in(7.6.3.8), the complex $\Omega_{D(\bullet)}$ is homotopic to 0 as a $D(\bullet)$-cosimplicial module.

Proof: This complex is the p-adic completion of the base change of the cosimplicial module $M_\bullet = (\Omega_{P^{\otimes_A^\bullet}/A})$ under the cosimplicial ring map $P^{\otimes_A^\bullet} \to D(\bullet)$. Then it suffices to show $M_\bullet$ is homotopic to 0. For this, the whole thing can be written down clearly, Cf.[Sta]07LA. □

Lemma (7.6.6.6). In situation(7.6.3.8), for any cosimplicial module M_* over the cosimplicial ring $D(*)$ and $i > 0$, the cosimplicial module

$$M_0 \widehat{\otimes}_{D(0)} \Omega^i_{D(0)} \to M_1 \widehat{\otimes}_{D(1)} \Omega^i_{D(1)} \to \dots$$

is homotopic to 0.

Proof: □

Crystal Case

Prop. (7.6.6.7). Situation as in(7.6.3.8), and let $\mathcal{F}$ be a crystal in Qco modules, and let (M, ∇) be the corresponding module with connection over D by(7.6.3.10), then the complex

$$M \widehat{\otimes}_D \Omega^\bullet_D$$

computes $R\Gamma((X/S)_{\mathrm{crys}}, \mathcal{F})$.

Proof: Use the spectral sequence associated to the double complex

$$K^{a,b} = M \widehat{\otimes}_D \Omega^a_{D(b)}$$

Then the rows $K^{a,\bullet}$ is acyclic for $a>0$ by(7.6.6.6) and(4.8.2.21), and $K^{0,\bullet}$ is quasi-isomorphic to $R\Gamma((X/S)_{\mathrm{crys}},\mathcal{F})$ by(7.6.6.4). Now we look at the other direction, (4.6.1.7) and(7.6.3.9) show that each of the b maps $D\to D(b)$ determines the same quasi-isomorphism

$$M\widehat{\otimes}_D\Omega^*_D\cong M\widehat{\otimes}_{D(b)}\Omega^*_{D(b)}$$

as their inverse is given by the same $D(b)\to D$. Then it is clear that the E_2 page in this direction is $H^a(M\widehat{\otimes}_D\Omega^*_D)$ in the zero-th row and vanish otherwise, so we get the desired isomorphism by edge morphisms. ☐

Prop. (7.6.6.8) [de Rham Comparison for Crystalline Cohomology]. In situation(7.6.3.12), let $\mathcal{F}$ be a crystal in Qco modules, and let (M',∇') be the corresponding module with connection over D' by(7.6.3.13), then the complex

$$M\widehat{\otimes}_{D'}\Omega^\bullet_{D'}$$

computes $R\Gamma((X/S)_{\mathrm{crys}},\mathcal{F})$.

Proof: Let $b:D'\to D, a:D\to D'$ be the maps defined in(7.6.3.13), then by(7.6.6.7), it suffices to prove the base change along a,b induces quasi-isomorphisms

$$M\widehat{\otimes}_D\Omega^\bullet_D\cong M\widehat{\otimes}_{D'}\Omega^\bullet_{D'}.$$

$a\circ b$ is trivial, thus it suffices to prove that $b\circ a$ induces anautomorphism of $M\widehat{\otimes}_D\Omega^\bullet_D$. In fact, this is true for any morphism $\rho:D\to D$ of pd-algebras over A compatible with the map $D\to C$:

Write $\rho(x_i)=x_i+z_i$, where $z_i\in J$ because ρ is compatible with $D\to C$. Then we can factor ρ as

$$D\xrightarrow{\sigma}D\langle\xi_i\rangle^\wedge\xrightarrow{\tau}C$$

where $\sigma(x_i)=x_i+\xi_i$ and $\tau(\xi_i)=z_i$.

Notice that there exists an automorphism α of $D\langle x_i\rangle^\wedge$ that maps x_i to $x_i-\xi_i$ and ξ_i to ξ_i. (Such a map exists because by universal property, it suffices to give a map of pairs

$$(P,J)\to D_{P,\gamma}(J)\langle\xi_i\rangle=D_{P[\xi_i],\gamma}(JP[\xi_i]+(\xi_i))$$

by(4.6.0.17), and we surely have.

Now α is an automorphism, we have a quasi-isomorphism

$$M\widehat{\otimes}_D\Omega^*_D\cong M\widehat{\otimes}_{D,\sigma}\Omega^*_{\widehat{D\langle\xi_i\rangle}}$$

by(4.6.1.7). Also τ induces an isomorphism because it has a right inverse, which is an isomorphism by(4.6.1.7) again, so ρ induces an isomorphism. ☐

Cor. (7.6.6.9) [Crystalline-de Rham Comparison modulo p]. In situation(7.6.3.12), if R is a smooth A/p-algebra, then there is a natural quasi-isomorphism

$$R\Gamma_{\mathrm{crys}}(R/A)\otimes^L_A A/p\cong\Omega^\bullet_{R/(A/p)}$$

of commutative algebra objects.

Proof: we choose P to be a smooth lift of R**?** to A, then $J=IP$, and by(4.6.0.11), the pd-structure extends to P, thus $D_{P/A,\gamma}=P$, and notice $\Omega^i_{P/A}$ is finite projective hence flat, so $\Omega^\bullet_{P/A}$ is K-flat(5.3.3.2), and the left side of is just $\widehat{\Omega}^\bullet_{P/A}\otimes_A A/p=\widehat{\Omega}^\bullet_{R/(A/p)}$ by(7.6.6.8)(4.6.1.2) and(4.4.3.6). ☐

7.7 Prismatic Cohomology

Main references are [[Sta]], [Prisms and Prismatic Cohomology, Scholze], [Notes on Prismatic Cohomology, Bhatt], [Prismatic Cohomology notes, Kedlaya].

1 Prisms

Def. (7.7.1.1) [Prisms]. A **prism** is a pair (A, I) where A is a δ-ring A and I is an ideal of A, that $V(I)$ is a Cartier divisor on $\operatorname{Spec} A$, A is derived (p, I)-complete, and $p \in I + \varphi(I)A$.

A prism (A, I) is called **perfect prism** if A is a perfect δ-ring(4.5.4.25). it is called **bounded prism** if A/I has bounded p^∞-torsion. It is called **crystalline prism** if $I = (p)$. It is called **orientable** if I is principal. It is called **oriented** if $I = (d)$ for d fixed.

A map of primes is called **(faithfully)flat** iff the map $A \to B$ is (p, I)-completely (faithfully)flat(4.9.7.1).

Lemma (7.7.1.2). Let A be a δ-ring and I be a locally principal ideal contained in $\operatorname{rad}(A)$ that $(p, I) \subset \operatorname{rad} A$, then the following are equivalent:

- $p \in I^p + \varphi(I)A$.
- $p \in I + \varphi(I)A$.
- There is a f.f. morphism of δ-rings $A \to A'$ where A' is a finite product of localizations of A φ-stable multiplicative subsets that IA' is generated by a distinguished element d and $d, p \in \operatorname{rad}(A')$.

Proof: $1 \to 2$ is trivial, for $2 \to 3$: Choose $(g_1, \ldots, g_r) = A$ that $IA_{g_{r_i}}$ is principal. Let $B = \prod_{i=1}^r A_{g_i}$, so $A \to B$ is f.f. and $IB = (f)$ is principal. Lt A' be the localization of B along the ideal (p, f)(4.1.1.31), then $p, f \in \operatorname{rad} A'$. Then $A \to A'$ is still f.f., because it is flat hence the image is stable under generalization by(4.4.1.19), so it must be all of $\operatorname{Spec} A$ because it contains (p, I) by construction, and $(p, I) \in \operatorname{rad} A$ by hypothesis.

Now because $p \in \operatorname{rad} A$, each localization of A has a compatible δ-structure, and $\widetilde{A}$ is a finite product of localizations of A, thus it has a δ-structure, and d is distinguished by(4.5.4.23).

$3 \to 1$: We need to check that $p = 0$ in $A/(I^p + \varphi(I)A)$, but this can be checked after base change to A', which is $p = 0 \in A'/(d^p, \varphi(d))$. This is true, because $d^p = d^p + p\delta(d)$ and $\delta(d)$ is a unit. □

Remark (7.7.1.3) [Examples of Prisms].

- If A is a p-torsionfree and p-adically complete δ-ring A, the pair $(A, (p))$ is a bounded crystalline prism.
- q-de Rham cohomology(4.5.4.24) determines a bounded prism. (completeness and boundedness is clear, and $p \in (d, \varphi(d))$ because?)
- Breuil-Kisin cohomology(4.5.4.24) determines a bounded prism. (boundedness is clear, and?)
- A_{inf}-cohomolgoy(4.5.4.24) detemines a bounded prism. (The same reason as item2).

Prop. (7.7.1.4) [Universal Oriented Prism]. Let $A_0 = \mathbb{Z}_{(p)}\{d, \delta(d)^{-1}\}$ be the localization δ-ring(4.5.4.15) of the free $\mathbb{Z}_{(p)}$-δ-ring on the variable d, and let A be the derived (p, d)-completion of A_0(it is discrete by(4.9.7.7)), and let $I = (d)$, then (A, I) is a bounded oriented prism, and it is the initial object in the category of bounded oriented prisms.

Moreover, the sequence (p, d) is regular and the Frobenius $\varphi : A/p \to A/p$ is d-completely flat.

Proof: It is clearly a prism and universal. For the assertions, firstly we show $A/(p,d) = A_0/(p,d)$: notice $A \otimes^L_{A_0} A_0/(p,d) = A_0/(p,d)$ by(4.9.7.4), so we can replace $\otimes^L$ with $\otimes$. Similarly for $A/(p,d^p)$ because A is (p,d^p)-complete. Now this map is .

(p,d) is regular by(4.9.7.7) applied to $(\mathbb{Z}_{(p)}[d], A)$**?**, for the last assertion, it suffices to show $A/(p,d) \xrightarrow{\text{Frob}} A/(p,d^p)$ is f.f.. □

Prop. (7.7.1.5). Let $(A,(d))$ be the universal prism(7.7.1.4) and let $B = A\{\frac{\varphi(d)}{p}\}^\wedge$(derived (p,d)-completion), then B is (p,d)-complete, p-torsionfree and it equals the derived (p,d)-completion of the pd-envelope $D_{A,\delta}((d))$ of $(A,(d))$. In particular, $(B,(p))$ is a crystalline prism, by(4.5.4.18).

Proof: B is p-complete by(4.9.6.16), as A is p-torsionfree. Also $d^p = p(\frac{\varphi(d)}{p} - \delta(d))$, so B is also (p,d)-complete. The last assertion follows from(4.6.0.21) and(7.7.1.4). □

Cor. (7.7.1.6) [Connection with Crystalline Prism]. In the above situation, B is also a δ-ring by(4.5.4.17), and both $\varphi(d), p$ are distinguished in B and $\varphi(d)$ divides p in B, so by(4.5.4.22) $(\varphi(d)) = (p)$.

Now the composition of maps of δ-rings(4.5.4.5) $\alpha : A \xrightarrow{\varphi} A \to B$ promotes to a morphism of prisms(7.7.1.5) $(A,(d)) \to (B,(p))$ which decompose as

$$(A,(d)) \xrightarrow{\varphi} (A,\varphi(d)) \to (B,(\varphi(d))) = (B,(p))$$

Prop. (7.7.1.7) [Rigidity of Maps]. If $(A,I) \to (B,J)$ is a morphism of prisms, then $I \otimes_A B = J$, in particular, $IB = J$. Conversely, if B is a derived (p,I)-complete δ-A-algebra, then (B,IB) is a prism iff $B[I] = 0$.

Proof: For the first assertion, it suffices to show that $I \otimes_A B \to J$ is surjective, because they are both invertible sheaves on B. Choose f.f. ring morphisms $A \to A', B \to B'$ as in(7.7.1.2) and there is a morphism $A' \to B'$ extending $A \to B$, (by taking B as the localization of $A' \times_A B$ along (p,J) and do the construction again). Then $IB' \subset JB'$ are an inclusion of principal ideals generated by distinguished elements, thus they are equal, by(4.5.4.22), finally we use faithfully flatness.

For the second assertion, notice $B[I] = 0$ iff $I \otimes_A B \to IB$ is an isomorphism. If (B,IB) is a prism, then clearly $I \otimes_A B \to IB$ is an isomorphism, because they are both invertible sheaves. The converse is also trivial. □

Prop. (7.7.1.8)[Prism is Nearly Principal]. Let (A,I) be a prism, then the ideal $\varphi(I)A$ is a principal ideal, and any generator is a distinguished element. In particular, if it is a perfect prism, then $I = (f)$ where f is a distinguished element.

Proof: It suffices to prove $\varphi(I)A$ is generated by a single distinguished element, and then use(4.5.4.21). By(7.7.1.2), we can assume $p = a + b$ where $a \in I^p, b \in \varphi(I)A$. Now we show b generate $\varphi(I)A$: choose a f.f. map as in(7.7.1.2), and then it suffices to check that $b : A' \to \varphi(I)A'$ is surjective. Now $\varphi(I)A' = (d), a = xd^p, b = y\varphi(d)$, so it suffices to show y is a unit in A'. Now $(p,d) \in \operatorname{rad} A'$, it suffices to show $A'/(p,f,y) = 0$. If not, we localize along (p,f,y), then we may assume $(p,f,y) \in \operatorname{rad} A'$.

The equation $p = a + b$ implies $p(1 - y\delta(d)) = d^p(x+y)$, and the left side is distinguished because p does and $1 - y\delta(d)$ is a unit, by(4.5.4.21). Then(4.5.4.22) shows $d^{p-1}(x+y)$ is a unit, then so does d, contradicting $d \in \operatorname{rad} A'$. □

Remark (7.7.1.9). Notice the proof goes through even I is only a locally principal ideal of A.

Cor. (7.7.1.10). If (A, I) is a prism, the invertible A-modules $\varphi^*(I) = I \otimes_{A,\varphi} A$ and I^p are trivial.

Proof: Cf.[Prisms, Scholze, P25]. □

Prop. (7.7.1.11) [Properties of Bounded Prisms]. Let (A, I) be a bounded prism, then

1. Any derived (p, I)-complete and (p, I)-completely flat A-complex $M \in D(A)$ is discrete and (p, I)-complete. For any $n \geq 0$, we have $M[I^n] = 0$ and $M/I^n M$ has bounded p^∞-torsion.
2. A is (p, I)-complete, A/I is p-adically complete, $A[I^n] = 0$ and A/I^n has bounded p^∞-torsions.
3. The category of (faithfully)flat prisms over (A, I) identifies with the category of (p, I)-completely (faithfully)flat δ-A-algebras B by the bijection $B \leftrightarrow (B, IB)$.
4. (Bounded Prisms are fpqc-Locally Orientable)There is a (p, I)-completely faithfully flat δ-A-algebra B that $IB = (d)$, where d is distinguished and determines a nonzero divisor of B. Also (B, IB) is bounded.

Proof: 1: By(4.9.7.7).

2 follows from1. For A/I, it is derived p-complete by(4.9.6.8), then it is p-adically complete by(4.9.6.16).

3: By definition, a (faithfully)flat (A, I)-prism is (p, I)-completely (faithfully)flat(4.9.7.1). Conversely, by(7.7.1.7), it suffices to show that $B[I] = 0$, and this follows from item1.

4: We may choose B to be the derived (p, I)-completion of the f.f. δ-ring defined in(7.7.1.2), then it is also (p, I)-completely faithfully flat(4.9.7.4), and by item2 and3 it determines a bounded prism (B, IB). □

Prop. (7.7.1.12) [The Site of Bounded Prisms]. The prismatic site is the opposite category of the category of bounded prisms where the covers are determined by f.f. map of prisms.

Then the functors that maps (A, I) to A or A/I are sheaves on this cohomology with vanishing higher cohomologies.

Proof: To show this is a site, we need to check the base change of covers. If $(C, IC) \xleftarrow{c} (A, IA) \xrightarrow{b} (B, IB)$ is a diagram that b is f.f., then we let D be the derived (p, I)-completion of $B \otimes^L_A C$, then $C \to D$ is also (p, I)-completely f.f. by(4.9.7.5), so by(7.7.1.11) and(7.7.1.7) D is discrete and (D, ID) is a bounded prism over (A, IA). It is clear this is a base change in the category of bounded prisms.

The assertion about cohomology follows from [Scholze, Prism, 3.12]. □

Prismatic Envelopes

Prop. (7.7.1.13) [Prismatic Envelopes]. Let (A, I) be a prism, then the forgetful functor from the prisms over (A, I) to δ-pairs over (A, I) admits a left adjoint, called the **prismatic envelope** which maps (B, J) to $B\{\frac{J}{I}\}^\wedge$.

Proof: If we can construct this locally, then we can construct it globally by gluing and the universal property, so we can localize and assume $I = (d)$ where d is distinguished. Let B' be the free δ-ring over A generated by $\{x/d | x \in J\}$(4.5.4.10) and B_1 the derived (p, d)-completion module of B which is a δ-algebra by(4.5.4.18).

If d is torsion-free in B_1, then $(B_1, (d))$ is a prism that satisfies the universal property. Otherwise we choose the maximal d-torsion-free quotient(4.1.1.14)(4.5.4.14) and taking the derived (p, d)-completion module, and we can do this to $\aleph_0$, where we take the filleted colimit, then it is d-torsion-free and (p, d)-complete, by(4.9.6.5) and any prism over A map factors through this chain. □

Cor. (7.7.1.14). In the above situation, if (B,J) is (p,I)-completely flat over A, and $J=(I,x_1,\ldots,x_n)$ where $(x_1,\ldots,x_n)$ is a (p,I)-completely regular sequence w.r.t. A, then the prismatic envelope of $(B\{\frac{J}{I}\}^\wedge, IB\{\frac{J}{I}\}^\wedge)$ is flat over (A,I)(7.7.1.1).

Moreover, It is compatible with completed derived base change on (A,I), by universal properties and the fact the completed derived base change of it is discrete(4.9.7.5). Also, it is compatible with completed derived base change along a (p,I)-completely flat map $(B,J)\to(B',J')$.

Proof: It suffices to check locally for $I=(d)$ that $B_1=(B\{\frac{x_1}{d},\ldots,\frac{x_n}{d}\})^\wedge$ as a simplicial δ-ring is (p,I)-completely flat over A, then it is discrete and is torsionfree by(7.7.1.11), thus it is a prism over $(A,(d))$ by(7.7.1.7). And for the flat localization, notice the image of $x_1,\ldots,x_n$ is also (p,I)-completely regular w.r.t. A.

Consider the following diagram of derived (p,d)-complete simplicial δ-rings:

$$\begin{array}{ccccccc}
\mathbb{Z}_p\{z\}^\wedge & \xrightarrow{z\mapsto d} & A & \longrightarrow & B & \longrightarrow & B\{\frac{x_1}{d},\ldots,\frac{x_n}{d}\}^\wedge = C \\
\big\downarrow{\scriptstyle z\mapsto\varphi(y)} & & \big\downarrow & & \big\downarrow & & \big\downarrow \\
\mathbb{Z}_p\{y\}^\wedge & \longrightarrow & A' & \longrightarrow & B' & \longrightarrow & B'\{\frac{x_1}{\varphi(d)},\ldots,\frac{x_n}{\varphi(d)}\}^\wedge = C' \\
 & & \big\downarrow & & \big\downarrow & & \big\downarrow \\
 & & D = A'\{\frac{\varphi(y)}{p}\}^\wedge & \longrightarrow & B'' & \longrightarrow & B''\{\frac{x_1}{p},\ldots,\frac{x_n}{p}\} = C''
\end{array}$$

where each square is completed derived tensor product. Notice the lat term has denominator p because $\varphi(y)$ and p are both distinguished in $\pi_0(D)$, so by(4.5.4.22) $\frac{\varphi(y)}{p}$ is a unit in D.

The leftmost arrow is (p,z)-completely f.f. by(4.5.4.10)(4.9.7.4), so all the vertical arrow in the upper row is (p,z)-completely flat by(4.9.7.5). Now the map $D\to C''$ is (p,z)-completely flat by(4.6.0.24), noticing that the conditions holds, by(4.9.7.5).

Now by definition the (p,d)-completely flatness is defined by flatness after base change to $Kos(A,p,d)$(4.8.3.5), it suffices to show that there is a map $D\to Kos(A',p,d)$. To show this, it suffices to assume $A'=\mathbb{Z}_p\{y\}=\mathbb{Z}_p[y,y_1,\ldots,y_n,\ldots]$ and base change. In this case, p,y is a regular sequence, so by(4.6.0.21) D is the derived completion of $D_{\mathbb{Z}_p\{y\}}((y))$, and $Kos(A',p,y)=\mathbb{F}_p[y_1,\ldots,y_n]$, so $A'\to Kos(A',p,d)$ factors through D by universal property. □

2 Perfect Prisms

Prop. (7.7.2.1) [Properties of Perfect Prisms]. Let (A,I) be a perfect prism(7.7.1.1), then:

- $I=(d)$ where d is distinguished and is a nonzero-divisor.
- A is p-torsionfree and p-adically complete, hence there is a natural isomorphism $A\cong W(A/p)$ of δ-rings.
- $A/I[p^\infty]=A/I[p]$, and $A/p[I^\infty]=A/p[I]$. In particular, (A,I) is bounded.
- A is (p,I)-complete.

Proof: 1: I is principal by(7.7.1.8). d is distinguished by(4.5.4.23), it is nonzero-divisor by definition of prisms.

2: This is because A is p-torsionfree by (4.5.4.27) and thus p-adically complete by(4.9.6.16), then $A\cong W(A/p)$ by the equivalence in(4.5.4.28).

3: Use item2, then A/p is perfect by(4.5.4.28), thus $A/p[I^\infty]=A/p[I]$. $A/d[p^\infty]=A/d[p]$ follows from(4.5.4.30).

4: This follows from item3 and(7.7.1.11). □

Prop. (7.7.2.2) [Perfection of Prisms]. There is a **perfection of prisms** functor that maps a prism (A, I) to a perfect prism (A_∞, IA_∞) left adjoint to the inclusion functor.

Proof: Let $A'_\infty = A_{\text{perf}}$ be the perfection of A as a δ-ring(4.5.4.26), and A_∞ be the derived (p, I)-complete of A'_∞ as a δ-ring(4.5.4.18), then the universal property follows form that of derived completion and perfection once we proved that A_∞ is perfect and $IA_\infty = (d)$ where d is a nonzero-divisor.

A_∞ is perfect because the Frobenius is isomorphism on A_{perf} and derived (p, I)-completion and $(p, \varphi(I))$-completion coincide(they have the same radical(4.9.6.15)).

A_∞ is p-adically complete because it is p-torsionfree(4.5.4.27), and then use(4.9.6.16).

Now(7.7.1.9) and the fact A_∞ is perfect shows $IA_\infty = (d)$ where d is distinguished, and(4.5.4.30) shows d is a nonzero-divisor, so we are done. □

Prop. (7.7.2.3) [Perfect Prisms are Final]. Let (A, I) be a perfect prism, then for any prism (B, J), a map $A/I \to B/J$ will induce a map of prisms $(A, I) \to (B, J)$.

Proof: Cf.[B-S19]4.8.

This map will induce a map $A \cong W((A/I)^\flat) \to W((B/J)^\flat)$. And there is a Fontaine's functor $W((B/J)^\flat) \to B$(10.3.9.7) which is a δ-map. Thus we obtain a map $A \to B$. And this map can be seen to be lifting $A/I \to B/J$. □

3 Integral Perfectoid Rings

Def. (7.7.3.1) [Integral Perfectoid Rings]. A commutative ring R is called a **integral perfectoid ring** if it has the form A/I for a perfect prism (A, I). An equivalent definition of an integral perfectoid ring is given in(7.7.3.6).

Def. (7.7.3.2) [Special Fiber]. For an integral perfectoid ring R, then **special fiber** of R is defined to be $\overline{R} = R/\sqrt{pR}$. It is perfect, by(7.7.3.5).

Prop. (7.7.3.3) [Perfect Prisms and Integral Perfectoid Rings]. The mapping $(A, I) \to A/I$ defines an equivalence of categories between perfect prisms and integral perfectoid rings, where the converse is given by $R \mapsto (A_{\inf}(R), \ker(A_{\inf}(R) \to R))$(4.5.1.15).

Proof: To show $A \cong A_{\inf}(A/I)$, by(4.5.4.28), it suffices to show there is a natural isomorphism $A/p \cong (A/I)^\flat$. By(4.5.1.18), $(A/I)^\flat$ identifies with d-adic completion of A/p. Then it suffices to show A/p is I-adically complete, which is by(4.9.6.16), as A/p is derived d-complete because A does(4.9.6.8).

Now we have the Fontaine's map $A = A_{\inf}(A/I) \to A/I$, this map is surjective because $\varphi : A/(p, I) \to A/(p, I)$ is surjective as A/p is perfect. Also this is just the quotient map $A \to A/I$ because they are equal when modulo p, and then use(4.5.4.28). □

Cor. (7.7.3.4). Any perfect $\mathbb{F}_p$-algebra is an integral perfectoid ring corresponding to a crystalline prism, by(4.5.4.28).

Any integral perfectoid ring is p-adically complete, by(7.7.1.11).

Prop. (7.7.3.5). If R is a perfectoid ring, then

- R is semiperfect.
- There exists an element $\varpi \in R$ that admits a compatible system ϖ^{1/p^n} of p-power roots s.t. $\varpi = pu$ for a unit u and the kernel of the Frobenius $\varphi : R/p \to R/p$ is generated by $\varpi^{1/p}$.

- $\sqrt{pR} = \cup_n(\varpi^{1/p^n})$, and it is flat.
- $R[p] = R[\sqrt{pR}]$.

Proof: 1: Let $R = A/d$ where $A = A_{\inf}(R)$, then $R/p = A/(p,d)$, so $\varphi_{R/p}$ is surjective, as $A/p = R^\flat$ is perfect.

2: Notice $d = [a_0] - pu$ for a unit $u \in A$ by(4.5.4.30), then we can take ϖ to be the image of $[a_0]$ in R, and then $\varpi^{1/p^n} = [a_0^{1/p^n}]$.

3: firstly the LHS contains the RHS, and $R/\cup_n(\varpi^{1/p^n})$ is perfect hence reduced, so the two sides are equal. To check it is flat, we need to check that $M\otimes_R^L\sqrt{pR}$ is discrete, or equivalently $M\otimes_R^L\overline{R} \in D^{\geq -1}$ where $\overline{R} = R/\sqrt{pR}$ is perfect. But there is a distinguished triangle $M\otimes^L_{\mathbb{Z}_p}\mathbb{Q}_p/\mathbb{Z}_p[-1] \to M \to M[\frac{1}{p}]$($\mathbb{Q}_p$ is $\mathbb{Z}_p$ flat(4.4.1.6)) and the fact $\overline{R}[\frac{1}{p}] = 0$, it suffices to prove $M\otimes^L_{\mathbb{Z}_p}\mathbb{Q}_p/\mathbb{Z}_p\otimes^L_R\overline{R} \in D^{\geq -2}(R)$. Now $M\otimes^L_{\mathbb{Z}_p}\mathbb{Q}_p/\mathbb{Z}_p$ has cohomology groups p^∞-torsion, so using canonical truncation, it suffices to show $M\otimes^L_R\overline{R} \in D^{\geq -1}$ for any p^∞-torsion M. Because tensoring commutes with filtered colimits, it suffices to show for M an R/p^n-module. Now using exact sequences like

$$0 \to M[p]/M[p^2] \to M/M[p^2] \to M[p]/M[p^2] \to 0,$$

we can reduce to the case M is a R/p-module.

Now there is a commutative diagram

$$\begin{array}{ccc} A_{\inf}(R) & \longrightarrow & R \\ \downarrow & & \downarrow \\ A_{\inf}(\overline{R}) & \longrightarrow & \overline{R} \end{array}$$

and d is p-torsionfree in both $A_{\inf}(R)$ and $A_{\inf}(\overline{R})$(4.5.4.30), and $d = [a_0] - pu = pu \in W(\overline{R})$(as $a_0 = 0 \in \overline{R}$), so $\overline{R} = W(\overline{R})/d$ and this is a Tor-independent pushout square. Thus $M\otimes^L_R\overline{R} \cong M\otimes^L_{W(R^\flat)}W(\overline{R})$. As p is nonzero divisor in both $A_{\inf}(R)$ and $A_{\inf}(\overline{R})$, and $pM = 0$, we have a similar diagram quotient by p, and by the same reason $M\otimes^L_{W(R^\flat)}W(\overline{R}) \cong M\otimes^L_{R^\flat}\overline{R}$. Now the kernel of $R^\flat \to \overline{R}$ is of the form (f^{1/p^∞}), where f corresponds to (ω^{1/p^n}), so the claim follows from(4.5.1.7).

4: notation as in the proof of item2, it suffices to show the A-module $R[p]$ is annihilated by $[a_0^{1/p^n}]$ for $n \geq 0$. But $R[p] = A/d[p] = A/p[d] = R^\flat[d]$, and $d = [a_0]$ on $R^\flat$, which is perfect, so we are done. □

Prop. (7.7.3.6) [Equivalent Definition of Integral Perfectoid Rings]. A commutative ring R is an integral perfectoid ring iff the following are satisfied:

- R is p-adically complete and R/p is semiperfect.
- The kernel of $\theta_R : A_{\inf}(R) \to R$((4.5.1.15), notice R is p-adically complete) is principal.
- There exists some $\varpi \in R$ that $(\varpi^p) = (p)$.

And if R is p-torsionfree, the condition2 can be replaced by: R is p-normal**??**.

Proof: If R is an integral perfectoid ring, then these are true by(7.7.3.5). Now if these are satisfied, then firstly θ is surjective by(4.5.1.16). Next, let $d \in A_{\inf}(R)$ be the generator of θ, we show $A_{\inf}(R)$ is derived (p,d)-complete. it is derived p-complete by(4.9.6.16). Now $R^\flat$ is derived d-complete by(4.5.1.18). By induction and(4.9.6.8), $A_{\inf}(R)/p^n$ are all derived d-complete, and also by induction

$A_{\inf}(R)/p^n$ has bounded d^∞-torsion, as $R^\flat$ is perfect. Then $A_{\inf}(R)/p^n$ are all d-adically complete. Thus

$$A_{\inf}(R) = \varprojlim_n A_{\inf}(R)/p^n = \varprojlim_n \varprojlim_m A_{\inf}(R)/(p^n, d^m),$$

which means $A_{\inf}(R)$ is (p,d)-adically complete thus derived (p,d) adically complete.

Then it suffices to show d is distinguished, by(4.5.4.30). Let $\varpi^p = up$, and lift ϖ, u to $x, v \in A_{\inf}(R)$. Since $A_{\inf}(R)$ is d-adically complete, v is unit in $A_{\inf}(R)$. Then $d|x^p - pv$ and $x^p - pv$ is distinguished(4.5.4.30). Now $d, p \in \mathrm{rad}(A_{\inf}(R))$ as $A_{\inf}(R)$ is (d,p)-adically complete, so by(4.5.4.22), d is distinguished.

Now if R is a p-torsionfree integral perfectoid ring, if $x \in R[\frac{1}{p}]$ satisfies $x^p \in R$, let $n \geq 0$ minimal that $y = \varpi^n x \in R$, then we show $n = 0$: if $n > 0$, then $(\varpi^n x)^p = \varpi^{np} x^p \in \varpi^{np} R$. Then we get $\varpi^n x \in \varpi^n R$, and then $x \in R$ as R is p-torsionfree.

Conversely, we use condition$1, 2, 4$ to prove 3: We first show the kernel of $\varphi : R/p \to R/p$ is generated by ϖ as in condition4: if $x^p \in pR = \varpi^p y$, then $(x/\varpi)^p = y$, thus $x \in \varpi R$ by hypothesis. Since R/p is semiperfect, $\overline{\varpi}$ admits a compatible p^n-th roots $\{\overline{\varpi}^{1/p^n}\}$. It can be shown by induction that $\ker(\varphi^n) = (\overline{\varpi}^{1/p^n})$. This implies that the kernel of $\overline{\theta}_R : R^\flat \to R/p$ is generated by the element $\varpi^\flat$ determined by the system $\{\overline{\varpi}^{1/p^n}\}$. As $W(R^\flat)$ and R are both p-torsionfree and p-adically complete, they kernel of θ_R is generated by any element in the kernel that lifts $\varpi^\flat$. In particular, the kernel is principal. □

Prop. (7.7.3.7) [Pushout of Integral Perfectoid Rings]. Integral perfectoid rings are closed under pushouts in the category of derived p-complete rings: i.e. if $C \leftarrow A \to B$ are maps of integral perfectoid rings, then $B \widehat{\otimes}^L_A C$ is also an integral perfectoid ring.

Proof: Let $R = C^\flat \otimes^L_{A^\flat} B^\flat = C^\flat \otimes_{A^\flat} B^\flat$ which is a perfect ring, by(4.5.1.3) and(4.5.1.7). Then we have

$$W(R) = W(A^\flat) \widehat{\otimes}^L_{W(A^\flat)} W(B^\flat),$$

because this can be checked via derived Nakayama(4.9.6.10). Now use the fact $A = W(A^\flat)/d$ for some distinguished element d, and then $B = W(B^\flat)/d, C = W(C^\flat)/d$ by rigidity(7.7.1.7), and d is nonzero-divisor in $W(B^\flat), W(C^\flat), W(R)$ by(4.5.4.28), so taking derived base change along $W(A^\flat) \to A$, we get

$$D = W(R)/d = B \widehat{\otimes}^L_A C,$$

and $W(R)$ is a perfect prism, by(7.7.1.7), so $D = W(R)/d$ is an integral perfectoid ring and equals $B \widehat{\otimes}^L_A C$. □

Cor. (7.7.3.8). The category of integral perfectoid rings is closed under arbitrary colimits and products in the category of derived p-complete rings.

But it is not closed under equalizers: Notice by Ax-Sen-Tate, $(\mathcal{O}_{\mathbb{C}_p})^{\mathrm{Gal}(\overline{\mathbb{Q}}_p/\mathbb{Q}_p)} = \mathbb{Z}_p$, but $\mathbb{Z}_p$ is not an integral perfectoid by(7.7.3.6).

Proof: It suffices to show it is closed under products and sums**?**. □

Prop. (7.7.3.9) [Gluing]. Let R be an integral perfectoid ring, $\overline{R} = R/\sqrt{pR}, S = R/R[\sqrt{pR}], \overline{S} = S/\sqrt{pS}$, then $\overline{R}, S, \overline{S}$ are perfectoids, and the square

$$\begin{array}{ccc} R & \longrightarrow & S \\ \downarrow & & \downarrow \\ \overline{R} & \longrightarrow & \overline{S} \end{array}$$

is both a homotopy fiber square(4.9.1.2) and pullback square. Moreover,

- S is p-torsionfree.
- $\sqrt{pR}$ maps isomorphically onto $\sqrt{pS}$.
- $R[\sqrt{pR}]$ maps isomorphically to $\ker(\overline{R} \to \overline{S})$, thus $x \mapsto x^p$ is bijective on $R[\sqrt{pR}]$.

In particular, any integral perfectoid ring is a fiber product of integral rings that is either perfect or p-torsionfree.

Proof: By(7.7.3.5), $R[\sqrt{pR}] = R[p^\infty]$. In particular, S is p-torsionfree. Now if we know this is a homotopy fiber square, then we get $2, 3$ by comparing the kernel. And if we know the kernel, then this is a pushout square by(4.1.1.23). So it suffices to show this is a homotopy fiber square.

Let $d = [a_0] - pu$ for a distinguished element of $A = A_{\inf}(R)$ that $R = A/(d)$, and the ideal $I = (a_0^{1/p^\infty}) \subset R^\flat$ and $J = R^\flat[I]$. Then the square

$$\begin{array}{ccc} W(R^\flat) & \longrightarrow & W(R^\flat/J) \\ \downarrow & & \downarrow \\ W(R^\flat/I) & \longrightarrow & W(R^\flat/I+J) \end{array}$$

is a homotopy fiber square: all vertices are p-torsionfree and p-adically complete, and the square gives a fiber square when modulo p^n(use induction on n and(4.5.1.8)), and then take derived p-completions. Next we apply**?** □

Cor. (7.7.3.10). Integral perfectoid rings are reduced.

Proof: By(7.7.3.9), we may assume R is p-torsionfree or perfect. Thus it suffices to assume R is p-torsionfree. Let $\varpi \in R$ that $\varpi^p = pu$ as in(7.7.3.6). If $x^p = 0$, we show inductively that $x \in \varpi^n R$. If $x = \varpi^n y$, then $y^p = 0$ as R is p-torsionfree. Now the kernel of Frobenius $\varphi : R/p \to R/p$ is generated by ϖ, thus we have $y \in \varpi R$, so we can use induction. □

4 Prismatic Site

Remark (7.7.4.1). In this subsection, fix a bounded prism (A, I), all formal schemes over A are assumed to have the (p, I)-adic topology, and formal schemes over A/I are assumed to have the p-adic topology.

Def. (7.7.4.2) [Prismatic Site]. Let (A, I) be a bounded prism and X be a smooth p-adic formal scheme over A/I, let $(X/A)_{\Delta}$ be the site whose objects are bounded prisms (B, IB) over (A, I) together with a map $\mathrm{Spf}(B/IB) \to X$ over A/I. The morphisms are the natural one, and the coverings in $(X/A)_{\Delta}$ are f.f. maps of prisms $(B, IB) \to (C, IC)$. There are structure sheaves $\mathcal{O}_{\Delta}((B, IB)) = B$ and $\overline{\mathcal{O}}((B, IB)) = B/IB$. They are sheaves by(7.7.1.12).

Thus $\mathcal{O}_{\Delta}$ is valued in (p, I)-complete δ-A-algebras and $\overline{\mathcal{O}}_{\Delta}$ is valued over p-complete-algebras(4.9.6.16).

Def. (7.7.4.3) [Perfect Prismatic Site]. The **perfect prismatic site** $(X/A)_{\Delta}^{\mathrm{perf}}$ is the full subcategory of $(X/A)_{\Delta}$ consisting of perfect prisms. By(7.7.3.3), objects in this site are equivalent to the category of perfectoid rings R over A/I with a map $\mathrm{Spf}\, R \to X$.

Remark (7.7.4.4). If we further restrict to the site of perfect prisms (S, I) that S/I is integrally closed in $S/i[\frac{1}{p}]$, then we will get the notion of diamond of $(X[\frac{1}{p}], X)$, in sense of[**?**].

Def. (7.7.4.5) [Absolute Prismatic Site]. For a p-adic formal scheme X the **absolute prismatic site** consisting of bounded prisms (B, J) with a map $\operatorname{Spf} B/J \to X$.

Prop. (7.7.4.6) [Prismatic Site and Étale Site]. Let $\mathcal{FS}\mathrm{ch}/X$ be the category of p-adic formal schemes over X with the étaletopology, then there is a natural functor $\mu : (X/A)_{\Delta} \to \mathcal{FS}\mathrm{ch}/X$ sending (B, IB) over X to $\operatorname{Spf} B/IB \to X$.

This functor is cocontinuous: for any p-completely étalemap $B/IB \to C$, it is a derived p-completion of some étalemap $B/IB \to \overline{C}'$ by(4.9.7.9), and this can be lifted to a map $B \to S'_C$ by(7.7.1.11)(4.3.10.6) and(4.3.10.9), and we choose the (p, I)-completion of S_C, then it is a prism that lifts C. Thus by(5.1.2.21) defines a morphism of topoi:

$$\mu : \mathcal{S}\mathrm{h}((X/A)_{\Delta}) \to \mathcal{S}\mathrm{h}(\mathcal{FS}\mathrm{ch}/X).$$

Also there is a natural map of topoi $\mathcal{S}\mathrm{h}(\mathcal{FS}\mathrm{ch}/X) \to \mathcal{S}\mathrm{h}(X_{\text{ét}})$ by restriction, by(4.9.7.1). So we get a morphism of topoi

$$\nu : \mathcal{S}\mathrm{h}((X/A)_{\Delta}) \to \mathcal{S}\mathrm{h}(X_{\text{ét}}).$$

In particular, for any étaleformal scheme U over X, by definition of ${}_s\mu$(5.1.2.11), for any sheaf $\mathcal{F}$,

$$(\nu_*\mathcal{F})(U/X) = H^0((U/A)_{\Delta}, \mathcal{F}|_{(U/A)_{\Delta}}).$$

Cor. (7.7.4.7) [Prismatic Complex and Hodge-Tate Complex]. In the above situation, we define **prismatic complexes**

$$\Delta_{X/A} = R\nu_*\mathcal{O}_{\Delta} \in D(X_{\text{ét}}, A)$$

and the **Hodge-Tate complex**

$$\overline{\Delta}_{X/A} = R\nu_*\overline{\mathcal{O}}_{\Delta} \in D(X_{\text{ét}}, \mathcal{O}_X).$$

The Frobenius action on $\mathcal{O}_{\Delta}$ induces a φ-semi-linear map $\Delta_{X/A} \to \Delta_{X/A}$. And there is a relation

$$\overline{\Delta}_{X/A} \cong \Delta_{X/A} \otimes^L_A A/I \in D(X_{\text{ét}}, A/I)$$

by the Grothendieck spectral sequences associated to the diagram of functors:

$$\begin{array}{ccc} \mathcal{M}\mathrm{od}((X/A)_{\Delta}, \mathcal{O}_{\Delta}) & \xrightarrow{-\otimes_{\mathcal{O}_{\Delta}}\overline{\mathcal{O}}_{\Delta}} & \mathcal{M}\mathrm{od}((X/A)_{\Delta}, \overline{\mathcal{O}}_{\Delta}) \\ \downarrow{\scriptstyle \Gamma((X/A)_{\Delta}, -)} & & \downarrow{\scriptstyle \Gamma((X/A)_{\Delta}, -)} \\ \mathcal{M}\mathrm{od}(X_{\text{ét}}, A) & \longrightarrow & \mathcal{M}\mathrm{od}(X_{\text{ét}}, A/I) \end{array}$$

Affine Case

Def. (7.7.4.8) [Situation]. In this subsubsection, fix a bounded prism (A, I) and a p-completely smooth(4.9.7.1) A/I-algebra R (or equivalently the p-adic completion of an étale$A$-algebra, by(4.9.7.9) and(4.9.6.16), and they define the same site by the universal property of completion).

Prop. (7.7.4.9) [Prismatic Site over Affine Formal Scheme]. The **prismatic site** of R relative to A, denoted by $(R/A)_{\Delta}$ is the site whose objects are bounded prisms over (A, I) together with an A/I-algebra map $R \to B/IB$. And it is endowed with the indiscrete topology(5.1.1.2), so sheaves on this site is just presheaves.

There are two natural sheaves on this site, $\mathcal{O}_{\Delta}$ maps a prism (B, IB) to B which is valued in (p, I)-complete δ-A-algebras, and $\overline{\mathcal{O}}_{\Delta}$ which maps a prism (B, IB) to B/IB which is valued in p-complete R-algebras(4.9.6.16)

Prop. (7.7.4.10) [Compare with Indiscrete Topology]. If $(X/A)'_{\Delta} \subset (X/A)_{\Delta}$ is a continuous map of sites that the former is endowed with the indiscrete topology, then it is a morphism of sites, by(5.1.2.14), so this induces a morphism of topoi

$$\mathcal{S}\mathrm{h}((X/A)_{\Delta}) \to \mathcal{S}\mathrm{h}((X/A)'_{\Delta})$$

by(5.1.2.20), then we have the Leray spectral sequence(5.3.1.9)

$$E_2^{p,q} = H^p(\mathcal{C}', R^q f_*(\mathcal{F}^\bullet)) \Rightarrow H^{p+q}(\mathcal{C}, \mathcal{F}^\bullet).$$

and by(5.3.1.7)(5.3.1.6) and(7.7.1.12), we have a natural isomorphism

$$R\Gamma((X/A)'_{\Delta}, \mathcal{F}) \to R\Gamma((X/A)_{\Delta}, \mathcal{F})$$

for $\mathcal{F} = \mathcal{O}_{\Delta}$ or $\overline{\mathcal{O}}_{\Delta}$.

How to Compute the Prismatic Complex in the Affine Case

Lemma (7.7.4.11) [Weakly Final Object]. Let (A, I) be a prism and let R be a p-completely smooth A/I-algebra, then the category $(R/A)_{\Delta}$ admits a weakly final object. Moreover, we can choose it to be flat over (A, I).

Proof: Let F_0 be the derived (p, I)-completion of a free δ-ring over A on the set R, then there is a surjection of A-algebras $F_0 \to R$, with kernel J derived (p, I)-complete**?**. Then(7.7.1.13) applied to the δ-ring (F_0, J) gives a prism (F, IF) over (A, I), and by construction it is an object of $(R/A)_{\Delta}$. And it is weakly final because of the universal properties of F_0(4.5.4.10) and F(7.7.1.13).

For the flatness, we temporarily call a δ-pair (B, J) **good** if

- B is (p, I)-completely flat over A and J is (p, I)-complete.
- the prismatic envelope is flat over (A, I) and its formation commutes with completed derived base change on a (p, I)-completely flat map $B \to B'$.

Then we need to show that (F_0, J) is good. We have the following observations:

- Good pairs are stable under filtered colimit in the category of δ-pairs (B, J) that J is derived (p, I)-complete. (Because filtered colimits of flat modules are flat(4.4.1.6).)
- If (B, J) is a δ-pair over A with B completely (p, I)-flat over A, and $B \to B'$ is a (p, I)-completely f.f. map that $(B', (JB')^\wedge)$ is good, then (B, J) is good. (This follows from(7.7.1.13) and the f.f. descent(7.7.1.13).)

Then we can write B as a filtered colimit of (p, I)-complete algebras $B_s \twoheadrightarrow R$, and the kernel of each of them is locally generate by a (p, I)-completely regular sequence, so we can use the observations to pass to f.f. localization and filtered colimit to show that (B, J) is good. Cf.[Prism, Scholze, 3.14].**?**
□

Lemma (7.7.4.12) [Products]. The category $(R/A)_{\Delta}$ admits products.

Proof: For δ-rings $B, C \in (R/A)_{\Delta}$, we can take the δ-ring colimit $D_0 = B \otimes_A C$(4.5.4.13), but it may not be compatible with R-actions. Instead, let J be the kernel of the natural map

$$D_0 \to D_0/ID_0 \to B/IB \otimes_{A/IA} C/IC \to B/IB \otimes_R C/IC,$$

then (D_0, J) is a δ-ring over (A, I), and then we can use(7.7.1.13) to get a prism (D, ID) over (A, I), then the maps $R \to B/IB \to D_0/ID_0 \to D/ID$ and $R \to C/IC \to D_0/ID_0 \to D/ID$ are equal(because they all factor through D/J), thus giving a product object in $(R/A)_{\Delta}$. □

Prop. (7.7.4.13) [Čech-Alexander Construction for Prismatic Cohomology]. By(5.3.1.20)(7.7.4.10) and the lemmas(7.7.4.11)(7.7.4.12) above, the prismatic complex $\Delta_{R/A}$ is represented by the complex

$$F^0 \to F^1 \to F^2 \to \ldots.$$

In particular, $F^0 = F$ as constructed in(7.7.4.11) and each F^n are (p, I)-completely A-flat, I-torsion-free and (p, I)-complete δ-rings by(7.7.1.11) and(7.7.1.14).

Moreover, this complex is the prismatic envelope functor applied to the Čech nerve of $A \to F_0$, w.r.t. the Čech nerve $F^\bullet$ of ideals $J^\bullet = \ker(F^\bullet \to F_0 \to R)$, because prismatic envelope is a left adjoint hence commutes with tensor product of pairs(7.7.1.13).

Cor. (7.7.4.14). $\Delta_{R/A}$ is derived (p, I)-complete and $\overline{\Delta}_{R/A}$ is derived p-complete, because each term of the complex $F^\bullet$ is derived (p, I)-complete, so does its cohomology groups(4.9.6.8), thus so does $\Delta_{R/A}$ itself. Similarly for $\overline{\Delta}_{R/A}$, because each term of $F^\bullet/I$ is p-complete(7.7.4.13) hence derived p-complete, by(4.9.6.16).

5 Hodge-Tate Comparison

Def. (7.7.5.1) [Breuil-Kisin Twist]. Let I be an invertible ideal of A, then for any A/I-module M, we define the **Breuil-Kisin twist** of M as $M\{n\} = M \otimes (I/I^2)^n$. Notice this definable for $n \in \mathbb{Z}$ because I/I^2 is an invertible $\mathcal{O}_{A/I}$-module, by definition(7.7.1.1). Also it is definable in the level of $D(A/I)$, as $(I/I^2)^n$ is locally free thus flat.

Def. (7.7.5.2)[Completed de Rham Complex]. The **completed de Rham complex** is the derived p-completion of the de Rham complex of $\Omega_{X/(A/I)}$. We will use the derived p-completed de Rham complex in the sequel. It has a property that it coincides with the p-completion of its separate terms by(4.9.7.8) and (4.9.6.16) and the fact $\Omega_{X/(A/I)}$ is finite projective hence flat(4.4.5.12).

In fact, as $\Omega_{X/S}$ is finite locally free, the derived p-completion is just by tensoring $- \otimes_{R_0} R$, where R_0 is a smooth A-algebra that $R_0^\wedge = R$ by(4.9.7.9). In particular, the completed de Rham complex is compatible with base change and p-completely étaleextension, because the ordinary de Rham complex does(4.4.3.6)(4.4.7.6).

Prop. (7.7.5.3) [Hodge-Tate Comparison Theorem]. We have a structure map $\eta^0 : \mathcal{O}_X \to H^0(\overline{\Delta}_{X/A})$, and $H^\bullet(\overline{\Delta}_{X/A})$ is a dga by(4.9.1.3) applied to $M^\bullet = \Delta_{X/A}$and(4.9.2.1) noticing $\overline{\mathcal{O}}_{\Delta}$ is a sheaf of algebras. then the universal property of de Rham complex(7.2.1.4) and lemma(7.7.5.4) shows η^0 extends to a map

$$\eta_R^\bullet : \Omega^\bullet_{X/(A/I)} \to H^\bullet(\overline{\Delta}_{X/A})\{\bullet\}$$

of sheaves of A/I-dgas on $X_{\text{ét}}$.

Then this is an isomorphism of differential graded A/I-algebra. In particular $\overline{\Delta}_{X/A} \in D(X_{\text{ét}}, A/I)$ is a perfect complex with $H^i(\overline{\Delta}_{X/A}) \cong \Omega^i_{X/(A/I)}\{-i\}$.

Proof: The proof of the isomorphism is given in(7.7.6.10). □

Lemma (7.7.5.4). For any local section $f \in \mathcal{O}_X(U)$, the differential $\beta_I(f) \in H^1(\overline{\Delta}_{X/A})\{1\}(U)$ squares to 0.

Proof: This follows from(7.7.6.9) in the affine line case because $H^2(\overline{\Delta}_{X/A})\{1\}(U) = 0$, and for the general case, use the étalelocalization(7.7.6.2) and base change theorem(7.7.6.1), noticing that cup product survives through derived tensor product. □

Cor. (7.7.5.5) [Base Change]. The formation of $\Delta_{X/A} \in D(X_{\text{ét}}, A)$ commutes with base change along a bounded prism $(A, IA) \to (B, IB)$: Let $g : X_B = X \otimes_{\mathrm{Spf}\, A/IA} \mathrm{Spf}\, B/IB \to X$ be the projection, then

$$(g^* \Delta_{X/A})^\wedge \cong \Delta_{X_B/B}, \quad (g^* \overline{\Delta}_{X/A})^\wedge \cong \overline{\Delta}_{X_B/B}$$

where $()^\wedge$ is the derived (p, I)-completion or p-completion.

Proof: Because both side are derived (p, I)-complete, we take their cylinder object and by derived Nakayama w.r.t. $B/(p, I)$(4.9.6.10) it suffices to show the second, which is true because this is true for completed de Rham complexes(7.7.5.2). □

6 Proof of Hodge-Tate Comparison

The strategy is as follows: we study the affine case to construct and prove the Hodge-Tate comparison isomorphism in the affine case, and then this gives the construction of Hodge-Tate map in the general case, then we can also prove the general Hodge-Tate comparison by localizing at affine subschemes, so the affine case is important.

To prove the Hodge-Tate comparison isomorphism in the affine case, we use étalelocalization to reduce to the polynomial case, and then use flat base change to reduce to the oriented case. Then we use a slick strategy to reduce to the crystalline case, and finally reduce to crystalline comparison.

Lemma (7.7.6.1) [Base Change]. Let R be a p-completely smooth A/I-algebra and $(A, I) \to (A', I')$ be a map of bounded prisms that $A \to A'$ has finite (p, I)-complete Tor amplitude(4.9.7.1). If $R' = R \widehat{\otimes}_A^L A'$ for the the base change, then the natural map induces an isomorphism

$$\Delta_{R/A} \widehat{\otimes}_A^L A' \cong \Delta_{R'/A'}, \quad \overline{\Delta}_{R/A} \widehat{\otimes}_A^L A' \cong \overline{\Delta}_{R'/A'}$$

Proof: We use the Čech nerve of a weakly final object (7.7.4.13) to compute the cohomology, then we notice the (p, I)-completed base change $-\widehat{\otimes}_A^L A'$ applied termwise to the Čech nerve of $A \to F^0$ is the Čech nerve of $A \to F^0 \widehat{\otimes}_A A'$, which is weakly final in $(R'/A')_{\Delta}$, by the universal property and the fact (p, I)-completed base change is a left adjoint.

Finally we use(4.9.7.8) to see that this termwise completed derived base change just represents $\Delta_{R/A} \widehat{\otimes}_A^L A'$ because each term of the prismatic envelope F is (p, I)-completely flat over A and the completed derived base change of F^n is discrete by(7.7.4.13). □

Lemma (7.7.6.2) [Étale Localization]. Let $R \to S$ be a p-completely étalemap of p-completely smooth algebras, then the natural map

$$\overline{\Delta}_{R/A} \widehat{\otimes}_R^L S \to \overline{\Delta}_{S/A}$$

is an isomorphism.

Proof: Firstly the forgetful functor $(R/A)_{\Delta} \to (S/A)_{\Delta}$ has a right adjoint, described as follows: a prims $(B, IB) \in (B/S)_{\Delta}$ induces a p-completely étalemorphism of (discrete)rings $B/IB \to B/IB \widehat{\otimes}_R^L S$ by(4.9.7.5), and by Elkik's algebrization(4.9.7.9), this is a derived p-completion of some étalemap $B/IB \to T_0$, and we can lift it to some étalemap $B \to S_0$ by Henselian pair property(4.9.6.12)(4.3.10.9), then we can also take the derived (p, I)-completion(discrete by(7.7.1.11))

S_B of S_0, then $S_B/IS_B \cong B/IB \otimes^L_R S$**?**. So we have the following base change diagram:

$$\begin{array}{ccccc} B & \longrightarrow & S_0 & \longrightarrow & S_B \\ \downarrow & & \downarrow & & \downarrow \\ B/IB & \longrightarrow & T_0 & \longrightarrow & B/IB\widehat{\otimes}^L_R S \end{array}$$

For the adjointness, it suffices for every prism (T, IT) with morphisms $B \to T, B/IB \otimes^L_R S \to T/IT$, we can lift to a map $S_B \to T$. But if we consider the p-completely étalemap $T \to T\widehat{\otimes}_B B_S$ and its base change, it suffices to find a section of this map, and this is by Henselian pair (T, IT)(4.3.10.6)(7.7.1.11)(4.3.10.9). Moreover, S_B has a δ-structure by(4.5.4.19) so it is clearly a prism, and the right adjoint F just takes $(T, IT) \to (S_B, IS_B)$.

This right adjoint preserves weakly final objects and products, and it is just the completed derived tensor $-\widehat{\otimes}^L_R S$ when modulo I by construction, so when combined with(4.9.7.8) we get the conclusion. □

Remark (7.7.6.3). Notice these two lemmas(7.7.6.1)(7.7.6.2) are consequences of Hodge-Tate comparison isomorphism, once we proved it!

Crystalline Comparison in Characteristic p

Prop. (7.7.6.4) [Crystalline Comparison in Characteristic p]. Let $(A, (p))$ be a crystalline prism and let $I \subset A$ be a pd-ideal with $p \in I$, in particular the Frobenius $A/p \to A/p$ factors through A/I by(4.6.0.3), inducing a map $\psi = \psi_I : A/I \to A/p$. Let R be a smooth A/I-algebra and let $R^{(1)} = R \otimes_{A/I,\psi} A/p$, then there is a canonical

$$\mathbb{\Delta}_{R^{(1)}/A} \cong R\Gamma_{\text{crys}}(R/A)$$

of E_∞-A-algebras compatible with Frobenius action.

Proof: **?** □

Cor. (7.7.6.5). If we have a smooth R over A/p and let $\widetilde{R} = R \otimes_{A/p} A/I$, then $\widetilde{R}^{(1)} = \varphi_* R$, and we can apply this theorem to $\widetilde{R}$ to get a canonical isomorphism

$$\varphi^* \mathbb{\Delta}_{R/A} \cong R\Gamma_{\text{crys}}(\widetilde{R}/A)$$

of E_∞-A-algebras compatible with Frobenius action.

Lemma (7.7.6.6) [Hodge-Tate Comparison for the Affine Line over $(\mathbb{Z}_p, (p))$]. If $(A, (p))$ is a p-torsionfree crystalline prism and $R = \mathbb{F}_p\langle X\rangle$, then the Hodge-Tate map constructed in(7.7.5.3) is an isomorphism.

Proof: WARNING: This proof will not use the construction of the Hodge-Tate map in degree> 1 and this lemma will be used in the proof of Hodge-Tate map in the general case, so there is no cycle in the reasoning.

The map

$$\Omega^\bullet_{R^{(1)}/(A/p)} \to H^*(R\Gamma_{\text{crys}}(R/A) \otimes^L_A A/p)\{*\} \cong H^*(\mathbb{\Delta}_{R^{(1)}/A} \otimes^L_A A/I)\{*\} = H^*(\overline{\mathbb{\Delta}}_{R^{(1)}/A})\{*\}$$

is an isomorphism by Cartier isomorphism**?**, where the middle is by prismatic-crystalline comparison(7.7.6.4).

It suffices to check this is the Hodge-Tate map for $R^{(1)}/(A/p)$. But the Hodge-Tate map is induces by the inclusion $\mathcal{O}_X \to H^0(\overline{\Delta}_{X/S})$. It is fairly easy to check the proof of(7.7.6.4) and(7.6.6.9) the composition is also the canonical one. Finally if we choose $\mathbb{F}_p\langle X\rangle = R = R^{(1)}$, then we get the desired Hodge-Tate isomorphism. □

Lemma (7.7.6.7) [Hodge-Tate Comparison for $(\mathbb{Z}_p,(p))$]. If $(A,(p))$ is a p-torsionfree crystalline prism and $R = \mathbb{F}_p[X_1,\ldots,X_n]$, then the Hodge-Tate map constructed in(7.7.5.3) is an isomorphism.

Proof: The proof is the same as that of(7.7.6.6), notice now we already have the Hodge-Tate Comparison map. □

Direct proof of the Hodge-Tate comparison for $(\mathbb{Z}_p,(p))$

The proof of(7.7.6.6) and(7.7.6.7) is sloppy because we somehow lose track of whether the composition morphism is the Hodge-Tate comparison map. As the situation is so explicit, we decided to give a direct proof.

Mix Characteristic Case

Prop. (7.7.6.8) [Comparing with the Characteristic p]. Let A be a universal oriented prism in any characteristic and $A \to B$ as in(7.7.1.5), let $\alpha : (A,(d)) \xrightarrow{\varphi} (A,(d)) \to (B,(p))$, then α is a map of prisms by(7.7.1.6), and:

1. α/p factors as $A/p \to A/(p,d) \xrightarrow{\varphi} A/(p,d^p) \to B/p = D_{A/p}((d))$ where the first map has finite Tor amplitude and the last two maps are f.f., thus α/p has finite Tor amplitude.
2. The functor $\widehat{\alpha^*} : D_{\mathrm{comp}}(A,(p,d)) \to D_{\mathrm{comp}}(B,(p))$ reflects isomorphisms.
3. For any p-completely smooth A/I-algebra R, let $R_B = R\widehat{\otimes}_A B$, then the map
$$\widehat{\alpha^*}\Delta_{R/A} \to \Delta_{R_B/B}$$
is an isomorphism.

Proof: 1: It factors because $d^p = p!\gamma_p(d) \in pB$, and $B/p = D_{A/p}((d))$ by(4.6.0.16), noticing $D_A((d)) = D_A((p,d))$. The first map is of finite Tor amplitude(4.9.7.1) because d is a nonzero-divisor in A/p by(7.7.1.4). φ is f.f. because it is a base change of $\varphi_{A/p}$ and the latter is f.f.(7.7.1.4). The last one is f.f. because it is a free summand as $D_{A/p}((d)) = A/p[X_1,X_2,\ldots]/(a^p,X_1^p,X_2^p,\ldots)$ by(4.6.0.20).

2: Because $D_{\mathrm{comp}}(A,I)$ is a weak Serre subcategory of $D(A)$(4.9.6.8), to show it reflects isomorphisms, by item1 and derived Nakayama applied to $-\otimes_B^L B/p$, it suffices to show if $X \in D_{\mathrm{comp}}(A,(p,d))$, if $X\otimes_A^L A/p \otimes_{A/p}^L A/(p,d) = 0$, then $X = 0$, but $X\otimes_A^L A/p\otimes_{A/p}^L A/(p,d) = X\otimes_A^L A/(p,d)$, and this follows from derived Nakayama again.

3: α has finite (p,d) Tor amplitude by(4.9.7.3) and(7.7.1.4), so 3 follows from(7.7.6.1). □

Final Proof

Prop. (7.7.6.9) [Hodge-Tate Comparison in the Affine Line Case]. In situation(7.7.4.8), If $R = A/I\langle X\rangle$, $\eta_R^0 : R \to H^0(\overline{\Delta}_{R/A})$ and the twisted morphisms $\eta_R^1\{-1\} : \Omega^1_{R/(A/I)}\{-1\} \to H^1(\overline{\Delta}_{R/A})$ defined by the universal property of $\Omega_{R/(A/I)}$ are isomorphisms, and $H^i(\overline{\Delta}_{R/A}) = 0$ for $i > 1$.

In particular, by étalelocalization of prismatic cohomology(7.7.6.2), lemma(7.7.5.4) holds for any p-completely smooth algebra R over A/I. But this doesn't say that higher cohomologies vanish for any R, this is because cup product can survive derived tensor but cohomology groups cannot.

Proof: In this case, $\Omega_{R/S}$ is topologically free over R, thus we can choose a map

$$\eta : R \oplus \Omega^1_{R/A}\{-1\}[-1] \to \overline{\mathbb{\Delta}}_{R/A}$$

lifting $\eta^0_R \oplus \eta^1_R\{-1\}$.

Firstly if $(A, I) = (\mathbb{Z}_p, (p))$, this case is done by(7.7.6.6).

Next, if $(A, (d))$ is oriented, then there is a map of prisms from the universal oriented prism(7.7.1.4) $A_0 \to A$, then we have a pushout diagram of simplicial commutative rings

$$\begin{array}{ccccc} & & A_0 & \longrightarrow & A \\ & & \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\beta} \\ \mathbb{Z}_p & \longrightarrow & D_0 & \longrightarrow & E = A\widehat{\otimes}^L_{A_0} D_0 \end{array}$$

and $(E, (p))$ is a simplicial prism.

Now the warning is what we have done so far can all be extended to the derived algebraic geometry setting, or at least to the "animated commutative algebra" setting!

We denote the composite of the lower row as γ, because $\widehat{\alpha^*}$ reflects isomorphisms, so does $\widehat{\beta^*}$, and we can show $\widehat{\beta^*}\overline{\mathbb{\Delta}}_{R/A} \cong \widehat{\gamma^*}\overline{\mathbb{\Delta}}_{\mathbb{F}_p\langle X\rangle/\mathbb{Z}_p}$, and identifies the Hodge-Tate map: This is because we are in the polynomial case, so we can make the construction of $\mathbb{\Delta}_{R/A}$ clear: we just take the F^0 to be the derived (p, I)-completion of the free δ-rings $A\{X\}$ in the construction of weakly final object(7.7.4.11), then the resulting Čech-Alexander complex is free and compatible with base change in the complex level.

Also β has finite (p, d)-Tor amplitude because α has because (p, d) is regular in A_0(7.7.1.4), also γ has finite p-Tor amplitude because E is p-torsionfree by(7.7.1.11), and use(4.9.7.3). So we are reduced to the $(\mathbb{Z}_p, (p))$ case, which we have done.

Finally, for a general bounded prism (A, I), we can reduce to the oriented case by base change along the f.f. extension defined in(7.7.1.11), then we reduce to the orientable case by(7.7.6.1). □

Prop. (7.7.6.10) [Hodge-Tate Comparison Theorem in General]. The map

$$\eta^\bullet_R : \Omega^\bullet_{X/(A/I)} \to H^\bullet(\overline{\mathbb{\Delta}}_{X/A})\{\bullet\}$$

constructed in(7.7.5.3) is an isomorphism of sheaves of A/I-dgas on $X_{\text{ét}}$.

Proof: Because we already have the Hodge-Tate comparison map, it suffices to prove the theorem for affine subscheme Spf R, and because both prismatic cohomology and de Rham complex are étale-local(7.7.6.2)(7.7.5.2), it suffices to prove for the polynomial case. In this case, $\widehat{\Omega}^i_{R/A}$ is topological free over R, then we can lift the Hodge-Tate map(7.7.5.3) to the level of chain complexes:

$$\eta : \otimes_{i=0}^n \Omega^i_{R/(A/I)}\{-i\}[-i] \to \overline{\mathbb{\Delta}}_{R/A}.$$

And then the rest is the same as the proof of(7.7.6.9), where in the $(\mathbb{Z}_p, (p))$ case, we use(7.7.6.7) instead of(7.7.6.6). □

de Rham Comparisons

Prop. (7.7.6.11)[de Rham Comparison]. In situation(7.7.4.2), if $W(A/I)$ is p-torsionfree, then there is a natural isomorphism

$$\Delta_{X/A}\widehat{\otimes}^L_{A,\varphi}A/I\cong\Omega^\bullet_{X/(A/I)}$$

of commutative algebra objects in $D(A/I)$.

Proof: Cf.[Sholze, Prism, 6.4].

It suffices to construct locally a functorial isomorphism $\Delta_{R/A}\widehat{\otimes}^L_{A,\varphi}A/I\cong\Omega^*_{R/(A/I)}$ and then glue.

Let $A\to W(A/I)$ be the canonical map, and $\psi:A\xrightarrow{\varphi}A\to W(A/I)$, then it takes I into (p)**?**. But the map $\psi/p:A/I\to W(A/I)/p=A/I$ factors through $A/(p,I)$, thus R' also equals $R/p\otimes_{A/(p,I)}W(A/I)/p$, so there is a base change diagram:

$$\begin{array}{ccccc} R & \longrightarrow & R/p & \longrightarrow & R^{(1)}=R\otimes_{A/I,\psi}W(A/I)/p \\ \uparrow & & \uparrow & & \uparrow \\ A/I & \longrightarrow & A/(p,I) & \xrightarrow{\psi_{(p,[p])}} & W(A/I)/p=A/I \end{array}$$

Base change for prismatic cohomology(7.7.5.5) gives an isomorphism

$$\Delta_{R/A}\widehat{\otimes}^L_{A,\psi}W(A/I)\cong\Delta_{R'/W(A/I)}.$$

Note that $W(A/I)\to A/(p,I)$ is a pd-thickening with ideal $(p,[p])$**?**, so we can use crystalline comparison w.r.t. the crystalline prism $(W(A/I),(p))$**?** to show that

$$\Delta_{R^{(1)}/W(A/I)}\cong R\Gamma_{\text{crys}}((R/p)/W(A/I)).$$

Then finally we use the crystalline de Rham comparison**?** to get the desired result. □

Remark (7.7.6.12). The technical condition $W(A/I)$ is p-torsionfree can be removed, by [Scholze, Prism, 15.4].

7 Derived de Rham Cohomology

Def. (7.7.7.1) [Derived de Rham Cohomology]. For an $\mathbb{F}_p$-algebra k, the **derived de Rham cohomology** functor $dR_{-/k}:\mathcal{CA}\mathrm{lg}/k\to D(k)$ is the left derived functor of the functor $\mathcal{P}\mathrm{oly}_k\to D(k)$ given by $R\to\Omega^\bullet_{R/k}$ via(4.8.4.2).

Prop. (7.7.7.2) [Derived Cartier Isomorphism].

Regular Semiperfect Rings

Def. (7.7.7.3) [Regular Semiperfect Rings]. Let k be a perfect ring, a **regular semiperfect ring** over k is an k-algebra of the form R/I where R is a perfect k-algebra and I is an ideal generated by a regular sequence.

Prop. (7.7.7.4). Let k be a perfect field and S be a regular semiperfect ring, then

8 Derived Prismatic Cohomology

Prop. (7.7.8.1) [Derived Hodge-Tate Comparison].

9 q-de Rham Cohomology

Prop. (7.7.9.1) [Hodge-Tate isomorphism via q-de Rham Complex]. Cf.[Bhatt, Prism, 5.3.9.].

10 Étale Comparison

Prop. (7.7.10.1) [Frobenius Fixed Points]. Fix an $\mathbb{F}_p$-algebra B with an element t, let $D(B[F])$ be the **derived category of Frobenius B-modules**: this is a category whose objects are (M, φ) where $M \in D(B)$ and φ is a morphism $M \to M \otimes^L_{B,\varphi} B$ in $D(B)$. And let $D_{\mathrm{comp}}(B[F])$ be the full subcategory spanned by pairs (M, φ) where $M \in D_{\mathrm{comp}}(B, (t))$(4.9.6.4).

Given $(M, \varphi) \in D_{\mathrm{comp}}(B[F])$, let $M^{\varphi=1} = R\operatorname{Hom}_{D(B[F]}((B, \varphi), (M, \varphi)) \in D(F_p)$**?**, called the **Frobenius fixed pts** of M.

Prop. (7.7.10.2). Fix an $\mathbb{F}_p$-algebra B with an element t, then

- The functor $D_{\mathrm{comp}}(B[F]) \to D(\mathcal{F}_p)$ given by $M \to M^{\varphi=1}$ and $M \mapsto (M[t^{-1}])^{\varphi=1}$ commute with colimits.
- For any $(M, \varphi) \in D_{\mathrm{comp}}(B[F])$ and

Main references are [Sta]Chap45, [Ful98], [Kle94], [Mil12] and [Lectures on Pure Motives, Murre]. [Jannsen, Uwe Motivic sheaves and filtrations on Chow groups. Motives (Seattle, WA, 1991), 245–302, Proc. Sympos. Pure Math., 55, Part 1, Amer. Math. Soc., Providence, RI, 1994.], [Jannsen, Uwe Equivalence relations on algebraic cycles. The arithmetic and geometry of algebraic cycles (Banff, AB, 1998), 225–260, NATO Sci. Ser. C Math. Phys. Sci., 548, Kluwer Acad. Publ., Dordrecht, 2000], [Jannsen, Uwe Mixed motives and algebraic K-theory. With appendices by S. Bloch and C. Schoen. Lecture Notes in Mathematics, 1400. Springer-Verlag, Berlin, 1990. xiv+246 pp. ISBN: 3-540-52260-3].

Notation (7.8.0.1).

- Let $k \in \mathtt{Field}$.

1 Correspondences

Def. (7.8.1.1). The full subcategory of $\mathcal{S}\mathrm{ch}/k$ consisting of smooth projective schemes over k is denoted by $\mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$.

Any $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$ has a decomposition $X = \coprod_n X_n$ into clopen subschemes that X_n is equidimensional of dimension n by(7.1.2.28). Thus we can talk about Rings $\mathrm{CH}^*(X)$ and $GH^*(X)$(7.1.2.29).

Def. (7.8.1.2) [Adequate Equivalent Relations of Cycles]. An **adequate equivalent relation** on cycles is an equivalence relation on $Z^*(X)$ for each $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$ s.t.

- it is compatible with gradings and additions.
- it is compatible with products: $Z \sim 0 \implies Z \times Y \sim 0$.
- it is compatible with intersections: $Z_1 \sim 0 \implies Z \cdot W = 0$.
- it is compatible with projections: If $Z \sim 0 \in Z^*(X \times Y) \implies (\mathrm{pr}_X)_*(Z) \sim 0$.
- it satisfies moving lemma: Given $Z, W_1, \ldots, W_\ell \in Z^*(X)$, there exists $Z' \sim Z$ s.t. Z' and W_i intersect properly for any i.

Def. (7.8.1.3) [(Rational)Correspondences]. Let $X, Y \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$ the group of (rational)**correpondences** from X to Y of degree(codimension) $r \in \mathbb{Z}$ is defined to be

$$\mathrm{Corr}^r_{\mathrm{rat}}(X, Y) = \bigoplus_d \mathrm{CH}^{d+r}(X_d \times_k Y)_{\mathbb{Q}} \subset \mathrm{CH}^*(X \times Y)_{\mathbb{Q}}.$$

Similarly we can define the groups of **Grothendieck correspondences** $\mathrm{Corr}^r_{\mathrm{num}}(X, Y)$.

Def. (7.8.1.4) [Compositions of Correspondences]. Let $X, Y, Z \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$, there is a **composition of correspondences** map

$$\mathrm{Corr}^s(Y, Z) \times \mathrm{Corr}^r(X, Y) \to \mathrm{Corr}^{r+s}(X, Z) : (c', c) \mapsto c' \circ c = \mathrm{pr}_{13*}(\mathrm{pr}_{23}^* c' \cdot \mathrm{pr}_{12}^* c').$$

Then composition of correspondences are $\mathbb{Q}$-linear and associative.

Proof: Cf.[Sta]0FG0. □

Prop. (7.8.1.5) [Tensor Product of Correspondences]. Let $X, Y, X', Y' \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$, there is a **tensor product of correspondences** map

$$\otimes : \mathrm{Corr}^r(X,Y) \times \mathrm{Corr}^s(X',Y') \to \mathrm{Corr}^{r+s}(X \times_k X', Y \times_k Y') : (c, c') \mapsto \mathrm{pr}_{13}^*(c) \cdot \mathrm{pr}_{24}^*(c').$$

which is $\mathbb{Q}$-linear and associative, and commutes with compositions in both coordinates.

Prop. (7.8.1.6). $\mathrm{Corr}^0(\mathbb{P}^1_k) = \mathrm{CH}^1(\mathbb{P}^1_k \times \mathbb{P}^1_k)_{\mathbb{Q}} \cong \mathbb{Q} \oplus \mathbb{Q}$, where a basis is given by $c_0 = [\{0\} \times \mathbb{P}^1]$ and $c_2 = [\mathbb{P}^1 \times \{0\}]$. And the diagonal $\Delta = c_0 + c_2$.

Also $c_0 \circ c_0 = c_0, c_2 \circ c_2 = c_2, c_0 \circ c_2 = 0 = c_2 \circ c_0$, so $\mathrm{Corr}^0(\mathbb{P}^1_k) \cong \mathbb{Q} \oplus \mathbb{Q}$ as a $\mathbb{Q}$-algebra.

Def. (7.8.1.7) [Push and Pull via Correspondences]. Let $c \in \mathrm{Corr}^r_{\mathrm{rat}}(X,Y)$, we can define the

- (Pullback): $\mathrm{CH}_k(Y) \to \mathrm{CH}_{k-r}(X) : \beta \mapsto c^*(\beta) = \mathrm{pr}_{1,*}(c \cdot \mathrm{pr}_2^* \beta)$.
- (Pushforward): $\mathrm{CH}^k(X) \to \mathrm{CH}^{k+r}(Y) : \alpha \mapsto c_*(\alpha) = \mathrm{pr}_{2,*}(c \cdot \mathrm{pr}_1^* \alpha)$.

by using stratification and (7.1.2.12)(7.1.2.9).

Prop. (7.8.1.8) [Correspondences and Chow Groups].

- There are canonical isomorphisms

  $$\mathrm{CH}_{-r}(X)_{\mathbb{Q}} \cong \mathrm{Corr}^r_{\mathrm{rat}}(X, \mathrm{Spec}\, k)$$

  s.t. pullbacks by correspondences correspond to compositions.
- There are canonical isomorphisms

  $$\mathrm{CH}^r(X)_{\mathbb{Q}} \cong \mathrm{Corr}^r_{\mathrm{rat}}(\mathrm{Spec}\, k, X)$$

  s.t. pushforwards by correspondences correspond to compositions.

Proof: Cf.[Sta]0FG0. □

Cor. (7.8.1.9). Pushforwards and pullbacks by correspondences commute with compositions, by(7.8.1.8) and(7.8.1.4).

Prop. (7.8.1.10) [Graphs]. Let $f : X \to Y \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$, its transposed graph Γ_f^t defines a correspondence $[\Gamma_f^t] \in \mathrm{Corr}^0(Y,X)$. $[\Gamma_{\mathrm{id}_X}] \in \mathrm{Corr}^0(X,X)$ is denoted by $[\Delta_X]$.

Def. (7.8.1.11) [Transpose]. Let $X, Y \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$ be equidimensional, then the isomorphism $X \times_k Y \cong Y \times_k X$ induces a **transpose isomorphism**

$$(-)^t : \mathrm{Corr}^r(X,Y) \to \mathrm{Corr}^{\dim X - \dim Y + r}(Y,X).$$

In particular, when $f : X \to Y \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$ and X, Y are equidimensional, then $[\Gamma_f^t]^t = [\Gamma_f]$.

Prop. (7.8.1.12). Let $\alpha \in \mathrm{Corr}^*(X,Y), \beta \in \mathrm{Corr}^*(Y,Z)$, then

1. $(\beta \circ \alpha)^t = \alpha^t \circ \beta^t$.
2. If $\beta = [\Gamma_g^t]$, then $\beta \circ \alpha = (\mathrm{id}_X \times g)^! \alpha$.
3. If $\alpha = [\Gamma_f^t]$, then $\beta \circ \alpha = (f \times \mathrm{id}_Z)_* \beta$.
4. If $\alpha = [\Gamma_f^t], \beta = [\Gamma_g^t]$, then $\beta \circ \alpha = [\Gamma_{fg}^t]$.
5. $\Delta_Y \circ \alpha = \alpha, \quad \beta \circ \Delta_Y = \beta$.

Proof: 1: This follows from commutativity and naturality of intersection products.

2: By(7.1.4.6) and(7.1.8.9),

$$[\Gamma_g^t]\circ\alpha = \mathrm{pr}_{13*}(\mathrm{pr}_{23}^*[\Gamma_g^t]\cdot \mathrm{pr}_{12}^*\alpha) = \mathrm{pr}_{13*}(1,g,1)_*((1,g,1)^!\,\mathrm{pr}_{12}^!\,\alpha) = (1,g)^!\alpha.$$

3 is similar to item2.

4, 5 follow from item2, 3. □

Prop. (7.8.1.13) [Push and Pull by Graphs]. Let $f : X \to Y \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/k$, then

- Pushforward by $[\Gamma_f]^t$ agrees with the Gysin map $f^! : \mathrm{CH}^*(Y) \to \mathrm{CH}^*(X)$.
- Pullback by $[\Gamma_f]^t$ agrees with the pushforward $f_* : \mathrm{CH}_*(X) \to \mathrm{CH}_*(Y)$.

Proof: These follows from(7.8.1.8) and(7.8.1.12). □

Prop. (7.8.1.14). Let $f : Y \to X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/k$ where X, Y are equidimensional, then there are commutative diagram of correspondences

$$\begin{array}{ccccc} X\times Y & \xrightarrow{[\Gamma_f^t]\otimes\Delta_Y} & Y\times Y & \xrightarrow{[\Gamma_{\Delta_Y}^t]} & Y \\ \big\downarrow{\scriptstyle \Delta_X\otimes[\Gamma_f]} & & & & \big\downarrow{\scriptstyle [Y]} \\ X\times X & \xrightarrow{[\Gamma_{\Delta_X}^t]} & X & \xrightarrow{[X]} & \mathrm{Spec}\,k \end{array}$$

Proof: By(7.8.1.12), it suffices to show that $(\mathrm{id}_X\times f)^!(\Delta_X)_*[X] = (f\times \mathrm{id}_Y)_*(\Delta_Y)_*[Y]$. But both sides equal $[\Gamma_f^t]$. $((\mathrm{id}_X\times f)^![\Delta_X] = [\Gamma_f^t]$ follows from [Sta]0FF7?). □

Prop. (7.8.1.15) [Virtual Number of Coincidences]. Let $X, Y \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/k, \alpha, \beta \in \mathrm{Corr}^*(X, Y)$, then

$$\mathrm{pr}_{1*}(\alpha\cdot\beta) = (\beta^t\circ\alpha)\cdot\Delta_X = (\alpha^t\circ\beta)\cdot\Delta_X.$$

In particular, if X, Y are equidimensional of dimension n, and $\alpha, \beta \in \mathrm{Corr}^0(X, Y)$, then the **virtual number of coincidence** of α and β, defined as $\int_{X\times Y}\alpha\cdot\beta$, equals the virtual number of fixed points of $\beta^t\circ\alpha$.

Proof: Cf.[Ful98]P309. □

Def. (7.8.1.16) [Degenerate Correspondences]. Let $X, Y \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/k$, then the subgroup of **degenerate correspondences** from X to Y is the subgroup of $\mathrm{Corr}^*(X, Y)$ generated by exterior products $\mathrm{CH}^*(X)\times\mathrm{CH}^*(Y)$(7.1.8.3). The subgroup of degenerate correspondences from X to Y is denoted by $I(X, Y)$.

Then $I(X, X)$ is a two-sided ideal in $\mathrm{Corr}^*(X, X)$, and is stable under transpose if X are equidimensional.

Def. (7.8.1.17) [Valence]. Let $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}^n\,/k$, then $\alpha \in \mathrm{Corr}^0(X, X)$ is said to be of **valence** ν iff $\alpha + \nu[\Delta_X] \in I(X, X)$.

Def. (7.8.1.18) [Degree of Correspondences]. Let $X, Y, Z \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}^n\,/k$ be irreducible, then for $\alpha \in \mathrm{Corr}^n(X, Y)$, the **degrees of** α is defined to

$$\alpha_*[X] = \mathrm{pr}_{2*}(\alpha) = d_2(\alpha)[Y],\quad \alpha^*[Y] = \mathrm{pr}_{1*}(\alpha) = d_1(\alpha)[X].$$

Then

- Let $\beta \in \mathrm{Corr}^n(Y, Z)$, then $d_i(\beta\circ\alpha) = d_i(\alpha)d_i(\beta)$.
- If $P \subset X$ is a rational point, then $d_1(\alpha) = \int_{X\times Y}\alpha\cdot[P\times Y]$.

Proof: 1 is clear. 2 follows by composing with the correspondence $[\Gamma_P] \in \mathrm{Corr}^{-n}(P, X)$. □

2 Weil Cohomology Theories

Pre-Weil Cohomology Theories

Prop. (7.8.2.1) [Non-Existence of a $\mathbb{Q}$-Cohomology Theory]. For any $p \in \mathbf{P} \cup \{0\}$, there exists an alg.closed field of characteristic p s.t. there doesn't exists a cohomology theory on the category of smooth projective varieties over k with coefficients in $\mathbb{Q}$ that specializes to the étale cohomology with $\mathbb{Q}_\ell$ coefficients, where $\ell \in \mathbf{P} \cap \{\mathbf{p}\}$.

Proof: For $p = 0$, take $k = \mathbb{C}$. For a smooth projective variety X over k, it is defined over a subfield k_0 finite over $\mathbb{Q}$. Let $\Gamma = \mathrm{Gal}(k/k_0)$, then Γ acts on $H^*(X, \mathbb{Q}_\ell)$. If $H^*(X, \mathbb{Q}_\ell)$ is specialized from a $\mathbb{Q}$-cohomology $\widetilde{H}^*(-, \mathbb{Q})$, then the continuous Γ-action on $H^*_{\text{ét}}(X, \mathbb{Q}_\ell)$ stablizes $\widetilde{H}^*(X, \mathbb{Q})$. But it is known that

$$H^*_{\text{ét}}(X, \mathbb{Q}_\ell) \cong H^*_{\text{Betti}}(X, \mathbb{Q}) \oplus \mathbb{Q}_\ell,$$

so $\dim_{\mathbb{Q}} \widetilde{H}^*(X, \mathbb{Q}) = \dim H^*_{\text{Betti}}(X, \mathbb{Q}) < \infty$. Then because infinite Galois group is uncountable, Γ acts $\widetilde{H}^*(X, \mathbb{Q})$ through a finite quotient. But this is not true in general.**?** In fact, This contradicts Tate's conjecture.

If $p > 0$, let $k = \overline{F}_p$ and E be an supersingular elliptic curve over $\overline{k}$, which exists by(13.9.3.12), then $\mathrm{End}(E) \otimes \mathbb{Q}$ is a definite quaternion algebra Q over $\mathbb{Q}$, and $\dim_{\mathbb{Q}_\ell} H^1_{\text{ét}}(E, \mathbb{Q}_\ell) = 2$(13.5.6.15), so if $H^*(X, \mathbb{Q}_\ell)$ is specialized from a $\mathbb{Q}$-cohomology $\widetilde{H}^*(-, \mathbb{Q})$, $\dim_{\mathbb{Q}} \widetilde{H}^1(E, \mathbb{Q}) = 2$, and $\mathrm{End}(E) \otimes \mathbb{Q}$ acts on it. But there is no ring homomorphism $Q \to M_2(\mathbb{Q})$. □

Def. (7.8.2.2) [Weil Cohomology Theories]. Let $k, F \in \texttt{Field}$, $\mathrm{char}\, F = 0$, then a **pre-Weil cohomology theory** over k with coefficients in F is given by a tuple $(F(1), H^*, \gamma, \mathrm{tr})$, where

- $F(1)$ is a 1-dimensional vector space over F. And denote $F(n) = F(1)^{\otimes n}$, $F(-n) = F(n)^*$, and for any $V \in \mathcal{V}\mathrm{ect}_F$, define $V(n) = V \otimes F(n)$.
- H^* is a functor $H^* : \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/k \to \mathcal{CR}\mathrm{ing}^{\mathrm{gr}}\,/F$. $H^*(X)$ is called the **cohomology ring of** X, and its multiplication is denoted by $\cup$.
- For every $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/k$ and $i \in \mathbb{N}$, γ_X is a homomorphism $\gamma_X : \mathrm{CH}^i(X) \to H^{2i}(X)(i)$, called the **cycle class maps** of X.
- For any $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}^d\,/k$, tr_X is a map $\mathrm{tr}_X : H^{2d}(X)(d) \to F$, called the **trace map** of X. The trace map is sometimes also denoted by $\int_X$.

that satisfy the following properties:

Poincaré duality: For any $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}^d\,/k$,

1. $\dim_F H^i(X) < \infty$ for any i and $H^i(X) = 0$ unless $0 \le i \le 2n$.
2. $H^i(X) \otimes_F H^{2d-i}(X)(d) \xrightarrow{\cup} H^{2d}(X)(d) \xrightarrow{\mathrm{tr}_X} F$ is a perfect pairing.

Künneth formula: For any $X, y \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/k$,

$$H^*(X) \otimes_F H^*(Y) \to H^*(X \times_k Y) : (a, b) \mapsto \mathrm{pr}_1^* a \cup \mathrm{pr}_2^* b$$

is an isomorphism in $\mathcal{CR}\mathrm{ing}^{\mathrm{gr}}\,/F$.

Cycle class map is natural:

1. For any $f : X \to Y \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/k$, $\gamma(f^!\beta) = f^*\gamma(\beta)$ for $\beta \in H^*(Y)$ and $\gamma(f_*\alpha) = f_*\gamma(\alpha)$ for $\alpha \in H^*(X)$.
2. $\gamma(a \cdot b) = \gamma(a) \cup \gamma(b)$.
3. $\int_{\mathrm{Spec}\, k} \gamma(\mathrm{Spec}\, k) = 1$.

H^* is called a **Weil cohomology theory** if moreover it satisfies:

- For $X \in \mathcal{S}m\mathcal{P}roj/k$ and $\Gamma(X, \mathcal{O}_X) = k'$, then the natural map $H^0(\operatorname{Spec} k') \to H^0(X)$ is an isomorphism.

Prop. (7.8.2.3) [Pushforward]. Let $k, F \in$ `Field` and H^* be a pre-Weil cohomology theory, for $f : X \to Y \in \mathcal{S}m\mathcal{P}roj/k$ where $\dim X = d, \dim Y = e$, we can define a **pushforward map of cohomology** $H^{2d-*}(X)(d) \to H^{2e-*}(Y)(e)$ via Poincaré duality, i.e.

$$\int_X f^* b \cup a = \int_Y b \cup f_* a$$

for any $a \in H^{2d-i}(X)(d), b \in H^i(Y)$. Then

- $f_*(f^* b \cup a) = b \cup f_* a$.
- $g_* f_* = (gf)_*$.

Proof: Use duality and the corresponding properties of f^*. □

Prop. (7.8.2.4)[$H^*(\operatorname{Spec} k)$]. Let $k, F \in$ `Field` and H^* be a pre-Weil cohomology, then $H^i(\operatorname{Spec} k) = 0$ unless $i = 0$, and there is a unique F-algebra isomorphism $H^0(\operatorname{Spec} k) \cong F$, sending $\gamma([\operatorname{Spec} k])$ to 1 and $\operatorname{tr}_{\operatorname{Spec} k}$ is identity under this identification.

Proof: Cf.[Sta]0FHE. □

Prop. (7.8.2.5) [Coproducts]. Let $k, F \in$ `Field` and H^* be a pre-Weil cohomology, then for $X, Y \in \mathcal{S}m\mathcal{P}roj/k$, $H^*(X \coprod Y) \to H^*(X) \times H^*(Y)$ is an isomorphism.

Proof: Cf.[Sta]0FHJ. □

<u>**Weil Cohomology Theories**</u>

Prop. (7.8.2.6) [Characterizing Weil Cohomology Theories]. Let $k, F \in$ `Field` and H^* be a pre-Weil cohomology theory, for $X \in \mathcal{S}m\mathcal{P}roj/k$ and $\Gamma(X, \mathcal{O}_X) = k'$, the following are equivalent:

- There exists f.m. geometric points $x_1, \ldots, x_r \in X$ s.t. $H^0(X) \to H^0(x_1) \oplus \ldots H^0(x_r)$ is injective.
- The map $H^0(\operatorname{Spec} k') \to H^0(X)$ is an isomorphism.

If these hold, then $H^0(X)$ is finite étale over F. Moreover, if X is equidimensional of dimension d, then these are further equivalent to

- The classes of closed points of X generate $H^{2d}(X)(d)$ as a module over $H^0(X)$.

Prop. (7.8.2.7) [Non-negativeness]. Let $k, F \in$ `Field` and H^* be a Weil cohomology theory, then for any $Y \in \mathcal{S}m\mathcal{P}roj/k$, $H^i(Y) = 0$ for $i < 0$.

Proof: If $H^i(Y) \neq 0$ for some $Y \in \mathcal{S}m\mathcal{P}roj/k$ and $i < 0$, we may assume Y is irreducible by(7.8.2.5), and also we may assume $i = -2j$ is even by changing Y to $Y \times Y$ using Künneth formula. Then take $X = Y \times (\mathbb{P}^1_k)^j$, then Künneth formula shows

$$H^0(Y) \oplus H^i(Y) \otimes H^2(\mathbb{P}^1_k)^{\otimes l} \subset H^0(X),$$

so $H^0(X)$ cannot be isomorphic to $H^0(\operatorname{Spec} \Gamma(X, \mathcal{O}_X)) = H^0(\operatorname{Spec} \Gamma(Y, \mathcal{O}_Y)) \cong H^0(Y)$. □

Prop. (7.8.2.8). ? Let $k, F \in$ `Field` and H^* be a Weil cohomology theory, then

- If $X \in \mathcal{S}m\mathcal{P}roj^d/k$, then $\mathrm{tr}_X \circ \gamma = \deg : \mathrm{CH}^d(X) \to F$(7.1.2.27).
- If $X, Y \in \mathcal{S}m\mathcal{P}roj/k$, then $\mathrm{tr}_{X\times_k Y} = \mathrm{tr}_X \otimes \mathrm{tr}_Y$ via Künneth formula(7.8.2.2). In particular, for $a \in H^{2\dim X}(X)(\dim X), b \in H^*(\dim Y)$, $\mathrm{pr}_{2,*}(a\otimes b) = (\int_X a)b \in H^*(Y)$.

Proof: 1: This holds for $X = \operatorname{Spec} k$ by hypothesis, and also for any other $x \in X(k)$ by pushforward.

2: For any $x \in X(k), y \in Y(k)$, by item1, $\gamma([x\times y]) \in H^{\mathrm{top}}(X\times Y)$ is mapped to $1 \in F$ via $\mathrm{tr}_{X\times Y}$, and it equals $\gamma([x])\otimes\gamma([y])$ by(7.8.2.2) as $[a\times b] = \mathrm{pr}_1^!(a)\cdot \mathrm{pr}_2^!(b)$. The latter is also mapped to $1 \in F$ by $\mathrm{tr}_X \otimes \mathrm{tr}_Y$.

For the last assertion, notice $\int_Y \mathrm{pr}_{2,*}(a\otimes b)\cup c = \int_{X\times Y}(a\otimes b)\cup(1\otimes c) = (\int_X a)\int_Y(b\cup c)$ □

Prop. (7.8.2.9). If $Z \in \mathrm{CH}^*(X)$ satisfies mZ is algebraically trivial for some $m \in \mathbb{Z}^*$, then $\gamma_X(Z) = 0$.

Proof: Cf.[Algebraic Cycles and the Weil Conjecture, Kleiman, Prop1.2.1]. □

Prop. (7.8.2.10)[Lefschetz Trace Formula]. Let $k, F \in \mathtt{Field}$ and H^* be a Weil cohomology theory, then for $X \in \mathcal{S}m\mathcal{P}roj/k$ and $\alpha, \beta \in H^{2*}(X\times X)(*)$, then

$$(\alpha\cdot\beta) = \sum_i (-1)^i \operatorname{tr}(\beta\circ\alpha | H^i(X)).$$

Proof: Cf.[Sta]0FH0.? □

Cor. (7.8.2.11). Let $k, F \in \mathtt{Field}$ and H^* be a Weil cohomology theory, then for $X \in \mathcal{S}m\mathcal{P}roj/k$,

$$\sum_{i=0}^{2\dim X} (-1)^i \dim_F H^i(X) = \deg([\Delta_X]\cdot[\Delta_X]) = \deg(c_d(\mathcal{T}_X)\cap[X]).$$

Conj. (7.8.2.12) [Betti Numbers]. Let $k, F \in \mathtt{Field}, k = \overline{k}$ and H^* be a Weil cohomology theory, is it true that for a smooth projective variety over k, the numbers $\beta_i = \dim_F H^i(X)$ are independent of F and the cohomology theory?

Proof: ? □

3 Pure Motives

Conj. (7.8.3.1)[Category of Motives as a Universal Cohomology Theory]. Let $k \in \mathtt{Field}$, then there should be a category of motives $\mathrm{Mot}(k)$ s.t.

- $\mathrm{Mot}(k)$ is a Tannakian category over $\mathbb{Q}$.
- There is a functor $h : \mathcal{S}m\mathcal{P}roj/k \to \mathrm{Mot}(k)$.
- Every correspondence $X \to Y$ of degree 0 defines a map $hX \to hY$.
- Every Weil cohomology theory(7.8.2.2) on the $\mathcal{S}m\mathcal{P}roj/k$ factors uniquely through h.

Proof: ? □

Def. (7.8.3.2) [Chow Motives]. The category $\mathrm{Mot}_{\mathrm{rat}}(k)$ of **Chow motives** over k consist of triples (X, e, m) where $X \in \mathcal{S}m\mathcal{P}roj/k$, e is an idempotent in $\mathrm{Corr}^0_{\mathrm{rat}}(X,X)_{\mathbb{Q}}$ and $m \in \mathbb{Z}$. And morphisms in $M_{\mathrm{rat}}(k)$ are defined to be

$$\mathrm{Hom}((X,e,m),(Y,f,n)) = f\circ \mathrm{Corr}^{n-m}_{\mathrm{rat}}(X,Y)\circ e.$$

The category $\mathrm{Mot}^{\mathrm{eff}}_{\mathrm{rat}}(k)$ of **effective Chow motives** over k is defined to be the full subcategory of $\mathrm{Mot}_{\mathrm{rat}}(k)$ consisting of triples $(X, e, 0)$.

There is a contravariant functor $\mathcal{S}m\mathcal{P}roj/k \to \mathrm{Mot}^{\mathrm{eff}}_{\mathrm{rat}}(k) : X \mapsto (X, [\Delta_X], 0)$ and $f \mapsto [\Gamma_f^t]$.

Def. (7.8.3.3) [Grothendieck Motives]. The category $\mathrm{Mot}_{\mathrm{num}}(k)$ of **Grothendieck motives** over k consist of triples (X, e, m) where $X \in \mathcal{S}m\mathcal{P}roj\,/k$, e is an idempotent in $\mathrm{Corr}^0_{\mathrm{num}}(X, X)_{\mathbb{Q}}$ and $m \in \mathbb{Z}$. And morphisms in $M_{\mathrm{num}}(k)$ are defined to be

$$\mathrm{Hom}((X, e, m), (Y, f, n)) = f \circ \mathrm{Corr}^{n-m}_{\mathrm{num}}(X, Y) \circ e.$$

The category $\mathrm{Mot}^{\mathrm{eff}}_{\mathrm{num}}(k)$ of **effective Grothendieck motives** over k is defined to be the full subcategory of $\mathrm{Mot}_{\mathrm{num}}(k)$ consisting of triples $(X, e, 0)$.

Prop. (7.8.3.4). There are natural functors $\mathrm{Mot}^{\mathrm{eff}}_{\mathrm{rat}}(k) \to \mathrm{Mot}^{\mathrm{eff}}_{\mathrm{num}}(k)$ and $\mathrm{Mot}_{\mathrm{rat}}(k) \to \mathrm{Mot}_{\mathrm{num}}(k)$, by definition(7.8.1.3).

Def. (7.8.3.5) [Tate Twists]. In $M_{\mathrm{rat}}(k)$ or $M_{\mathrm{num}}(k)$, define $\mathbb{1}(n) = (\mathrm{Spec}\, k, \mathrm{id}, n)$, and for any object M, define $M(n) = M \otimes \mathbb{1}(n)$.

Prop. (7.8.3.6). $M_{\mathrm{rat}}(k)$ and $M_{\mathrm{num}}(k)$ are Karoubian categories(3.7.1.15) and symmetric monoidal categories with identity $\mathbb{1}(0)$(7.8.3.5).

Proof: The symmetric monoidal structure is given by(7.8.1.4). It is clearly an additive category. To show it is Karoubian, for $M = (X, e, m) \in M_{\mathrm{rat}}(k), p \in \mathrm{End}(M)$ be an idempotent, then $p = epe$, and $N = (X, p, m) \in M_{\mathrm{rat}}(k)$, and $p : N \to M$ is a morphism. □

Prop. (7.8.3.7). $h(\mathbb{P}^1_k) = \mathbb{1} \oplus \mathbb{1}(-1) \in M_{\mathrm{rat}}(k)$.

Proof: Cf.[Sta]0FGG. □

Prop. (7.8.3.8) [$\mathrm{Mot}_{\mathrm{rat}}(k)$ as Inverting c_2]. For any $\mathbb{Q}$-Karoubian category $\mathcal{C}$ and a symmetric monoidal functor $f : M^{\mathrm{eff}}_{\mathrm{rat}}(k) \to \mathcal{C}$ s.t. $f(c_2) \in f(\mathbb{P}^1_k)$ is an invertible object, f factors through uniquely through a symmetric monoidal functor $M_{\mathrm{rat}}(k) \to \mathcal{C}$.

Proof: Cf.[Sta]0FGH. □

Prop. (7.8.3.9) [Left Duals]. Let $X \in \mathcal{S}m\mathcal{P}roj^d\,/k$, then $h(X)(d)$ is a left dual of $h(X)$. In particular, every element in $M_{\mathrm{rat}}(k)$ has a left dual.

Proof: Cf.[Sta]0FGI, 0FGJ.**?** □

Def. (7.8.3.10) [Chow Groups of Motives]. Let $k \in \mathtt{Field}$ and $M = (X, e, m) \in M_{\mathrm{rat}}(k)$, the i-th **Chow group** of M is defined to be

$$\mathrm{CH}^i(M) = e \circ \mathrm{CH}^{i+m}(X)_{\mathbb{Q}} = \mathrm{Hom}(\mathbb{1}(-i), M).$$

Then each CH^i defines a functor $M_{\mathrm{rat}}(k) \to \mathcal{V}ect_{\mathbb{Q}}$ via pushforwards**?**.

Prop. (7.8.3.11) [Manin]. Let $k \in \mathtt{Field}$ and $M \in M_{\mathrm{rat}}(k)$. If $c : M \to N \in \mathrm{Mot}_{\mathrm{rat}}(k)$ satisfies that for $X \in \mathcal{S}m\mathcal{P}roj\,/k$, the map $c \otimes 1 : M \otimes h(X) \to N \otimes h(X)$ induces isomorphisms on Chow groups, then c is an isomorphism.

Proof: Cf.[Sta]0FGN.**?** □

Prop. (7.8.3.12) [Weil Cohomologies and Chow Motives]. Let $k, F \in \mathtt{Field}$, $k = \overline{k}, \mathrm{char}\, F = 0$, then a classical Weil cohomology over k with coefficients in F is equivalent to a $\mathbb{Q}$-linear monoidal functor $G : \mathrm{Mat}_{\mathrm{rat}}(k) \to \mathcal{CR}ing^{\mathrm{gr}}\,/F$ together with an isomorphism $F[2] \to G(\mathbb{1}(1))$ s.t.

- $G(h(X)) \subset \mathcal{CR}ing^{\mathrm{gr}\geq 0}\,/F$.
- $\dim_F G^0(h(X)) = 1$.

Proof: Cf.[Sta]0FH3. □

Theorems

Thm. (7.8.3.13) [Voisin-Voevodsky]. For $k \in \texttt{Field}$ and $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$, $Z^i_{\mathrm{alg}}(X)_{\mathbb{Q}} \subset Z^i_{\times}(X)_{\mathbb{Q}}$.

Proof: Cf.[Lectures on Pure Motives, Murre]P19. □

Thm. (7.8.3.14) [Jannsen]. For $k \in \texttt{Field}, k = \overline{k}$, let $\sim$ be an adequate equivalence relation(7.8.1.2), and $F \in \texttt{Field}^0$, then the following are equivalent:

- $\mathrm{Mot}_{\sim}$ is an Abelian semisimple category.
- $\sim$ is the numerical equivalence relation.
- For all $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$, $\mathrm{Corr}^0_{\sim}(X,X)_F$ is a f.d. semisimple F-algebras.

Proof: Cf.[Lectures on Pure Motives, Murre]P39 or [Jan92]. □

Realizations

Cor. (7.8.3.15) [Realization Functors]. For $k \in \texttt{Field}$, suppose the category of motives exists(7.8.3.1), then there should be **realization functors**

- $\mathrm{Real}_p : \mathrm{Mot}(k) \to \mathrm{Rep}_{\mathbb{Q}_p}(\mathrm{Gal}_k)$ s.t. $H^i(-,\mathbb{Q}_p) = \mathrm{Real}_p \circ h^i$,
- $\mathrm{Real}_{\iota,\mathrm{Betti}} : \mathrm{Mot}(k) \to \mathrm{Hdg}_{\mathrm{int}}$ s.t. $H^i_{\iota,\mathrm{Betti}}(-,\mathbb{Z})_{\mathrm{lf}} = \mathrm{Real}_\iota \circ h^i$, for each embedding $\iota : k \to \mathbb{C}$.
- $\mathrm{Real}_{\mathrm{dR}} : \mathrm{Mot}(k) \to \mathrm{Fil}_K$ s.t. $H^i_{\mathrm{dR}}(-) = \mathrm{Real}_{\mathrm{dR}} \circ h^i$.

And comparison isomorphisms

$$I_\ell : \mathrm{Real}_\iota \otimes \mathbb{Q}_\ell \cong \mathrm{Real}_\ell : \mathrm{Mot}(k) \to \mathcal{V}\mathrm{ect}/\mathbb{Q}_\ell$$

$$I_{\mathrm{dR}} : \mathrm{Real}_{\iota,\mathrm{Betti}} \otimes \mathbb{C} \cong \mathrm{Real}_{\mathrm{dR}} \otimes_{k,\iota} \mathbb{C} : \mathrm{Mot}(k) \to \mathrm{Fil}^\bullet_{\mathbb{C}}$$

and the Tate twist(7.8.3.5) acts on the relations via

- $\mathrm{Real}_{\iota,\mathrm{Betti}}(M(r)) = (\Lambda, \Lambda^{p,q}_{\mathbb{C}})$ is given as follows:
$$\Lambda = (2\pi\,\mathrm{i})^r \,\mathrm{Real}_{\iota,\mathrm{Betti}}(M), \quad \Lambda^{p,q}_{\mathbb{C}} = (2\pi\,\mathrm{i})^r \,\mathrm{Real}_{\iota,\mathrm{Betti}}(M)^{p-r,q-r}.$$
- $\mathrm{Real}_p(M(r)) = \mathrm{Real}_p(M)(r) = \mathrm{Real}_p(M) \otimes \mu_{p^\infty}^{\otimes r}$.
- $\mathrm{Real}_{\mathrm{dR}}(M(n)) = \mathrm{Real}_{\mathrm{dR}}(M)$.

Proof: It suffices to show that these are all Wei cohomology theories,? □

Prop. (7.8.3.16). By(11.10.3.7), if $\iota : k \to \mathbb{C}$ factors through $\mathbb{R}$, then

$$I_{\mathrm{dR}} : \mathrm{Real}_{\iota,\mathrm{Betti}} \otimes \mathbb{C} \cong \mathrm{Real}_{\mathrm{dR}} \otimes_{k,\iota} \mathbb{C}$$

identifies $\mathfrak{e}^* \otimes \mathfrak{e}$ on the LHS with $\mathfrak{e}$ on the RHS.

Prop. (7.8.3.17) [Tate Conjecture and Motives]. The Tate conjecture(13.15.1.2) and Grothendieck-Serre conjecture(7.4.7.36) hold iff the functor $\mathrm{Mot}(k) \to \mathrm{Rep}_{\mathbb{Q}_p}(\mathrm{Gal}_K) : M \mapsto \mathrm{H}^*_{\text{ét}}(M)$ is fully faithful.

Proof: ? □

Prop. (7.8.3.18). For $k \in \texttt{Field}$, the functor $\mathrm{Mot}(k) \to \mathrm{Hdg}(M)$ is fully faithful iff the Hodge conjecture holds for k.

Proof: Cf.[Hodge-de Rham Structure and Periods of Automorphic Forms, Michael Harries, in Motives 2]Prop1.2.? □

Chow-Künneth Decompositions

Def. (7.8.3.19) [Chow-Künneth Decompositions]. For $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}^d/k$, a **Chow-Künneth decomposition** is a decomposition

$$\Delta_X = \sum_{i=0}^{2d} \pi_i \in \mathrm{CH}^d(X \times X, \mathbb{Q})$$

s.t.

- $\pi_j \pi_i = \delta_{i,j} \pi_i$.
- For any Weil cohomology over $\overline{k}$, π_i is mapped to the usual Künneth component $\Delta(2d-i,i)$?.

4 Mixed Motives

Remark (7.8.4.1). The motives are conjectured to be the subcategory of semisimple objects in a larger category of **mixed motives**.

There is at present no definition of a category of mixed motives, but several mathematicians have constructed triangulated categories that are candidates to be its derived category; it remains to define a T-structure on one of these categories whose heart is the category of mixed motives.?

Beilinson-Bloch-Murre Filtration Conjecture

Conj. (7.8.4.2) [Beilinson]. For X/k, there exists a descending filtration $\mathrm{Fil}^\bullet \mathrm{CH}^\bullet(X)_\mathbb{Q}$ s.t.

- $\mathrm{Fil}^0 \mathrm{CH}^j(X)_\mathbb{Q} = \mathrm{CH}^j(X)_\mathbb{Q}$, $\mathrm{Fil}^1 \mathrm{CH}^j(X)_\mathbb{Q} = \mathrm{CH}^j(X)_\mathbb{Q} = \mathrm{CH}^j(X)_{\mathrm{hom}\,0,\mathbb{Q}}$.
- this filtration is multiplicative.
- $\mathrm{gr}^v \mathrm{CH}^j(X)_\mathbb{Q}$ only depends on the motive modulo homological equivalence, $h^{2j-v}(X)$.
- $\mathrm{Fil}^{j+1} \mathrm{CH}^j(X)_\mathbb{Q} = 0$.

And moreover, if $k = \mathbb{Q}$, then $\mathrm{Fil}^2 = 0$.

Proof: □

5 Standard Conjectures

Cf. [Kle94].

Remark (7.8.5.1). The standard conjectures over k are necessary conditions to make the $\mathrm{Mot}_{\mathrm{num}}(k)$ a universal cohomology theory(7.8.3.1).

Conj. (7.8.5.2) [Lefschetz Standard Conjecture]. Let $k, F \in \texttt{Field}, k = \overline{k}$ and H^* be a Weil cohomology theory, $X \subset \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}^d/k$, then the Lefschetz operator $L : \mathrm{CH}^i(X) \to \mathrm{CH}^{i+2}(X)$ satisfies for any $i \leq d$,

$$L^{n-i} : H^i(X) \to H^{2d-i}(X)$$

is an isomorphism?. and for $i \leq d$ we can define

$$\Lambda = (L^{d-i+2})^{-1} L(L^{d-i}) : H^i \to H^{i-2}, \Lambda = L^{n-i} L(L^{n-i+2})^{-1} : H^{2n-i+2}(X) \to H^{2n-i}(X),$$

then this Λ is induced from a correspondence from X to X of degree -1.

Conj. (7.8.5.3) [Standard Conjecture D]. Let $k, F \in \texttt{Field}, k = \overline{k}$ and H^* be a Weil cohomology theory, then for $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$, a cycle $Z \in \mathrm{CH}^*(X)$ is numerically trivial iff $\gamma_X(Z) = 0$.

Remark (7.8.5.4). This conjecture was shown by Lieberman for varieties of dimension$\leq$ 4 and for Abelian varieties.

Conj. (7.8.5.5)[Künneth Standard Conjecture]. Let $k \in \texttt{Field}$. Assume the conjecture D(7.8.5.3) holds, which implies $\mathrm{Corr}^r_{\mathrm{num}}(X)$ can acts on $H^*(X)$ for any Weil cohomology H^*.

Then for any $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$, there exists a decomposition of $\Delta_X \in \mathrm{Corr}^{\dim X}_{\mathrm{num}}(X \times X)$ into orthogonal idempotents

$$\Delta_X = h^0(X) + \ldots + h^{2\dim X}(X)$$

s.t. it induces the decomposition

$$H^*(X) = H^0(X) \oplus H^1(X) \oplus \ldots \oplus H^{2\dim X}(X)$$

for any Weil cohomology theory H^*.

Remark (7.8.5.6) [Murre]. Murre even conjecture that such a decomposition exists in $\mathrm{CH}^*(X)$ with certain properties, which is equivalent to a filtration on $\mathrm{CH}^*(X)$, conjectured by Beilinson and Bloch.**?**

Prop. (7.8.5.7) [Hodge Standard Conjecture]. Let $k, F \in \texttt{Field}, k = \overline{k}$ and H^* be a Weil cohomology theory, $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}^d/k$, $P^k(X) = \ker(L|H^k(X))$ be the primitive cohomologies, $A^i(X) = \gamma_X(\mathrm{CH}^i(X))$, then for any $i < d/2$, the $\mathbb{Q}$-valued pairing on $A^i(X) \cap P^{2i}(X)$:

$$(x, y) \mapsto (-1)^i \langle L^{r-2i} x, y\rangle$$

is positive definite.

Remark (7.8.5.8). This conjecture is true in characteristic 0 by Hodge theory. This conjecture is shown for surfaces by Grothendieck(1958). This conjecture is shown for Abelian varieties of dimension 4 by Ancona(2020).

Prop. (7.8.5.9). The conjecture D implies the Lefschetz standard conjecture. The Hodge standard conjecture and the Lefschetz standard conjecture implies conjecture D.

Proof: □

Prop. (7.8.5.10)[Hodge Conjecture and Standard Conjecture]. The Hodge conjecture(13.15.4.3) implies the Lefschetz and Künneth standard conjectures and conjecture D for varieties over fields of characteristic 0.

Proof: □

Prop. (7.8.5.11). If the Lefschetz standard conjecture and the Hodge standard conjecture hold, then for any $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/k$,

- $\mathrm{Corr}^*_{\mathrm{num}}(X, X)$ is a semisimple $\mathbb{Q}$-algebra.
- (Generalized Riemann Hypothesis)If k is a finite field with Frobenius φ, then for any Weil cohomology H^*, the Frobenius action Φ on $H^i(X)$ is semisimple with characteristic polynomial in $\mathbb{Z}[T]$, and eigenvalues of absolute value $q^{i/2}$.

Proof: Cf.[Kle94]P19. □

Prop. (7.8.5.12)[Tate Conjecture and Standard Conjectures]. The Tate conjecture implies Lefschetz, Künneth standard conjectures and conjecture D for ℓ-adic étale cohomology over any field.

Proof: □

7.9 Motivic Cohomology(Voevodsky-Suslin)

References are [Motivic Cohomology, Voevodsky], [$\mathbb{A}^1$-Homology of Schemes, Voevodsky], [Bloch-Kato conjecture and motivic cohomology with finite coefficients, Suslin-Voevodsky] and [Voe02].

Def. (7.9.0.1) [Bloch's Motivic Cohomology Groups]. For $k \in \mathtt{Field}$ and $X \in \mathcal{S}m\mathcal{P}\mathrm{roj}/k$, define the complex

$$C^p_{\mathrm{Blo},\bullet}(X) = C^p(X \times \mathbb{A}^\bullet),$$

and it is a complex via the pullback along the embedding from edges of $\Delta^n \subset \mathbb{A}^n$. And in fact the cycles must satisfy that the intersections are all proper.(This is what makes it impossible to work with.)

Then define

$$H^{2p-q}_{\mathrm{Mot}}(X, \mathbb{Z}(p)) = \mathrm{CH}^p(X, q).$$

Def. (7.9.0.2) [Beilinson's Motivic Cohomology Groups]. For $X \in \mathcal{S}m\mathcal{P}\mathrm{roj}/\mathbb{Q}$,

$$H^p_{\mathrm{Mot}}(X, \mathbb{Q}(q)) = (K_{2q-p}(X)_{\mathbb{Q}})^{(q)},$$

where the RHS is the Adam operator q-part.

Then this definition is compatible with Bloch's definition(7.9.0.1).? In particular, $H^{2q}_{\mathrm{Mot}}(X, \mathbb{Q}(q)) = \mathrm{CH}^q(X)_{\mathbb{Q}}$, and

$$\bigoplus \mathrm{CH}^p(X, q) \otimes \mathbb{Q} \cong K_q(X).$$

Proof: □

Prop. (7.9.0.3). There are ℓ-adic comparison maps

$$H^p_{\mathrm{Mot}}(X, \mathbb{Q}(q)) \to \mathrm{H}^p_{\text{ét}}(X, \mathbb{Q}_\ell(q)), \ell \in \mathbf{P},$$

and Deligne comparison maps

$$H^p_{\mathrm{Mot}}(X, \mathbb{Q}(q)) \to H^p_{\mathrm{Del}}(X, \mathbb{Q}(q)).$$

Proof: □

Conj. (7.9.0.4) [Modified Motivic Cohomology Groups]. For $X \in \mathcal{S}m\mathcal{P}\mathrm{roj}/\mathbb{Q}$, define

$$H^p_{\mathrm{Mot}}(X_{\mathbb{Z}}, \mathbb{Q}(q)) = \mathcal{H}^p_{\mathrm{Mot}}(\mathcal{X}, \mathbb{Q}(q)),$$

Where $\mathcal{X}/\mathbb{Z}$ is a proper flat model of X, which always exists?.

Then this definition is conjectured to be independent of $\mathcal{X}$ chosen.

Proof: □

Conj. (7.9.0.5) [Beilinson]. For $k \in \mathtt{Field}$ and any $n \in \mathbb{N}$, there exists sheaf $\mathbb{Z}(n) \in K(\mathcal{S}h(\mathcal{V}ar^{\mathrm{sm},quasi-proj}_{\mathrm{Zar}}/k))$ s.t.

1. $\mathbb{Z}(0) = \mathbb{Z}[0]$, $\mathbb{Z}(1) = \mathcal{O}^*[-1]$,
2. $H^n(\mathrm{Spec}\, F, \mathbb{Z}(n)) = K^n_{\mathrm{Mil}}(F)$ for any $F \in \mathtt{Field}$.
3. $H^{2n}(X, \mathbb{Z}(n)) = \mathrm{CH}^n(X)$.

4. $H^p(X, \mathbb{Z}(n)) = 0$ for $p < 0$.
5. There are spectral sequences
$$H^{p-q}(X, \mathbb{Z}(-q)) \implies K_{-p-q}(X).$$
6. For $\ell \in \mathfrak{P} \setminus \{\mathrm{char}\, k\}$,
$$\mathbb{Z}(n) \otimes^L \mathbb{Z}/(\ell) \cong \tau_{\leq n}(R\pi_* \mu_\ell^{\otimes n}).$$
7. $H^i(X, \mathbb{Z}(n)) \otimes \mathbb{Q} \cong H^i_{\mathrm{Mot}}(X, \mathbb{Q}(n))$(7.9.0.2).

Proof: ? Voevodsky constructed candidates $\mathbb{Z}(n)$ satisfying these conditions except for item4. □

Def. (7.9.0.6) [Absolute Chern Class Maps]. There are Chern class maps:
$$c_{j,m} : K_j(X) \to H^{2m-j}_{\mathrm{Del}}(X/\mathbb{R}, \mathbb{R}(m)),$$
$$\mathrm{ch}_j = \sum_{m \geq 0} \frac{(-1)^{m-1}}{(m-1)!} c_{j,m} : K_j(X) \otimes \mathbb{Q} \to \bigoplus_{m \geq 0} H^{2m-j}_{\mathrm{Del}}(X/\mathbb{R}, \mathbb{R}(m)).$$
such that ch_j maps $(K_j(X)_{\mathbb{Q}})^j$ to $H^{2m-j}_{\mathrm{Del}}(X/\mathbb{R}, \mathbb{R}(m))$.

Proof: Cf.[Notes on Beilinson's Conjecture, Yihang] or [Nekovar]. □

8 Algebraic Geometry III: Group Theory

8.1 Group Schemes I: Structure Theory

Main references are [Sta]Chap38, [Mil17].

1 Group Schemes

Def. (8.1.1.1) [Group Scheme]. A **monoid scheme** over S is a monoid object in the Cartesian monoidal category $\mathcal{S}\mathrm{ch}/S$. The category $\mathcal{G}\mathrm{rp}_S$ of **group schemes** over S consists of group objects in the Cartesian category $\mathcal{S}\mathrm{ch}/S$(3.1.1.65).

An **open/closed subgroup scheme** of a group scheme G/S is an open/closed subscheme of G/S that represents a subgroup functor of G/S.

A **smooth/flat/separated/... group scheme** is a group scheme G/S that G is smooth/flat/separated/... over S.

We have the left(right)translation for an elements in $G(R)$, equivalently, a natural transformation on G, and base change $(G\otimes_S S')(T'/S')=G(T'/S)$

Remark (8.1.1.2) [Yoneda Interpretation]. We do not need to verify all the relations, whenever we have a functorial commutative group structure on all the set $\mathrm{Hom}(T,G)$, we immediately recover the map $m:G\times G\to G$ as $\mathrm{pr}_1\cdot\mathrm{pr}_2\subset G(G\times G)$, $\mathrm{inv}:G\to G$ as inv in $G(G)$, $u:S\to G$ as e in $G(S)$, by Yoneda lemma.

Cor. (8.1.1.3) [Group Schemes as Functors]. From the Yoneda Interpretation and strong Yoneda lemma(8.7.1.1), a group scheme over S is equivalent to a contravariant functor

$$\mathcal{A}\mathrm{ff}_S\to\mathcal{G}\mathrm{rp}:R\mapsto\mathrm{Hom}(\mathrm{Spec}\,R,G)$$

(or equivalently a functor $\mathcal{S}\mathrm{ch}_S\to\mathcal{G}\mathrm{rp}$) that is represented by a scheme over S.

In particular, the category of affine group scheme over $\mathrm{Spec}\,R$ is equivalent to the category of commutative Hopf algebras over R(2.9.2.1).

Def. (8.1.1.4) [Categorical Group Definitions]. Because we can regard group schemes as functors by(8.1.1.3), we can define categorical constructions of group schemes:

- (Trivial Group Scheme)S is a trivial group scheme over S. It is the zero object in $\mathcal{G}\mathrm{rp}_S$, denoted by e.
- (Commutative Group Schemes)A group scheme G is called a **commutative group scheme** if each $G(R)$ is commutative.
- ($[n]_G$)For any $n\geq 1$, the natural transformation of commutative groups functors $x\mapsto x^n$ induces a morphism of commutative group schemes $[n]:G\mapsto G$ for any group scheme G.

- (Semi-Direct Product)Let G be a group scheme acting on a group scheme H, then we can form a **semi-direct product group scheme** $G \ltimes H$ representing the functor $T \mapsto G(T) \ltimes H(T)$. and $G \ltimes H$ is isomorphic to $G \times H$ as schemes.
- (Kernel)For a homomorphisms of group schemes $\varphi : G \to H$ over R, we define the **kernel group scheme** $\ker \varphi$ representing the functor $R \mapsto \ker(\varphi(R))$. it is represented by the fibered product
$$\begin{array}{ccc} \ker\varphi & \longrightarrow & \operatorname{Spec} R \\ \downarrow & & \downarrow \varepsilon_H \\ G & \xrightarrow{\varphi} & H \end{array}$$
then it is a group scheme over R.
When G, H are affine group schemes, it corresponds to the cokernel Hopf algebra defined in(2.9.2.17).
- (Short Exact Sequences)A sequence of homomorphisms of algebraic groups $e \to N \xrightarrow{i} G \xrightarrow{q} Q$ is called an **exact** if they are exact as sheaves in $\mathcal{S}\mathrm{h}(\mathcal{A}\mathrm{ff}_S)$(or $\mathcal{S}\mathrm{h}(\mathcal{S}\mathrm{ch}_S)$). Exact sequences are stable under base change of fields
- (Quotient Scheme)Let $H \subset G$ be subgroup schemes. If $\widetilde{G}/\widetilde{H}$ is representable, then it is called the **quotient group scheme**, denoted by G/H.
- (Monomorphism)A homomorphism $H \to G$ of group schemes is called a **monomorphism** if $\widetilde{H} \to \widetilde{G}$ is injective.
- (Quotient Map)A homomorphism $H \to G$ of group schemes is called a **quotient map** if $\widetilde{G} \to \widetilde{H}$ is surjective.
- (Normal/Characteristic/Central Subgroups)A subgroup scheme H of G is called normal/characteristic/central if $H(R)$ is normal/characteristic/central in $G(R)$ for any k-algebra R.
- (Normalizing) Let H, N be subgroup schemes of G, then we say H normalizes N if H is contained in the normalizer of N in G.
- (Product Subgroup)Let H, N be algebraic subgroups of an algebraic group G such that H normalizes N, then we define $NH \subset G$ be the algebraic subgroup that is the image of the homomorphism $N \rtimes H \to G$, if it is representable.
- (Generated Subgroup Scheme)Let $\{X_i \to G\}$ be a family of maps to a group scheme G, then the smallest algebraic subgroup H of G generated by φ_i is called the **generated subgroup scheme** if it is representable, denoted by $\langle X_i, \varphi_i \rangle$. It is clear such generated subgroup scheme commutes with base change of fields.
- (Commutator Subgroup)If H_1, H_2 are subgroups of G, let $[H_1, H_2]$ be the subgroup generated by the commutators of H_1, H_2 if it is representable. Or equivalently, it is the subgroup generated by the map $H_1 \times H_2 \to G : [h_1, h_2] \mapsto h_1 h_2 h_1^{-1} h_2^{-1}$.
- (Derived Series)For a group scheme G, define $G^{(1)} = [G, G]$ and define inductively $G^{(n+1)} = [G^{(n)}, G^{(n)}]$.
- (Derived Central Series)For a group scheme G, define $G^1 = [G, G]$ and define inductively $G^{n+1} = [G^n, G^n]$.
- (Subnormal Series)For a group scheme G, a **subnormal series** is a finite sequence of algebraic subgroups $G = G_0 \rhd G_1 \rhd \ldots \rhd G_r = e$ s.t. G_{i+1} is normal in G_i.

- (Solvable Group Schemes) A **solvable group scheme** is a group scheme G that has a subnormal series $G = G_0 \rhd G_1 \rhd \ldots \rhd G_s = \{e\}$ that each quotient G_i/G_{i+1} is commutative.
- (Nilpotent Group Schemes) A **nilpotent group scheme** is a group scheme G that has a subnormal series $G = G_0 \rhd G_1 \rhd \ldots \rhd G_s = \{e\}$ that each quotient G_i/G_{i+1} is central in G/G_{i+1}. Such a sequence is called a **central series**
- (Split Solvable(resp. Nilpotent) Group Schemes)A **split solvable(resp. nilpotent) group** is a group scheme G that has a subnormal(resp. central) series $G = G_0 \rhd G_1 \rhd \ldots \rhd G_s = \{e\}$ that each quotient G_i/G_{i+1} is isomorphic to either $\mathbb{G}_a$ or $\mathbb{G}_m$.
- (Perfect Group Schemes)A group scheme G is called **perfect** if $G = [G, G]$.

Lemma (8.1.1.5) [Butterfly Lemma]. Let H_1, H_2 be algebraic subgroups of an algebraic group G, N_1, N_2 are normal subgroups of H_1 and H_2, then there is a canonical isomorphism of algebraic groups:

$$N_1(H_1 \cap H_2)/N_1(H_1 \cap N_2) \cong N_2(H_2 \cap H_1)/N_2(H_2 \cap N_1).$$

Proof: Use the Butterfly lemma for groups(2.1.9.2) and shifify. □

Def. (8.1.1.6) [Translation Map]. For $G \in \mathcal{G}\mathrm{rp}/S$ and any $a \in G(S)$, there is a (left)translation map

$$l_a : G \cong S \times_S G \xrightarrow{(a,\mathrm{id})} G \times_S G \xrightarrow{m} G.$$

and it satisfies l_a, l_b by associativity.

Prop. (8.1.1.7) [Common Group Schemes].

- $D(\Gamma) = \operatorname{Spec} \mathbb{Z}[\Gamma]$ for a group Γ(2.9.2.3).
- $\mu_n = \mathbb{Z}[T]/(T^n - 1)$(2.9.2.5)
- $\mathbb{G}_a = \mathbb{Z}[T]$(2.9.2.6)
- $\underline{\Gamma} = \operatorname{Spec} \prod_{\gamma \in \Gamma} \mathbb{Z}$(2.9.2.9).
- $\alpha_{p^r} = \operatorname{Spec} \mathbb{F}_p[X]/X^{p^r}$(2.9.2.15).
- $V_{\mathfrak{a}} = \operatorname{Spec} \operatorname{Sym}(V^\vee)$(2.9.2.8).

Prop. (8.1.1.8). $\operatorname{Hom}(\mathbb{G}_{m,R}, \mathbb{G}_{a,R}) = 0$.

Proof: Such a homomorphism corresponds to an element $f(T) = \sum a_i T^i$ s.t. $\sum a_i T^i \otimes T^i = \sum a_i (T^i \otimes 1 + 1 \otimes T^i)$, which implies $a_i = 0$ for all i. A homomorphism $\mathbb{G}_{m,R} \to \mathbb{G}_{a,R}$ corresponds to an element $f(T) = \sum a_i T^i$ s.t. $\sum a_i T^i \otimes T^i = \sum a_i (T^i \otimes 1 + 1 \otimes T^i)$, which implies $a_i = 0$ for all i. □

Prop. (8.1.1.9). $\operatorname{Hom}(\mathbb{G}_{a,R}, \mathbb{G}_{m,R}) = 0$.

Proof: The proof is the same as that of(8.1.1.8). □

Prop. (8.1.1.10). If R is reduced, then $\operatorname{Aut}(\mathbb{G}_{a,R}) \cong R$.

Proof: Any endomorphism of $\mathbb{G}_{a,R}$ is of the form $X \mapsto a_0 + a_1 X + \ldots + a_n T^n$. If it is an automorphism, then for any prime ideal $\mathfrak{p}$, $a_0 \notin \mathfrak{p}$ and $a_i \in \mathfrak{p}, i > 0$, thus a_0 is a unit and a_i are nilpotent for $i > 1$, so $a_i = 0$ for $i > 1$. □

Prop. (8.1.1.11). For $G \in \mathcal{G}\mathrm{rp}/S$, there is a Cartesian diagram:

$$\begin{array}{ccc} G & \xrightarrow{\Delta_{X/S}} & G \times_S G \\ \downarrow & & \downarrow{\scriptstyle (g,g')\mapsto m(i(g),g')} \\ S & \xrightarrow{e} & G \end{array}$$

This can be seen by a testing scheme T.

Cor. (8.1.1.12) [Separatedness]. $G \in \mathcal{G}\mathrm{rp}/S$ is (quasi-)separated iff e is qc(closed immersion). In particular, if S is a field, then G is separated.

Def. (8.1.1.13)[Character Group]. A **character** of a group scheme G is a homomorphism $G \to \mathbb{G}_m$. It is easy to see that a character of G is equivalent to a group-like element(2.9.2.19) in $\Gamma(G)$. The characters of G form a group, denoted by $\mathbb{X}(G)$. $\mathbb{X}(G)(k)$ is denoted by $X(G)$.

Moreover, let k^s/k be a separable closure, then the character group of G_{k^s} is denoted by $\mathbb{X}^*(G)$.

In particular, if G is an algebraic group scheme over a field, then the set of characters of G are linearly independent, by(2.9.2.20).

Prop. (8.1.1.14)[Sheaf of Differentials is Parallel]. If $f : G \to S \in \mathcal{G}\mathrm{rp}/S$, then there are canonical isomorphisms

$$\Omega_{G/S} \cong f^*\mathcal{C}_{G/S} \cong f^*e^*\Omega_{G/S}.$$

In particular, if S is the spectrum of a local ring, then $\Omega_{G/S}$ is a free $\mathcal{O}_G$-module.

Proof: By base change, $\Omega_{G\otimes_S G/S} = \pi_0^*\Omega_{G/S}$, and the transition map

$$\tau : G \otimes_S G \to G \otimes_S G : (g, h) \mapsto (m(g, h), h)$$

is an automorphism of $G \otimes_S G$ over G, so there is an isomorphism

$$\tau^*\pi_0^*\Omega_{G/S} \cong \pi_0^*\Omega_{G/S}$$

but $\pi_0 \circ \tau = m$, showing this isomorphism is $m^*\Omega_{G/S} \cong \pi_0^*\Omega_{G/S}$. Now pulling this isomorphism along the isomorphism by $(e \circ f, \mathrm{id}) : G \to G \otimes_S G$ we obtain the isomorphism

$$\Omega_{G/S} \cong f^*e^*\Omega_{G/S}.$$

Finally $e^*\Omega_{G/S} \cong \mathcal{C}_{S/G}$ by(5.5.5.14). □

Prop. (8.1.1.15). If $k \in$ `Field`, then any $G \in \mathcal{G}\mathrm{rp}/k$ is geo.reduced.

Proof: Cf.[Sta]047O.**?** □

Prop. (8.1.1.16) [Galois Descent]. Let $k \in$ `Field`, $G \in \mathcal{G}\mathrm{rp}/k$ and K/k is a Galois extension with Galois group Γ. If H' is a subgroup of $G \otimes_k K$, then H' is stable under the action of Γ iff there exists a subgroup H of G that $H \otimes_k K = H'$. In this case, H is unique.

Proof: Use(5.1.5.19) and(5.1.5.22). □

Prop. (8.1.1.17). Let X, Y be varieties over a field k that both have at least one K-point, and X is complete. Then any morphism $X \times Y \to G$ to a group scheme G over k factorizes as $f(x, y) = g(x)h(y)$, where $f : X \to G$ and $h : Y \to G$.

Proof: Fix a $y_0 \in Y(K)$ and define a morphism $g : X \to G : x \mapsto f(x, y_0)$, then the morphism $F : X \times Y \to G : (x, y) \mapsto g(x)^{-1} f(x, y)$ is constant on $X \times \{y_0\}$. Then the rigidity lemma(5.10.1.20) and(8.1.1.12) shows $F(x, y) = h(y)$ where $h : Y \to G$ is a morphism. Then we are done. □

Cor. (8.1.1.18). Any morphism from a $\mathbb{P}^1_K$ to a group scheme G is constant.

Proof: Let (x_0, x_1) be a homogenous coordinate of $\mathbb{P}^1$, consider the morphism $s : \mathbb{P}^1 \times \mathbb{A}^1 \to \mathbb{P}^1 : (x_0, x_1) \times y \mapsto (x_0, x_0 + x_1 y)$. Let $f : \mathbb{P}^1 \to G$ be a morphism, consider the composition

$$\mathbb{P}^1 \times \mathbb{A}^1 \xrightarrow{s} \mathbb{P}^1 \xrightarrow{f} G$$

then by(8.1.4.19), $f \circ s$ factors as $f(s(x, y)) = g(x)h(y)$.

We take $y = 0$, then $s(x, 0) = x$, and $g(x) = f(x)h(0)^{-1}$. Thus $f(s(x, y)) = f(x)h(0)^{-1}h(y)$. Next we take $x = (0, 1)$, then $s((0, 1), y) = (0, 1)$, and $f((0, 1)) = f((0, 1))h(0)^{-1}h(y)$. This shows $h(y) = h(0)$ is constant, thus $f(s(x, y)) = f(x)$. Finally, let $x = (0, 1)$, then $s((0, 1), y) = y$, and $f(y) = h(0)$ is constant. □

Cor. (8.1.1.19). Let U be an open subset of $\mathbb{P}^1$, then any morphism from U to a group variety G is constant. In particular, G contains no rational curve, and any morphism from a rationally connected variety to G is constant, in particular $\mathbb{P}^n_K$.

Proof: Any rational map from $\mathbb{P}^1$ to G can be extended to a morphism, by(5.11.1.15), thus it is constant, by the proposition above. □

Prop. (8.1.1.20) [Singularity in Codimension1]. Let $S \in \mathcal{S}\mathrm{ch}$ be normal and Noetherian, $Z, G \in \mathcal{S}\mathrm{ch}/S$ s.t. Z/S is smooth and G/S is a smooth separated S-group scheme. If $\varphi : Z \to G$ is an S-rational map, then every irreducible component of $X \backslash \mathrm{dom}(\varphi)$ is of codimension 1.

Proof: Cf.[BLR90]P109.? □

Classification of groups schemes of height 1 over a field

Quotients of Group Schemes

Prop. (8.1.1.21) [Grothendieck]. Let G be a group scheme of f.t. over S and H is a closed subgroup scheme of G. If H is proper and flat over S and if G is quasi-projective over S, then the quotient functor $\widetilde{G}_{fppf}/\widetilde{H}_{fppf}$ is representable, denoted by G/H.

Proof: Cf.[Grothendieck, A. Technique de descente et theoremes d'6xistence en geometrie algebrique, III]. □

Cor. (8.1.1.22) [Existence of Quotient Space]. Let $H \to G$ be a monomorphism of algebraic groups over a field k(8.1.5.6), then the quotient functor $\widetilde{G}_{fppf}/\widetilde{H}_{fppf}$ is representable by an algebraic scheme. And $G \to G/H$ is faithfully flat.

Proof: Cf.[Mil17b]P605.? □

Cor. (8.1.1.23) [Quotient by Normal Subgroups]. Every normal algebraic group N of an algebraic group G arises as the kernel of a quotient map $G \to G/N$. And if G is affine, G/N is also affine.

Proof: This is a corollary of(8.1.1.22) and(8.1.1.26) and(8.7.1.12).

The second assertion follows from[Mil17]P103.? □

Cor. (8.1.1.24)[Quotient Map is a Cokernel]. Let $q : G \to Q$ be a quotient map of algebraic groups over k and let N be the kernel, then every homomorphism $G \to H$ whose kernel contains N factors uniquely through q.

Prop. (8.1.1.25). Let G/H be a quotient space, then the map

$$(g, h) \mapsto (g, gh) : G \times H \mapsto G \times_{G/H} G$$

is an isomorphism.

Proof: This is because for any R, $G(R) \times H(R) \to G(R) \times_{G(R)/H(R)} G(R)$ is an isomorphism, and use the fact $G(R)/H(R) \subset (G/H)(R)$ as $\widetilde{G}/\widetilde{H}$ is a subfunctor of $\widetilde{G/H}$. □

Cor. (8.1.1.26). For any k-algebra R, the nonempty fibers of $G(R) \to G/H(R)$ are cosets of $H(R)$. In particular, the fiber over $o \in G/H$ is just H.

Cor. (8.1.1.27) [Quotient is a Torsor]. G is a (fppf) H-torsor over G/H.

Proof: This follows from(8.1.1.22) and(8.1.1.27). □

Prop. (8.1.1.28) [Additivity of Dimensions]. Let G be an algebraic group and H an algebraic subgroup, then

$$\dim G = \dim H + \dim G/H.$$

Proof: This follows from(5.6.3.17) and(8.1.1.26). (Notice $G(\overline{k}) \to H(\overline{k})$ is surjective(8.1.5.5)). □

Thm. (8.1.1.29)[Homomorphism Theorem]. Every homomorphism of algebraic groups $f : G \to H$ factors uniquely as

$$G \xrightarrow{q} I \xrightarrow{i} H$$

where q is a quotient map and i is a monomorphism. I is called the **image of** f.

Proof: Let $N = \ker(f)$, and $q : G \to I = G/N$(8.1.1.23), then by(8.1.1.24), f factors through I via a monomorphism I by(8.1.1.21). □

Cor. (8.1.1.30). A homomorphism of algebraic groups is a quotient map iff it is an epimorphism in the category of algebraic schemes.

Proof: For any homomorphism of group schemes $\varphi : G \to H$, factor it as in(8.1.1.29), then we can form the quotient space H/I, so if it is an epimorphism, $I = H$, and φ is a quotient map. Conversely, if it is a quotient map, then $\mathcal{O}_H \to \varphi_* \mathcal{O}_G$ is injective by(8.1.5.3), thus it is an epimorphism. □

Cor. (8.1.1.31). If f is surjective and H is reduced, then f is a quotient map.

Prop. (8.1.1.32). Let H, N be subgroup schemes of G with N normal, then the canonical map

$$N \rtimes H \to G$$

is an isomorphism iff $N \cap H = e$ and $NH = G$.

Proof: This follows from the exact sequence $e \to N \cap H \to N \rtimes H \to NH \to e$. □

Prop. (8.1.1.33) [Isomorphism Theorem]. Let H, N be algebraic subgroups of an algebraic group G such that H normalizes N, then $H \cap N$ is a normal algebraic subgroup of H, and the natural map

$$H/H \cap N \to HN/N$$

is an isomorphism.

Proof: The isomorphism is induced by shifification of the natural isomorphism

$$T_R : H(R)/H(R) \cap N(R) \cong H(R)N(R)/N(R)(2.1.3.8).$$

□

Prop. (8.1.1.34)[Correspondence Theorem]. Let N be a normal algebraic subgroup of an algebraic group G, then

- An algebraic subgroup H of G, the inverse image of the image of H in G/N is HN.
- The map $H \mapsto H/N$ is a bijection between the set of algebraic subgroups of G containing N to the set of algebraic subgroups of G/N.
- An algebraic subgroup H of G containing N is normal in G iff H/N is normal in G/N, in which case the natural map $G/H \to (G/N)/(H/N)$ is an isomorphism.

Proof: Cf.[Mil17]P113.? □

Prop. (8.1.1.35) [Group Formation]. WARNING: the category $\mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}_k$ of algebraic groups is not Abelian, not even an exact category, but it is a group formation(3.2.2.1), and its subcategory $\mathcal{C}\mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}_k$ of commutative algebraic groups is an Abelian category, by(8.1.1.23)(8.1.5.2)(8.1.1.4).

Also the subcategory of affine algebraic groups is a Serre subcategory, by(8.1.1.23) and(8.1.5.29).

Cor. (8.1.1.36). By taking shifification, it can be shown that the same categorical properties of $\mathcal{G}\mathrm{rp}$ holds for $\mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}_k$, such as the nine lemma, five lemma, and the restrictive snake lemma.

2 Finite Groups

Main references are [Finite Flat Group Schemes and p-Divisible Groups, Jakob], [Finite Group Schemes, Pink], [Introduction to Finite Group Schemes], [Finite Flat Group Schemes, Tate].

Def. (8.1.2.1) [Finite Locally Free Group Schemes]. A **finite Locally Free group scheme** is a group scheme G that is finite locally free(5.6.2.22) over S. It is said to have **order/rank** d if G is finite locally free of rank d over S, where d is a locally constant integral-valued function on S.

Def. (8.1.2.2) [Finite Groups]. A finite locally free group scheme over a field k is called a **finite group scheme** over k. An **infinitesimal group scheme** is a finite group scheme G s.t. $|G| = e$.

Prop. (8.1.2.3) [Cartier]. Let k be a field of characteristic 0, then

- Every affine finite commutative group scheme over k is finite étale.
- If k is alg.closed, then there is an equivalence of categories between finite commutative group schemes over k and $\mathcal{A}\mathrm{b}$, by $G \mapsto G(k)$ and $\Gamma \mapsto \underline{\Gamma}_k$.

Proof: 1: by(2.9.2.22) and(4.4.7.20).

2: $\underline{\Gamma}_k$ is clearly affine commutative group schemes over k. If A is finite locally free Hopf algebra over k, then it is finite étale by item1 and isomorphic to a fintie product of copies of k. Now the equivalence is clear. □

Prop. (8.1.2.4)[Finite Group Schemes of Order Invertible in S is Finite Étale]. A finite group scheme G over S of order invertible in S is finite étale.

Proof: Cf.[Jakob, P45].? □

Prop. (8.1.2.5) [Finite Étale Group Schemes]. Let X be a connected smooth scheme with a geometric point $\overline{x}$, then there is a equivalence of categories:

$$\{\text{Finite étale group schemes over } X\} \leftrightarrow \{\text{Finite groups with a continuous action of } \pi_1(X,\overline{x})\}$$

by(7.3.2.5). In particular, constant group schemes correspond to finite groups with trivial $\pi_1(X,x)$ actions.

Cor. (8.1.2.6). The category of finite étale commutative group schemes over X is Abelian.

The category of commutative group schemes over X of order invertible in X is Abelian, by(8.1.2.4).

Commutative Finite Groups

Prop. (8.1.2.7) [Cartier Duality]. Let G be a finite commutative locally free group scheme over S, then $\mathcal{O}_G$ is a finite locally free $\mathcal{O}_S$-Hopf algebra, then $\mathrm{Hom}_{\mathcal{O}_S}(\mathcal{O}_G,\mathcal{O}_S)=\mathcal{O}_G^\vee$ is again a finite locally free $\mathcal{O}_S$-Hopf algebra(5.2.5.2), and thus $\mathbf{Spec}\,\mathcal{O}_G$ is a finite locally free group scheme over S, called the **Cartier dual** G^D of G.

Moreover, this Cartier dual of G represents the Hom sheaf $\underline{\mathrm{Hom}}_{\mathrm{Sch}/S}(G,\mathbb{G}_m)$.

If G is dual to G', then their base changes are dual, too.

Finally, $(G^D)^D=G$ by(5.2.5.2), so Cartier duality is a contravariant autoequivalence of the category of commutative finite locally free group schemes over S.

Proof: For the Hom sheaf, we need to show

$$G^D(T)\cong \mathrm{Hom}_T(G\otimes_S T,\mathbb{G}_{m,T})$$

for any T/S. Notice a $g\in G^D(T)$ corresponds to an R-algebra morphism $g\in \mathrm{Hom}_{\mathcal{O}_S}(\mathcal{O}_G^\vee\to\mathcal{O}_T)=\mathcal{O}_G\otimes_{\mathcal{O}_S}\mathcal{O}_T$(5.2.5.2) that satisfies

$$(\Delta\otimes\mathrm{id}_T)(g)=g\otimes_T g\in(\mathcal{O}_G\otimes_{\mathcal{O}_S}\mathcal{O}_G)\otimes_{\mathcal{O}_S}\mathcal{O}_T,\quad (\varepsilon\otimes\mathrm{id}_T)(g)=1$$

Also, g is a unit, as

$$g\cdot(\iota\times\mathrm{id}_T)(g)=\mu\circ((\mathrm{id}_{\mathcal{O}_G}\otimes\iota)\otimes\mathrm{id}_{\mathcal{O}_T})(g\otimes g)=\mu\circ((\mathrm{id}_{\mathcal{O}_G}\otimes\iota)\otimes\mathrm{id}_T)\circ(\Delta\otimes\mathrm{id}_T)(g)=(\eta_{\mathcal{O}_G}\otimes\mathrm{id}_T)(\varepsilon\otimes\mathrm{id}_T)(g)=1$$

so g corresponds to a $\mathcal{O}_T$-Hopf algebra map

$$\mathcal{O}_T[X,X^{-1}]\to\mathcal{O}_G\otimes_{\mathcal{O}_S}\mathcal{O}_T$$

which maps X to G, □

Prop. (8.1.2.8)[$\underline{\Gamma}$ is Cartier Dual to $D(\Gamma)$]. Let Γ be a finite commutative group and S be a scheme, then $\underline{\Gamma}_S$ is Cartier dual to $D(\Gamma)_S$.

Proof: By(8.1.2.7), it suffices to show for $S = \operatorname{Spec}\mathbb{Z}$. Now $\underline{\Gamma} = \prod_{\gamma\in\Gamma}\mathbb{Z}$, and $\Delta(e_\gamma) = \sum_{gg'=\gamma} e_g \otimes e_{g'}$. Let $f_\gamma \in \underline{\Gamma}^\vee$ be dual to e_γ, then

$$f_\gamma \cdot f_{\gamma'} = \sum_{g\in\Gamma}\Delta^\vee(f_\gamma\otimes f_{\gamma'})(e_g)f_g = \sum_{g\in\Gamma} f_\gamma\otimes f_{\gamma'}(\sum_{st=g} e_s\otimes e_t)f_g = f_{\gamma\gamma'}$$

so $\underline{\Gamma}^\vee \cong \mathbb{Z}[\Gamma]$, and

$$\Delta(f_\gamma) = \sum_{g,g'\in\Gamma}\mu^\vee(f_\gamma)(e_g\otimes e_{g'})f_g\otimes f_{g'} = f_\gamma\otimes f_\gamma.$$

□

Cor. (8.1.2.9). $\underline{\mathbb{Z}/n\mathbb{Z}}$ is Cartier Dual to μ_n.

Prop. (8.1.2.10) [α_p is Cartier Dual to α_p]. Over a $\mathbb{F}_p$-scheme S, the group scheme $\alpha_{p,S}$ is Cartier dual to itself.

Proof: By(8.1.2.7), it suffices to show for $S = \operatorname{Spec}\mathbb{F}_p$. Then $\alpha_p = \mathbb{F}_p[X]/X^p$ with

$$\Delta(X) = X\otimes 1 + 1\otimes X,\quad \varepsilon(X) = 0, S(X) = -X.$$

Let $Y_i \in \alpha_p^\vee$ dual to X^i then

$$Y_i{\cdot}Y_j = \sum_{k=0}^{p-1}\Delta^\vee(Y_i\otimes Y_j)(X^k)Y_k = \sum Y_i\otimes Y_j(\Delta(X^k))Y_k = \sum Y_i\otimes Y_j(\sum_{a+b=k}\binom{k}{a}X^a\otimes X^b)Y_k = \binom{i+j}{i}$$

Now $\binom{i+j}{i}$ is unit, so $\alpha_p^\vee = \mathbb{F}_p[Y]/Y^p$ where $Y = Y_1$. and

$$\Delta(Y) = \sum_{a,b}\mu^\vee(Y)(X^a\otimes X^b)Y_a\otimes Y_b = \sum Y(X^{a+b}) = Y\otimes 1 + 1\otimes Y,$$

so $\alpha_p^\vee = \alpha_p$. □

Prop. (8.1.2.11). If G_1, G_2 are finite groups over a field k, then there are no non-trivial homomorphism from G_1 to G_2 or from G_2 to G_1 if G_1 is étaleand G_2 is connected.

Proof: Cf.[Van de Geer, P67]. □

Prop. (8.1.2.12). If $e \to G_1 \to G \to G_2 \to e$ is an exact sequence of finite locally free group schemes over S, then $\operatorname{rank}(G) = \operatorname{rank}(G_1)\cdot\operatorname{rank}(G_2)$.

Proof: Cf.[Van de Geer, P68]. □

Prop. (8.1.2.13). Let $\operatorname{char} k = p > 0$, then the rank of any finite group over k is a power of p.

Proof: Cf.[Van de Geer, P68]. □

Cor. (8.1.2.14). Let $\operatorname{char} k = p > 0$, then a finite group over k is étaleand coétaleiff $p \nmid \operatorname{rank}(G)$.

Proof: Cf.[Van de Geer, P68]. □

Prop. (8.1.2.15). Over a $\mathbb{F}_p$-scheme S, the three group schemes $\underline{\mathbb{Z}/p\mathbb{Z}}_S, \mu_{p,S}, \alpha_{p,S}$ are mutually non-isomorphic.

Proof: We may take a fiber and assume $S = \operatorname{Spec} K$, then $\underline{\mathbb{Z}/p\mathbb{Z}}_S$ is reduced, $\mu_{p,S}$ is non-reduced and $\alpha_{p,S}$ is non-reduced. Then we can look at the reducedness of the group scheme and its Cartier dual. □

Prop. (8.1.2.16) [The Order Kills the Group, Deligne]. If G is a finite locally free commutative group scheme over S of constant order n, then $[n]_G = 0 : G \to G$.

Proof: Cf.[Jakob P12].? □

Finite Locally Free Group Schemes over Henselian Local Rings

Remark (8.1.2.17). Throughout this subsubsection, let R be a Henselian local ring $(R, \mathfrak{m})$.

Prop. (8.1.2.18).

Proof: □

Cor. (8.1.2.19). Let R be a equicharacteristic Henselian local ring of characteristic $p > 0$, then every finite locally free group scheme over R of prime order is automatically commutative.

Proof: Cf.[Shatz, P50]. □

Cor. (8.1.2.20). Let R be a strict Henselian local ring with residue field of characteristic $p > 0$, then any connected finite locally free group scheme over R has order p^t for some $t > 0$.

Proof: Cf.[Shatz, P50]. □

Commutative p-Group Schemes

Cf.[Finite Flat Group Schemes, Tate]Section4.

3 Groupoid Schemes

Cf.[Sta]Cha38, 39.

4 Algebraic Groups over Fields

All group schemes G in this subsection are algebraic over a field k.

Prop. (8.1.4.1) [Smoothness and Geo.Reducedness]. For a locally algebraic group scheme G over a field k, smoothness is equivalent to geo.reducedness at a closed point.

Proof: If G is smooth, then it is geo.regular thus geo.reduced. The converse follows from(8.2.1.10). □

Cor. (8.1.4.2) [Cartier]. Any locally algebraic group scheme over a field of char 0 is smooth.

Proof: This is a consequence of(8.1.1.15) and(8.1.4.1). Alternative proof: $\Omega_{G/k}$ is free, by(8.1.1.14), so it is smooth by(5.6.4.15). □

Prop. (8.1.4.3) [Reduced Structure]. If G_{red} is geo.reduced, then it is a subgroup of G. This is the case if k is perfect.

Proof: This is because $G_{\text{red}} \times G_{\text{red}}$ is reduced so the multiplication factors through $G_{\text{red}} \times G_{\text{red}}$. □

Prop. (8.1.4.4)[Smoothness in Characteristic p]. Let G be an affine algebraic groups over a perfect field k of characteristic $p \neq 0$, and $r \geq 0$, then image of the relative Frobenius $F_{G/k} : G \to G^{(p^r)}$ is geo.reduced group scheme when r is sufficiently large.

Proof: To show it is a group scheme, notice F^r is a homomorphism and use homomorphism theorem(8.1.1.29). And It corresponds to

$$\Gamma(G)\otimes_{k,\varphi^r} k \to \Gamma(G) : a\otimes c \mapsto ca^{p^r}.$$

The image of which is just $\Gamma(G)^{p^r}$ as k is perfect. To show it is geo.reduced, we can assume k is alg.closed, then the nilradical N of $\Gamma(G)$ is nilpotent, so some $N^m = 0$, and then the image is reduced for any $p^r > m$. □

Prop. (8.1.4.5) [Smoothness and Tangent Space]. A locally algebraic group scheme G over a field is smooth iff it is regular iff $\dim_k T_e \le \dim_e G$, where e is the identity element.

Proof: By homogeneity and the fact smooth locus is open, G is smooth iff it is smooth at e. Now e is a rational point, by(4.4.5.26), G is smooth at e iff it is regular at e. □

Prop. (8.1.4.6) [Closed Subgroups and Points]. Let G be a locally algebraic subgroup over k and $S\subset G(k)$ a closed subgroup, then there is a unique reduce closed subgroup H of X that $H(k) = S$. Moreover, H is geo.reduced. The algebraic subgroups of G arising in this way are exactly those that $H(k)$ is schematically dense in H. linear In particular, when k is sep.closed, then $H\mapsto H(k)$ is a bijection between closed subgroups of G and closed subgroups of $G(k)$, by(5.4.3.10).

Proof: Let H be a reduced closed subscheme of G that $H(k) = S$, then S is dense in $|H|$ and H is reduced, so by(5.4.3.5) and(5.4.3.8) shows S is schematically dense in H and H is geo.reduced. Therefore $H\times H$ is reduced and thus multiplication map $H\times H\to G$ factors through H, also does inversion and unit, so H is a subgroup of G.

The converse is also true. □

Cor. (8.1.4.7) [Zariski Closure]. Let G be a locally algebraic subgroup over k and $S\subset G(k)$ a subgroup, then there is a unique geo.reduced closed subscheme H of G, called the Zariski closure of S in G, such that $H(k)$ is the Zariski closure of $S\subset G(k)$.

Prop. (8.1.4.8) [Algebraic Group Scheme is Quasi-Projective]. Any algebraic group scheme over a field k is quasi-projective.

Proof: Cf.[Sta]0BF7**?**. □

Prop. (8.1.4.9) [Center Subgroup]. For a locally algebraic group scheme G over a field k, its center is an algebraic subgroup of G.

Proof: Cf.[Sta]0BF8. □

Prop. (8.1.4.10). Every étale normal subgroup of a connected algebraic group is central.

Proof: This is because the automorphism group scheme of an étale group scheme is étale**?**. □

Prop. (8.1.4.11) [Identity Component]. For a locally algebraic group G over a field k, consider its identity component G^0, then

- It commutes with the formation of identity component commutes with base change of fields. In particular, G^0 is geo.connected.
- G is locally connected(5.4.1.23), thus G^0 is clopen in G.
- G^0 is a a characteristic algebraic subgroup of G

Proof: 1, 2 follows from(5.4.3.15).

3: By(5.4.3.12), $G^0 \times G^0$ is connected, thus $G^0 \times G^0$ is mapped into G^0, and it is an open subscheme, thus it is an algebraic subgroup of G. □

Cor. (8.1.4.12)[$\pi_0(G)$]**.** Let G be a locally algebraic group, then group structure induces a group structure on the maximal étalesubalgebra of $\Gamma(G)$, thus $G \to \pi_0(G)$ is a group homomorphism(7.3.1.1), which is faithfully flat by(7.3.1.3), and the stabilizer of the identity in $\pi_0(G)$ is just G^0 by(7.3.1.3) again. Thus $\pi_0(G) = G/G^0$ by(8.2.1.11).

Prop. (8.1.4.13). Every connected component of a locally algebraic group G over a field k is irreducible.

Proof: By(8.1.4.11), $G^0_{\overline{k}}$ is connected. To show it is irreducible, it suffices to consider its reduced structure, and in this case it is smooth(Notice in this case G^0_{red} is an algebraic group because $G^0_{\mathrm{red}} \times G^0_{\mathrm{red}}$ is reduced). Thus no closed point is connected in two irreducible component, thus it is irreducible. Then G^0, as a quotient space of $G^0_{\overline{k}}$, is also irreducible.

For another connected component H, choose a closed point h, let L be a finite normal extension of k containing $k(h)$, then each connected component of H_L maps surjectively onto H, thus contains one of the finitely many inverse images of h in H_L. And they are all rational points, thus isomorphic to G^0_L, which is irreducible, thus H is also irreducible. □

Cor. (8.1.4.14) [Connected Algebraic Group is Geo.Irreducible]. A connected algebraic group over a field is geo.irreducible by(8.1.4.11) and(8.1.4.13).

Cor. (8.1.4.15). If G is a connected algebraic group over a field k, then for any non-empty open subschemes U, V of G, $U \times V \to G$ is surjective.

Proof: By(5.4.1.29), it suffices to check on closed points. Let p be a closed point, by base change, we may assume $x \in G(k)$, then $xV^{-1} \cap U \neq \varnothing$ as G is geo.irreducible(8.1.4.14), thus $x \in UV$. □

Cor. (8.1.4.16). Every connected component of a locally algebraic group scheme over a field k is algebraic over k.

Proof: For the identity component, take a non-empty affine open subset U, then $U^2 = G^0$ by(8.1.4.15), thus G^0 is quasi-compact. For the other components, the same proof as that of(8.1.4.13) shows they are also quasi-compact. □

Def. (8.1.4.17) [Torsion Component]. Let G be a locally algebraic commutative group over k, then $G^\tau = \cup_{n>0}[n]^{-1}G^0 \subset G$ is an open group subscheme, called the **torsion component** of G. Forming G^τ commutes with change of fields, and if G^τ is quasi-compact, it is a clopen subgroup.

Prop. (8.1.4.18). Let G be a locally algebraic commutative group over k, then any algebraic subgroup of G is contained in G^τ. In particular, if G^τ is algebraic over k, then it is the maximal algebraic subgroup of G.

Proof: As H is qc, it is covered by f.m. translates of G^0, thus G^0 has finite index in G^0H, which means $[n](H) \subset G^0$ for some $n \in \mathbb{Z}_+$. □

Prop. (8.1.4.19). Let X, Y be varieties over a field k that both have at least one K-point, and X is complete. Then any morphism $X \times Y \to G$ to a group scheme G over k factorizes as $f(x, y) = g(x)h(y)$, where $f : X \to G$ and $h : Y \to G$.

Proof: Fix a $y_0 \in Y(K)$ and define a morphism $g : X \to G : x \mapsto f(x, y_0)$, then the morphism $F : X \times Y \to G : (x, y) \mapsto g(x)^{-1} f(x, y)$ is constant on $X \times \{y_0\}$. Then the rigidity lemma(5.10.1.20) and(8.1.1.12) shows $F(x, y) = h(y)$ where $h : Y \to G$ is a morphism. Then we are done. □

Cor. (8.1.4.20). Any morphism from a $\mathbb{P}^1_K$ to a group scheme G is constant.

Proof: Let (x_0, x_1) be a homogenous coordinate of $\mathbb{P}^1$, consider the morphism $s : \mathbb{P}^1 \times \mathbb{A}^1 \to \mathbb{P}^1 : (x_0, x_1) \times y \mapsto (x_0, x_0 + x_1 y)$. Let $f : \mathbb{P}^1 \to G$ be a morphism, consider the composition

$$\mathbb{P}^1 \times \mathbb{A}^1 \xrightarrow{s} \mathbb{P}^1 \xrightarrow{f} G$$

then by(8.1.4.19), $f \circ s$ factors as $f(s(x, y)) = g(x)h(y)$.

We take $y = 0$, then $s(x, 0) = x$, and $g(x) = f(x)h(0)^{-1}$. Thus $f(s(x, y)) = f(x)h(0)^{-1}h(y)$. Next we take $x = (0, 1)$, then $s((0, 1), y) = (0, 1)$, and $f((0, 1)) = f((0, 1))h(0)^{-1}h(y)$. This shows $h(y) = h(0)$ is constant, thus $f(s(x, y)) = f(x)$. Finally, let $x = (0, 1)$, then $s((0, 1), y) = y$, and $f(y) = h(0)$ is constant. □

Cor. (8.1.4.21). Let U be an open subset of $\mathbb{P}^1$, then any morphism from U to a group variety G is constant. In particular, G contains no rational curve, and any morphism from a rationally connected variety to G is constant, in particular $\mathbb{P}^n_K$.

Proof: Any rational map from $\mathbb{P}^1$ to G can be extended to a morphism, by(5.11.1.15), thus it is constant, by the proposition above. □

Def. (8.1.4.22) [Anti-Affine Group Schemes]. An **anti-affine algebraic group** is an algebraic group over k s.t. $\Gamma(G) = k$. For example, Abelian varieties are anti-affine by(5.10.1.12)

Prop. (8.1.4.23). Let $\varphi : G \to H$ be a homomorphism of algebraic groups over k that G is anti-affine and H is connected, then φ factors through the center of H(8.1.4.9).

Proof: Cf.[**?**]P151. □

Cor. (8.1.4.24). If G is a connected algebraic group over k, then every anti-affine algebraic subgroup is contained in the center of G.

Cor. (8.1.4.25). Any anti-affine algebraic group is commutative and connected.

Proof: $G \to \pi_0(G)$ is surjective but $\pi_0(G)$ is affine thus this map is trivial, so G is connected. Then it is also commutative by(8.1.4.24). □

Construction of Algebraic Groups

Prop. (8.1.4.26)[Generated Closed Subgroup]. Let $\varphi_i : X_i \to G$ be a family of maps from algebraic schemes X to an algebraic group over a field k.

- If X_i and G are all affine, then the generated group scheme is representable by an algebraic subgroup H.
- If X_i are all geo.reduced. Then the generated group scheme is representable by a smooth subgroup H.

Moreover, in both cases, if there is only a single map $\varphi : X \to G$ and X is geo.connected, and $e \subset \varphi(X)$, then $\langle X, \varphi \rangle$ is geo.connected.

Proof: Cf.[Mil17]P54, 55, 56. □

Def. (8.1.4.27) [Commutator Group]. Let G be an algebraic group that is affine or smooth, then $[G, G]$ exists by(8.1.4.26), and:

- $[G, G]$ is the intersection of all normal subgroups H of G s.t. G/H is commutative.
- For a field extension k'/k, $[G_{k'}, G_{k'}] = [G, G]_{k'}$.
- If G is geo.connected/smooth, then $[G, G]$ is also geo.connected/smooth.
- If G is an affine smooth geo.connected group scheme, then $[G, G]$ is the unique smooth geo.connected subgroup scheme that satisfies $[G, G](\overline{k}) = [G(\overline{k}), G(\overline{k})]$.

Proof: 1: Cf.[Mil17]P129.
2: This is formal.
3: This follows from(8.1.4.26).
1: Cf.[Mil17]P130. □

Def. (8.1.4.28) [Transporter]. Let $G \times X \to X$ be an action of an algebraic group on a scheme, and Y, Z be subschemes of X, Z is a closed subscheme and Y is an algebraic scheme, then the functor

$$R \mapsto \{g \in G(R) | gY_R \subset Z_R\}$$

is represented by a closed subscheme of G, called the **transporter** $T_G(Y, Z)$.

Proof: $T_G(Y, Z)$ is in fact the sheaf $\mathcal{H}om(Y, Z) \times_{\mathcal{H}om(Y,X)} G$, and notice $\mathcal{H}om(Y, Z) \to \mathcal{H}om(Y, X)$ is a closed subfunctor(8.7.1.3), thus $T_G(Y, Z)$ is a closed subfunctor of G, thus represented by a closed subscheme of G. □

Cor. (8.1.4.29). Let $G \times X \to X$ be an action of an algebraic group on a scheme, and Y, Z be closed subschemes of X, then the functor

$$R \mapsto \{g \in G(R) | gY_R = Z_R\}$$

is represented by a closed subscheme of G.

Proof: In this case, the functor is represented by the closed subscheme $T_G(Y, Z) \cap \mathrm{inv}(T_G(Z, Y))$. □

Cor. (8.1.4.30) [Stablizer]. Let $G \times X \to X$ be an action of an algebraic group on a scheme, and Y be closed subschemes of X, then the functor

$$\mathrm{Stab}_G(Y) : R \mapsto \{g \in G(R) | gY_R = Y_R\}$$

is represented by a closed subscheme of G, called the **stablizer subgroup of** Y.

Def. (8.1.4.31) [Normalizer].

Def. (8.1.4.32) [Centralizer].

Group Varieties

Def. (8.1.4.33) [Group Varieties]. A **group variety** over a field k is a k-variety(5.10.1.3) that is also a group scheme.

Prop. (8.1.4.34) [Group Varieties are Smooth]. A group variety over k is smooth by(8.1.4.1). Conversely, any smooth connected algebraic group over k is a group variety, by(8.1.4.14)(8.1.1.12).

Prop. (8.1.4.35) [Tangent Bundle Trivial]. For a group variety over a field k, $T_{X,e}$ is the tangent space at e, then there is a natural isomorphism $\Omega_{X/k} \cong T^*_{X,e} \otimes \mathcal{O}_X$. Also true for $\mathcal{T}_X$(because $\Omega_{X/k}$ is locally free as X is smooth(8.1.4.34)(5.10.1.14)).

Proof: There should be another proof using relation in(5.5.5.14)**?**.

Use a dual number characterization of tangent spaces and tangent vector fields(5.6.4.22)(5.10.1.15), then notice a tangent vector $\tau \in T_{X,e}$ is a $S = k[\varepsilon]$-point of X, then right translation gives a translation $X_S \to X_S$ that is invariant on X, which gives a tangent vector on X.

So there is a map $T_{X,e} \otimes \mathcal{O}_X \to \Omega_{X/k}$. To check isomorphism, both are locally free of the same rank, so it suffices to show it is surjective. But on closed pts, pass to Nakayama, this is clearly true, so it is surjective by(5.10.1.13). □

Prop. (8.1.4.36) [Dimension Theorem]. Let $\varphi : G \to H$ be a surjective homomorphism of group varieties, then

$$\dim(G) = \dim(H) + \dim(\ker(\varphi)).$$

Proof: This is a consequence of(5.6.3.19), as the fiber over any closed pt is isomorphic to a field base change of $\ker(\varphi)$. □

Prop. (8.1.4.37). Every binational homomorphism of a connected affine group varieties is an isomorphism.

Proof: Such an isomorphism induces a homomorphism $A \to B$ of integral Hopf algebras that is an isomorphism on the fraction field, then it is an isomorphism by(2.9.2.24). □

Def. (8.1.4.38) [Quasi-Central Homomorphisms]. A **quasi-central homomorphism** $\varphi : G' \to G$ of group varieties over k is a homomorphism the kernel of $\varphi(\overline{k})$ is central in $G'(\overline{k})$.

Prop. (8.1.4.39). If a homomorphism of group varieties $\varphi : G' \to G$ is quasi-central and the kernel of $\mathrm{Lie}(\varphi)$ is central, then $\ker(\varphi) \subset Z(G')$.

Proof: Cf.[Bruhat-Tits, 2.1]. □

Prop. (8.1.4.40) [1-Dimensional Group Varieties]. Let G be a group variety over a field $k = \overline{k}$, then either $G \cong \mathbb{G}_a$, $\mathbb{G}_m$ or an elliptic curve.

Proof: Cf.[Sil99]. □

5 Homomorphisms

Prop. (8.1.5.1) [Connected-étale Sequence]. Cf.[Mil17]P114, [Finite Flat Group Schemes, Tate]Section3.7 and [Mil17b]P117.

Prop. (8.1.5.2) [Algebraic Subgroups are Closed]. Algebraic subgroups H of an algebraic group G are closed subgroups. In particular, an algebraic subgroup of an affine algebraic group is affine.

WARNING: H must first be an algebraic group, so we can use Chevalley theorem to show it is locally closed.

Proof: As $H_{k'} \to H$ is a quotient map(5.4.6.3), we can assume k is alg.closed, and also assume H, G are reduced. Now Chevalley shows that the image is a constructible set of G. Then we can consider all on the level of $\overline{k}$ points, because G is Jacobson. Then H contains an open subset of $\overline{H}$ by(3.11.3.17), which implies $H(\overline{k})$ is open in $\overline{H} \cap G(\overline{k})$. Now $\overline{H} \cap G(\overline{k})$ is the closure of $H(\overline{k})$ in $G(\overline{k})$, thus it is also a subgroup of $G(\overline{k})$, and we can consider the coset of $H(\overline{k})$ in $\overline{H} \cap G(\overline{k})$. H is open in $\overline{H}$, and $\overline{H}$ is compact, and also $\overline{H} \cap G(\overline{k})$ is compact because G is Jacobson, so there are only f.m. coset, thus $H(\overline{k})$ is also closed in $\overline{H} \cap G(\overline{k})$, thus H is also closed in $\overline{H}$, so $H = \overline{H}$. **?** Cf.[Mil17]P19. □

Prop. (8.1.5.3) [Characterizating Quotient Maps]. The following conditions on a homomorphism $\varphi : G \to Q$ of algebraic groups are equivalent:

- φ is fully faithful.
- φ is a quotient map(8.1.1.4).
- The homomorphism $\mathcal{O}_Q \to \varphi_* \mathcal{O}_G$ is injective.

Proof: $1 \to 2$ follows from the very definition of fat subfunctors, as f.f. map is a fppf cover. Cf.[Mil17]P109.**?** □

Prop. (8.1.5.4). Let $\varphi : G \to H$ be a surjective homomorphism of group schemes and H is reduced, then φ is a quotient map.

Proof: The hypothesis implies $G(\overline{k})$ acts transitively on $H(\overline{k})$, thus φ is faithfully flat by(8.2.1.4). □

Prop. (8.1.5.5) [Check Quotient Map on Closed Points]. Let $\varphi : G \to H$ be a quotient map of locally algebraic groups, then $\varphi : G(\overline{k}) \to H(\overline{k})$ is surjective. The conversely is also true if H is reduced. In particular, if $e \to N \to G \to H \to e$ is an exact sequence, then $e \to N(\overline{k}) \to G(\overline{k}) \to H(\overline{k}) \to e$ is exact.

Moreover, if φ is étale, then $\varphi : G(k^s) \to H(k^s)$ is also surjective.

Proof: This follows from the fact for any $x \in H(\overline{k})$(resp. k^s), G_x is non-empty and locally algebraic(resp. étale) over $k(x)$, thus has a $\overline{k}$(resp. k^s-point).

For the converse, notice the image of φ has the same $\overline{k}$-points as H, thus it equals H as H is reduced and locally algebraic. □

Prop. (8.1.5.6) [Characterizing Monomorphisms]. For a homomorphism $\varphi : G \to H$ of algebraic groups over k, the following are equivalent:

- φ is a monomorphism.
- $\ker(\varphi) = e$(8.1.1.4).

- φ is a monomorphism in the category of algebraic groups over k.
- φ is a monomorphism in the category of algebraic schemes over k.

Moreover, a monomorphism is just a closed embedding.

Proof: $1 \to 4 \to 3$ is obvious.

$3 \to 2$: the composition of $\ker(\varphi) \to G$ with φ is trivial, thus $\ker(\varphi)$ is trivial.

$2 \iff 1$: This follows from the definition of $\ker(\varphi)$(8.1.1.4).

For the last assertion, if φ is a closed embedding, then , conversely, if φ is a monomorphism, consider the quotient space $G \to G/H$(8.1.1.21), then by(8.1.1.26), H is the fiber over $o \in G/H$, thus a closed subscheme. □

Def. (8.1.5.7)[Embedding]. An **embedding of algebraic groups** is a closed immersion of algebraic groups.

Isogenies

Def. (8.1.5.8)[Finite Index Subgroups]. An algebraic subgroup H of an algebraic group scheme G is said to have finite index if the quotient G/H is a finite scheme.

Prop. (8.1.5.9). For any algebraic group G over k, the identity component G^0 is of finite index in G.

Proof: Notice an algebraic group H is finite iff $\#H(\overline{k}) < \infty$. And $(G/G^0)(\overline{k}) = G(\overline{k})/G^0(\overline{k})$(8.1.4.11) is finite as G is compact. □

Def. (8.1.5.10) [Isogeny]. A homomorphism of algebraic groups $G \to H$ is called an **isogeny** if its kernel is finite and its image is of finite index in H(8.1.5.8).

Def. (8.1.5.11) [Strongly Connected Groups]. An algebraic group G is called a **strongly connected group** if it has no non-trivial subgroup of finite index.

Def. (8.1.5.12) [Strongly Identity Components]. The **strongly identity component** G^{s0} of an algebraic group G is defined to be the intersection of the algebraic subgroups of finite index. Thus it is a characteristic subgroup of G.

Prop. (8.1.5.13). G/G^{s0} is a a finite scheme. In particular, G^{s0} is the smallest algebraic subgroup having the same dimension as G.

Proof: As G is Noetherian, $G^{s0} = H_1 \cap \ldots H_r$ for G/H_i finite schemes. Thus $G/G^{s0} \hookrightarrow H_1 \cap \ldots H_r$ is a finite scheme. □

Prop. (8.1.5.14)[Strongly Identity Components and Identity Components]. G^{s0} is connected, and the converse is true if G is smooth. In fact, if G is smooth, $G^{s0} = G^0$.

In particular, a group variety has no algebraic subgroup of finite index. Thus an isogeny to a group varieties is surjective(thus a quotient map by(8.1.1.31)).

Proof: G^{s0} is connected because the identity component is of finite index(8.1.5.9). Conversely, G^0/G^{s0} is smooth and connected and finite(8.1.5.29), thus it is a group variety of dimension0, which is trivial. □

Prop. (8.1.5.15). Let G be an algebraic group over a perfect field k, then $G^0_{\text{red}} = G^{s0}$.

Proof: Cf.[Mil17]P122. □

Def. (8.1.5.16). A **central/multiplicative isogeny** is an isogeny that the kernel is central/of multiplicative type.

Prop. (8.1.5.17). Any isogeny with kernel order prime to the characteristic has étalekernel by(8.1.2.4), thus it is central, by(8.1.4.10).

Prop. (8.1.5.18). Every multiplicative isogeny from a connected algebraic group is central, by(8.2.3.22).

Def. (8.1.5.19). A composition of multiplicative isogenies is a multiplicative isogeny.

Proof: This is because there is an exact sequence $e \to \ker(\varphi_1) \to \ker(\varphi_2 \circ \varphi_1) \to \ker(\varphi_2) \to e$, thus $\ker(\varphi_2 \circ \varphi_1)$ is central, hence of multiplicative type by(8.2.3.16). □

Prop. (8.1.5.20) [Isogenies between Group Varieties]. Let $\varphi : G \to H$ be a surjective homomorphism of group varieties, then φ is flat. And if $\dim G = \dim H$, then φ is finite, and the rank of $\ker(\varphi)$ equals the separable degree of $K(G)/K(H)$.

Proof: φ is flat by(8.2.1.4). By(5.10.3.4), there exists a dense open subscheme U' s.t. $\varphi^{-1}(U') \to U'$ is finite, thus by homogeneity, φ is finite, and rank of $\ker(\varphi)$ is $[K(G) : K(H)]_s$. □

Subnormal Series

Prop. (8.1.5.21) [Solvability]. Let G be an algebraic group that is either affine of smooth, then G is solvable iff $G^{(n)} = e$ for some n large. In particular, for a field extension k'/k, G is solvable iff $G_{k'}$ is solvable.

Prop. (8.1.5.22) [Nilpotency]. Let G be an algebraic group that is either affine of smooth, then G is nilpotent iff $G^n = e$ for some n large. In particular, for a field extension k'/k, G is solvable iff $G_{k'}$ is solvable.

In particular, if G is a nilpotent and geo.connected, then it contains a non-trivial geo.connected subgroup scheme in its center, by(8.1.4.27).

Prop. (8.1.5.23). A split solvable algebraic group G is an affine group variety, by(8.1.5.29) and(8.1.5.29).

Lemma (8.1.5.24). If $G = G_0 \rhd G_1 \rhd \ldots \rhd G_s = \{e\}$ is a subnormal series and $\dim G = \dim G_i/G_{i+1}$ for some i, then $G \sim G_i/G_{i+1}$.

Proof: The maps $G_i \to G_i/G_{i+1}$ and $G_i \to G_{i-1} \to \ldots \to G_0 = G$ are isogenies(8.1.5.10). □

Def. (8.1.5.25) [Composition Series]. A **composition series of** G is defined to be a maximal object among the subnormal series

$$G = G_0 \rhd G_1 \rhd \ldots \rhd G_s = \{e\}$$

that satisfies $\dim G_0 > \dim G_1 \ldots > \dim G_s$.

Prop. (8.1.5.26). Any two composition series of an algebraic group G has refinements that the quotients are isogenous.

Cor. (8.1.5.27) [Jordan-Holder].

Maximal Subgroup with Properties

Def. (8.1.5.28) [Good Properties]. A property of algebraic groups is called a **good property** s.t.

- e has P.
- Every extension of groups with property P has P.
- Every quotient of a group with property P has P.

Prop. (8.1.5.29) [List of Good Properties(Not Complete)].

1. Strongly connectedness.
2. Solvability. Moreover, subgroups of solvable groups are solvable.
3. Smoothness.
4. Unipotency.
5. affineness.
6. connectedness.
7. finiteness. Moreover, subgroups of finite groups are finite.
8. unipotency. Moreover, subgroups of unipotent groups are unipotent.

Proof:

1. This follows from the isomorphism and correspondence theorems(8.1.1.33)(8.1.1.34).
2. This follows from standard argument and correspondence theorems(8.1.1.33)(8.1.1.34).
3. Let $e \to N \to G \to H \to e$ be an exact sequence of algebraic groups, then if G is smooth, then so is H by(8.2.1.10) and the fact G/H is geo.reduced by(5.1.5.28) and(8.1.5.3). If N, H are smooth, then so is G by the fact smoothness is stalkwise.
4. Quotient case is clear. If N is a normal subgroup of G s.t. N and G/N are both unipotent, then (for) any non-zero linear representation V of G, $V^N \neq 0$, and V^N is stable under G-actions, thus G/N acts on V^N, thus $V^G = (V^N)^{G/N} \neq 0$.
5. Notice by(8.1.1.27) and(5.1.5.29). $G \to Q$ is affine.
6. Cf.[Mil17]P114.
7. This follows from(8.1.1.28).
8. Cf.[Mil17]P282.

□

Prop. (8.1.5.30) [Maximal Group Variety Exists]. If P is a good property of algebraic groups, then every algebraic group G over k contains a largest normal subgroup variety H with property H. And also G/H has contains no non-trivial such subgroups.

Proof: G contains at least one normal subgroup variety, namely e. There exists a maximal such one, by taking the one with maximal dimension(because smooth varieties are reduced), then it is the largest, because if H' is another, then HH' is a larger one, by(8.1.5.29) and the fact NH is a quotient of $N \rtimes H$.

And if G/H contains a normal subgroup variety H' that has P, then the inverse image of H' in G is also a normal subgroup variety that has P, contradiction. □

6 Cohomology and Extensions

Cf.[Mil17]Chap15.

8.2 Group Schemes II: Solvable Groups

1 Group Actions

Remark (8.2.1.1). Group action of an group functor on an object is defined in(3.1.1.66).

Prop. (8.2.1.2) [Group Action]. An action of an algebraic group G on an algebraic group X is equivalent to a right $\Gamma(G)$-comodule structure on $\Gamma(X)$ as $\Gamma(G)$-modules. This action will induce a right comodule structure on $\Gamma(X)$.

The action of G on itself is called the **regular action** of G.

Prop. (8.2.1.3). Let $\mu : G \times X \to X$ be an action of an group scheme G on a scheme X, then it is faithfully flat, and it is called a smooth/finite/...action if μ is smooth/finite/..

Proof: We can see this from the commutative diagram(3.1.1.67). □

Prop. (8.2.1.4) [Image of Equivariant Map]. Let G be a group functor and X, Y be non-empty algebraic schemes on which G acts, and $f : X \to Y$ is an equivariant map.

- If Y is reduced and $G(\overline{k})$ acts transitively on $Y(\overline{k})$, then f is faithfully flat.
- If $G(\overline{k})$ acts transitively on $X(\overline{k})$, then the set $f(|X|)$ is locally closed in $|Y|$, so we can let $f(X)_{\mathrm{red}}$ denote its reduced subscheme structure(5.4.1.14).
- If X is reduced and $G(\overline{k})$ acts transitively on $X(\overline{k})$, then f factors into

$$X \xrightarrow{\text{faithfully flat}} f(X)_{\mathrm{red}} \xrightarrow{\text{immersion}} Y.$$

Moreover, $f(X)_{\mathrm{red}}$ is stable under the action of G.

Proof: Cf.[Mil17]P26.?

1:

2:

3: f factors through $f(X)_{\mathrm{red}}$ because X is reduced(5.4.1.14). Then the first assertion follows from 1 and 2. The last assertion follows from universal property again. □

Def. (8.2.1.5) [Orbit Map]. Let $\mu : G \times X \to X$ be an action of an algebraic group G on an algebraic scheme X. For any $x \in X(k)$, the **orbit map**

$$\mu_x : G \to X : g \mapsto gx$$

is defined to be the restriction to μ to $G \times \{x\} \cong G$. The image of the orbit map is locally closed in X by(8.2.1.4), and then its reduced structure subscheme is called the **orbit scheme** O_x of x.

Prop. (8.2.1.6) [Fixed Subscheme]. Let $\mu : G \times X \to X$ be an action of a group functor G on a separated algebraic scheme over k, then the functor

$$\widetilde{X}^G : R \mapsto \{x \in X(R) | \mu(g, x_{R'}) = x_{R'}, \forall R-\text{algebra } R', g \in G(R')\}$$

is representable by a closed subscheme X^G of X, called the **fixed subscheme** of this action. Then it can be seen directly that the formation of fixed subscheme commutes with extension of base fields.

Proof: An element $x \in X(R)$ defines two functors

$$G(R') \to X(R') : g \mapsto gx_{R'}$$

$$G(R') \to X(R') : g \mapsto x_{R'}$$

which are both natural in R'. Thus we get a map $X(R) \to \mathrm{Hom}(G_R, X_R \times X_R)$ which is also natural in R, thus induce a map $X \mapsto \mathcal{H}om(G, X \times X)$.

Then there is a Cartesian diagram

$$\begin{array}{ccc} \widetilde{X}^G & \longrightarrow & \mathcal{H}om(G, \Delta_X) \\ \downarrow & & \downarrow{\scriptstyle closed} \\ \widetilde{X} & \longrightarrow & \mathcal{H}om(G, X \times X) \end{array}.$$

The right vertical map is a closed subfunctor by(8.7.1.10), as Δ_X is closed in $X \times X$ because X is separated. Hence $\widetilde{X}^G$ is a closed subfunctor of $\widetilde{X}$, thus represented by a closed subscheme of X, by(8.7.1.3). □

Def. (8.2.1.7) [Isotropy Group]. Let G be a group scheme acting on an algebraic scheme X, and $x \in X(k)$, then the **isotropy group scheme** G_x is defined to be the fiber of the orbit map $\mu_x : G \to X$ over x.

Prop. (8.2.1.8) [Orbit Map is Faithfully Flat]. Let $\mu : G \times X \to X$ be an action of an algebraic group G on an algebraic scheme X and $x \in X(k)$.

- If X is reduced and $G(\overline{k})$ acts transitively on $X(\overline{k})$, then the orbit map $\mu_x : G \to X$ is faithfully flat.
- If G is reduced, then O_x is stable under G, and the map $\mu_x : G \to O_x$ is faithfully flat. If G is smooth, then O_x is also smooth.

Proof: 1: this follows from(8.2.1.4).

2: The first statement follows from(8.2.1.4)3, and then $\mathcal{O}_{O_x} \to \mu_{x*}(\mathcal{O}_G)$ is universally injective. Therefore if G is smooth, then $\mathcal{O}_{O_x}$ is geometrically reduced. Then O_x is smooth by(8.2.1.10). □

Def. (8.2.1.9) [Homogenous Space]. A non-empty algebraic scheme X with an action of a group scheme G is called a **homogeneous space** for G if $G(\overline{k})$ acts transitively on $X(\overline{k})$, and for any(some) $x \in X(\overline{k})$, μ_x is faithfully flat (thus surjective).

Prop. (8.2.1.10) [Smoothness for Homogenous Spaces]. If G is a group scheme and X is a generically geo.reduced G-homogeneous space, then X is smooth.

Proof: By(5.6.4.21), it has an open dense smooth locus. Now smoothness can be checked after base change to alg.closed field(4.4.2.1), but then because $G(\overline{k})$ acts transitively on itself, thus all the geometric points are smooth. But geometric points are dense in G(5.4.1.26), thus G is smooth. □

Action of Algebraic Groups

Prop. (8.2.1.11) [Homogenous Space as Quotients]. Let $\mu : G \times X \to X$ be an action of an algebraic group G on a separated algebraic scheme X over k with a rational point $x \in X(k)$, then (X, x) is a quotient of G by G_x iff the orbit map $\mu_x : G \to X$ is faithfully flat.

Proof: If (X,x) is a quotient space, then by(8.1.1.22). Conversely, if it is faithfully flat, then clearly $\mu_x(\widetilde{G})$ is a fat subfunctor of $\widetilde{X}$, thus X represents the quotient functor $\widetilde{G}/\widetilde{G}_x$. □

Cor. (8.2.1.12). Let $\mu: G\times X\to X$ be an action of a reduced algebraic group G on a separated algebraic scheme X over k with a rational point $x\in X(k)$, then (O_x,x) is a quotient space of G by G_x.

Proof: Because G is reduced, $\mu_x: G\to O_x$ is faithfully flat by(8.2.1.8), and O_x is stable under the action of G by(8.2.1.4), thus(8.2.1.11) applies to this case. □

Prop. (8.2.1.13). Let $\mu: G\times X\to X$ be an action of a smooth algebraic group on an algebraic scheme.

- A reduced closed subscheme Y of X is stable under G iff $Y(\overline{k})$ is stable under $G(\overline{k})$.
- Let Y be a locally closed subscheme of X, then if Y is stable under G, then $(\overline{Y})_{\mathrm{red}}$ and $(\overline{Y}\backslash Y)_{\mathrm{red}}$ is also stable under G.

Proof: 1: Because G is geo.reduced and Y is reduced, $G\times Y$ is reduced(5.4.3.2), thus $\mu: G\times Y\to X$ factors through Y iff $\mu(\overline{k})$ factors through $Y(\overline{k})$.

2: $|\overline{Y}|_{\mathrm{red}}(\overline{k})$ is the closure of $Y(\overline{k})$ in $X(\overline{k})$**?**. So as $G(\overline{k})$ acts continuously on $X(\overline{k})$, if it fixes $Y(\overline{k})$, then it also fixes $(\overline{Y})(\overline{k})$ and $(\overline{Y}\backslash Y)(\overline{k})$, thus we finish by 1. □

Cor. (8.2.1.14). Let G be a smooth algebraic group acting on an algebraic scheme X and let Y be a non-empty locally closed subscheme of X stable under the action of G of the smallest dimension, then it is closed.

Proof: This is because $\dim Y>\dim(\overline{Y}\backslash Y)_{\mathrm{red}}$(Because irreducible components of $\overline{Y}$ is not contained in $\overline{Y}\backslash Y$). □

Cor. (8.2.1.15)[Orbit Lemma]. Let G be a smooth algebraic group acting on an algebraic group over an alg.closed field k, then every orbit of minimal dimension is closed.

Proof: If Y is an orbit of minimal dimension, then $(\overline{Y}\backslash Y)_{\mathrm{red}}$ is stable under G and has smaller dimensions. If it is non-zero, then it contains an orbit. □

Prop. (8.2.1.16). A representation (V,ρ) of an algebraic group G induces an action of G on the affine algebraic scheme $V_{\mathfrak{a}}$, and also an action of G on the projective algebraic scheme $\mathbb{P}(V)$.

Prop. (8.2.1.17). Let $G\times X\to X$ be an action of an affine algebraic group G on an affine algebraic scheme X over k, then there exists a f.d. representation (V,ρ) of G and an equivariant closed embedding $X\hookrightarrow V_{\mathfrak{a}}$.

Proof: Cf.[Mil17b]P145. □

Def. (8.2.1.18) [Linear Action]. A **linear action** of an algebraic group G on an algebraic scheme X is an action (r,V) s.t. there exists a f.d. linear representation (V,ρ) of G and an equivariant non-degenerate immersion $X\hookrightarrow\mathbb{P}(V)$.

Prop. (8.2.1.19). If $G\times X\to X$ is a transitive action of an affine algebraic group G on an algebraic variety X that $X(k)$ is non-empty, then this action is linear.

Proof: Cf.[Mil17b]P145. □

Def. (8.2.1.20) [Grassmannian Variety]. The **Grassmannian variety** $\mathrm{Gra}(n,k)$ is a scheme over $\mathbb{Z}$ defined to be the quotient of $\mathrm{GL}(n)$ by the algebraic subgroup B fixing a subspace of dimension k(8.1.1.21).

The Grassmannian varieties are projective by(8.7.2.16).

Remark (8.2.1.21). For an explicit construction of $\mathrm{Gra}(n,k)$, Cf.[Sta]089T or [Nit05]P6.

Def. (8.2.1.22) [Flag Varieties]. The **flag variety** is a scheme over $\mathbb{Z}$ defined to be the quotient of GL_n by the algebraic subgroup B_F fixing a flag F(8.1.1.21).

The flag varieties are projective by(8.7.2.19).

Prop. (8.2.1.23) [An Algebraic Theorem]. Let F be a local field and X is an algebraic variety over F, then the F-topology makes $X(F)$ into a locally profinite space(because varieties are closed, and use(3.3.4.6)). Let G be a linear algebraic group over F and $G\times X\to X$ is a F-rational map, then $G(F)\times X(F)\to X(F)$ is a continuous action, and this action is constructible(3.11.1.21).

Proof: Cf.[Bernstein-Zelevinsky, Appendix]. □

Prop. (8.2.1.24) [Projectivity of Quotient Spaces]. How to generally prove that a quotient space is projective**?**.

2 Lie Algebras of Algebraic Groups

In this subsection, all algebraic groups G is affine over a field k.

Def. (8.2.2.1) [Lie Algebra of an Algebraic Group]. Let k be a field and G a locally algebraic group, then the tangent space at the unit element $e\subset G$ define by(5.6.4.25) is isomorphic to

$$L(G)=\ker(G(k[\varepsilon])\to G(k)),\varepsilon^2=0.$$

as a vector space. For any homomorphism $f:G\to H$, there is a Lie algebra map

$$\mathrm{Lie}(f):\mathrm{Lie}(G)\to\mathrm{Lie}(H)$$

induced by f.

In particular, if G is affine, it is the set of homomorphisms $\Gamma(G)\to k[\varepsilon]$ that the composition with $k[\varepsilon]\to k$ is the counit map $\varepsilon:\Gamma(G)\to k$(8.1.1.2).

If G is affine, φ maps the augmentation ideal $I_G=\ker(\varepsilon)$ into (ε), and thus is trivial on I_G^2. So φ factors through $\Gamma(G)/I_G^2$. Now $\Gamma(G)/I_G^2\cong k\oplus I_G/I_G^2$ by(2.9.2.11), so

$$L(G)\cong\mathrm{Hom}_k(I_G/I_G^2,k).$$

And we define $\mathrm{Lie}(G)$ to be $L(G)$.

In general, if R is any k-algebra, then we define $\mathfrak{g}(R)=\ker(G(R[\varepsilon])\to G(R))$, then similarly

$$\mathfrak{g}(R)=\mathrm{Hom}_R(I_R/I_R^2,R)=\mathrm{Hom}_k(I_G/I_G^2,k)\otimes R=\mathfrak{g}\otimes R.$$

Now $G(R[\varepsilon])$ acts on $\mathfrak{g}(R)$ by inner automorphism, so also does $G(R)$. So we get a homomorphism of algebraic groups

$$\mathrm{Ad}:G\to\mathrm{GL}(\mathfrak{g}).$$

This homomorphism commutes with Lie algebra homomorphism: If $f : G \to H$ is a homomorphism of algebraic groups, then there is a commutative diagram

$$\begin{array}{ccc} G \times \mathfrak{g} & \xrightarrow{(x,X)\mapsto \mathrm{Ad}(x)X} & \mathfrak{g} \\ \downarrow f & & \downarrow \mathrm{Lie}(f) \\ H \times \mathfrak{h} & \xrightarrow{(y,Y)\mapsto \mathrm{Ad}(y)Y} & \mathfrak{h} \end{array}$$

Then we define a Lie bracket on $\mathfrak{g}$ as follows: $[X, Y] = \mathrm{ad}(X)(Y) = \mathrm{Lie}(\mathrm{Ad})(X)(Y)$. Then this is a Lie algebra structure on $\mathfrak{g}$, and it commutes with arbitrary base change.

Proof: To verify this is truly a Lie algebra, we take a faithful embedding of G into some GL_V(15.5.1.22). Thus it suffices to prove the Lie algebra of GL_V is a Lie algebra. Now for $A, B \in M_n(R)$, pondering the definition shows

$$(1 + \delta A)(1 + \varepsilon B)(1 - \delta A) = 1 + \varepsilon B + \varepsilon\delta[X, Y] \in k[\varepsilon, \delta]/(\varepsilon^2, \delta^2).$$

So in fact $[X, Y] = XY - YX$, so it is truly a Lie algebra.

To show the group structure on $\mathrm{Lie}(G)$ equals the structure on the tangent space, use the Eckmann-Hilton argument, notice the hypothesis is satisfies because both composition is the morphism $\mathrm{Spec}\, k[\varepsilon] \to \mathrm{Spec}(k[\varepsilon] \otimes k[\varepsilon]) \xrightarrow{\varphi} G \times G \xrightarrow{\mu} G$, where $\varphi = (a, b, c, d) : k[\varepsilon] \otimes k[\varepsilon] \xrightarrow{\varphi} G \times G$. □

Cor. (8.2.2.2) [Exponential Map]. As there are natural isomorphisms $\mathfrak{g}(R) \cong \mathfrak{g} \otimes R$, we can write $e^{\varepsilon X}$ the element of $\mathfrak{g}(R) \subset G(R[\varepsilon])$ corresponding to $X \in \mathfrak{g} \times R$. Then $e^{\varepsilon X + \varepsilon Y} = e^{\varepsilon X} e^{\varepsilon Y}$, and by functoriality, for any homomorphism $f : G \to H$,

$$f(e^{\varepsilon X}) = e^{\varepsilon\, \mathrm{Lie}(f)(X)}.$$

Also

$$x \cdot e^{\varepsilon Y} x^{-1} = e^{\varepsilon\, \mathrm{Ad}(x) Y}$$

and also the commutative diagram in(8.2.2.1) means

$$f(e^{\varepsilon X}) = e^{\varepsilon\, \mathrm{Lie}(f)(X)}.$$

Cor. (8.2.2.3) [Lie algebra commutes with Limits]. It can be seen from the definition that the Lie algebra construction commutes with limits of algebraic groups. In particular it commutes with kernel map.

Prop. (8.2.2.4). Let $H \subset G$ be algebraic groups s.t. $\mathrm{Lie}(H) = \mathrm{Lie}(G)$. If H is smooth and G is connected, then $H = G$.

Proof: Recall that $\dim \mathfrak{g} \geq \dim G$, with equality iff G is smooth(8.1.4.5), so the condition forces G to be smooth. Now G is smooth and connected thus irreducible(8.1.4.14) and $\dim G = \dim H$, so $H = G$. □

Cor. (8.2.2.5). Let H_1, H_2 be connected algebraic subgroups of G and $H_1 \cap H_2$ is smooth. If $\mathrm{Lie}(H_1) = \mathrm{Lie}(H_2)$, then $H_1 = H_2$.

Cor. (8.2.2.6). If G is an algebraic group over a field of characteristic 0, then the connected subgroups of G corresponds 1 to 1 to Lie subalgebras of $\mathrm{Lie}(G)$, because every subgroup is smooth, by(8.1.4.2).

Cor. (8.2.2.7). Let H_i be a family of smooth algebraic subgroups of an algebraic subgroup G over a field k. If $\mathrm{Lie}(H_i)$ generate $\mathrm{Lie}(G)$ as a Lie algebra, then H_i generates G(8.1.4.26).

Proof: Let H be the subgroup they generate, then H is smooth(8.1.4.26) and $\mathrm{Lie}(H) = \mathrm{Lie}(G)$, thus $H = G$ by(8.2.2.4). □

Stabilizers, Centers and Centralizers

Prop. (8.2.2.8) [Lie Algebra of Stabilizer]. Let G be an algebraic group and (V, r) be a representation of G, then it induces an action of $\mathfrak{g}$ on W(8.2.2.1). Let $W \subset V$ be a subspace, then the stabilizer $\mathrm{Stab}_G(W)$ is a subgroup of G(15.5.1.3)

$$\mathrm{Lie}(\mathrm{Stab}_G(W)) = \mathrm{Stab}_{\mathfrak{g}}(W).$$

In particular, $\dim(\mathrm{Stab}_G(W)) \leq \dim \mathrm{Stab}_{\mathfrak{g}}(W)$, with equation iff $\mathrm{Stab}_G(W)$ is smooth.

Proof: By(8.2.2.2),

$$\begin{aligned} X \in \mathrm{Lie}(\mathrm{Stab}_G(W)) &\iff r(e^{\varepsilon X})W[\varepsilon] \subset W[\varepsilon] \\ &\iff e^{\varepsilon \mathrm{Lie}(r)(X)} W_R[\varepsilon] \subset W_R[\varepsilon] \\ &\iff (1 + \varepsilon \mathrm{Lie}(r)(X))(W_R + \varepsilon W_R) \subset (W_R + \varepsilon W_R) \\ &\iff \mathrm{Lie}(r)(X)(W_R) \subset W_R \\ &\iff X \subset \mathrm{Stab}_{\mathfrak{g}}(W) \end{aligned}$$

□

Prop. (8.2.2.9) [Lie Algebra of Center]. Let G be a smooth connected algebraic group, then

$$\dim z(\mathfrak{g}) \geq \dim Z(G),$$

and if equality holds, then $Z(G)$ is smooth and $\mathrm{Lie}(Z(G)) = z(\mathfrak{g})$.

Proof: There are maps

$$\mathrm{Ad} : G \mapsto GL_{\mathfrak{g}}, Z(G) \subset \ker(\mathrm{Ad}),$$

$$\mathrm{ad} : \mathfrak{g} \to \mathfrak{gl}_{\mathfrak{g}}, \ker(\mathrm{ad}) = z(\mathfrak{g}).$$

Because Lie algebra commutes with kernel(8.2.2.3), $\mathrm{Lie}(Z(G)) \subset \mathrm{Lie}(\ker(\mathrm{Ad})) = \ker(\mathrm{ad})$. So

$$\dim z(\mathfrak{g}) = \dim \ker(\mathrm{ad}) = \dim \mathrm{Lie}(\ker(\mathrm{Ad})) \geq \dim \ker(\mathrm{Ad}) \geq \dim Z(G)$$

with equality iff $\ker(\mathrm{Ad})$ is smooth and $\dim \ker(\mathrm{Ad}) = \dim Z(G)$ and thus $\ker(\mathrm{Ad})^0 = Z(G)^0$, so $Z(G)$ is also smooth. Finally, $\mathrm{Lie}(Z(G)) \subset z(\mathfrak{g})$, so they are equal if they have the same dimensions. □

Prop. (8.2.2.10) [Lie Algebra of Centralizer]. Let G be an algebraic group and H a subgroup, then H acts on $\mathfrak{g}$ by Ad. Then

$$\mathrm{Lie}(C_G(H)) = \mathfrak{g}^H, \quad \mathrm{Lie}(N_G(H))/\mathrm{Lie}(H) = (\mathrm{Lie}(G)/\mathrm{Lie}(H))^H.$$

Proof:

$$X \in \mathrm{Lie}(C_G(H)) \iff x(e^{\varepsilon X})_S x^{-1} = e^{\varepsilon X}_S, \quad \forall k[\varepsilon] \to S, x \in H(S)$$
$$X \in \mathfrak{g}^H \iff y e^{\varepsilon X_R} y^{-1} = e^{\varepsilon X_R}, \quad \forall k \to R, x \in H(R)$$

And it can be shown these two are equal. Similarly, there is a natural map $\mathrm{Lie}(N_G(H)) \to \mathrm{Lie}(G)/\mathrm{Lie}(H)$, and the image lies in the fixed subgroup of H, because

$$X \in \mathrm{Lie}(N_G(H)) \iff (e^{\varepsilon X})_S x (e^{\varepsilon X})^{-1}_S \subset H(S) \iff e^{\varepsilon\,\mathrm{ad}(x) X_S} \in H(S) e^{\varepsilon X_S}, \quad \forall k[\varepsilon] \to S, x \in H(S)$$

$$X \in (\mathrm{Lie}(G)/\mathrm{Lie}(H))^H \iff e^{\varepsilon\,\mathrm{ad}(x) X_R} \subset e^{\varepsilon(X_R + \mathrm{Lie}(H)(R))}, \quad \forall k \to R, x \in H(R)$$

Then it can be shown that X satisfies condition in 1 iff $\overline{X}$ satisfies condition in 2, thus we are done. □

3 Groups of Multiplicative Type

Throughout this subsection, G is an affine(linear) algebraic group over a field k.

Diagonalizable Groups

Def. (8.2.3.1) [Diagonalizable Groups]. An algebraic group G is called **diagonalizable** if the group-like elements in $\Gamma(G)$ generate $\Gamma(G)$ as a k-vector space.

Prop. (8.2.3.2). An algebraic group G is diagonalizable iff it is isomorphic to the the algebraic group corresponding to a group algebra $D(M)$ for some commutative group M.

Proof: For the group algebra $D(M)$, its group-like elements are just $\{m | m \in M\}$ by(2.9.2.21), and they clearly span $D(M)$. Conversely, if the set M of group-like elements in $\Gamma(G)$ spans $\Gamma(G)$, then by(2.9.2.20) they form a basis of $\Gamma(G)$, so there is an isomorphism of vector spaces $D(M) \to \Gamma(G)$. But this is also a homomorphism, because they are on a basis. □

Cor. (8.2.3.3) [Diagonalizable Groups].

- The functor $M \mapsto D(M)$ is a contravariant equivalence from $\mathcal{CA}\mathrm{lg}_k^{fg}$ to the category of diagonalizable algebraic groups, with inverse give by $G \mapsto X(G)$.
- This functor preserves exact sequences.
- Algebraic subgroups and quotient groups of diagonalizable groups are diagonalizable.

Proof: 1: By(8.2.3.2), it suffices to show that $\mathrm{Hom}(M, M') \to \mathrm{Hom}(D(M'), D(M))$ is an isomorphism. Because D sends direct sums to direct products, it suffices to check the case that M, M' is cyclic. This is easy to check, just notice that a group homomorphism maps group-like elements to group-like elements.

2: If $M' \to M$ is injective, then $k[M'] \to k[M]$ is injective, thus faithfully flat by(2.9.2.23), and $D(M) \to D(M')$ is a quotient map. Conversely, $D(M) \to D(M')$ is a quotient map iff $k[M'] \to k[M]$ is faithfully flat thus injective thus $M' \to M$ is injective. Now the kernel of $D(M) \to D(M')$ is represented by $k[M]/I_{k[M']}$, where $I_{k[M']}$ is the augmentation ideal. Then it is isomorphic to $k[M/M']$.

3: Let H be an algebraic subgroup of G, then the map $\Gamma(G) \to \Gamma(H)$ is surjective, and sends group-like elements to group-like elements, thus $\Gamma(H)$ is also spaned by group-like elements, and H is diagonalizable.

if $D(M) \to Q$ is a quotient map, then its kernel is an algebraic subgroup thus equals $D(M'')$ for some quotient M'' of M. Let M be the kernel of $M \to M''$, then $D(M) \to D(M')$ and $D(M) \to Q$ are quotient maps with the same kernel, so they are isomorphic, by(8.1.1.24). □

Prop. (8.2.3.4) [Representation of Diagonalizable Groups]. The following conditions are equivalent for an algebraic group G over a field k:

1. G is diagonalizable.
2. Every representation of G is diagonalizable.
3. Every f.d. representation of G is diagonalizable.

Proof: $1 \to 2$: We need to show for any comodule $\rho: V \to V \otimes \Gamma(G)$, V is a sum of 1-dimensional representations, or equivalently, it is spanned by vectors u that $\rho(u) \in ku \otimes \Gamma(G)$. Let $v \in V$, we can write $\rho(v) = \sum u_i \otimes e_i$ where e_i are group-like in G.

Applying comodule relations, we get

$$\sum u_i \otimes e_i \otimes e_i = \sum \rho(u_i) \otimes e_i, \quad v = \sum u_i (2.9.2.19).$$

so $\rho(u_i) = u_i \otimes e_i$ and they span V.

$2 \to 1$: The regular representation of G is diagonalizable, so $\Gamma(G)$ is spanned by its eigenvectors, for any eigenvector $f \in \Gamma(G)$, so $\mu(f) = f \otimes e$ where e is group-like. Applying $\varepsilon \otimes \mathrm{id}$ shows $f = \varepsilon(f)e$, so G is diagonalizable.

$2 \to 3$: trivial.

$3 \to 2$: Every representation of G is a sum of f.d. representation, so it is a sum of 1-dimensional representations, so it is diagonalizable by(15.5.1.17). □

Tori

Def. (8.2.3.5) [Linear Tori]. Let k be a field, then a **split torus** over k is a linear group scheme of the form $T = \mathbb{G}_{m,k}^n$, and a **linear torus** over k is defined to be a linear algebraic group T over k that $T_{\overline{k}}$ is a split torus over $\overline{k}$.

Prop. (8.2.3.6). By(8.2.3.3), a split torus is just $D(\mathbb{Z}^n)$ for some n, and quotient of a split torus is a split torus.

Thus a quotient of a torus is a torus, and an algebraic subgroup of a torus is a torus iff it is a group variety.

Prop. (8.2.3.7). Any torus over a separably closed field is a split torus. in particular, any torus split over a finite separable extension.

Proof:

□

Def. (8.2.3.8) [Quasi-Split Tori]. Let A be a f.d. separable k-algebra, then there is a linear algebraic group G defined by $G(B) = G_m(A \otimes_k B) = (A \otimes_k B)^*$, denoted by $\mathrm{res}_{A/k} \mathbb{G}_m$.

This is a linear algebraic group because if we choose a basis $\{v_1, \ldots, v_r\}$ of A over k, which induces a ring homomorphism $\varphi: A \to M_r(k)$. Then $f = \det(\varphi(x_1 v_1 + \ldots + x_r v_r))$ is a polynomial in $x_1, \ldots, x_r$. Thus $G(B)$ is the set of points in $\mathbb{A}^r(B)$ that $f(x_1, \ldots, x_r)$ is invertible in B. So G is a linear algebraic variety. Moreover, as A is separable, $A \otimes_k \overline{k} \cong \oplus_{i=1}^r M_{n_i}(\overline{k})$, so $G_{\overline{k}} \cong \mathbb{G}_{m,\overline{k}}^r$, so G is a torus, called a **quasi-split torus** over k.

Def. (8.2.3.9) [Monoidal Transformation]. For a matrix $A \in SL(n, \mathbb{Z})$ with $\det A = \pm 1$, we define an isomorphism of $\mathbb{G}_{n,k}$:

$$\varphi_A(x) = (x_1^{a_{11}} x_2^{a_{12}} \ldots x_n^{a_{1n}}, \ldots, x_1^{a_{n1}} \ldots x_n^{a_{nn}}).$$

these isomorphisms φ_A is called the **monoidal transformations**.

Prop. (8.2.3.10). Let G be a group variety over k and T a central torus, then

- $T \cap [G, G]$ is finite.
- If G/T is perfect, then the sequence

$$e \to T \cap [G, G] \to T \times [G, G] \to G \to e$$

is exact.

In particular, $G/[G, G]$ is a torus.

Proof: Cf.[Mil17]P246. □

Groups of Multiplicative Type

Def. (8.2.3.11) [Groups of Multiplicative Type]. An **algebraic group of multiplicative type** over a field k is an algebraic group G that G_K is diagonalizable over K for some field K containing k.

Subgroups and quotient groups of groups of multiplicative type are also of multiplicative type, because this is true for diagonalizable groups(8.2.3.3).

Prop. (8.2.3.12) [Characterization of Groups of Multiplicative Type]. The follows are equivalent for an algebraic group G over k:

- G is of multiplicative type.
- G is commutative and $\mathrm{Hom}(G, \mathbb{G}_a) = 0$.
- G is commutative and $\Gamma(G)$ is coétale.
- G becomes diagonalizable over k^s.

Proof: Cf.[?]237. □

Cor. (8.2.3.13). An algebraic group over k becomes diagonalizable over some field extension of k iff it becomes diagonalizable over some finite separable extension of k.

Cor. (8.2.3.14). If a group of multiplicative type splits over a purely inseparable extension of k, then it splits over k.

Proof: Cf.[Mil17]P238. □

Cor. (8.2.3.15). A smooth commutative algebraic group G over k is of multiplicative type iff $G(\overline{k})$ consists of semisimple elements.

Proof: We can assume that $k = \overline{k}$, and embed G into GL_n for some n(15.5.1.22). If G is of multiplicative type, then by(8.2.3.4), there is a basis that $G \subset \mathbb{D}_n$, so all the elements in $G(k)$ is diagonalizable hence semisimple. Conversely, if $G(k)$ are all semisimple, then they form a commutative family of semisimple elements, so $G(k) \subset \mathbb{D}_n(k)$ in some basis. Because G is smooth thus reduced, $G \subset \mathbb{D}_n$. □

Cor. (8.2.3.16). An extension of algebraic groups of multiplicative type is of multiplicative type iff it is commutative.

Proof: A exact sequence $e \to G' \to G \to G'' \to e$ of commutative group schemes gives rise to an exact sequence

$$0 \to \mathrm{Hom}(G'', \mathbb{G}_a) \to \mathrm{Hom}(G, \mathbb{G}_a) \to \mathrm{Hom}(G', \mathbb{G}_a)$$

of Abelian groups by(8.1.1.24), thus we can use characterization(8.2.3.12). □

Prop. (8.2.3.17) [Largest Subtorus]. Cf.[Mil17]P241.

Prop. (8.2.3.18) [Representation of Groups of Multiplicative Type]. Let G be an algebraic group over k, then $\mathrm{Rep}(G)$ is a semisimple Abelian category, and the isomorphism classes of simple objects in $\mathrm{Rep}(G)$ are classified by the orbits of $G(k^s/k)$ acting on $X^*(G)$.

Let (V, r) be a representation corresponding to an orbit Σ, and let $\chi \in \Sigma$, then $\mathrm{End}(V, r) \cong k_\chi$, where k_χ is the subfield of k^s fixed by the subgroup of $G(k^s/k)$ fixing χ.

Proof: The group G is split by a finite Galois extension K/k by(8.2.3.13). Let $\overline{\Gamma} = G(K/k)$, then $\overline{\Gamma}$ acts on $\Gamma(G_K)$ through its action on K. Let (V, r) be a representation of G_K and let ρ be the corresponding co-action, then by(5.1.5.24), the functor $V \mapsto V \otimes_k K$ induces an equivalence between $\mathrm{Rep}(G)$ and $\mathrm{Rep}(G_K)$ with a semi-linear action of $\overline{\Gamma}$ fixing ρ.

Let V be a representation of G over k, then $K \otimes V$ decomposes as a representation of G_K into

$$K \otimes V = \oplus_{\chi \in X(G_K)} V_\chi.$$

and an element $\gamma \in \overline{\Gamma}$ maps V_χ isomorphically onto $V_{\sigma\chi}$. Thus the set of χ occurring in $K \otimes V$ is stable under the action of $\overline{\Gamma}$.

Conversely, if Σ is an orbit of $\overline{\Gamma}$ in $X(G_K)$ and V is a 1-dimensional K vector space, then $\oplus_{\chi \in \Sigma} V_\chi$ has a natural semi-linear action of $\overline{\Gamma}$, so it arises from a simple representation of G over k. □

Prop. (8.2.3.19) [Density Theorem for Groups of Multiplicative Type]. Let G be a smooth algebraic group of multiplicative type, thus G is commutative. Let G_n be the kernel of multiplication by n on G.

- The only closed subscheme containing every G_n is G itself.
- If G is smooth, then the only closed subscheme containing G_n for n prime to characteristic of k, is G itself.

Proof: 1: 2: Cf.[Mil17]P242.? □

Cor. (8.2.3.20). Let G be an algebraic group of multiplicative type. If two homomorphisms from G to another algebraic group H coincides on G_n for all $n \geq 1$, then they are equal.

Proof: This is because the equalizer is a closed subscheme of G, as H is separated(8.1.1.12). □

Prop. (8.2.3.21) [Rigidity Theorem for Groups of Multiplicative Type]. Let G, H be diagonalizable groups over k, and let X be a connected group scheme over k. Let $\varphi : X \times G \to H$ be a morphism that for all k-algebra R and $x \in X(R)$, the map $g \mapsto \varphi(x, g) : G(R) \to H(R)$ is a homomorphism. Then for any $x_0 \in X(k)$, we have $\varphi(x, g) = \varphi(x_0, g)$ for any k-algebra R and $(x, g) \in X(R) \times G(R)$.

Proof: Cf.[Mil17]P243.? □

Cor. (8.2.3.22). Every action of a connected algebraic group G on an algebraic group H of multiplicative type by group homomorphisms is trivial.

Cor. (8.2.3.23). Every normal algebraic subgroup of multiplicative type of a connected algebraic group G is contained in the center of G.

Proof: The action of G on N by inner automorphism is trivial. □

Cor. (8.2.3.24). Let H be a subgroup of multiplicative type of an algebraic group G, then $N_G(H)^0 = C_G(H)$, i.e. $C_G(H)$ is an open subgroup of $N_G(H)$.

Proof: The inner action of $N_G(H)^0$ on H by inner automorphism is trivial. □

Cor. (8.2.3.25). If N is a normal subgroup of an algebraic group H that N and H/N are of multiplicative type, then every action of a connected algebraic group G on H by group homomorphisms preserving N is trivial.

Proof: The action of G on N is trivial, thus the action factors through $G \times H/N \to H$, thus also factors through $G \times H/N \to N$. Now the action is trivial, by(8.2.3.21). □

Cor. (8.2.3.26). An extension of algebraic groups of multiplicative type is of multiplicative type if it is connected.

Proof: The adjoint action of G is trivial, by(8.2.3.25), thus G is commutative. Thus it is of multiplicative type by(8.2.3.16). □

4 Actions of Tori

Prop. (8.2.4.1) [Białynicki-Birula Decomposition]. Cf.[Mil17]P272.

5 Solvable Groups

All group schemes G in this subsection are affine and algebraic over a field k.

Prop. (8.2.5.1). Let H be an algebraic group of a solvable group variety G, then G/H doesn't contain a proper subscheme of dimension> 0. In particular, $G = H$ if G/H is proper.

Proof: Cf.[Mil17]P353. □

Cor. (8.2.5.2). If G is a solvable group variety acting on a separated algebraic scheme X over k, then no orbits of X contains a proper subscheme of dimension> 0.

Proof: By(8.2.1.12), the orbits are quotients of G. □

Cor. (8.2.5.3) [Borel Fixed Point Theorem]. If G is a solvable group variety acting on a proper algebraic scheme X over k, then $X^G \neq \varnothing$, in particular, $X^G(\overline{k}) \neq \varnothing$.

Proof: It suffices to change to $\overline{k}$, then by(8.2.1.15) X has a closed orbit, which is then proper, thus must be a point. □

Triangularizable Algebraic Groups

Def. (8.2.5.4) [Triangularizable Algebraic Groups]. A **triangularizable algebraic group** is an algebraic group s.t. every simple representation has dimension 1. Equivalently, for any f.d. linear representation V of G, there exists a basis that G is mapped into $\mathbb{B}(n)$.

Prop. (8.2.5.5) [Lie-Kolchin]. Let G be a solvable group variety over an alg.closed field k, then G is triangularizable. In particular, any solvable group variety over k is a triangularizable after a finite field extension.

Proof: Let (V, r) be any linear representation of G, then G acts on the maximal flag variety of V. Thus by Borel's fixed point theorem(8.2.5.3), there is a flag in V that is fixed by G, which means G is mapped into $\mathbb{U}(V)$. □

Nilpotent Algebraic Groups

8.3 Group Theory III: Reductive Groups

All group schemes G in this section are assumed to be linear algebraic over a base scheme S.

Main references are [Mil17]. For relative reductive group schemes, Cf.[reductive group schemes, Conrad].

1 Borel Subgroups

Def. (8.3.1.1) [Borel Subgroups]. A **Borel subgroup** of a group variety G is a maximal solvable subgroup variety of G. A **Borel pair** is a pair (B, T) where B is a Borel subgroup of G and T is a maximal torus of G contained in B.

Def. (8.3.1.2) [Parabolic Subgroups]. A **parabolic subgroup** P of a group variety G is a subgroup variety s.t. G/P is proper.

Prop. (8.3.1.3) [Parabolic and Borel]. Parabolic subgroups are exactly those containing a Borel subgroup. In particular, if B be a Borel subgroup of G, then G/B is proper.

Proof: Cf.[Mil17]P354, P356.? □

Prop. (8.3.1.4) [Characterizing Borel Subgroups]. Let G be a group variety over k, then a subgroup B is Borel iff it is solvable and G/B is proper.

Prop. (8.3.1.5) [Borel Pairs are Conjugate]. Let G be a group variety over k, then

- Any two Borel subgroups of G are conjugate by an element of $G(k)$.
- Any two maximal tori of G are conjugate by an element of $G(k)$.
- Any two Borel pairs are conjugate by an element of $G(k)$.

Proof: Cf.[Mil17]P354.?

3: This follows from the first two(by applying item2 on a Borel subgroup B). □

Def. (8.3.1.6) [Split Group Variety]. A **split group variety** is a group variety whose Borel subgroup is split solvable.

Def. (8.3.1.7) [Cartan Subgroup]. A **Cartan subgroup** of a group variety is the centralizer of a maximal tori.

2 Geometric Aspects

Def. (8.3.2.1) [Simply Connected Groups]. A **simply-connected group variety** is a group variety G that every multiplicative isogeny(8.1.5.16) from a group variety $G' \to G$ is an isomorphism.

Prop. (8.3.2.2) [Lifting]. Let G be a simply connected group variety over k and $\varphi : G' \to G$ is a multiplicative isogeny, then φ admits a section if k is perfect or G is a perfect group.

Proof: Cf.[Mil17]P388. □

Def. (8.3.2.3) [Universal Covering]. A **universal covering** of a group variety G is a multiplicative isogeny $\pi : G' \to G$ from a simply connected group variety G'. If such a covering exists, $\ker \pi$ is called the **fundamental group** $\pi_1(G)$ of G.

Prop. (8.3.2.4) [Galois Theory]. Let $\pi : \widetilde{G} \to G$ be a universal covering of a group variety over k. If k is perfect or G is perfect, then π factors uniquely through any other multiplicative isogeny of group varieties $G' \to G$.

Proof: As $\widetilde{G}$ is a group variety, it admits no finite quotient(8.1.5.14), thus if $[G, G] = G$, then $[\overline{G}, \overline{G}] \ker \pi = \overline{G}$, thus $G/[G, G]$ is finite, thus trivial, so $\widetilde{G}$ is also perfect.

The map $G' \times_G \widetilde{G}$ is surjective with finite kernel of multiplicative type, thus it has a section by(8.3.2.2), and the composite of this section with projection to G' is the desired lifting. If α, β are two liftings, then α/β is a map from $\widetilde{G}$ to $\ker(\varphi)$, which is finite, thus $\alpha = \beta$. □

Prop. (8.3.2.5). Every semisimple algebraic group admits an essentially unique isogeny $\widetilde{G} \to G$ that $\widetilde{G}$ is simply connected.

Proof: □

3 Reductive Groups

In this subsection, k is a field.

Linearly Reductive Groups

Def. (8.3.3.1) [Linearly Reductive Groups]. An algebraic group over a field is called **linearly reductive** if every f.d. representation of G is semisimple.

Prop. (8.3.3.2). Let G be an algebraic group over k, and k' a field containing k. If $G_{k'}$ is linearly reductive, then so is G. Conversely, if G is linearly reductive and k' is separable over k, then $G_{k'}$ is linearly reductive.

Proof: Cf.[Mil17]P248. □

Prop. (8.3.3.3). A commutative algebraic group is linearly reductive iff it is of multiplicative type.

Proof: Cf.[Mil17]P248. ? □

Prop. (8.3.3.4) [Hilbert]. Let G be a linearly reductive group of $\mathrm{GL}(n)$ and let $A = k[T_1, \ldots, T_n]$, then A^G is f.g. as a k-algebra.

Proof: Cf.[Mil17]P249. ? □

Semisimple Groups

Def. (8.3.3.5) [Radicals]. The **radical** $R(G)$ of an algebraic group G over a field k is the largest smooth connected solvable normal subgroup of G, which exists by(8.1.5.29) and(8.1.5.30).

G is called a **semisimple algebraic group** iff it is an affine group variety and $R(G_{\overline{k}}) = e$.

Prop. (8.3.3.6). Let k'/k be a field extension, then an algebraic group G over k is semisimple iff $G_{k'}$ is semisimple.

Proof: Affineness, Smoothness and geo.connectedness satisfies field descent by(5.1.5.26), so it suffices to prove for k', k alg.closed. But if N is non-trivial normal solvable subgorup variety of $G_{k'}$, it is defined on a f.g. field extension $K = k(x_1, \ldots, x_n)$ of k, thus N_K is a normal solvable subgroup variety of G_K, and they extends to smooth group varieties $\mathcal{G}$ and $\mathcal{N}$ on some open subscheme $\operatorname{Spec} A \subset \operatorname{Spec} k[x_1, \ldots, x_n]$. But on some maximal ideal $\mathfrak{m}$, $\mathcal{N}_{k(\mathfrak{m})}$ is non-zero(4.2.6.11) normal open subgroup of $\mathcal{G}_{k(\mathfrak{m})}$, and $k(\mathfrak{m}) \cong k$ as $k = \overline{k}$, contradiction. □

Prop. (8.3.3.7). If k'/k is a separable algebraic extension, then $R(G_{k'}) = R(G)_{k'}$.

Proof: $R(G)_{k'} \subset R(G_{k'})$ by definition, and it suffices to prove they are the same when k'/k is Galois. But then this follows from Galois descent(5.1.5.19) and the fact connectedness, smoothness, normality and solvability is reflexive(8.1.5.21). □

Cor. (8.3.3.8). Let G be a group variety over a perfect field k, then G is semisimple iff $R(G) = e$. In particular, $G/R(G)$ is semisimple, by(8.1.5.30).

Cor. (8.3.3.9). Let G be a group variety over a perfect field k, then G is semisimple iff it contains no non-trivial commutative normal subgroup varieties.

Def. (8.3.3.10)[Simple Groups]. A **simple algebraic group** is a semisimple non-commutative group with no non-trivial normal algebraic subgroups.

An **almost-simple algebraic group** is a semisimple non-commutative group s.t. every non-trivial normal algebraic subgroup is finite.

A **geometrically (almost-)simple algebraic group** is an algebraic group G s.t. $G_{\overline{k}}$ is (almost-)simple.

A(n) **(almost-)pseudo simple algebraic group** is a non-commutative group variety G s.t. every non-trivial normal algebraic subgroup is trivial(finite). (May not by semisimple).

Reductive Groups

Def. (8.3.3.11) [Unipotent Radicals]. By(8.1.5.29) and(8.1.5.30), any algebraic group G has a maximal connected smooth normal unipotent subgroup $R_u(G)$, which is called the **unipotent radical** of G, denoted by $R_u(G)$.

Let G be an affine group variety over k, then G is called a **reductive group** iff $R_u(G_{\overline{k}}) = e$.

G is called a **pseudo-reductive group** if $R_u(G) = e$.

Prop. (8.3.3.12). Let k'/k be a field extension, then an algebraic group G over k is reductive iff $G_{k'}$ is reductive.

Proof: The proof is verbatim as that of(8.3.3.6). □

Prop. (8.3.3.13). If k'/k is a separable algebraic extension, then $R_u(G_{k'}) = R_u(G)_{k'}$.

Proof: $R(G)_{k'} \subset R(G_{k'})$ by definition, and it suffices to prove they are the same when k'/k is Galois. But then this follows from Galois descent(5.1.5.19) and the fact connectedness, smoothness, normality and unipotency is reflexive(15.5.3.2). □

Cor. (8.3.3.14). Let G be a group variety over a perfect field k, then G is reductive iff $R_u(G) = e$. In particular, $G/R_u(G)$ is reductive, by(8.1.5.30).

Prop. (8.3.3.15). Let G be a reductive group, then

- the center $Z(G)$ is of multiplicative type.
- $R(G)$ is the largest subtorus of $Z(G)$.
- $R(G_{k'}) = R(G)_{k'}$ for any field extension k'/k.
- $G/R(G)$ is semisimple.
- $G/Z(G)$ has trivial center.

- $Z(G)\cap[G,G]$ is finite.

Proof: Cf.[Mil17]P372.
4: This is because $(G/R(G))_{k'}=G_{k'}/R(G)_{k'}=G_{k'}/R(G_{k'})$ is semisimple.
5: Cf.[Mil17]P402. □

Cor. (8.3.3.16). Central and multiplicative isogenies from a group variety are the same thing, by(8.1.5.18).

Prop. (8.3.3.17) [Reductive Groups and Semisimple Groups]. A semisimple group is reductive, because $R_u(G)\subset R(G)$ as a unipotent group is solvable. Conversely, if G is a reductive group, then the following are equivalent:

- G is semisimple.
- $R(G)=e$.
- $Z(G)$ is finite.
- $G/[G,G]$ is finite.

Proof: 1 $\iff$ 2 follows from(8.3.3.15).
2 $\iff$ 3: As $R(G)$ is the maximal subtorus of the group $Z(G)$ of multiplicative type, $Z(G)/R(G)$ is finite(8.2.3.17). So if $R(G)=e$, $Z(G)$ is finite. And if $Z(G)$ is finite, $R(G)=e$ because it is a torus. □

Prop. (8.3.3.18). Let G be a group variety over a field k, then if G is reductive, then every commutative normal subgroup variety of G is a torus, and the converse is also true if k is perfect.

Proof: If N is a commutative normal subgroup variety of G, then $N\subset R(G)$, which is a torus by(8.3.3.15) and(8.2.3.6). The converse follows from the fact $R_u(G)=e$ because $\mathrm{U}(n)$ has no non-zero subtorus by(8.3.5.4). □

Prop. (8.3.3.19). If G is reductive, then $[G,G]$ is semisimple of rank equal to the semisimple rank of G.

Proof: Cf.[Mil17]P402. □

Prop. (8.3.3.20) [Maximal Central Torus]. If G is a reductive group over a perfect field k, then $R(G)=Z(G)^0_{\mathrm{red}}$, which is the maximal central torus by(8.3.3.21). In particular, G is semisimple if and only if $Z(G)$ is finite.

Proof: □

Prop. (8.3.3.21). Any commutative affine group variety G is of the form $U\times T$ where U is unipotent and T is a torus.

Proof: ? □

Prop. (8.3.3.22). Let $\varphi:G'\to G$ be an isogeny of group varieties. If G is reductive or semisimple, then so is G'.

Proof: It suffices to assume $k=\overline{k}$. Let U be a normal unipotent/solvable subgroup variety of G, then $\varphi(U)$ is also a unipotent/solvable group variety by(8.1.5.29), and it is normal because φ is a quotient map(8.1.5.29). Thus $\varphi(U)=e$, which implies U is a finite group variety, thus trivial. □

Prop. (8.3.3.23) [Matsushima's Criterion]. If G is a reductive group and H a smooth algebraic subgroup, then G/H is affine iff H^0 is reductive.

Proof: Cf. [Borel, On affine algebraic homogeneous spaces]. □

Def. (8.3.3.24) [Ranks]. The **rank of a group variety** G over k is the dimension of the maximal torus in $G_{\overline{k}}$. The **semisimple rank** is the rank of $G_{\overline{k}}/R(G_{\overline{k}})$.

The **k-rank** is the dimension of a maximal split torus in G. The **semisimple k-rank** of G is is k-rank of $G/R(G)$.

These are well-defined by(8.3.1.5).

Prop. (8.3.3.25). Let G be a reductive group, then the semisimple rank of G equals $\dim G - \dim Z(G)$.

Proof: Cf.[Mil17]P402. □

Parabolic Subgroups of Reductive Groups

Prop. (8.3.3.26)[Levi Factors]. Let P be a group variety over k, a **Levi subgroup** of P is a subgroup variety L of P s.t. $L_{\overline{k}} \to P_{\overline{k}}/R_u(P_{\overline{k}})$ is an isomorphism. In other words, L is a reductive subgroup of P s.t. $P_{\overline{k}} = R_u(P_{\overline{k}}) \ltimes L_{\overline{k}}$.

Prop. (8.3.3.27). Let P be a parabolic subgroup of a reductive group G, then P has Levi subgroups, and any two Levi subgroups of P are conjugate by a unique element of $R_u(P)(k)$.

Proof: Cf.[Mil17]P559. □

4 Split Reductive Groups

Def. (8.3.4.1) [Split Reductive Groups]. For $k \in \texttt{Field}$, a **split reductive pair** is a pair (G, T) where G is a reductive group over k and T is a split maximal torus. A reductive group is called **split reductive** if it is contained in some reductive pair. By(8.2.3.7), any reductive group is reductive after a finite separable change of fields.

Def. (8.3.4.2) [Anisotropic Reductive Groups]. For $k \in \texttt{Field}$, a reductive group is isotropic if it contains a non-central split torus; otherwise, it is anisotropic. Notice for semisimple groups, any split torus is central**?**.

Reductive Groups of Semisimple Rank≤ 1

Prop. (8.3.4.3) [Classifying Reductive Groups of Semisimple Rank≤ 1]. Any reductive group over k of semisimple rank 1 is isomorphic to exactly one of the groups

$$\mathbb{G}_m^r \times \mathrm{SL}(2), \quad \mathbb{G}_m^r \times \mathrm{PGL}(2), \quad \mathbb{G}_m^r \times \mathrm{PGL}(2), \quad r \in \mathbb{N}.$$

Proof: Cf.[Mil17]P419. □

5 Classical Groups

Def. (8.3.5.1) [Examples of Classical Groups].

- the **general linear group** $\mathrm{GL}(n) = \mathbb{Z}[T_{ij}][1/\det]$ representing the group functor $\mathcal{CA}\mathrm{lg}_{\mathbb{Z}} \to \mathcal{G}\mathrm{rp} : R \mapsto GL(n, R)$.
- the **multiplicative group** $\mathbb{G}_m = \operatorname{Spec} \mathbb{Z}[T, T^{-1}]$, which is just GL(1).
- the **special linear group** $\mathrm{SL}(n)$ is the algebraic subgroup scheme of $\mathrm{GL}(n)$ defined by the ideal $(\det -1)$, representing the group functor $\mathcal{CA}\mathrm{lg}_{\mathbb{Z}} \to \mathcal{G}\mathrm{rp} : R \mapsto SL(n, R)$.
- the **orthogonal group** $\mathrm{O}(n)$ is the algebraic subgroup of $\mathrm{GL}(2n)\times\mathbb{G}_m \subset \mathrm{GL}(2n+1)$ generated by the n^2 entries of the equation $(T_{ij})^t C_n (T_{ij}) = TC_n$, where $C_n = \begin{bmatrix} 0 & I_k & 0 \\ I_k & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ if $n = 2k+1$ and $\begin{bmatrix} 0 & I_k \\ I_k & 0 \end{bmatrix}$ if $n = 2k$, representing the functor $\mathcal{CA}\mathrm{lg}_{\mathbb{Z}} \to \mathcal{G}\mathrm{rp} : R \mapsto \{g \in GL(2n, R)\times\mathbb{R}^\times | g^t C_n g = rC_n\}$.
- the **special orthogonal groups** $\mathrm{SO}(n) = \mathrm{O}(n) \cap \mathrm{SL}(n)$.
- the **symplectic group** $\mathrm{Sp}(2n)$ is the algebraic subgroup of $\mathrm{GL}(n)$ defined by the ideal generated by the n^2 entries of the equation $(T_{ij})^t J_{2n} (T_{ij}) = J_{2n}$, where $J_{2n} = \begin{bmatrix} 0 & I_n \\ -I_n & 0 \end{bmatrix}$, representing the functor

  $$\mathcal{CA}\mathrm{lg}_{\mathbb{Z}} \to \mathcal{G}\mathrm{rp} : R \mapsto \{g \in GL(2n, R) | g^t J_{2n} g = J_{2n}\} = \{\begin{bmatrix} A & B \\ C & D \end{bmatrix} | A^t C = C^t A, A^t D - C^t B = I, B^t D = D^t B\}.$$
- $\mathrm{PGL}(n)$ is the quotient group of $\mathrm{GL}(n)$ by its center.
- $\mathrm{PSL}(n)$ is the quotient group of $\mathrm{SL}(n)$ by its center.
- $\mathrm{PSO}(n)$ is the quotient group of $\mathrm{SO}(n)$ by its center.
- the **general symplectic group** $\mathrm{GSp}(2n)$ is the algebraic subgroup of $\mathrm{GL}(2n)\times\mathbb{G}_m \subset \mathrm{GL}(2n+1)$ generated by the entries of the equation $(T_{ij})^t J_n (T_{ij}) = TJ_n$, representing the functor $\mathcal{CA}\mathrm{lg}_{\mathbb{Z}} \to \mathcal{G}\mathrm{rp} : R \mapsto \{(g, r) \in GL(2n, R) \times \mathbb{R}^\times | g^t J_n g = rJ_n\}$.
- the **standard Borel subgroup** $\mathrm{B}(n)$ is the algebraic subgroup of $\mathrm{GL}(n)$ representing the upper-triangular matrices.
- the **standard unipotent subgroup** $\mathrm{Unip}(n)$ is the algebraic subgroup of $\mathrm{B}(n)$ representing the unipotent matrices.
- the **diagonal group** $\mathrm{D}(n)$ is the algebraic subgroup of $\mathrm{B}(n)$ representing the diagonal matrices.
- **unitary groups**.
- **special unitary groups**.

Proof: By(8.1.1.3), it suffices to show $\mathrm{Hom}(-, G)$ is a group functor when restricted to affine schemes. □

Prop. (8.3.5.2) [Amplitude Character]. There is an **amplitude character** $\mathrm{GSp}_{2n} \to \mathbb{G}_m : T \mapsto T$, which represents the natural transformation $R \mapsto ((g, r) \mapsto r)$.

Prop. (8.3.5.3) [Borel Subgroups of $\mathrm{GL}(n)$**].** If $k = \overline{k}$ and $G = \mathrm{GL}(n)$, then by Lie-Kolchin(8.2.5.5), the Borel subgroups of G are exactly the conjugates by $G(k)$ of $\mathbb{B}(n)$.

Proof: Cf.[Mil17]P354. □

Prop. (8.3.5.4). $\mathrm{B}(n)$ is split solvable and $\mathrm{Unip}(n)$ is split nilpotent.

Moreover, $\mathrm{Unip}(n)$ has no non-zero subtorus, by successively using(8.1.1.8).

Proof: Cf.[Mil17]P137. □

Prop. (8.3.5.5). Let $G = \mathrm{SO}(2n), \mathrm{SO}(2n+1)$ or $\mathrm{Sp}(2n)$, then the maximal Borel subgroup of G are the stabilizers of the maximal totally anisotropic flags in G(of length n).

Proof: Cf.[Mil17]P354. □

Prop. (8.3.5.6) [Reductive and Semisimple Groups]. $\mathrm{GL}(n), \mathrm{SL}(n), \mathrm{SO}(n), \mathrm{Sp}(2n)$ are reductive, as they are connected, and their standard representation is simple, by(15.5.4.1).

$\mathrm{SL}(n), \mathrm{SO}(n), \mathrm{Sp}(2n)$ are semisimple, as they have finite centers(8.3.3.17).

6 Real Reductive Groups

Main references are [Gaitsgory, Real Reductive Groups] and [Mil17b].

Def. (8.3.6.1) [Real Forms]. Let G be a connected complex Lie group, then a **real form** of G is a connected real Lie subgroup $K \subset G$ that $\mathfrak{k} \otimes_{\mathbb{R}} \mathbb{C} \cong \mathfrak{g}$.

Prop. (8.3.6.2) [Real Lie Groups and Algebraic Groups]. Let $(H, \mathfrak{h})$ be a connected Lie group in $\mathrm{Lie}\,\mathcal{G}\mathrm{rp}/\mathbb{C}$, then there needs not be an algebraic group G over $\mathbb{R}$ that $G(\mathbb{R})^0 = H$. For example, the topological fundamental group of $SL(2, \mathbb{R})$ is $\mathbb{Z}$, so it has many coverings of finite degree, none of which is algebraic, because SL_2 as an algebraic group is simply connected**?**.

However, if H admits a f.d. representation $H \hookrightarrow GL(V)$, then there exists an algebraic group $G \subset GL(V)$ that $\mathrm{Lie}(G) = [\mathfrak{h}, \mathfrak{h}]$. So if H is semisimple, then there exists an algebraic group $G \subset GL(V)$ s.t. $\mathrm{Lie}(G) = [\mathfrak{h}, \mathfrak{h}]$. When H is semisimple, this means $G^0 = H$.

Compact Real Algebraic Groups

Def. (8.3.6.3) [Compact Real Algebraic Groups]. A **compact real algebraic group** is an algebraic group $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}/\mathbb{R}$ s.t. $G(\mathbb{R})$ is a compact Lie group.

Prop. (8.3.6.4) [Compactness and Representations]. Let $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}_{\mathrm{cntd}}/\mathbb{R}$. If G is compact, then every f.d. real representation $\rho : G \to \mathrm{GL}(V)$ carries a $G(\mathbb{R})$-invariant inner form. Conversely, if a faithful f.d. real representation carries such a form, then G is compact.

Proof: If G is compact, then $H = \rho_{\mathbb{R}}(G(\mathbb{R}))$ is compact, so we can take an arbitrary inner form on V and take average on H. The converse is easy. □

Def. (8.3.6.5) [Relevant Groups]. A compact real algebraic group is called **relevant** iff the map $\pi_0(G(\mathbb{R})) \to \pi_0(G)(\mathbb{R})$ is surjective.

Lemma (8.3.6.6). Let Z be an affine variety over $\mathbb{R}$, let X be a subset of $Z(\mathbb{R})$, and let I_X be the ideal of regular functions on Z that vanishes at X, then $X' = V(I_X)$ satisfies $X \subset X'(\mathbb{R})$. Also by construction, X' is relevant and X intersects real points of every connected components of X'.

Now if Z is acted on by a compact Lie group K and X is a single K-orbit, then $X \cong X'(\mathbb{R})$.

Proof: Cf.[Gaitsgory P17]. □

Prop. (8.3.6.7) [Compact Relevant Groups and Compact Real Lie Groups]. The functor $G \mapsto G(\mathbb{R})$ is an equivalence of categories from the category of relevant real compact algebraic groups to the category of compact real Lie groups.

Proof: For the fully faithfulness: given a map $\varphi : G_1(\mathbb{R}) \to G_2(\mathbb{R})$, we need to show it comes from a unique algebraic group homomorphism. Let $K \subset G_1(\mathbb{R}) \times G_2(\mathbb{R})$ be the graph of φ, then let Γ be the subgroup of $G_1 \times G_2$ corresponding to K in(8.3.6.6), then it suffices to prove that the map $\Gamma \to G_1$ is an isomorphism. It is an isomorphism after passing to real points, so isomorphism on the level of Lie algebras. And then it is an isomorphism, because both groups are relevant**?**. □

Cor. (8.3.6.8). The proof actually works only if G_1 is relevant compact real group. So if we choose $G_2 = GL(n, \mathbb{C})_{\mathbb{R}}$, then by adjointness there is a bijection

$$\mathrm{Hom}_{\mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}\,/\mathbb{C}}(G_{\mathbb{C}}, \mathrm{GL}(n)_{\mathbb{C}}) \cong \mathrm{Hom}_{\mathcal{L}\mathrm{ie}\mathcal{G}\mathrm{rp}}(G(\mathbb{R}), GL_n(\mathbb{C})).$$

That is, their complex representations correspond.

Complex Reductive Algebraic Groups

Prop. (8.3.6.9). If G is a real reductive group, then its complexification $G_{\mathbb{C}}$ is complex reductive.

Proof: It suffices to show that $\mathrm{Rep}(G(\mathbb{C}))$ is semisimple. For this, notice $\mathrm{Rep}(G)$ is semisimple by definition, so it suffices to show for any representation V of $G_{\mathbb{C}}$, if W is a G-invariant subspace, then W is also W is $G_{\mathbb{C}}$-invariant. But the invariance condition is a vanishing of some matrix coefficients, they vanish on G so also vanish on $G_{\mathbb{C}}$. □

Def. (8.3.6.10) [Real Form]. A **real form** on a complex reductive algebraic group is an anti-linear group isomorphism $\sigma : G \to G$ that $\sigma^2 = 1$. It is called **compact** iff G^σ is compact real, and it is called **relevant** iff G^σ is relevant compact(8.3.6.5).

Prop. (8.3.6.11) [Polar Decomposition]. If G is a complex algebraic group and $K \in G(\mathbb{C})$ is a compact Lie subgroup. Assume that

- $\mathfrak{g} \cong \mathfrak{k} \otimes_{\mathbb{R}} \mathbb{C}$.
- K intersects non-trivially every connected components of $G(\mathbb{C})$.

Then the group G contains a unique real structure σ that $K = G(\mathbb{C})^\sigma$. And if $\mathfrak{p} \subset \mathfrak{g}$ be the subspace $\{\xi \in \mathfrak{g} | \sigma(\xi) = -\xi\}$, then the map

$$k \times \mathfrak{p} \to G(\mathbb{C}) : (k, p) \mapsto k \cdot \exp(p)$$

is a diffeomorphism.

Proof: Cf.[Gaitsgory P18]. □

Cor. (8.3.6.12). If we denote $P = \exp(\mathfrak{p})$, then $P \subset \widetilde{P} = \{g \in G(\mathbb{C}) | \sigma(g) = g^{-1}\}$, and there is a diffeomorphism:

$$\coprod_{k \in K, k^2 = 1} \{k\} \times P \cong \widetilde{P}.$$

Cor. (8.3.6.13). In the situation of(8.3.6.11), G is reductive, by(8.3.6.9).

Cor. (8.3.6.14). $K \to G(\mathbb{C})$ is a homotopy equivalence.

Cartan Involutions

Def. (8.3.6.15)[Cartan Involutions]. Let $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}_{\mathrm{cntd}}/\mathbb{R}$, an **involution on** G is an isomorphism $\theta : G \cong G$ s.t. $\theta^2 = \mathrm{id}$.

A **Cartan involution** is an involution s.t. $G^{(\theta)}(\mathbb{R}) = \{g \in G(\mathbb{C}) | g = \theta(\overline{g})\}$ is compact.

Prop. (8.3.6.16). Cartan involution and compactness.

Example (8.3.6.17). Let $G = \mathrm{SL}(2)_{\mathbb{R}}$ and $\theta = \mathrm{ad}(\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix})$, then $\mathrm{SL}(2)^{(\theta)}(\mathbb{R}) = SU(2)$ is compact, so this is a Cartan involution on G.

Thm. (8.3.6.18)[Satake]. Let $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}_{\mathrm{cntd}}/\mathbb{R}$, then G admits a Cartan involution iff G is reductive. And in this case, any two Cartan involutions differ by a conjugation by elements in $G(\mathbb{R})$, i.e. $(\tau = \mathrm{ad}(g_0)^{-1} \circ \theta \circ \mathrm{ad}(g_0))$.

Proof: Cf.[Satake, Algebraic structures of symmetric domains, volume 4 of Kano Memorial Lectures, 1980]I.4.3. □

Cor. (8.3.6.19) [Satake].

- G is a connected algebraic group, then G is compact iff id is a Cartan involution on G. And in this case, this is the only Cartan involution of G. In particular, a compact connected algebraic group is reductive.
- If V is a f.d. real vector space and $G = \mathrm{GL}(V)$, then the choice of a basis for V determines a Cartan involution $M \mapsto M^t$, and by(8.3.6.18), any Cartan involution is of this form.
- If $G \subset \mathrm{GL}(V)$, then G is reductive iff g is stable under a Cartan involution of $\mathrm{GL}(V)$. And any Cartan involutions of G is of this form.

Proof: Cf.[Satake, Algebraic structures of symmetric domains, volume 4 of Kano Memorial Lectures, 1980]I.4.4. □

Prop. (8.3.6.20)[c-Polarizations]. Let $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}/\mathbb{R}$ and $c \in G(\mathbb{R})$(equivalently $c^2 \in Z(G(\mathbb{R}))$, and $\mathrm{ad}(c)^{-1} = \mathrm{ad}(c^{-1})$). Then for a real representation V of G, a c**-polarization** is a $G(\mathbb{R})$-invariant bilinear form φ s.t. the form $(u, v) \mapsto \varphi(u, cv)$ is symmetric and positive-definite.

Then for such c, if $\mathrm{ad}(c)$ is a Cartan involution, then any f.d. real representation of G admits a c-polarization. Conversely, if a faithful real representation of G admits a c-involution, then $\mathrm{ad}(c)$ is a Cartan involution.

Proof: Cf.[Mil17b]P16. □

Maximal Compact Subgroup

Cor. (8.3.6.21). For any compact subgroup $K' \subset G(\mathbb{R})$, there exists an element $g \in P^\tau$ s.t. $Ad_g(K') \in K^\tau$.

Proof: Cf.[Gaitsgory P25]. □

Complex Reductive Lie Groups

Def. (8.3.6.22) [Complex Reductive Lie Groups]. A **connected complex reductive Lie group** is a connected complex Lie group G of the form $((\mathbb{C}^\times)^r \times G_{ss})/Z$ where G_{ss} is semisimple and Z is a finite central subgroup. A **complex reductive Lie group** is a complex Lie group G that G^0 is connected reductive and G/G^0 is finite.

Def. (8.3.6.23) [Compact Part]. If $G = ((\mathbb{C}^\times)^r \times G_{ss})/Z$ is a connected complex reductive Lie group, then $Z \subset (S^1)^r \times G_{ss}^c$(the compact part), then we denote $G^c = (S^1)^r \times G_{ss}^c/Z$ the compact subgroup of G. Then the restriction of f.d. representations of G to G^c is an equivalence by(11.7.7.3).

Example (8.3.6.24). $GL(n, \mathbb{C}) = (\mathbb{C}^* \times SL(n, \mathbb{C}))/\mu_n$ is a complex reductive Lie group.

Prop. (8.3.6.25) [Abstract Jordan Decomposition]. Let G be a connected reductive complex Lie group. A **semisimple/unipotent element** of G is an element that acts on every f.d. representation of G by a semisimple/reductive operator. By(11.7.5.5), it suffices to check for one faithful representation of G by(11.7.5.5) and(8.3.6.23)(faithful representations exist by(8.3.6.23) and(11.7.5.4)).

Then every element $g \in G$ has a decomposition $g = g_s g_u$ where g_s is semisimple, g_u is unipotent, and $g_s g_u = g_u g_s$.

Proof: Cf.[Etingof, P210]. □

7 Reductive Group Schemes

8.4 Topics in Group Schemes

Thm. (8.4.0.1) [Lang-Steinberg]. Let $k \in \texttt{Field}, k = \overline{k}, G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}_{\mathrm{cntd}} /k, F \in \mathrm{End}(G) \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp} /k$ s.t. the fixed point of $F(\overline{k})$ is finite, then the **Lang map**

$$\mathcal{L} : G \to G : g \mapsto g^{-1}F(g)$$

is surjective.

Proof: Cf.[Steinberg, Endomorphisms of Linear Algebraic Groups, P67].**?**

We only prove for the case $\#k < \infty$ and some Power of F is given by a standard Frobenius of G.

By(8.1.4.3), we can assume G is smooth. G acts on itself as $g(x) = gxF(g)^{-1}$. By(8.2.1.15), it has a closed orbit Ω. Thus it suffices to show that $\dim \Omega = \dim G$. Take $x \in \Omega(k)$, by(8.2.1.12) and(8.1.1.28), it suffices to show there exists only f.m. $g \in G(k)$ s.t. $gxF(g)^{-1} = x$. Let $F^m(x) = x, f : G \to G : f(g) = xF(g)x^{-1}$. Notice $xF(x) \cdot F^2(x) \cdot \ldots \cdot F^{m-1}(x)$ is contained in $\ker(F^m)$, so it is of finite order, let's say r. Then $f^{mr} = F^{mr}$, which has only f.m. solutions, thus there are only f.m. g s.t. $gxF(g)^{-1} = x$. □

1 over Finite Fields

Main references are [Representations of Finite Groups of Lie Type, Digne and Michel].

Notation (8.4.1.1).

- $p \in \mathbf{P}, r \in \mathbb{Z}_+, q = p^r, k \in \texttt{Field}^p, \#k = q$.

Prop. (8.4.1.2) [Orbits Contains a Rational Point]. Let $V \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}} /k, G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}_{\mathrm{cntd}} /k$, G acts on V, then any G-orbits O contains a rational point.

Proof: Let $v \in O(\overline{k})$, then $F(v) = gv$ for some $g \in G(\overline{k})$. Then by Lang's theorem(8.4.0.1), $g = F(h)^{-1}h$ for some $h \in G(\overline{k})$. Then $F(h(v)) = h(v)$, so $h(v) \in O$ is a rational point. □

Cor. (8.4.1.3). If $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp} /k$, $H \leq G$ is a connected subgroup, then $G(k)/H(k) = G/H(k)$.

8.5 Formal Groups and p-Divisible Groups

Main References are [Zin84].

1 Formal Power Series

Def. (8.5.1.1) [Notations]. Let $\underline{X} = \{X_1, \ldots, X_n\}$, $\underline{Y} = \{Y_1, \ldots, Y_n\}$.

Let R be a commutative unital ring, $R[[\underline{X}]]$ be the power series ring. It is a local ring with the maximal ideal $(\underline{X})$.

Let $i_1 : R[[\underline{X}]] \to R[[\underline{X}, \underline{Y}]]$ and $i_2 : R[[\underline{Y}]] \to R[[\underline{X}, \underline{Y}]]$ be the natural embeddings.

Let $\Omega^1_{R[[\underline{X}]]/R}$ be the free $R[[X]]$-module with basis given by $dX_1, \ldots, dX_n$. And there is a universal derivative $D : R[[\underline{X}]] \to \Omega^1_{R[[\underline{X}]]/R}$ given by $D(f) = \sum_i \frac{\partial f}{\partial X_i} dX_i$. It satisfies the usual universal property of Kähler differentials, but with morphisms changed to continuous morphisms.

Prop. (8.5.1.2) [Formal Sums and Products].

- Let $f_n \in R[[\underline{X}]]$ for any $n \in \mathbb{N}$ s.t. for any $m \in \mathbb{N}$, there exists a $N(m) \in \mathbb{N}$ s.t. $f_n \in (\underline{X})^m$ for any $n \geq N(m)$, then define the **formal sum**
$$\sum_n f_n = \varinjlim_{n \to \infty} \sum_{k=0}^{n} f_k.$$
In this case, we say $\sum_n f_n$ is well-defined.
- Let $g_n \in R[[\underline{X}]]$ for any $n \in \mathbb{N}$ s.t. for any $m \in \mathbb{N}$, there exists a $N(m) \in \mathbb{N}$ s.t. $g_n \in 1 + (\underline{X})^m$ for any $n \geq N(m)$, then define the **formal product**
$$\prod_n g_n = \varinjlim_{n \to \infty} \prod_{k=0}^{n} g_k.$$
In this case, we say $\prod_n g_n$ is well-defined.

Prop. (8.5.1.3) [Automorphisms]. If F_i are power series without constant terms that the matrix degree 1 terms of (F_i)(the Jacobi matrix) is invertible in R, then there are unique power series G_i without constant terms that $G \circ F = \mathrm{id}$ and $F \circ G = \mathrm{id}$.

Proof: It F_i induces a map $F : R[[X_1, \ldots, X_n]] \to R[[X_1, \ldots, X_n]]$ which in turn induces a graded map $K[X_1, \ldots, X_n] \to K[X_1, \ldots, X_n]$. It is clear that $(\frac{\partial F_i}{\partial X_j})_{ij}$ is invertible iff the induced graded ring map is an isomorphism, and because $K[[X_1, \ldots, X_n]]$, a map is an isomorphism iff its induced graded map is an isomorphism. □

Prop. (8.5.1.4). If R be a torsion-free algebra, and let
$$f(T) = \sum_{n \geq 1}^{\infty} \frac{a_n}{n!} T^n \in (R \otimes \mathbb{Q})[[T]], \quad a_1 \in R^*.$$
Then the unique $g(T)$ s.t. $f(g(T)) = T$ is of the form
$$g(T) = \sum_{n \geq 1}^{\infty} \frac{b_n}{n!} T^n \in (R \otimes \mathbb{Q})[[T]], \quad b_1 \in R^*.$$

Proof: Repeatedly differentiating the equation $f(g(T)) = T$, we get that $f\prime(g(T))g^{(n)}(T)$ can be expressed as integral polynomials in the variables

$$f^{(i)}(g(T)), 1 \leq i \leq n, \quad g^{(j)}(T), 1 \leq j \leq n-1.$$

Then evaluating at $T = 0$, we get that $b_n \in R$ and $b_1 \in R^*$, as $a_1 \in R^*$. □

1-Dimensional Formal Power Series

Def. (8.5.1.5) [Formal Exponential and Logarithm]. The **formal exponential** and **formal logarithm** is defined to be elements in $\mathbb{Q}[[x]]$:

$$\exp(x) = \sum_{n\geq 0} \frac{x^n}{n!}, \quad \log(1+x) = -\sum_{n>0} \frac{(-x)^n}{n}.$$

They satisfies $\exp(\log(1+x)) = 1 + x, \log(\exp(x)) = x$.

Remark (8.5.1.6). WARNING: It should be made clear that $\log(1+f)$ is defined only for $f \in xK[[x]]$, and $\log(1+x)$ is a symbol for the function $\mathrm{Log}(x) = \log(1+x)$. $\log(x)$ is not defined.

Proof: It suffices to prove $\mathrm{Exp}(x) = \exp(x) - 1$ and $\mathrm{Log}(x) = \log(1 + x)$ are inverse to each other. It suffices to show $\log(\exp(x)) = x$, because then by(8.5.1.3) the inverse of Log must be just Exp by(8.5.1.3).

We notice Exp are the unique formal power series without constant term that satisfied $d(\mathrm{Exp}) = \mathrm{Exp} + 1$, and Log is the unique formal power series that satisfies $d(\mathrm{Log}(x)) = \frac{1}{1+x}$. Thus

$$d(\log(\exp(x))) = \frac{\exp(x)}{\exp(x)} = 1,$$

so $\log(\exp(x)) = x$, because it has no constant term. □

Prop. (8.5.1.7) [Multiplicative Properties]. Suppose $\mathbb{Q} \subset R$, then

- for any $f, g \in R[[\underline{X}]]$, $\exp(f + g) = \exp(f)\exp(g)$.
- If $\sum_n f_n$ is well-defined(8.5.1.2), then $\prod_n \exp(f_n)$ is well-defined and
$$\exp(\sum_n f_n) = \prod_n \exp(f_n).$$
- for any $f, g \in 1 + (\underline{X})$, $\log(f) + \log(g) = \log(fg)$.
- If $g_n \in 1 + (\underline{X})$ and $\prod_n g_n$ is well-defined(8.5.1.2), then $\sum_n \log(f_n)$ is well-defined and
$$\log(\sum_n f_n) = \prod_n \log(f_n).$$

Proof: Brutal force calculation.**?** □

Def. (8.5.1.8) [Formal Powers]. Let $f \in 1 + xR[[x]], g \in R[[x]]$, f^g is defined to be

$$\exp(g \log(f)).$$

In particular, $\log(f^g) = g \log(f)$ by(8.5.1.5).

Prop. (8.5.1.9). In $\mathbb{Q}[[x]]$, if $p \in \mathbf{P}$, $m, n \in \mathbb{Z}$, $(n,p) = 1$, and $f(x) \in 1 + x\mathbb{Z}_{(p)}[[x]]$, then $f(x)^{m/n} \in 1 + x\mathbb{Z}_{(p)}[[x]]$.

Proof: If $g(x) = f(x)^{m/n}$, it is easy to see $g(x)^n = f(x)^m$ and $g(x) \in 1 + x\mathbb{Q}[[x]]$. Let

$$f(x)^m = 1 + \sum_{m\geq 1} a_m x^m, \quad g(x) = 1 + \sum_{m\geq 1} b_m x^m,$$

Then it is easy to use induction to show $b_m \in \mathbb{Z}_{(p)}$ for any $m \in \mathbb{Z}_+$. □

Prop. (8.5.1.10). In $\mathbb{Q}[[x]]$,

$$\exp(x) = \prod_{d>0} (\frac{1}{1-x^d})^{\frac{\mu(d)}{d}}.$$

Proof: Taking log, we prove its convergence and equality at once:

$$\sum_{d>0} \log((\frac{1}{1-x^d})^{\frac{\mu(d)}{d}}) = \sum_{d>0} \frac{\mu(d)}{d} \log(\frac{1}{1-x^d}) = \sum_{d>0} \frac{\mu(d)}{d} \sum_{d'>0} \frac{x^{dd'}}{d'} = \sum_{n>0} \frac{x^n}{n} \sum_{d|n} \mu(d) = x (24.1.3.15).$$

□

Prop. (8.5.1.11) [Artin-Hasse Exponential]. For $p \in \mathbf{P}$, the **Artin-Hasse exponential** is the power series $\text{hexp}(x)$ defined to be

$$\text{hexp}(x) = \exp(x + \frac{x^p}{p} + \frac{x^{p^2}}{p^2} + \ldots) \in \mathbb{Q}[[x]].$$

Then it satisfies

$$\text{hexp}(x) = \prod_{d>0, p\nmid d} (\frac{1}{1-x^d})^{\frac{\mu(d)}{d}}.$$

and in fact $\text{hexp}(x) \in \mathbb{Z}_{(p)}[[x]]$.

Proof: Taking log, we prove its convergence and equality at once:

$$\sum_{d>0, p\nmid d} \log((\frac{1}{1-x^d})^{\frac{\mu(d)}{d}}) = \sum_{d>0, p\nmid d} \frac{\mu(d)}{d} \log(\frac{1}{1-x^d}) = \sum_{d>0, p\nmid d} \frac{\mu(d)}{d} \sum_{d'>0} \frac{x^{dd'}}{d'} = \sum_{n>0} \frac{x^n}{n} \sum_{d|n, p\nmid d} \mu(d) = \sum_{k\in\mathbb{N}} \frac{x^{p^k}}{p^k} (24.1.3.15).$$

Then the last assertion follows from(8.5.1.9). □

Def. (8.5.1.12) [Bernoulli Numbers]. The **Bernoulli numbers** $B_k, k \geq 0$ are defined to be

$$\frac{X}{e^X - 1} = \sum_{k=0}^{\infty} B_k \frac{X^k}{k!} \in \mathbb{Q}[[X]].$$

Then B_k are all rational numbers, and

$$B_0 = 1, B_1 = -\frac{1}{2}, B_{2k+1} = 0 (k \geq 1), B_2 = \frac{1}{6}, B_4 = -\frac{1}{30}, B_6 = \frac{1}{42}, B_8 = -\frac{1}{30}.$$

More numbers can be found at`https://oeis.org/wiki/Bernoulli_numbers`.

For simplicity, for $k \in \mathbb{Z}_{<0}$, denote $B_k = 0$.

Def. (8.5.1.13)[Hankel Determinants]. Let K be a field and $f = \sum a_i T^i \in K[[T]]$, then for $k, M > 0$, define the **Hankel determinants** to be

$$H_k = \det(a_{i+j+k}), 1 \le i, j \le M$$

Prop. (8.5.1.14) [Characterizing Rational Functions]. Let $f \in K[[T]]$, then $f \in K[T]$ iff the Hankel determinants H_k of f vanishes for k, M large.

Proof: □

Cor. (8.5.1.15). If $K \subset L$ are fields, then $K[[T]] \cap L[T] = K[T]$.

Prop. (8.5.1.16). Let $P, Q \in \mathbb{Q}[T]$ be prime to each other with constant coefficient 1. if $P/Q = Z \in \mathbb{Z}[[T]]$, then we have $P, Q \in \mathbb{Z}[T]$.

Proof: Let λ be a root of $Q(T)$, we prove that $|\lambda^{-1}|_p \le 1$ for any $p \in \mathbf{P}$: If $|\lambda|_p < 1$, then $Z(\lambda)$ converges in $\mathbb{Q}_p$ because it has integral coefficients, and then

$$P(\lambda) = Q(\lambda)Z(\lambda) = 0.$$

This contradicts the fact that P, Q are coprime. So $\lambda^{-1} \in \mathbb{Z}$, and $Q \in \mathbb{Z}[T]$. Consequently, $P(T) = Q(T)Z(T) \in \mathbb{Z}[[T]] \cap \mathbb{Q}[T] = \mathbb{Z}[T]$. □

Geometric Objects

Def. (8.5.1.17) [Differential Operators]. A continuous R-linear mapping $D : R[[\underline{X}]] \to R[[\underline{X}]]$ is called a **formal differential operator** of order $N \ge -1$ iff

$$L_D : R[[\underline{X}, \underline{Z}]] \to R[[\underline{X}]] : \sum p_\alpha(\underline{X}) Z^\alpha \to \sum p_\alpha(X) D(X^\alpha)$$

vanish on J^{N+1}, where $J = (X_i - Z_i)$.

Then D is an operator of order N if $fD - Df$ has order $N - 1$ for any $f \in R[[X]]$.

Proof: Let D be a differential operator of order N, since $f(\underline{X}) - f(\underline{Z}) \in J$, for all $g(\underline{X}, \underline{Z}) \in J^N$, we have $L_D((f(\underline{X}) - f(\underline{Z}))g(\underline{X}, \underline{Z})) = 0$, which is equivalent to $L_{D\circ f - f\circ D}(g) = 0$, so $D \circ f - f \circ D$ is an operator of order $N - 1$. Conversely, if $D \circ f - f \circ D$ is an operator of degree $N - 1$, then $L_D((f(\underline{X}) - f(\underline{Z}))g) = 0$ for all $g \in J^N$, then D is an operator of order N. □

Cor. (8.5.1.18). A differential operator $D : R[[\underline{X}]] \to R[[\underline{X}]]$ of order 1 is a linear map that satisfies $D(fg) = D(f)g + fD(g)$, which is just a derivative on $R[[\underline{X}]]$. Equivalently, $D = \sum_i u_i(\underline{Z}) \frac{\partial}{\partial Z_i}$.

Prop. (8.5.1.19) [Graded Module of Differential Operators]. Let D_1, D_2 be differential forms of order N_1, N_2, then $D_1 \circ D_2$ is a differential form of order $N_1 + N_2$, and $[D_1, D_2]$ is a differential form of order $N_1 + N_2 - 1$. The R-algebra of differential operators on $R[[\underline{X}]]$ is denoted by $\mathcal{DO}$.

In particular, the graded module of differential operators

$$\mathrm{gr}\, \mathcal{DO} = \oplus\, \mathcal{DO}_N \,/\, \mathcal{DO}_{N-1}$$

is a commutative graded ring.

Proof:

□

Prop. (8.5.1.20) [Basis of Differential Operators]. There is a representation $g(X+Y) = \sum_\alpha D_\alpha g(X) Y^\alpha$ for any $g \in R[[\underline{X},\underline{Y}]]$, where D_α is a differential operator of degree $|\alpha|$. And $\{D_\alpha\}$ form a free $K[[\underline{X}]]$-basis for the module of differential operators(8.5.1.19).

In fact, D_α is just mimicking $\frac{\partial^\alpha}{\alpha!}$ in all fields.

Proof: $g(\underline{Z}) = \sum_\alpha D_\alpha g(\underline{X})(\underline{Z}-\underline{X})^\alpha$, thus if D is a differential operator of order N, then

$$D(g)(\underline{X}) = L_D(g(\underline{Z})) = \sum_{|\alpha|\leq N} L((\underline{Z}-\underline{X})^\alpha) D_\alpha g(\underline{X}),$$

which means $D = \sum_{|\alpha|\leq N} a_\alpha(\underline{X}) D_\alpha$, where $a_\alpha = L((\underline{Z}-\underline{X})^\alpha)$. □

Def. (8.5.1.21)[Tangent Space]. The tangent space of $K[[\underline{X}]]$ is the K-module $\mathrm{Hom}_K((\underline{X})/(\underline{X})^2, K)$.

Def. (8.5.1.22) [Formal Curves]. A **formal curve** in $K[[\underline{X}]]$ is an n-tuple $(\gamma_1(T),\ldots,\gamma_n(T))$ of elements in $K[[T]]$. The **tangent space of formal curve** is the map $\mathrm{Hom}_K((\underline{X})/(\underline{X})^2, K)$ given by $X_i \mapsto \gamma_i(T) \in (T)/(T^2) \cong K$.

Prop. (8.5.1.23)[Integral Curves]. For any

2 Formal Identities

Prop. (8.5.2.1). In $\mathbb{Z}[[T]]$,

$$\frac{1}{(1-T)^2} = \sum_{n\geq 0}(n+1)z^n$$

Proof:

$$(1-T)^2\sum_{n\geq 0}(n+1)z^n = (1-T)\sum_{n\geq 0} z^n = 1.$$

□

Prop. (8.5.2.2). In $\mathbb{Z}[[T]]$,

$$\sum_{n\geq 1}\frac{nT^n}{1-T^n} = \sum_{n\geq 1}\frac{T^n}{(1-T^n)^2}$$

Proof: □

Prop. (8.5.2.3). In $R[[z]]$, if

$$\sum_{r=0}^\infty A(r)z^r = \frac{1}{(1-\alpha_1 z)(1-\alpha_2 z)}, \quad \sum_{r=0}^\infty B(r)z^r = \frac{1}{(1-\beta_1 z)(1-\beta_2 z)},$$

then

$$\sum_{r=0}^\infty A(r)B(r)z^r = (1-\alpha_1\alpha_2\beta_1\beta_2 z^2)\prod_{i=1}^2\prod_{j=1}^2\frac{1}{(1-\alpha_i\beta_j z)}.$$

Proof: $A(n)B(n) = \sum_{0\leq k,j\leq n}\alpha_i^k\alpha_2^{n-k}\beta_1^j\beta_2^{n-j}$, and the coefficients in the z^n term of $\prod_{i=1}^2\prod_{j=1}^2\frac{1}{(1-\alpha_i\beta_j z)}$ is

$$\sum_{0\leq k,j\leq n}\#\{(r_1,r_2,r_3,r_4)|0\leq r_i\leq n, r_1+r_2=a, r_1+r_3=b, r_1+r_2+r_3+r_4=n\}\alpha_i^k\alpha_2^{n-k}\beta_1^j\beta_2^{n-j}.$$

Notice

$$\#\{(r_1,r_2,r_3,r_4)|0\le r_i\le n, r_1+r_2=a, r_1+r_3=b, r_1+r_2+r_3+r_4=n\}=\min(a,b)-(a+b-n).$$

Thus the effect of multiplying $(1-\alpha_1\alpha_2\beta_1\beta_2z^2)$ reduces the coefficients of $\alpha_i^k\alpha_2^{n-k}\beta_1^j\beta_2^{n-j}z^n$ to 1. So the assertion follows. □

Prop. (8.5.2.4) [Euler Identities].

- In $\mathbb{Z}[x][[q]]$,
$$\prod_{n\ge 0}(1+xq^n)=\sum_{n=0}^\infty\frac{q^{n(n-1)/2}x^n}{(1-q)\dots(1-q^n)}.$$
- In $\mathbb{Z}[[x,q]]$,
$$\prod_{n\ge 0}(1-xq^n)^{-1}=\sum_{n=0}^\infty\frac{x^n}{(1-q)\dots(1-q^n)}.$$

Proof: These follow from interesting combinatorial identies. □

Prop. (8.5.2.5) [Jacobi's Triple Product Formula, [And65]]. in $\mathbb{Z}[x][[x^{-1}q]]$,

$$\sum_{n=-\infty}^\infty x^nq^{n^2}=\prod_{n=1}^\infty(1-q^{2n})(1+xq^{2n-1})(1+x^{-1}q^{2n+1}).$$

Proof: By substituting $q=q^2, x=xq$ in Euler identities1(8.5.2.4), in $\mathbb{Z}[x][[x^{-1}q]]$,

$$\begin{aligned}
\prod_{n\ge 0}(1+xq^{2n+1})&=\sum_{n=0}^\infty\frac{q^{n^2}x^n}{(1-q^2)(1-q^4)\dots(1-q^{2n})}\\
&=(\prod_{j\ge 0}(1-q^{2j+2}))^{-1}\sum_{n=0}^\infty q^{n^2}x^n\prod_{j=0}^\infty(1-q^{2n+2+2j})\\
&=(\prod_{j\ge 0}(1-q^{2j+2}))^{-1}\sum_{n=-\infty}^\infty q^{n^2}x^n\prod_{j=0}^\infty(1-q^{2n+2+2j})\\
(q=q^2,x=q^{2n+2}\text{ in}(8.5.2.4))&=(\prod_{j\ge 0}(1-q^{2j+2}))^{-1}\sum_{n=-\infty}^\infty q^{n^2}x^n\sum_{m=0}^\infty\frac{(-1)^mq^{m^2+m+2nm}}{(1-q^2)(1-q^4)\dots(1-q^{2n})}\\
&=(\prod_{j\ge 0}(1-q^{2j+2}))^{-1}\sum_{m=0}^\infty\frac{(-x^{-1}q)^m}{(1-q^2)\dots(1-q^{2n})}\sum_{n=-\infty}^\infty q^{(m+n)^2}x^{m+n}\\
(q=q^2,x=-x^{-1}q\text{ in}(8.5.2.4))&=(\prod_{j\ge 0}(1-q^{2j+2}))^{-1}\prod_{j=0}^\infty(1+x^{-1}q^{2j+1})^{-1}\sum_{n=-\infty}^\infty q^{n^2}x^n.
\end{aligned}$$

□

Cor. (8.5.2.6) [Dedekind Eta Function]. Substitute $q=q^{3/2}$ and $x=q^{-1/2}$, we get:

$$\sum_{n=-\infty}^\infty(-1)^nq^{(3n^2+n)/2}=\prod_{n=1}^\infty(1-q^{3n})(1-q^{3n-1})(1-q^{3n-2})=\prod_{n=1}^\infty(1-q^n)\in\mathbb{Z}[[q]].$$

By completing the square,

$$\sum_{n=-\infty}^\infty(-1)^nq^{(6n+1)^2/24}=q^{1/24}\prod_{n=1}^\infty(1-q^n)\in\mathbb{Z}[[q^{1/24}]].$$

the last term is known as the **Dedekind eta function** $\eta(q(z))=q^{1/24}\prod_{n=1}^\infty(1-q^n)\in\mathbb{Z}[[q^{1/24}]]$.

3 Formal Group Law

In this subsection, the local structure of an algebraic group scheme at the origin is studied.

Def. (8.5.3.1) [Formal Group Laws]. A **formal group law** $\mathcal{G}$ of dimension n over $R \in \mathcal{CA}\mathrm{lg}$ is a continuous local map $\mu_{\mathcal{G}} : K[[\underline{X}]] \to K[[\underline{X}, \underline{Y}]]$ given by an n-tuple of power series $G = (G_1, \ldots, G_n)$ in $R[[\underline{X}, \underline{Y}]]$ that

$$G(X, Y) \equiv X + Y \mod (\underline{X}, \underline{Y})^2, \quad G(G(\underline{X}, \underline{Y}), Z) = G(X, G(Y, Z)).$$

A **formal R-module** is a formal group law $\mathcal{G}$ over R together with a ring homomorphism $R \to \mathrm{End}_R(G)$ that $[a](X) = aX + \ldots$.

A morphism of formal groups laws $\mathcal{G} \to \mathcal{H}$ is a continuous local map $\varphi^* : R[[\underline{X}']] \to R[[\underline{X}]]$ given by an n'-tuple of power series $\varphi = (\varphi_1, \ldots, \varphi_{n'})$ in $R[[\underline{X}]]$ that satisfies

$$\mu_{\mathcal{G}} \circ \varphi^* = (\varphi^* \otimes \varphi^*) \circ \mu_{\mathcal{H}}.$$

Or equivalently, $\varphi(G(\underline{X}, \underline{Y})) = H(\varphi(\underline{X}), \varphi(\underline{Y}))$.

Prop. (8.5.3.2). For a formal group Law G,

- $G(0, \underline{Y}) = \underline{Y}, G(\underline{X}, 0) = \underline{X}$.
- There exists a unique inverse $i(\underline{X})$ that $G(\underline{X}, i(\underline{X})) = 0$. And this $i(\underline{X})$ satisfies $G(i(\underline{X}), \underline{X}) = 0$, and $i^2 = \mathrm{id}$.

Proof: **?** □

Cor. (8.5.3.3) [Formal Group Laws and Group Schemes]. WARNING: A formal group law of dimension n is not equivalent to a group scheme structure on $\mathrm{Spec}\, \mathbb{Z}[[X_1, \ldots, X_n]]$(8.1.1.1), as here we are taking a completion.

Def. (8.5.3.4) [Multiplication Map]. Let G be a commutative formal group law over R and $m \in \mathbb{Z}$, then we can define a group homomorphism $[m] : G \to G$ inductively as follows:

$$[0](\underline{X}) = 0, \quad [m+1](\underline{X}) = G([m](\underline{X}), \underline{X}), \quad [m-1](\underline{X}) = G([m](\underline{X}), i(\underline{X})).$$

Then it can be verified that this is well-defined and $[m]$ is a group homomorphism.

Prop. (8.5.3.5) [Multiplications as Automorphisms]. Let $\mathcal{G}$ be a commutative formal group law over R and $m \in \mathbb{Z}$, then $[m](\underline{X}) = m\underline{X} + o(\underline{X})$. In particular, if m is invertible in R, then $[m]$ is an automorphism of G, by(8.5.1.3).

Prop. (8.5.3.6). $\mathbb{G}_a$ is the one-dimensional formal group with $\mathbb{G}_a(\underline{X}, \underline{Y}) = X + Y$, $\mathbb{G}_m$ is the one-dimensional formal group with $\mathbb{G}_m(\underline{X}, \underline{Y}) = X + Y + XY$. Over a $\mathbb{Q}$-algebra K, there is an isomorphism between $\mathbb{G}_a$ and $\mathbb{G}_m$ giving by $X \to \exp(X) - 1$.

Def. (8.5.3.7) [Invariant Differential Forms]. An **invariant differential form** on a formal group law G over R is an element $\omega = \sum a_i(\underline{X}) dX_i \in \Omega^1_{R[[X]]/R}$ that satisfies $(\underline{Y} \mapsto G(\underline{X}, \underline{Y}))_* \omega = \omega$, i.e.

$$\sum_j a_j(\underline{Y}) dY_j = \sum_i a_i(G(\underline{X}, \underline{Y})) \frac{\partial G_i}{\partial Y_j}(\underline{X}, \underline{Y}) dY_j.$$

If G is commutative, then this is equivalent to $\mu_* \omega = i_{1*}\omega + i_{2*}\omega$.

Prop. (8.5.3.8). The mapping $\omega \mapsto (u_1(0), \ldots, u_n(0))$ is an isomorphism of the R-module of invariant differential forms and R^n.

Proof: Cf.[Zin84]P14. □

Prop. (8.5.3.9)[Pullback of Invariant Differential Forms]. Let $\varphi : G \to H$ be a homomorphism of formal group laws, then for any invariant differential form $\omega = \sum a_i(\underline{X})dX_i$ on H, $\varphi^*\omega$ is a differential form on G, given by expanding $\sum a_i(\varphi(\underline{X}))d(\varphi_i(\underline{X}))$.

Proof:

$$\begin{aligned}(\underline{Y} \mapsto G(\underline{X}, \underline{Y}))^*\varphi^*\omega &= \sum a_i(\varphi(G(\underline{X}, \underline{Y})))d(\varphi(G(\underline{X}, \underline{Y})))\\ &= \sum a_i(H(\varphi(\underline{X}), \varphi(\underline{Y})))d(H(\varphi(\underline{X}), \varphi(\underline{Y})))\\ &= \sum_i a_i(\varphi(\underline{Y}))d(\varphi(\underline{Y}))\\ &= \varphi^*\omega\end{aligned}$$

□

Def. (8.5.3.10) [Invariant Differential Operators]. An **invariant differential operator** on a formal group G of dimension n is a differential operator D s.t.

$$\mu \circ D = (1 \otimes D) \circ \mu.$$

Equivalently, if $D = \sum_i u_i(\underline{Z})\frac{\partial}{\partial Z_i}$, it satisfies

$$\sum_j u_j(\underline{Y})\frac{\partial G_i}{\partial Y_j} = u_i(G(\underline{X}, \underline{Y})).$$

The space of invariant operators is stable under composition. The R-algebra of invariant differential operators on G is denoted by $\mathcal{DO}_G$.

Prop. (8.5.3.11). The space of invariant differential operators on G of order$\leq N$ are in bijection with the space of K-linear maps $l : K[[\underline{X}]] \to K$ s.t. $l((\underline{X})^{N+1}) = 0$ via

$$Df(\underline{X}) = (1 \otimes l)f(G(\underline{X}, \underline{Y})).$$

Proof: Cf.[Zin84]P22. □

Cor. (8.5.3.12) [Basis of Invariant Differential Operators]. For any $f \in K[[\underline{X}]]$, write $f(G(\underline{X}, \underline{Y})) = \sum_\alpha (H_\alpha f)(\underline{X})Y^\alpha$.

Then H_α are differential operators of order $|\alpha|$, and the space of invariant differential operators of order N form a free R-module with basis H_α. In particular, the space of invariant derivatives is isomorphic to R^n.

Proof: By(8.5.3.11),

$$Df(\underline{X}) = (1 \otimes l)f(G(\underline{X}, \underline{Y})) = (1 \otimes l)(\sum_\alpha (H_\alpha f)(\underline{X})Y^\alpha) = \sum_\alpha l(\underline{Y}^\alpha)(H_\alpha f)(\underline{X}).$$

□

Cor. (8.5.3.13) [Composition of Invariant Differential Operators]. Let $D_1, D_2 \in \mathcal{DO}_G$, then

$$(D_1 \circ D_2)f(\underline{Z}) = (1 \otimes l_1 \otimes l_2)f(G(\underline{Z}, G(\underline{X}, \underline{Y}))),$$

in particular,

$$l_{D_1 \circ D_2}(f) = (l_1 \otimes l_2)f(G(\underline{X}, \underline{Y})).$$

Proof:

$$(D_1 \circ D_2)f(\underline{Z}) = D_1(1 \otimes l_1)f(G(\underline{Z}, \underline{Y})) = (1 \otimes l_2 \otimes 1)(1 \otimes 1 \otimes l_1)f(G(G(\underline{Z}, \underline{X}), \underline{Y})) = (1 \otimes l_1 \otimes l_2)f(G(\underline{Z}, G(\underline{X}, \underline{Y}))).$$

□

Prop. (8.5.3.14) [Pushforward of Invariant Differential Operators]. A homomorphism φ of formal groups $G \to H$ induces a map from the linear maps $l : K[[\underline{X}]] \to K$ to linear maps $l \circ \varphi^* : K[[\underline{X}']] \to K$, which induces a K-homomorphism of algebras $\varphi_* : \mathcal{DO}_G \to \mathcal{DO}_H$.

Proof: To show preserves algebra structure, notice for any $f \in R[[\underline{X}']]$, by(8.5.3.13),

$$\begin{aligned}\varphi_*(D) \circ \varphi_*(D')f(0) &= (l \circ \varphi^*) \otimes (l' \circ \varphi^*)f(H(\underline{X}', \underline{Y}')) \\ &= (l \otimes l')f(H(\varphi(\underline{X}), \varphi(\underline{Y}))) \\ &= (l \otimes l')f(\varphi(G(\underline{X}, \underline{Y}))) \\ &= [(l \otimes l') \circ \varphi^*]f(G(\underline{X}, \underline{Y})) \\ &= \varphi_*(D \circ D')f(0).\end{aligned}$$

Thus $\varphi_*(D) \circ \varphi_*(D') = \varphi_*(D \circ D')$, by(8.5.3.11). □

Prop. (8.5.3.15) [$\mathbb{Q}$-Theorem]. Any commutative connected formal group over a $\mathbb{Q}$-algebra R is a direct sum of $\widehat{\mathbb{G}}_a$.

Proof: Cf.[Zin84]P19. □

1-dimensional Formal Groups

Def. (8.5.3.16) [Normalized Invariant Differential Form]. For a 1-dimensional formal group G over $R[[X]]$, the module of invariant differentials is isomorphic to R(8.5.3.10). An invariant differential form $\omega = P(T)dT$ is called **normalized** if $P(0) = 1$.

Then the unique normalized invariant differential form on G is given by $\omega_G = G_X(0, T)^{-1}dT$.

Proof: We need to check $G_X(0, G(T, S))^{-1}G_X(T, S) = G_X(0, T)^{-1}$, and this is just $G(U, G(T, S)) = G(G(U, T), S)$ differentiated at U and let $U = 0$. □

Prop. (8.5.3.17). For a morphism $\varphi : \mathcal{F} \to \mathcal{G}$ of 1-dimensional formal groups laws over R, $\varphi^*\omega_{\mathcal{G}} = \varphi'(0)\omega_{\mathcal{F}}$.

Proof: By(8.5.3.9), $\varphi^*\omega_{\mathcal{G}}$ is an invariant differential form, and compare their constant coefficients. □

Cor. (8.5.3.18). Let p be a prime, then for any formal group law of dimension 1,

$$[p](T) = pf(T) + g(T^p)$$

for some $f(0) = g(0) = 0$.

Proof: If suffices to show that $[p]'(T)\subset pR[[T]]$. But by(8.5.3.17) and(8.5.3.5),

$$p\omega(T)=[p]^*\omega(T)=G_X(0,[p](T))^{-1}[p]'(T)dT$$

so this is true. □

Def. (8.5.3.19) [Formal Logarithm]. When R is torsion-free, the **formal logarithm** $\log_{\mathcal{F}}$ for a 1-dimensional formal group is the integration of invariant differential

$$\int_0^T\omega_{\mathcal{F}}=T+\frac{c_1}{2}T^2+\cdots\in(R\otimes\mathbb{Q})[[T]].$$

Then the **formal power exponential** is the the unique power series $\exp_{\mathcal{F}}$ that is the inverse of $\log_{\mathcal{F}}$. It exists uniquely by(8.5.1.3), and by(8.5.1.4), it is of the form

$$\exp_{\mathcal{F}}=\sum_{n\geq 1}^{\infty}\frac{b_n}{n!}T^n\in(R\otimes Q)[[T]],b_n\in R.$$

Prop. (8.5.3.20). For R is torsion-free and an 1 dimensional formal group $\mathcal{F}$ over R,

$$\log_{\mathcal{F}}:\mathcal{F}\to\mathbb{G}_a$$

is an isomorphism of formal groups laws over $R\otimes_{\mathbb{Z}}\mathbb{Q}$.

And if $\mathcal{F}$ is a formal R-module, then it is an isomorphism of R-modules, because from(8.5.3.17) that $\omega_{\mathcal{F}}\circ[a]=a\omega_{\mathcal{F}}$, thus $\log_{\mathcal{F}}\circ[a]=a\cdot\log_{\mathcal{F}}$.

Proof: From $\omega_{\mathcal{F}}(F(T,S))=\omega_{\mathcal{F}}(T)$, we get that $\log_{\mathcal{F}}(F(T,S))=\log_{\mathcal{F}}(S)+\log_{\mathcal{F}}(T)$. So it is a homomorphism. Now the inverse $\exp_{\mathcal{F}}$ is already given, so it is an isomorphism. □

Cor. (8.5.3.21) [1-Dimensional Formal Group Law is Commutative]. Any 1-dimensional formal group over a ring R that has no torsion nilpotents is commutative.

Proof: We only prove for R torsion free?. $F(T,S)=\exp_{\mathcal{F}}(\log_{\mathcal{F}}(T)+\log_{\mathcal{F}}(S))$. □

Lubin-Tate Formal Group Law

Notation (8.5.3.22).

- Let $(K,v,\mathcal{O}_K,\mathfrak{p}_v,k)\in p$-`LField`.

Def. (8.5.3.23) [Lubin-Tate Formal Group Law]. Let ϖ be a uniformizer for K, a **Lubin-Tate power series** for ϖ is a power series $\varphi(X)\in\mathcal{O}_K[[X]]$ s.t.

$$\varphi(X)\equiv\varpi X\mod X^2,\quad\varphi(X)\equiv X^q(\mathrm{mod}\ \mathfrak{p}_v).$$

A **Lubin-Tate module** G over $\mathcal{O}_K$ is a formal $\mathcal{O}_K$-module(8.5.3.1) s.t. $[\pi_K](X)$ is a Lubin-Tate power series.

Prop. (8.5.3.24). Given a p-adic number field K with residue field $\mathbb{F}_q$, we consider the set ξ_π of all Lubin-Tate power series for π.

If $f,g\in\xi_\pi$ and $L(\underline{X})=\sum a_iX_i$ be a linear form, then there exists a unique power series $F(\underline{X})$ that $F(X)\equiv L(X)\mod(\underline{X})^2$ and $f(F(\underline{X}))=F(g(\underline{X}))$.

Proof: Choose F consecutively, if $F_{r+1} = F_r + \Delta_r$, then must

$$\Delta \equiv \frac{f(F_r(X)) - F_r(g(X))}{\pi^{r+1} - \pi} \text{ mod degree } (r+2).$$

This has coefficient in $\mathcal{O}$ because $f \equiv g \equiv Z^q \bmod \pi$. □

Cor. (8.5.3.25). If we let $f = g, L = X + Y$ to get F_f and $f, g, L = aX$ to get $a_{f,g}$, then

- $F_f(\underline{X}, \underline{Y}) = F_f(Y, X)$.
- $F_f(F_f(\underline{X}, \underline{Y}), Z) = F_f(X, F_f(Y, Z))$.
- $a_{f,g}(F_g(\underline{X}, \underline{Y})) = F_f(a_{f,g}(X), a_{f,g}(Y))$.
- $a_f b_f(Z) = (ab)_f(Z)$.
- $(a+b)_f(Z) = F_f(a_f(Z), b_f(Z))$.
- $\pi_f(Z) = f(Z)$.

all follow from the unicity of the last proposition.

Cor. (8.5.3.26) [Existence of Lubin-Tate Modules]. We get a commutative formal $\mathcal{O}$-module F_f for every f. And this group can act on $\mathfrak{p}_L$ for an alg.ext L/K. The set of zeros $\Lambda_{f,n}$ of f^n in L, as the elements annihilated by π^n, is a submodule of $\mathfrak{p}_L^{(f)}$.

And $u_{g,f}$ for any unit $u \in \mathcal{O}$ defines an isomorphism between F_f and F_g, thus this formal group only depends on π, called F_π. Hence $L_{f,n} = K(\Lambda_{f,n})$ only depends on π, with Galois group $G_{\pi,n}$.

Prop. (8.5.3.27) [Different Uniformizers]. For two uniformizers ϖ, ϖ', it is proven that F_ϖ and $F_{\varpi'}$ are isomorphic, but isomorphic over $\mathcal{O}_{\widehat{K^{\mathrm{ur}}}}$.

Thus $L_{\varpi,n}$ and $L_{\varpi',n}$ may not be isomorphic, but $K^{\mathrm{ur}}.L_{\pi,n} = K^{\mathrm{ur}}.L_{\pi',n}$ since $\widehat{K^{\mathrm{ur}}}.L_{\pi,n} = \widehat{K^{\mathrm{ur}}}.L_{\varpi',n}$ and both of them is the algebraic closure of K in it.

Proof: Cf.[Neukirch CFT P105].**?** □

Lemma (8.5.3.28). The Newton polygon of $[\pi_K^n]/\pi_K^n$ has vertices

$$(1, 0), (q, -1/e_K), (q^2, -2/e_K), \ldots.$$

Proof: Notice $[\pi_K^n]$ has no infinite edge of negative slope because all its coefficient are in $\mathcal{O}_K$. Now look at its roots, it has a root 0, and $q-1$ roots of valuation $v_p(\pi_K)/(q-1)$, $q(q-1)$ roots of valuation $v_p(\pi_K)/q(q-1)$, and so on. So by factor out these roots, $[\pi_K^n]/\pi_K^n$ is left with a power series whose Newton polygon is a single line, which shows the desired result. □

Prop. (8.5.3.29). The formal logarithm(8.5.3.19) of the Lubin-Tate formal group F_π satisfies:

$$\log_{\mathcal{F}_\varpi}(T) = \lim_{n\to\infty} [\pi_{\mathcal{F}}^n]/\pi_{\mathcal{F}}^n.$$

Proof: By(8.5.3.20) we have

$$\log_{\mathcal{F}}(T) = \log_{\mathcal{F}}([\pi_{\mathcal{F}}^n])/\pi_{\mathcal{F}}^n = ([\pi_K^n] + a_2/2[\pi_K^n]^2 + \ldots)/\pi_K^n$$

and for any degree n, the coefficient of $[\pi_K^{2n}]/\pi_K^{2n}$ is bounded below by a $c(n)$, so $[\pi_K^{2n}]/\pi_K^n$ converges to 0, thus the result. □

Cor. (8.5.3.30). The Newton polygon of $\log_{\mathcal{F}}(T)$ has vertices $(1, 0), (q, -1/e_K), (q^2, -2/e_K), \ldots$.

The discussion is continued at2.

4 Formal Groups

Prop. (8.5.4.1) [Formal Group Law as Functors]. Let $\mathcal{N}\mathrm{il}_R$ be the Abelian category of nilpotent commutative (non-unital)R-algebras, then the category of commutative formal group law are equivalent to Abelian functors on $\mathcal{N}\mathrm{il}$ whose underlying set-theoretic functor if $N\mapsto N^n$.

Proof: Each commutative formal group law G of dimension n defines a functor

$$\mathcal{N}\mathrm{il}_R\to\mathcal{A}\mathrm{b}:N\mapsto(N^n,G)$$

Conversely, if $\widetilde{G}:\mathcal{N}\mathrm{il}_R\to\mathcal{A}\mathrm{b}$ is a functor s.t. the underlying set-theoretic map is $N\mapsto N^n$, then $\widetilde{G}((\underline{X},\underline{Y})/(\underline{X},\underline{\ })^k)\cong[(\underline{X},\underline{\ })/(\underline{X},\underline{Y})^k]^n$ as sets. Suppose

$$(X_1,\ldots,X_n)+(Y_1,\ldots,Y_n)=(G_1^k(\underline{X},\underline{Y}),\ldots,G_n^k(\underline{X},\underline{Y}))$$

in $\widetilde{G}((\underline{X},\underline{Y})/(\underline{X},\underline{Y})^k)$, then $G_i^{k+1}\equiv G_i^k \mod (\underline{X},\underline{Y})^k$, and their limit defines a commutative formal group law of dimension n. Because for any nilpotent algebra N and $(a_1,\ldots,a_n),(b_1,\ldots,b_n)\in N^n$, there is a surjective map $(\underline{X},\underline{Y})/(\underline{X},\underline{\ })^k\to N$ for some k that maps X_i to a_i, Y_i to b_i, thus by functoriality, $\widetilde{G}(N)\cong G(N)$. □

Def. (8.5.4.2) [Formal Groups]. A (commutative)**formal group** is an exact Abelian functors on $\mathcal{N}\mathrm{il}$ whose underlying set-theoretic functor if $N\mapsto N^n$ and commutes with infinite direct sums.

Remark (8.5.4.3). Don't confuse formal groups with formal schemes, they are totally different notions.

Example (8.5.4.4). Let $S\in\mathcal{N}\mathrm{il}$, then the functor $\mathrm{res}_{S/R}(\mathbb{G}_m)$ is a commutative formal group.

Prop. (8.5.4.5). Let G be a commutative formal group law defined over a complete local ring $(R,\mathfrak{m})$, then

- For each n, $G(\mathfrak{m}^n)/G(\mathfrak{m}^{n+1})\cong\mathfrak{m}^n/\mathfrak{m}^{n+1}$ as groups.
- Let p be the characteristic of the residue field k (p may be 0), then $\mathcal{F}(\mathfrak{m})_{tor}=\mathcal{F}(\mathfrak{m})[p^\infty]$.

Proof: 1: This is because $F(x,y)\equiv x+y \mod \mathfrak{m}^n$.

2: This is because $[m]$ is an automorphism by(8.5.3.5) as m is invertible in R. □

1-Dimensional Commutative Formal Groups over DVR

Prop. (8.5.4.6). Let $(R,\mathfrak{m})$ be a CDVR with residue field k of characteristic p, $\mathcal{F}$ a formal group law over R. Then $\mathcal{F}(\mathfrak{m})_{\mathrm{tor}}=\mathcal{F}[p^\infty]$, and if $x\in\mathcal{F}(\mathfrak{m})$ has exact order p^n, then $v(x)\le\frac{v(p)}{p^n-p^{n-1}}$.

Proof: If $(m,p)=1$, then $\mathcal{F}(\mathfrak{m})[m]=0$ by(8.5.3.5).

By(8.5.3.18), $[p](x)=pf(x)+g(x^p)$, where $f(0)=1$. Thus it is possible only if $pv(x)\ge v(p^x)$, which means $v(x)\le v(p)/(p-1)$.

Now if this is true for $n\ge1$, let $x\in\mathcal{F}(\mathfrak{m})$ with order p^{n+1}, then $v([p](x))=v(pf(x)+g(x^p))\ge\min(v(px),pv(x))$. But $[p](x)$ has order p^n, thus $\frac{v(p)}{p^n-p^{n-1}}\ge\min(v(px),pv(x))$. But $n\ge1$ and $v(x)>0$, it is impossible that $\frac{v(p)}{p^n-p^{n-1}}\ge v(px)$, thus we have $\frac{v(p)}{p^n-p^{n-1}}\ge pv(x)$. □

Prop. (8.5.4.7). Let $(K,\mathcal{O}_K,\mathfrak{m},\kappa)$ be a complete valued field of mixed characteristic $(0,p)$, $\mathcal{F}$ a formal group law over K, then

- the formal logarithm(8.5.3.19) induces an homomorphism $\log_{\mathcal{F}}:\mathcal{F}(\mathfrak{m})\to K$.

- For $r > \frac{v(p)}{p-1}$, $\log_{\mathcal{F}}$ is an isomorphism $\log_{\mathcal{F}} : \mathcal{F}(\mathfrak{m}^r) \cong \mathfrak{m}^r$.

Proof: This follows from determining the convergence of $\log_{\mathcal{F}}$ and $\exp_{\mathcal{F}}$ by(12.2.5.20), after which it is a homomorphism by(8.5.3.20). □

Cor. (8.5.4.8) [Group Structure of CDVRs]. Take $F(X,Y) = (1+X)(1+Y) - 1$, then $\log_{\mathcal{F}}$ is given by $\log(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \ldots$, and it induces an isomorphism $(1+\mathfrak{m}^r)^\times \cong \mathfrak{m}^r$ for $r > \frac{v(p)}{p-1}$.

Prop. (8.5.4.9) [$\mathbb{Z}_p$-Multiplication]. Let $(R, \mathfrak{m})$ be a CDVR with residue field k of characteristic p, F a formal group law over R, then for any $x \in \mathcal{F}(\mathfrak{m})$, $\lim_{n\to\infty}[p^n](x) \to 0$.

In particular, we can define $[\alpha](x)$ for any $\alpha \in \mathbb{Z}_p$.

Proof: By(8.5.3.18), $v([p](x)) = v(pf(x) + g(x^p)) \geq \min(v(x) + v(p), pv(x))$. □

5 Cartier Theory

Main References are[Zin84].

Isogenies of Formal Groups

Def. (8.5.5.1) [Heights over Positive Characterestic]. Let R be a ring of characteristic $p > 0$, $\varphi : F \to G$ be a homomorphism of formal group laws over R of dimension 1, the **height of homomorphism** $\mathrm{ht}(\varphi)$ is the largest integer h s.t. $\varphi(T) = g(T^{p^h})$ for some h.

For a formal group law F over R, the **height of formal group law** $\mathrm{ht}(F)$ is $\mathrm{ht}([p]_F)$. By(8.5.3.18), the height is always positive.

Prop. (8.5.5.2). Let R be a ring of characteristic $p > 0$, $f : F \to G$ be a homomorphism of formal group laws over R of dimension 1, then

- If $f'(0) \neq 0$, then $\mathrm{ht}(f) > 0$.
- If $f = g(T^{p^h})$ with $h = \mathrm{ht}(f)$, then $g'(0) \neq 0$.

In particular, the first non-zero term of $f(T)$ is T^{p^h}, where h is the height of f.

Proof: 1: Let ω_F, ω_G be the normalized invariant differential forms of F and G, then

$$0 = f'(0)\omega_F(T) = \omega_G(f(T)) = G_X(0,T)^{-1} f'(T) dT,$$

thus $f'(T) = 0$, which means $\mathrm{ht}(f) > 0$.

2: Let $q = p^h$ and $F^{(q)}(T) = F(X^{1/q}, Y^{1/q})^q$. Then it is easy to see $F^{(q)}$ is another formal group law, and g is a homomorphism from $F^{(q)}$ to F:

$$g(F^{(q)}(X^q, Y^q)) = g(F(X,Y)^q) = f(F(X,Y)) = F(f(X), f(Y)) = F(g(X^q), g(Y^q)).$$

Which means $g(F^{(q)}(X,Y)) = F(g(X), g(Y))$. Thus if $g'(T) = 0$, by item1, $g(T) = g_1(T^p)$, contradicting $h = \mathrm{ht}(f)$. □

Prop. (8.5.5.3). Let $F \xrightarrow{f} G \xrightarrow{g} H$ be homomorphisms of formal group laws over ring R of characteristic $p > 0$, then $\mathrm{ht}(g \circ f) = \mathrm{ht}(f) + \mathrm{ht}(g)$.

Proof: Let $f(T) = f_1(T^{p^{\mathrm{ht}(f)}})$, $g(T) = g_1(T^{p^{\mathrm{ht}(g)}})$, where $f_1(0) \neq 0, g_1(0) \neq 0$ by(8.5.5.2), then

$$g \circ f(T) = g_1(f_1(T^{p^{\mathrm{ht}(f)}})^{p^{\mathrm{ht}(g)}}) = g_1(\widetilde{f}_1(T^{p^{\mathrm{ht}(f)+\mathrm{ht}(g)}}))$$

where $g_1(0)\widetilde{f}_1(0) \neq 0$, thus by(8.5.5.2) again, $\mathrm{ht}(g \circ f) = \mathrm{ht}(f) + \mathrm{ht}(g)$. □

6 p-divisible Groups

Def. (8.5.6.1)[Λ-Formal Schemes]. Let Λ be a local complete Noetherian ring and A_Λ^f be the category of finite length(Artinian) Λ-algebra,

Then a **Λ-formal functor** is a functor $A_\Lambda^f \to \mathcal{S}et$.

The **formal completion** of a functor $A_\Lambda \to \mathcal{S}et$ is its restriction on A_Λ^f. We denote the formal completion of $\operatorname{Spec} A$ by $\operatorname{Spf} A$.

Then a **Λ-formal scheme** is a filtered colimits of functors $\varinjlim \operatorname{Spf} A_i$, or equivalently a profinite Λ-algebra $A = \varprojlim A_i$ with profinite topology.

Def. (8.5.6.2)[Λ-Formal Group Schemes]. A **Λ-formal group** is a Λ-formal scheme with values in groups.

Def. (8.5.6.3) [p-Divisible Formal Lie Group Schemes]. A **formal Lie group** $\mathcal{G}$ over Λ is a connected formally smooth Λ-formal group. It is necessarily isomorphic to $\mathcal{G} = \operatorname{Spf} \Lambda[[X_1, \ldots, X_n]]$ where $n = \dim \mathcal{G}$. The number n is called the **dimension** of $\mathcal{G}$.

A **p-divisible formal Lie group** is a commutative formal Lie group $\mathcal{G} = \operatorname{Spf} \Lambda[[X_1, \ldots, X_n]]$ that multiplication by $p : [p]^*$ is a finite flat morphism on $\Lambda[[X_1, \ldots, X_n]]$.

Def. (8.5.6.4) [p-Divisible Groups]. Let p be a prime and S a scheme, a **p-divisible group** is a commutative group functor on Sch_{fppf}/S that

- G is p-divisible: $[p]_G$ is an epimorphism.
- G is p-torsion: $G = \varinjlim_n G(n)$, where $G(n) = \ker([p]_G : G \to G)$.
- $G(n)$ are representable as sheaves on Sch_{fppf}/S.

The category of p-divisible groups over S is denoted by $pdiv(S)$.

Prop. (8.5.6.5)[Equivalent Definitions of p-Divisible Groups]. Let p be a prime and S a scheme, then a p-divisible group over S is an ind system (G_v, i_v) of finite commutative groups schemes over S s.t.

- $0 \to G_v \xrightarrow{i_v} G_{v+1} \xrightarrow{p^v} G_{v+1}$ is an exact sequence of group schemes over S.
- the rank of fiber of $G(n)$ at $s \in S$ is $p^{nh(s)}$ where h is a locally constant function on S.

and (G_v, i_v) is called a **p-divisible group of height** h over S.

Proof: Cf.[Shatz, P61], [P-Divisible Groups, Haoran Wang]. □

Prop. (8.5.6.6)[Connected p-Divisible Groups and Formal Lie Groups]. Cf.[Shatz, P62].

Def. (8.5.6.7)[Tate Module]. Let G be a p-divisible group over an integral domain $\mathcal{O}$ with fraction field K of characteristic 0, then the **Tate module** of G is defined to be

$$T_p(G) = \varprojlim_n G_n(\overline{K}),$$

and the **Tate comodule** of G is defined to be

$$\Phi_p(G) = \varinjlim_n G_n(\overline{K}).$$

Hodge-Tate Decomposition

Prop. (8.5.6.8) [Hodge-Tate Decomposition]. If $\mathcal{O}$ is a CDVR of mixed characteristic with perfect residue field k and fraction field K, then there is an isomorphism of f.d. $\mathbb{Q}_p$-representation of G_K:

$$T_p(G)\otimes_{\mathbb{Z}_p}\widehat{\overline{\mathbb{Q}_p}}\cong tangent\oplus cotangent\ spaces\ of\ G.$$

Proof: Cf.[p-divisible Groups, Morrow]. □

8.6 Geometric Invariant Theory

8.7 Moduli Problems

1 Schemes as Functors

Prop. (8.7.1.1) [Strong Yoneda Lemma]. For any $S \in \mathcal{S}\mathrm{ch}$, the functor

$$\mathcal{S}\mathrm{ch}_S \to \mathcal{S}\mathrm{h}_{\mathrm{fpqc}}/S \to \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{A}\mathrm{ff}_{\mathrm{fpqc}}/S) \to \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{A}\mathrm{ff}_S) : X \mapsto (\widetilde{X} : \mathrm{Spec}\, R \mapsto \mathrm{Mor}_S(\mathrm{Spec}\, R, X))$$

is a fully faithful embedding of the categories.

Proof: (5.1.2.25) applied to $\mathcal{A}\mathrm{ff}_{\mathrm{fpqc}}/S \to \mathcal{S}\mathrm{ch}_{\mathrm{fpqc}}/S$ implies the restriction map $\mathcal{S}\mathrm{h}_{\mathrm{fpqc}}/S \to \mathcal{S}\mathrm{h}(\mathcal{A}\mathrm{ff}_{\mathrm{fpqc}}/S)$ is an equivalence, thus the assertion follows from Yoneda lemma and the fact $\mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{A}\mathrm{ff}_{\mathrm{fpqc}}/S) \to \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{A}\mathrm{ff}_S)$ is fully faithful. □

Def. (8.7.1.2) [Closed Subfunctors]. Let $S \in \mathcal{S}\mathrm{ch}$ and Z be a subfunctor of $X \in \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{A}\mathrm{ff}_S)$. Z is called a **closed subfunctor** of X if for any $T \in \mathcal{A}\mathrm{ff}_S$, $f \in \mathrm{Mor}(h_T, X)$, the functor $Z \otimes_X h_T$ is represented by a closed subscheme of T.

Prop. (8.7.1.3) [Closed Subfunctor of Schemes]. Let $S \in \mathcal{S}\mathrm{ch}$ and $X \in \mathcal{S}\mathrm{ch}_S$, then the closed subfunctors of $\widetilde{X}$(8.7.1.2) are exactly of the form $\widetilde{Z}$ for a closed subscheme $\widetilde{Z}$ of $\widetilde{X}$.

Proof: If Z is a closed subscheme of X, then for any $f : h^A \to X$, $f^{-1}(Z)$ is the pullback of Z along $\mathrm{Spec}\, A \to X$, so it is a closed subscheme of $\mathrm{Spec}\, A$. Conversely, if Z is a closed subfunctor of X, then for each affine open subset U of X, $Z \cap h_U$ is represented by a quotient of $\mathcal{O}(U)$ by some ideal $\mathcal{I}(U)$. Because of the uniqueness, $\mathcal{I}(U)$ and $\mathcal{I}(U')$ coincides on the intersection $U \cap U'$, thus $U \mapsto \mathcal{I}(U)$ defines a sheaf of ideals $\mathcal{I}$ on X.

Now $Z = h_{Z'}$, where Z' is the closed subscheme of X defined by $\mathcal{I}$, because for any $\mathrm{Spec}\, R \to X$, the pullback of Z and Z' to R are the same, because they are all closed subschemes of $\mathrm{Spec}\, R$ and they are equal on an open covering of $\mathrm{Spec}\, R$(The pullback of the open coverings of X). Now if $\mathrm{Spec}\, R \to X$ is represented by an element $\alpha \in X(R)$, $Z \times_X h^R(R)$ is the set $\{\varphi \in \mathrm{Hom}(R, R) | X(\varphi)(\alpha) \in Z(R)\}$. So $\mathrm{id}_R \in Z \times_X h^R(R) \iff \alpha \in Z(R)$/ From this we see that $Z(R) = Z'(R)$ for any R. □

Def. (8.7.1.4) [Open Subfunctors]. Let $S \in \mathcal{S}\mathrm{ch}$ and Z be a subfunctor of $X \in \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{A}\mathrm{ff}_S)$. Z is called an **open subfunctor** of X if for any $T \in \mathcal{A}\mathrm{ff}_S$, $f \in \mathrm{Mor}(h_T, X)$, the functor $U \otimes_X h_T$ is represented by an open subscheme of T.

Prop. (8.7.1.5) [Open Subfunctor of Schemes]. Let $S \in \mathcal{S}\mathrm{ch}$ and $X \in \mathcal{S}\mathrm{ch}_S$, then closed subfunctors of $\widetilde{X}$(8.7.1.2) are exactly of the form $\widetilde{U}$ for an open subscheme $\widetilde{Z}$ of $\widetilde{X}$.

Proof: The proof is exactly the same as that of(8.7.1.3). □

Def. (8.7.1.6) [Open Coverings by Functors]. Let $S \in \mathcal{S}\mathrm{ch}$, an **open covering of a functor** $X \in \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{S}\mathrm{ch}_S)$ is a family of open subfunctors $\{U_i\}$ that for any $T \in \mathcal{A}\mathrm{ff}_S$, $h_T \times_X U_i$ is an open covering of T.

Prop. (8.7.1.7) [Open Coverings of Schemes]. Let $S \in \mathcal{S}\mathrm{ch}$ and $X \in \mathcal{S}\mathrm{ch}_S$, then open coverings of the functor $\widetilde{X}$ are exactly open coverings of X.

Proof: The proof is exactly the same as that of(8.7.1.3). □

Prop. (8.7.1.8). The pullback of a closed subfunctor is also a closed subfunctor. The intersection of closed subfunctors is a closed subfunctor.

Lemma (8.7.1.9). Let k be a field and $B \in \mathcal{CA}\mathrm{lg}_k$, $X \in \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{CA}\mathrm{lg}_B)$, define

$$X_* \in \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{CA}\mathrm{lg}_k) : X_*(R) = X(R \otimes_k B).$$

Then if Z is a closed subfunctor of X, Z_* is also a closed subfunctor of X_*.

Proof: Let A be a k-algebra, and $\alpha \in X_*(A)$. To prove Z_* is closed in X_*, we need to show there exists an ideal $\mathfrak{a} \subset A$ that for any homomorphism $\varphi : A \to R$,

$$X_*(\varphi)(\alpha) \in Z_*(R) \iff \varphi(\mathfrak{a}) = 0.$$

Because Z is closed in X, there exists an ideal $\mathfrak{b}$ of $A \otimes_k B$ that for any $\varphi : A \to R$,

$$X(\varphi \otimes B)(\alpha) \in Z_*(R) \iff (\varphi \otimes B)(\mathfrak{b}) = 0.$$

Now by(4.1.1.26), there is an ideal $\mathfrak{a} \subset A$ that an ideal I of A satisfies $\mathfrak{b} \subset I \otimes B \iff \mathfrak{a} \subset I$, thus we are done. □

Prop. (8.7.1.10). Let $S \in \mathcal{S}\mathrm{ch}$, $X \in \mathcal{PS}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{A}\mathrm{ff}/S)$ and Z a closed subfunctor of X. If $Y \in \mathcal{S}\mathrm{ch}_R$, then $\underline{\mathrm{Mor}}(h_Y, Z)$ is a closed subfunctor of $\underline{\mathrm{Mor}}(h_Y, X)$.

Proof: If $Y = h^B$, then $\underline{\mathrm{Mor}}(Y, X)(R) = X(B \otimes R)$, thus the conclusion follows from(8.7.1.9). For a general Y, let Y_i be an affine open covering of Y, then there are maps $\rho_i : \underline{\mathrm{Hom}}(Y, X) \to \underline{\mathrm{Hom}}(Y_i, X)$. Now $\underline{\mathrm{Hom}}(Y_i, Z)$ is closed subfunctor of $\underline{\mathrm{Hom}}(Y_i, X)$, thus we are done if we can show that $\underline{\mathrm{Hom}}(Y, Z) = \cap_i \rho_i^{-1}(\underline{\mathrm{Hom}}(Y_i, Z))$. But this is equivalent to any map $Y_R \to X_R$ that maps $(Y_i)_R$ into Z_R maps Y_R into Z_R, which is clear. □

Def. (8.7.1.11) [Fat Subfunctors]. Let $S \in \mathcal{S}\mathrm{ch}$ and $\mathcal{F} \in \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{A}\mathrm{ff}_{\mathrm{fppf}}/S)$, then a subfunctor D of $\mathcal{F}$ is called a **fat subfunctor** if the shifification of D w.r.t. the fppf topology is just $\mathcal{F}$.

Prop. (8.7.1.12) [Extending Group Structures]. Let $S \in \mathcal{S}\mathrm{ch}$, $\mathcal{F} \in \mathcal{S}\mathrm{h}^{\mathcal{G}\mathrm{rp}}(\mathcal{A}\mathrm{ff}_{\mathrm{fppf}}/S)$ and D a fat subfunctor of $\mathcal{F}$, then every group structure on D extends uniquely to a group structure on $\mathcal{F}$ by shifification.

Representability

Prop. (8.7.1.13)[A Representability Criterion]. Let $\mathcal{F} \in \mathcal{S}\mathrm{h}^{\mathcal{S}\mathrm{et}}(\mathcal{S}\mathrm{ch}_{\mathrm{Zar}})$ and there is a covering $F = \cup F_i$ by open subfunctors(8.7.1.4)(8.7.1.6) that are representable by schemes, then F is representable by a scheme.

Proof: Let (X_i, ξ_i) represents F_i, where $\xi \in F_i(X_i)$. Because $F_j \subset F$ is representable by open immersion, there are open subsets $U_{ij} \subset X_i$ that $T \to X_i$ factors through U_{ij} iff $\xi|_T \in F_j(T)$. In particular, $\xi_i|_{U_{ij}} \subset F_j(U_{ij})$, and therefore there is a canonical map $\varphi_{ij} : U_{ij} \to X_j$ that $\varphi_{ij}^*\xi_j = \xi_i|_{U_{ij}}$. By definition of U_{ji} this map factors through U_{ji}.

For the rest, Cf.[Sta]01JJ.**?** □

Cor. (8.7.1.14) [Representing Group Functors]. Let $S \in \mathcal{S}\mathrm{ch}$ and $\mathcal{G} \in \mathcal{S}\mathrm{h}^{\mathcal{G}\mathrm{rp}}(\mathcal{A}\mathrm{ff}_{\mathrm{Zar}}/S)$ and there is an open subfunctor $\mathcal{F} \subset \mathcal{G}$ s.t. for any $\mathrm{Spec}\, K \in \mathcal{A}\mathrm{ff}_S$ where K is a field and $g \in \mathcal{G}(K)$, there exists a $g' \in G(k)$ s.t. $gg' \in \mathcal{F}(K)$, then $\mathcal{G}$ is representable.

Proof: For any $g \in G(S)$, let $F_g = \tau_g^* F$, then $F_g \cong F$ and are also open subfunctors of $\mathcal{G}$. then $\{F_g \to G\}$ is an open covering because for any $T \in \mathcal{S}\mathrm{ch}$ and $\xi \in \mathrm{Mor}(h_T, \mathcal{G})$, $F_g \times_{\mathcal{G}} h_T$ is represented by open subschemes of T, and it must covers T because otherwise there are some map $\mathrm{Spec}\, k(x) \to T$ s.t. $F_g \times_{\mathcal{G}} h_{k(x)}$ are all empty, contradicting the hypothesis. Thus the assertion follows from(8.7.1.13). □

Prop. (8.7.1.15) [$\underline{\mathrm{Hom}}(\mathcal{E}, \mathcal{F})$ for Coherent Sheaves]. Let S be a locally Noetherian scheme and X a projective scheme over S. Let $\mathcal{E}, \mathcal{F}$ be coherent sheaves on X and $\mathcal{F}$ is flat, then the functor

$$\underline{\mathrm{Hom}}(\mathcal{E}, \mathcal{F}) : \mathcal{S}\mathrm{ch}_S \to \mathcal{S}\mathrm{et} : T \mapsto \mathrm{Hom}_T(\mathcal{E}_T, \mathcal{F}_T)$$

is representable by a vector bundle $\mathbf{V}$ over S(5.5.2.21).

Proof: Cf.[Kle05]P16. □

Cor. (8.7.1.16). For any $f \in \mathrm{Hom}(\mathcal{E}, \mathcal{F})$, f corresponds to a morphism $X \to \mathbf{V}$, then the inverse image of $\mathbf{V}_0 \subset \mathbf{V}$ in X is the closed subscheme X' with the universal property that for any $\varphi : T \to X$, $\varphi^* f = 0$ iff φ factors through X'.

2 Hilbert & Quot Schemes

References are [Nit05]. For simplicity, we restrict to the category of locally Noetherian schemes over S, and assume X/S is separated.

Def. (8.7.2.1) [Hilbert Functors]. Let $X \in \mathcal{S}\mathrm{ch}_S$, then the **Hilbert functor** is the functor

$$\underline{\mathrm{Hilb}}_{X/S} : \mathcal{S}\mathrm{ch}_S \to \mathcal{S}\mathrm{et} : T \mapsto \text{closed subschemes of } X_T \text{ that is flat over } Z\}.$$

Def. (8.7.2.2) [Quot Functors]. Let S be a locally Noetherian scheme and $f : X \to S$ be a f.t. scheme over S and $\mathcal{E} \in \mathcal{C}\mathrm{oh}(X)$, then for any $T \in \mathcal{S}\mathrm{ch}_S$, define a **family of quotients of $\mathcal{E}$ parametrized by** T to be a pair $(\mathcal{F}, q)$ where

- $\mathcal{F} \in \mathcal{C}\mathrm{oh}(X_T)$ s.t. $\mathrm{Supp}(\mathcal{F})$ is proper over T.
- A surjective homomorphism of sheaves $q : \mathcal{E}_T \to \mathcal{F}$.

Then the **Quot functor** is the functor

$$\underline{\mathrm{Quot}}_{\mathcal{E}/X/S} : \mathcal{S}\mathrm{ch}_S \to \mathcal{S}\mathrm{et} : T \mapsto \{\text{isomorphism classes of family of quotients of } \mathcal{E} \text{ parametrized by } T\}.$$

Cor. (8.7.2.3) [Hilbert Functors as Quot Functors]. $\underline{\mathrm{Hilb}}_{X/S} = \underline{\mathrm{Quot}}_{\mathcal{O}_X/X/S}$.

Prop. (8.7.2.4) [$\underline{\mathrm{Quot}}_{\mathcal{F}/X/S}$ are Fpqc Sheaves]. $\underline{\mathrm{Quot}}_{\mathcal{F}/X/S}$ are fpqc sheaves.

Proof: This follows from the fact $\mathcal{QC}\mathrm{oh} / \mathcal{S}\mathrm{ch}$ is a fpqc sheaf(5.1.5.12). □

Prop. (8.7.2.5) [Stratification by Hilbert Polynomials]. Let $\mathcal{L}$ be a line bundle on X_T, then for any line bundle $\mathcal{L}$ on X_T, then for any $t \in T$, the Hilbert polynomial of $\mathcal{F}_t$ w.r.t. the line bundle $\mathcal{L}_t$ on X_t is locally constant on T, and is stable under extension of residue fields, thus we can define $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}$ to represent the subfunctor of $\underline{\mathrm{Quot}}_{\mathcal{E}/X/S}$ consisting of pairs $(\mathcal{F}, q)$ s.t. $\mathcal{F}_t$ has Hilbert polynomial Φ w.r.t. $\mathcal{L}_t$ for all $t \in T$.

Then if each $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}$ is representable, $\underline{\mathrm{Quot}}_{\mathcal{E}/X/S}$ is also representable, and there is a decomposition

$$\underline{\mathrm{Quot}}_{\mathcal{E}/X/S} = \coprod_{\Phi \in \mathbb{Q}[\lambda]} \underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}.$$

Prop. (8.7.2.6) [Valuation Criterion]. Let $X \to S$ be proper, then the morphism of functors $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S} \to h_S$ satisfies the discrete valuation criterion for properness.

Proof: The valuation criterion says if R is a valuation ring with fraction field K with a morphism $\mathrm{Spec}\, R \to S$, then any pairs $(\mathcal{F}_K, q_K)$ where $\mathcal{F}_K \in \mathfrak{Coh}(X_K)$ and $q_K : \mathcal{E}_K \to \mathcal{F}_K$ a surjection can extends uniquely to a surjective map $q_R : \mathcal{E}_R \to \mathcal{F}_R \in \mathfrak{Coh}(X_R)$ s.t. $\mathcal{F}_R$ is flat over R.

For this, let $j : X_K \to X_R$ be the open immersion, take $\mathcal{F}_R$ to be the image of the map $\mathcal{E}_R \to i_*\mathcal{E}_K \xrightarrow{i_* q_K} i_*\mathcal{F}_K$, then $i^*\mathcal{F}_R = \mathcal{F}_K$, and $\mathcal{F}_R$ is flat over R because it is torsion-free(4.4.1.12). Notice the properness of X/S is used to show that $\mathrm{Supp}(\mathcal{F}) \subset X_R$ is proper over R. □

Lemma (8.7.2.7) [Preliminary Reductions]. Situation as in(8.7.2.2), then

- Let $\nu \in \mathbb{Z}$, then tensoring $\mathcal{L}^\nu$ gives an isomorphism of functors $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S} \cong \underline{\mathrm{Quot}}^{\Psi,\mathcal{L}}_{\mathcal{E}(\nu)/X/S}$, where $\Psi(\lambda) = \Phi(\lambda + \nu)$.
- Let $\varphi : \mathcal{E} \to \mathcal{G}$ be a surjective homomorphism in $\mathfrak{Coh}(X)$, then the corresponding natural transformation $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{G}/X/S} \to \underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}$ is a closed subfunctor.
- If X/S is proper, let $i : U \to X$ be an open subscheme, then $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{i^*\mathcal{E}/U/S}$ is an open subfunctor of $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}$.

Proof: 1 is obvious.

2: It suffices to show for any locally Noetherian scheme $T \in \mathcal{S}\mathrm{ch}_S$ and a pair $(\mathcal{F}, q) \in \underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}(T)$, there exists a closed subscheme T' of T s.t. for any locally Noetherian scheme U and $f : U \to T$, $q_U : \mathcal{E}_U \to \mathcal{F}_U$ factors through $\mathcal{G}_U$ iff f factors through T'. For this, just take T' to be the vanishing scheme of $\ker(\varphi_T) \to \mathcal{E}_T \to \mathcal{F}_T$(8.7.1.16)(or by direct verification).

3: Firstly the natural transformation $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{i^*\mathcal{E}/U/S} \to \underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}$ is given by

$$\eta_T : (\mathcal{F}, i^*\mathcal{E}_T \to \mathcal{F}) \mapsto (\mathrm{Im}(\mathcal{E}_T \to i_*\mathcal{F}), \text{adjunction}).$$

Notice restriction is a left inverse to this transformation. Then by inspection, this is an open subfunctor iff for any locally Noetherian scheme $T \in \mathcal{S}\mathrm{ch}_S$ and a pair $(\mathcal{F}, q) \in \underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}(T)$, for any locally Noetherian scheme Q and $f : Q \to T$, the restriction of $(\mathcal{F}, q)$ to Q is in $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{i^*\mathcal{E}/U/S}(Q)$ iff $\mathcal{F}_Q \to i_{Q*}i_Q^*\mathcal{F}_Q$ is injective.**?** □

Thm. (8.7.2.8) [Grothendieck]. Let S be a Noetherian scheme and $f : X \to S$ a (quasi-)projective morphism, $\mathcal{L}$ an f-very ample line bundle on X, then for any coherent $\mathcal{O}_X$-module $\mathcal{E}$ and any polynomial $\Phi \in \mathbb{Q}[\lambda]$, the functor $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}$ is representable by a (quasi-)projective S-scheme.

Proof: Cf.[Nit05]P24.

For the quasi-projective case, use(8.7.2.7) and the fact any coherent sheaf can be extended. □

Remark (8.7.2.9). Cf.[Hartshorne Appendix B, 3.4.1] has an example of a 3-dimensional smooth proper scheme over $\mathbb{C}$ with a free $G = \mathbb{Z}/(2)$-action for which the quotient X/G is not a scheme. Which means that $\underline{\mathrm{Hilb}}_{X/\mathbb{C}}$ is not representable by a scheme.

Cor. (8.7.2.10). Let S be a locally Noetherian scheme and $f : X \to S$ be H-projective, $\mathcal{L} = \mathcal{O}_{\mathbb{P}_S(V)}(1)|_X$, $\mathcal{E}$ a coherent quotient sheaf of $\mathcal{O}_X^{\oplus p}(\nu)$ where $p > 0, \nu \in \mathbb{Z}$, and $\Phi \in \mathbb{Q}[\lambda]$, then he functor $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}$ is representable by an H-projective S-scheme.

Lemma (8.7.2.11) [Altman-Kleinman]. Let S be a locally Noetherian scheme and $f : X \to S$ be a closed subscheme of some $\mathbb{P}_S(V)$ where V is a finite locally free sheaf on S, $\mathcal{L} = \mathcal{O}_{\mathbb{P}_S(V)}(1)|_X$, $\mathcal{E}$ a coherent quotient sheaf of $f^*(W)(\nu)$ where W is a finite locally free sheaf on S and $\nu \in \mathbb{Z}$, and $\Phi \in \mathbb{Q}[\lambda]$, then the functor $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}$ is representable by a projective S-scheme that can be embedded in $\mathbb{P}_S(F)$ for some finite locally free sheaf F on S that is an exterior power of W with a symmetric power of V.

Proof: Cf.[Nit05]P24. □

Lemma (8.7.2.12). Let S be a locally Noetherian scheme and $f : X = \mathbb{P}_S(V) \to S$ where V is a finite locally free sheaf on S, $\mathcal{L} = \mathcal{O}_{\mathbb{P}_S(V)}(1)$, $\mathcal{E} = f^*(W)(\nu)$ where W is a finite locally free sheaf on S and $\nu \in \mathbb{Z}$, and $\Phi \in \mathbb{Q}[\lambda]$, then the functor $\underline{\mathrm{Quot}}^{\Phi,\mathcal{L}}_{\mathcal{E}/X/S}$ is representable by a projective S-scheme that can be embedded in $\mathbb{P}_S(F)$ for some finite locally free sheaf F on S that is an exterior power of W with a symmetric power of V.

Proof: Cf.[Nit05]P24. □

Examples of Quot Schemes

Prop. (8.7.2.13) [Projective Spaces]. $\underline{\mathrm{Quot}}^{1,\mathcal{O}_\mathbb{Z}}_{\oplus^{n+1}\mathcal{O}_\mathbb{Z}/\mathbb{Z}/\mathbb{Z}} \cong \mathbb{P}^n_\mathbb{Z}$, with the universal element the tautological quotient $\oplus^{n+1}\mathcal{O}_{\mathbb{P}^n} \to \mathcal{O}_{\mathbb{P}^n}(1)$.

Moreover, if $\mathcal{E} \in \mathfrak{Coh}^{\mathrm{free}}(S)$, then $\underline{\mathrm{Quot}}^{1,\mathcal{O}_S}_{\mathcal{E}/S/S} \cong \mathbf{P}(\mathcal{E})$, with the universal element the tautological quotient $\pi^*(\mathcal{E}) \to \mathcal{O}_{\mathbf{P}(\mathcal{E})}(1)$.

Proof: For any surjective map $\mathcal{E}_T \to \mathcal{L}$ where $\mathcal{L}$ is a line bundle, locally $H^0(\mathcal{L}) \cong H^0(\mathcal{E}_T)$ is of dimension n and thus $\mathcal{L}$ is basepoint-free. Now the associated map $\varphi_\mathcal{L} : T \to \mathcal{O}_{\mathbf{P}(\mathcal{E})}$**?** pulls $\mathcal{O}_{\mathbf{P}(\mathcal{E})}(1)$ to $\mathcal{L}$. □

Def. (8.7.2.14) [Relative Grassmannian of a Coherent Sheaf]. Let $\mathcal{E} \in \mathfrak{Coh}(S)$, define the **relative Grassmannian of** $\mathcal{E}$ to be $\mathrm{Gra}(\mathcal{E}, k) = \underline{\mathrm{Quot}}^{k,\mathcal{O}_S}_{\mathcal{E}/S/S}$.

Then if $\mathcal{E}$ is finite locally free, it is a quotient of the group scheme $\mathrm{GL}(n)_S$, and when $\mathcal{E} \cong \mathcal{O}_S^n$ and $S = \mathbb{Z}$, this is just the Grassmannian variety $\mathrm{Gra}(n, k)$ defined in(8.2.1.20).

In particular, $\mathrm{Gra}(n+1, 1) \cong \mathbb{P}^n_\mathbb{Z}$ by(8.7.2.13).

Proof: First we prove for $\mathcal{E}$ finite locally free: There is a natural action of $\mathrm{GL}(n)$ on $\underline{\mathrm{Quot}}^{k,\mathcal{O}_S}_{\mathcal{E}/S/S}$, it is clearly a quotient map, and the kernel is a closed subgroup of $\mathrm{GL}(n)_S$ by(15.5.1.4). Thus $\mathrm{Gra}(\mathcal{E}, k)$ is a quotient of $\mathrm{GL}(n)$ by definition(8.1.1.21).

In general, $\mathcal{E}$ is a locally a quotient of a finite locally free sheaf, thus $\mathrm{Gra}(\mathcal{E}, k)$ is locally projective by(8.7.2.7). □

Prop. (8.7.2.15) [Quotient by Flat Projective Equivalence Relations].

Proof: Cf.[Nit05]P31. □

Prop. (8.7.2.16) [Grassmannian Varieties are projective]. The Grassmannian variety $\mathrm{Gra}(\mathcal{E}, k)$ is locally projective, and when $\mathcal{E}$ is locally free, it is projective, and if $\mathcal{E}$ is trivial, it is H-projective.

Proof: It injects into $\mathbb{P}(\wedge^k\mathcal{E})$ by the natural transformation

$$T_S : (\mathcal{O}_T^n \to \mathcal{Q}) \mapsto (\wedge^k(\mathcal{O}_T^n) \to \wedge^k\mathcal{Q}).$$

In particular, the corresponding very ample line bundle is just $\wedge^k\mathcal{F}$, where $f^*\mathcal{E} \to \mathcal{F}$ is the universal element and $f : \mathrm{Gra}(\mathcal{E}, k) \to S$, by(8.7.2.13). □

Cor. (8.7.2.17) [Grassmannian Varieties and Projective Space]. There is a canonical isomorphism $G(n, n-1) \cong \mathbb{P}^{n-1}$ identifying sections with surjections from $\mathcal{O}_X^n$.

Prop. (8.7.2.18) [Flag Varieties]. The flag variety(8.2.1.22) represents the functor $T \mapsto \{$ the isomorphism classes of flags in $\mathcal{O}_T^n$ of the given dimensions$\}$.

Cor. (8.7.2.19) [Flag Varieties are Projective]. The flag varieties are projective as they are closed subsets of a product of Grassmannian varieties.

3 Picard Schemes

Main references are [Kle05]. For simplicity, we assume S is locally Noetherian and restrict to the category of locally Noetherian schemes over S, and X/S is separated.

Notice a morphism $X \to S$ is said to have integral geometric fibers if for any alg.closed field k and a morphism $\operatorname{Spec} k \to S$, X_k is integral.

Picard Functors

Def. (8.7.3.1) [Picard Functor]. Let $X \in \mathcal{S}\mathrm{ch}_S$, the **Picard functor** is the functor

$$\underline{\mathrm{Pic}}_X : \mathcal{S}\mathrm{ch}_S \to \mathcal{G}\mathrm{rp} : T \mapsto \mathrm{Pic}(X_T) = H^1(X_T, \mathcal{O}_{X_T}^*).$$

The problem of this functor is that it is not a Zariski sheaf.

Define the **relative Picard functor** $\widetilde{\underline{\mathrm{Pic}}}_{X/S} : \mathcal{S}\mathrm{ch}_S \to \mathcal{G}\mathrm{rp} : T \mapsto \mathrm{Pic}(X_T)/\operatorname{pr}_T^*(\mathrm{Pic}(T))$. Let the shifification of this ring in the Zariski/étale/fppf topology denoted by $\underline{\mathrm{Pic}}_{X/S,\mathrm{Zar}}, \underline{\mathrm{Pic}}_{X/S,\text{ét}}, \underline{\mathrm{Pic}}_{X/S}$. Then there are maps of presheaves:

$$\underline{\mathrm{Pic}}_X \to \widetilde{\underline{\mathrm{Pic}}}_{X/S} \to \underline{\mathrm{Pic}}_{X/S,\mathrm{Zar}} \to \underline{\mathrm{Pic}}_{X/S,\text{ét}} \to \underline{\mathrm{Pic}}_{X/S}.$$

Remark (8.7.3.2). In the following we will frequently use a technical condition s.t. $\mathcal{O}_S \to f_*(\mathcal{O}_X)$ is an isomorphism. This is true when X is a proper variety over S, by(5.10.5.2).

Prop. (8.7.3.3). Assume $\mathcal{O}_S \cong f_*\mathcal{O}_X$, then the functor $\mathcal{N} \to f^*\mathcal{N}$ is fully faithful from the category of finite locally free sheaves on S to the category of finite locally free sheaves on S s.t. f_* is a left partial inverse.

Proof: For any finite locally free sheaf $\mathcal{N}$, there is an isomorphism $\mathcal{N} \cong f_*f^*\mathcal{N}$ by checking locally, and for any other finite locally free sheaf $\mathcal{N}'$, $\mathcal{H}om(\mathcal{N}, \mathcal{N}')$ is also finite locally free, thus the natural map $f^*\mathcal{H}om(\mathcal{N}, \mathcal{N}') \to \mathcal{H}om(f^*\mathcal{N}, f^*\mathcal{N}')$ is an isomorphism by checking locally. Thus $\mathrm{Hom}(\mathcal{N}, \mathcal{N}') \cong \mathrm{Hom}(f^*\mathcal{N}, f^*\mathcal{N}')$. □

Def. (8.7.3.4) [Rigidification]. Assume $f : X \to S$ has a section $g : S \to X$, then for any $T \in \mathcal{S}\mathrm{ch}_S$ and $\mathcal{L} \in \mathrm{Pic}(X_T)$, a **$g$-rigidification of $\mathcal{L}$** is an isomorphism $u : \mathcal{O}_T \cong g_T^*\mathcal{L}$.

Prop. (8.7.3.5). Let $f : X \to S$ be a morphism of schemes with a section g, then for any $T \in \mathcal{S}\mathrm{ch}_S$, the group of isomorphism classes of pairs $(\mathcal{L}, u)$ where $\mathcal{L} \in \mathrm{Pic}(X_T)$ and u is a g-rigidification of $\mathcal{L}$, is isomorphism to $\widetilde{\underline{\mathrm{Pic}}}_{X/S}(T)$.

Proof: For any $\mathcal{M} \in \mathrm{Pic}(X_T)$, let $\mathcal{L} = \mathcal{M} \otimes (f_T^*g_T^*\mathcal{M})^{-1}$, then $\mathcal{L} = \mathcal{M} \in \mathrm{Pic}(X_T)/\operatorname{pr}_T^*\mathrm{Pic}(T)$, and there is a canonial isomorphism $g_T^*\mathcal{L} \cong \mathcal{O}_T$.

Conversely, if $u : \mathcal{O}_T \cong g_T^*\mathcal{L}$ and there exists some $\mathcal{N} \in \mathrm{Pic}(T)$ s.t. $v : \mathcal{L} \cong f_T^*\mathcal{N}$, let $w = g_T^* \circ u : \mathcal{O}_T \cong g_T^*\mathcal{L} \cong \mathcal{N}$, then there are isomorphism of pairs: $v : (\mathcal{L}, u) \cong (f_T^*\mathcal{N}, w)$, $f_T^*w : (\mathcal{O}_{X_T}, \mathrm{can}) \cong (f_T^*\mathcal{N}, w \circ \mathrm{can})$, thus $(\mathcal{L}, u) = e$. □

Prop. (8.7.3.6) [No Automorphisms after Rigidification]. Let $f : X \to S$ be a morphism of schemes. If for any $T \in \mathcal{S}\mathrm{ch}_S$, $f_T : X_T \to T$ satisfies $\mathcal{O}_T \cong (f_T)_*\mathcal{O}_{X_T}$, and f has a section g, then for any $(\mathcal{L}, u)$ where u is a g-rigidification of $\mathcal{L}$, $\mathrm{Aut}(\mathcal{L}, u)$ is trivial.

Proof: For such an automorphism $v : \mathcal{L} \to \mathcal{L}$, $g_T^*(v) = \mathrm{id}$, Also notice $\mathrm{Hom}(\mathcal{L},\mathcal{L}) = H^0(\mathcal{H}om(\mathcal{L},\mathcal{L})) = H^0(\mathcal{O}_{X_T}) \cong H^0(\mathcal{O}_T)$, thus v is tensoring a line bundle $\mathcal{L}$ from $\mathcal{O}_T$. Thus g^*v is multiplying $\mathcal{L}$. So $\mathcal{L} \cong \mathcal{O}_T$ and v is trivial. □

Prop. (8.7.3.7) [Comparison Theorems]. Let $f : X \to S$ be a morphism of schemes. If for any $T \in \mathcal{S}\mathrm{ch}_S$, $f_T : X_T \to T$ satisfies $\mathcal{O}_T \cong (f_T)_*\mathcal{O}_{X_T}$, then

- The morphisms $\underline{\widetilde{\mathrm{Pic}}}_{X/S} \hookrightarrow \underline{\mathrm{Pic}}_{X/S,\mathrm{Zar}} \hookrightarrow \underline{\mathrm{Pic}}_{X/S,\text{ét}} \hookrightarrow \underline{\mathrm{Pic}}_{X/S}$ are injections. In particular, $\underline{\widetilde{\mathrm{Pic}}}_{X/S}$ is separated in the fppf topology.
- If f has a section, then $\underline{\widetilde{\mathrm{Pic}}}_{X/S} \cong \underline{\mathrm{Pic}}_{X/S,\mathrm{Zar}} \cong \underline{\mathrm{Pic}}_{X/S,\text{ét}} \cong \underline{\mathrm{Pic}}_{X/S}$.
- If f has a section Zariski locally, then $\underline{\mathrm{Pic}}_{X/S,\mathrm{Zar}} \cong \underline{\mathrm{Pic}}_{X/S,\text{ét}} \cong \underline{\mathrm{Pic}}_{X/S}$.
- if f has a section étale locally, then $\underline{\mathrm{Pic}}_{X/S,\text{ét}} \cong \underline{\mathrm{Pic}}_{X/S}$.

Proof: 1: It suffices to show that $\underline{\widetilde{\mathrm{Pic}}}_{X/S} \to \underline{\mathrm{Pic}}_{X/S}$ are injective. For this, notice first $\underline{\mathrm{Pic}}_{X/S}$ is also the fppf-sheaf associated to $\underline{\mathrm{Pic}}_X$, as any line bundle on T is Zariski-locally trivial. Then if $\mathcal{L} \in \mathrm{Pic}(X_T)$ is fppf-locally trivial, then for some fppf covering $\pi : T' \to T$, $(f_{T'})_*\pi_X^*\mathcal{L} \cong \mathcal{O}_{T'}$ by hypothesis. And this equals $\pi^*(f_T)_*\mathcal{L}$ by flat base change. So $(f_T)_*\mathcal{L}$ is an invertible sheaf(by hypothesis used on f_T) and $(f_T)_*(f_T)^*\mathcal{L} \cong \mathcal{L}$ because it is true after f.f. base change to T'(flat base change used).

2: By item1, it suffices to show $\widetilde{\mathrm{Pic}}_{X/S}$ satisfies the fppf-descent, but this follows from the fact $\mathrm{Pic}_{X/S}$ is a rigid fibered category(5.1.3.5), $\mathfrak{QCoh}\,/\,\mathcal{S}\mathrm{ch}$ is a stack(5.1.5.12) and line bundles satisfy the fpqc descent(5.5.3.1).

3, 4 follow from 2 by base change. □

Prop. (8.7.3.8) [Comparison of Points]. Let $\mathrm{Spec}\, A \in \mathcal{S}\mathrm{ch}_S$ where A is a local ring, then

- the natural maps $\mathrm{Pic}_X(A) \cong \underline{\widetilde{\mathrm{Pic}}}_{X/S}(A) \cong \underline{\mathrm{Pic}}_{X/S,\mathrm{Zar}}(A)$ are isomorphisms.
- If A is Artin local with alg.closed residue field, then $\mathrm{Pic}_X(A) \cong \underline{\mathrm{Pic}}_{X/S,\text{ét}}(A)$.
- If A is an alg.closed field k, then $\mathrm{Pic}_X(k) \cong \underline{\mathrm{Pic}}_{X/S}(k)$

Proof: 1: Since A is local, $\mathrm{Pic}(\mathrm{Spec}\, A) = 0$, and it has a unique minimal point, thus 1 is clear.

2: Every étale A-algebra of f.t. is a direct product of copies of A**?**, thus it is clear any fppf local scheme is a scheme.

3: In this case, any fppf covering of $\mathrm{Spec}\, k$ has a section, thus this follows from(8.7.3.7). □

Prop. (8.7.3.9). If X/S is proper of f.p., then an element in $\underline{\mathrm{Pic}}_{X/S}(S)$ is trivial iff it is trivial Zariski-locally on S.

Proof: Cf.[Neron Model, P202]. □

Relative Effective Divisors

Prop. (8.7.3.10) [Divisor Functor]. The **divisor functor** $\underline{\mathrm{Div}}_{X/S} : \mathcal{S}\mathrm{ch}_S \to \mathcal{G}\mathrm{rp}$ is given by $T \mapsto \{\text{relative effective divisors on } X_T/T\}$. This is truly a functor by(5.8.1.12).

Thm. (8.7.3.11) [$\underline{\mathrm{Div}}_{X/S}$ is Representable]. If S is a locally Noetherian scheme and $X \to S$ is projective and flat, then $\underline{\mathrm{Div}}_{X/S}$(8.7.3.10) is representable by an open subscheme of the Hilbert scheme $\underline{\mathrm{Hilb}}_{X/S}$.

Proof: Let $H = \underline{\mathrm{Hilb}}_{X/S}$ and $W \subset X \times H$ the universal closed subscheme. Then pr_H is projective and flat. Let V be the open loci of points of W s.t. W is an effective divisor, $U = H \backslash q(W \backslash V)$, then U is open in H and $q^{-1}U$ is an effective divisor on $X \times U/U$. By definition of Hilbert scheme, for any effective divisor D on some X_T/T is the pullback of W via g. Now we show for any $t \in D$, $g(t) \in U$. This follows from(5.8.1.10) and f.f. descent of regularness(5.1.5.28). Thus g factors through U, as U is open. □

Def. (8.7.3.12) [Relative Abel Map]. The **relative Abel map** is the functor

$$A_{X/S}(T) :\mapsto \underline{\mathrm{Div}}_{X/S}(T) \to \underline{\widetilde{\mathrm{Pic}}}_{X/S}(T) : D \mapsto \mathcal{L}_{X_T}(D).$$

Def. (8.7.3.13) [Linear System Functor]. Let $X \in \mathcal{S}\mathrm{ch}_S$ and $\mathcal{L} \in \mathrm{Pic}(X)$, the **linear system functor** $\underline{\mathrm{LinSys}}_{\mathcal{L}/X/S} : \mathcal{S}\mathrm{ch}_S \to \mathcal{S}\mathrm{et}$ is defined to be the inverse image of $\mathcal{L} \in \underline{\widetilde{\mathrm{Pic}}}_{X/S}$ in $\underline{\mathrm{Div}}_{X/S}$ via the Abel map(8.7.3.12).

Thm. (8.7.3.14) [$\underline{\mathrm{LinSys}}_{\mathcal{L}/X/S}$ is Representable]. Let X be a proper variety over S and $\mathcal{L} \in \mathrm{Pic}(X)$, then $\underline{\mathrm{LinSys}}_{\mathcal{L}/X/S}$ is represented by some projective space $\mathbb{P}(\mathcal{Q})$ over S.

Proof: Cf.[Kle05]P25.**?** □

Prop. (8.7.3.15). Assume X/S is proper and $\mathcal{F} \in \mathcal{C}\mathrm{oh}(X)$, then there exists a unique $\mathcal{Q} \in \mathcal{C}\mathrm{oh}(S)$ with functorial isomorphism

$$q : \mathcal{H}om(\mathcal{Q}, \mathcal{N}) \cong f_*(\mathcal{F} \otimes f^*\mathcal{N})$$

for any $\mathcal{N} \in \mathcal{QC}\mathrm{oh}(S)$.

And the formation of $\mathcal{Q}$ commutes with base change.

Proof: Cf.[Kle05]P24.**?** □

Prop. (8.7.3.16). Situation as in(8.7.3.15), if S is a local ring with closed point s, the following are equivalent:

- The $\mathcal{O}_S$-module $\mathcal{Q}$ is locally free.
- For all $\mathcal{N} \in \mathcal{QC}\mathrm{oh}(\mathcal{O}_S)$, the functor $\mathcal{N} \mapsto f_*(\mathcal{F} \otimes f^*\mathcal{N})$ is right exact.
- For all $\mathcal{N} \in \mathcal{QC}\mathrm{oh}(\mathcal{O}_S)$, the natural map $f_*(\mathcal{F}) \otimes \mathcal{N} \to f_*(\mathcal{F} \otimes f^*\mathcal{N})$ is an isomorphism.
- The natural map $H^0(X, \mathcal{F}) \otimes k(s) \to H^0(X_s, \mathcal{F}_s)$ is a surjection.

Proof: Cf.[Kle05]P24.**?** □

Prop. (8.7.3.17) [$\underline{\mathrm{Div}}_{X/S}$ and $\underline{\mathrm{LinSys}}_{\mathcal{P}/X_{\underline{\mathrm{Pic}}_{X/S}}/\underline{\mathrm{Pic}}_{X/S}}$]. If X is a proper variety over S and $\underline{\widetilde{\mathrm{Pic}}}_{X/S}$ is representable with the universal sheaf $\mathcal{P}$, then $\underline{\mathrm{Div}}_{X/S}$ with the relative Abel map(8.7.3.12) is isomorphic to $\underline{\mathrm{LinSys}}_{\mathcal{P}/X_{\underline{\mathrm{Pic}}_{X/S}}/\underline{\mathrm{Pic}}_{X/S}}$ and also $\mathbb{P}(\mathcal{Q})$ over $\underline{\mathrm{Pic}}_{X/S}$, where $\mathcal{Q}$ is the coherent sheaf associated to $\mathcal{P}$(8.7.3.15).

Proof: It follows from definitions(8.7.3.13)(8.7.3.10) and(8.7.3.12) and the definition of a universal sheaf. The last assertion follows from(8.7.3.14). □

Prop. (8.7.3.18) [$\underline{\mathrm{Div}}_{X/S}$ is Proper over $\underline{\mathrm{Pic}}_{X/S}$]. Let X/S be locally projective flat with integral geometric fibers, then

- $A_{X/S} : \underline{\mathrm{Div}}_{X/S} \to \underline{\mathrm{Pic}}_{X/S}(T)$ is proper.
- If $\widetilde{\underline{\mathrm{Pic}}}_{X/T} \cong \mathrm{Pic}_{X/T}$, then $A_{X/S} : \underline{\mathrm{Div}}_{X/S} \to \underline{\mathrm{Pic}}_{X/S}(T)$ is projective.

Proof: If $\widetilde{\underline{\mathrm{Pic}}}_{X/T} \cong \mathrm{Pic}_{X/T}$, then by(8.7.3.17), it is projective. For general case, notice proper satisfies fpqc descent, so we can base change to $X \times_S X \to X$, then it has a section, i.e. the diagonal section. Thus by(8.7.3.7), $\widetilde{\underline{\mathrm{Pic}}}_{X/T} \cong \mathrm{Pic}_{X/T}$ and $A_{X\times_S X/X}$ is projective, thus $A_{X/S}$ is proper. □

Picard Schemes

Def. (8.7.3.19) [Picard Scheme]. For the 5 different presheaves on $\mathcal{S}\mathrm{ch}_S$ in(8.7.3.1), if one of them is representable, then all the sheaves after it are all isomorphic to it and representable, because fpqc sites are subcanonical. So it will make no confusion to call the representing scheme the **Picard scheme**.

Prop. (8.7.3.20). If $\underline{\mathrm{Pic}}_{X/S}$ is representable, then it is locally of f.t. over S.

Proof: Because S is locally Noetherian, by(5.8.4.2), it suffices to show that for any directed inverse system $(T_i, f_{ii'}) \in \mathcal{A}\mathrm{ff}_S$,

$$\varinjlim_I \underline{\mathrm{Pic}}_{X/S}(T_i) \cong \underline{\mathrm{Pic}}_{X/S}(\varinjlim_I T_i).$$

For the rest, Cf.[Kle05]P33.? □

Prop. (8.7.3.21) [Points of $\underline{\mathrm{Pic}}_{X/S}$]. If $\mathrm{Pic}_{X/S}$ exists, then schematic points of $\mathrm{Pic}_{X/S}$ corresponds to line bundles on the geometric fibers of X/S.

Proof: This follows from the definition of schematic points and(8.7.3.8)item3. □

Thm. (8.7.3.22) [Grothendieck]. Let $f : X \to S$ be locally projective, flat with integral geometric fibers, then

- $\underline{\mathrm{Pic}}_{X/S,\text{ét}}$ is representable by a scheme separated and locally of f.p. over S.
- If moreover S is Noetherian and X/S is projective, then $\underline{\mathrm{Pic}}_{X/S,\text{ét}}$ is a disjoint union of open subschemes, each an increasing union of open quasi-projective S-schemes.

Proof: Cf.[Kle05]P27.? □

Cor. (8.7.3.23). If S is Noetherian and X/S is projective flat with integral geometric fibers, then any qc locally closed subscheme of $\underline{\mathrm{Pic}}_{X/S}$ is quasi-projective.

Prop. (8.7.3.24) [Tangent Space of $\underline{\mathrm{Pic}}_{X/k}$]. Let X be a scheme over a field. Assume $\underline{\mathrm{Pic}}_{X/k}$ is representable by a scheme and equals $\underline{\mathrm{Pic}}_{X/k,\text{ét}}$, then $T_e(\underline{\mathrm{Pic}}_{X/k}) \cong H^1(X, \mathcal{O}_X)$.

Proof: By(8.2.2.1), the tangent space equals $\ker(\underline{\mathrm{Pic}}_{X/k}(k[\varepsilon]) \to \underline{\mathrm{Pic}}_{X/k}(k))$.

Take the first order thickening $X_k \subset X_{k[\varepsilon]} = X_\varepsilon$, there is an exact sequence $0 \to \mathcal{O}_X \to \mathcal{O}^*_{X_\varepsilon} \to \mathcal{O}^*_X \to 1$, where $\mathcal{O}_X \to \mathcal{O}^*_{X_\varepsilon} : a \mapsto 1 + a\varepsilon$. And it is split. Thus we have a split exact sequence

$$0 \to H^1(\mathcal{O}_X) \to H^1(\mathcal{O}^*_{X_\varepsilon}) \to H^1(\mathcal{O}^*_X) \to 0.$$

Now $\underline{\mathrm{Pic}}_{X/S,\text{ét}}$ is also the shifification of $\widetilde{\underline{\mathrm{Pic}}}_{X/k}: T \mapsto H^1(X_T, \mathcal{O}^*_{X_T})$, thus there is a natural map

$$H^1(\mathcal{O}_X) \to \ker(\underline{\mathrm{Pic}}_{X/k}(k[\varepsilon]) \to \underline{\mathrm{Pic}}_{X/k}(k)) = T_e(\underline{\mathrm{Pic}}_{X/k}).$$

And it can be shown that this is a k-homomorphism.

To show this map is an isomorphism, by flat base change we can assume k is alg.closed. Then by(8.7.3.8), the maps $H^1(\mathcal{O}^*_X) \to \underline{\mathrm{Pic}}_{X/k}(k)$ and $H^1(\mathcal{O}^*_{X_\varepsilon}) \to \underline{\mathrm{Pic}}_{X/k}(k[\varepsilon])$ are isomorphisms, thus $H^1(\mathcal{O}_X) \to T_e(\underline{\mathrm{Pic}}_{X/k})$ is also an isomorphism by five lemma. □

Thm. (8.7.3.25) [Grothendieck]. Assume X is proper over S integral, then there exists a non-empty open subscheme V of S s.t. $\underline{\mathrm{Pic}}_{X_V/V}$ is representable, and is a disjoint union of quasi-projective subschemes.

Proof: Cf.[Kle05]P34. □

Cor. (8.7.3.26) [Murre-Oort/Artin]. Let X be a proper scheme over a field k, then $\underline{\mathrm{Pic}}_{X/k}$ is representable by a disjoint union of quasi-projective subschemes.

Prop. (8.7.3.27). Let $X \to Y$ be a surjective morphism of proper schemes over a field k, then the dual map $\underline{\mathrm{Pic}}_{Y/k} \to \underline{\mathrm{Pic}}_{X/k}$ is affine.

Proof: □

Prop. (8.7.3.28). If X/S is projective and flat with integral geometric fibers, then any connected component of $\underline{\mathrm{Pic}}_{X/S}$ is clopen of f.t..

Proof: By(8.7.3.22), $\underline{\mathrm{Pic}}_{X/S}$ is locally Noetherian, so each connected components are clopen(5.4.1.23), and they are of f.t. as $\underline{\mathrm{Pic}}^{\Phi}_{X/S}$ are(8.7.3.40). □

Prop. (8.7.3.29) [Projectiveness of Subschemes]. Let S be Noetherian and $X \to S$ be smooth projective with irreducible geometric fibers, then every quasi-compact closed subscheme of $\underline{\mathrm{Pic}}_{X/S}$ over S is projective.

Proof: By(8.7.3.23), it suffices to show it is universally closed. As $X \to S$ is both proper and flat, it suffices to show for $X \to S$ f.f.. Then we can base change via the f.f. covering $X \to S$, thus we can assume it has a section, so $\widetilde{\underline{\mathrm{Pic}}}_{X/S} \cong \mathrm{Pic}_{X/S}$. Then we use valuation criterion: for any valuation ring A with fraction field K, it suffices to extend a line bundle on X_K to a line bundle on X_A, because Z is closed and A is reduced. By replacing $\mathcal{L}$ with $\mathcal{L}(n)$, we can assume $\mathcal{L}$ has a global section, which implies $\mathcal{L}$ is an effective Cartier divisor D, as X_K is integral. Notice A is regular and X_T/T is smooth, so X_T is regular?? and thus locally factorial. Then the closure of D in X_T is also a divisor?. □

Cor. (8.7.3.30). If X is a smooth projective variety over a field k, then all connected components of $\underline{\mathrm{Pic}}_{X/k}$ are proper.

Proof: This follows from(8.7.3.29) and(8.1.4.16). □

Prop. (8.7.3.31) [Product Varieties]. If X, Y are two complete varieties over a field k with rational points, then $\underline{\mathrm{Pic}}_{X\times Y/k} \cong \underline{\mathrm{Pic}}_{X/k} \times \underline{\mathrm{Pic}}_{Y/k}$, with $p_{X\times Y} = \mathrm{pr}_1^* p_X \otimes \mathrm{pr}_2^* p_Y$.

Proof: This follows from see-saw principal(5.10.1.22), the theorem of the cube(5.10.1.23) and(8.7.3.5). □

$\underline{\mathrm{Pic}}^0_{X/S}$

Def. (8.7.3.32) [$\underline{\mathrm{Pic}}^0_{X/S}$]**.** If $\underline{\mathrm{Pic}}_{X/S}$ exists, then its identity component is a subgroup scheme, denoted by $\underline{\mathrm{Pic}}^0_{X/S}$.**?**

Prop. (8.7.3.33)[Projectiveness of $\underline{\mathrm{Pic}}^0_{X/k}$]. Let X be a projective variety over a field k, then $\underline{\mathrm{Pic}}^0_{X/S}$ is representable(8.7.3.22) and is quasi-projective. And if X/k is geo.normal, then it is projective.

Proof: Cf.[Kle05]P37.**?** □

Cor. (8.7.3.34)[Subfamily and Morphisms Relations]. The Poincaré class p_X in $\mathrm{Pic}(X\times\underline{\mathrm{Pic}}^0(X))$ is the unique line bundle that satisfies $p_b = b$ for a point $b\in\underline{\mathrm{Pic}}^0(X)$, and p_{P_0} is trivial.

For a subfamily c of $\mathrm{Pic}^0(X)$ parametrized by an scheme T over k, there is a morphism

$$T\to\underline{\mathrm{Pic}}^0(X): t\mapsto c_t\in\underline{\mathrm{Pic}}^0(X)(k(t))$$

over k.

Proof: A point $b\in\underline{\mathrm{Pic}}^0(X)$ is a morphism $k(b)\to\underline{\mathrm{Pic}}^0(X)$, and the restriction of p to b is just b, by(8.7.3.22).

The second assertion follows from the first, because this subfamily corresponds to a morphism $T\to\underline{\mathrm{Pic}}^0(X)$, and the restriction of p at the. image of t in $\underline{\mathrm{Pic}}^0(X)$ is just the subfamily restricted at t, which is c_t. □

Prop. (8.7.3.35) [$\underline{\mathrm{Pic}}^0_{X/k,\mathrm{red}}$ is an Abelian Variety]. If X is a smooth projective variety over a field k, then $\underline{\mathrm{Pic}}^0_{X/k,\mathrm{red}}$ is an Abelian variety.

Proof: $\underline{\mathrm{Pic}}^0(X)$ is a group scheme because it represents a group functor. $\underline{\mathrm{Pic}}^0_{X/S,\mathrm{red}}$ is also a smooth proper connected algebraic group by(8.7.3.30)(8.7.3.28), thus it is an Abelian variety. □

Prop. (8.7.3.36) [Dual Picard Map]. By functoriality, if $X/S, X'/S$ are connected schemes s.t. $\underline{\mathrm{Pic}}_{X/S}$ and $\underline{\mathrm{Pic}}_{X'/S}$ are representable, then the pullback along φ induces a dual homomorphism of group schemes:

$$\widehat{\varphi}:\underline{\mathrm{Pic}}^0_{X'/S,\mathrm{red}}\to\underline{\mathrm{Pic}}^0_{X/S,\mathrm{red}}.$$

In other words, it is the unique morphism $\underline{\mathrm{Pic}}^0_{X'/S,\mathrm{red}}\to\underline{\mathrm{Pic}}^0_{X/S,\mathrm{red}}$ s.t.

$$(\varphi\times\mathrm{id}_{\underline{\mathrm{Pic}}^0_{X'/S,\mathrm{red}}})^*p_{X'/S}=(\mathrm{id}_X\times\widehat{\varphi})^*p_{X/S}.$$

Prop. (8.7.3.37) [Double Picard Map]. Let X/S be a connected scheme s.t. $\widetilde{\underline{\mathrm{Pic}}}_{X/S,\mathrm{red}}$ is representable with a Poincaré class $p_X\in\mathrm{Pic}(X\times\underline{\mathrm{Pic}}^0_{X/S,\mathrm{red}})$, and $\widehat{\underline{\mathrm{Pic}}^0_{X/S,\mathrm{red}}}$ is representable, then p_X satisfies $(p_X)_0=0$, thus inducing a map $X\to\widehat{\underline{\mathrm{Pic}}^0_{X/S,\mathrm{red}}}$.

Def. (8.7.3.38) [Néron-Severi Group Scheme]. Let X be a complete k-variety, the **Néron-Severi group** $\mathrm{NS}(X_{\overline{k}})$ of $X_{\overline{k}}$ is defined to be

$$\mathrm{NS}(X_{\overline{k}})=\mathrm{Pic}(X_{\overline{k}})/\underline{\mathrm{Pic}}^0(X_{\overline{k}})=\pi_0(\underline{\mathrm{Pic}}_{\overline{X}/\overline{k}})(\overline{k})(7.1.12.4)(7.3.1.2),$$

which in fact equals $\pi_0(\underline{\mathrm{Pic}}_{X_{k^s}/k^s})(k^s)=\mathrm{Pic}(X_{k^s})/\underline{\mathrm{Pic}}^0(X_{k^s})=\mathrm{NS}(X_{k^s})$.

Also denote

$$N^1(X_{\overline{k}})=\mathrm{Pic}(X_{\overline{k}})/\mathrm{Pic}^\tau(X_{\overline{k}})=\mathrm{NS}(X_{\overline{k}})/\mathrm{NS}(X_{\overline{k}})_{\mathrm{tor}}(7.1.12.25)=N^1(X_{k^s}).$$

Prop. (8.7.3.39) [Theorem of the Base]. $\mathrm{NS}(X_{\overline{k}})$ is f.g. In particular, $N^1(X_{\overline{k}})$ is a finite free $\mathbb{Z}$-module, and its rank $\rho(X)$ is called the **Picard number** of X.

Proof: Cf. [Kleiman, Toward a numerical theory of ampleness, P334]. □

Prop. (8.7.3.40) [$\underline{\mathrm{Pic}}^{\Phi}_{X/S}$]. If X/S is locally projective, flat with integral geometric fibers, $\Phi \in \mathbb{Q}[\lambda]$, let $\underline{\mathrm{Pic}}^{\Phi}_{X/S}$ denote the subfunctor of $\underline{\mathrm{Pic}}_{X/S}$ representing invertible sheaves $\mathcal{L}$ with $\chi(\mathcal{L}(n)) = \Phi(n)$, then $\underline{\mathrm{Pic}}^{\Phi}_{X/S}$ are clopen subschemes of $\underline{\mathrm{Pic}}_{X/S}$ of f.t. and form a disjoint cover of it, and forming it commutes with base change. Moreover, if X/S is projective and S is Noetherian, then each $\underline{\mathrm{Pic}}^{\Phi}_{X/S}$ is quasi-projective over S.

Proof: Cf.[Kle05]P60.?

The first assertion follows from the fact Euler character is locally constant so $\underline{\mathrm{Pic}}^{\Phi}_{X/S}$ form a clopen disjoint covering of $\underline{\mathrm{Pic}}_{X/S}$ and use(8.7.1.5) and(8.7.1.7). □

Prop. (8.7.3.41) [Quasi-Coherence and Boundedness]. If $\underline{\mathrm{Pic}}_{X/S}$ is representable and $\Lambda \subset \underline{\mathrm{Pic}}_{X/S}$ be a subset with corresponding set of line bundles L, then Λ is qc iff L is bounded(7.1.12.24).

Proof: If L is bounded by $T \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}}/S$, then there is a map $\theta : T \to \underline{\mathrm{Pic}}_{X/S}$ that $\Lambda \subset \theta(T)$. Notice T is a Noetherian space, thus so is $\theta(T)$, and Λ is qc.

Conversely, if Λ is qc, then it is contained in an open subscheme $U \subset \underline{\mathrm{Pic}}_{X/S}$ of f.t. over S, then U gives out a line bundle on X_T for some fppf covering T of U. Such T can be chosen to be f.t. over S as U is f.t., so L is bounded by T. □

Cor. (8.7.3.42) [Quasi-Coherence and Hilbert Polynomials]. If S is Noetherian and X/S is projective and flat, and $\underline{\mathrm{Pic}}_{X/S}$ is representable, let $\Lambda \subset \underline{\mathrm{Pic}}_{X/S}$ be any subset and Π the corresponding set of Hilbert polynomials, then $\#\Pi < \infty$ if Λ is qc, and $\#\Pi = 1$ if Λ is connected.

Proof: If Λ is qc, then L is bounded by some $T \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}}/S$, and then by locally constancy of Hilbert polynomials, $\#\Pi < \infty$.

If Λ is connected, then so is the induced reduced structure on its closure $\overline{\Lambda}$. $\overline{\Lambda}$ gives out a line bundle on X_T for some fppf covering T of $\overline{\Lambda}$. Notice $T \to \overline{\Lambda}$ is open and Hilbert polynomial is locally constant on T, so there is only one Hilbert polynomial type. □

Torsion Components

Prop. (8.7.3.43). If X/S is projective, flat with integral geometric fibers, then for $n \in \mathbb{Z}_+$, $[n] : \underline{\mathrm{Pic}}_{X/S} \to \underline{\mathrm{Pic}}_{X/S}$ is of f.t.

Proof: Cf.[**?**]. □

Prop. (8.7.3.44). If X/S is proper and $\underline{\mathrm{Pic}}_{X/S}$ exists, then $\underline{\mathrm{Pic}}^{\tau}_{X/S}$ is an open subgroup of f.t..

Proof: Cf.[Kle05]P59. □

Prop. (8.7.3.45). If X is a k-scheme s.t. $\underline{\mathrm{Pic}}_{X/k}$ is representable, then $\underline{\mathrm{Pic}}^{\tau}_{X/S}$ is an open subgroup, and forming it commutes with change of fields. Moreover, if X/S is projective, then $\underline{\mathrm{Pic}}^{\tau}_{X/S}$ is clopen of f.t..

Proof: Using(8.1.4.17) and(8.7.3.20), it suffices to prove $\underline{\mathrm{Pic}}^{\tau}_{X/S}$ is of f.t. when X is projective over S. For this, it suffices to prove for $k = \overline{k}$. In this case, by(7.1.12.25) and(7.1.12.26), there is an algebraic k-scheme T and $\mathcal{M} \in \mathcal{T}$ s.t. the corresponding map $\theta : T \to \underline{\mathrm{Pic}}_{X/k}$ satisfies $\underline{\mathrm{Pic}}^{\tau}_{X/S} \subset \theta(T)$. Notice T is a Noetherian space, thus so is $\theta(T)$, and Λ is qc. □

Cor. (8.7.3.46). Let X is a projective variety over a field k, then $\underline{\mathrm{Pic}}^{\tau}_{X/k}$ is quasi-projective. And if X is geo.normal, then it is projective.

Proof: By(8.7.3.45)(8.7.3.23), $\underline{\mathrm{Pic}}_{X/S}$ is quasi-projective. To show it is proper, it suffices to show for $k = \overline{k}$. In this case, $\underline{\mathrm{Pic}}^{\tau}_{X/k}$ is covered by f.m. translates of $\mathrm{Pic}^0_{X/k}$ as it is qc, and $\underline{\mathrm{Pic}}^0_{X/k}$ is projective by(8.7.3.33), so $\underline{\mathrm{Pic}}_{X/k}$ is also proper, as it is closed so is the scheme-theoretic image of these copies $\underline{\mathrm{Pic}}^0_{X/k}$. □

Prop. (8.7.3.47). Let X/S be locally projective flat with integral geometric fibers, then $\underline{\mathrm{Pic}}^{\tau}_{X/S}$ is a clopen subgroup of $\underline{\mathrm{Pic}}_{X/S}$ of f.t., and forming it is compatible with base change. Moreover, if X/S is projective with S Noetherian, then $\underline{\mathrm{Pic}}^{\tau}_{X/S}$ is quasi-projective.

Proof: Cf.[Kle05]P58. □

Cor. (8.7.3.48) [Torsion Components are Projective]. If X/S is smooth projective with integral geometric fibers and S is Noetherian, then $\underline{\mathrm{Pic}}^{\tau}_{X/S}$ is projective.

Proof: This follows from(8.7.3.47) and(8.7.3.29). □

Prop. (8.7.3.49). If S is Noetherian and X/S is locally projective flat with integral geometric fibers, then for any $s \in S$ with residue field $k(s)$ and an alg.closure $\overline{k}(s)$, the group

$$\underline{\mathrm{Pic}}^{\tau}_{X_{\overline{k}(s)}/\overline{k}(s)}(\overline{k}(s))/\,\underline{\mathrm{Pic}}_{X_{\overline{k}(s)}/\overline{k}(s)}(\overline{k}(s))$$

is a finite group, and its order is uniformly bounded.

Proof: It is finite by(8.7.3.47), and the number of connected components of $\underline{\mathrm{Pic}}^{\tau}_{X_{\overline{k}(s)}/\overline{k}(s)}$ is constant for a non-empty open subset of S by [EGA 4.3, 9.7.9], so it is bounded by Noetherian induction. □

4 Picard Spaces

Thm. (8.7.4.1) [Artin]. If $X \to S$ is proper flat and f.p. morphism of algebraic spaces s.t. forming $f_*\mathcal{O}_X$ commutes with base change, then $\underline{\mathrm{Pic}}_{X/S}$ is representable by an algebraic space, and is locally of f.p. over S.

Proof: □

5 Moduli of Curves

Def. (8.7.5.1) [Smooth Curves of Genus g]. Given a scheme S, there is a category $\mathcal{M}_g$ fibered in sets over $\mathcal{S}\mathrm{ch}/S$ where $\mathcal{M}_g(T)$ is the set of smooth and proper morphisms of schemes $C \to T$ that the fibered are all geometrically connected curves of genus g.

Similarly there is a category Z_g fibered in sets over $\mathcal{S}\mathrm{ch}/S$ of smooth pointed curves of genus g

8.8 Algebraic Stacks

Basic references are [Sta], [Ols16], [Vis08] and [Fibered Category to Algebraic Stacks Lamb].

Notation (8.8.0.1).

- Use notations as in Sites, Sheaves and Stacks5.1.
- Fix $S \in \mathcal{S}\mathrm{ch}$. A fibered category/stack over S means a fibered category/stack over $\mathcal{S}\mathrm{ch}_{\mathrm{fppf}}/S$(obsolete).

1 Algebraic Spaces

Def. (8.8.1.1) [Schematic Morphism]. A **schematic morphism** of fibered categories $\mathcal{X} \to \mathcal{Y}$ over S is a representable morphism of fibered categories over S(3.1.8.36).

Def. (8.8.1.2) [Properties of Schematic Morphisms]. For a property $\mathcal{P}$ of maps of schemes which is stable under base change, we say that $\mathcal{P}$ holds for a schematic map $\mathcal{X} \to \mathcal{Y}$ iff for any $S \in \mathcal{S}\mathrm{ch}$, $\mathcal{P}$ holds for the map $S \times_{\mathcal{Y}} \mathcal{X} \to S$.

Def. (8.8.1.3) [Algebraic Space]. An **algebraic space** is a sheaf $\mathcal{F} \in \mathcal{S}\mathrm{h}_{\mathrm{fppf}}/S$ that the diagonal is schematic, and there exists some scheme $U \in \mathcal{S}\mathrm{ch}/S$ with an étale surjective map $h_U \to \mathcal{F}$ in $\mathcal{S}\mathrm{ch}_{\mathrm{fppf}}/S$, called an **atlas for the algebraic space** $\mathcal{F}$.

The category of algebraic spaces is the full subcategory of $\mathcal{S}\mathrm{h}_{\mathrm{fppf}}/S$, denoted by $\mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}/S$.

Prop. (8.8.1.4) [Schemes is an Algebraic Space]. $\mathcal{S}\mathrm{ch}/S$ is a full subcategory of $\mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}/S$.

Proof: For $X \in \mathcal{S}\mathrm{ch}/S$, h_X is a sheaf because fppf site is subcanonical by(5.1.4.34), its diagonal is representable, and the identity $\mathrm{id}_X : X \to X$ is surjective and étale. □

Remark (8.8.1.5). In general, the quotient of a scheme by a finite group action is an algebraic space that is not a scheme. Naively one can think of algebraic spaces as quotients of schemes by finite groups. ——Kollar.

Def. (8.8.1.6) [Sites over Algebraic Spaces]. The Zariski/étale/smooth/fppf/... sites over an algebraic space is defined verbatim as that of over algebraic schemes.

Prop. (8.8.1.7) [Algebraic Spaces and Étale Equivalence Relations]. Cf.[Sta]02WW.

Proof: □

Prop. (8.8.1.8). If $\mathcal{X}$ is an algebraic space over S, then the diagonal map $\Delta_{\mathcal{X}/S}$ is locally of finite type, locally quasi-finite, separated and is a monomorphism.

Proof: Cf.[Sta]02X4. □

Def. (8.8.1.9) [Underlying Space of Algebraic Spaces]. For $\mathcal{X} \in \mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}/S$, the underlying space $|\mathcal{X}|$ is a topological space whose points are the equivalence classes of morphisms $\mathrm{Spec}\, K \to \mathcal{X} \in \mathcal{S}\mathrm{h}_{\mathrm{fppf}}/S$, where $K \in \mathtt{Field}$.

Prop. (8.8.1.10). Let $\mathcal{X} \in \mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}/S, T \in \mathcal{S}\mathrm{ch}/S, f : T \to \mathcal{X} \in \mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}/S$, then f is surjective iff $|f| : |T| \to |X|$ is surjective.

Proof:

□

2 Algebraic Stacks

Def. (8.8.2.1)[Representable by Algebraic Spaces]. A morphism of fibered categories $\mathcal{X} \to \mathcal{Y}$ over S is called **representable by algebraic spaces** if for any $U \in \mathcal{C}$ and a morphism $\mathcal{C}/U \to \mathcal{Y}$, the fibered category $(\mathcal{C}/U) \times_{\mathcal{Y}} \mathcal{X} \to \mathcal{C}/U$ is equivalent to an algebraic space(8.8.1.3).(Notice it is a fibered category by(3.1.8.15) and(3.1.8.16))

Def. (8.8.2.2)[Properties of Morphisms Representable by Algebraic Spaces]. For a property P of maps of schemes which is stable under base change, we say that P holds for a morphism $\mathcal{X} \to \mathcal{Y}$ representable by algebraic spaces iff for every $U \in \mathcal{S}\mathrm{ch}_{\mathrm{fppf}}/S$, P holds for the map of algebraic spaces $U \times_Y X \to S$.

Def. (8.8.2.3)[2-Category of Algebraic Stack]. An **algebraic stack** is a stack in groupoids $\mathcal{X}$ over $\mathcal{S}\mathrm{ch}_{\mathrm{fppf}}/S$ that the diagonal is representable by an algebraic space(8.8.2.1), and there exists some scheme $U \in \mathcal{S}\mathrm{ch}/S$ with a smooth surjective map $\mathcal{S}\mathrm{ch}_{\mathrm{fppf}}/U \to X$ in $\mathcal{S}\mathrm{ta}_{\mathrm{fppf}}/S$, called an **atlas for the algebraic stack** X. It is called a **Deligne-Mumford stack** if moreover there exists some scheme U with a smooth étale map $\mathcal{S}\mathrm{ch}_{\mathrm{fppf}}/U \to X$ in $\mathcal{S}\mathrm{ta}_{\mathrm{fppf}}/S$.

The 2-category of algebraic(Deligne-Mumford) stacks is the full sub-2-category of $\mathcal{S}\mathrm{ta}_{\mathrm{fppf}}/S$, denoted by $\mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{ta}/S(\mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{ta}^{\mathrm{DM}}/S)$.

Prop. (8.8.2.4). If $\mathcal{X}, \mathcal{Y}$ are categories equivalent in $\mathcal{S}\mathrm{ch}/S$ and $\mathcal{X}$ is an algebraic/Deligne-Mumford stack over S, then so is $\mathcal{Y}$.

Proof: By(5.1.3.7), $\mathcal{Y}$ is also a stack in groupoid, and Cf.[Sta]03YQ**?**. □

Prop. (8.8.2.5) [Algebraic Stacks and Étale Groupoid Object]. There is a bijection of étale groupoid objects on a scheme with the category of algebraic stacks.

Proof: Cf.[Lamb, P39]. □

Prop. (8.8.2.6)[Algebraic Spaces and Étale Equivalence Relations]. There is a bijection of étale equivalence relations on a scheme with the category of algebraic spaces.

Proof: This is a corollary of(8.8.2.5). □

8.9 Group Algebraic Spaces

Main references are [Sta]Chap76.

Notation (8.9.0.1).

- Use notations defined in Algebraic Stacks8.8.
- Fix $S \in \mathcal{S}\mathrm{ch}$ and $B \in \mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}\,/S$. $\mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}\,/B = (\mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}\,/S)/B$.

Def. (8.9.0.2) [Group Algebraic Spaces]. The category $\mathcal{G}\mathrm{rp}\mathcal{S}\mathrm{p}\,/B$ of **group algebraic space** over B is defined to be

$$\mathcal{G}\mathrm{rp}\mathcal{S}\mathrm{p}\,/B = \mathcal{S}\mathrm{h}^{\mathcal{G}\mathrm{rp}}_{\mathrm{fppf}}\,/B \cap \mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}\,/B \subset \mathcal{S}\mathrm{h}_{\mathrm{fppf}}\,/B.$$

1 Quotient of Groupoids

Main references are [Quotient Spaces Modulo Algebraic Groups, Kollar, 1997].

Def. (8.9.1.1) [Quotients of Groupoids]. Let $U \in \mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}\,/B, j : R \to U \times_B U$ be a pre-relation on U over B, $\varphi : U \to X \in \mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}\,/B$, then

- For $u \in |U|$, the R**-orbit** of u is the equivalent class of $u \in |U|$ generated by $|R| \subset |U| \times |U|$.
- For $T \subset |U|$, T is called R**-invariant** if $s^{-1}(T) = t^{-1}(T) \subset |R|$.
- φ is said to be R**-invariant** if for it equalizes the two maps $s, t : R \to U$.
- φ is said to be **set-theoretically** R**-invariant** if for any $\operatorname{Spec} k \in \mathcal{S}\mathrm{ch}\,/B, k = \overline{k}$, $\varphi(k)$ equalizes the two maps $s, t : R(k) \to U(k)$.
- φ is said to **separate** R**-orbits** if it is set-theoretically R-invariant and for any $\operatorname{Spec} k \in \mathcal{S}\mathrm{ch}\,/B, k = \overline{k}$ and $u, u' \in U(k)$, $\varphi(u) = \varphi(u') \in X(k)$ implies u, u' are in the same R-orbits.
- φ is said to be an **orbit space for** R if it is R-invariant and surjective, and separates R-orbits.
- φ is said to be a **course quotient for** R if it is a categorical quotient and it is an orbit space for R.
- If $S = B, U, R, X \in \mathcal{S}\mathrm{ch}$, then φ is said to be a **course quotient in schemes for** R if it is a categorical quotient in schemes and it is an orbit space for R.
- If φ is R-invariant, The **sheaf of** R**-invariant functions** $(\varphi_*\mathcal{O}_U)^R$ as the étale $\mathcal{O}_X$-subalgebra of $\varphi_*\mathcal{O}_U$ which is the equalizer of two maps induced from $s, t : R \to X$.

Prop. (8.9.1.2). Situation as in(8.9.1.1), if R, U are locally of f.t. over B, φ is an orbit space for R iff it is R-invariant and for any $\operatorname{Spec} k \in \mathcal{S}\mathrm{ch}\,/B, k = \overline{k}$,

$$U(k)/(\text{equivalent relations generated by } j(R(k))) \to X(k)$$

is bijective.

Proof: Cf.[Sta]04A0. □

Def. (8.9.1.3) [Good Quotients]. Situation as in(8.9.1.1), φ is said to be a **good quotient** if

- φ is affine, surjective, R-invariant.
- For any base change φ' of φ, $|\varphi'|$ is a closed map, and $|\varphi|(Z_1 \cap Z_2) = |\varphi|(Z_1) \cap |\varphi|(Z_2) \subset |X|$ for any closed subsets $Z_1, Z_2 \subset |U|$.

- $\mathcal{O}_X \to (\varphi_* \mathcal{O}_U)^R$ is an isomorphism.

Def. (8.9.1.4)[Geometric Quotients]. Situation as in(8.9.1.1), φ is said to be a **geometric quotient** if

- φ is an orbit space for R,
- φ is universally submersive,
- $\mathcal{O}_X \to (\varphi_* \mathcal{O}_U)^R$ is an isomorphism.

Thm. (8.9.1.5) [Kollar]. Let $S \in \mathcal{S}\mathrm{ch}$ be excellent, $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}_{\mathcal{A}\mathrm{ff}} / S, X \in \mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}^{\mathrm{sep,ft}} / S$. Let $m : G \times X \to X$ be a proper G-action on X, and one of the following holds:

- G is a reductive group scheme over S,
- $S = \operatorname{Spec} k$ where $k \in \mathtt{Field}, \operatorname{char} k > 0$.

Proof: then a geometric quotient $\varphi : X \to X/G$ exist(8.9.1.4), and $X/G \in \mathcal{A}\mathrm{lg}\mathcal{S}\mathrm{p}^{\mathrm{sep,ft}} / S$. Cf.[Quotient Schemes modulo Algebraic Groups, Kollar]P35. □

2 Quotients of Schemes

Prop. (8.9.2.1). Let $u_0, u_1 : X_1 \to X_0$ be an equivalence relation on the algebraic scheme X_0 over R_0. Assume that

- $u_0 : X_1 \to X_0$ is locally free of rank r.
- For all $x_0 \in X$, $u_0(u_1^{-1}(x))$ is contained in an open affine subscheme of X_0.

Then a quotient $u : X_0 \to X$ exists. Moreover, u is locally free of rank r.

9 Algebraic K-Theory of Schemes

9.1 Algebraic K-Theory

1 Introduction

Algebraic K-theory is about natural constructions of cohomology theories/spectra from algebraic data such as commutative rings, symmetric monoidal categories and various homotopy theoretic refinements of these.

When applied to the stack of vectors bundles then algebraic K-theory subsumes topological K-theory and also differential K-theory.

2 K-Theory of Rings

Def. (9.1.2.1) [K-Theories of Rings]. For $R\in\mathcal{CR}\mathrm{ing}$, Let $\mathcal{P}\mathrm{roj}_R^{\mathrm{fg}}$ be the 1-category of f.g. projective R-modules, and let $\iota\,\mathcal{P}\mathrm{roj}_R^{\mathrm{fg}}$ be the maximal subgroupoid, then it is a E_∞-space. Let

$$K(R)=(\iota\,\mathcal{P}\mathrm{roj}_R^{\mathrm{fg}})^{\infty-\mathrm{ab}}(3.8.2.7).$$

And let

$$K_0(R)=\pi_0(K(R)),\quad K_j(R)=\pi_j(K(R),0).$$

Prop. (9.1.2.2) [Ring Structure]. There is an $\mathbb{E}_\infty$-Ring structure on $K_{\geq 0}(R)$, so

$$K_*(R)=\oplus_{j\geq 0}K_j(R)$$

has a graded ring structure.

Prop. (9.1.2.3) [Matsumoto]. For $k\in\texttt{Field}$, there are natural isomorphisms

$$K_i^{\mathrm{Mil}}(k)\cong K_i(k)$$

for $i=0,1,2$, thus inducing a map

$$K_*^{\mathrm{Mil}}(k)\to K_*(k)$$

that is not necessarily an isomorphism.

Proof: ? □

3 K-Theory of Schemes

Thm. (9.1.3.1) [Thomason, Quillen]. Let X be an affine regular and separated scheme, and $X = U \cup V$ is an affine open cover, then there is a Cartesian square of spectra

$$\begin{array}{ccc} K(X) & \longrightarrow & K(U) \\ \downarrow & & \downarrow \\ K(V) & \longrightarrow & K(U\cap V) \end{array}$$

Proof: □

Cor. (9.1.3.2) [Descent Spectral Sequence]. There is a spectral sequence

$$H^p(X;\pi_q(K)) \Rightarrow K_{p-q}(X).$$

Proof: ? □

Def. (9.1.3.3) [Graded Determinant Map]. For $X \in \mathcal{S}ch$ affine or regular, let $\mathbf{Pic}^{\mathbb{Z}}(X) = \mathbf{Pic}(X) \rtimes H^0(X;\mathbb{Z})$, where $H^0(X;\mathbb{Z})$ acts on $\mathbf{Pic}(X)$ locally by $n.\mathcal{L} = \mathcal{L}^{(-1)^n}$. Then there is a graded determinant map

$$(\det, \mathrm{rank}) : \iota\,\mathcal{P}\mathrm{roj}^{\mathrm{fg}}(X) \to \mathbf{Pic}^{\mathbb{Z}}$$

that is a morphism of $\mathbb{E}_\infty$-rings:

$$\begin{array}{ccc} \det(M\oplus N) & \xrightarrow{\cong} & \det(M)\otimes\det(N) \\ \downarrow{\scriptstyle \cong,(-1)^{\mathrm{rank}(M)\,\mathrm{rank}(N)}} & & \downarrow{\scriptstyle\cong} \\ \det(N\oplus M) & \xrightarrow{\cong} & \det(N)\otimes\det(M) \end{array}$$

is commutative. Thus by universal property of group completion, we get a map

$$K(X) \to \mathbf{Pic}^{\mathbb{Z}}(X).$$

Thus we have maps

$$K_j(X) \xrightarrow{(\det,\mathrm{rank})} \pi_j(\mathbf{Pic}^{\mathbb{Z}}(X)),$$

and the kernel is denoted by $SK_j(X)$.

Prop. (9.1.3.4). The graded determinant map(9.1.3.3) induces a surjective ring homomorphism

$$K_0(X) \to \mathbf{Pic}^{\mathbb{Z}}(X).$$

Proof: $\mathcal{L}\otimes\mathcal{O}_X^{n-1}$ is mapped to $(\mathcal{L}, n)$, and these generate $\mathrm{Pic}^{\mathbb{Z}}(X)$. □

Prop. (9.1.3.5). If R is a local ring, then there is an isomorphism

$$K_1(R) \xrightarrow{(\det,\mathrm{rank})} \pi_1(\mathbf{Pic}^{\mathbb{Z}}(R)) \cong R^*.$$

Prop. (9.1.3.6). Let X be a an irreducible regular Noetherian scheme of dimension 1, then there is an isomorphism

$$K_0(X) \xrightarrow[\cong]{(\det,\mathrm{rank})} \mathrm{Pic}^{\mathbb{Z}}(X).$$

Proof: [Motives at p]L7P4.**?** □

Prop. (9.1.3.7) [Properties of K-Groups]. For $j \in \mathbb{Z}$, $K_j : \mathcal{S}\mathrm{ch}^{\mathrm{op}} \to \mathcal{A}\mathrm{b}$ are functors satisfying the following properties:

- there is a rank map rank : $K_0(X) \to H^0(X, \mathbb{Z})$, which is an isomorphism if X is a local scheme.
- If X is qcqs and $X = U \cup V$ is an open cover, there is a long exact sequence

$$\cdots \to K_j(X) \to K_j(U) \oplus K_j(V) \to K_j(U \cap V) \to K_{j-1}(X) \to \cdots .$$

- If X is qcqs and $Y \to X$ is a closed immersion s.t. Y is regular, then there are natural maps

$$i_* : K_j(Y) \to K_j(X)$$

that fits into a long exact sequence

$$\cdots \to K_j(Y) \xrightarrow{i_*} K_j(X) \to K_j(X \setminus Y) \to K_{j-1}(Y) \to \cdots .$$

- If X is regular, then the projection $X \times \mathbb{A}^1 \to X$ induces isomorphisms

$$K_j(X) \cong K_j(X \times \mathbb{A}^1).$$

- If X is qcqs, there is a natural isomorphism

$$K_j(X)\{\mathtt{0}\} \oplus K_j(X)\{\mathtt{0}(1) - \mathtt{0}\} \cong K_j(\mathbb{P}^1_X).$$ **?**

Proof: **?** □

Def. (9.1.3.8) [K-Groups of Schemes]. For $X \in \mathcal{S}\mathrm{ch}_{\mathrm{qcqs}}$, its algebraic K-theory is defined to be the spectrum

$$K(X) = \varprojlim_{\mathrm{Spec}\, R \to X} K(R).$$

It follows from(9.1.3.1) that this defines a

Conj. (9.1.3.9) [Beilinson-Parshin]. For $k \in \mathtt{Field}$, $\#k < \infty$, $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/k$, $i > 0$, $K_i(X) \otimes \mathbb{Q} = 0$.

Proof: □

Remark (9.1.3.10). In fact, when $\dim X = 0$ this is done by Quillen's computation of K-groups of fields, Cf.[On the Cohomology and K-theory of the General Linear Groups over a Finite Field, Quillen, 1972].

when $\dim X = 1$, $K_i(X)$ are in fact finite, by [Finite Generation of K-Groups of a Curve over a Finite Field, Don 1982].

9.2 Brauer-Grothendieck Groups

References are [Central Simple Algebras and Galois Cohomology, Gille and Szamuely] and [The Brauer-Grothendieck Group].

1 Brauer Groups

Def. (9.2.1.1) [Brauer Groups]. For $X \in \mathcal{S}\mathrm{ch}$, the **Brauer group** $\mathrm{Br}(X)$ is defined to be $\mathrm{Br}(X) = \mathrm{H}^2_{\text{ét}}(X, \mathbb{G}_m) = H^2_{\text{fppf}}(X, \mathbb{G}_m)$(7.4.7.34). And for $R \in \mathcal{CR}\mathrm{ing}$, $\mathrm{Br}(R)$ is defined to be $\mathrm{Br}(R) = \mathrm{Br}(\mathrm{Spec}\, R)$.

Prop. (9.2.1.2). If X is a regular Noetherian scheme that is qc or integral, $\mathrm{Br}(X) \to \mathrm{Br}(R(X))$ is injective, and $\mathrm{Br}(X)$ is a torsion Abelian group.

Proof: The qc case reduces to the integral case, and this follows from [Brauer-Grothendieck Groups]Chap3.5.

The second assertion follows from the first and the fact $\mathrm{Br}(R(X))$ is torsion(9.2.2.3). □

Cor. (9.2.1.3). If $X \to Y$ is a birational morphism of integral regular schemes, then $\mathrm{Br}(Y) \to \mathrm{Br}(X)$ is injective.

Proof: This follows from the fact $\mathrm{Br}(Y) \to \mathrm{Br}(X) \to \mathrm{Br}(R(X)) = \mathrm{Br}(R(Y))$ is injective. □

Azumaya Brauer Groups

Prop. (9.2.1.4) [Azumaya Algebras of Schemes]. For $X \in \mathcal{S}\mathrm{ch}$, an **Azumaya algebra** over X is a coherent $\mathcal{O}_X$-algebra $\mathcal{A}$ s.t. $\mathcal{A}_x \neq 0$ for any $x \in X$, and satisfies the following equivalent definitions:

- There exists an étale covering $\{U_i \to X\}$ s.t. for each i, there exists $r_i \in \mathbb{Z}_+$ s.t. $\mathcal{A} \otimes_{\mathcal{O}_X} \mathcal{O}_{U_i} \cong \mathbf{End}(\mathcal{O}_{U_i}^{\otimes r_i})$.
- There exists an fppf covering $\{U_i \to X\}$ s.t. for each i, there exists $r_i \in \mathbb{Z}_+$ s.t. $\mathcal{A} \otimes_{\mathcal{O}_X} \mathcal{O}_{U_i} \cong \mathbf{End}(\mathcal{O}_{U_i}^{\otimes r_i})$.
- $\mathcal{A} \in \mathcal{V}\mathrm{ect}_X$, and for any arithmetic point $x \in X$, $\mathcal{A}_x$ is isomorphic to $\mathrm{Mat}(r_x, \kappa(x))$ for some $r_x \in \mathbb{Z}_+$. And this r_x is called the **degree of** $\mathcal{A}$ at x.
- $\mathcal{A} \in \mathcal{V}\mathrm{ect}_X$, and the canonical homomorphism $\mathcal{A} \otimes \mathcal{A}^{\mathrm{op}} \to \mathbf{End}_{\mathcal{O}_X}(\mathcal{A})$ is an isomorphism.

In particular, this definition is compatible with the definition of Azumaya algebras over fields in(2.4.3.2), by(2.4.3.25).

The category of Azumaya algebras over X is denoted by Az_X. For $n \in \mathbb{Z}_+$, the subset of Azumaya algebras over X of constant degree n is denoted by $\mathrm{Az}^b(X)$.

Proof: $1 \to 2 \to 3 \to 4$ is trivial by(2.4.3.25). $4 \to 1$: Cf.[Milne80 Etale Cohomologies]P141.? □

Def. (9.2.1.5) [Azumaya Brauer Groups]. Let $X \in \mathcal{S}\mathrm{ch}$, the **Azumaya Brauer group** $\mathrm{Br}_{\mathrm{Az}}(X)$ is defined to be the set of equivalence class of Azumaya algebras over X under the equivalence relation that $\mathcal{A} \sim \mathcal{A}'$ iff there exists $\mathcal{E}, \mathcal{E}' \in \mathcal{V}\mathrm{ect}(X)$ with positive ranks at each point s.t.

$$\mathcal{A} \otimes_{\mathcal{O}_X} \mathbf{End}(\mathcal{E}) \cong \mathcal{A}' \otimes_{\mathcal{O}_X} \mathbf{End}(\mathcal{E}').$$

Moreover, $\mathrm{Br}_{\mathrm{Az}}(X)$ is a group under tensor product and the inverse is given by $\mathcal{A} \to \mathcal{A}^{\mathrm{op}}$.

Proof: To show this is an equivalence and the group operation is well-defined, use the fact that for $\mathcal{E}, \mathcal{E}' \in \mathcal{V}\text{ect}(X)$,

$$\mathbf{End}(\mathcal{E}) \otimes_{\mathcal{O}_X} \mathbf{End}(\mathcal{E}) \cong \mathbf{End}(\mathcal{E} \otimes \mathcal{E}').$$

And the inverse is of the form given, by(9.2.1.4). □

Lemma (9.2.1.6). Let $(\mathcal{C}, \mathcal{O})$ be a ringed site and $\mathcal{F}, \mathcal{G} \in \mathcal{V}\text{ect}(\mathcal{O})$ s.t. $\mathbf{End}(\mathcal{F}) \cong \mathbf{End}(\mathcal{G})$, then there exists an invertible sheaf $\mathcal{L}$ s.t. $\mathcal{F} \otimes \mathcal{L} \cong \mathcal{G}$.

Proof: Let $\mathcal{L} \subset \mathcal{H}om(\mathcal{F}, \mathcal{G})$ be generated as an $\mathcal{O}_X$-module by local isomorphisms $\varphi : \mathcal{F} \cong \mathcal{G}$ s.t. the conjugation by φ coincides with the given isomorphism, then local computation and the fact all automorphisms of $\mathrm{Mat}(n)$ is inner shows that $\mathcal{L}$ is invertible, and the evaluation map

$$\mathcal{F} \otimes \mathcal{L} \to \mathcal{G}$$

is an isomorphism. □

Prop. (9.2.1.7). If $\mathcal{A} \in \mathrm{Az}_X$ has constant degree d, then $[\mathcal{A}] \in \mathrm{Br}_{\mathrm{Az}}(X)$ is annihilated by d.

Proof: Choose an étale covering $\{U_i \to X\}$ and isomorphisms $\mathcal{A}|_{U_i} \cong \mathrm{Hom}(\mathcal{F}_i, \mathcal{F}_i)$, where $\mathcal{F}_i \in \mathcal{V}\text{ect}^d(X)$, then

$$\mathcal{A}^{\otimes d}|_{U_i} \cong \mathbf{End}(\mathcal{F}_i^{\oplus d}).$$

Consider the maps

$$p_i : \mathcal{F}_i^{\oplus d} \to \wedge^d \mathcal{F}_i \subset \mathcal{F}_i^{\oplus d},$$

then $p_i^2 = d! p_i$ and $\mathrm{rank}(p_i) = 1$. We show now that these p_i glue together to get a global section p of $\mathcal{A}^{\otimes d}$: by(9.2.1.6), there exist compatible invertible sheaves $\mathcal{L}_{ij}$ on $U_i \cap U_j$ s.t.

$$\mathcal{F}_i|_{U_{ij}} \otimes \mathcal{L}_{ij} \cong \mathcal{F}_j|_{U_{ij}}.$$

These isomorphisms can clearly generate isomorphisms to glue $\{p_i\}$ together.

Then consider $\mathcal{H} = \mathcal{A}^{\otimes d} \circ p \subset \mathcal{A}^{\otimes d}$, we claim that

- $\dim \mathcal{H} = d^d$,
- left multiplication by $\mathcal{A}^{\otimes d}$ induces an isomorphism $\mathcal{A}^{\otimes d} \cong \mathbf{End}(\mathcal{H})$.

Which will imply that $d[\mathcal{A}] = 0 \in \mathrm{Br}_{\mathrm{Az}}(X)$. To show these claims, it suffices to do local calculations: If $\mathcal{F} \cong \mathcal{O}_X e_1 \oplus \ldots \oplus \mathcal{O}_X e_d$, then $\mathcal{A} \cong \mathbf{End}(\mathcal{O}_X^d)$, and

$$p : e_{\sigma(1)} \otimes \ldots \otimes e_{\sigma(d)} \mapsto \mathrm{sgn}(\sigma) e_1 \otimes \ldots \otimes e_d, \sigma \in \mathcal{S}_d, \quad 0 \text{ on other basis vectors}$$

So

$$\mathcal{H} = \{f : \mathcal{F}^{\otimes d} \to \mathcal{F}^{\otimes d} : e_{\sigma(1)} \otimes \ldots \otimes e_{\sigma(d)} \mapsto \mathrm{sgn}(\sigma) v_1 \otimes \ldots \otimes v_d, \quad 0 \text{ on other basis vectors}\}$$

Then $\mathcal{A} \cong \mathbf{End}(\mathcal{O}_X^d)$ is clear. □

Cor. (9.2.1.8)[Azumaya Brauer Groups are Torsion]. If $X \in \mathcal{S}\text{ch}$ is qc or connected, then $\mathrm{Br}_{\mathrm{Az}}(X)$ is a torsion Abelian group.

Comparison of Two Brauer Groups

Prop. (9.2.1.9)[Azumaya Brauer Groups via Cohomology]. Let $X \in \mathcal{S}\mathrm{ch}$, there exists an isomorphism of pointed sets

$$\mathrm{Az}_X^n \cong \check{H}^1_{\text{ét}}(X, \mathrm{PGL}(n)).$$

Proof: As $\mathrm{PGL}(n) = \mathrm{Aut}(\mathrm{Mat}(n))$ and any Azumaya algebra is a twist-form for $\mathrm{Mat}(n)_X$, any $\mathcal{A} \in \mathrm{Az}_X^n$ defines a 1-cocycle for $\mathrm{PGL}(n)$. It is clear that if this cocycle is a coboundary, then $\mathcal{A} \cong \mathrm{Mat}(n)_X$. Its left to show that any 1-cocycle comes from these: As $\mathrm{PGL}(n) \subset \mathrm{GL}(n^2)$, and 1-cocycle is a 1-cocycle for $\mathrm{GL}(n^2)$, thus by(5.1.6.1) corresponds to a vector bundle $\mathcal{E}$ of rank n^2. By taking a refinement, this means there is a covering $\{U_i \to X\}$ and isomorphisms $\varphi_i : \mathrm{Mat}(n, \mathcal{O}_{U_i}) \cong \mathcal{E}|_{U_i}$ as modules such that the transformation maps $\varphi_i^{-1} \circ \varphi_j \in \mathrm{PGL}(n, \mathcal{O}_{U_{ij}}) \subset \mathrm{GL}(n^2, \mathcal{O}_{U_{ij}})$, which means exactly $\mathcal{E} \in \mathrm{Az}_X^n$. □

Prop. (9.2.1.10)[$\mathrm{Br}(X)$ and $\mathrm{Br}_{\mathrm{Az}}(X)$]. Assume $X \in \mathcal{S}\mathrm{ch}$ is qc and every finite subset of X is contained in an affine scheme, by(5.3.2.19), the exact sequence

$$1 \to \mathbb{G}_m \to \mathrm{GL}(n) \to \mathrm{PGL}(n) \to 1$$

of algebraic groups gives a map

$$\check{H}^1_{\text{ét}}(X, \mathrm{GL}(n)) \to \mathrm{Az}^n(X) = \check{H}^1_{\text{ét}}(X, \mathrm{PGL}(n)) \xrightarrow{\delta_n} \check{H}^2_{\text{ét}}(X, \mathbb{G}_m) \hookrightarrow \mathrm{H}^2_{\text{ét}}(X, \mathbb{G}_m) = \mathrm{Br}(X).$$

by(9.2.1.9) and(5.3.2.14). So the kernel of $\delta : \mathrm{Az}_X^n \to \mathrm{Br}(X)$ is given by Azumaya algebras of the form $\mathbf{End}(\mathcal{E})$ for $\mathcal{E} \in \mathcal{V}\mathrm{ect}^n(X)$. These maps for various n give a map

$$\mathrm{Az}(X) \to \mathrm{Br}(X).$$

Then

- This map is an injective homomorphism, so $\mathrm{Br}_{\mathrm{Az}}(X) \subset \mathrm{Br}(X)$.
- If X has an ample invertible sheaf, then the map induces an isomorphism

$$\mathrm{Br}_{\mathrm{Az}}(X) \cong \mathrm{Br}(X)_{\mathrm{tor}}.$$

In particular, if X is a regular quasi-projective scheme over some $A \in \mathcal{CR}\mathrm{ing}$, then by(9.2.1.2),

$$\mathrm{Br}_{\mathrm{Az}}(X) \cong \mathrm{Br}(X)_{\mathrm{tor}} = \mathrm{Br}(X).$$

For general X, this is also doable, by Gabber and de Jong**?**.

Proof: 1: By taking disjoint union, it suffices to show that for $\mathcal{A} \in \mathrm{Az}_X^n, \mathcal{B} \in \mathrm{Az}_X^m$,

$$\delta_{mn}(\mathcal{A} \otimes \mathcal{B}) = \delta_n(\mathcal{A}) \cdot \delta_m(\mathcal{B}).$$

But this is clear from the description of δ_n: by the hypothesis and [Milne80 Etale Cohomology, Prop4.2.19]**?** and(5.3.2.19), we may take an étale refinement $\{U_i\}$ and assume the cocycle corresponding to $\mathcal{A}$ is given by a cocycle c_{ij} s.t. $c_{ij} \in \Gamma(U_{ij}, \mathrm{GL}(n))$. Then $\delta(\mathcal{A})$ is represented by the 2-cocycle with $a_{ijk} = c_{jk} c_{ik}^{-1} c_{ij} \in \Gamma(U_{ijk}, \mathbb{G}_m)$.

The injectivity follows from the presentation

$$\mathrm{Br}_{\mathrm{Az}}(X) \cong \varinjlim \mathrm{Az}_X^n / \sim = \varinjlim \check{H}^1_{\text{ét}}(X, \mathrm{PGL}(n)) / \check{H}^1_{\text{ét}}(X, \mathrm{GL}(n)).$$

and the fact the image of $\check{H}^1_{\text{ét}}(X,\mathrm{GL}(n))$ in $\check{H}^1_{\text{ét}}(X,\mathrm{PGL}(n))$ is the class of $\mathbf{End}(n,E)$: a $\mathtt{a}\in\check{H}^1_{\text{ét}}(X,\mathrm{GL}(n))$ corresponds to a vector bundle $\mathcal{E}$ of rank n with trivializations $\varphi_i:\mathcal{O}_{U_i}^n\cong E|_{U_i}$ s.t. $\mathtt{a}$ is represented by $(\varphi_i^{-1}\varphi_j)$. Then $\mathcal{A}=\mathbf{End}(n,\mathcal{E})\in\mathrm{Az}_X^n$ has trivializations $\psi_i:\mathrm{Mat}(n,\mathcal{O}_{U_i})\cong\mathbf{End}(n,\mathcal{E})|_{U_i}$, and $\mathcal{A}$ corresponds to the 1-cocycle

$$(\psi_i^{-1}\psi_j)=(\alpha_{ij}),\quad \alpha_{ij}(a)=\varphi_j^{-1}\varphi_i a\varphi_i^{-1}\varphi_j, a\in\mathrm{Mat}(n,\mathcal{O}_{U_{ij}})$$

which is exactly the image of the class $\mathtt{a}$ under the map $\mathrm{GL}(n)\to\mathrm{PGL}(n):u\mapsto\mathrm{conj}(u)$.

2: Cf.[Brauer-Grothendieck Group]Chap4.**?** □

Prop. (9.2.1.11) [Kummer Exact Sequences]. For $X\in\mathcal{S}\mathrm{ch}, n\in\mathbb{Z}_+$, the Kummer exact sequence of algebraic groups

$$1\to\mu_n\to\mathbb{G}_m\xrightarrow{n}\mathbb{G}_m\to 1$$

gives exact sequences

$$0\to\mathrm{Pic}(X)/n\,\mathrm{Pic}(X)\to H^2_{\text{fppf}}(X,\mu_n)\to\mathrm{Br}(X)[n]\to 0,$$

$$0\to\mathrm{Br}(X)/n\,\mathrm{Br}(X)\to H^3_{\text{fppf}}(X,\mu_n)\to\mathrm{H}^3_{\text{ét}}(X,\mathbb{G}_m)[n]\to 0.$$

by(7.4.7.34).

Prop. (9.2.1.12) [Mayer-Vietoris Exact Sequence]. Let $X\in\mathcal{S}\mathrm{ch}$ and $X=U\cup V$ be a Zariski covering with $U\cap V=W$, then by(9.2.1.2) there is an exact sequence

$$\begin{aligned}0&\to\Gamma(X,\mathcal{O}_X^\times)\to\Gamma(V,\mathcal{O}_X^\times)\oplus\Gamma(V,\mathcal{O}_X^\times)\to\Gamma(W,\mathcal{O}_X^\times)\\&\to\mathrm{Pic}(X)\to\mathrm{Pic}(U)\oplus\mathrm{Pic}(V)\to\mathrm{Pic}(W)\\&\to\mathrm{Br}(X)\to\mathrm{Br}(U)\oplus\mathrm{Br}(V)\to\mathrm{Br}(W)\to\mathrm{H}^3_{\text{ét}}(X,\mathbb{G}_m)\to\ldots\end{aligned}$$

And when U is locally factorial, then $\mathrm{Pic}(U)\to\mathrm{Pic}(W)$ is surjective**?**, so there is an exact sequence

$$0\to\mathrm{Br}(X)\to\mathrm{Br}(U)\oplus\mathrm{Br}(V)\to\mathrm{Br}(W)\to\mathrm{H}^3_{\text{ét}}(X,\mathbb{G}_m).$$

Prop. (9.2.1.13) [Hochschild Spectral Sequence].

Residue Homomorphism

Prop. (9.2.1.14) [Faddeev]. For $k\in\mathtt{Field}$, there is an exact sequence

$$0\to\mathrm{Br}(k)\to\mathrm{Br}(\mathbb{P}^1_k)\xrightarrow{\text{res}}\bigoplus_{x\in\text{closed}(\mathbb{P}^1_k)}H^2(\kappa(x),\mathbb{Q}/\mathbb{Z})\to H^1(k,\mathbb{Q}/\mathbb{Z})\to 0$$

Proof: Cf. [GS06, 6.4.5]**?**. □

Artin Conjecture

Conj. (9.2.1.15) [Artin]. For $X\in\mathcal{S}\mathrm{ch}/\mathbb{Z}$ proper, $\#\mathrm{Br}(X)<\infty$.

Proof: Cf.[Central Simple Algebras and Galois Cohomology, 6.4.5.]. □

Prop. (9.2.1.16) [Artin & Tate Conjecture]. For a proper surface $X/\mathbb{Z}$, the Artin conjecture for X(9.2.1.15) is equivalent to Tate conjecture for divisors of X.

Proof: □

Prop. (9.2.1.17) [Artin vs. Tate-Šafarevič Conjecture]. For $F \in \texttt{NField}$, for a regular integral scheme X of dimension 2 that is flat proper over $\mathcal{O}_F$ that has a section, the Artin conjecture for X is equivalent to the finiteness of $\text{Ш}(\text{Jac}(X_F))$.

Proof: □

2 Field cases

Prop. (9.2.2.1) [Indexes of Brauer Classes]. For $k \in \texttt{Field}$, any Brauer class in $\text{Br}_{\text{Az}}(k)$ is represented by a unique central division ring.

So we can define the **index of the Brauer class** D as the $\text{ind}([D]) = \sqrt{[D:k]} \in \mathbb{Z}_+$(2.4.3.16).

Proof: The existence of this division ring follows from Wedderburn theorem(2.4.1.22), and to show uniqueness, notice if

$$\text{Mat}(n; D) \cong \text{Mat}(m; D') = A$$

when we can recover D as $D = D' = \text{End}_A(V)$, where V is the unique simple module, by(2.4.1.21). □

Prop. (9.2.2.2)[Brauer Groups and Galois Cohomology]. For any $k \in \texttt{Field}$, the **Brauer group** $\text{Br}(k)$ is defined as the profinite cohomology $H^2(\text{Gal}(k^{\text{sep}}/K), (k^{\text{sep}})^\times)$. For a Galois extension L/k, $\text{Br}(L/k)$ is defined as $H^2(\text{Gal}(L/k), L^\times)$. Then by(10.1.2.2) we have

$$\varinjlim \text{Br}(L/k) = \text{Br}(k).$$

And by Hochschild-Serre spectral sequence and by Hilbert's multiplicative theorem90: $H^1(H, k_s^*) = 0$, we have the low term:

$$0 \to \text{Br}(L/k) \xrightarrow{\text{inf}} \text{Br}(k) \xrightarrow{\text{res}} \text{Br}(L)^{\text{Gal}(L/k)} \to H^3(\text{Gal}(L/k), L^\times) \to H^3(k, (k^{\text{sep}})^\times).$$

So $\text{Br}(L/k)$ is the kernel of $\text{Br}(k) \to \text{Br}(L)$.

Proof: Cf.[Neukirch Cohomology of Number Fields Chap6.3].**?** □

Cor. (9.2.2.3) [Brauer Groups are Torsion]. For any $k \in \texttt{Field}$, $\text{Br}(k) \in \mathcal{A}\text{b}^{\text{tor}}$, by(10.1.2.3). In particular, $\text{Br}_{\text{Az}}(k) \cong \text{Br}(k)$ by(9.2.1.10).

Cor. (9.2.2.4). For any $k \in \texttt{Field}$, $\#k < \infty$, $\text{Br}(\mathbb{F}_q) = 0$, because the finite Galois extension are cyclic and unramified.

Prop. (9.2.2.5)[Finite Fields]. If $k \in \texttt{Field}^{\text{fin}}$, then for any $n \in \mathbb{N}$, $\check{H}^1(k, \text{PGL}(n)) = 0$, and $\text{Br}(k) = 0$.

Proof: This follows from(9.2.2.1) and the fact any finite division ring is commutative(2.2.1.8). □

Prop. (9.2.2.6) [Valued Fields]. Let (R, K, k) be a complete DVR, then there exists a split exact sequence

$$0 \to \text{Br}(k) \to \text{Br}_{\text{tame}}(K) \to H^1(k, \mathbb{Q}/\mathbb{Z}) \to 0.$$

Proof: Cf.[Brauer-Grothendieck Group, P32]. □

3 Local Field cases

Thm. (9.2.3.1) [Brauer Groups of Local Fields]. For $K \in \texttt{LField}$,

- the invariant map(12.6.2.7) is a canonical injection
$$\mathrm{inv} : \mathrm{Br}(K) \hookrightarrow \mathbb{Q}/\mathbb{Z}$$
whose image is
$$\begin{cases} \mathbb{Q}/\mathbb{Z} & , K \in p\text{-}\texttt{LField} \\ \frac{1}{2}\mathbb{Z}/\mathbb{Z} & , K = \mathbb{R} \\ 0 & , K = \mathbb{C} \end{cases}$$
- Every Azumaya algebra over K is cyclic**?**.
- Every element of $\mathrm{Br}(K)$ has exponent equal to index.

Proof: 1: This follows from the definition of a class formation(12.6.1.1).
The rest follows from [Poonen, P25].**?** □

Cor. (9.2.3.2). For $K \neq \mathbb{C} \in \texttt{LField}$, there exists a unique nontrivial quaternion algebra over K, and its the only division ring with exponent 2.

4 Global Field cases

Thm. (9.2.4.1) [Brauer-Hasse-Noether]. For $F \in \texttt{NField}$,

- there is a canonical exact sequence
$$1 \to \mathrm{Br}(F) \to \bigoplus_{\mathfrak{p}\in\Sigma_F} \mathrm{Br}(F_\mathfrak{p}) \xrightarrow{\mathrm{inv}_F} \mathbb{Q}/\mathbb{Z} \to 0,$$
and in the characterization via Azumaya algebras(9.2.1.5)(9.2.1.10), the first map sends $[D]$ to the family $([D \otimes_F F_v])_v$.
- Every Azumaya algebra over F is cyclic**?**.
- Every element of $\mathrm{Br}(F)$ has exponent equal to index.

Proof: 1, 2: Cf.[Neukirch P146] and [Poonen, P26].**?**
3: It follows from item1 that for any division ring D/F, $[D] \in \mathrm{Br}(F)$has exponent $n = \mathrm{lcm}(\mathrm{ord}(\mathrm{inv}_v([D])))$. So it follows from(9.2.3.1) that there $n_v | \mathrm{ind}([D])$ for any v, so $n | \mathrm{ind}([D])$.
And it follows from Grünwald-Wang(12.6.4.32) and the local-global compatibility of inv_v that there exists a cyclic extension L/K of degree n that splits D. Then it follows from(2.4.3.17)(9.2.2.1) that there exists $B = \mathrm{Mat}(r; D)$ s.t. $L \subset B$ and $[B : F] = [L : K]^2$. Thus $[D : F] | [L : K]^2$, so $\mathrm{ind}(D) = n$. □

Prop. (9.2.4.2) [Norm Groups of Division Rings, Eichler]. If $F \in \texttt{NField}$ and D/F is a division ring of index n, then $\mathrm{Nm}_{D/K}(D^\times) \subset F^\times$ is the set of elements that is positive under all $v \in \Sigma_F^\mathbb{R}$ s.t. $D_v \not\cong \mathrm{Mat}(n; F_v)$.

Proof: Cf.[**?**]P38. □

Prop. (9.2.4.3) [Wang]. If $F \in \texttt{NField}$ and D/F is a division ring of index n, then $SL(1; D) = [D^\times, D^\times]$.

Prop. (9.2.4.4).

5 Severi-Brauer Varieties

References are [Severi – Brauer varieties: a geometric treatment, Kollar] and [Central Simple Algebras and Galois Cohomology].

Def. (9.2.5.1) [Severi-Brauer Varieties]. For $k \in \texttt{Field}$, a **Severi-Brauer variety** over k is a k-variety X that is a k-form for $\mathbb{P}^n_k$ for some $n \in \mathbb{N}$.

If K/k is a field extension and $X_k \cong \mathbb{P}^n_K$, then K is called a **splitting field** for X.

Prop. (9.2.5.2). Let $k \in \texttt{Field}$ and X a Severi-Brauer variety over k, then a **twisted-linear subvariety** of X is a closed subvariety of X s.t. the inclusion $Y_{\overline{k}} \subset X_{\overline{k}} \cong \mathbb{P}^n_{\overline{k}}$ embeds $Y_{\overline{k}}$ as a linear subvariety of $\mathbb{P}^n_{\overline{k}}$.

Prop. (9.2.5.3) [Châtelet]. For $k \in \texttt{Field}$ and an n-dimensional Severi-Brauer variety X over k, the following are equivalent:

- $X \cong \mathbb{P}^n_k$.
- $X \sim \mathbb{P}^n_k$.
- $X(k) \neq \varnothing$.
- X contains a twisted-linear subvariety of codimension 1.

Proof: 1 → 2 is trivial. If 2 holds, then to show item3, if $\#k = \infty$, then any Zariski open subset of $\mathbb{P}^n_k$ contains a k-point, and if $\#k < \infty$, clearly any Severi-Brauer variety over k splits over a finite Galois field extension of k, so by the proof of(9.2.5.6)**?** shows that $SB_n(K) \cong H^1(k, \mathrm{PGL}(n)) = 1$(9.2.2.5). Thus $X \cong \mathbb{P}^n_k$ has a rational point.

4 → 1: The twisted-linear subvariety is a divisor of X**?**, so it defines a rational map φ_D into some projective variety, and when base changed to $\overline{k}$, it is the isomorphism of X with $\mathbb{P}^n_{\overline{k}}$. Thus it must be an isomorphism.

3 → 4: Cf.[Central Simple Algebras]P341.**?** □

Cor. (9.2.5.4) [Galois Splitting Fields]. Let $k \in \texttt{Field}$ and X a Severi-Brauer variety over k, then X has a finite Galois splitting field.

Proof: It suffices to show that k^s is a splitting field for X. But for this, by the theorem, it suffices to notice X_{k_s} always has a rational point(5.10.1.10). □

Cor. (9.2.5.5). Severi-Brauer groups satisfy the local-global property.

Proof: Cf.[Poonen]P108. □

Prop. (9.2.5.6) [Severi-Brauer Varieties and Galois Cohomologies]. For $k \in \texttt{Field}$, there is an isomorphism of pointed sets $H^1(k, \mathrm{PGL}(n)) \cong SB_n(L/K)$, where $SB_n(L/K)$ is the isomorphism classes of Severi-Brauer varieties of dimension $n-1$ that splits in L.

Proof: Cf.[Neukirch Cohomology of Number Fields P348]. □

6 Brauer-Manin Obstruction

Prop. (9.2.6.1). For $F \in \texttt{GField}$ and $X \in \mathcal{S}\mathrm{ch}^{\mathrm{sm}}/F$, there is a natural continuous right-linear pairing

$$\gamma : X(\mathbf{A}_F) \times \mathrm{Br}(X) \to \mathbb{Q}/\mathbb{Z}$$

s.t. the restriction to $X(F) \times \mathrm{Br}(X)$ is trivial.

Let $X(\mathbf{A}_F)^{\mathrm{Br}}$ denote the left kernel of γ, then we say the **Brauer-Manin obstruction** is sufficient for X if $X(F) \subset X(\mathbf{A}_F)^{\mathrm{Br}}$ is dense.

Proof: ? □

Prop. (9.2.6.2). If $F \in \texttt{GField}$ and $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/F$, then if X satisfies the weak approximation, then Brauer-Manin obstruction is sufficient.

Proof: □

7 Norm Residue Isomorphism Theorem

See Voevodsky's work.

10 Condensed Mathematics and Analysis

10.1 Profinite Cohomology

Reference are [Neu15] and the giant book [Neukirch Cohomology of Number Fields].

1 Group Cohomology

Let G be a finite group.

Def. (10.1.1.1) [Group Cohomologies]. For $G \in \mathcal{G}\mathrm{rp}^{\mathrm{fin}}$, the **group cohomology** $H^n(G, A)$ is the derived functor of the left exact functor

$$\mathcal{M}\mathrm{od}_G \to \mathcal{A}\mathrm{b} : H^0(G, A) = A^G = \mathrm{Hom}_{\mathbb{Z}[G]}(\mathbb{Z}, A),$$

so $H^n(G, A) = \mathrm{Ext}^n_{\mathbb{Z}[G]}(\mathbb{Z}, A)$.

The **group homology** $H_n(G, A)$ is the left derived functor of the right exact functor

$$\mathcal{M}\mathrm{od}_G \to \mathcal{A}\mathrm{b} : H_0(G, A) = A_G = \mathbb{Z} \otimes_{\mathbb{Z}[G]} A,$$

so $H_n(G, A) = \mathrm{Tor}_n^{\mathbb{Z}[G]}(\mathbb{Z}, A)$。

Prop. (10.1.1.2). For a normal subgroup H of G, $A \mapsto A^H$ is left exact from G-mod to G/H-mod and preserves injectives **??** because it is right adjoint to the exact inclusion functor as $\mathrm{Hom}_G(B, A) = \mathrm{Hom}_{G/H}(B, A^H)$. Dually for A_H.

Prop. (10.1.1.3). For $G = \mathbb{Z}$, we have a free resolution $0 \to Z[t, t^{-1}] \xrightarrow{1-t} Z[t, t^{-1}] \to Z \to 0$. In particular, thus $H_n(\mathbb{Z}, \mathbb{Z}) = \mathbb{Z}$ iff $n = 0, 1$ and vanish otherwise.

Prop. (10.1.1.4) [Tate Cohomology]. There is a standard resolution of the $\mathbb{Z}[G]$-module $\mathbb{Z}$:

$$\cdots \longleftarrow X_{-2} \longleftarrow X_{-1} \xleftarrow{\mu\circ\varepsilon} X_0 \longleftarrow X_1 \longleftarrow \cdots$$

that $X_q = X_{-q-1}$ are $\mathbb{Z}[G]$-module generated by q-cells $(\sigma_1, \ldots, \sigma_q)$, $X_0 = X_{-1} = \mathbb{Z}[G]$.

It then can be verified that for $G \in \mathcal{A}\mathrm{b}^{\mathrm{fin}}$, Hom from this resolution gives out the Tate cohomology

$$H^n_T(G, A) = \begin{cases} H^n(G, A) & n \geq 1 \\ A^G / \mathrm{tr}_G A & n = 0 \\ {}_{\mathrm{tr}_G}A / I_G A & n = -1 \\ H_{-1-n}(G, A) & n \leq -2 \end{cases}$$

and H^n_T is a long exact sequence.

In particular, the Hom complex looks like:

$$\cdots \to A_{-2} \xrightarrow{\partial_{-1}} A_{-1} \xrightarrow{\partial_0} A_0 \xrightarrow{\partial_1} A_1 \xrightarrow{\partial_2} A_2 \to \cdots$$

where $A_{-1} = A_0 = A$ and $\partial_0 x = \mathrm{tr}_G x$, $(\partial_1 x)(\sigma) = \sigma x - x$,
$\partial_2(x)(\sigma_1, \sigma_2) = \sigma_1 x(\sigma_2) - x(\sigma_1\sigma_2) + x(\sigma_1)$.

Proof: Cf.[Neukirch CFT P13]? □

Remark (10.1.1.5). From now on, consider only Tate cohomology.

Prop. (10.1.1.6).

$$H^{-2}(G,\mathbb{Z}) = G^{ab}, \quad H^{-1}(G,\mathbb{Z}) = 0, \quad H^0(G,\mathbb{Z}) = \mathbb{Z}/|G|\mathbb{Z}, \quad H^1(G,\mathbb{Z}) = 0, \quad H^2(G,\mathbb{Z}) = \chi(G).$$

Proof: H^0 is trivial and $H^1(G,\mathbb{Z}) = H^0(G,\mathbb{Q}/\mathbb{Z}) = 0$, $H^2(G,\mathbb{Z}) = H^1(G,\mathbb{Q}/\mathbb{Z}) = \mathrm{Hom}(G,\mathbb{Q}/\mathbb{Z})$. $H^{-1}(G,\mathbb{Z}) = {}_{N_G}\mathbb{Z}/I_G A = 0$.

For $H^{-2}(G,\mathbb{Z})$, use the dimension shifting $0 \to I_G \to \mathbb{Z}[G] \to \mathbb{Z} \to 0$, $= H^{-1}(G, I_G) = I_G/I_G^2$. And $G^{ab} \cong I_G/I_G^2$ by $\sigma \mapsto \sigma - 1$. □

Prop. (10.1.1.7) [Group Cohomologies are Torsion]. For $G \in \mathcal{A}\mathrm{b}^{\mathrm{fin}}$, $\#G \cdot H^n(G,A) = 0$ for any $A \in \mathcal{M}\mathrm{od}_G$. (True for H^0 and use dimension shifting). In particular, a divisible G-module A has trivial cohomology.

Operations

Prop. (10.1.1.8) [Dimension Shifting]. There are fundamental split exact sequence $0 \to I_G \to \mathbb{Z}[G] \to \mathbb{Z} \to 0$ and $0 \to \mathbb{Z} \to \mathbb{Z}[G] \to J_G \to 0$, thus $A_G = A/I_G A$. This can be used to tensor with A and define natural dimension shifting of cohomology δ.

Lemma (10.1.1.9). If H is a subgroup of G, then by Grothendieck spectral sequence applied to $\mathcal{M}\mathrm{od}_G \xrightarrow{\mathrm{res}} \mathcal{M}\mathrm{od}_H \xrightarrow{(\cdot)^H} \mathcal{A}\mathrm{b}$ shows that for $A \in \mathcal{M}\mathrm{od}_G$, $H^*(H,A)$ is the same as the right derived functor of the functor $(\cdot)^H$ on $\mathcal{M}\mathrm{od}_G$.

Def. (10.1.1.10) [Restrictions, Corestrictions and Inflations]. Let H be a subgroup of G,

- The **inflation** is the δ-morphism $H^*(G/H,A) \to H^*(G,A)$ on $\mathcal{M}\mathrm{od}_{G/H}$ induced by the natural transformation? How to define it?
- The **restriction** are the δ-morphisms $H^*(G,A) \to H^*(H,A)$ on $\mathcal{M}\mathrm{od}_G$ induced by the natural transformation $A^G \to A^H$.
- The **corestriciton** are the δ-morphisms $H^*(H,A) \to H^*(G,A)$ on $\mathcal{M}\mathrm{od}_G$ induced by the natural transformation $A^H \to A^G : a \mapsto N_{G/H} a$.

Proof: These exist by(3.9.3.5) and(10.1.1.9). □

Cor. (10.1.1.11). Let H be a subgroup of G, then $\mathrm{cor} \circ \mathrm{res} = [G : H]\,\mathrm{id}$.

Prop. (10.1.1.12) [Kernel of Restriction]. If G is a finite group and H_1, H_2 are conjugate subgroups of G and $M \in \mathcal{M}\mathrm{od}_G$, then the kernel of the restriction maps $H^1(G,M) \to H^1(H_i,M)$ are identical.

Proof: If a 1-cycle $\sigma \mapsto f(\sigma)$ is a cocycle, then it is a boundary when restricted to H_1 iff $f(\sigma) = \sigma(a) - a$ for some $a \in M$ for any $\sigma \in H_1$. Thus

$$f(x^{-1}\sigma x) = f(x^{-1}) + x^{-1}f(\sigma x) = -x^{-1}f(x) + x^{-1}f(\sigma) + x^{-1}\sigma f(x) = x^{-1}(\sigma(f(x)+a) - (f(x)+a))$$

is also boundary when restricted to $x^{-1}H_1x$. □

Prop. (10.1.1.13) [Serre-Hochschild Spectral Sequence]. If H is a normal subgroup of a finite group G, by Grothendieck spectral sequence, the relation $A^G = (A^H)^{G/H}$ gives us a spectral sequence E that

$$E_2^{p,q} = H^p(G/H, H^q(H,A)) \Longrightarrow E^n = H^n(G,A).$$

The edge morphisms are:

- inflation maps $H^k(G/H, A^H) \xrightarrow{\text{inf}} H^k(G,A)$.
- restriction maps $H^k(G,A) \xrightarrow{\text{res}} H^k(H,A)^{G/H}$.

And the lower parts give us:

$$0 \to H^1(G/H, A^H) \xrightarrow{\text{inf}} H^1(G,A) \xrightarrow{\text{res}} H^1(H,A)^{G/H} \xrightarrow{transgression} H^2(G/H, A^H) \xrightarrow{inf} H^2(G,A).$$

dually for homology group.

Moreover if $H^k(H,A) = 0$ for $k = 1, \ldots, n-1$, then the rows are blank, thus the above lower part can change to dimension n.

Proof: Prove the compatibility of inflation, restriction with the definition given in(10.1.1.10).**??**
□

Cor. (10.1.1.14)[Hopf]. If $G = F/R$, F is free, then use the homology spectral sequence, $H_2(G,\mathbb{Z}) \cong \frac{R\cap[F,F]}{[F,R]}$. Cf.[Weibel P198].

Prop. (10.1.1.15). For an isomorphism (σ^*, σ) of a group and its cochain map in the sense that $\sigma^*(g)(\sigma(a)) = g(a)$, we have an isomorphism of Conjugation acts trivially on the group cohomology, because it does on H^0 because $H^0 = A^G$ fixed by G, and it commutes with dimension shifting. (Warning, if you count directly $a(\sigma\tau\sigma^{-1}) - \sigma a(\tau)$, you won't get 0, but a 1-coboundary).

Prop. (10.1.1.16) [Cup Products]. The cup product is defined by $C^p(X,A) \times C^q(X,B) \to C^{p+q}(X, A\otimes B)$:

$$(a \smile b)(\sigma_1, \ldots, \sigma_{p+q}) = a(\sigma_1, \ldots, \sigma_p) \otimes \sigma_1 \ldots \sigma_p b(\sigma_{p+1}, \ldots, \sigma_{p+q}).$$

It satisfies $\partial(a \smile b) = \partial(a) \smile b + (-1)^p a \smile \partial(b)$, thus defines a:

$$\smile: H^p(G,A) \times H^q(G,B) \to H^{p+q}(G, A\otimes B)$$

for $p, q \geq 0$. And in negative dimension this is also definable but not computable, Cf.[Neukirch Cohomology of Number Fields P42] or [Neukirch Class Field Theory 2015 P45].

- $a \smile b = a \otimes b$ for $a \in H^0(G,A), b \in H^0(G,B)$.
- $\delta(a \smile b) = \delta a \smile b, \delta(a \smile b) = (-1)^p(a \smile \delta b)$ for $a \in H^p(G,A)$.
- $\smile$ is associative and skew-symmetric (follows from dimension shifting and the last one.)

Proof: □

Prop. (10.1.1.17) [Duality and Cup Product]. Let $0 \to A' \xrightarrow{i} A \xrightarrow{j} A'' \to 0$ and $0 \to B' \xrightarrow{u} B \xrightarrow{v} B'' \to 0$ be exact and there is a pairing $\varphi : A \times B \to C$ that $\varphi(A' \times A') = 0$ hence induce a compatible pairing on $A' \times B''$ and $A'' \times B'$, then we have

$$\delta(\alpha) \smile \beta + (-1)^p \alpha \smile \delta(\beta) = 0$$

for $\alpha \in H^p(G, A'')$ and $\beta \in H^q(G, B'')$.

Proof: Use the definition of δ, let a, b be the preimage of α, β in A and B, and $ia' = \partial a, ub' = \partial b$, then $\delta(\alpha) \smile \beta + (-1)^p \alpha \smile \delta(\beta) = a' \smile vb + (-1)^p ja \smile b' = \partial a \smile b + (-1)^p a \smile \partial b = \partial(a \smile b)$ is a boundary. □

Prop. (10.1.1.18) [Naturality of Cup Products].

$$\mathrm{res}(a \smile b) = \mathrm{res}(a) \smile \mathrm{res}(b), \quad \inf(a \cup b) = \inf(a) \cup \inf(b), \quad \mathrm{cor}(\mathrm{res}\, a \smile b) = a \smile \mathrm{cor}\, b.$$

Proof: Cf.[Neukirch CFT P48] or [Central Simple Algebras]P100.? □

Prop. (10.1.1.19). Let $\sigma \in G^{ab} = H^{-2}(G, \mathbb{Z})$ and $a_1 \in H^1(G, A), a_2 \in H^2(G, A)$, then

$$a_1 \smile \sigma = a_1(\sigma), \quad a_2(\sigma) = \sum_\tau a_2(\tau, \sigma).$$

Cf.[Neukirch CFT P50,P51].

Prop. (10.1.1.20) [Cyclic Group Cohomologies]. For cyclic group, the Tate cohomology is 2-cyclic.

In particular, if σ be a generator for $\mathbb{Z}/(n)$, then $H^p(\mathbb{Z}/(n), A) = A^G/\mathrm{tr}(A)$ for p even and $H^p(\mathbb{Z}/(n), A) = {}_{\mathrm{tr}}A/(\sigma - 1)A$ for p odd.

Proof: There is an exact sequence $0 \to \mathbb{Z} \to \mathbb{Z}[G] \xrightarrow{\sigma-1} \mathbb{Z}[G] \to \mathbb{Z} \to 0$, and this defines an isomorphism $\delta^2 : H^0(G, \mathbb{Z}) \cong H^2(G, \mathbb{Z})$. And this is also true for any A when tensored with it. The isomorphism is $a \mapsto \delta^2 a = \delta^2(1) \smile a$. □

Prop. (10.1.1.21) [Duality]. The cup product induces an isomorphism $H^i(G, A^\vee) \cong (H^{-i-1}(G, A))^\vee$, i.e, $H^n(G, A^\vee)$ and $H_n(G, A)$ are dual to each other when $n > 0$, where $A^\vee = \mathrm{Hom}(A, \mathbb{Q}/\mathbb{Z})$.

Proof: We only need to verify $A^{*G}/N_G A^* \cong ({}_{N_G}A/I_G A)^*$ and use dimension shifting. Should use the injectivity of $\mathbb{Q}/\mathbb{Z}$ and the compatibility of cup product with dual. □

Cor. (10.1.1.22). When A is $\mathbb{Z}$-free, the cup product also induce an isomorphism $H^i(G, \mathrm{Hom}(A, \mathbb{Z})) \cong H^{-i}(G, A)^\vee$.

Prop. (10.1.1.23) [Theorem of Cohomological Triviality]. For a G-module A, if there is a q s.t. $H^q(g, A) = H^{q+1}(g, A) = 0$ for all subgroups of G, then $H^p(g, A) = 0$ for any p and subgroup g. Cf.[Neukirch CFT P57].

Prop. (10.1.1.24) [Tate's Theorem]. Assume A is a G-module that $H^1(G, A) = 0$ and $H^2(g, A)$ is cyclic of order $|g|$ for any subgroup g of G, then for a generator a of $H^2(G, A)$, there is an isomorphism

$$a \smile : H^q(G, \mathbb{Z}) \cong H^{q+2}(G, A).$$

Cf.[Neikirch CFT P79].

Cor. (10.1.1.25). In particular, by dimension shifting, if A is a G-module that $H^1(G, A) = 0$ and $H^2(g, A)$ is cyclic of order $|g|$ for any subgroup g of G this gives an isomorphism:

$$a \smile : H^q(G, \mathbb{Z}) \cong H^{q+2}(G, A).$$

for a generator a of $H^2(G, A)$, because cup product commutes with dimension shifting.

Miscellaneous

Prop. (10.1.1.26) [H^2 and Extensions, Schreier]. For a G-module A, there is a correspondence of equivalence classes of extension of G over A that are compatible with the G action and $H^2(G, A)$.

Proof: Cf.[Weibel P183]. In fact there are also interpretations of $H^3(G, A)$ as $0 \to A \to N \to E \to G$ under some equivalences. □

Prop. (10.1.1.27) [Herbrand Quotients for Cyclic Groups]. When G is a cyclic group and A is a G-module, let $f = \sigma - 1$, $g = 1 + \sigma + \ldots + \sigma^{n-1}$, then we can form a cyclic complex of order 2 and compute the Herbrand quotient(3.7.5.7). In this case, $g_{f,g}$ is just $|H^0(G, A)|/|H^{-1}(G, A)|$. And by(3.7.5.9), if a G-morphism $A \to B$ has finite kernel and cokernel, then they have the same Herbrand quotient.

2 Cohomology of Profinite Groups

Prop. (10.1.2.1) [Abelian Sheaves on T_G]. For $G \in \mathcal{P}\mathrm{rof}$, the category of Abelian sheaves on the canonical topology(5.1.2.4) T_G of G-sets is equivalent to the the category $\mathcal{M}\mathrm{od}_G^{\mathrm{alg}}$, by $Z \mapsto \mathrm{Hom}(-, Z)$. The inverse map is given by $F \mapsto \varinjlim F(G/H)$.

Proof: The task is to prove $F \cong h_{\varinjlim F(G/H)}$. Cf.[Tamme P29].

The inverse of the Yoneda functor is the functor $F \mapsto F(G)$ as a left G-set where $gs = F(\cdot g)s$. The task is to show that $F \cong h_{F(G)}$. For this, for any U we consider the covering $\{G \xrightarrow{\varphi_u} U$ where $\varphi_U(g) = gu$. Sheaf condition says

$$F(U) \to \prod_{u \in U} F(G) \rightrightarrows F(G \times_U G)$$

is exact, in other words, $F(U) \cong \mathrm{Hom}_G(U, F(G))$. □

Prop. (10.1.2.2) [Profinite Cohomologies]. The **profinite cohomology** is the derived functor of $A \to A^G$ on the Abelian category $\mathcal{M}\mathrm{od}_G^{\mathrm{alg}}$(10.1.2.1)(It has enough injectives by(15.1.2.1)). It satisfies

$$H^*(G, A) \cong H^*(C^\bullet(G, A)) \cong \varinjlim H^*(G/U, A^U)$$

where $C^\bullet(G, A)$ is the set of continuous cochain complex of morphisms from G to A and the colimit is taken over the transition maps defined by inflations. Moreover, for the same reason, when $G = \varprojlim G_i$, and $A = \varinjlim A_i$, then

$$H^*(G, A) \cong \varinjlim H^*(G_i, A_i).$$

Proof: The second is an isomorphism because $C^n(G, A) = \varinjlim C^n(G/U, A^U)$ and direct limit is exact.

For the first, the H^0 obviously coincide, so it suffice to prove $H^*(C(G, A))$ form a universal δ-functor. It is effaceable because $(-)^U$ preserves injective modules(10.1.1.2).

For the last one, we need to check $C^n(G, A) = \varinjlim C^n(G_i, A_i)$. Notice G has the profinite topology, thus must factor through some G_i, and the right through some A_i because the image of a morphism from G^n to A has finite image. Thus the result follows. □

Prop. (10.1.2.3) [Cohomology Groups are Torsion]. For $G \in \mathcal{P}\mathrm{rof}$, $M \in \mathcal{M}\mathrm{od}_G^{\mathrm{alg}}$, $i \in \mathbb{N}$, $H^i(G, M)$ are torsion Abelian groups. And if G is a pro-p-group, then $H^i(G, M)$ are p-primary torsion subgroups.

Proof: Notice if $M \in \mathcal{M}\mathrm{od}_G^{\mathrm{alg}}$, this follows from(10.1.2.2) and(10.1.1.7). The last assertion is similar. □

Def. (10.1.2.4)[Restrictions, Corestrictions and Inflations]. Let $G \in \mathcal{P}\mathrm{rof}$ and $H < G$ be a closed subgroup, for any $A \in \mathcal{M}\mathrm{od}_G^{\mathrm{alg}}$, taking colimits over all open subgroup U_α of G of the restriction maps

$$\mathrm{res} : H^i(G/U_\alpha, A^{U_\alpha}) \to H^i(H/(H \cap U_\alpha), A^{U_\alpha}) \to H^i(H/H \cap U_\alpha, A^{H\cap U_\alpha}),$$

by(2.1.14.6), we get a restriction map

$$\mathrm{res} : H^i(G, A) \to H^i(H, A).$$

Similarly, if H is open in G, we can define a corestriction map

$$H^i(H, A) \to H^i(G, A).$$

And if $H \lhd G$ is normal, we can define an inflation map

$$H^i(G/H, A^H) \to H^i(G, A).$$

as the colimit of the inflation maps

$$H^i(G/HU_\alpha, A^{HU_\alpha}) \to H^i(G/H, A^{U_\alpha}).$$

Prop. (10.1.2.5). $\mathrm{cor} \circ \mathrm{res} = [G : H]$ for a subgroup H is also true for profinite cohomology(10.1.1.11), if H is an open subgroup of G. This is because of(10.1.2.2).

Prop. (10.1.2.6). If H is a closed subgroup of a profinite group G, $p \in \mathbf{P}$ s.t. $p \nmid [G : H]$, then for any $A \in \mathcal{M}\mathrm{od}_G^{\mathrm{alg}}, i \in \mathbb{N}$, $\mathrm{res} : H^i(G, A) \to H^i(H, A)$ is injective on the p-primary part of $H^i(G, A)$.

Proof: This follows from(10.1.2.5) and(10.1.2.4) by taking filtered colimits. □

Lemma (10.1.2.7) [Shapiro].

$$H_*(G, \mathrm{Ind}_H^G(A)) \cong H_*(H, A), \quad H^*(G, \mathrm{ind}_H^G(A)) \cong H^*(H, A)$$

because (co)induction is adjoint to exact functors, so it preserves injectives(projectives) and it is exact because $\mathbb{Z}[G]$ is free $\mathbb{Z}[H]$-module.

And in the finite case, this is also true for Tate cohomology using dimension shifting.

Prop. (10.1.2.8)[Serre-Hochschild Spectral sequence]. The same spectral sequence as in the finite case(10.1.1.13) also applies to profinite cohomology with H closed normal in G.

Def. (10.1.2.9) [Cup Products]. For any $U < G$ open and $A, B \in \mathcal{M}\mathrm{od}_G^{\mathrm{alg}}$, there are natural cup product maps

$$H^*(G/U, A^U) \times H^*(G/U, B^U) \to H^*(G/U, A^U \otimes B^U) \to H^*(G/U, (A \otimes B)^U).$$

Then by the naturality of inflation and the fact inflation commutes with cup product(10.1.1.18), we get a natural cup product map

$$H^*(G, A) \times H^*(G, B) \to H^*(G, A \otimes B).$$

Prop. (10.1.2.10). The cup products for profinite groups(10.1.2.9) is associative, graded-commutative, and commutes with inflations, restrictions and corestrictions as in(10.1.1.18).

Proof: □

Cohomological Dimensions

Def. (10.1.2.11)[Cohomological Dimensions]. The **p-cohomological dimension** $cd_p(G)$ of a profinite group G is defined as the smallest integer n that $H^i(G,A)[p^\infty]=0$ for any torsion G-module A. The **strict p-cohomological dimension** $scd_p(G)$ of a profinite group G is defined as the smallest integer n that the $H^i(G,A)[p^\infty]=0$ for any G-module A.

The **cohomological dimension** $cd(G)$ is defined to be $cd(G)=\sup_p(cd_p(G))$. The **strict cohomological dimension** $scd(G)$ is defined to be $\sup_p(scd_p(G))$.

Prop. (10.1.2.12). For $G\in\mathcal{P}rof$, the following are equivalent:

- $cd_p(G)\leq n$.
- $H^i(G,A)=0$ for any $i>n$ and any p-torsion G-module A.
- $H^{n+1}(G,A)=0$ for any simple p-torsion G-module A.

And if G is pro-p, then it suffice to check $H^{n+1}(G,\mathbb{Z}/p\mathbb{Z})=0$

Proof: For any torsion G-module A, $A=\oplus_p A(p)$, so $H^i(G,A(p))$ is the p-primary part of $H^i(G,A)$, so $1\iff 2$. For $3\to 1$: use the fact cohomology commutes with colimits(10.1.2.2), reduce to the case of A finite, and then use use the quotient tower.

The last assertion is by(2.1.14.15). □

Prop. (10.1.2.13). For any $G\in\mathcal{P}rof$, $cd_p(G)\leq scd_p(G)\leq cd_p(G)+1$.

Proof: Let $A_p=\ker(p:A\to A)$. There are exact sequences $0\to A_p\to A\xrightarrow{p} pA\to 0$ and $0\to pA\to A\to A/pA\to 0$. A_p and A/pA are p-torsion G-modules, so if $i>cd_p(G)+1$, then $H^i(G,A_p)$ and $H^{i-1}(G,A/pA)$ vanish. so $H^i(G,A)\xrightarrow{p} H^i(G<pA)$ and $H^i(G,pA)\to H^i(G,A)$ are injections, so their composition $H^i(G,A)\xrightarrow{p} H^i(G,A)$ is injective, showing $(H^i(G,A))_p=0$, so $scd_p(G)\leq cd_p(G)+1$. □

Prop. (10.1.2.14). For a closed subgroup H of a profinite group G, $cd_p(H)\leq cd_p(G)$ and $scd_p(H)\leq scd_p(G)$, and if $[G:H]$ is relatively prime to p, then equality holds.

Proof: The first is because of Shapiro's lemma(10.1.2.7). For the equality, use(10.1.2.6). □

Cor. (10.1.2.15). $cd_p(G)=cd_p(G_p)=cd(G_p)$, $scd_p(G)=scd_p(G_p)=scd(G_p)$.

Prop. (10.1.2.16). If H is a closed normal subgroup of G, then $cd_p(G)\leq cd_p(H)+cd_p(G/H)$, by Hochschild-Serre spectral sequence.

Prop. (10.1.2.17). If K is a field of char p, then $cd_p(\mathrm{Gal}_K)=0$.

If $H^2(G(K_s/L),K_s^*)=0$ for all L/K separable, then $cd(G(K_s/K))\leq 1$. In particular $H^i(G(K_s/K),K_s^*)=0$ for $i\geq 1$.

Proof: Let G_p be the Sylow p-subgroup of $G(K_s/K)$ and $M=K_s^{G_p}$. There is an exact sequence $0\to\mu_p\to K_s\xrightarrow{x^p-x} K_s\to 0$, and combined with the fact that $H^i(G_p,K_s)=H^i(G(K_s/M),K_s)=0$ for $i\geq 1$(10.1.3.1), so $H^i(G_p,\mathbb{Z}/p\mathbb{Z})=0$ for $i\geq 2$. Thus by(10.1.2.12) and(10.1.2.15), $cd_p(G(K_s/K))\leq 1$.

For the second assertion, similarly, for $l\neq p$, consider the kernel of x^l, μ_l of l-th roots of unity in K_s, and $H^2(G_l,\mu_l(K_s))=\varinjlim_L H^2(G(K_s/L),\mu_l(K_s))=0$, so $cd_l(G(K_s/K))\leq 1$. Then $cd(G(K_s/K))\leq 1$, and $scd(G(K_s/K))\leq 2$, so $H^i(G(K_s/K),K_s^*)=0$ for $i\geq 1$. □

Prop. (10.1.2.18). For L/K field extension, $cd_p(\mathrm{Gal}_L) \le cd_p(\mathrm{Gal}_K) + \mathrm{tr.deg}(L/K)$.

Proof: Cf.[Etale Cohomology Fulei P169]. □

Cor. (10.1.2.19). If $k = k^s$ and K be a function field over k, then $cd(\mathrm{Gal}_K) \le 1$.
And if K is of char $p > 0$, $H^2(G(K_s/K), K_s^*)$ is a p-torsion group.

Proof: Th first one is clear, for the second, for any $l \ne p$, use the exact sequence $\mu_l(K_s) \to K_s^* \xrightarrow{x \to x^l} K_s^* \to 0$, then $H^2(G(K_s/K), \mu_l(K_s)) = 0$, and $H^2(G(K_s/K), K_s^*) \xrightarrow{l} H^2(G(K_s/K), K_s^*)$ is injective. l is arbitrary, so $H^2(G(K_s/K), K_s^*)$ must be a p-torsion group. □

3 Galois Cohomology

References are [Neukirch, Cohomology of Number Fields]Chap6. Should include [Galois Cohomology Serre].

Prop. (10.1.3.1) [Hilbert's Additive Satz 90]. For $K \in \mathtt{Field}$, if L/K is a Galois extension, then $H^n(\mathrm{Gal}(L/K), L) = 0$ for $n > 0$, where L is equipped with the discrete topology.

Proof: Form the normal basis theorem**??**, for finite Galois extension L/K, L is an induced module over K, thus $H^*(G, L) = H_*(G, L) = 0$ for $* \ne 0$ and $H^*_T(G, L) = 0$ by(10.1.2.7).

Hence the same is true, for arbitrary Galois extension, when L is equipped with the discrete topology, the same as in the proof of(10.1.3.16). □

Prop. (10.1.3.2) [Hilbert's Multiplicative Satz 90]. $H^1(\mathrm{Gal}(L/K), L^\times) = 0$ for any Galois extension L/K, where L is equipped with the discrete topology.

Proof: This follows from(10.1.3.16). □

Prop. (10.1.3.3) [Generalized Hilbert's Additive Satz 90]. For L/K a Galois extension and $k \in \mathbb{Z}_+$, $H^1(\mathrm{Gal}(L/K), W^+_{p,k}(L)) = 0$.

Proof: By linear independence of characters, if L/K is finite, then there is some $x_0 \in L$ s.t. $\mathrm{tr}_{L/K}(x_0) \ne 0$. Then by(4.5.3.17), $x = (x_0, 0, \ldots, 0)$ is a unit in $W^+_{p,k}(L)$. Given any cocycle $\mu : \sigma \mapsto \mu_\sigma$, let

$$\theta = \mathrm{tr}_{L/K}(x)^{-1} \sum_{\sigma \in \mathrm{Gal}(L/K)} \mu_\sigma \sigma(x),$$

then for $\tau \in \mathrm{Gal}(L/K)$,

$$\theta - \tau(\theta) = \mathrm{tr}_{L/K}(x)^{-1} \sum_{\sigma \in \mathrm{Gal}(L/K)} [\mu_{\tau\sigma}(\tau\sigma)(x) - \tau(\mu_\sigma)(\tau\sigma)(x)] = \mathrm{tr}_{L/K}(x)^{-1} \mu_\tau \sum_{\sigma \in \mathrm{Gal}(L/K)} (\tau\sigma)(x) = \mu_\tau.$$

Thus μ is a coboundary.

Hence the same is true, for arbitrary Galois extension, when L is equipped with the discrete topology, the same as in the proof of(10.1.3.16). □

Def. (10.1.3.4) [Galois Cohomologies]. For $k \in \mathtt{Field}$, for any $M \in \mathcal{M}\mathrm{od}^{\mathrm{alg}}(\mathrm{Gal}_k)$, denote $H^i(k, M) = H^i(\mathrm{Gal}_k, M)$.

Prop. (10.1.3.5). $\mathrm{Br}(\mathbb{R}) = \mathbb{Z}/(2)$.

Proof: By(10.1.1.20) and(10.1.1.4), $H^2(\mathrm{Gal}(\mathbb{C}/\mathbb{R}),\mathbb{C}^\times)\cong\{u\in\mathbb{C}^\times|\overline{u}=u\}/\{|u|^2,u\in\mathbb{C}^\times\}\cong\mathbb{Z}/(2)$. □

Prop. (10.1.3.6) [Kummer Cohomology]. For L/K a Galois extension and $\mathrm{char}\,k=p\in\mathbf{P},r\in\mathbb{Z}_+$, then there exists an isomorphism

$$k^\times/(k^\times)^m\xrightarrow{\partial,\cong}H^1(k,\mathbb{Z}/(p^r)).$$

Proof: This follows from the Kummer exact sequence and Hilbert's theorem90(10.1.3.2). □

Prop. (10.1.3.7) [Restrictions and Corestrictions on H^0]. Let K/k be a separable field extension, then

$$\mathrm{res}_k^K=i:k\to K,\quad \mathrm{cor}_k^K=\mathrm{Nm}_{K/k}:K\to k$$

Proof: This follows from the definition(10.1.1.10). □

Cor. (10.1.3.8) [Change of Fields and Kummer Cohomology]. Let K/k be a separable field extension and $m\in\mathbb{Z}\cap k^\times$, then there are commutative diagrams

$$\begin{array}{ccc} k^\times & \xrightarrow{\partial} & H^1(k,\mu_m) \\ \downarrow & & \downarrow\mathrm{res} \\ K^\times & \xrightarrow{\partial} & H^1(K,\mu_m)\end{array}\qquad \begin{array}{ccc} K^\times & \xrightarrow{\partial} & H^1(K,\mu_m) \\ \downarrow\mathrm{Nm}_{K/k} & & \downarrow\mathrm{cor} \\ k^\times & \xrightarrow{\partial} & H^1(k,\mu_m)\end{array}$$

Proof: Cf.[Central Simple Algebras]P131.**?** □

Prop. (10.1.3.9) [Artin-Schreier Cohomology]. Let $k\in\texttt{Field}, m\in\mathbb{Z}\cap k^\times$, then there exists an isomorphism

$$W_{p,r}(k)^+/(\mathrm{Frob}-\mathrm{id})W_{p,r}(k)^+\cong H^1(k,\mu_m).$$

Proof: This follows from the Artin-Schreier exact sequence(10.1.3.3) and Hilbert's theorem90(10.1.3.3). □

Prop. (10.1.3.10) [Unramified Classes]. Let F be a global field and $G=\mathrm{Gal}_F$, then for a Gal_F-module M, is called a **unramified class** at a place $v\in\Sigma_F$ if it is trivial when restricted to $H^k(I_v,M)$, where I_v is the inertia group at v, which is defined only up to conjugacy, but this notion is well-defined by(10.1.1.12).

Prop. (10.1.3.11) [Unramified Classes are Rare]. Let C be a proper Dedekind domain or a complete non-singular curve over a field k with fraction field F and $G=\mathrm{Gal}_F$, then for any finite G_F-module M, if S is a finite set of places in F and $H^1(\mathrm{Gal}_F,M,S)$ the set of elements of $H^1(\mathrm{Gal}_F,M,S)$ that is unramified outside S, then $\#H^1(G_F,M,S)<\infty$.

Proof: By the inflation restriction exact sequence(10.1.1.13), we can reduce G to a subgroup of finite index. And because M is a finite G-module, there is a finite index subgroup of G that acts trivially on M. Thus we can assume M is G-trivial. But then if $m>0$ s.t. $mM=0$, then the assertion follows from the fact the maximal Abelian extension of exponent m unramified outside S is finite over K(12.6.4.4). □

Non-Abelian Cohomology

Def. (10.1.3.12) [Non-Abelian Cohomology]. Let G, M be topological groups, with a continuous action of G on M, then we define $H^0(G,M) = M^G$.

We define $Z^1(G,M)$=continuous maps $x : G \to M$ that

$$\sigma_1(x(\sigma_2))x(\sigma_1\sigma_2)^{-1}x(\sigma_1) = 1, \quad \text{i.e.} \quad x(gh) = x(g)g(x(h))$$

If $x \in Z^1(G,M)$, then $x_m : \sigma \to m^{-1}x(\sigma)\sigma(m) \in Z^1(G,M)$ too. This defines an equivalence relation on $Z^1(G,M)$, the equivalence classes are called $H^1(G,M)$. This is compatible with the commutative case.

Prop. (10.1.3.13). Restriction map and inflation map is definable for H^0 and H^1, and $H^1(H,M)$ is a G/H-set where G acts on $H^1(H,M)$ by $g(c)(h) = g(c(g^{-1}hg))$.

Prop. (10.1.3.14). There is an exact sequence of pointed sets:

$$0 \to H^1(G/H, M^H) \xrightarrow{\text{inf}} H^1(G,M) \xrightarrow{\text{res}} H^1(H,M)^{G/H}.$$

Proof: First $\text{res}(H^1(G,M)) \subset H^1(H,M)^{G/H}$ because $g(c)(h) = c(g)^{-1}c(h)h(c(g))$ is checked so $g(c)$ is cohomologous to c.

$\text{res} \circ inf = 0$ is easy, if $\text{res}(c) = 0$, then c is trivial on H, hence $c(gh) = c(g)$ and $h(c(g)) = c(hg) = c(g \cdot g^{-1}hg) = c(g)$, so c is inflated from $H^1(G/H, M^H)$.

For the injectivity of inf. If $c(\overline{g}) = g^{-1}g(a)$, then $a \in M^H$, so it is a coboundary in $H^1(G/H, M^H)$. □

Prop. (10.1.3.15). Let $1 \to A \to B \to C \to 1$ be an exact sequence of G-groups, then there is a long exact sequence of pointed sets

$$1 \to A^G \to B^G \to C^G \xrightarrow{\delta} H^1(G,A) \to H^1(G,B) \to H^1(G,C) \xrightarrow{\Delta} H^2(G,A)$$

the last term is defined only when A is in the center of B.

Where δ is defined as follows: for $c \in C^G$, let b be an inverse image of c in B, then $a_\sigma = b^{-1}\sigma(b) \in A$, and it defines a cocycle in $H^1(G,A)$, different choice differ by a coboundary, so it is well-defined.

Δ is defines as: for c_σ a cocycle in $H^1(G,C)$, choose b_s inverse images of c_s, then $a_{\sigma,\tau} = b_\sigma\sigma(b_\tau)b_{\sigma\tau}^{-1}$ is a cocycle in $H^2(G,A)$.

Proof: Similar to (5.3.2.19), but need to show continuity**?** □

Prop. (10.1.3.16) [Hilbert's Theorem 90]. For $L/K \in \text{Gal}$, $H^1(\text{Gal}(L/K), \text{GL}_n(L)) = 1$, where L is equipped with the discrete topology.

Proof: We prove any cocycle is a coboundary, for this, notice any cocycle factor through a finite quotient, and the images of it is contained in a finite extension of K, hence it reduce to the case of L/K finite.

By definition, this is equivalent to any B-semi-linear representation of G free of finite rank is trivial, which is by(15.1.1.14). □

Cor. (10.1.3.17). $H^1(G(L/K), \text{SL}_n(L)) = 1$. This is seen from the exact sequence $1 \to \text{SL}(n,L) \to \text{GL}(n,L) \to L^\times \to 1$.

Interpretation of H^1 and Torsors

Def. (10.1.3.18) [A-Torsors]. A G-set X is a discrete set with a continuous G-action on X. Let A be a G-group, an **A-torsor** is a G-set with a right A-action that is simply transitive and semi-linear in G.

Prop. (10.1.3.19) [H^1 and Torsors]. We have a canonical bijection of pointed sets: $H^1(G,A) \cong TORS(A)$.

Proof: Let X be an A-torsor, choose $x \in X$, then $\sigma(x) = xa_\sigma$ for $a_\sigma \in A$. Now that $\sigma \mapsto a(\sigma)$ is checked to be a cocycle, and change of x changes to $\sigma \mapsto b^{-1}a_\sigma\sigma(b)$. Conversely, for an $a \in H^1(G,A)$, we let $X = A$ be a right A-module, and let $\sigma'(x) = a_\sigma\sigma(x)$, i.e. regarding coming from $x = 1$, then this is a inverse map. □

Prop. (10.1.3.20) [Extension of Rings].

Prop. (10.1.3.21). There is an isomorphism of pointed sets $H^1(G, O(\varphi_L)) \cong E_\varphi(L/K)$.

Proof: Cf.[Neukirch Cohomology of Number Fields P346]. □

4 Continuous Cohomologies

In this subsubsection cohomology of G-modules with topology is studied. References are [Cohomology of Number Fields, Neukirch Chap 2.7].

Prop. (10.1.4.1). $H^*_{\text{cont}}(G,-)$ forms a long exact sequence for any $0 \to A \to B \to C \to 0$ of continuous G-modules.

Proof: ? □

Prop. (10.1.4.2). If A is a compact G-module which is an inverse limit of finite discrete G-modules A_n, then if $H^i(G,A_n)$ is finite for all n, then

$$H^{i+1}_{\text{cont}}(G,A) = \varprojlim_n H^{i+1}(G,A_n).$$

Proof: Cf.[Cohomology of Number Fields Neukirch P142]. □

Lemma (10.1.4.3). Let π be a topologically nilpotent element of A which is complete in the ϖ-adic topology and ϖ is not a zero-divisor, let $R = A/(\varpi)$ equipped with discrete topology. Let G be a group which acts continuously on A and fix π, then if $H^1(G,R)$ is trivial, then $H^1(G,A)$ is trivial, and if moreover $H^1(G,GL(n,R))$ is trivial, then $H^1(G,GL(n,A))$ is trivial.

Proof: Cf.[Galois Representations Berger P15]. □

Prop. (10.1.4.4) [Cyclic Case]. if G is a topological cyclic group $\overline{\langle g\rangle}$, then the map $H^1(G,M) \to M/(1-g)$ is well-defined and injective. And when M is profinite, p-adically complete, then the map is also surjective.

Proof: The surjection: there is only one choice: $c(g^i) = (1+g+\ldots+g^{i-1})(m)$. And we need to verify that it is continuous. The case of p-adic can be deduced from profinite case, because $c(\gamma) \in p^{-k}M$ for some k, and $p^{-k}M$ is then profinite. For any finite quotient N of M, there is a k that $kM = 0$, and a n that $g^n = \text{id}$ on N, so $c(g^{rkn}) = 0$ on N, which shows c is continuous. □

Prop. (10.1.4.5) [Inf-Res Exact Sequence].

Prop. (10.1.4.6) [Cohomology as Extensions]. Let G be a topological group acting on a field K and $W \in \mathrm{Rep}_K(G)$, there exists a bijection continuous extensions

$$0 \to W \to W' \to K \to 0$$

and $H^1_{\mathrm{cont}}(G, W)$ that is K-linear.

Proof: For any such extension, choose a K-linear splitting $W' \cong W \oplus K$, then

$$g(w, c) = (g(w) + g(c)\tau(g), g(c)),$$

where $\tau : G \to W$ is a continuous 1-coboundary in $H^1(G, W)$, and clearly changing a splitting changes this coboundary by a 1-cocycle, and it is clearly a bijection. □

10.2 Condensed Mathematics(Scholze)

Main references are [Condensed Mathematics, Scholze]. [Lectures on Condensed Mathematics, Clausen-Scholze], [Lectures on Analytic Geometry, Clausen-Scholze].

Notation (10.2.0.1).

- Use notations defined in Profinite Cohomology.

1 Introduction

Remark (10.2.1.1). Delete this subsection.?

Condensed mathematics is invented to overcome the subtleties when dealing with algebra together with topology. For example, the category of topological Abelian groups doesn't form an Abelian category.

2 Condensed Objects

Def. (10.2.2.1) [κ-Condensed Objects]. The pro-étale site $*_{pro\,\text{ét}}$ of a point is isomorphic to $\mathcal{P}\mathrm{rof}$ in the standard topology. For any uncountable strong limit cardinal κ, the site $\mathcal{P}\mathrm{rof}_\kappa$ is the category of κ-small profinite sets S in the standard topology.

Then for any $\mathcal{C} \in \mathcal{C}\mathrm{at}$, we can define the category $\mathrm{Cond}_\kappa(\mathcal{C})$ of **κ-condensed objects** in $\mathcal{C}$ to be the category $\mathrm{Func}(\mathcal{P}\mathrm{rof}_\kappa, \mathcal{C})$.

Prop. (10.2.2.2) [Adjointness]. Given an uncountable strong limit cardinal κ, the functors

$$X \mapsto \underline{X} : \mathcal{T}\mathrm{op} \,/\, \mathcal{G}\mathrm{rp} \,/\, \mathcal{CA}\mathrm{lg} \to \mathrm{Cond}(\mathcal{S}\mathrm{et}) / \mathrm{Cond}(\mathcal{G}\mathrm{rp}) / \mathrm{Cond}(\mathcal{CA}\mathrm{lg})$$

are faithful, and fully faithful when restricted to the category of κ-small objects.

And there is an adjunction

$$X \mapsto \underline{X} : \mathcal{T}\mathrm{op} \rightleftharpoons \mathrm{Cond}(\mathcal{S}\mathrm{et}) : T \mapsto T(*)_{\mathrm{top}} = \varinjlim_{S \in \mathcal{P}\mathrm{rof}_\kappa / T} S.$$

In particular, $\underline{X}(*)_{\mathrm{top}} \cong X_{\kappa\text{-}\mathcal{CG}}$.

Proof: Firstly, $\underline{X}$ is truly a condensed set: for the sheaf condition, let $S' \to S$ be surjective morphism of profinite spaces, then the sheaf condition is true set-theoretically, and for any map $S \to T$, if $S' \to S \to T$ is continuous, then $S \to T$ is continuous, because $S' \to S$ is a closed map.

It suffices to check the set case, and the faithfulness and fully faithfulness follows from the adjointness

$$\mathrm{Hom}_{\kappa\text{-}\mathrm{Cond}(\mathcal{S}\mathrm{et})}(T, \underline{X}) = \mathrm{Hom}(T(*)_{\mathrm{top}}, X).$$

Notice that any $s \in T(S)$ induces a map of sets $\overline{s} : S \to T(*) : x \mapsto T(* \xrightarrow{x} S)(s)$, inducing the topology of $T(*)$. And by definition, a morphism $T \to \underline{X}$ is just a morphism $T(*) \to X$ that for any $S \to T$, the composition $S \to T(*) \to X$ is continuous. And by definition, this is just a morphism from $T(*)_{\mathrm{top}} \to X$.

The last assertion follows from the fact any compact Hausdorff space S is a quotient space of its Stone-Čech compactification. □

Prop. (10.2.2.3)[Free Condensed Abelian Groups]. By the adjoint functor theorem(3.1.1.34), the forgetful functor from $\mathrm{Cond}(\mathcal{A}\mathrm{b})$ to $\mathrm{Cond}(\mathcal{S}\mathrm{et})$ has a left adjoint $T \mapsto \mathbb{Z}[T]$. Concretely, $\mathbb{Z}[T]$ is the sheafification of the functor that sends a compact Hausdorff space S to the free Abelian group $\mathbb{Z}[T(S)]$. In particular, by Yoneda lemma, for any compact Hausdorff space S, there is a condensed Abelian group $\mathbb{Z}[S]$ that for any condensed Abelian group M, $\mathrm{Hom}(\mathbb{Z}[S], M) = M(S)$.

Lemma (10.2.2.4). Consider the site of all κ-small compact Hausdorff topological spaces, then the category of sheaves on this site is equivalent to that of $\mathcal{P}\mathrm{rof}_\kappa$(via restriction).

Proof: Use(5.1.2.25), because any κ-small compact Hausdorff space is a quotient space of a κ-small profinite space(βS_0(3.3.2.15), noticing that $|\beta S| \le 2^{2^{|S|}} < \kappa$). □

Lemma (10.2.2.5). Consider the site of all κ-small extremally disconnected spaces, then the category of sheave son this site is equivalent to that of κ-small condensed sets, via restriction.

Proof: Because any κ-small compactly generated space is a quotient space of a κ-small extremally disconnected space(βS(3.3.2.17), noticing that $|\beta S| \le 2^{2^{|S|}} < \kappa$). □

Cor. (10.2.2.6) [$\mathrm{Cond}(\mathcal{A}\mathrm{b})$ and Extremally Disconnected Spaces]. The category of κ-condensed Abelian groups is equivalent to the category of presheaves $\mathcal{F}$ on the category of κ-extremally disconnected spaces that $\mathcal{F}(\varnothing) = 0$ and $\mathcal{F}(S_1 \coprod S_2) = \mathcal{F}(S_1) \times \mathcal{F}(S_2)$.

Proof: It suffices to show that the second sheaf condition is automatic: For a surjective map of extremally disconnected spaces $f : \widetilde{S} \to S$, there is an isomorphism

$$\mathcal{F}(S) \xrightarrow{\mathcal{F}(f)} \{g \in \mathcal{F}(\widetilde{S}) | \mathcal{F}(p_1)(g) = \mathcal{F}(p_2)(g)\}.$$

By(3.3.1.30), there is a section $\sigma : S \to \widetilde{S}$ that $f \circ \sigma = \mathrm{id}_S$, thus $\mathcal{F}(\sigma) \circ \mathcal{F}(f) = \mathrm{id}$, thus $\mathcal{F}(f)$ is injective. For the surjectivity, suppose $\mathcal{F}(p_1)(g) = \mathcal{F}(p_2)(g)$, then

$$\mathcal{F}(p_2)(\mathcal{F}(f)\mathcal{F}(\sigma)(g)) = \mathcal{F}((\sigma \circ f) \times_S \mathrm{id}_{\widetilde{S}})\mathcal{F}(p_1)(g) = \mathcal{F}((\sigma \circ f) \times_S \mathrm{id}_{\widetilde{S}})\mathcal{F}(p_2)(g) = \mathcal{F}(p_2)(g)$$

And similarly $\mathcal{F}(p_2)$ is injective, thus $g = \mathcal{F}(f)\mathcal{F}(\sigma)(g)$ is in the image. □

Prop. (10.2.2.7)[Category of Condensed Abelian Groups]. The category of κ-condensed Abelian groups satisfies Grothendieck's Axiom $AB3, AB4, AB5, AB6, AB3^*, AB4^*$. And also it is generated by compact projective objects.

Proof: We use(10.2.2.6). Because all limits and colimits of Abelian groups commutes with finite products, the limits and colimits in the category of condensed Abelian groups are just the pointwise limits and colimits, thus the axioms follow form that of the category $\mathcal{A}\mathrm{b}$.

By(10.2.2.3), the condensed Abelian group $\mathbb{Z}[S]$ for S κ-extremally disconnected satisfies $\mathrm{Hom}(\mathbb{Z}[S], M) = M(S)$, and by arguments above, $M \to M(S)$ commutes with all limits and colimits, thus $\mathbb{Z}[S]$ is compact and projective. And we show every M admits a surjection from some direct sum of $\mathbb{Z}[S]$: use Zorn's lemma, choose the maximal object M' that admits a surjection, if $M/M' \neq 0$, then find a nonzero map $\mathbb{Z}[S] \to M/M'$(because $M(S) = 0$ for any S implies $M = 0$), then it lifts to a nonzero map $\mathbb{Z}[S] \to M$ by projectivity, contradiction. □

Cor. (10.2.2.8).

- We can define the tensor of two condensed Abelian groups M, N as the shifification of the presheaf $S \mapsto M(S) \otimes N(S)$.

- We can define an internal Hom, which is right adjoint to tensor operator. In particular, for any compact Hausdorff space S, $\underline{\mathrm{Hom}}(M,N)(S) = \mathrm{Hom}(\mathbb{Z}[S]\otimes M, N)$.
- The derived category $D(\mathrm{Cond}(\mathcal{A}\mathrm{b}))$ is also compactly generated, and we can define Rtensor and RHom as in2.

Proof: Cf.[Condensed Mathematics, P13].? □

Prop. (10.2.2.9). Let $\kappa' > \kappa$ be uncountable strongly limit cardinals, then there is a natural functor from the set of κ-condensed sets to the category of κ'-condensed sets by pulling back along the morphism of sites $\mathcal{P}\mathrm{rof}_{\kappa'} \to \mathcal{P}\mathrm{rof}_{\kappa}$. Then this functor is fully faithful and commutes with all colimits and λ-small limits, where λ is the cofinality of κ.

Proof: This should have something to do with(5.1.2.25), thus it is left adjoint to the restriction functor and $i^s i_s \cong \mathrm{id}$, thus it is fully faithful and commutes with all colimits. For the limits, cf.[Condensed Mathematics, P14].? □

Def. (10.2.2.10) [Condensed Objects]. For any $\mathcal{C} \in \mathcal{C}\mathrm{at}$, define the category $\mathrm{Cond}(\mathcal{C})$ of **condensed objects** in $\mathcal{C}$ is defined to be the filtered colimits of the category of κ-condensed sets along the filtered poset of all uncountable limit cardinals κ.

Prop. (10.2.2.11). If X is a T1 topological space, then $\underline{X}$ is a condensed set that all maps from points are quasicompact. Conversely, if T is a condensed set that all maps from points are quasicompact, then $T(*)_{\mathrm{top}}$ is a compactly generated $T1$ space.

Proof: Cf.[Condensed Mathematics, P16].? □

Prop. (10.2.2.12) [$\mathcal{T}\mathrm{op}$ and $\mathrm{Cond}(\mathcal{S}\mathrm{et})$].

- The functor $X \mapsto \underline{X}$ induces an equivalence between compact Hausdorff space and qcqs condensed sets.
- A compactly generated space X is weak Hausdorff iff $\underline{X}$ is quasi-separated. For any quasi-separated condensed set T, the space $T(*)_{\mathrm{top}}$ is compactly generated weak Hausdorff.

Proof: Cf.[Condensed Mathematics, P16].? □

Prop. (10.2.2.13). The example $(R, \mathrm{disc}) \to (\mathbb{R}, \mathrm{Nat})$.?

In particular, enlarging topological abelian groups into an abelian category precisely forces us to include non-quasi-separated objects.

3 Cohomologies

Prop. (10.2.3.1). For any set I, there is an isomorphism

$$\check{H}^i(\prod_I S^1, \mathbb{Z}) \cong \bigwedge^i(\oplus_I \mathbb{Z}).$$

preserving the natural cup product.

Proof: If I is finite, this follows from the classical calculation of the cohomology of the tori. If I is infinite, then we should use lemma(10.2.3.2) below. □

Lemma (10.2.3.2). If $S_j, j \in J$ is a filtered system of compact Hausdorff spaces and $S = \varprojlim_{j\in J} S_j$, then there are natural maps

$$\varinjlim_j \check{H}^i(S_j, \mathbb{Z}) \to \check{H}^i(S, \mathbb{Z})$$

are isomorphisms.

Proof:

□

Prop. (10.2.3.3) [$\mathbb{Z}$-Cohomology]. Let S be a compact Hausdorff space, then there are natural functorial isomorphisms

$$H^i(S, \underline{\mathbb{Z}}) \cong H^i_{\mathrm{Cond}}(S, \mathbb{Z}).$$

Proof: Because the Čech and sheaf cohomology of S are equal by(5.3.5.13), it suffices to calculate for Čech cohomology.

Firstly, if S is a profinite set, let $S = \varprojlim_j S_j$ where S_j are finite, then □

Prop. (10.2.3.4) [$\mathbb{R}$-Cohomologies Vanish]. For any compact Hausdorff space S,

$$H^i_{\mathrm{Cond}}(S, \mathbb{R}) = 0$$

for $i > 0$, and $H^0(S, \mathbb{R}) = C(S, \mathbb{R})$.

Proof: Cf.[Condensed Mathematics, P21]. □

4 LCAs

5 Solid Abelian Groups

Def. (10.2.5.1) [Solid Abelian Group]. For a profinite set $S = \varprojlim S_i$, define the condensed Abelian group

$$\mathbb{Z}[S]^{\blacksquare} = \varprojlim \mathbb{Z}[S_i].$$

There is a natural map $S \to \mathbb{Z}[S]^{\blacksquare}$, inducing a map $\mathbb{Z}[S] \to \mathbb{Z}[S]^{\blacksquare}$.

Then a **solid Abelian group** is a condensed Abelian group A that for any profinite set S and a morphism of Abelian groups $\mathbb{Z}[S] \to A$ extends to a morphism $\mathbb{Z}[S]^{\blacksquare} \to A$.

A complex $C \subset D(\mathrm{Cond}(\mathcal{A}\mathrm{b}))$ is called a **solid complex** if for all profinite set S, the natural map

$$R\operatorname{Hom}(\mathbb{Z}[S]^{\blacksquare}, C) \to R\operatorname{Hom}(\mathbb{Z}[S], C)$$

is an isomorphism.

Prop. (10.2.5.2) [Free Solid Abelian Group]. For a profinite set S,

- Consider**?**
  $$\mathbb{Z}[S]^{\blacksquare} = \varprojlim \mathbb{Z}[S_i] = \varprojlim \underline{\operatorname{Hom}}(C(S_i, \mathbb{Z}), \mathbb{Z}) = \underline{\operatorname{Hom}}(C(S, \mathbb{Z}), \mathbb{Z}).$$
  This means that the underlying Abelian group of $\mathbb{Z}[S]^{\blacksquare}$ is the $\mathbb{Z}$-valued measures on S.
- There is some set $|I| \le 2^{|S|}$, that there is an isomorphism $\mathbb{Z}[S]^{\blacksquare} \cong \prod_I \mathbb{Z}$.
- $\mathbb{Z}[S]^{\blacksquare}$ is solid both as a module and a complex.

Proof: 2: Take an isomorphism $C(S,\mathbb{Z})\cong\oplus_I\mathbb{Z}$**?**, then

$$\mathbb{Z}[S]^{\blacksquare}=\underline{\mathrm{Hom}}(C(S,\mathbb{Z}),Z)\cong\underline{\mathrm{Hom}}(\bigoplus_I\mathbb{Z},\mathbb{Z})\cong\prod_I\mathbb{Z}.$$

3: We need to show the extension property, but by2, it suffices to show for $\mathbb{Z}[S]^{\blacksquare}=\mathbb{Z}$.**?** □

Prop. (10.2.5.3) [Category of Solid Abelian Groups]. The category Solid $\subset$ Cond($\mathcal{A}$b) is an Abelian subcategory that is stable under all limits, colimits and extensions. The objects $\prod_I\mathbb{Z}$, where I is any set, form a family of compact projective generators. The inclusion Solid $\subset$ Cond($\mathcal{A}$b) admits a left adjoint $M\mapsto M^{\blacksquare}$ which is the unique colimit-preserving extension of $\mathbb{Z}[S]\mapsto\mathbb{Z}[S]^{\blacksquare}$.

The functor $D(\text{Solid})\to D(\text{Cond}(\mathcal{A}\text{b}))$ is fully faithful and its essential image is precisely the solid Abelian groups, and the inclusion admits a left adjoint $C\to C^{L\blacksquare}$ which is left derived functor of $M\to M^{\blacksquare}$.

7 Complex Geometry

10.3 Topological Commutative Algebra

Main references are [Hub93], [Bos15], [B-S19], [Mor19] and [Sch12].

1 Topological Abelian Groups and Rings

Def. (10.3.1.1) [Topological Rings]. A **topological Abelian group** is an Abelian group with a topology structure that the addition and inversion are all continuous.

A **topological ring** is a ring endowed with a topology structure that the addition, multiplication and inversion are all continuous.

Similarly we can define a **topological module** over a topological ring.

Def. (10.3.1.2) [Topologically Nilpotent Element]. Let A be a topological ring, then $x \in A$ is called **topologically nilpotent** iff $x^n \to 0$ when $n \to \infty$.

Def. (10.3.1.3) [Bounded Sets]. A subset S in a topological ring is called **bounded** iff for all open nbhd U of 0, there exists an open nbhd V of 0 that $VS \subset U$

Def. (10.3.1.4)[Strict Morphism]. A **strict morphism** of topological rings is a continuous morphism that the quotient topology and the subspace topology coincides on the image.

Completion of Topological Abelian Groups

Prop. (10.3.1.5) [Completion]. There exists a completion functor left adjoint to the forgetful functor from the category of complete topological Abelian groups to the category of topological Abelian groups, given by Cauchy filters.

Proof: □

Prop. (10.3.1.6) [Subgroups and Completion]. Let A be a topological Abelian group, then the completion $i : A \to A^\wedge$ induces a bijection between the set of open subgroups of A and the open subgroups of $A^\wedge$, given by $G \mapsto \overline{i(G)} = G^\wedge$.

Proof: Cf.[Mor19]P74. □

Def. (10.3.1.7) [Restricted Power Series]. Let R be a topological ring, then we can define the **restricted power series** over R to be

$$R\langle X_1, \ldots, X_n\rangle = \{\sum a_v X^v \in R[[X_1, \ldots, X_n]] | \lim_{v\to\infty} a_v \to 0\}$$

Adic Rings

Def. (10.3.1.8) [Adic Rings]. An **adic ring** R is a topological ring that the topology coincides with the $\mathfrak{a}$-adic topology for some ideal $\mathfrak{a}$ of R, and any such $\mathfrak{a}$ is called a **ideal of definition**.

Prop. (10.3.1.9) [Topologically Nilpotent Elements]. Let A be an adic ring and $x \in A$, then the following are equivalent:

- x is topologically nilpotent.
- There exists an ideal of definition I that the image of x in A/I is nilpotent.
- There exists an ideal of definition I that $x \in I$.

In particular, the set A^{00} of nilpotent elements is an open radical ideal of A, and it is the union of all ideals of definitions in A.

Proof: $3 \to 1 \to 2$ is trivial. $2 \to 3$: if x is nilpotent in A/I, let $J = I + xA$, then J is an open ideal, and $J^n \in I$, so I-adic and J-adic topologies on A coincide, so J is an ideal of definition.

The rest is easy. □

Prop. (10.3.1.10)[Adic Localization]. If R is an adic ring with an ideal of definition $\mathfrak{a}$, the restricted power series $R\langle\xi\rangle$ is complete w.r.t. the $(\mathfrak{a})$-adic topology, and in fact

$$R\langle\xi\rangle \cong \varprojlim_n R/\mathfrak{a}^n[\xi].$$

For $f \in R$, we can define the **adic completion** of R at f to be the

$$R\langle f^{-1}\rangle = \varprojlim_n (R/\mathfrak{a}^n[\frac{1}{f}]).$$

The the natural map $R\langle\xi\rangle \to R\langle f^{-1}\rangle$ induces an isomorphism

$$R\langle\xi\rangle/(1-f\xi) \cong R\langle f^{-1}\rangle.$$

Proof: There is an isomorphism $R[f^{-1}]/(\mathfrak{a}^n) \cong (R/\mathfrak{a}^n)[f^{-1}]$ because localization is flat, so we are done. □

Remark (10.3.1.11). There is another canonical morphism $R[f^{-1}] \to R\langle f^{-1}\rangle$ which exhibits $R\langle f^{-1}\rangle$ as the completion of $R[f^{-1}]$ w.r.t. the ideal $\mathfrak{a}R[f^{-1}]$.

Then $R\langle f^{-1}\rangle$ is endowed with an $\mathfrak{a}$-adic topology, and if $\mathfrak{a}$ is f.g., then $R\langle f^{-1}\rangle$ is complete w.r.t. to the $\mathfrak{a}R\langle f^{-1}\rangle$-adic topology. Also we see $R\langle f^{-1}\rangle$ doesn't depend on the choice of ideal of definition of $\mathfrak{a}$.

Proof: Consider the projective system of exact sequences:

$$0 \to (1-f\xi)R/\mathfrak{a}^n[\xi] \to R/\mathfrak{a}^n[\xi] \to R/\mathfrak{a}^n[f^{-1}] \to 0.$$

which is a surjective system so by Mittag-Leffler(3.1.1.44), $\varprojlim$ is exact(4.9.3.2), and there is an exact sequence

$$0 \to \varprojlim_n (1-f\xi)R[\xi] \to \varprojlim_n R[\xi] \to \varprojlim_n R[f^{-1}] \to 0.$$

Now $\varprojlim_n (1-f\xi)R[\xi] \cong (1-f\xi) \cong (1-f\xi)R\langle\xi\rangle$, because $(1-f\xi)$ is not a zero-divisor in $R/\mathfrak{a}^n$, and we get the desired isomorphism. □

Def. (10.3.1.12) [Completed Tensor Product]. Let $(A,\mathfrak{a}),(B,\mathfrak{b})$ be two complete adic rings, then we can define a **complete tensor product** ring $A\widehat{\otimes}B$ as

$$A\widehat{\otimes}B = \varprojlim_n (A/\mathfrak{a}^n \otimes B/\mathfrak{b}^n)$$

this is just the $(\mathfrak{a}\otimes B + A\otimes b)$-adic completion of the tensor product $A\otimes B$, because $(\mathfrak{a}\otimes B + A\otimes b)^n$ and $(\mathfrak{a}^n \otimes B + A\otimes \mathfrak{b}^n)$ are cofinal.

Properties of R-Algebras

Def. (10.3.1.13) [Topologically of Finite Presentation]. Let R be an adic ring with an ideal of definition I, then an R-algebra A is called

- **of topologically finite type** if it is isomorphic to an R-algebra $R\langle\zeta_1,\dots,\zeta_n\rangle/\mathfrak{a}$ that is endowed with the I-adic topology and $\mathfrak{a}$ is an ideal of $R\langle\zeta_1,\dots,\zeta_n\rangle$.
- **of topologically finite presentation** if moreover the ideal $\mathfrak{a}$ is f.g..
- **admissible** if it is of topologically finite presentation and has no I-torsion.

Prop. (10.3.1.14) [Raynaud–Gruson]. Let A be an R-algebra of topologically finite type and M a finite A-module that is flat over R. Then M is an A-module of finite presentation.

Proof: Cf.[Bos15]P165. □

Cor. (10.3.1.15). Let A be an R-algebra of topologically finite type, then if A has no I-torsion, then A is of topologically finite presentation, in particular admissible(10.3.1.13).

Proof: Cf.[Bos15]P166. □

Prop. (10.3.1.16) [Topologically of Finite Presentation is Local]. Let A be an R-algebra that is I-adically complete and separated, $f_1,\dots,f_r$ be a set of elements generating the unit ideal, then A is of topologically finite type/topologically finite presentation/admissible iff each $A\langle f_i^{-1}\rangle$ does.

Proof: Cf.[Bos15]P169. □

2 Valuation Rings

Def. (10.3.2.1) [Valuation Ring]. A **valuation ring** is the maximum elements in the dominating ordering of local rings in a field K, where B **dominates** A iff $A\subset B$ and $\mathfrak{m}_B\cap A=\mathfrak{m}_A$.

A valuation ring in K is called **absolutely algebraically closed** if K is alg.closed.

Prop. (10.3.2.2) [Valuation is Maximal]. Any local ring A in a field K is dominated by a valuation ring with fractional field K.

Proof: Note that the dominating relation satisfies the condition of the Zorn's lemma, so it suffices to prove that A is not maximal if its fractional field is not K. Let $t\notin K_0=\operatorname{frac}A$. If t is transcendental over K_0, then $A[t]$ with the maximal ideal $(\mathfrak{m},t)$ dominate A. If t is algebraic over K_0, then there is a a that at is integral over A, hence by(4.2.1.5) there is a maximal ideal of $A[at]$ above A, which proves the lemma. □

Prop. (10.3.2.3) [Valuation Ring Criterion]. A is a valuation ring with field of fraction K iff for any $x\in K$, x or x^{-1} is in A.

Proof: If A is a valuation ring, then for $x\notin A$, we know that $A[x]$ is a local ring, hence there is no prime over $\mathfrak{m}$ otherwise $A[x]_\mathfrak{p}$ is a bigger local ring, so we see $\mathfrak{m}A[x]=A[x]$, i.e. $1=\sum t_ix^i$, so x^{-1} is integral over A. Now $A[x^{-1}]$ has a $\mathfrak{m}'$ over $\mathfrak{m}$, so $A=A[x^{-1}]_{\mathfrak{m}'}$, which shows $x^{-1}\in A$.

Conversely, if for any $x\in K$, x or x^{-1} is in A, we assume A is not K, so A is not field by the condition. Then it has a non-zero maximal ideal, but only one, otherwise we can choose x,y that $x/y,y/x\notin A$. And A is maximal because if there is a $A\subset A'$, and a $x\in A'$, then if $x\notin A$, then $x^{-1}\in A$, hence also in $\mathfrak{m}_A$, so it is in $\mathfrak{m}_{A'}$, but now x^{-1} cannot be in A', contradiction. □

Cor. (10.3.2.4). For $K \subset L$ subfield, if A is a valuation ring of L, then $A \cap K$ is a valuation ring of K. And if L/K is algebraic and A is not a field, then $A \cap K$ is not a field.(This is because the primes of A are all over 0 so cannot contain each other(4.2.1.5) so A is a field).

Cor. (10.3.2.5). The quotient A/p at a prime is a valuation ring, and any localization of valuation ring is a valuation ring, by this criterion.

Prop. (10.3.2.6)[Valuation Ring is Normal]. Valuation ring is normal, because for x algebraic over A, either $x \in A$, or x is a combination of x^{-1} thus in A, by(10.3.2.3).

Cor. (10.3.2.7)[Integral Closure and Valuation Ring]. The integral closure of a subring in a field K is the intersection of valuation rings containing A.

Proof: Valuation ring is integrally closed, so it suffices to prove if x is not algebraic over A, then there is a valuation ring of A not containing x. This is because $x \notin B = A[x^{-1}]$ otherwise x is integral over A. Now x^{-1} is not a unit in B, hence $x \in p \in B$, hence B_p is dominated by some valuation ring V, and $x \notin V$ because $x^{-1} \in \mathfrak{m}_V$. □

Prop. (10.3.2.8)[Bezout Domain and Valuation Ring]. A valuation ring is equivalent to a Bezout local domain.

Proof: One way is because the element of minimum valuation generate the ideal. Conversely, for $f, g \in A$, $(f, g) = (h)$, so $f = ah, g = bh$, and $h = cf + dg$, then $ab + cd = 1$, hence a or b is a unit, so $f/g \in A$ or $g/f \in A$. By(10.3.2.3), A is a valuation ring. □

Prop. (10.3.2.9). A valuation ring is Noetherian iff it is discrete valuation iff it is PID.

Proof: Only need to prove Noetherian then $\Gamma = \mathbb{Z}$. we know ideals of Γ of the form $\{x|x \geq \gamma\}$, where $\gamma > 0$ has a maximal element, so there is a minimal element bigger than 0, so $\Gamma \cong \mathbb{Z}$. □

Prop. (10.3.2.10). In a fixed field, any inclusion relation of two valuation ring is given by localization.

Proof: Just localize at the image of the maximal ideal $\mathfrak{m}_B \cap A$, then they are valuation rings(10.3.2.5) that dominate each other, thus they are the same by definition(10.3.2.1). □

Def. (10.3.2.11) [Extension of Valuation Rings]. An injective local homomorphism of valuation rings is called an **extension of valuation rings**. By(4.4.1.29), it is equivalent to a f.f. morphism of valuation rings.

3 Valuations

Def. (10.3.3.1) [Valuations]. A **valuation** on a field K is surjective map $v : K \to \Gamma$ where Γ is an ordered Abelian group(2.2.8.1), called the **value group** of K.

The **rank of a valuation** is defined as the height of its value group(2.2.8.4).

Prop. (10.3.3.2)[Valuation Ring and Valuation]. Valuation rings(10.3.2.1) A of a field K is equivalent to valuations on K(10.3.3.1).

The equivalence is given by $K = Q(A)$, $\Gamma = K^*/A^*$ and that $A = v^{-1}(\{x \geq 0\})$.

Proof: These are definitely valuation rings, and if A is a valuation ring by(10.3.2.3), then we set $\Gamma = K^*/A^*$, where A^* is the invertible elements of A and $x \leq y$ iff $y/x \in (A - \{0\})/A^*$. This is totally ordered by(10.3.2.3). □

Cor. (10.3.3.3) [Rank and Dimension]. A valuation ring of rank n has Krull dimension n, because clearly the convex subgroups of Γ is in bijection with ideals of A.

Prop. (10.3.3.4) [DVRs]. For a Noetherian local domain A of dimension 1 with maximal ideal $\mathfrak{m}$ and residue field k that is not a field, the following are equivalent:

1. A is a valuation ring corresponding to a discrete valuation in(10.3.3.2).
2. A is normal.
3. $\mathfrak{m}$ is a principal ideal.
4. A is regular.
5. Every nonzero ideal is a power of $\mathfrak{m}$.
6. There exists a $x \in A$ that every nonzero ideal is of the form (x^k).

Such a ring is called a **discrete valuation ring** or a DVR.

Proof: $1 \to 2$: Valuation ring is integrally closed, by(10.3.2.6).

$2 \to 3$: As the radical of any non-trivial ideal (a) is $\mathfrak{m}$, and A is Noetherian, so there is an n that $\mathfrak{m}^n \subset a$ and $\mathfrak{m}^{n-1} \not\subset a$. Then choose $b \in a - \mathfrak{m}^{n-1}$, $x = a/b \in K$, then $x^{-1} \notin A$, then it is not integral over A. So $x^{-1}\mathfrak{m} \not\subset \mathfrak{m}$, but $x^{-1}\mathfrak{m} \subset A$, so it equals A, which means $\mathfrak{m} = (x)$.

$3 \to 4$: Clear.

$4 \to 5$: For any ideal a, its radical is $\mathfrak{m}$ and A is Noetherian, so $\mathfrak{m}^n \subset a$. Now $A/\mathfrak{m}^n$ is Artinian by(4.1.3.4), so by(4.1.3.6) a is a power of $\mathfrak{m}$.

$5 \to 6$: And $x \in \mathfrak{m} - \mathfrak{m}^2$ will do.

$6 \to 1$: Define $v(a) = k$ if $(a) = (x^k)$. □

Cor. (10.3.3.5) [Noetherian Valuation Rings are DVRs]. A Noetherian valuation rings are automatically DVRs.

Proof: This is implicit in the proof above. □

Prop. (10.3.3.6). Let R be a Noetherian local domain with fraction field K and $R \neq K$, then there exists a Noetherian local ring R' of dimension 1 that dominates R s.t. $R \to R'$ is essentially of f.t..

Proof: Cf.[Sta]00P8. □

Cor. (10.3.3.7) [Dominance by DVRs]. Let R be a Noetherian local domain with fraction field K and $R \neq K$, L/K a f.g. filed extension, then there exists a a DVR A with fraction field L which dominants R.

Proof: First we can reduce to the case L/K is finite: If it is not finite, choose a transcendence basis $x_1, \ldots, x_r$, and replace R by $R[x_1, \ldots, x_r]_{\mathfrak{m}_R, x_1, \ldots, x_r}$.

In the finite case, first we can reduce to the case $\dim R = 1$ by(10.3.3.6), and let A be the integral closure of R in L, then by(4.1.1.50), A is Noetherian, and $R \to A$ is integral so there exists a maximal prime $\mathfrak{n} \subset A$ that $\mathfrak{n} \cap R = \mathfrak{m}_R$. Thus $A_\mathfrak{n}$ is a DVR by(10.3.3.5). □

Valuations of Rank 1

In this subsubsection, all valuations are of rank 1.

Remark (10.3.3.8) [Real Valuations]. As an ordered Abelian group of height 1 can be embedded into $\mathbb{R}$(2.2.8.5), a valuation v on a field of rank 1 is equivalent to a real-valued valuation.

Def. (10.3.3.9) [Multiplicative Valuation]. For a real continuous valuation v, we can define a **multiplicative valuation** $|\cdot|$ where $|a| = \exp(-v(a))$. Then it is multiplicative.

Def. (10.3.3.10) [non-Archimedean Valuations]. A valuation is called **non-Archimedean** iff $|x+y| \leq \max\{|x|, |y|\}$. It is called **Archimedean** iff it is not non-Archimedean .

Def. (10.3.3.11) [Non-Archimedean field]. A **non-Archimedean field** is a topological field that the valuation is given by a rank1-valuation.

Prop. (10.3.3.12). A valuation is non-Archimedean iff $\{|n||n \in \mathbb{N}\}$ is bounded.

Proof: If it is non-archimedean, then clearly by induction and $n = 1 + (n-1)$ $|n| \leq 1$. Conversely, if $|n| \leq M$, then consider $|x+y|^n = |(x+y)^n| \leq \sum |C_n^k| x^k y^{n-k}| \leq M \max\{|x|, |y|\}$, so letting n be large, clearly $|x+y| \leq \max\{|x|, |y|\}$. □

Cor. (10.3.3.13). Any valuation on a field of char$\neq 0$ is non-Archimedean.

Prop. (10.3.3.14) [Equivalent Valuations]. Two valuation on a field is equivalent iff $|x|_1 < 1 \Rightarrow |x|_2 < 1$ and is equivalent to $|x|_1 = |x|_2^s$ for some $s > 0$.

Proof: if two valuation are equivalent, then $x^n \to 0$ in τ_1 iff $x^n \to 0$ in τ_2, so $|x|_1 < 1 \Rightarrow |x|_2 < 1$.

If $|x|_1 < 1 \Rightarrow |x|_2 < 1$, then let y be an element that $|y|_1 > 1$, then any element $|x| = |y|^\alpha$ for some $\alpha \in \mathbb{R}$. Let $\frac{n_i}{m_i}$ converges to α from above, then $|\frac{x^{n_i}}{y^{m_i}}|_1 < 1$, so $|\frac{x^{n_i}}{y^{m_i}}|_2 < 1$, so $|x|_2 \leq |y|_2^\alpha$. Similarly, $|x|_2 \geq |y|_2^\alpha$, so $|x|_2 = |y|_2^\alpha$. So $|x|_1 = |x|_2^s$ for some $s > 0$.

If $|x|_1 = |x|_2^s$ for some $s > 0$, then these two valuations are clearly equivalent. □

Cor. (10.3.3.15) [Weak Approximation]. If $|\cdot|_1, \ldots, |\cdot|_n$ be pairwise inequivalent valuations on K, then for any $a_1, \ldots, a_n \in K$ and $\varepsilon > 0$, there is an $x \in K$ that $|x - a_i|_i < \varepsilon$.

Proof: As $|\cdots|_1, |\cdots|_n$ are inequivalent, there are α, β that $|\alpha|_1 < 1, |\alpha|_n \geq 1$, $|\beta|_n < 1, |\beta|_1 \geq 1$ by(10.3.3.14), so let $y = \beta/\alpha$, then $|y|_1 > 1$, $|y|_n < 1$.

Now we prove by induction that there is an α that $|\alpha|_1 > 1, |\alpha|_i < 1$ for $i = 2, \ldots, n$. the case $n = 2$ is done, for general n, if the z for $n-1$ satisfies $|z|_n \leq 1$, then $z^m y$ will do, for m large. if $|z| > 1$, then the sequence $|t_m|_i = |\frac{z^m}{1+z^m}|_i$ converges to 1 for $i = 1, n$ and converges to 0 for $i = 2, \ldots, n-1$, so $t^m y$ will do, for m large. □

Prop. (10.3.3.16) [Gelfand]. Any field K with an Archimedean valuation is a subfield of $\mathbb{C}$.

Proof: We consider its completion. when it contains $\mathbb{C}$, this is a corollary of**??**, otherwise, we consider $K \otimes \mathbb{C}$, then it is a finite dimensional module over K thus also complete. □

Remark (10.3.3.17). Because of this, we usually don't consider only non-Archimedean valuations, and refer to all valuations as **places**, cf.(12.4.2.5).

Prop. (10.3.3.18) [Ostrowski].

1. $\Sigma_{\mathbb{Q}} = \mathbf{P} \cup \{\infty\}$. Thus any complete Archimedean field is isomorphic to $\mathbb{R}$ or $\mathbb{C}$ by(10.3.3.16).
2. Any non-trivial valuation on $\mathbb{F}_q(t)$ is of the form $|\cdot|_p$ or $|\cdot|_\infty$, where p is an irreducible polynomial in $\mathbb{F}_q[t]$.

Proof: 1: if it is non-Archimedean, then $|n|\leq 1$, and it is not trivial, so there is a minimal p that $|p|<1$. Then p is easily seen to be a prime. Then for any $(a,p)=1$, $a=dp+r$, so $|r|=1$, so $|a|=1$.

And if it is Archimedean, then we prove that in $\mathbb{N}$, $|m|=m^\lambda$ for some λ: Let $F(n)=|n|$ and $f=\log_2 F$, then $f(m+n)\leq\max\{f(m),f(n)\}+1$, and if $m=\sum_{i=1}^r d_i n^i$, then $f(m)\leq r(1+f(n))+a_n$, where $a_n=\sup\{f(k)|k<n\}$. And $r\leq\log m/\log n$, so

$$\frac{f(m)}{\log m}\leq\frac{a+f(n)}{\log n}+\frac{b}{\log n}$$

then letting $m\to m^k, k\to\infty$, and then let $n\to n^k, k\to\infty$, we get $\frac{f(m)}{\log m}\leq\frac{f(n)}{\log n}$, for any m,n.

2: Any valuation on $\mathbb{F}_q(t)$ is non-Archimedean(10.3.3.13), and $|n|=1$ if $(n,p)=1$, because $n^{p-1}=1$. Similarly, if there is a minimal hence irreducible P that $|P|<1$, then use induction and $Q=sP+r$ for some s,r of degree$<\deg Q$, so $|Q|=1$ for all $(Q,P)=1$. Otherwise, $|P|\leq 1$ for all P, then $|t|>1$, otherwise $|\cdot|$ is trivial, so it is easy by induction that $|F(t)|=|t|^{\deg F}$. □

Lemma (10.3.3.19) [Continuity of Roots]. For a separable polynomial f over a valued alg.closed field $\overline{K}$, there is a ε that every polynomial g that are closed enough to f, the roots of g is closed to roots of f respectively.

Proof: This is easy to see by decomposition as each root of f is close to a root of g. f,g have the same degree so the roots correspond to each other. □

Prop. (10.3.3.20) [Fundamental Inequality]. if (K,v) is a valued field and L/K be a field extension of degree n, if w_i are the valuations of L above v, then

$$\sum_{w_i|v}e(w_i/v)f(w_i/v)\leq[L:K].$$

The equality holds when v is discrete and L/K is separable.

Proof: Cf.[Clark note Theorem4].**?** □

Def. (10.3.3.21) [Spherically Complete Valued Field]. A valued field K is called **spherically complete** iff each descending chain of metric balls has a nonempty intersection.

Microbial Valuations

Prop. (10.3.3.22) [Microbial Valuation]. For a valuation ring $R\subset K$, a $f\neq 0\in R$ is called **topologically nilpotent** iff $f^n\to 0$ in the valuation topology of A. The following are equivalent:

- The topology on K coincides with a rank 1 topology.
- There exists a nonzero topologically nilpotent element in K.
- R has a prime ideal of height 1.

If this is the case, then the valuation defined by A is called **microbial**.

And in this case, for any topological nilpotent element ϖ, $K=R[\varpi^{-1}]$, and $\varpi^r\in R$ for some r, and the topology on R is ϖ^r-adic. And if $\mathfrak{p}$ is a prime ideal of rank 1, then the valuation ring $R_\mathfrak{p}$ is of rank 1, and defines the same topology on R.

Proof: 1 → 2: if there is a rank 1 valuation $|-|'$ that defines the same topology as R, then any $|x|'<1$ will be a topological nilpotent element by(10.3.3.23).

2 → 3: if ϖ is a topological nilpotent element, then $\mathfrak{p}=\sqrt{(\varpi)}$ is a prime ideal, and it is minimal, because if there is another $\mathfrak{q}\subsetneq\mathfrak{p}$, then $\varpi\notin\mathfrak{q}$, but $\mathfrak{p}\subset(\varpi^n)$ by induction: because $(\varpi)\nsubseteq\mathfrak{q}$, $\mathfrak{q}\subset(\varpi)$, and if $x\in\mathfrak{q}$, then $x=\varpi^n y$, and $\varpi\notin\mathfrak{q}$, so $y\in\mathfrak{q}\subset(\varpi^n)$, so $x\in(\varpi^{n+1})$. Now $\mathfrak{q}=0$ because ϖ is topological nilpotent.

3 → 1: It suffices to prove that the valuation defined by $R_{\mathfrak{p}}$ is the same as the topology of R. But this is true in general, just notice that the valuation topology of a nontrivial valuation is also defined by $B(a,\gamma]$.

The final remark is clear as $x\varpi^n\in R\iff|\varpi^n|\le|x^{-1}|$. □

Lemma (10.3.3.23). Let R be a valuation ring, if $x\in R^*$ is topologically nilpotent, then $|x|<1$, and the converse is also true if R has rank 1.

Proof: if $|x|\ge 1$, then $x^{\mathbb{N}}\notin B(0,1)$, so it is not topologically nilpotent. And if R has rank 1, $|x|<1$, then for any $\delta\neq 0$, there is some n that $|\delta^{-1}|<|x^{-n}|$(2.2.8.5), so $|x^m|<|\delta|$ for m large, thus x is topologically nilpotent. □

Prop. (10.3.3.24) [Constructing Microbial Valuations]. If A is a valuation ring and $f\in A$ is a non-zero non-unit, then the f-adic Hausdorffization $\overline{A}=A/\cap_n f^nA$ and the completion $\widehat{A}$ are all microbial.

Proof: Easy, Cf.[Bhatt Perfectoid Spaces, P63]. □

4 Affinoid Algebras

Tate Algebras

Def. (10.3.4.1) [Tate Algebra]. For a complete non-Archimedean field K with residue field k, we define the **Tate algebra** $T_n=K\langle x_1,\ldots,x_n\rangle$ to be the restricted power series(10.3.1.7) consists of elements $\sum_v a_v x^v$ that $\varinjlim_{|v|\to\infty}|a_v|=0$. It is endowed with the norm $|f|=\max|a_v|$.

The norm satisfies $|fg|=|f||g|$ and $|f+g|\le|f|+|g|$.

There is a **reduction map** from T_n to $k[x_1,\ldots,x_n]$, it is surjective.

Proof: T_n is an algebra because the values of coefficients of f is bounded. $|fg|\le|f||g|$ is easy, to show $|fg|\ge|f||g|$, we assume $|f|=|g|=1$, then their reduction in $K[x_1,\ldots,x_n]$ is non-zero, thus $\overline{fg}$ is non-zero, which shows $|fg|\ge 1$. □

Prop. (10.3.4.2) [Maximum Principle]. A formal power series f converges in $B^n(\overline{K})$ iff it is in T_n.

And when it is in T_n, $|f(x)|$ attains a maximum$=|f|$ in $B^n(\overline{K})$.

Proof: If it converges at $(1,\ldots,1)$, then $\varinjlim_{|v|\to\infty}|a_v|=0$ by(12.2.1.19). Conversely, for any point in $B^n(\overline{K})$, it can be considered in a finite extension field of K, thus complete, hence we can apply(12.2.1.19) again.

For the second assertion, we assume $|f|=1$, then consider its reduction to $k[x_1,\ldots,x_n]$, then there is a $\overline{x}$ in the alg.closure of k that $\overline{f}(\overline{x})\neq 0$. Now $\overline{k}$ can be seen as the residue field of $\overline{K}$. Then the lifting of $\overline{x}$ to a $x\in\overline{K}$ has valuation 1 and $|f(x)|=1$. □

Prop. (10.3.4.3). T_n is a Banach algebra(Easy).

Cor. (10.3.4.4). An element f of norm 1 of T_n is invertible in T_n iff its reduction in $k[x_1,\dots,x_n]$ is a unit. Elements of other norms can be reduced to the case of norm 1.

Proof: One direction is trivial, the other is because $|f-f(0)|<1$, hence $f=f(0)(1+g)$, this is invertible by power expansion as T_n is complete. □

Def. (10.3.4.5). A restricted power series $g=\sum g_v X_n^v \in T_n$ with coefficients in T_{n-1} is called X_n-**distinguished of order** s iff g_s is a unit in T_{n-1}, $|g_s|=|g|$ and $|g_s|>|g_v|$ for all $v>s$.

Lemma (10.3.4.6). For any f.m. elements $f_i\in T_n$, there is a continuous automorphism of T_n that maps $T_n\to T_n, T_i\to T_i+T_n^{\alpha_i}$ that maps f_i to X_n-distinguished elements.

Proof: Cf.[Rigid and Formal Geometry P16]. □

Prop. (10.3.4.7) [Weierstrass Division]. If $g\in T_n$ is X_n-distinguished of order s, for any $f\in T_n$, there is a unique form $f=qg+r$, where $q\in T_n$ and $r\in T_{n-1}[X_n]$ of degree $r<s$. Moreover, $|f|=\max\{|q||g|,|r|\}$.

Proof: Cf.[Rigid and Formal Geometry P17]. □

Cor. (10.3.4.8)[Weierstrass Preparation]. If $g\in T_n$ is X_n-distinguished of order s, then there exists uniquely a $r\in T_{n-1}[X_n]$ of degree s and $g=re$, where e is a unit in T_n.

Proof: By(10.3.4.7) applied to $X_n^s=qg+r$ with $|r|\le 1$. Then $\omega=X_n^s-r$ is X_n is the desired polynomial, it suffice to show q is a unit. Let g be normalized that $|g|=1$, then $|q|=1$, by reduction to polynomials, we see $\widetilde{\omega}=\widetilde{q}\widetilde{g}$, and $\widetilde{\omega},\widetilde{g}$ are both polynomials of degree s, so $\widetilde{q}\in k^*$, so q is a unit by(10.3.4.4).

Uniqueness: if $g=e\omega$, then $X_n^s=e^{-1}g+(X_n^s-\omega)$, so uniqueness follows from that of Weierstrass division. □

Prop. (10.3.4.9) [Noether Normalization]. For any proper ideal $\mathfrak{a}$ of T_n, There is a d and a finite injection $T_d\to T_n/\mathfrak{a}$.

Proof: We may assume $\alpha\neq 0$, thus choose a $g\in\alpha\neq 0$, then using(10.3.4.6), we may assume g is X_n-distinguished. Now the Weierstrass division theorem(10.3.4.7) says that $T_{n-1}\to T_n/(g)$ is finite. Hense $T_{n-1}\to T_n/(g)\to T_n/\mathfrak{a}$ is finite. Now we can use induction to find a $T_d\to T_{n-1}/T_{n-1}\cap\mathfrak{a}$ finite, thus also $T_d\to T_n/\mathfrak{a}$ is finite. □

Cor. (10.3.4.10) [Residue Field of Tate Algebra]. The residue field of a maximal ideal of T_n is a finite extension field of K, because $T_n/\mathfrak{m}$ has dimension 0, thus $K\to T_n/\mathfrak{m}$ finite injective.

Proof: Because finite injection $T_d\to T_n/\mathfrak{m}$ shows T_n is a field(4.2.1.3), thus we must have $d=0$. □

Cor. (10.3.4.11). The map from $B^n(\overline{K})$ to the set of maximal ideals of T_n are surjective.

Proof: Evaluation map defines a map $T_n\to K(x_1,\dots,x_n)$ that is surjective, thus the kernel is a maximal ideal. Conversely, for any maximal ideal $\mathfrak{m}\subset T_n$, $K'=T_n/\mathfrak{m}$ is finite over K, so we may assume $K'\subset\overline{K}$.

We show that this map $\varphi:T_n\to\overline{K}$ is contractive, otherwise there is a $|a|=1,|\alpha=\varphi(a)|>1$. Consider the minimal polynomial p of $|\alpha|$, all the conjugates of α has the same valuation as K, as K is Henselian, thus p has ascending Newton polygon, thus by(10.3.4.4) it is invertible in T_n. But $\varphi(p(a))=0$, contradiction.

So $|\varphi(x)|\le|x|$, then it is continuous, and $(\varphi(T_1),\dots,\varphi(T_n))\subset B^n(K^n)$, so we are done. □

Cor. (10.3.4.12) [Main Theorem]. T_n is Noetherian, UFD, Jacobson of Krull dimension n.

Proof: Noetherian: Use induction, as in the proof of(10.3.4.9), $T_{n-1} \to T_n/(g)$ is finite for some $g \subset \mathfrak{a}$, then also $T_n/\mathfrak{a}$ is finite over T_{n-1}, thus Noetherian as a T_{n-1} module, thus Noetherian as a ring.

UFD: Cf.[Rigid and Formal Geometry P20].

Jacobson: We need to show that any prime ideal $\mathfrak{p}$ is an intersection of maximal ideals. The case of $\mathfrak{p}$ is by(10.3.4.2). For $\mathfrak{p} \neq 0$, by Noetherian normalization(10.3.4.9), there is a $T_d \subset T_n/\mathfrak{p}$ finite. Then use induction and generalized Nullstellensatz(4.2.6.10), $T_n/\mathfrak{p}$ is Jacobson, thus $\mathfrak{p} = \mathrm{rad}(T_n/\mathfrak{p})$.

Dimension n: Cf.[Formal and Rigid Geometry P22]. □

Prop. (10.3.4.13). For an ideal $\mathfrak{a} \in T_n$, there are $a_1, \ldots, a_r$ which generate $\mathfrak{a}$ that $|a_i| = 1$, and any elements in f has a representation of the form $\sum f_i a_i$ with $|f_i| \leq |f|$.

The same assertion holds for submodules of T_n^k.

Proof: Cf.[Formal and Rigid Geometry P27,29].? □

Cor. (10.3.4.14). Each ideal of T_n is closed hence complete in T_n. This follows immediately from(10.3.4.12) and(12.2.4.13).

Cor. (10.3.4.15). For any ideal $\mathfrak{a}$ of T_n, the distance from an element to $\mathfrak{a}$ attains minimum.

Proof: Cf.[Bos15] P28. □

Affinoid Algebras

Def. (10.3.4.16) [Affinoid Tate Algebra]. A normed algebras of the form $A = T_n/\mathfrak{a}$ are called **affinoid (Tate) algebras**, so it is Noetherian and Jacobson by(10.3.4.12). An affinoid algebra has a natural semi-norm by $|f|_{\sup} = \sup |f|_{\mathfrak{m}}$ in $A/\mathfrak{m}$ for a maximal ideal $\mathfrak{m}$ of A by(10.3.4.10).

Proof: We need to show the sup is finite, for this, notice $|f| = |g|$ for some g in the residue norm(10.3.4.17), so for any maximal ideal $\mathfrak{m}$ of A, the inverse is a maximal ideal $\mathfrak{n}$ in T_n by finiteness, thus $|f|_{\mathfrak{m}} = |g|_{\mathfrak{n}} \leq |g|_{\sup} = |g| = |f|$, so $|f|_{\sup} \leq |f|$.

For the second-last equality, notice on T_n, $|\cdot|_{\sup}$ and $|\cdot|$ equal, by(10.3.4.2) and(10.3.4.11). □

Def. (10.3.4.17) [Residue Norm]. For a Tate algebra $A = T_n/\mathfrak{a}$, there is a natural residue norm on it. This is a complete K-algebra norm on A, and $T_n \to A$ is continuous and open. For any $f \in A$, the residue norm is attained at an element of T_n.

Any residue norm is bigger than the sup-norm, by the proof of(10.3.4.16).

Proof: It is a K-algebra norm is easily verified, should notice $|f| = 0$ iff $f = 0$, because $\mathfrak{a}$ is closed(10.3.4.14). The last assertion follows from(10.3.4.15). □

Remark (10.3.4.18). The sup norm may not even be a norm, if $\mathfrak{a}$ is not radical, but the fact that sup norm is smaller than any residue norm, together with(10.3.4.22), is enough for use.

Prop. (10.3.4.19). For $T_d \to A$ a finite injection, assume A is a torsion-free T_d-module, then for any $f \in A$, there is a unique minimal monic polynomial P of f over T_d.

In this case, $|f|_{\sup} = \sup |a_i|_{\sup}^{1/i}$ where a_i are coefficients of P.

Proof: Because A is torsion-free, we reduce to the quotient field of T_n, then f has a minimal monic polynomial, and T_n is UFD, hence Gauss lemma shows that this polynomial has coefficients in T_d. Hence $T_n[f] = T_n[X]/(p)$.

For the second, notice first for finite extension the Spec map is surjective, thus we may assume $A = T_n[f] = T_n[X]/(p)$, and for a maximal ideal $\mathfrak{m}$ of T_n, let $T_n/\mathfrak{m} = k$, then $A/(\mathfrak{m}) = k[X]/(\overline{p})$, then maximal ideals of $A/(\mathfrak{m})$ corresponds to roots α_i of $\overline{p}$ in $\overline{k}$, so

$$\sup_{\varphi^{-1}(\mathfrak{n})=\mathfrak{m}} |f|_{\mathfrak{n}} = \sup |\alpha_i| = \max |a_i|_{\mathfrak{m}}^{1/i},$$

so the result follows. □

Cor. (10.3.4.20). $|f|_{\sup} \in \sqrt[N]{|K|}$ for some N and all $f \in A$, because the minimal polynomial has coefficients in T_n, and sup norm and Gauss norm coincide on T_n by the proof of(10.3.4.16).

Cor. (10.3.4.21) [Maximum Principle]. $|f|_{\sup} = |f|_{\mathfrak{m}}$ for some maximal ideal $\mathfrak{m}$.

Proof: Since A is Noetherian(10.3.4.12), it has f.m. minimal primes, hence $|f|_{\sup} = |f|_{\sup}$ in A/p_i for some minimal prime of A. Hence we reduce to the case of(10.3.4.19), hence the conclusion follows from(10.3.4.2) and the proof of(10.3.4.19). □

Prop. (10.3.4.22) [Residue Norms Equivalent]. Any morphism from a Noetherian k-algebra to an affinoid algebras A is continuous w.r.t any residue norms. In particular, any k-Banach algebra topology on A coincides with the k-affinoid topology on A, and all residue norms on an affinoid algebra are equivalent.

Moreover, for any morphism of k-affinoid algebras $B \to A$, the norm on A can be replaced by an equivalent one that makes A into a normed B-algebra.

Proof: Use(12.2.4.10), it suffices to show the condition holds, for $\mathfrak{B} = \{\mathfrak{m}^v\}$ where $\mathfrak{m}$ are maximal ideals of A: The residue field is finite by(10.3.4.10), their intersections is (0) because if $f \in \cap_{\mathfrak{m}} \cap_n \mathfrak{m}^n$, Krull's theorem(4.2.2.15)(use localization) says for each maximal ideal $\mathfrak{m}$ there is a $m \in \mathfrak{m}$ that $(1-m)f = 0$, so $Ann(f) = (1)$, so $f = 0$.

For the second assertion, see [non-Archimedean Analysis P229]. □

Cor. (10.3.4.23). The notion of power-boundedness and topological nilpotence is independent of residue norm chosen.

Cor. (10.3.4.24) [Restricted Power Series]. For an affinoid algebra A, the restricted power series in A:

$$A\langle X_i\rangle = \{\sum a_v X^v | \varinjlim_{|v|\to\infty} a_v = 0\}$$

is an affinoid algebra, this is independent of the residue norm chosen.

Def. (10.3.4.25) [Strongly Noetherian]. A is called **strongly Noetherian** if $A\langle T_1, \ldots, T_n\rangle$ are Noetherian for any $n \geq 0$.

Lemma (10.3.4.26). The image A is dense in $A\langle X\rangle/(X-f)$(in the residue norm, and thus in all other norms, by(10.3.4.22)(10.3.4.17)), this is because a restricted power series can be truncated by a finite part and a part with small norm, and the finite part is in the image of A.

Def. (10.3.4.27)[Affinoid Generator]. For a morphism of affinoid algebras $A \to A'$, a set of elements h_i in A' is called a set of **affinoid generator** iff there is a surjection

$$A\langle X_1, \ldots, X_n\rangle \to A', \quad X_i \mapsto h_i$$

Of course h_i is power-bounded, by the residue norm given.

Lemma (10.3.4.28). If $\pi' : A\langle X_1, \ldots, X_n\rangle \to A' : X_i \to h_i'$ is a surjective morphism of affinoid algebras that $A\langle X_1, \ldots, X_n\rangle$ is endowed with the Gauss norm and A' is endowed with the residue norm, then any set of elements $h = (h_1, \ldots, h_n)$ that $|h_i - h_i'| < 1$ is a set of affinoid generators.

Proof: By non-Archimedean property, $|h_i| \le 1$ thus also $|h_i'| \le 1$, and Let $\varepsilon = \max\{|h_i - h|\} < 1$. The strategy is simple, if for each g in A', we can find a f that $|f| = |g|, |\pi(f) - g| \le \varepsilon|g|$, then by iteration, there is a f that $\pi(f) = g$. But by(10.3.4.17) and(10.3.4.15), if we choose a f that $\pi'(f) = g$ and $|f| = |g|$, then

$$|\pi(f) - g| = |\sum a_v h^v - \sum a_v h'^v| = |\sum a_v(h^v - h'^v)| \le \varepsilon|f| = \varepsilon|g|.$$

□

Def. (10.3.4.29) [Distinguished Element]. For an affinoid algebra A and an element $x \in \operatorname{Sp} A$(14.5.1.1), a element $f \in A\langle X_1, \ldots, X_n\rangle$ is called X_n**-distinguished of order** s **at** x iff it is distinguished in $A/\mathfrak{m}_x\langle X_1, \ldots, X_n\rangle$ is distinguished of order s in the sense of(10.3.4.5)(notice $A/\mathfrak{m}_x$ is a complete valued field by(10.3.4.10)).

Prop. (10.3.4.30) [Fibererd-Pushouts]. When R, A_1, A_2 are all affinoid algebras, the amalgamated sum is also an affinoid algebra. In other words, the category of affinoid algebras admits amalgamated sums(fibered pushouts by(12.2.1.15)).

Proof: Cf.[Formal and Rigid Geometry P245]. □

Prop. (10.3.4.31). $T_n \widehat{\otimes} T_m \cong T_{m+n}$. $K' \widehat{\otimes} T_{n,K} = T_{n,K'}$.

Prop. (10.3.4.32). For affinoid algebras R, A_1, A_2 and ideals $\mathfrak{a}_1 \subset A_1, \mathfrak{a}_2 \subset A_2$, there is an isomorphism:

$$(A_1 \widehat{\otimes}_R A_2)/(\mathfrak{a}_1, \mathfrak{a}_2) \cong (A_1/\mathfrak{a}_1) \widehat{\otimes}_R (A_2/\mathfrak{a}_2)$$

Proof: Cf.[Rigid and Formal Geometry P248]. □

Prop. (10.3.4.33) [Finite Extension of Affinoid Algebras]. If B is an affinoid K-algebra and $\varphi : B \to A$ is a finite ring map, then A can be provided a topology to make it an affinoid K-algebra, and φ is continuous.

Proof: We can associate to A a Banach algebra topology induced from $B^n \to A \to 0$ that is continuous. Now it is an affinoid K-algebra: we may assume $B = T_n$, then $A = \sum T_n a_i$, and we may assume $|a_i| < 1$ then clearly there is a continuous extension $T_n\langle X_i\rangle \to A$ extending this map, so A is affinoid. □

Construction of Affinoid Tate Algebras

Def. (10.3.4.34) [Affinoid Localizations]. Let A be an affinoid Tate algebra, then for a finite set of elements $\{f_i, g_j\} \subset A$, we can define the localization

$$A\langle f_i, g_j^{-1}\rangle = A\langle \zeta_1, \ldots, \zeta_i, \xi_1^{-1}, \ldots, \xi_j\rangle/(\zeta_i - f_i, 1 - \xi_j g_j).$$

5 Huber Rings

Def. (10.3.5.1) [Huber Ring]. A topological ring is called **Huber** if there exists an open subring A_0 that the induced topology on A_0 is I-adic for some f.g. ideal I of A. Such a A_0 is called a **ring of definition**, and I is called the **ideal of definition**. Morphisms of Huber rings are just a continuous morphisms of topological rings.

Prop. (10.3.5.2) [Boundedness and Rings of Definition]. A subring $A_0 \subset A$ of a Huber ring is a ring of definition iff it is open and bounded.

Proof: Clearly a ring of definition is open and bounded, for the converse, let (A_0', I) be a couple of definition, and A_0 is an open and bounded subset of A, then $I^k \subset A_0$ for some n, and set $J = I^k A_0$. As A_0 is bounded, for any open nbhd U of 0, there exists $m > 0$ that $I^{km} A_0 \subset U$, thus $J^m \subset U$. This shows J is a fundamental system of nbhd of 0, thus A_0 is J-adic and is a ring of definition. □

Cor. (10.3.5.3). Let A be a Huber ring, then

- If A_0, A_1 are two rings of definition of A, then so does $A_0 \cap A_1$ and $A_0 A_1$.
- Every open subring B of A is a Huber ring.
- If $B \subset C$ are subrings of A and B is bounded, C is open, then there is a ring of definition A_0 that $B \subset A_0 \subset C$.

Proof: 1: By(10.3.5.2).

2: Let $I^n \subset B$, then $(B \cap A_0, I^n)$ is a couple of definition of B.

3: By2, C is Huber, take a ring of definition A_0 of C, then $A_0 B$ is open and bounded in C, thus a ring of definition. □

Lemma (10.3.5.4). If A is a Huber ring and $T \subset A$ is a subset that generates an open ideal of A, then for any open nbhd U of A, the subgroup $T^n U$ is open.

Proof: Let (A_0, I) be a couple of definition. By assmption the ideal J generated by T is open, thus J^n is also open, and contains some I^m. Now we can change I^m to I. Now I is f.g., so there is a finite subset $M \subset A$ that $I \subset T^n M$. Notice M is bounded because it is finite, so there is an integer r that $I^r M \subset U$, thus $I^{r+1} \subset T^n U$, and $T^n U$ is open. □

Def. (10.3.5.5) [Tate Huber Ring]. A **Tate Huber ring** is a Huber ring s.t. there exists an open subring A_0 that the induced topology on A_0 is t-adic for some $t \in A_0$ which becomes a unit in A. Such a t is called a **pseudo uniformizer**.

Prop. (10.3.5.6) [Examples of Tate Huber Rings].

- If K is a complete non-Archimedean field and R is a K-Banach algebra, then R is Tate with a ring of definition by $(R_{\leq 1}, t)$, where t is a pseudo-uniformizer of K.
- If A_0 is any ring and $g \in A_0$ is a nonzero-divisor, and let $A = A_0[g^{-1}]$ equipped with the g-adic topology, then it is an Tate Huber ring.

Prop. (10.3.5.7) [Properties of Tate Huber Rings]. If a Huber ring A is Tate with a topological nilpotent unit g and $A_0 \subset A$ is any ring of definition, then there exists n large that $g^n \subset A_0$. And in this case, A_0 is g^n-adic and $A = A_0[(g^n)^{-1}]$.

In this case, a subset $S \subset A$ is bounded iff $S \subset g^{-n} A_0$ for some n.

Proof: Because A_0 is open in g, there is some n that $g^n \subset A_0$, and then with n even larger we can assume $g \in I$, because g is topologically nilpotent, and gA_0 is also open in A_0, thus it contains I^m for some m. So now $g^{mn}A_0 \subset I^m \subset g^n A_0$, which means A_0 is g^n-adic.

To show $A = A_0[(g^n)^{-1}]$, it suffices to notice $g^{kn}x \to 0$ as $k \to \infty$ for any $x \in A$, so for k large, $g^{kn}x \in A_0$.

The last assertion is easy, as open subsets of A and $g^{kn}A_0$ are cofinal. □

Prop. (10.3.5.8) [Power-Bounded Elements and Topologically Nilpotent Elements]. The subset A^0 of power-bounded elements in A is a subring, and it is the filtered colimit of all the ring of definition in A, thus open. It is also integrally closed in A.

The subset A^{00} fo topologically nilpotent elements of A is a radical ideal of A^0. But it is in general not an ideal of A.

Recall A is called uniform if A^0 is bounded(12.2.1.6), or equivalently A^0 is a ring of definition, by(10.3.5.2).

Proof: By(10.3.5.3), every power-bounded element is contained in a ring of definition, and any ring of definition is bounded, so A^0 is the union of all rings of definitions of A, and this is filtered by(10.3.5.3).

To show A^0 is integrally closed, notice by what we already proved, if a is integral over A^0, then it is integral over a ring of definition A_0, but then $\{a^n\} \subset A_0[a]$ is bounded, so $a \in A^0$.

Showing A^{00} is a radical ideal of A^0 is easy and ommited. □

Cor. (10.3.5.9). If a Huber ring A is separated, Tate and uniform, then A is reduced.

Proof: Assume that A_0 the set of power-bounded elements is a ring of ideal and $g \in A_0$ is a pseudo-uniformizer. If x is nilpotent, then g^{-n} is nilpotent for any x, so power-bounded and $g^{-n}x \in A_0$, which means $x \in g^n A_0$ for any n. But A_0 is separated, so $x = 0$. □

Cor. (10.3.5.10). Let A be a Huber ring, then an ideal J is open iff $A^{00} \in \sqrt{J}$.

Proof: If J is open, then clearly $A^{00} \subset \sqrt{J}$. Conversely, if $A^{00} \subset \sqrt{J}$ and (A_0, I) is a couple of definition, then $I \subset A^{00}$ by(10.3.1.9), so $I \subset \sqrt{J}$. And I is f.g., so $I^N \subset J$ for some J, thus J is open. □

Prop. (10.3.5.11). If K is a complete non-Archimedean field, then any Banach K-algebra R is a complete Tate ring, and if K, R are perfectoids, then $R^{00} = K^{00}R^0$.

Proof: In the perfectoid case, first $K^{00}R^0 \subset R^{00}$, and for any topological nilpotent α, $\alpha^n \subset tR^{00}$ for a pseudo-uniformizer t. Thus R^{00} and $K^{00}R^0$ has the same radical, it suffices to show $K^{00}R^0$ is radical, but the quotient $R^0/K^{00}R^{00}$ is a perfect K^0/K^{00}-algebra by perfectoidness, thus it must be radical. □

Prop. (10.3.5.12) [Complete Perfect Tate ring is Uniform, André]. If A is a complete Tate ring of char$p$ that is perfect, then A is uniform.

Proof: Let (A_0, t) be a ring of definition, let $A_n = A_0^{\frac{1}{p^n}}$, then $A_\infty = \operatorname{colim} A_n = (A_0)_{\mathrm{perf}}$. We check $t^{\frac{1}{p^n}}A^0 \subset A_\infty \subset t^{-1}A_0$, which shows A^0 is bounded.

If $f \in A^0$, then $t^a f^{\mathbb{N}} \subset A \subset A_\infty$, and A_∞ is perfect, so $t^{\frac{a}{p^n}} f \in A_\infty$ for all n. Notice the Frobenius is a continuous bijection of Banach spaces, so it is open by Banach theorem(10.8.2.4), so $A_0^p \supset t^{mp}A_0$, thus $t^m A_1 \subset A_0$, and then $t^{\frac{m}{p^n}}A_{n+1} \subset A_n$. So $t^{\sum_n m/p^n}A_n \subset A_1$. So $t^c A_\infty \subset A_0$, for c large. □

Huber Pairs

Def. (10.3.5.13) [Huber Pairs]. For a Tate ring A, a **ring of integral elements** is an open and integrally closed subring of A contained in A^0(10.3.5.8)(for example A^0 itself). A **Huber pair** is a pair (A, A^+) that A is a Huber ring and A^+ is a ring of integral elements. A morphism of Huber pairs should preserve the ring of integers.

A Huber ring is called an **Affinoid Tate ring** if A is Tate.

Prop. (10.3.5.14). $A^{00} \subset A^+$ as an ideal for any ring of integral elements A^+. In particular, A^+ contains any pseudo-uniformizer, and the set of rings of integral elements is in bijection with integrally closed subrings of A/A^{00}.

Also, A^+ is a filtered colimits of rings of definitions.

Proof: $t \in A^{00}$ is topologically nilpotent hence $t^n \subset A^+$ for some n as it is open, and then $t \in A^+$ as it is integrally closed. It is an ideal because it is an ideal of A^0(10.3.5.8).

For the last assertion, notice that A^0 is the filtered colimits of rings of definitions(10.3.5.8), and the intersection of a ring of definition with A^+ is also a ring of definition, because it is open and bounded(10.3.5.2), the result follows. □

Def. (10.3.5.15) [Zariski, Henselian, Complete Huber Pairs]. A Huber ring (A, A^+) is called

- **complete** iff A is complete.
- **Henselian** iff (A^+, A^{00}) is a Henselian pair.
- **Zariski** iff (A^+, A^{00}) is a Zariski pair.

Prop. (10.3.5.16). An affinoid Tate ring (A, A^+) with a ring of definition (A_0, I) that $A_0 \subset A^+$ is

- Zariski iff I is in the Jacobson radical of A_0.
- Henselian iff the pair (A_0, I) is Henselian.
- Complete then it is Henselian.
- Henselian then it is Zariski.

Proof: 1: We prove that if $t \in \mathrm{rad}(A_0)$, the for any other $B_0 \supset A_0$, $t \in \mathrm{rad}(B_0)$. If this is true, then as A^+ is a filtered colimits of rings of definitions(because A^0 does), it is clear that t lies in the maximal ideal (check $1 + at$ is unit). For this, if $\mathfrak{m} \subset B_0$ is maximal and $t \notin \mathfrak{m}$, choose n that $t^n B_0 \subset A_0$, and an element $b \in B_0$ that maps to t^{-n-1} modulo $\mathfrak{m}$, then $a = t^n b \in A_0$ is mapped to t^{-1}. Thus the composition $A_0 \to B_0 \to B_0/\mathfrak{m}$ is surjective: $\bar{b}$ is the image of $a^n(t^n b) \in A$. So t is not in a maximal ideal of A_0, contradiction.

Conversely, Cf.[Bhatt Perfectoid Space P57].

2: Cf.[Bhatt Perfectoid Spaces P57].

3: A is complete then A_0 is complete, hence (A_0, I) is Henselian by(4.3.10.6), so it is Henselian by item2. 4: Trivial. □

Adic Morphisms

Def. (10.3.5.17) [Adic Morphisms]. A morphism of Huber rings $f : A \to B$ is called an **adic morphism** if we can choose rings of definitions A_0, B_0 and an ideal of definition I of A that $f(A_0) \subset B_0$, and $f(I)B_0$ is an ideal of definition of B_0.

A morphism $(A, A^+) \to (B, B^+)$ of Huber pairs is called adic if $A \to B$ is.

Prop. (10.3.5.18). Let $f : A \to B$ be an adic morphism between Huber rings, then:

1. f is continuous and open.
2. If A_0, B_0 are rings of definition s.t. $f(A_0) \subset B_0$, then for any ideal of definition $I \subset A_0$, $f(I)B_0$ is an ideal of definition in B_0.
3. f maps bounded sets to bounded sets.

Proof: Let $f(A_0) \subset B_0$ and $J = f(I)B_0$. Then $I^n \subset f^{-1}(J^n)$, so f is continuous.

If E is bounded in A, for any n, let m be that $I^m E \subset I^n$, then $f(E)f(I)^m = f(EI^m) \subset f(I^n) \subset J^n$, thus $f(E)J^m \subset J^n$, so $f(E)$ is bounded. □

Construction of Huber Rings

Main references are [Mor19].

Prop. (10.3.5.19) [Quotient]. Let (A, A^+) be a Huber ring and $\mathfrak{a}$ be an ideal of A, then the quotient pair $(A/\mathfrak{a}, (A/\mathfrak{a})^+)$ where $A/\mathfrak{a}$ is the integral closure of $A^+/\mathfrak{a}$ in $A/\mathfrak{a}$.

Prop. (10.3.5.20) [Completion of Huber Rings]. Let A be a Huber ring and (A_0, I) be a couple of definition. Set $\widehat{A} = \varprojlim_n A/I^n$(as an Abelian group), then:

1. The canonical map $\widehat{A_0} \to \widehat{A}$ is injective and $\widehat{A_0} \cap A = A_0$.
2. If we put the unique topology on $\widehat{A}$ that $\widehat{A_0}$ is an open subgroup, then $\widehat{A}$ is complete.
3. There is a unique topological ring structure on $\widehat{A}$ that $A \to \widehat{A}$ is continuous.
4. $\widehat{A}$ is Huber with a couple of definition $(\widehat{A_0}, I\widehat{A_0})$, and the canonical map $A \to \widehat{A}$ is adic.
5. $\widehat{A_0} \otimes_{A_0} A \to \widehat{A}$ is an isomorphism.

Proof: Cf.[Mor19]P72. □

Prop. (10.3.5.21). Let A be a Huber ring and $i : A \to \widehat{A}$ be the completion, then under the bijection of(10.3.1.6),

- $\widehat{A}^0 = \widehat{A^0}, \widehat{A}^{00} = \widehat{A^{00}}$.
- $G \subset A$ is a ring of definition iff $\widehat{G} \subset \widehat{A}$ is a ring of definition.
- the map $\mathrm{Cont}(\widehat{A}) \to \mathrm{Cont}(A)$ is a bijection.

Proof: Cf[Mor19] P75. □

Prop. (10.3.5.22). Let A be a Huber ring, then under the bijection of(10.3.1.6), an open ring A_0 is a ring of integral elements of A iff $A_0^\wedge$ is a ring of integral elements of $A^\wedge$.

Proof: It is easy to show A_0 is a ring iff $A_0^\wedge$ is a ring, and by(10.3.5.21), $A_0 \subset A^0$ iff $A_0^\wedge \subset (A^\wedge)^0$.

It suffices to prove that if A_0 is open and integrally closed, then $A_0^\wedge$ is integrally closed in $A^\wedge$. Let $x \in A^\wedge$ satisfy $x^d + a_{d-1}x^{d-1} + \ldots + a_0 = 0$, where $a_i \in A_0^\wedge$, because $A_0^\wedge$ is open, we can find $x' \in A$ and $a_i' \in A_0$ that $(x')^d + a_{d-1}'(x')^{d-1} + \ldots + a_0' \in A_0'$, but then $x' \in A_0$ because A_0 is integrally closed, and thus $x = (x - x') + x' \in A_0'$. □

Cor. (10.3.5.23) [Completion of Huber Pairs]. The forgetful functor from the category of complete Huber pairs to the category of Huber pairs has a left adjoint called completion, where $(A, A^+)^\wedge = (A^\wedge, (A^\wedge)^+)$, where $(A^\wedge)^+$ is the closure of the image of $A^\wedge$ in $A^\wedge$.

Prop. (10.3.5.24) [Completion, Henselization, Zariski Localization]. There are left adjoint to the forgetful functors from the category of complete/Henselian/Zariski pairs to the category of pairs, called the **completion/Henselization/Zariski localization** of pairs. And there are natural maps

$$(A, A^+) \to (A, A^+)_{\text{Zar}} \to (A, A^+)_{Hens} \to (\widehat{A}, \widehat{A}^+)$$

Proof:

□

Prop. (10.3.5.25) [Tensor Products of Adic Maps of Huber Rings].

- If $(A, A^+) \to (B, B^+)$ is adic, then pullback along the associated map of topological spaces $\mathrm{Spa}(B, B^+) \to \mathrm{Spa}(A, A^+)$ preserves rational subsets.
- Let $(B, B^+) \leftarrow (A, A^+) \to (C, C^+)$ be a diagram of Huber pairs where both morphisms are adic. Let A_0, B_0, C_0 be rings of definition compatible with the morphisms, and $I \subset A_0$ be an ideal of definition. Let $D = B \otimes_A C$ and let D_0 be the image of $B_0 \times_{A_0} C_0$ in D. Make D into a Huber ring by declaring D_0 to be a ring of definition with ID_0 as its ideal of definition and D^+ be the integral closure of the image of $B^+ \otimes_{A^+} C^+$ in D. Then (D, D^+) is a Huber pair, and it is the pushout of the diagram in the category of Huber pairs.

Proof: For 1, it suffices to show that if T is a finite set of A that TA is open, then TB is open in B: $I \subset TA$ for some ideal of definition $I \subset A_0$, in which case $IB_0 \subset B_0$ is also an ideal of definition by(10.3.5.18), thus open, and so TB is also open as $IB \subset TB$.

2 just follows from the definition. □

Remark (10.3.5.26) [Non-Adic Morphisms]. Pushouts may not exists for non-adic morphisms of Huber rings. For example, $\mathbb{Z}_p \to \mathbb{Z}_p[[T]]$ is not adic(10.3.5.18), and the diagram

$$(\mathbb{Z}_p[[T]], \mathbb{Z}_p[[T]]) \leftarrow (\mathbb{Z}_p, \mathbb{Z}_p) \to (\mathbb{Q}_p, \mathbb{Z}_p)$$

has no pushout in the category of Huber pairs: If there is a pushout (D, D^+), then we will have a morphism

$$(D, D^+) \to (\mathbb{Q}_p\langle T, \frac{T^n}{p}\rangle, \mathbb{Z}_p\langle T, \frac{T^n}{p}\rangle)$$

for each $n \geq 1$. But notice that T is nilpotent in D, and $1/p \in D<$ so $T^n/p \to 0 \in D$ as $n \to \infty$. So $T^n/p \in D^+$ for some n, but then $T^n/p \in \mathbb{Z}_p\langle T, \frac{T^{n+1}}{p}\rangle$, which is impossible.

Def. (10.3.5.27) [Topological Polynomial Functions]. Let A be a non-Archimedean topological ring, and $\{X_i\}_{i\in I}$ be a family of indeterminates, $\{T_i\}_{i\in I}$ be a family of subsets of A that satisfies $T_i^n U$ is open for any $n > 0, i$ and open nbhd U of A.

Let $\mathbb{N}^{(I)}$ be the set of functions $I \to \mathbb{N}$ with finite support, then for any $\nu \in \mathbb{N}^{(I)}$, let $T^\nu = \prod T_i^{\nu(i)}$. For any nbhd U of A, we set

$$U_{[X,T]} = \{\sum_{\nu\in\mathbb{N}^{(I)}} a_\nu X^\nu | a_\nu \in T^\nu U\},$$

Then there exists a unique topological structure on $A[X]$ that $U_{[X,T]}$ form a fundamental system of nbhds of 0, and denote it by $A[X]_T$. It satisfies:

- the canonical inclusion $\iota : A \to A[X]_T$ is continuous and the set $\{T_i X_i\}_{i\in I}$ is power-bounded.

- ι satisfies the universal property that any continuous map $f : A \to B$ to another non-Archimedean topological ring B that $\{f(T_i)X_i\}_{i\in I}$ is power-bounded factors through $A[X]_T$.

Proof: Just notice that $(U\cap V)_{[X,T]}\subset U_{[X,T]}\cap V_{[X,T]}$ and $U_{[X,T]}\cdot V_{[X,T]}=(UV)_{[X,T]}$, so they form a topological basis because A is topological.

The first properties are easily verified. For the second, the extension $f' : A[X]\to B$ exists abstractly, and it suffices to show it is continuous. If we let $E\subset B$ be the subring generated by $\{f(T_i)X_i\}_{i\in I}$, then E is bounded, so for any open subgroup $H\subset B$, there is some open subgroup $G\subset B$ that $EG\subset H$, and thus $f^{-1}(G)$ is open and contains some nbhd U, then $U_{[X,T]}\subset (f')^{-1}(G)$, so f' is continuous. □

Def. (10.3.5.28) [Topological Power Series]. Let A, X, T as in(10.3.5.27), then the set

$$A\langle X\rangle_T=\{\sum_{\nu\in\mathbb{N}^{(I)}}a_\nu X^\nu\in A[[X]]|a_\nu\in T^\nu U\ a.e.\},$$

is a subring of $A[[X]]$, and there is a unique topological structure on $A[[X]]$ that

$$U_{\langle X,T\rangle}=\{\sum_{\nu\in\mathbb{N}^{(I)}}a_\nu X^\nu\in A\langle X\rangle_T|a_\nu\in T^\nu U\},$$

form a fundamental system of nbhds of $A\langle X\rangle_T$.

Proof: The proof is not hard and similar to that of (10.3.5.27) so omitted. □

Prop. (10.3.5.29). Let A, X, T as in(10.3.5.27), then

- $A[X]_T$ is dense in $A\langle X\rangle_T$ and the topology coincide.
- If A is Hausdorff and T_i is bounded for any $i\in I$, then $A[X]_T$ and $A\langle X\rangle_T$ are all Hausdorff.
- If A is complete and T_i is bounded for any $i\in I$, then $A\langle X\rangle_T$ is complete, so it is the completion of $A[X]_T$.

Proof: Only the completeness needs proof, Cf.[**?**]P80. □

Prop. (10.3.5.30)[Power Series is Huber]. Let A be a Huber ring with a couple of definition (A_0, I), and $X=\{X_\lambda\}$ be a finite set of indeterminates, T_λ is a family of subsets of A that $T_\lambda A$ is open in A, then

- $A[X]_T$ is a Huber ring with a couple of definition $((A_0)_{[X,T]}, I_{[X,T]})$, and there is a canonical map $A\to A[X]_T$ which is adic.
- $A\langle X\rangle_T$ is Huber with a couple of definition $((A_0)_{\langle X,T\rangle}, I_{\langle X,T\rangle})$, and there is a canonical map $A\to A\langle X\rangle_T$ which is adic.

Proof: It suffices to prove for any ideal of definition J, $J_{[X,T]}=J\cdot(A_0)_{[X,T]}$ and $J_{\langle X,T\rangle}=J\cdot(A_0)_{\langle X,T\rangle}$. The first is clear. For the second, use the fact J is f.g. and $\{J^n\}$ is a fundamental basis of nbhds of 0. □

Prop. (10.3.5.31) [Example]. Let $A=\mathbb{Z}_p$ and $T=p$, then there is a Huber ring

$$\mathbb{Z}_p\langle X\rangle_T=\{\sum_{n\geq 0}a_nX^n\in\mathbb{Z}_p[[X]]|l^{-n}a_n\to 0\}$$

with a ring of definition

$$(Z_p)_{\langle X,T\rangle}=\{\sum_{n\geq 0}a_nX^n\in\mathbb{Z}_p\langle X\rangle_T|a_n\in p^n\mathbb{Z}_p\}.$$

Notice that $\mathbb{Z}_p\langle X\rangle_T$ is not adic although $\mathbb{Z}_p$ is(because p is nilpotent but pX is not).

Def. (10.3.5.32) [Localizations]. Let A be a non-Archimedean topological ring and $\{T_i\}$ is a family of subsets of A satisfying $T_i^n U$ is open for any $n>0, i$ and open nbhd U of A, and $\{s_i\}$ is a family of elements of A, which generates a multiplicative subset $R\subset A$.

Then there is a unique non-Archimedean ring structure on $R^{-1}A$, denoted by $A(\frac{T}{S})$, that the canonical map $\varphi: A\to A(\frac{T}{S})$ is continuous and the set $\{\frac{\varphi(t)}{\varphi(s_i)}\}$ is power-bounded, and it is the initial map for all maps $A\to B$ satisfying this property.

Proof: Cf.[Mor19]P83. □

Cor. (10.3.5.33). Let J be the ideal of $A[X]_T$ generated by $\{1-s_iX_i\}$, then $A[X]_T/J$ with the quotient topology satisfies the same universal property as $A(\frac{T}{S})$, so there is a canonical isomorphism

$$A[X]_T/J\cong A(\frac{T}{S}).$$

In particular, $A(\frac{T}{S})$ is a Huber ring, and the canonical map $A\to A(\frac{T}{S})$ is adic. Explicitly, B_0 is the $(A_0)_{[X,T]}$-subalgebra of B generated by the elements $\frac{T_i}{s_i}$.

Def. (10.3.5.34). If A is Huber ring, then we denote the completion of $A(\frac{T}{S})$ by $A\langle\frac{T}{S}\rangle$, which is also a Huber ring, and the canonical map $A\to A\langle\frac{T}{S}\rangle$ is adic, by(10.3.5.30) and(10.3.5.33). It satisfies the natural universal property.

Cor. (10.3.5.35). If A is complete, then we can also regard $A\langle\frac{T}{S}\rangle$ as the quotient of $A\langle X\rangle_T$ by the closure of the ideal generated by $\{1-s_iX_i\}$.

Prop. (10.3.5.36) [Example]. Let $A=\mathbb{Z}_p[[T]]$ with the (p,T)-adic topology, then

$$A(\frac{p,T}{T})=\mathbb{Z}_p[[T]][T^{-1}]$$

with a ring of definition $A[\frac{p}{T}]$, and

$$A(\frac{p,T}{p})=\mathbb{Z}_p[[T]][p^{-1}]$$

with a ring of definition $A[\frac{T}{p}]$.

In $A\langle\frac{p,T}{T}\rangle$, a ring of definition is $A_{\langle X,T\rangle}/(1-pX)$, which is isomorphic to

$$A\langle\frac{T}{p}\rangle=\{\sum_{n\geq 0}a_n(\frac{T}{p})^n|a_n\in A, a_n\to 0\}$$

by(10.3.5.33).

6 Analytic Points and Analytic Huber Pairs

Def. (10.3.6.1) [Analytic Huber Rings]. A Huber ring is called **analytic** if the ideal generated by the topologically nilpotent elements is the unit ideal. Any Tate ring is analytic.

Prop. (10.3.6.2) [Equivalent Definitions of Analytic Rings]. For a Huber ring A, the following are equivalent:

1. A is analytic.

2. Any ideal of definition in any ring of definition of A generates the unit ideal of A.
3. Any open ideal of A is trivial.
4. For any non-trivial ideal I of A, the quotient topology on A/I is not discrete.
5. The only discrete A-module is the 0-module.
6. The set $\mathrm{Spa}(A, A^+)$ contains no point with induced topology on the residue field trivial.

Proof: Cf.[?] P4.? □

Prop. (10.3.6.3) [Analytic Open Mapping Theorem]. If A is an analytic Huber ring, and M, N are complete Banach A-modules, then any continuous surjective map $M \to N$ is open.

Proof: Hub94, L2.4(i).? □

Analytic Points

Def. (10.3.6.4) [Analytic Points]. Let A be a Huber ring, then a point $x \in \mathrm{Cont}(A)$ is called an **analytic point** if $\mathfrak{p}_x$ is not open in A. The set of analytic points of $\mathrm{Cont}(A)$ is denoted by $\mathrm{Cont}(A)_{\mathrm{an}}$.

If A is Tate, then $\mathrm{Cont}(A)_{an} = \mathrm{Cont}(A)$, because the only open ideal of A is A itself.

Prop. (10.3.6.5) [Characterizations of Analytic Points]. Let A be a Huber ring, then for a point $x \in \mathrm{Cont}(A)$, the following is equivalent:

1. x is analytic.
2. $|A^{00}|_x \neq 0$.
3. For any ring of definition and ideal of definition (A_0, I) of A, $|I|_x \neq 0$.

Proof: $1 \to 2$: $\mathfrak{p}_x$ is non-open, so it cannot contain the open subset A^{00} of A??.

$2 \to 3$: trivial because any ring of definition contains A^{00}(10.3.5.8). □

Cor. (10.3.6.6). Let A be a Huber ring and I an ideal of definition with a set of generators $(f_1, \ldots, f_n)$, then

$$\mathrm{Cont}(A)_{an} = \cup_{i=1}^n U(\frac{f_1, \ldots, f_n}{f_i}).$$

Prop. (10.3.6.7) [Analytic Valuation Microbial]. Let A be a Huber ring and $x \in \mathrm{Cont}(A)_{an}$, then x has rank≥ 1, and the valuation $|\cdot|_x$ on $k(x)$ is microbial(10.3.3.22).

Proof: If x has rank 1, then $\Gamma_x = 1$, and $\mathfrak{p}_x = \{a \in A | |a|_x < 1\}$ is open.

If x is analytic, then there are some $a \in A^{00}$ that $|a|_x \neq 0$(10.3.3.22), thus the image of a in $k(x)$ is non-zero and topologically nilpotent, thus $k(x)$ is microbial by(10.3.3.22). □

Prop. (10.3.6.8)[Adic Morphism and Analytic Points]. Let $\varphi : (A, A^+) \to (B, B^+)$ be a morphism of Huber pairs, then:

- If $x \in \mathrm{Spa}(B, B^+)$ is not analytic, then $\mathrm{Spa}(\varphi)(x)$ is not analytic.
- If φ is is adic, then $\mathrm{Spa}(\varphi) : \mathrm{Spa}(B, B^+) \to \mathrm{Spa}(A, A^+)$ carries analytic points to analytic points.
- If B is complete and $\mathrm{Spa}(\varphi) : \mathrm{Spa}(B, B^+) \to \mathrm{Spa}(A, A^+)$ carries analytic points to analytic points, then φ is adic.

- If φ is adic, then the $\mathrm{Spa}(\varphi)$ maps rational subsets to rational subsets. In particular, $\mathrm{Spa}(\varphi)$ is spectral.

Proof: 1: Trivial.

2: If $f(x)$ is not analytic, then $I \subset \varphi^{-1}(\mathfrak{p}_x)$, so $f(I) \subset \mathfrak{p}_x$, which means $\mathfrak{p}_x$ is not analytic because $f(I)A_0$ is open.

3: Cf.Morel P96**?**.

4: Only notice that $(f(T))$ is open if (T) is open. □

Cor. (10.3.6.9). If A is an analytic Huber ring, then any continuous morphism $f : A \to B$ is adic, by(14.8.4.24).

7 Huber and Banach Rings

Cf.[Ked19]1.5.

Prop. (10.3.7.1). Let A be a uniform Huber ring, then for $x = \sum_{n=0}^{\infty} x_n T^n \in A\langle T\rangle$ such that the coefficients x_n generate the unit ideal of A, then multiplication by x defines a strict inclusion $A\langle T\rangle \to A\langle T\rangle$, i.e. $|xg| \geq |g|$.

Proof: Cf.[Ked19]P25. □

8 Perfectoid Fields

Notation (10.3.8.1). Let $(K, \mathcal{O}_K, \mathfrak{m}_K, k)$ be a non-Archimedean complete valued field.

Prop. (10.3.8.2). The valuation can in fact be constructed from K^0 as $|x| = \sup\{\frac{n}{k} | x^k \in t^n K^0\}$ by(2.2.8.5), as it is a rank 1 valuation.

Def. (10.3.8.3) [Perfectoid Field]. If K has residue characteristic p, then it is called a **perfectoid field** iff:

- The value group $|K^\times| \subset \mathbb{R}_+^\times$ is not discrete.
- $\mathcal{O}_K/(p)$ is semi-perfect.

Prop. (10.3.8.4) [Examples of Perfectoid Fields].

- $K = \mathbb{Q}_p(p^{\frac{1}{p^\infty}})^\wedge$. $\mathcal{O}_K = \mathbb{Z}_p(p^{\frac{1}{p^\infty}})^\wedge$, and $\mathcal{O}_K/(p) \cong [\mathbb{F}_p(t^{\frac{1}{p^\infty}})/(t)]^\wedge$, which is clearly semi-perfect. And its value group is $\mathbb{Z}[p^{-1}]$.
- $K = \mathbb{C}_p$, its value group is $\mathbb{Q}$, and $K = \overline{K}$, so $\mathcal{O}_K/(p)$ is clearly perfect.
- if $\mathrm{char}\, K = p$, then K is a perfectoid field iff K is perfect: if K is perfect, then it is clearly perfectoid, and the semi-perfectness of $\mathcal{O}_K$ implies its perfectness, so also K is perfect(multiply by a p-power of an element in $\mathfrak{m}_K$).
- If K is a perfectoid field and $|p| \leq |\varpi| < 1$ is a pseudo-uniformizer, then $K/(\varpi)$ is perfect hence perfectoid.

Prop. (10.3.8.5) [Perfectoid Field and Integral Perfectoid Rings]. The ring of integers $\mathcal{O}_K$ for a perfectoid field K is an integral perfectoid ring(7.7.3.1).

Proof: We assume that K is of char0, then we check conditions in(7.7.3.6). It is clear that $\mathcal{O}_K$ is p-adically complete, p-normal. To find $\varpi^p = pu$, as $|K^*|$ is not discrete, we find x that x^p divides p, and then there exists some y that $y^p \equiv x^p/p \mod p$, thus $(xy)^p \equiv 1 \mod p$, thus $\varpi = xy$ satisfies the condition. □

Prop. (10.3.8.6). If $K \in \text{Perfd}$, then

- $|K^\times|$ is a p-divisible Abelian group.
- $\mathfrak{m}_K^2 = \mathfrak{m}_K$, and $\mathfrak{m}_K$ is flat?.
- $\mathcal{O}_K$ is not Noetherian.

Proof: 1 : First if $|p| < |x| \leq 1$, we show $|x|$ is p-divisible: there is a $y, z \in K^0$ that $y^p = x + pz$, so $|y|^p = |x|$. Now because $|K^*|$ is not discrete, so there is a $|x| \notin |p|^{\mathbb{Z}}$, by rescaling, we may assume $|p| < |x| \leq 1$, thus $p = xy$ for some y, and $|p| < |y| \leq 1$, too. So $|p|$ is also divisible by p, so it is clear now $|K^*|$ is divisible by p.

2 follows from(7.7.3.5)(10.3.8.5).

$2 \to 3$ by Nakayama's lemma, because otherwise $K^{00} = 0$. □

Cor. (10.3.8.7). The proof of 1 also shows that $|K^\times|$ is generated by $|x|$ that $|p| < |x| < 1$.

Lemma (10.3.8.8). If $C^\flat$ is a perfectoid space of residue characteristic p, then $1 + \mathfrak{m}_{C^\flat}$ is a $\mathbb{Q}_p$-algebra.

Proof: Both φ and exponentiation of $\mathbb{Z}_p^*$ is definable, so $p^n t \cdot (1 + x) = (\varphi^n(1 + x))^k$. □

<u>**Tilting**</u>

Prop. (10.3.8.9) [Pseudo-Uniformizers]. Fix a **pseudo-uniformizer** $|p| \leq |\varpi| < 1$, consider the tilting(4.5.1.9) $\mathcal{O}_K^\flat$, then by(4.5.1.12), this topological group doesn't depends on π chosen.

Remark (10.3.8.10). There are diagrams:

$$\begin{array}{ccc} \lim_{x \to x^p} \mathcal{O}_K & \longrightarrow & \mathcal{O}_K \\ \downarrow \cong & \overset{\sharp}{\nearrow} & \downarrow \\ \mathcal{O}_K^\flat = \lim_\varphi K^0/(\varpi) & \longrightarrow & \mathcal{O}_K/(\varpi) \end{array}.$$

Prop. (10.3.8.11) [Tilting of $\mathcal{O}_K$]. There is an element $t \in \mathcal{O}_K^\flat$ that $|t^\sharp| = |\varpi|$, t maps into (π) and gives an isomorphism $\mathcal{O}_K^\flat/(t) \cong \mathcal{O}_K/(\varpi)$.

Moreover, the t-adic topology on $\mathcal{O}_K^\flat$ is complete, and coincides with the topology of $\mathcal{O}_K^\flat$ given as in(4.5.1.9).

Proof: There are canonical surjective map $K^{0\flat} \to K^0/p \to K^0/\pi$, and by p-divisibility of the value group(10.3.8.6), there is a $f \in K^0$ that $|f|^p = |\pi|$, so in particular $|f| > |\pi|$, thus $f \neq 0 \in K^0/\pi$. and choose a $g \in K^{0\flat}$ lifting $f \mod \pi$, then $g^\sharp \equiv f \mod \pi$, see diagram(10.3.8.10). so $|g^\sharp| = |f|$ as $|f| > |\pi|$. Now let $t = g^p$, then $|t^\sharp| = |f|^p = |\pi|$.

Now clearly t maps into (π), and if g maps to 0 in K^0/π, then by the diagram again, $g^\sharp \in (\pi)$, and $(t^\sharp) = (\pi)$, so $g^\sharp = at^\sharp$ for some $a \in K^0$. so $t|g$ in $K^{0\flat}$, as by(4.5.1.17), $R^{0\flat}$ is a valuation ring in the valuation $|\cdot| \circ \sharp$.

For the last assertion, just use the commutative diagrams:

$$\begin{array}{ccc} K^{0\flat}/(t^{p^n}) & \longrightarrow & K^{0\flat}/(t^{p^{n-1}}) \\ \downarrow & & \downarrow \\ K^0/(\pi) & \xrightarrow{\varphi} & K^0/(\pi) \end{array},$$

where the vertical are isomorphisms, and compute their inverse limits. □

Cor. (10.3.8.12) [Tilting of Perfectoid Fields].

- $\mathcal{O}_K^\flat$ is a valuation ring of rank 1, with the field of fraction $K^\flat = \mathcal{O}_K^\flat[t^{-1}] \in \mathrm{Perfd}$.
- Its maximal ideal is $(t^{\frac{1}{p^\infty}})$, with Krull dimension 1.
- The value group and residue field of K and $K^\flat$ is canonical isomorphic.

Proof: $K^{0\flat}$ has rank no more than K^0 which is 1(10.3.8.3), and it is non-trivial because $|t| = |\pi|$, so the rank is 1, and it is perfect by definition, so K is perfectoid by(10.3.8.4).

For the maximal ideal, the maximal ideal of $K^{0\flat}/t$ is its nilradical, as it is a valuation ring of rank 1(2.2.8.5), which is clearly $(t^{\frac{1}{p^\infty}})$. For the dimension, by(10.3.3.3), the Krull dimension equal the rank, which is 1.

For the residue field, use the isomorphism(10.3.8.11), $K^{0\flat}/t = K^0/\pi$ and the second item just proved, and for the value group, the same lemma(10.3.8.11) gives any $|p| \le |\pi| < 1$ are in the value group of $K^\flat$, and $|K^\times|$ is generated by these values by(10.3.8.7). □

Prop. (10.3.8.13) [Tilting Continuous Valuations]. If $K \in \mathrm{Perfd}$, for any continuous valuation on K of any rank, the function $|\cdot|^\flat = |\cdot| \circ \sharp$ is a continuous valuation on $\mathcal{O}_K^\flat$, and every continuous valuation of $\mathcal{O}_K^\flat$ comes from this way.

Proof: Clearly $|-|^\flat$ is multiplicative and has trivial kernel, and it is non-Archimedean: for $f = (f_n), g = (g_n) \in K^\flat$, $f + g = (\lim_k (f_{n+k} + g_{n+k})^{p^k})$ by(4.5.1.14). So

$$|f+g|^\flat = |(f+g)^\sharp| = |\lim_k (f_k+g_k)^{p^k}| = \lim_k |f_k+g_k|^{p^k} \le \lim_n \max\{|f_n|, |g_n|\}^{p^n} = \max\{|f_0|, |g_0|\}.$$

so it is non-Archimedean. It is also continuous because $\sharp$ is continuous.

Conversely, we notice a continuous valuation on a rank 1 valuation field corresponds to valuation rings in the residue field k, so by(10.3.8.12), we get a bijection on the continuous valuations. □

Prop. (10.3.8.14) [Almost Purity in Dimension 0]. If $K \in \mathrm{Perfd}$ and L/K is a finite field extension, with the natural topology, then:

- $L \in \mathrm{Perfd}$.
- $[L^\flat : K^\flat] = [L : K]$.
- The map $L \to L^\flat$ defines an isomorphism $K_{fet} \cong K^\flat_{fet}$.

Proof: This is a special case of almost purity theorem(10.3.10.1). □

Cor. (10.3.8.15). For $K \in \mathrm{Perfd}$, $\mathrm{Gal}_K \cong \mathrm{Gal}_{K^\flat}$.

Lemma (10.3.8.16) [Kedlaya]. For $K \in \mathrm{Perfd}$, then $K^\flat$ is alg.closed iff K is alg.closed.

Proof: Let $P(X) = X^d + a_{d-1}X^{d-1} + \ldots + a_0 \in K^0[X]$ be a irreducible monic polynomial, then its Newton polygon is a line, and we may assume $|a_0| = 1$, as $K^{0\flat}$ is alg.closed, so $|K^{0*}| = |K^{0\flat*}|$(10.3.8.12) is a Q=vector space.

Next we choose a $Q(X) \in K^{0\flat}[X]$ that $Q(X) \equiv P[X] \mod t$, as $K^{0\flat}/t \cong K^0/\pi$(10.3.8.11). Now we consider $P(x + y^\sharp)$, then $P(y^\sharp)$ is divisible by π, so its Newton polygon is now of positive slope, so $c^{-d}P(cx + y^\sharp) \in K^0[X]$ again, where $c^d = |P(y^\sharp)| \le |\pi|$. Then notice by iteration this argument, we get a sequence of $y_n^\sharp$, and then $y_1^\sharp + c_1 y_2^\sharp + c_1 c_2 y_3^\sharp + \ldots + c_1 \ldots c_n y_{n+1}^\sharp$ that converges to a root of $P(X)$. □

Prop. (10.3.8.17) [Examples of Tilting].

- If $K = \mathbb{Q}_p(p^{\frac{1}{p^\infty}})^\wedge$, then $\mathcal{O}_K = \mathbb{Z}_p[p^{\frac{1}{p^\infty}}]^\wedge$, thus $K^\flat = \mathbb{F}_p\widehat{((t))}_{\text{perf}}$(4.5.1.11). And if $L = K(\sqrt{p})$, then similarly $L^0 = \widehat{\mathbb{Z}_p[p^{\frac{1}{2p^\infty}}]}$, and $L^\flat = K^\flat(\sqrt{t})$.
- If $K = \mathbb{Q}_p(\mu_{p^\infty})^\wedge$, then $\mathcal{O}_K = \widehat{\mathbb{Z}_p[\mu_{p^\infty}]}$, notice there is a map $\mathbb{Z}_p[\varepsilon^{\frac{1}{p^\infty}}] \to \mathbb{Z}_p[\mu_{p^\infty}]$ with kernel $(1 + \varepsilon^{\frac{1}{p}} + \ldots + \varepsilon^{\frac{p-1}{p}})$, so
$$\mathcal{O}_K/(p) = \mathbb{F}_p[\varepsilon^{\frac{1}{p^\infty}}]/(\varepsilon^{\frac{1}{p}} - 1)^{p-1} \cong \mathbb{F}_p[t^{\frac{1}{p^\infty}}]/(t^{p-1})$$
with the substitution $t = \varepsilon^{\frac{1}{p}} - 1$. Then by(10.3.8.4), $K^{0\flat} = \mathbb{F}_p\widehat{[t^{\frac{1}{p^\infty}}]}$, and $K^\flat = \mathbb{F}_p\widehat{((t))}_{\text{perf}}$.

Remark (10.3.8.18). Notice that $K = \mathbb{Q}_p(\mu_{p^\infty})^\wedge$ and $K = \mathbb{Q}_p(p^{\frac{1}{p^\infty}})^\wedge$ have the same tiltings, so the tilting functor is not faithful. this is due to the fact that $\mathbb{Q}_p$ is not perfectoid. This will not happen over a perfectoid base field, see(10.3.9.13).

9 Perfectoid Algebras

Def. (10.3.9.1) [Perfectoid Algebra]. For K a perfectoid field with tilt $K^\flat$, let $t \in K^\flat$ be a pseudo-uniformizer??ith $\varpi = t^\sharp$, so it has a compatible collection of p^n-th roots $(t^{\frac{1}{p^n}})^\sharp$. Now:

- A **perfectoid algebra** over K is a uniform Banach K-algebra R that R^0/π is semi-perfect.
- A **perfectoid algebra** over K^{0a} is a K^{0a}-algebra A that is t-adically complete and flat over K^{0a}(or A_* over K^0, by(4.7.3.3)), and $K^{0a}/\pi \to A/\pi$ is relative perfect, i.e. the Frobenius induces an isomorphism $A/\pi^{\frac{1}{p}} \cong A/\pi$.
- A **perfectoid algebra** over K^{0a}/π is a K^{0a}/π-algebra A that is flat over K^{0a}/π(or A_* over K^0/π, by(4.7.3.3)), and the map $K^{0a}/\pi \to A$ is relatively perfect, i.e. the Frobenius induces an isomorphism $A/\pi^{\frac{1}{p}} \cong A$.

Remark (10.3.9.2). notice the definition regarding the relative perfectness doesn't depends on π chosen, by the power lifting theorem(24.1.3.4).

Prop. (10.3.9.3) [Faithfully flatness of Perfectoids]. Nonzero flat $\mathcal{O}_K^a/(\varpi)$-algebras are faithfully flat, so does t-adically complete flat K^{0a}-algebras. In particular, $\text{Perfd}_{\mathcal{O}_K^a/(\varpi)}$ and $\text{Perfd}_{\mathcal{O}_K^a}$ are all faithfully flat modules.

Proof: If $K^{0a}/\pi \to A$ is not faithfully flat, then there is an ideal $J \subset K^{0a}/\pi$ that $K^0/J \neq 0$ but $A/J = 0$. Now this implies $J \subsetneq I$, so there is a $\varpi \in I - J$ hence $J \subset (\varpi)$. Hence $A/\varpi = 0$ as well. Now there are exact sequences $0 \to K^{0a}/\varpi^n \xrightarrow{\varpi} K^{0a}/\varpi^{n+1} \to K^{0a}/\varpi \to 0$, so tensoring with A and induct, we get $K^{0a}/\varpi^n \otimes A = 0$, but $|\varpi^n| < |\pi|$ for some n, so $A = 0$.

The other case is similar, now $A/\varpi = 0$, so use(4.7.3.3), $A_*/\varpi \subset (A/\varpi)_* = 0$, but A_* is also t-adically complete, so $A_* = 0$, and $A = (A_*)^a = 0$. □

Prop. (10.3.9.4) [Examples of Perfectoid Algebras].

- If $\text{char}\, K = p$, then a K-Banach algebra is perfectoid iff it is uniform and perfect. Likewise, a π-adically complete and π-torsion free K^{0a}-algebra is perfectoid iff it is perfect.
- Let $A = \mathcal{O}_K[x_1^{\frac{1}{p^\infty}}, \ldots, x_n^{\frac{1}{p^\infty}}]^\wedge$, then $A^a \in \text{Perfd}_{\mathcal{O}_K^a}$, and $R = A[\pi^{-1}] \in \text{Perfd}_K$ in the Banach metric as in(12.2.4.8).

Proof: 1: a perfectoid algebra of char$p$ is perfect, because by semi-perfectness, $x = x_1^p + \pi z_1 = x_1^p + \pi x_2^p + \pi^2 z_2 = \ldots$, so $x = (x_1 + \pi^{\frac{1}{p}} x_2 + \pi^{\frac{2}{p}} x_3 + \ldots)^p$. In fact, uniformity is automatically implied by perfectness, by(10.3.5.12). The case of $\mathcal{O}_K^a$-algebra is similar.

2: A^a is K^{0a}-flat because A_* does, because it is a colimit of completions of polynomial algebras over I and I is flat over K^0(10.3.8.6). and R is perfectoid by(12.2.4.8) because A is totally integrally closed in R, because $K^0[x_1^{\frac{1}{p^\infty}}, \ldots, x_n^{\frac{1}{p^\infty}}]$ does(trivially), and use(4.7.2.10). □

Tilting Equivalence

Prop. (10.3.9.5) [Tilting Equivalence]. There are canonical isomorphisms of categories:

$$\mathrm{Perfd}_K \cong \mathrm{Perfd}_{K^{0a}} \cong \mathrm{Perfd}_{K^{0a}/\pi},$$

where the first map is by $R \mapsto R^{0a}$ and $A \to A_*[t^{-1}]$ just as in(12.2.4.8). The second map is reduction by π.

In particular, using tilting(10.3.8.11), there are canonical isomorphisms of categories:

$$\mathrm{Perfd}_K \cong \mathrm{Perfd}_{K^{0a}} \cong \mathrm{Perf}_{K^{0a}/\pi} = \mathrm{Perf}_{K^{\flat 0a}/t} \cong \mathrm{Perf}_{K^{\flat 0a}} \cong \mathrm{Perf}_{K^\flat}.$$

If $R \in \mathrm{Perf}_K$ corresponds to $S \in \mathrm{Perf}_{K^\flat}$, then we call $S = R^\flat$ the **tilting** of R and $R = S^\sharp$ the **untilting** of S.

Proof: [$\mathrm{Perf}_K \cong \mathrm{Perf}_{K^{0a}}$]

Firstly, if $R \in \mathrm{Perf}_K$, then $A = R^{0a} \in \mathrm{Perf}_{K^{0a}}$: $R^0/\pi^{\frac{1}{p}} \to R^0/\pi$ is surjective by definition, for injectivity, if $x^p/\pi \in R^0$, then $x/\pi^{\frac{1}{p}}$ is also power bounded, thus in R^0. And by(12.2.4.8), A is π-adically complete and π-torsion-free, hence R-flat by(4.4.1.12).

Next we show if $A \in \mathrm{Perf}_{K^{0a}}$, then A_* is π-adically complete, t-torsion free and p-root closed in $A[\pi^{-1}]$, hence is an left inverse to the mapping $R \to R^{0a}$, by(4.7.3.5). It is complete by(4.7.3.3)2,3.

For p-root closedness, by(4.7.3.3), $A_*/\pi^{\frac{1}{p}} \subset (A/\pi^{\frac{1}{p}})_* \hookrightarrow (A/\pi)_*$ by Frobenius, and then so does $A_*/\pi^{\frac{1}{p}} \to A_*/\pi$. Now if $x \in A_*[\pi^{-1}]$ satisfies $x^p \in A_*$, then $y = \pi^{\frac{k}{p}} x \in A_*$ for some k, and we want to lower k by 1 inductively, thus showing $x \in A_*$: As $y^p \in \pi A_*$, $y \in \pi^{\frac{1}{p}} A_*$ by what we have proved, thus $\pi^{\frac{k-1}{p}} x \subset A_*$.

For surjectivity of Frob: $A_*/\pi \to A_*/\pi$, notice first it is almost surjective, because $(A_* \to A_*/\pi)^a = A \to (A_*/\pi)^a \subset (A/\pi)^a_* = A/\pi$ is surjective by hypothesis, then by(4.7.2.3), it suffices to show that Frob is surjective on A/IA. For some $x \in A^*$, choose $0 < 1 < c$, almost surjectivity shows that $\pi^c x \equiv y^p \mod \pi A_*$, so $(y/p^{\frac{c}{p}})^p \in A_*$, thus $y \in p^{\frac{c}{p}} A_*$, thus $x \equiv (y/p^{\frac{c}{p}})^p \mod \pi^{1-c} A_* \subset IA$, so we are done.

Finally, this is also a right inverse, because we know that $A_* \cong R^0$ by(4.7.3.5), thus $A \cong R^{0a}$ in Mod_R^a. □

Proof: [$\mathrm{Perf}_{K^{0a}} \cong \mathrm{Perf}_{K^{0a}/\pi}$]

Firstly the reduction is a perfectoid K^{0a}/π-algebra: it is flat because flatness is stable under base change, and the rest are trivial. To construct a converse is a problem of deformation theory, we need to lift from K^{0a}/π-algebra via K^{0a}/π^n-algebras to a K^{0a}-algebra, suppose each lifting is unique up to isomorphism and the lift A_n is flat over K^{0a}/π^n, then we can form their inverse limit, which is flat, because it is π-torsion-free: if $\pi(x_n) = 0$, then by $0 \to \pi^n K^{0a}/\pi^{n+1} \to K^{0a}/\pi^{n+1} \xrightarrow{\pi} K^{0a}/\pi^n \to 0$ and the flatness of A_{n+1}, $x_{n+1} \in \pi^n A_{n+1}$, thus $x_n = 0$, and $x = 0$.

Now $0 \neq A \in \mathrm{Perf}_{K^{0a}/\pi}$, then A is faithfully flat by(10.3.9.3), then by(4.7.1.8), $A_{!!}$ is faithfully flat, and $(-)_{!!}$ is preserves all colimits and also Frobenius, so $A_{!!}$ is relatively perfect. Then we use the above argument, and(6.1.4.1) to show that there is a $\widetilde{A} \in \mathcal{C}$ which is π-adically complete and K^0-flat, then $\widetilde{A} = (\widetilde{A_{!!}})^a$ is also p-adically complete and K^{0a}-flat, by(4.7.3.3).

And we check $\widetilde{A}/\pi = (\widetilde{A_{!!}/\pi})^a = (A_{!!})^a = A$ as $(-)_{!!}$ commutes with colimits, and conversely, if $A \in \mathrm{Perf}_{K^{0a}}$, we need to show $A = \widetilde{A/\pi}$, notice by hypothesis, $A_{!!}$ is faithfully flat K^0-algebra that is relatively flat over K^0/π, now it is also complete, because $A_{!!} \to A_*$ is an injection(because $(-)^a$ is exact) and almost isomorphism, so the cokernel is π-torsion, and A_* is complete, so does $A_{!!}$, by(4.2.3.9). Now $A_{!!}/\pi = (A_{!!}/\pi)$ as $(-)_{!!}$ commutes with colimits, so $A_{!!}$ is just the lift, and $(\widetilde{A_{!!}/\pi})^a = A_{!!}^a \cong A$. □

Cor. (10.3.9.6) [Tilting via Fountain's Functors]. The tilt $R^\flat$ is just the Foutain's tilting, i.e. $R^\flat = R^{0\flat}[t^{-1}]$, and $R^\flat = \lim_{x\mapsto x^p} R$, $R^{0\flat} = (R^\flat)^0$.

Proof: Consider the diagram

$$\begin{array}{ccccc} K^{\flat 0}/t^{p^n} & \xrightarrow[\cong]{\varphi^{-n}} & K^{\flat 0}/t \cong K^0/\pi & \longrightarrow & R^0/t \\ & \searrow & \downarrow \varphi^n & & \downarrow \varphi^n \\ & & K^{\flat 0}/t \cong K^0/\pi & \longrightarrow & R^0/t \end{array}$$

Then the upper row is just the unique flat and relative perfect lifting along $K^{\flat 0}/t^{p^n} \to K^{\flat 0}/t$. Taking inverse limit, we get the structure map $K^{\flat 0} \to R^{\flat 0}$, so after almostification, this is just the lifting we are looking for, because it is unique. So $(R^{0\flat})^a = (R^{\flat 0})^a$, and $R^\flat = R^{0\flat}[t^{-1}]$ unwinding the tilting equivalence.

For $R^\flat$, notice there is a map

$$R^\flat \cong (\lim_{x\mapsto x^p} R^0)[t^{-1}] \to \lim_{x\mapsto x^p}(R^0[\pi^{-1}]) \cong \lim_{x\mapsto x^p} R$$

Now injectivity is clear as t is non-zero-divisor, and if $(f_n) \in \lim_{x\mapsto x^p} R$, then $\pi^c f_n \in R^0$ for some c, then $\pi^{\frac{c}{p^n}} f_n \in R^0$ because R^0 is p-root closed(4.7.3.5), so $t^c(f_n) \subset R^{0\flat}$.

For the last assertion, it is true if $R^{0\flat}$ is totally integrally closed in $R^\flat$, by(4.7.3.5). For this, if $t^c f^{\mathbb{N}} \subset R^{0\flat}$, then $\pi^c (f^\sharp)^{\mathbb{N}} \subset R^0$, thus $f^\sharp \in R^0$. And by p-root closedness, p^n-th roots of $f^\sharp$ are all in R^0, so $f = (f_n) \in \lim_{x\mapsto x^p} R$ is in $R^{0\flat}$. □

Prop. (10.3.9.7)[Fountain's Functor θ]. Given a perfectoid field K, the kernel of the Fontaine's map $\theta : A_{\inf}(K) \to K^0$(4.5.1.15) is generated by a non-zero-divisor, in fact, if $\mathrm{char} K = 0$, the generator can be chosen to be any element that maps to a generator of $\ker\overline{\theta}$ and if $\mathrm{char} K = p$ this diagram is trivial. In particular, the diagram is a pushout.

Proof: See the proof of(7.7.3.6) in the p-torsionfree case. □

Prop. (10.3.9.8)[Untilting via $A_{\inf}$]. For any perfect $\mathcal{O}_K^\flat$-algebra A, by deformation theory(or in fact Witt theory) there is a unique lifting $W(A)$ lifting it to $A_{\inf}(K^{0\flat})$. And then pushout $W(A) \otimes_{A_{\inf}(K^0)} K^0$ is just the lifting of A/π, because the diagram above is pushout. This is in fact the method of [Kedlaya-Liu] used to prove the tilting-equivalence without the use of almost mathematics and deformation theory.

Cor. (10.3.9.9) [Limits and Colimits]. Any of the categories in(10.3.9.5) has arbitrary limits and colimits.

Proof: We construct for $\mathrm{Perf}_{K^{0\flat a}}$: The limits is just the limits of topological rings, as the properties of t-adically complete, t-torsion free and perfect is preserved by limits(4.2.3.19). For the colimit, just use the t-adic completion of the left perfection of the colimits in the category of $K^{0\flat a}$-algebras, its t-torsion is almost zero because of perfectness, thus it is almost flat(4.7.3.3). □

Remark (10.3.9.10). Note also for further reference that in the category $\mathrm{Perf}_{K^{0a}}$, a filtered colimits is just the π-adically completion of the filtered limits as rings, because perfectness and flatness is preserved(4.4.1.6).

Prop. (10.3.9.11) [Tilting Equivalence Identifies Fields]. $R\in\mathrm{Perfd}_K$ is a perfectoid field iff its tilt $R^\flat$ is a perfectoid field.

Proof: It is proven that if R is a perfectoid field, then $R^\flat$ is a perfectoid field. Conversely, R is a perfectoid field if the spectral norm given by $||x||=\inf\{|t|^{-1}|t\in R^*,tx\in R^0\}$ is the Banach valuation of R and R is a field.

For the multiplicativeness of $||-||_R$, notice that $R^\flat$ is a perfectoid field, so its non-Archimedean valuation coincides with the spectral norm of $||-||_{R^\flat}$, and this equals $||-||_R\circ\sharp$, because $R^{0\flat}=R^{\flat 0}$, an element $f\in R^{\flat 0}$ iff $f^\sharp\in R^0$. Now the norm extends that of K and commutes with scalar multiplication, so for any f,g, we may assume $f,g\in R^0-0\pi^{\frac{1}{p}}R^0$, now choose $a,b\in R^\flat$ that $a^\sharp-f,b^\sharp-g\in\pi R^0$, this can be done because $R^{\flat 0}=R^{0\flat}\to R^0/\pi$ is surjective, then $a,b,ab\notin tR^{\flat 0}$ because $R^{0\flat}=R^{\flat 0}$. Then clearly $||f||_R=||a||_{R^\flat},||g||=||b||_{R^\flat},||fg||_R=||ab||_{R^\flat}$, so it is multiplicative by the multiplicativeness of $R^\flat$.

To show R is a field, consider and $f\in R-\pi^{\frac{1}{p}}R$, choose $a\in R^\flat$ that $f=a^\sharp+\pi g$, then as $R^\flat$ is a field, there is a b that $ab=1$. Now $||\pi||_R<||\pi^{\frac{1}{p}}||_R\subset||f||_R=||a||_{R^\flat}\leq 1$, so we get $||\pi b^\sharp g||<1$, then

$$f^{-1}=\frac{1}{a^\sharp+\pi g}=\frac{b^\sharp}{1+\pi b^\sharp g}=b^\sharp(\sum(-\pi b^\sharp g)^k)$$

can be constructed in R. □

Perfectoid Affinoid Algebra

Def. (10.3.9.12) [Perfectoid Affinoid K-algebras]. An **affinoid K-algebra** (R,R^+) is just an affinoid Tate ring over (K,K^0). It is called a **perfectoid affinoid K-algebra** iff R is a perfectoid algebra.

Prop. (10.3.9.13) [Affinoid Tilting Equivalence]. The categories of perfectoid affinoid algebras(10.3.9.12) over K and $K^\flat$ are equivalent, where (R,R^+) is identified with $(R^\flat,R^{\flat+})$ iff $R^\flat$ is the tilting of R and

$$\begin{array}{ccc} R^+/\mathfrak{m}R^0 & \xrightarrow{\cong} & R^{\flat+}/\mathfrak{m}^\flat R^{\flat 0} \\ \downarrow & & \downarrow \\ R^0/\mathfrak{m}R^0 & \xrightarrow{\cong} & R^{\flat 0}/\mathfrak{m}^\flat R^{\flat 0} \end{array}.$$

Moreover, in this case, R^+/π is semi-perfect, and $R^{+\flat}\cong R^{\flat+}$ as a subring of $R^{0\flat}\cong R^{\flat 0}$.

Proof: The case $R^+=R^0$ is already known by tilting equivalence(10.3.9.5) and(10.3.9.6).

By(10.3.5.11) and(10.3.5.14), $\mathfrak{m}R^0=R^{00}\subset R^+\subset R^0$, thus $R^+\to R^0$ is an almost isomorphism and R^+ is determined by its image $\overline{R^+}\subset R^0/\mathfrak{m}R^0$, which is integrally closed if R^+ does, so the identification is clear.

For the semi-perfectness: as $R^+/\mathfrak{m}R^0$ is integrally closed, it is perfect. Now $R^+ \to R^0$ is an almost isomorphism, so Frob on R^+/π is almost surjective because it does on R^0/π by definition, and now we know Frob is surjective on R^+/π by(4.7.2.3).

To show $R^{+\flat} \cong R^{+\flat}$, we show there is a Cartesian diagram $\begin{array}{ccc} R^{+\flat} & \longrightarrow & R^{\flat+}/\mathfrak{m}^\flat R^{\flat 0} \\ \downarrow & & \downarrow \\ R^\flat & \longrightarrow & R^\flat/\mathfrak{m}^\flat R^{\flat 0} \end{array}$, but this is the Cartesian diagram $\begin{array}{ccc} R^+/\pi & \longrightarrow & R^+/\mathfrak{m}R^0 \cong R^{\flat+}/\mathfrak{m}^\flat R^{\flat 0} \\ \downarrow & & \downarrow \\ R^0/\pi & \longrightarrow & R^0/\mathfrak{m}^\flat R^0 \end{array}$ applied the functor $(-)^{\mathrm{perf}}$, which preserves limits(4.5.1.9). (Notice that $R^+/\mathfrak{m}R^0 \cong R^{\flat+}/\mathfrak{m}^\flat R^{\flat 0}$ is already perfect). □

Cor. (10.3.9.14). Notice that the proof also shows that $R^+ \to R^0$ is an almost isomorphism, thus if R is a perfectoid K-algebra, then R^+ is automatically a perfectoid K^{0a}-algebra by(10.3.9.1).

Cor. (10.3.9.15) [Perfectoid Affinoid Field]. A perfectoid affinoid K-algebra (R, R^+) is called a **perfectoid affinoid field** iff R is a perfectoid field and R^+ is an open valuation ring.

Notice this is equivalent to $R^+/\mathfrak{m}R^0$ is a valuation ring in $R^0/\mathfrak{m}R^0$. In particular, combining with(10.3.9.11), affinoid perfectoid fields are preserved under tilting and untilting.

Cor. (10.3.9.16). The tilting equivalence also shows that for any perfectoid affinoid K-algebra (R, R^+), the tilting induces an equivalence of categories $\mathrm{Perf}_R \cong$

Prop. (10.3.9.17) [Filtered Colimits of Perfectoid Affinoid K-Algebras]. The category of perfectoid affinoid K-algebras has filtered colimits, and it is just the colimits in the category of complete uniform affinoid Tate rings(14.8.2.27). In particular, the filtered colimits of (A_i, A_i^+) is $(\mathrm{colim}_i\, A_i, \mathrm{colim}\, A_i^+)$.

Proof: The colimit is perfectoid because the filtered colimits is exact. □

10 Almost Purity Theorem

Thm. (10.3.10.1) [Almost Purity Theorem]. For $R \in \mathrm{Perfd}_K$ with tilt S(10.3.9.5),

- Almost purity in characteristic p: (take $(-)_*$ and)Inverting t gives an equivalence $S^0_{a\,\text{fét}} \cong S_{\text{fét}}$.
- Almost purity in characteristic 0: Inverting π gives an equivalence $R^0_{a\,\text{fét}} \cong R_{\text{fét}}$.
- Tilting and untilting functors induce equivalences $R^0_{a\,\text{fét}} \cong S^0_{a\,\text{fét}}$.

In particular, there are equivalences

$$S_{\text{fét}} \xleftarrow{a} S^{0a}_{a\,\text{fét}} \xrightarrow{b} (S^{0a}/t)_{a\,\text{fét}} \cong (R^{0a}/\pi)_{a\,\text{fét}} \xleftarrow{c} R^{0a}_{a\,\text{fét}} \xrightarrow{d} R_{\text{fét}},$$

Proof: The map a is already given in(4.7.2.14) by passing the power bounded-elements(equivalently, S_*) and inverting t. And it is an isomorphism.

The equivalence of b and c follows from[Almost Ring theory, Thm5.3.27]**?**.

The functor d is given by $A \to A_*[t^{-1}]$. Firstly, A is a perfectoid K^{0a}-algebra. This is because it is almost finite projective thus almost flat, and $R^{0a}/\pi \to A/\pi$ is weakly relative perfect by(4.7.2.15), so does $K^{0a}/\pi \to A/\pi$ because relative perfect is stable under composition. And it is finite projective thus almost direct summand of a finite free module.

So now the tilting equivalence(10.3.9.5) shows that $A_*[t^{-1}] \in R_{\text{fét}}$: it is finite etale because the A_* is finite projective by the right adjointness of $(-)_*$, and unramified is defined in terms of A_*. The converse of d is supposed to be the functor that extract from A_* from $A_*[t^{-1}]$ the total integral closure A_{tic} of R^0, which is functorial. We already know that A_* is totally integrally closed in $A_*[t^{-1}]$ by(10.3.9.5), so $A_{tic} \subset A_*$. Conversely, as A is almost finitely generated over R^0, for $f \in A_*$, $\pi f^{\mathbb{N}}$ lies in a f.g. R^0-submodule of A_*, so $f^{\mathbb{N}}$ is totally integral over R^0, so $A_* = A_{tic}$.

It's left to show that d is essentially surjective, but this uses perfectoid spaces. For now, we only check that this is true for R being a perfectoid field(of char 0).For this, we show directly that the untilting functor $\sharp : K^\flat_{\text{fét}} \to K_{\text{fét}}$ is essentially surjective. Now $\sharp$ is an equivalence of categories $\text{Perf}_{K^\flat} \to \text{Perf}_K$, and it preserves degree, at least for field extensions, so it preserves Galois extensions. Now that finite étale algebra over fields are just disjoint of finite separable extensions(4.4.7.19), so it suffices to show that any finite extension of K is contained in some $L^\sharp$.

Consider $M = \widehat{\overline{K^\flat}}$, it is alg.closed of char$p$ so clearly a perfectoid field, and by(10.3.8.16) $M^\sharp$ is alg.closed. $M^\sharp$ is just the colimit in the category of uniform Banach K-algebras, so its valuation ring is just the completion of the valuation ring of $L^\sharp$ for $L/K^\sharp$ finite Galois. Then if $N = \cup L^\sharp$, then N is dense in $M^\sharp$, and N/K is clearly algebraic and in particular Hensel. So $N \subset \overline{N} \subset M^\sharp$ is dense, so by Krasner's lemma(12.2.1.37), $N = \overline{N}$. Now $N = \cup L^\sharp$ is an alg.closure of K, so every finite extension of K is contained in some $L^\sharp$.

The proof of the general case of the essentially surjectivity of d is continued at(14.8.7.10). □

10.4 Real Analysis(Functions on $\mathbb{R}^n$)

Basic references are [Fol99], [周 08], [?] and [譚-伍 06], [Measure theory and fine properties of functions, Evans].

Notation (10.4.0.1).

- Use notations defined in Topology I.
- Use notations defined in Formal Power Series.

1 Measures

Def. (10.4.1.1) [σ-Algebras]. Let $A \in \mathcal{S}\mathrm{et}$, then an **algebra of subsets** of A is a subset of $\mathcal{P}(A)$ that is closed under finite intersections and finite unions. A **σ-algebra** on A is an algebra of subsets of A that is closed under countable unions.

Def. (10.4.1.2) [Measurable Space]. A **measurable space** is a tuple $(X, \mathcal{M})$ where X is a set and $\mathcal{M}$ is a σ-algebra on X.

Def. (10.4.1.3) [Measure]. A **measure** on a measurable space $(X, \mathcal{M})$ is a function $\mathcal{M} \to [0, \infty]$ that

- $\mu(\varnothing) = 0$.
- If E_i is a countable family of disjoint sets in $\mathcal{M}$, then $\mu(\cup_{i=1}^{\infty} E_i) = \sum_{i=1}^{\infty} \mu(E_i)$.

A **measure space** is a measurable space together with a measure μ. A **probabilistic measure** is a measure μ on $(X, \mathcal{M})$ that $\mu(X) = 1$.

Def. (10.4.1.4) [Complex Measure]. A **complex measure** on a measurable space $(X, \mathcal{M})$ is a function $\nu : \mathcal{M} \to \mathbb{C}$ that

- $\nu(\varnothing) = 0$.
- If E_i is a countable family of disjoint sets in $\mathcal{M}$, then $\mu(\cup_{i=1}^{\infty} E_i) = \sum_{i=1}^{\infty} \mu(E_i)$, where the series converges absolutely.

Def. (10.4.1.5) [Measurable Map]. A **measurable map** $f : (X, \mathcal{M}) \to (Y, \mathcal{N})$ is a map $f : X \to Y$ that $f^{-1}(E) \in \mathcal{M}$ for any $E \in \mathcal{N}$.

Def. (10.4.1.6) [Non-Singular Maps]. A **non-singular measurable map** is a measurable map of measure spaces that the preimage of every set of measure0 has measure0.

Def. (10.4.1.7) [Lebesgue Space]. A one-point subset with positive measure is called an **atom**. A **Lebesgue space** is a finite measure space that is isomorphic to a finite union of intervals and countably many atoms.

Thm. (10.4.1.8) [Radon-Nikodym]. If two σ-finite measures v, μ on a measurable space satisfies v is absolutely continuous w.r.t μ, then there is a μ-integrable function f such that

$$dv = f d\mu.$$

Proof: This is a special case of the Freudenthal spectral theorem (10.10.4.18). □

Borel Sets

Def. (10.4.1.9) [Radon Measure]. Let $X \in \mathfrak{Top}$, a **Borel measure** on X is a measure defined on the σ-algebra generated by open sets.

A Borel measure μ is called **inner regular** on a Borel set E iff $\mu(E) = \inf\{\mu(K)|K \subset E \text{ compact}\}$ for every Borel set E. It is called **outer regular** iff $\mu(E) = \sup\{\mu(U)|E \subset U \text{ open}\}$.

A **Radon measure** is a Borel measure that is finite on compact set, outer regular on Borel sets, inner regular on open sets.

Prop. (10.4.1.10). Every Radon measure is inner regular on all of its σ-finite sets.

Proof: Cf.[Folland, Real Analysis, P216]. □

Cor. (10.4.1.11). Every σ-finite Radon measure is regular. In particular, if X is σ-compact, then every Radon measure is regular.

Measurable Functions

Prop. (10.4.1.12) [convergences]. There are three different kinds of convergences:

- **almost everywhere convergence** iff $f_n(x) \to f(x)$ a.e.
- **almost uniform convergence** iff for any $\delta > 0$, there is a measurable subset E_δ that f_n convergent to f uniformly on $E - E_\delta$.
- **convergence in measure** iff $\lim_{k\to\infty} m(\{x \in E||f_n(x) - f(x)| > \varepsilon\}) = 0$.

Prop. (10.4.1.13) [Relations between Convergences].

- (Egoroff) If $m(E) < \infty$ and f_k converges to f a.e. then f_k converges to f almost uniformly.
- If f_k converges to f almost uniformly, then f_k converges to f in measure.
- (Riesz) If f_k converges to f in measure, then there is a subsequence f_{n_k} that converges to f a.e..

Proof: 1: Cf.[实变函数周明强 P113].
2: Trivial.
3: Cf.[实变函数周明强 P118]. □

2 Integrations

Def. (10.4.2.1) [Simple Functions].

Def. (10.4.2.2). A measurable function $f : \mathbb{R}^n \to \mathbb{C}$ is called **locally integrable** if $\int_K |f(x)|dx < \infty$ for every bounded measurable set K of $\mathbb{R}$. The set of locally integrable function is denoted by $L^1_{loc}(\mathbb{R}^n)$.

Prop. (10.4.2.3). A function f is real analytic on an open set of $\mathbb{R}$ iff there is a extension to a complex analytic function to an open set of $\mathbb{C}$. And this is equivalent to: For every compact subset, there is a constant C that for every positive integer k, $|\frac{d^k f}{dx^k}(x)| \leq C^{k+1}k!$.

Proof: Use Lagrange residue(中值定理) to show that it will converge to f. □

Prop. (10.4.2.4) [Monotone-convergence-theorem].

Prop. (10.4.2.5) [Dominant Convergence Theorem].

Prop. (10.4.2.6). The set E of nowhere differentiable functions are of second category in $C[0,1]$, and its complement set is of first category.

Proof: let A_n be the sets of functions f that there exists a s that for any $|h| \le 1/n$, $|\frac{f(s+h)-f(s)}{h}| \le n$. It is easy to see that $C[0,1] - E \subset \cup_n A_n$, so it suffices to show each A_n is of first category.

Firstly A_n is closed, because if $s \notin A_n$, then for any s, there is a $|h_s| \le 1/n$ that $|f(s+h_s)-f(s)| > n|h_s|$. So by continuity, there is a $\varepsilon_s > 0$ and some nbhd J_s of s that $|f(\sigma - h_s) - f(\sigma)| > n|h_s| + 2\varepsilon_s$ for all $\sigma \in J_s$. Then there are f.m. J_{s_i} that covers $[0,1]$, so let $\varepsilon = \min\{\varepsilon_i\}$, then if $||g - f|| < \varepsilon$, then $g \notin A_n$.

And A_n has no interior point, because for any $f \in A_n$, f can be approximated by a polynomial g, by Stone-Weierstrass theorem(10.4.8.1), and by Mean-value theorem, there is a M that $|g(s+h) - g(s)| \le M|h|$ for all s and $|h| < 1/n$. So if p is a pairwise-linear function that $||p||$ is small and the slopes of p are bigger than $M+n$, then $g+p$ is near f but $g+p \notin A_n$.

Finally, E is of second category by Baire theorem(3.3.9.2). □

Prop. (10.4.2.7) [Fubini-Tonelli]. For two σ-finite measure spaces X, Y,

- If $f \in L^+(X \times Y)$, then $f_x \in L^+(Y)$ and $f^y \in L^+(X)$, and
$$\int_{X\times Y} f dxdy = \int_Y \int_X f dxdy = \int_X \int_Y f dydx.$$
- If $f \in L^1(X \times Y)$, then $f_x \in L^1(Y)$ and $f^y \in L^1(X)$, a.e. and the product formula is definable and holds.

Proof: Cf.[Folland P67]. □

Miscellaneous

Lemma (10.4.2.8). If $f : \mathbb{R}_{\ge 1} \to \mathbb{R}$ is a non-decreasing function and $\int_1^\infty \frac{f(t)-t}{t^2}\mathrm{d}t$ converges, then $f(x) \sim x, x \to \infty$.

Proof: Let $F(x) = \int_1^x \frac{f(t)-t}{t^2}\mathrm{d}t$, then the hypothesis implies that for any $\lambda > 1$ and $\varepsilon > 0$, $|F(\lambda x) - F(x)| < \varepsilon$ for x large.

Suppose there exists $\lambda \in \mathbb{R}_{>1}$ and a sequence $(x_n)_{n\in\mathbb{Z}_+}$ s.t. $\lim_{n\to\infty} x_n = \infty$, and $f(x_n) \ge \lambda x_n$ for each n, then
$$F(\lambda x_n) - F(x_n) = \int_{x_n}^{\lambda x_n} \frac{f(t)-t}{t^2}\mathrm{d}t \ge \int_{x_n}^{\lambda x_n} \frac{\lambda x_n - t}{t^2}\mathrm{d}t = \int_1^\lambda \frac{\lambda - t}{t^2}\mathrm{d}t = C$$
where C is a positive constant independent of n. This clearly contradicts the statement above.

A similar statement shows that there are no $\lambda \in \mathbb{R}_{>1}$ and sequences $(x_n)_{n\in\mathbb{Z}_+}$ s.t. $\lim_{n\to\infty} x_n = \infty$, and $f(x_n) \le \lambda^{-1} x_n$ for each n. So $f(x) \sim x, x \to \infty$. □

3 Differentiations

Lemma (10.4.3.1) [Vitali Covering Theorem]. Let $\mathcal{C}$ be a collection of balls in $\mathbb{R}^n$, and let $U = \cup_{B\in\mathcal{C}} B$. Then if $c > m(U)$, then there exists disjoint $B_1, \ldots, B_k \in \mathcal{C}$ that $\sum_{i=1}^k m(B_k) > 3^{-n}c$.

Proof: □

Lemma (10.4.3.2). If $f \in L^1_{\text{loc}}$ and $A_r f(x) = \frac{1}{\text{Vol}(B(r,x))}\int_{B(r,x)} f(y)dy$, then $A_r f$ is continuous in both r and x.

Proof: Cf.[Folland P96]. □

Prop. (10.4.3.3). If $f \in L^1_{\text{loc}}$, then $\lim_{r\to 0} A_r f(x) = f(x)$ for a.e. $x \in \mathbb{R}^n$.

Proof: Cf.[Folland P97]. □

Differentiation on Euclidean Spaces

Prop. (10.4.3.4) [Fermat]. Let $x_0 \in \mathbb{R}, \delta \in \mathbb{R}_+, f$ is a function on $U(x_0, \delta)$. If x_0 is an extreme point of f, and $f'(x_0)$ exists, then $f'(x_0) = 0$.

Proof: By changing f to $-f$ if necessary, we can assume x_0 is a supremum point. Then for $0 < h < \delta$, $\frac{f(x_0+h)-f(x_0)}{h} \leq 0$, and for $-\delta < h < 0$, $\frac{f(x_0+h)-f(x_0)}{h} \geq 0$, so $f'(x) = 0$. □

Lemma (10.4.3.5) [Rolle's Mean Value Theorem]. If $a < b \in \mathbb{R}$, $f \in C([a, b])$ is differentiable on $[a, b]$, and $f(a) = f(b)$, then there exists some $\xi \in (a, b)$ s.t. $f'(\xi) = 0$.

Proof: As f is continuous on $[a, b]$, which is compact, f has minimum m and maximum M on $[a, b]$. If $m = M$, then f is constant, and any $\xi \in (a, b)$ will do. If $M > m$, then $M \neq f(a)$ or $m \neq f(a)$. Suppose WLOG the first case happens, then if $f(\xi) = M, \xi \in (a, b)$, then $f'(\xi) = 0$ by Fermat's theorem(10.4.3.4). □

Thm. (10.4.3.6) [Lagrange's Mean Value Theorem]. If $a < b \in \mathbb{R}$, $f \in C([a, b])$ is differentiable on $[a, b]$, then there exists some $\xi \in (a, b)$ s.t. $f'(\xi) = \frac{f(b)-f(a)}{b-a}$.

Proof: This follows from Rolle's mean value theorem by considering the function

$$F(x) = f(x) - [f(a) + \frac{f(b) - f(a)}{b - a}(x - a)].$$

□

Cor. (10.4.3.7) [Cauchy's Mean Value Theorem]. If $a < b \in \mathbb{R}$, $f, g \in C([a, b])$ is differentiable on $[a, b]$, and $g' \neq 0$. then there exists some $\xi \in (a, b)$ s.t. $\frac{f(b)-f(a)}{g(b)-g(a)} = \frac{f'(\xi)}{g'(\xi)}$.

Proof: This follows from Rolle's mean value theorem by considering the function

$$G(x) = f(x) - [f(a) + \frac{f(b) - f(a)}{g(b) - g(a)}(g(x) - g(a))].$$

□

Prop. (10.4.3.8) [Commutativity of Integration]. Let $n \in \mathbb{Z}_+, n \geq 2, \Omega \subset \mathbb{R}^n$ be open and $f \in C(\Omega)$. If $1 \leq j < k \leq n$ and $\frac{\partial}{\partial x_j}\frac{\partial}{\partial x_k}f, \frac{\partial}{\partial x_k}\frac{\partial}{\partial x_j}f$ exist and continuous on Ω, then

$$\frac{\partial}{\partial x_j}\frac{\partial}{\partial x_k}f = \frac{\partial}{\partial x_k}\frac{\partial}{\partial x_j}f.$$

In particular, this holds for $f \in C^2(\Omega)$.

Proof: For simplicity we prove for $n = 2, i = 1, j = 2$, and the general case is verbatim. For $\mathbf{x} = (x, y) \in \Omega$, if $\Delta x, \Delta y$ is sufficiently small, define

$$I(\Delta x, \Delta y) = \frac{f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0 + \Delta x, y_0)}{\Delta x \Delta y} - \frac{f(x_0, y_0 + \Delta y) - f(x_0, y_0)}{\Delta x \Delta y}$$

and

$$g(x) = f(x, y_0 + \Delta y) - f(x, y_0), \quad h(y) = f(x_0 + \Delta x, y) - f(x_0, y).$$

Then by mean value theorem(10.4.3.6),

$$\begin{aligned} I(\Delta x, \Delta y) &= \frac{g(x_0 + \Delta x) - g(x_0)}{\Delta x \Delta y} \\ &= \frac{g`(x_0 + \theta_1 \Delta x)}{\Delta y} \\ &= \frac{\frac{\partial}{\partial x} f(x_0 + \theta_1 \Delta x, y_0 + \Delta y) - \frac{\partial}{\partial x} f(x_0 + \theta_1 \Delta x, y_0)}{\Delta y} \\ &= \frac{\partial}{\partial y} \frac{\partial}{\partial x} f(x_0 + \theta_1 \Delta x, y_0 + \theta_2 \Delta y) \end{aligned}$$

where $\theta_1, \theta_2 \in [0, 1]$, and

$$\begin{aligned} I(\Delta x, \Delta y) &= \frac{h(y_0 + \Delta y) - h(y_0)}{\Delta x \Delta y} \\ &= \frac{h`(y_0 + \theta_3 \Delta y)}{\Delta x} \\ &= \frac{\frac{\partial}{\partial y} f(x_0 + \Delta x, y_0 + \theta_3 \Delta y) - \frac{\partial}{\partial x} f(x_0, y_0 + \theta_3 \Delta y)}{\Delta x} \\ &= \frac{\partial}{\partial x} \frac{\partial}{\partial y} f(x_0 + \theta_4 \Delta x, y_0 + \theta_3 \Delta y) \end{aligned}$$

where $\theta_3, \theta_4 \in [0, 1]$. Then we get

$$\frac{\partial}{\partial y} \frac{\partial}{\partial x} f(x_0 + \theta_1 \Delta x, y_0 + \theta_2 \Delta y) = \frac{\partial}{\partial x} \frac{\partial}{\partial y} f(x_0 + \theta_4 \Delta x, y_0 + \theta_3 \Delta y).$$

Now let $\Delta x, \Delta y \to 0$ and use the fact $\frac{\partial}{\partial x_j} \frac{\partial}{\partial x_k} f, \frac{\partial}{\partial x_k} \frac{\partial}{\partial x_j} f$ are continuous to finish the proof. □

4 Functions of Bounded Variation

Def. (10.4.4.1) [Absolute Continuity]. For $a, b \in [-\infty, \infty]$, $f \in C([a, b])$ is called **absolutely continuous** on $[a, b]$ if for any $\varepsilon > 0$, there exists $\delta < 0$ s.t. for any f.m. disjoint intervals $(a_i, b_i), i \le N$,

$$\sum_{i=1}^N (b_i - a_i) < \delta \implies \sum_{i=1}^N |F(b_i) - F(a_i)| < \varepsilon.$$

Prop. (10.4.4.2). For $a < b \in [-\infty, \infty]$, $f \in C([a, b])$ is differentiable and $F`$ is bounded, then F is absolutely continuous.

Proof: This follows from the fact $|F(b_i) - F(a_i)| \leq (\sup|F'|)|b_i - a_i|$ by mean value theorem(10.4.3.6). □

Thm. (10.4.4.3) [Fundamental Theorem of Calculus for Lebesgue Measure]. If $a, b \in \mathbb{R}$ and $F \in C([a,b])$, then the following are equivalent:

- F is absolutely convergent on $[a,b]$.
- $F(x) - F(a) = \int_a^x f(t)dt$ for some $f \in L^1([a,b], m)$.
- F is differentiable a.e. on $[a,b]$, $F' \in L^1([a,b], m)$, and $F(x) - F(a) = \int_a^x F'(t)dt$.

In particular, this is the case for F everywhere differentiable and F' bounded, by(10.4.4.2).

Proof: Cf.[Fol99]P106. □

5 Series

Lemma (10.4.5.1). For a sequence $(a_n)_{n\in\mathbb{N}}$ in $\mathbb{R}_+$,

$$\underline{\lim}_{n\to\infty} \frac{a_{n+1}}{a_n} \leq \underline{\lim}_{n\to\infty} a_n^{1/n} \leq \overline{\lim}_{n\to\infty} a_n^{1/n} \leq \overline{\lim}_{n\to\infty} \frac{a_{n+1}}{a_n}$$

Proof: Let $\underline{\lim}_{n\to\infty} a_n^{1/n} = R$. If $R > 0$, then by definition, for any $\varepsilon > 0$ and $M \in \mathbb{Z}_+$, there exists some $m \geq M$ s.t. $a_m^{1/m} < R + \varepsilon$. Then for such M, $a_m/a_1 \leq (R+\varepsilon)^m/a_1$. So for some $k \leq m$, $a_k/a_{k-1} \leq ((R+\varepsilon)^m/a_1)^{m-1}$. Then if M is very large, $a_k/a_{k-1} < R + 2\varepsilon$. Thus $\underline{\lim}_{n\to\infty} \frac{a_{n+1}}{a_n} \leq R$.

Then $\overline{\lim}_{n\to\infty} a_n^{1/n} \leq \overline{\lim}_{n\to\infty} \frac{a_{n+1}}{a_n}$ follows from this by considering the sequence $b_n = a_n^{-1}$. The other inequality is trivial. □

Def. (10.4.5.2) [Euler's Constant]. The limit

$$\lim_{N\to\infty} \Big[\sum_{n=1}^N \frac{1}{n} - \log N\Big]$$

exists, and is denoted by γ, called the **Euler's constant**.

Proof: As

$$\sum_{n=1}^N \frac{1}{n} - \log N = \sum_{n=1}^{N-1} \int_n^{n+1} [\frac{1}{n} - \frac{1}{x}]\mathrm{d}x,$$

this sequence is increasing. And

$$\sum_{n=1}^{N-1} \int_n^{n+1} [\frac{1}{n} - \frac{1}{x}]\mathrm{d}x + \frac{1}{N} < \sum_{n=1}^{N-1} \frac{1}{n(n+1)} + \frac{1}{N} = 1,$$

so it converges. □

Power Series

Prop. (10.4.5.3) [Cauchy-Hadamard]. For any power series $a_0 + a_1x + \ldots + a_nx^n + \ldots$ in $\mathbb{R}$, take $1/R = \overline{\lim}\,|a_n|^{1/n}$, where we assume $1/0 = \infty$ and $1/\infty = 0$, then

- The series converges absolutely for every $|x| < R$, and if $\rho < R$, then the convergence is uniform for $|x| \leq \rho$.

- If $|x| > R$, the terms are unbounded, and the series diverges.

And R is called the **radius of convergence** of the sequence.

Proof: 1: For $0 < \rho < R$, take $\rho_1 \in (\rho, R)$, then the definition of R implies that for some $N \in \mathbb{Z}_+$ and any $n \geq N$, $|a_n| \leq R^{-n} < \rho_1^{-n}$, so $|a_n x^n| \leq (\rho/\rho_1)^n$, so $\sum_{n\in\mathbb{N}} a_n x^n$ converges absolutely and uniformly for $|x| \leq \rho$.

2: For $R < |x|$, the definition of R implies that for any $N \in \mathbb{Z}_+$, there exists $n \geq N$ s.t. $|a_n| \geq R^{-n}$, so $|a_n x^n| \geq |x/R|^n > 1$, so this sequence cannot be convergent. □

Prop. (10.4.5.4). For any power series $a_0 + a_1 x + \ldots + a_n x^n + \ldots$ in $\mathbb{R}$, by(10.4.5.1), if $\lim_{n\to\infty} |\frac{a_{n+1}}{a_n}| = \rho \in [0, \infty]$, then the radius of convergence(10.5.3.1) $R = 1/\rho$, where we assume $1/0 = \infty$ and $1/\infty = 0$.

6 L^p-space

Lemma (10.4.6.1) [Hölder]. if $\sum x_i = 1, x_i \geq 0$, then for any $a_i \geq 0$

$$\prod a_i^{x_i} \leq \sum a_i x_i.$$

Proof: □

Prop. (10.4.6.2) [Holder's Inequality]. Let (S, Ω, μ) be a measure space, and $1 \leq p, q \leq \infty$ satisfies $1/p + 1/q = 1$, then

$$||fg||_1 \leq ||f||_p ||g||_q$$

More generally, if $\sum_{i=1}^n 1/p_i = 1$, then

$$||\prod f_i||_1 \leq \prod ||f_i||_{p_i}$$

Proof: The both sides are homogenous for f_i, so we may assume $||f_i||_{p^i} = 1$, then use Hoder's Lemma(10.4.6.1) for $x_i = q/p_i$. □

Prop. (10.4.6.3) [Dual of $L^p(\mu)$]. For a σ-finite measurable space $(X, \mathcal{M}, \mu)$, for $1 \leq p < \infty$

$$L^p(X, \Omega, \mu)^* = L^q(X, \Omega, \mu).$$

Proof: Firstly, Holder inequality(10.4.6.2) shows that a $g \in L^q(X, \Omega, \mu)$defines a functional by $f \mapsto \int fg d\mu$. Conversely, if given a functional F, define a measure $v(E) = F(\chi_E)$ for all measurable set $E \in \Omega$. It is countably additive: first it is finitely additive, and if E_n is a descending sequence of measurable sets that $\cap E_n = \varnothing$, then

$$v(E_n) \leq ||F||||\chi_{E_n}||_{L^p} = ||F||\mu(E_n)^{\frac{1}{p}} \to 0.$$

(where we used the fact $p < \infty$). And it is clearly absolutely continuous w.r.t. μ.

So by Radon-Nikodym(10.4.1.8), there is a measurable function g that $v(E) = \int_E g d\mu$. So for all simple function f, $F(f) = \int f(x)g(x)$. Next we want to prove $||g||_q \leq ||F||$, because any measurable function f can be approximated by simple functions f_i in L^p norm(10.4.8.4), so

$$|\int (f(x) - f_i(x))g(x) d\mu| \leq ||f - f_i||_p ||g||_q \leq ||f - f_i||_p ||g||_q$$

So $F(f) = \lim F(f_i) = \lim \int f_i g d\mu = \int fg d\mu$.

To prove this, if $1 < p$, then let $E_t = \{x||g(x)| \le t\}$, and $f = \chi_{E_t}|g|^{q-2}g$, then

$$\int_{E_t} |g|^q d\mu = \int fgd\mu = F(f) \le ||F||||f||_{L^p} = ||F||(\int_{E_t} |g|^q d\mu)^{\frac{1}{p}}$$

which is equivalent to $||g\chi E_t||_{L^q} \le ||F||$. Let $t \to \infty$, then the monotone convergence theorem(10.4.2.4) gives us the result.

If $p = 1$, then $q = \infty$. For any $\varepsilon > 0$, let $A = \{x||g(x)| > ||F|| + \varepsilon\}, E_t = \{x||g(x)| \le t\}$, and let $f = \chi_{E_t \cap A}\operatorname{sgn}(g)$, then $||f||_{L^1} = \mu(E_t \cap A)$, and

$$\mu(E_t \cap A)(||F|| + \varepsilon) \le \int_{A\cap E_t} |g|d\mu = \int fgd\mu \le ||F||\mu(E_t \cap A)$$

If $\mu(A) \neq 0$, then let $t \to \infty$, this is a contradiction. So $||g||_\infty \le ||F||$. □

Prop. (10.4.6.4) [Hilbert Basis for Products]. For two σ-finite measure spaces M, N and Hilbert basis(10.8.4.9) $\{e_i\}$ of $L^2(M)$ and $\{f_j\}$ of $L^2(N)$, $\{e_i \otimes f_j\}$ gives a Hilbert basis for $L^2(M \times N)$. (Use Fubini).

Proof: It is easily verified that $e_i \otimes f_j$ are mutually orthogonal, and if some $f \in L^2(M \times N)$ satisfies $(f, e_i \otimes f_j) = 0$ for all i, j, then

$$\int_M e_i(x) \int_N f(x, y)f_j(y) = 0$$

for all i. But $\int_N f(x, y)f_j(y) \in L^2(M)$ for a.e. $x(f(x, y) \in L^2(N)$ a.e. x by Fubini-Tonelli), thus it vanishes. So $f_x(y) = f(x, y) = 0 \in L^2(N)$ for a.e. x, so by Fubini-Tonelli again, $||f||_{L^2(M\times N)} = 0$, thus $f = 0$. □

Prop. (10.4.6.5) [Minkowski's Inequality]. Let $(X, \mathcal{M}, \mu), (Y, \mathcal{N}, \nu)$ be σ-finite measure spaces, and f a $(\mathcal{M} \otimes \mathcal{N})$-measurable function on $X \times Y$.

- If $f \ge 0$ and $1 \le p < \infty$, then

$$[\int (\int f(x, y)d\nu(y))^p d\mu(x)]^{1/p} \le \int [\int f(x, y)^p d\mu(x)]^{1/p} d\nu(y).$$

- If $1 \le p \le \infty$, $f(\cdot, y) \in L^p(\mu)$ for a.e. y, and the function $y \mapsto ||f(\cdot, y)||_p$ is in $L^1(\nu)$, then $f(x, \cdot) \in L^1(\nu)$ for a.e. x, and the function $x \mapsto \int f(x, y)d\nu(y)$ is in $L^p(\mu)$, and

$$||\int f(\cdot, y)d\nu(y)||_p \le \int ||f(\cdot, y)||_p d\nu(y).$$

Proof: 1: If $p = 1$, then this is just Tonelli's theorem(10.4.2.7), and when $1 < p < \infty$, let $q^{-1} + p^{-1} = 1$, and $g \in L^q(\mu)$, then by Tonelli's theorem and Holder's inequality(10.4.6.2),

$$\int [\int f(x, y)d\nu(y)]|g(x)|d\mu(x) = \int\int f(x, y)|g(x)|d\mu(x)d\nu(y) \le ||g||_q \int [f(x, y)^p d\nu(y)]^{1/p} d\nu(y).$$

So we finish by(10.4.6.3).

2 follows from 1 and Fubini's theorem. And when $p = \infty$, this is trivial. □

L^2-Space

Def. (10.4.6.6). Let X be a measure space, then there is a map

$$\star : L^2(X\times X)\times L^2(X\times X)\to L^2(X\times X) : (K_1\star K_2)(u,v)=\int_X K_1(u,x)K_2(x,v)dx.$$

By Schwarz inequality, $||K_1\star K_2||_2\le ||K_1||_2\star||K_2||_2$, thus $\star$ makes $L^2(G\times G)$ into a Banach algebra(without a unit).

This Banach algebra can left and right act on $L^2(X)$, also denoted by $\star$, then for $K\in L^2(X\times X), P,Q\in L^2(X)$,

$$(P\otimes Q)\star K=P\otimes(Q\star K),\quad K\star(P\otimes Q)=(K\star P)\otimes Q.$$

And also for $S,T\in L^2(X)$,

$$(P\otimes Q)\star(\overline{S}\otimes T)=(Q,S)_{L^2}P\otimes T.$$

Prop. (10.4.6.7).

- An element $K\in L^2(X\times X)$ has the form $P\otimes Q$ iff $K\star K'\star K$ is proportional to K for all $K'\in L^2(X\times X)$.
- Let $K_1=P_1\otimes Q_1$ and $K_2=P_2\otimes Q_2$, then P_1 and P_2 are proportional iff $K_1\star K$ and $K_2\star K$ are proportional for all pure tensors $K\in L^2(X\times X)$. Similarly, Q_1 and Q_2 are proportional iff $K\star K_1$ and $K\star K_2$ are proportional for all pure tensor K.
- For any uniform transformation $s: L^2(X\times X)\to L^2(X\times X)$ respecting $\star$, there exists a unitary transformation $s_0: L^2(X)\to L^2(X)$ s.t. $s(P\otimes\overline{Q})=s_0(P)\otimes\overline{s_0(Q)}$. And it can be chosen to be invertible iff s is.

Proof: Cf.[Bump, P527].? □

L^∞-Spaces

Def. (10.4.6.8)[Slowly Oscillating Functions]. A **slowly oscillating function** on $\mathbb{R}^n$ is a function $f\in L^\infty(\mathbb{R}^n)$ s.t. for any $\varepsilon\in\mathbb{R}_+$, there exists $A,\delta\in\mathbb{R}_+$ s.t. $|f(x)-f(y)|<\varepsilon$ whenever $|x|>A, |y|>A, |x-y|<\delta$.

7 Estimations

Prop. (10.4.7.1). $\lim_{n\to\infty}n^{1/n}=1$.

Proof: Let $n^{1/n}=1+\delta_n,\delta_n>0$, then $n=(1+\delta_n)^n\ge 1+\frac{n(n-1)}{2}\delta_n^2$, so $\delta_n\le\sqrt{2/n}$, and $\lim_{n\to\infty}\delta_n=0$. □

Prop. (10.4.7.2). For any $x\in(0,\frac{\pi}{2})$, $\frac{2}{\pi}x<\sin x<x$.

Proof: it suffices to show that $\frac{\sin x}{x}$ is decreasing on $x\in(0,\frac{\pi}{2})$:

$$(\frac{\sin x}{x})'=\frac{x\cos x-\sin x}{x},$$

and $x\cos x-\sin x<0$ because

$$(x\cos x-\sin x)'=-x\sin x<0.$$

□

8 Approximations

Prop. (10.4.8.1) [Stone-Weierstrass Approximation]. If a unital C^*-algebra A of continuous functions on a compact Hausdorff space separates points, then it is dense in $C(X)$.

Proof: This is a consequence of Bishop theorem(10.9.3.18) because in this case the real functions in A separate points, so all A-antisymmetric sets consists of one point. □

Cor. (10.4.8.2). The polynomial functions are dense in $C[-1,1]$.

Prop. (10.4.8.3) [Simple Function Approximation]. Let E be a measure space,

- If $f(x)$ is a non-negative measurable function on E, then there is an ascending sequence of simple functions $(\varphi_n(x))$ that converges to f point-wise.
- If $f(x)$ is a measurable function on E, then there is a sequence of simple functions φ_n that $|\varphi_k(x)| \leq |f(x)|$, and converges to f pointwise.
- If $f(x)$ is bounded, then the convergence can be chosen to be uniform.

Proof: Cf.[实变函数周明强 P110]. □

L^p-Approximation

Prop. (10.4.8.4) [Simple Function Approximation]. Any function in L^p can be approximated by compactly supported simple functions in L^p norm.

Proof: □

Prop. (10.4.8.5). for $1 \leq p < +\infty$, $C_c(X)$ are dense in $L^p(X)$ for a Radon measure, but not for $p = \infty$.

Proof: Use compactly supported simple function approximation(10.4.8.4) and then use outer regular approximation(10.4.1.9) and then Tietz extension. □

Prop. (10.4.8.6) [Lusin]. If f is almost everywhere finite on E, then for any $\delta > 0$, there is a closed subset $F \subset E$ that f is continuous function on F.

Proof: First if f is a simple function $f = \sum_{i=1}^n c_i\chi_{E_i}$, then for each E_i, choose a closed subset $F_i \subset E_i$ that $m(E_i - F_i) < \frac{\delta}{n}$, and then $\cup F_i$ satisfies the required condition.

Now if f is arbitrary, let $g(x) = \frac{f(x)}{1+|f(x)|}$ to make it bounded, then by(10.4.8.3), there is a sequence of simple functions φ_k converging to f, and for each k, we choose a closed subset F_k that $m(E-F_k) < \frac{\delta}{2^k}$, so if we let $F = \cap F_k$, then φ_k are all continuous on F, so by the uniform convergence, f is also continuous on F. □

Cor. (10.4.8.7). If f is measurable function on E that is a.e. finite, then for any δ, there is a continuous function g that $m(\{x \in E | f(x) \neq g(x)\}) < \delta$. And if E is bounded, g can be chosen to be compactly supported.

Proof: Now that there is a closed subset F that $m(E - F) < \delta$ and f is continuous on F, we can use Tietze extension(3.3.6.3), there is a function g that equals f on F.

If $E \subset B(0, R)$, the we can choose a bump function to multiply with g. □

Prop. (10.4.8.8). for $1 \leq p < +\infty$, trigonometric polynomials are dense in $L^p(\mathbb{T})$ and $C(\mathbb{T})$, but not for $p = \infty$. So $e^{2\pi inx}$ forms an orthogonal basis in $L^2(\mathbb{T})$.

Thus, the Parseval's identity holds.

Proof: Just use the fact that Fejer kernels are an approximate identity. □

Prop. (10.4.8.9). For a integrable function u that has compact support, $u_\delta = j_\delta * u$ is a smooth function of compact support that $||u_\delta - u||_{C^k} \to 0$ when $u \in C^k$. Where j_δ is the scaling of a smooth function of compact support. So Smooth function of compact support are dense in C_0^k.

Prop. (10.4.8.10). $D(\mathbb{R}^n)$ is dense in $W^{m,p}(\mathbb{R}^n)$.

Proof: Use the fact that C_0 are dense in L^p by(10.4.8.9). And $f_\delta \to f$ in L^p norm for $f \in C_0$. So we can use the three-part argument applied to $D_\alpha u$ to get $D_\alpha(u_\delta) \to D_\alpha u$ in L^p norm for $|\alpha| \le m$. Thus the result. □

9 Convolutions

Prop. (10.4.9.1). Convolution with a smooth function makes the function smooth, in particular, $\frac{\partial}{\partial x}(f * g) = \frac{\partial f}{\partial x} * g$.

Prop. (10.4.9.2) [Young's Inequality]. $||f * g||_r \le ||f||_p ||g||_q$ for all $1 \le r, p, q \le \infty$ and

$$1 + \frac{1}{r} = \frac{1}{p} + \frac{1}{q}.$$

In particular, $||K * f||_p \le ||K||_1 ||f||_p$.

Proof: By Riesz representation(10.11.1.10), it suffices to show that: for $\frac{1}{p} + \frac{1}{q} + \frac{1}{r} = 2$,

$$\int\int f(x)g(y-x)h(y) \le ||f||_p ||g||_q ||h||_r.$$

write the LHS as

$$\int\int (f^p(x)g(y-x)^q)^{1-\frac{1}{r}}(f^p(x)h^r(y))^{1-\frac{1}{q}}(g^q(y-x)h^r(y))^{1-\frac{1}{p}}$$

and use Holder inequality for three functions(10.4.6.2). □

10 Examples of Calculations

Prop. (10.4.10.1). Assume $\mathrm{Re}(s) > 1/2$, then

$$\int_{-\infty}^{\infty} (1+x^2)^{-s} e^{ik \arctan - \frac{1}{x}} dx = (-i)^k \sqrt{\pi} \frac{\Gamma(s)\Gamma(s-\frac{1}{2})}{\Gamma(s+\frac{k}{2})\Gamma(s-\frac{k}{2})}.$$

Proof: Cf.[Bump, Automorphic Forms and Representations, P230]. □

11 Hausdorff Measures

12 Area and Coarea Formulas

13 Sobolev Spaces

10.5 Complex Analysis I

References are [Ahl78], [S-S03], [谭-伍 06] and [李 04].

Notation (10.5.0.1).

- Use notations defined in Real Analysis(Functions on $\mathbb{R}^n$).
- Let Ω be a region(10.5.1.1).

1 Basics

Def. (10.5.1.1) [Regions]. A **region** is a nonempty connected open subset of $\mathbb{C}$.

Def. (10.5.1.2) [Conjugations]. The non-zero element in $\mathrm{Gal}(\mathbb{C}/\mathbb{R})$ is denoted by $\mathfrak{c}$. And for $z\in\mathbb{C}$, $\mathfrak{c}(z)$ is also denoted by $\overline{z}$.

For $z\in\mathbb{C}$, denote $\mathrm{Re}(z)=\frac{z+\overline{z}}{2},\mathrm{Im}(z)=\frac{z-\overline{z}}{2\,\mathrm{i}}$, called the **real part** and **complex part** of z resp.. So

$$z=\mathrm{Re}(z)+\mathrm{i}\,\mathrm{Im}(z),\quad \overline{z}=\mathrm{Re}(z)-\mathrm{i}\,\mathrm{Im}(z).$$

Prop. (10.5.1.3) [$\mathbb{C}$ is Complete]. The natural extended value from $\mathbb{R}$ to $\mathbb{C}$ is of the form $|x+\mathrm{i}\,y|=\sqrt{x^2+y^2}$. In particular, it is easy to prove that $\mathbb{C}$ is a complete valued field.

Def. (10.5.1.4) [Derivatives]. We introduce the following notations:

$$\frac{\partial}{\partial z}=\frac{1}{2}(\frac{\partial}{\partial x}-\mathrm{i}\,\frac{\partial}{\partial y}),\quad \frac{\partial}{\partial \overline{z}}=\frac{1}{2}(\frac{\partial}{\partial x}+\mathrm{i}\,\frac{\partial}{\partial y}),\quad \mathrm{d}z=\mathrm{d}x+\mathrm{i}\,\mathrm{d}y\quad \mathrm{d}\overline{z}=\mathrm{d}x-\mathrm{i}\,\mathrm{d}y.$$

Then $\mathrm{d}z$ is dual to $\frac{\partial}{\partial z}$ and $d\overline{z}$ is dual to $\frac{\partial}{\partial \overline{z}}$. And for any function f,

$$\mathrm{d}f=\frac{\partial f}{\partial x}\mathrm{d}x+\frac{\partial f}{\partial y}\mathrm{d}y=\frac{\partial f}{\partial z}\mathrm{d}z+\frac{\partial f}{\partial \overline{z}}\mathrm{d}\overline{z}.$$

And also,

$$\mathrm{d}z\mathrm{d}\overline{z}=2\mathrm{d}x\mathrm{d}y=2r\mathrm{d}r\mathrm{d}\theta$$

Def. (10.5.1.5) [Cross Ratios]. For any three pts $z_2,z_3,z_4\in\overline{\mathbb{C}}$, there is a unique linear transformation that maps them to $1,0,\infty$. In fact, the linear transformation is just $Sz=\frac{z-z_3}{z-z_4}/\frac{z_2-z_3}{z_2-z_4}$.

Then for any for point z_1,z_2,z_3,z_4, the **cross ratio** $(z_1,z_2,z_{3,4})$ is the image of z_1 under the linear transformation that carries z_2,z_3,z_4 to $1,0,\infty$.

Prop. (10.5.1.6). The cross ratio is invariant under linear transformation, and it is real iff z_1,z_2,z_3,z_4 are colinear or cocycle.

Proof: The first is because there is only one linear transformation that maps z_2,z_3,z_4 to $1,0,\infty$.

For the second, notice by(10.5.1.5), $\arg(z_1,z_2,z_{3,4})=\arg\frac{z_1-z_3}{z_1-z_4}-\arg\frac{z_2-z_3}{z_2-z_4}$, and this is real iff $\angle z_4z_2z_3=\angle z_4z_1z_3$ or $\pi-\angle z_4z_1z_3$, which is equivalent to cocycle. For other degenerate cases, we need some other argument. □

Cor. (10.5.1.7). A linear transformation maps colinear/cocycle points to colinear/cocycle points.

Lemma (10.5.1.8) [Invariant Factor]. If $a,b,c,d\in\mathbb{R}$, then

$$\mathrm{Im}(\frac{az+b}{cz+d})=\frac{ad-bc}{|cz+d|^2}\,\mathrm{Im}(z).$$

Analytic Functions

Def. (10.5.1.9) [Analytic Functions]. For an open subset $\Omega \subset \mathbb{C}$, a complex-valued function f on Ω is called **analytic** or **holomorphic** if $\frac{\partial}{\partial \bar{z}} f(z) = 0$ for any $z \in \Omega$(10.5.1.4). Equivalently,

$$\frac{\partial}{\partial x} f = -\mathrm{i}\frac{\partial}{\partial y} f, \quad \text{i.e.} \begin{cases} \frac{\partial}{\partial x}\mathrm{Re}(f) = \frac{\partial}{\partial y}\mathrm{Im}(f) \\ \frac{\partial}{\partial x}\mathrm{Im}(f) = -\frac{\partial}{\partial y}\mathrm{Re}(f) \end{cases}$$

i.e. f has the same derivative vertically and horizontally, hence in every direction.

The space of analytic functions on Ω is denoted by $\mathcal{O}(\Omega)$. More generally, if $\Omega \subset \mathbb{C}$ is any subspace, $\mathcal{O}(\Omega) = C(\Omega) \cap \mathcal{O}(\Omega^o)$.

For $f \in \mathcal{O}(\Omega)$, denote

$$f^{\backprime}(z) = \frac{\partial}{\partial z} f(z) = \frac{\partial}{\partial x} f(z) = -\mathrm{i}\frac{\partial}{\partial y} f(z).$$

and for $n \in \mathbb{N}$, denote inductively

$$f^{(0)} = f, \quad f^{(1)} = f^{\backprime}, \quad f^{(n+1)} = (f^{(n)})^{\backprime}.$$

Lemma (10.5.1.10). Let $\Omega \subset \mathbb{C}$ be a region and $f \in \mathcal{O}(\Omega)$ s.t. $f^{\backprime} = 0$, then f is a constant function.

Proof: This follows from the fact any two points in Ω can be connected by a path consisting of vertical or horizontal segments, and use the fundamental theorem of calculus(10.4.4.3). □

Prop. (10.5.1.11) [$\bar{\partial}$-Equation]. Let $\Omega \subset \mathbb{C}$ be a region and $f \in C^k(\Omega), k \geq 1$, then locally near every point, there exists a C^k-function g s.t.

$$\frac{\partial}{\partial \bar{z}} g = f.$$

And such a function is defined up to an analytic function.

Proof: Taking a bump function, we may assume $f \in C^k_c(\Omega)$. Then define

$$g(z) = \frac{1}{2\pi \mathrm{i}}\int_{\mathbb{C}} \frac{f(\zeta)}{\zeta - z} \mathrm{d}\zeta \wedge \mathrm{d}\bar{\zeta} = \frac{1}{2\pi \mathrm{i}}\int_{\mathbb{C}} \frac{f(\zeta + z)}{\zeta} \mathrm{d}\zeta \wedge \mathrm{d}\bar{\zeta}.$$

This singular integration is convergent because $h(\zeta) = \frac{1}{\zeta - z}$ is locally L^1(this follows from(10.5.1.4)). And the integration is uniformly convergent in z. Then the differentiation commutes with integration and shows g is C^k. Moreover,

$$\frac{\partial}{\partial \bar{z}} g(z) = \lim_{\varepsilon \to 0} \frac{1}{2\pi \mathrm{i}} \int_{\mathbb{C}\setminus \mathbb{D}(0,\varepsilon)} \frac{\partial}{\partial \bar{\zeta}} f(\zeta) \frac{\mathrm{d}\zeta \wedge \mathrm{d}\bar{\zeta}}{\zeta - z} = \lim_{\varepsilon \to 0} \frac{1}{2\pi \mathrm{i}} \int_{\partial \mathbb{D}(0,\varepsilon)} f(\zeta) \frac{\mathrm{d}\zeta}{\zeta - z} = f(z)$$

by Stoke's formula and continuity. □

2 Complex Integration

Lemma (10.5.2.1). If f is analytic on a rectangle R minus f.m. points ζ_i and if $\lim_{z \to \zeta_i}(z - \zeta_i) f(z) = 0$, then $\int_{\partial R} f(z) \mathrm{d}z = 0$.

Proof: We consider first the case that no points are omitted. Cut the rectangle R into 4 rectangles R^1, R^2, R^3, R^4 that is similar to R, then

$$\int_{\partial R} f(z)\mathrm{d}z = \sum_{i=1}^{4} \int_{\partial R^i} f(z)\mathrm{d}z.$$

Let $|\int_{\partial R} f(z)\mathrm{d}z| = T$, then there exists some R^i that $|\int_{\partial R^i} f(z)\mathrm{d}z| \geq \frac{1}{4}T$. Denote this R^i by R_1. Then we can do the same for R_1 to find an R_2 s.t. $|\int_{\partial R_2} f(z)\mathrm{d}z| \geq \frac{1}{4^2}T$. Continuing this process, we find a sequence $R_1 \supset R_2 \supset \ldots \supset R_n \supset$, and their intersection is a single point z_0 as R is compact. Now as f is analytic, for any $\varepsilon > 0$, for n sufficiently large, for any $z \in \partial R_n$,

$$|\frac{f(z) - f(z_0)}{z - z_0} - f^{`}(z_0)| \leq \varepsilon.$$

Notice also by direct calculating that

$$\int_{\partial R_n} \mathrm{d}z = 0, \quad \int_{\partial R_n} z\mathrm{d}z = 0,$$

we have

$$\frac{T}{4^n} \leq |\int_{\partial R_n} f(z)\mathrm{d}z| = |\int_{\partial R_n} [f(z) - f(z_0) - f^{`}(z_0)(z - z_0)]\mathrm{d}z| \leq \varepsilon \int_{\partial R_n} |z - z_0||\mathrm{d}z| \leq \varepsilon \frac{dL}{4^n}$$

where d, L are the length of the diagonal and the perimeter of R. So $T \leq \varepsilon$. As ε is arbitrary, this means $T = 0$.

In general, by cutting into several rectangles, it suffices to prove for the case that only one point is omitted, and in this case, we can use what we have proved and the hypothesis to reduce the rectangle to any small enough rectangle R_0 around ζ_1 s.t. for any $z \in \partial R_0$,

$$f(z) \leq \frac{\varepsilon}{|z - \zeta_1|}.$$

And then

$$|\int_{\partial R_0} f(z)\mathrm{d}z| \leq \varepsilon \int_{\partial R_0} \frac{|\mathrm{d}z|}{|z - \zeta_1|} \leq 8\varepsilon$$

by elementary estimation. As ε is arbitrary, this means $\int_{\partial R_0} f(z)\mathrm{d}z = 0$. □

Thm. (10.5.2.2) [Cauchy]. If $\Omega \subset C$ is a simply-connected region and Ω' is the region obtained from Ω by omitting f.m. points ζ_i. Suppose $f \in \mathcal{O}(\Omega')$, and $\lim_{z \to \zeta_i} (z - \zeta_i) f(z) = 0$, then $\int_\gamma f(z)dz = 0$ for any closed piecewise C^1 curve $\gamma \subset \Omega'$.

Moreover, if $f \in \mathcal{O}(\overline{\Omega'})$, then $\int_\gamma f(z)dz = 0$ for any closed piecewise C^1 curve $\gamma \subset \overline{\Omega'} \backslash \{\zeta_1, \ldots, \zeta_i\}$.

Proof: Fix a $z_0 \in \Omega$, then for any $z \in \Omega$, choose a path γ from z_0 to z consisting of vertical or horizontal segments, and let $F(z) = \int_\gamma f(z)dz$. Then this F is well-defined: if there are two paths γ, γ', $\gamma - \gamma'$ is a sum oriented boundary of rectangles, and these rectangles must be contained in Ω because Ω is simply-connected. Thus the above lemme(10.5.2.1) shows that $F(z)$ is independent of the path chosen, and it is clear that $F(z)$ has the same derivative in both directions so analytic by definition(10.5.1.9). So clearly $\int_\gamma f(z)dz = F(z)\Big|_{\gamma(0)}^{\gamma(1)} = 0$.

For the last assertion, any such a closed piecewise C^1 curve $\gamma \subset \overline{\Omega'} \backslash \{\zeta_1, \ldots, \zeta_i\}$ can be uniformly approximated by a path in Ω'. □

Cor. (10.5.2.3) [Existence of Primitive]. If $\Omega \subset \mathbb{C}$ is a simply connected region and $f \in \mathcal{O}(\Omega)$, then there exists a function $F \in \mathcal{O}(\Omega)$ s.t. $F' = f$.

Proof: Take $z_0 \in \Omega$ and take $F(z) = \int_\gamma f(z)\mathrm{d}z$ for any path γ from z_0 to z. F is well-defined by the Cauchy theorem(10.5.2.2). □

Prop. (10.5.2.4) [Generating Analytic Functions]. If $\varphi(\zeta)$ is continuous on an arc γ, then the function

$$F_n(\zeta) = \int_\gamma \frac{\varphi(\zeta)}{(\zeta - z)^n}\mathrm{d}\zeta$$

is analytic on each connected component of $\mathbb{C}\backslash\gamma$, and its derivative is $F_n'(z) = nF_{n+1}(z)$.

Proof: Use induction on n: for $n = 1$, firstly we prove F_1 is continuous: for $z_0 \notin \gamma$, choose $\delta > 0$ s.t. $U(z_0, \delta) \cap \gamma = \varnothing$, then for $z \in U(z_0, \delta)$, $d(z, \gamma) > \delta/2$, and

$$|F_1(z) - F_1(z_0)| = |z - z_0|| \int_\gamma \frac{\varphi(\zeta)}{(\zeta - z)(\zeta - z_0)}\mathrm{d}\zeta| \leq |z - z_0|\frac{2}{\delta^2}\int_\gamma |\varphi||\mathrm{d}\zeta|,$$

thus F_1 is continuous. Moreover, the above argument applied to the function $\Phi(\zeta) = \varphi(\zeta)/(\zeta - z_0)$ implies that

$$\lim_{z\to z_0} \frac{F_1(z) - F_1(z_0)}{z - z_0} = \lim_{z\to z_0}\int_\gamma \frac{\varphi(\zeta)}{(\zeta - z)(\zeta - z_0)}\mathrm{d}\zeta = \lim_{z\to z_0}\int_\gamma \frac{\Phi(\zeta)}{(\zeta - z)}\mathrm{d}\zeta = \int_\gamma \frac{\Phi(\zeta)}{(\zeta - z_0)}\mathrm{d}\zeta = F_2(z_0),$$

hence $F_1' = F_2$.

For $n > 1$, suppose we have shown $F_{n-1}' = (n-1)F_n$, then with notations as above, we have

$$\begin{aligned} F_n(z) - F_n(z_0) &= [\int_\gamma \frac{\varphi(\zeta)}{(\zeta - z)^{n-1}(\zeta - z_0)}\mathrm{d}\zeta - \int_\gamma \frac{\varphi(\zeta)}{(\zeta - z_0)^n}\mathrm{d}\zeta] + (z - z_0)\int_\gamma \frac{\varphi(\zeta)}{(\zeta - z)^n(\zeta - z_0)}\mathrm{d}\zeta \\ &= [\int_\gamma \frac{\Phi(\zeta)}{(\zeta - z)^{n-1}}\mathrm{d}\zeta - \int_\gamma \frac{\Phi(\zeta)}{(\zeta - z_0)^{n-1}}\mathrm{d}\zeta] + (z - z_0)\int_\gamma \frac{\Phi(\zeta)}{(\zeta - z)^n}\mathrm{d}\zeta \end{aligned}$$

Then we see by induction hypothesis that $\lim_{z\to z_0} F_n(z) - F_n(z_0) = 0$ and F_n is continuous for any φ. Moreover,

$$\begin{aligned} \lim_{z\to z_0} \frac{F_n(z) - F_n(z_0)}{(z - z_0)} &= \lim_{z\to z_0} \frac{1}{(z - z_0)}[\int_\gamma \frac{\Phi(\zeta)}{(\zeta - z)^{n-1}}\mathrm{d}\zeta - \int_\gamma \frac{\Phi(\zeta)}{(\zeta - z_0)^{n-1}}\mathrm{d}\zeta] + \int_\gamma \frac{\Phi(\zeta)}{(\zeta - z)^n}\mathrm{d}\zeta \\ &= n\int_\gamma \frac{\Phi(\zeta)}{(\zeta - z_0)^n}\mathrm{d}\zeta + \int_\gamma \frac{\Phi(\zeta)}{(\zeta - z_0)^n}\mathrm{d}\zeta \\ &= (n+1)F_{n+1}(z) \end{aligned}$$

□

Prop. (10.5.2.5) [Index of a Point w.r.t a Curve]. If γ is a piecewise C^1 curve that doesn't pass a point a, then $\frac{1}{2\pi\,\mathrm{i}}\int_\gamma \frac{\mathrm{d}z}{z-a}$ is an integer $n(\gamma, a)$, called the **index of a w.r.t γ**.

And this index function is constant on each connected component of $\mathbb{C}\backslash\gamma$, and 0 on the unbounded component. In particular, if γ is a circle and a is contained in the interior of this circle, then $n(\gamma, a) = 1$.

Proof: Cf. [?]P115.?

this index function is constant on each connected component of $\mathbb{C}\backslash\gamma$, and 0 on the unbounded component by the continuity of the integral by(10.5.2.4).

For the last assertion, it suffices to show for $\gamma = \partial\mathbb{D}(0, R)$ and $a = 0$, by what we just said. And in this case,

$$\frac{1}{2\pi\,\mathrm{i}}\int_\gamma \frac{\mathrm{d}z}{z-a} = \frac{1}{2\pi\,\mathrm{i}}\int_0^{2\pi} \frac{\mathrm{i}\,Re^{i\theta}}{Re^{\mathrm{i}\,\theta}}\mathrm{d}\theta = 1$$

□

Cor. (10.5.2.6) [Cauchy Integral Formula, Cauchy1825]. if $\Omega \subset \mathbb{C}$ is a simply-connected region, $f \in \mathcal{O}(\Omega)$, then for any piecewise C^1 closed curve $\gamma \subset \Omega$ and $a \notin \gamma$,

$$\frac{1}{2\pi\,\mathrm{i}}\int_\gamma \frac{f(\xi)}{\xi - a}\mathrm{d}\xi = n(\gamma, a)f(a)(10.5.2.5).$$

In particular, if γ is the boundary of a disk D contained in $\mathbb{C}$, then for any $a \in D$,

$$\frac{1}{2\pi\,\mathrm{i}}\int_\gamma \frac{f(\xi)}{\xi - a}\mathrm{d}\xi = f(a).$$

Moreover, if $f \in \mathcal{O}(\overline{\Omega})$, then this is true for any piecewise C^1 closed curve $\gamma \subset \Omega$ and $a \notin \gamma$.

Proof: Consider the function $F(z) = \frac{f(z)-f(a)}{z-a}$, then it is analytic for $z \neq a$, and at a it satisfies the condition of Cauchy theorem(10.5.2.2), so $\int_\gamma F(z)dz = 0$ which is $\int_\gamma \frac{f(z)dz}{z-a} = f(a)\int \frac{dz}{z-a}$, and use(10.5.2.5). □

Cor. (10.5.2.7) [Higher Derivations]. For any region Ω $f \in \mathcal{O}(\Omega)$, if $a \in \Omega$ and γ is a small circle γ in Ω centered at a,

$$f(a) = \frac{1}{2\pi\,\mathrm{i}}\int_\gamma \frac{f(\zeta)}{\zeta - a}\mathrm{d}\zeta$$

by Cauchy integral theorem(10.5.2.6). So derivatives of f are all analytic, and satisfy:

$$f^{(n)}(z) = \frac{n!}{2\pi\,\mathrm{i}}\int_\gamma \frac{f(\zeta)}{(\zeta - z)^{n+1}}\mathrm{d}\zeta.$$

In particular, $\mathcal{O}(\Omega) \subset C^\infty(\Omega)$.

Cor. (10.5.2.8) [Morera]. If f is continuous on a region Ω and if $\int_\gamma f\mathrm{d}z = 0$ for any piecewise closed curve $\gamma \subset \Omega$ consisting of vertical or horizontal segments, then $f(z) \in \mathcal{O}(\Omega)$.

Proof: There is an analytic function F that $F' = f$, by the same method of the proof of(10.5.2.2), so f is analytic, by(10.5.2.7). □

Cor. (10.5.2.9)[Cauchy Estimate]. If $f \in \mathcal{O}(\overline{\mathbb{D}(a, r)})$, and $|f| \leq M$ on the boundary, then $|f^{(n)}(a)| \leq Mn!r^{-n}$ for any $a \in \mathbb{D}$.

Cor. (10.5.2.10) [Liouville]. Any bounded holomorphic function on $\mathbb{C}$ is constant.

Proof: if $|f(z)| \leq M$, then the Cauchy estimate shows that $|f'(a)| \leq Mr^{-1}$, letting r tends to ∞, then $f'(a) = 0$ for all a, thus f is constant. □

Cor. (10.5.2.11) [Mean Value Property]. If $f \in \mathcal{O}(\mathbb{D})$, then $|f(0)| \leq \int_{\mathbb{D}} |f(z)| \mathrm{d}x\mathrm{d}y$.

Proof: $|f(0)| \leq \frac{1}{2\pi} \int f(re^{\mathrm{i}\,\theta})\mathrm{d}\theta$, so if multiplied by $r\mathrm{d}r$ and integrate, then

$$|f(0)| \leq \int\int f(re^{\mathrm{i}\,\theta})r\mathrm{d}r\mathrm{d}\theta = \int\int f(z)\mathrm{d}x\mathrm{d}y.$$

□

Prop. (10.5.2.12). For any $f \in \mathcal{O}(\overline{\mathbb{D}(0,R)})$, for $z \in \mathbb{D}(0,R)$:

$$f(z) = \frac{1}{2\pi\,\mathrm{i}} \int_{|\zeta|=R} \mathrm{Re}(\frac{\zeta+z}{\zeta-z}) f(\zeta) \frac{\mathrm{d}\zeta}{\zeta}.$$

Proof: Let $F(\zeta) = \frac{f(\zeta)}{\zeta - R^2/\overline{z}}$, then $F \in \mathcal{O}(\overline{\mathbb{D}(0,R)})$, and by Cauchy's theorem(10.5.2.2),

$$\int_{|\zeta|=R} \frac{f(\zeta)}{\zeta - R^2/\overline{z}} \mathrm{d}\zeta = 0.$$

And by Cauchy's integral formula,

$$\frac{1}{2\pi\,\mathrm{i}} \int_{|\zeta|=R} \frac{f(\zeta)}{\zeta - z} \mathrm{d}\zeta = f(z).$$

so

$$f(z) = \frac{1}{2\pi\,\mathrm{i}} \int_{|\zeta|=R} [\frac{f(\zeta)}{\zeta - z} - \frac{f(\zeta)}{\zeta - R^2/\overline{z}}] d\zeta = \frac{1}{2\pi\,\mathrm{i}} \int_{|\zeta|=R} [\frac{\zeta}{\zeta - z} + \frac{\overline{z}}{\overline{\zeta} - \overline{z}}] f(\zeta) \frac{d\zeta}{\zeta} = \frac{1}{2\pi\,\mathrm{i}} \int_{|\zeta|=R} \mathrm{Re}(\frac{\zeta+z}{\zeta-z}) f(\zeta) \frac{\mathrm{d}\zeta}{\zeta}$$

□

Constructing Analytic Functions

Prop. (10.5.2.13) [Holomorphic Function Defined by Integrations]. Let $(X, \mathcal{M}, \mu)$ be a σ-finite measure space and $\Omega \subset \mathbb{C}$ be a region. For any $F \in L^1(\Omega \times X)$, if

- $F(z,x)$ is analytic in z for any $x \in X$.
- $z \mapsto \int_X |F(z,x)| \mathrm{d}x$ is uniformly convergent on compact subsets.

then $f(z) = \int_X F(z,x)\mathrm{d}x$ is an analytic function on Ω.

In particular, item2 holds if $F \in C(\Omega \times X)$ and X is compact.

Proof: This follows from Morera's theorem(10.5.2.8) and Fubini-Tonelli theorem(10.4.2.7). □

Cor. (10.5.2.14) [Weierstrass]. If $(f_n)_{n\in\mathbb{Z}_+}$ is a sequence of holomorphic functions on Ω that converges uniformly to f on every compact subset, then f is holomorphic on Ω. And for any $k \in \mathbb{N}$, $(f_n^{(k)})_{n\in\mathbb{Z}_+}$ converges uniformly on f on every compact subset.

Proof: For the last assertion, use Cauchy's integral formula(10.5.2.6). □

Local Properties of Analytic Functions

Prop. (10.5.2.15) [Taylor Expansions]. Let $\Omega \subset \mathbb{C}$ be a region and $f \in \mathcal{O}(\Omega)$, then if $D \subset \Omega$ be a closed disk with center z_0, then for any $z \in D$,

$$f(z) = \sum_{n\in\mathbb{N}} \frac{f^{(n)}(z_0)}{n!}(z-z_0)^n.$$

Proof: By Cauchy's integral formula(10.5.2.6), if C is the boundary of D, then

$$f(z) = \frac{1}{2\pi\,\mathrm{i}}\int_C \frac{f(\xi)}{\xi - z}\mathrm{d}\xi$$

But

$$\frac{1}{\xi - z} = \frac{1}{\xi - z_0}\frac{1}{1-(\frac{\xi - z}{\xi - z_0})} = \sum_{n\in\mathbb{N}} \frac{(\xi - z)^n}{(\xi - z_0)^{n+1}}$$

and the convergence is uniform on C, so by(10.5.2.7),

$$f(z) = \int_C \Big(\frac{1}{2\pi\,\mathrm{i}}\int_C \frac{f(\xi)}{(\xi - z_0)^{n+1}}\Big)(\xi - z)^n = \sum_{n\in\mathbb{N}} \frac{f^{(n)}(z_0)}{n!}(z-z_0)^n.$$

□

Cor. (10.5.2.16). For any region $\Omega \subset \mathbb{C}$ and $f \in \mathcal{O}(\Omega)$. If $z_0 \in \Omega$ and $f^{(n)}(z_0) = 0$ for any $n \in \mathbb{N}$, then $f = 0 \in \mathcal{O}(\Omega)$.

Proof: The subset $E = \{z_0 \in \Omega | f^{(n)}(z_0) = 0, \forall n \in \mathbb{N}\}$ is an open subset by the Taylor expansion(10.5.2.15), and the complement is also an open subset as all the derivatives are continuous. So $E = \Omega$, and Ω is connected. □

Prop. (10.5.2.17) [Removable Singularities]. Let $\Omega \subset \mathbb{C}$ and Ω' is the region obtained from Ω by omitting f.m. points ζ_i, $f \in \mathcal{O}(\Omega')$, then f can be extended to an analytic function $f \in \mathcal{O}(\Omega)$ iff $\lim_{z\to\zeta_i}(z-\zeta_i)f(z) = 0$ for each i.

Proof: The necessary is clear. For the other direction, choose for each ζ_i a disk $D(\zeta_i, \delta)$ contained in Ω with boundary γ, then for any $z_0 \in D(\zeta_i, \delta)$, by Cauchy theorem(10.5.2.2) applied to the analytic function $F(z) = \frac{f(z)-f(z_0)}{z-z_0}$ on $D(z_0, \delta)\backslash\{z_0, \zeta_i\}$, we see

$$\int_\gamma \frac{f(\xi)}{\xi - z_0}\mathrm{d}\xi = \int_\gamma \frac{f(z_0)}{\xi - z_0} = f(z_0)(10.5.2.5).$$

But by(10.5.2.4), $z \mapsto \int_\gamma \frac{f(\xi)}{\xi - z}\mathrm{d}\xi$ is a holomorphic function on $D(\zeta_i, \delta)$, and it extends $f(z_0)$. So f can be extended to an analytic function $f \in \mathcal{O}(\Omega)$. □

Def. (10.5.2.18)[Orders of Vanishing]. For any region $\Omega \subset \mathbb{C}$ and $f \neq 0 \in \mathcal{O}(\Omega)$, then for any $z_0 \in \Omega$, there exists a smallest $n \in \mathbb{N}$ s.t. $f^{(n)}(z_0) \neq 0$ by(10.5.2.16). So by repeatedly using(10.5.2.17) on $\frac{f(z)}{z-z_0}$, we get

$$f(z) = (z-z_0)^n f_n(z)$$

on a nbhd of z_0, where $f_n \in \mathcal{O}(\Omega')$ and $f_n(z_0) \neq 0$ for some nbhd Ω' of $z_0 \in \Omega$. Such an n is called the **order of vanishing** of f at z_0.

In particular, if $n > 0$, $f_n(z) \neq 0$ on a nbhd of z_0, so $f(z) \neq 0$ on nbhd of z_0, thus the vanishing point of f is isolated in Ω.

Cor. (10.5.2.19) [Uniqueness]. If the zeros of a holomorphic function f has a convergent point in the domain of definition, then $f = 0$. In particular, if $f, g \in \mathcal{O}(\Omega)$ satisfies $f(z) = g(z)$ for any $z \in E$, where $E \subset \Omega$ is a subset with convergence points in Ω, then $f = g \in \mathcal{O}(\Omega)$.

Prop. (10.5.2.20) [Singularities]. If $\Omega \subset C$ is region and Ω' is the region obtained from $\Omega \backslash E$ where $E = \{\zeta_1, \ldots \zeta_n, \ldots\} \subset \Omega$ is a discrete subset. Suppose $f \in \mathcal{O}(\Omega')$, then f is said to have a **singularity** at ζ_i. For each i, let $\zeta = \zeta_i$, the following are all the cases:

- $\lim_{z\to\zeta} |z-\zeta|^\alpha |f(z)| = 0$ for any $\alpha \in \mathbb{R}$. In this case, $f = 0 \in \mathcal{O}(\Omega)$.
- there exists $h \in \mathbb{R}$ s.t. $\lim_{z\to\zeta} |z-\zeta|^\alpha |f(z)| = \begin{cases} 0 & ,\alpha < h \\ \infty & ,\alpha > h \end{cases}$. In this case, $h \in \mathbb{Z}$, and z_0 is called a **zero** of f if $h > 0$ and **pole** of f if $h < 0$. And if $h = 0$, it is called a **removable singularity**, which is discussed in(10.5.2.17).
- Neither of the above holds. In this case, z_0 is called a **essential singularity** of f.

Proof: In case 1, f can be extended to a function on $\Omega' \cup \{\zeta\}$ with $f(\zeta) = 0$ by(10.5.2.17), and at this point, all the derivatives of f vanish by(10.5.2.18), so $f = 0 \in \mathcal{O}(\Omega)$ by(10.5.2.19).

In case 2, $|z-\zeta|^m |f(z)| = 0$ for some $m \in \mathbb{Z}$ larger than h, so $(z-\zeta)^m f(z)$ can be extended to a function on $\Omega' \cup \{\zeta\}$. As f is not identically zero, $(z-\zeta)^m f(z)$ has a finite order of vanishing at ζ, so $(z-\zeta)^m f(z) = (z-\zeta)^k f_k(z)$ for some $k \in \mathbb{Z}$, and f_k is analytic on a nbhd of ζ, by(10.5.2.18). Thus $f(z) = (z-\zeta)^{k-m} f_k(z)$, and clearly h is an integer. □

Def. (10.5.2.21) [Meromorphic Functions]. Situation as in(10.5.2.20), if all the singularities of f on Ω are zeros or poles, f is called a **meromorphic function** on Ω. Notice the poles and zeros of f are discrete. The space of meromorphic functions on Ω is denoted by $\mathcal{M}(\Omega)$. $\mathcal{M}(\Omega)$ is a field.

Prop. (10.5.2.22). $\mathcal{M}(\Omega)$ is a field, and for any $f \in \mathcal{M}(\Omega)$ and $z_0 \in \Omega$, either $f(z_0) \neq 0$, or $f(z) = (z-z_0)^{n_{z_0}} g(z)$ for some $n_{z_0} \in \mathbb{Z}$ and $g(z) \in \mathcal{M}(\Omega)$ s.t. $g(z_0) \neq 0$.

Proof: This follows from(10.5.2.20) and(10.5.2.17). □

Prop. (10.5.2.23) [Maximum Principle]. Let $f(z)$ be analytic and non-constant on a region Ω, then its absolute value attains no minimum or maximum on Ω.

Proof: This follows easily from Cauchy's integral formula(10.5.2.6). Notice if its attains an extremal at $z_0 \in \Omega$, then the Cauchy integral implies that f is constant on a small circle surrounding z_0, so it is constant by uniqueness theorem(10.5.2.19). □

Prop. (10.5.2.24) [Analytic Functions on Annulus]. If $0 \leq r < R \leq \infty$ and f is holomorphic on $\{z \in \mathbb{C} | r \leq |z| \leq R\}$, show that f has a series expansion

$$f = \sum_{n\in\mathbb{Z}} a_n z^n$$

Proof: For $\zeta \in C_R$,

$$\frac{1}{\zeta - z} = \frac{1}{\zeta} \cdot \frac{1}{1 - \frac{z}{\zeta}} = \sum_{n\in\mathbb{N}} \frac{z^n}{\zeta^{n+1}},$$

and the convergence is uniform on C_R, so

$$\frac{1}{2\pi \mathrm{i}} \int_{C_R} \frac{f(\zeta)}{\zeta - z} \mathrm{d}\zeta = \sum_{n\in\mathbb{N}} \underbrace{\Big(\frac{1}{2\pi \mathrm{i}} \int_{C_R} \frac{f(\zeta)}{\zeta^{n+1}}\Big)}_{a_n} z^n.$$

Similarly, for $\zeta \in C_r$,

$$\frac{1}{\zeta - z} = \frac{1}{z}\cdot\frac{1}{1-\frac{\zeta}{z}} = \sum_{n\in\mathbb{N}} \frac{\zeta^n}{z^{n+1}},$$

and the convergence is uniform on C_R, so

$$\frac{1}{2\pi\,\mathrm{i}}\int_{C_r}\frac{f(\zeta)}{\zeta - z}\mathrm{d}\zeta = \sum_{n\in\mathbb{Z}+}\underbrace{\Big(\frac{1}{2\pi\,\mathrm{i}}\int_{C_r} f(\zeta)\zeta^{n-1}\Big)}_{a_{-n}} z^{-n}.$$

Thus it follows form the Cauchy integral formula(10.5.2.6) that

$$f(z) == \frac{1}{2\pi\,\mathrm{i}}\int_{C_R}\frac{f(\zeta)}{\zeta - z}\mathrm{d}\zeta - \frac{1}{2\pi\,\mathrm{i}}\int_{C_r}\frac{f(\zeta)}{\zeta - z}\mathrm{d}\zeta = \sum_{n\in\mathbb{Z}} a_n z^n,$$

and the convergence is uniform on the annulus. □

Residues

Def. (10.5.2.25) [Residues]. If $\Omega \subset \mathbb{C}$ is a simply-connected region and f is a function on Ω analytic except for isolated singularities $\{a_j\}$, then for each i, if $\mathbb{D}(a_i, \delta)$ is a nbhd of a_i contained in Ω and contains no other singularities of f, then define

$$\operatorname{res}_{z=a_i} f = \frac{1}{2\pi\,\mathrm{i}}\int_\gamma f(z)\mathrm{d}z,$$

where $\gamma = \partial\mathbb{D}(a_i, \delta)$. This quantity is invariant of the nbhd chosen by Cauchy's theorem(10.5.2.2), and is called the **residue** of f at a_i.

Thm. (10.5.2.26) [Residue theorem]. If $\Omega \subset \mathbb{C}$ is a simply-connected region and f is a function on Ω analytic except for isolated singularities $\{a_j\}$, then for any piecewise C^1 closed curve $\gamma \subset \Omega$ not passing through the singularities,

$$\frac{1}{2\pi\,\mathrm{i}}\int_\gamma f(z)\mathrm{d}z = \sum_i n(\gamma, a_i)\operatorname{res}_{z=a_i} f,$$

where the RHS is a finite sum.

Proof: This is because the interior of γ contains only f.m. singularity points, and γ is homologous to a linear combination of cycles around each singularity with multiplicity $n(\gamma, a_i)$. □

Prop. (10.5.2.27). For $n \in \mathbb{Z}$,

$$\operatorname{res}_{z=0} z^n = \begin{cases} 1 & , n = -1 \\ 0 & , n \neq -1 \end{cases}.$$

In particular, if locally near $z = 0$, $f(z) = \sum_{n\in\mathbb{Z}} a_n z^n$, then

$$\operatorname{res}_{z=0} f(z) = a_{-1}.$$

Proof:

$$\begin{aligned}\int_{|z|=r} z^n \mathrm{d}z &= \int_0^{2\pi} z^n(t)z'(t)\mathrm{d}t = \int_0^{2\pi} \mathrm{i}\, r^{n+1}e^{\mathrm{i}(n+1)t}\mathrm{d}t\\ &= \begin{cases} \frac{r^{n+1}}{n+1}e^{\mathrm{i}(n+1)t}\Big|_{t=0}^{2\pi} = 0 & ,n\neq -1\\ 2\pi\,\mathrm{i} & ,n=-1\end{cases}\end{aligned}$$

□

Prop. (10.5.2.28). If $\Omega\subset\mathbb{C}$ is a region and f is a function on Ω analytic with singularities. If f is analytic around $z_0\in\Omega$, then for $n\in\mathbb{Z}_+$, by(10.5.2.7),

$$\mathrm{res}_{z=z_0}\frac{f(z)}{(z-z_0)^n} = \frac{f^{(n-1)}(z_0)}{(n-1)!}.$$

Prop. (10.5.2.29) [Generalized Argument Principle]. If $\Omega\subset\mathbb{C}$ is a simply-connected region and $f\in\mathcal{M}(\Omega)$ with zeros $\{a_i\}$ and poles $\{b_i\}$, and $g(z)\in\mathcal{O}(\Omega)$, then for any piecewise C^1 closed curve $\gamma\subset\Omega$ not passing through zeros or poles of f,

$$\frac{1}{2\pi\,\mathrm{i}}\int_\gamma g(z)\frac{f'(z)}{f(z)}\mathrm{d}z = \sum_i n(\gamma,a_i)g(a_i) - \sum_j n(\gamma,b_j)g(b_i)$$

where the RHS is a finite sum, and counted with multiplicity by the order.

Moreover, notice if Γ is the closed curve $f\circ\gamma$, then

$$\frac{1}{2\pi\,\mathrm{i}}\int_\gamma \frac{f'(z)}{f(z)}\mathrm{d}z = \frac{1}{2\pi\,\mathrm{i}}\int_\Gamma \frac{1}{z}\mathrm{d}z = n(\Gamma,0).$$

Proof: Notice if $z_0\in\Omega$ and $f(z)=(z-z_0)^h f_h(z)$ near z_0 where $h\in\mathbb{Z}$, $f_h(z)$ is analytic on a nbhd of z_0 and $f_h(z_0)=0$, then

$$g(z)\frac{f'(z)}{f(z)} = \frac{hg(z)}{z-z_0} + f_h'(z)g(z),$$

so $\mathrm{res}_{z=z_0}[g(z)\frac{f'(z)}{f(z)}] = hg(z_0)$ by(10.5.2.28) and(10.5.2.5). Thus the assertion follows from the residue formula(10.5.2.26) applied to the meromorphic function $F=gf'/f\in\mathcal{M}(\Omega)$. □

Cor. (10.5.2.30) [Rouché]. If $\Omega\subset\mathbb{C}$ is a region and $\gamma\subset\Omega$ is a piecewise C^1 closed curve that is a boundary of a subset of Ω homeomorphic to a $\mathbb{D}$. Suppose $f,g\in\mathcal{O}(\Omega)$ satisfies $|f(z)-g(z)|<|f(z)|$ for $z\in\gamma$, then $f(z)$ and $g(z)$ have the same number of zeros or poles on the interior of γ.

Proof: This follows from the argument principle(10.5.2.29) applied to the meromorphic function $F=f/g\in\mathcal{M}(\Omega)$. Notice that $n(\gamma,a)=1$ for any a in the interior of γ, and $n(F\circ\gamma,0)=0$ because

$$|F(z)-1|<1$$

For $z\in\gamma$ by hypothesis. □

Logarithm

Def. (10.5.2.31) [Branch of Logarithm]. Let $\Omega \subset \mathbb{C}^\times$ be a region, a branch of **logarithm** is an analytic function $\ell \in (\Omega)$ s.t. $e^{\ell(z)} = z$.

By connectedness, If no confusion is made, we will denote any branch of logarithm by log.

Prop. (10.5.2.32). If $\Omega \subset \mathbb{C}$ is a simply-connected region, and $f \in \mathcal{O}(\Omega)$ is non-vanishing, then there exists some $g \in \mathcal{O}(\Omega)$ s.t. $f(z) = e^{g(z)}$.

Proof: By(10.5.2.3), there exists $\ell \in \mathcal{O}(\Omega)$ s.t. $g' = \frac{f'}{f}$ and we can assume $e^{g(z_0)} = f(z_0)$ for some $z_0 \in \Omega$ because $\exp : \mathbb{C} \to \mathbb{C}^\times$ is clearly surjective. Then notice $[f(z)\exp(-g(z))]' = \exp(-g(z))(f'(z) - f(z)g'(z)) = 0$, so $f(z)\exp(-g(z)) = 0$. □

Cor. (10.5.2.33)[Existence of Logarithm]. If $\Omega \subset \mathbb{C}^\times$ be simply-connected region, then there exists a branch of logarithm on Ω, and also a branch of $\sqrt[n]{f}$ on Ω.

3 Series and Product Developments

Prop. (10.5.3.1) [Abel-Hadamard]. For any power series $a_0 + a_1 z + \ldots + a_n z^n + \ldots \in \mathbb{C}[[z]]$, take $1/R = \overline{\lim}\, |a_n|^{1/n}$, where we assume $1/0 = \infty$ and $1/\infty = 0$, then

- The series converges absolutely for every $|z| < R$, and if $\rho < R$, then the convergence is uniform for $|z| \le \rho$.
- If $|z| > R$, the terms are unbounded, and the series diverges.

And R is called the **radius of convergence** of the sequence. Notice the radius of convergence is the same as that of $|a_0| + |a_1|z + \ldots + |a_n|z^n + \ldots$ in $\mathbb{R}$(10.4.5.3).

Proof: 1: For $0 < \rho < R$, take $\rho_1 \in (\rho, R)$, then the definition of R implies that for some $N \in \mathbb{Z}_+$ and any $n \ge N$, $|a_n| \le R^{-n} < \rho_1^{-n}$, so $|a_n z^n| \le (\rho/\rho_1)^n$, so $\sum_{n\in\mathbb{N}} a_n z^n$ converges absolutely and uniformly for $|z| \le \rho$.

2: For $R < |z|$, the definition of R implies that for any $N \in \mathbb{Z}_+$, there exists $n \ge N$ s.t. $|a_n| \ge R^{-n}$, so $|a_n z^n| \ge |z/R|^n > 1$, so this sequence cannot be convergent. □

Cor. (10.5.3.2). By(10.4.5.4) and(10.5.3.1), for any power series $a_0 + a_1 x + \ldots + a_n x^n + \ldots$ in $\mathbb{R}$, if $\lim_{n\to\infty} \frac{|a_{n+1}|}{|a_n|} = \rho \in [0, \infty]$, then the radius of convergence(10.5.3.1) $R = 1/\rho$, where we assume $1/0 = \infty$ and $1/\infty = 0$.

Prop. (10.5.3.3). The power series $a_0 + a_1 z + \ldots + a_n z^n + \ldots$ defines an analytic function $f(z)$ on its disk of convergence. And also

$$f'(z) = \sum_{n\in\mathbb{N}} n a_n z^{n-1}.$$

In particular, $f(z)$ is infinite differentiable in its disk of convergence.

Proof: The partial sum converges to f uniformly on compact subset of the disk of convergence(10.5.3.1), so this follows from(10.5.2.14). □

Prop. (10.5.3.4). Any holomorphic function f defined on the punctured disk $0 < |z| < 1$ is of the form

$$f(z) = \sum_{n\in\mathbb{Z}} a_n z^n$$

where $\overline{\lim}_{n\to\infty} |a_n|^{1/n} \le 1$, and $\lim_{n\to\infty} |a_{-n}|^{1/n} = 0$.

Proof:

□

Prop. (10.5.3.5). If $f \in C((0,1])$ has an expansion

$$f(x) = \sum_{\nu \in \Sigma} a(\nu) x^{\nu}$$

near $x = 0$, where $\Sigma \subset \mathbb{R}$ is a discrete subset bounded from below, then

$$\int_0^1 f(x) x^s \frac{dx}{x}$$

has meromorphic continuation to all $s \in \mathbb{C}$, and has only simple poles at $s \in -\Sigma$, and the residue at $s = -\nu$ is $a(\nu)$. Moreover, for any $N \in \mathbb{R}$, f is essentially bounded on $\mathrm{Re}(s) > -N$.

Proof: For any $N \in \mathbb{R}$, let

$$f(x) = \sum_{\nu \in \Sigma, \nu < N} a(\nu) x^{\nu} + R(x), \quad R(x) = O(x^N),$$

then

$$\int_0^1 f(x) x^s \frac{dx}{x} = \sum_{\nu \in \Sigma, \nu < N} \frac{a(\nu)}{s+\nu} + \int_0^1 R(x) x^s \frac{dx}{x}.$$

□

Prop. (10.5.3.6) [Trigonometric Functions]. The exponential function

$$\exp(z) = \sum_{n \in \mathbb{N}} \frac{z^n}{n!} (8.5.1.5)$$

is convergent and analytic on $\mathbb{C}$, by(10.5.3.1), and it is also denoted by e^z. We can also define the **trigonometric functions**

$$\cos(z) = \frac{e^{\mathrm{i} z} + e^{-\mathrm{i} z}}{2} = \sum_{n \in \mathbb{N}} (-1)^n \frac{z^{2n}}{(2n)!}, \quad \sin(z) = \frac{e^{\mathrm{i} z} - e^{-\mathrm{i} z}}{2\,\mathrm{i}} = \sum_{n \in \mathbb{N}} (-1)^n \frac{z^{2n+1}}{(2n+1)!},$$

which are analytic on $\mathbb{C}$.

Prop. (10.5.3.7) [Eulerian Identity]. The smallest positive real number ρ that $e^{\mathrm{i}\rho} + 1 = 0$ is π. In particular, the Eulerian identity $e^{\pi \mathrm{i}} + 1 = 0$ holds.

Proof: □

Prop. (10.5.3.8) [Infinite Products]. For a sequence $(b_n) \in \mathbb{C} \backslash \{-1\}$, the infinite product $\prod_{n \in \mathbb{Z}_+} (1 + b_n)$ is said to **converge** if the sequence

$$\Pi_m = \prod_{n=1}^{m} (1 + b_n)$$

converges. It is said to **converge absolutely** if $\prod_{n \in \mathbb{Z}_+} \log(1 + b_n)$ converges absolutely. Then:

- If $\prod_{n \in \mathbb{Z}_+} (1 + b_n)$ converges absolutely, then $\prod_{n \in \mathbb{Z}_+} (1 + b_n)$ converges to a non-zero limit.

- $\prod_{n\in\mathbb{Z}_+}(1+b_n)$ converges absolutely iff $\sum_{n\in\mathbb{Z}_+} b_n$ converges absolutely.
- If $(a_n)\in\mathbb{C}$ and $\sum_{n\in\mathbb{Z}_+} a_n$ converges absolutely, then $\prod_{n\in\mathbb{Z}_+}(1+a_n)=0$ iff $a_k=-1$ for some k.

Proof: 1: $\prod_{n\in\mathbb{Z}_+}(1+b_n)=\exp(\sum_n \log(1+b_n))$.

2: It follows from the fact $\lim_{z\to 0}\frac{\log(1+z)}{z}=1$ that there exists a $0<\varepsilon<1/2$ that

$$(1-\varepsilon)|a_n|<|\log(1+a_n)|\le(1+\varepsilon)|a_n|$$

for n sufficiently large.

3: By omitting f.m. terms, this follows from item2. □

Prop. (10.5.3.9). If (F_n) is a sequence of holomorphic functions on a region Ω, and there exists constants $c_n>0$ s.t.

$$\sum c_n<\infty, |F_n(z)-1|\le c_n, \forall z\in\Omega,$$

then

- The product $\prod_n F_n(z)$ converges uniformly on Ω to a holomorphic function $F(z)$.
- If $F_n\ne 0$ for any n, then
$$\frac{F'(z)}{F(z)}=\sum_n\frac{F_n'(z)}{F_n(z)}.$$
- If $F_n\ne 0$ for any n, then the zeros of $F(z)$ are exactly zeros of $F_n(z)$(counting multiplicity).

Proof: 1: The proof is the same as that of(10.5.3.8), and notice that the convergence is uniform so the resulting function is holomorphic.

2: we can omit f.m. terms, so we may assume that each F_n is non-vanishing. Let $G_N(z)=\prod_{k=1}^N F_n(z)$, then $G_N(z)\to F(z)$ uniformly on compact subsets. So by(10.5.2.14), G_N' converges to $F'(N)$ uniformly on compact subset, and

$$\frac{F'(z)}{F(z)}=\lim_{N\to\infty}\frac{G_N'(z)}{G_N(z)}=\sum_n\frac{F_n'(z)}{F_n(z)}.$$

3: This is because we can omit f.m. terms and assume that each F_n is non-vanishing. Then the resulting □

Partial Fractions

Def. (10.5.3.10).

Prop. (10.5.3.11).

$$\pi\cot(\pi z)=\frac{1}{z}+\sum_{n\ne 0\in\mathbb{Z}}(\frac{1}{z-n}+\frac{1}{n})=\frac{1}{z}+\sum_{n\in\mathbb{Z}_+}\frac{2z}{z^2-n^2}=\frac{1}{z}-2\sum_{k\in\mathbb{Z}_+}\zeta(2k)z^{2k-1}.$$

Proof: This follows from taking logarithmic derivative of the Hadamard product of $\sin(\pi z)$(10.5.3.23). □

Cor. (10.5.3.12).

$$\frac{\pi^2}{\sin^2(\pi z)}=\sum_{n\in\mathbb{Z}}\frac{1}{(z-n)^2}.$$

Proof: This follows form taking derivative of(10.5.3.12). □

Entire Functions

Thm. (10.5.3.13) [Product Development, Weierstrass].

- If f is an entire function, then the zeros of f is at most countable(counting multiplicity), and if they can be ordered by their modules, $|a_1| \leq |a_2| \leq \ldots \leq |a_n| \leq$ with $\lim_{n\to\infty} |a_n| = \infty$.
- If $S \subset \mathbb{Z}_+$, and $(a_n)_{n\in S} \subset \mathbb{C}$ be a sequence of complex numbers, which satisfies $\lim_{n\to\infty} a_n = \infty$ when $\#S = \infty$, then every entire function with (a_n) as zeros(counting multiplicity) can be written in the form

$$f(z) = z^m e^{g(z)} \prod_{n\in S} \Big[(1 - \frac{z}{a_n}) \exp(\frac{z}{a_n} + \frac{1}{2}(\frac{z}{a_n})^2 + \ldots + \frac{1}{m_n}(\frac{z}{a_n})^{m_n})\Big]$$

for some sequence $(m_n)_{n\in S}$ of positive integers.

Proof: Firstly, for any such sequence, the RHS converges to an entire function: for any $z \in \mathbb{C}$, we can discard f.m. terms s.t. $|a_n| \leq |z|$, and for $|a_n| > |z|$,

$$(1 - \frac{z}{a_n}) \exp(\frac{z}{a_n} + \frac{1}{2}(\frac{z}{a_n})^2 + \ldots + \frac{1}{m_n}(\frac{z}{a_n})^{m_n}) = \exp(-\frac{1}{m_n + 1}(\frac{z}{a_n})^{m_n+1} - \frac{1}{m_n + 2}(\frac{z}{a_n})^{m_n+2} - \ldots)$$

and the module of the exponent is bounded by

$$\frac{1}{m_n + 1}(\frac{|z|}{|a_n|})^{m_n+1}(1 - \frac{|z|}{|a_n|})^{-1}$$

So if we choose $m_n = n$, the RHS converges in a nbhd of z, and it is entire.

Then any such function with the desired zeros differ by the RHS by an entire non-vanishing function, which must be of the form $\exp(g(z))$ by(10.5.2.33). □

Cor. (10.5.3.14). Any entire function on $\mathbb{C}$ is a quotient of two meromorphic functions.

Cor. (10.5.3.15). If $S \subset \mathbb{Z}_+$, and $(a_n)_{n\in S}, (A_n)_{n\in S} \subset \mathbb{C}$ be two sequence of complex numbers s.t. $a_m \neq a_n$ for $m \neq n$, which satisfies $\lim_{n\to\infty} a_n = \infty$ when $\#S = \infty$, then there exists an entire function $f(z)$ which satisfies $f(a_n) = A_n$.

Proof: Let $g(z)$ be an entire function satisfying $g(z)$ has simple zeros at a_n, then consider

$$f(z) = \sum_{n\in S} g(z) \frac{e^{\gamma_n(z-a_n)}}{z - a_n} \frac{A_n}{g'(a_n)}.$$

□

Def. (10.5.3.16) [Genus of Entire Functions and Canonical Products]. The **genus of an entire function** f is the smallest $h \in \mathbb{N}$ s.t. f can be written in the form

$$f(z) = z^m e^{g(z)} \prod_{n\in S} \Big[(1 - \frac{z}{a_n}) \exp(\frac{z}{a_n} + \frac{1}{2}(\frac{z}{a_n})^2 + \ldots + \frac{1}{h}(\frac{z}{a_n})^h)\Big]$$

where $S \subset \mathbb{N}, m \in \mathbb{N}, g(z)$ is a polynomial of degree$\leq h$. if no such h exists, f is said to have genus ∞.

In view of the Weierstrass theorem(10.5.3.13), this h is equal to the minimal non-negative integer s.t.

$$\sum_{n\in\mathbb{Z}_+} |a_n|^{-h-1} < \infty.$$

If f has finite genus, then the canonical form of f is unique.

Def. (10.5.3.17) [Order of Growth]. The **order of growth** of an entire function f is defined to be

$$\lambda = \overline{\lim_{r\to\infty}} \frac{\log\log \max_{|z|=r}|f(z)|}{\log r},$$

or equivalently the smallest number $\lambda \in \mathbb{R}\cup\{\infty\}$ s.t.

$$\max_{|z|=r}|f(z)| \leq e^{r^{\lambda+\varepsilon}}$$

for any $\varepsilon > 0$.

Lemma (10.5.3.18). Let f be an entire function with order of growth ρ.

- For $r \in \mathbb{R}_+$, let $N(r)$ be the number of zeros of f in $\mathbb{D}(0,r)$, then for any $\varepsilon > 0$, there exists $C > 0$ s.t. $N(r) \leq Cr^{\rho+\varepsilon}$ for r sufficiently large.
- Let $\{a_n\}_{n\in\mathbb{Z}_+}$ be the zeros of f, then for any $\varepsilon > 0$, $\sum_{k\in\mathbb{N}}|a_k|^{-\rho-\varepsilon} < \infty$.

Proof: 1: dividing $f(z)$ by a power of z, we may assume $f(0)\neq 0$. Then it follows from the Jensen formula(10.6.2.11) on the disk $\mathbb{D}(0,2\rho)$ that

$$N(r)\log 2 \leq \frac{1}{2\pi}\int_0^{2\pi}\log|f(2re^{\mathrm{i}\theta})|\mathrm{d}\theta - \log|f(0)| \leq (2r)^{\rho+\varepsilon} - \log|f(0)|.$$

2: By item1, for n large, $n \leq N(|a_n|) \leq |a_n|^{\rho+\varepsilon/2}$, so

$$\sum |a_n|^{-\rho-\varepsilon} \leq \sum_{n\in\mathbb{Z}_+}|n|^{-\frac{\rho+\varepsilon}{\rho+\varepsilon/2}} < \infty.$$

□

Lemma (10.5.3.19). If g is an entire function on $\mathbb{C}$, $\rho\in\mathbb{R}_+$ and there is a sequence of positive real numbers (r_n) that extends to infinity, and $u = \mathrm{Re}(g)$ satisfies

$$\max_{|z|=r_n} u(z) \leq Cr_n^\rho$$

for each n, then g is a polynomial of degree$\leq s$.

Proof: Let $g(z) = \sum_{n\in\mathbb{N}} a_n z^n$, then for any $k\in\mathbb{Z}_+$, let $r = r_k$, by Cauchy's formula

$$\frac{1}{2\pi}\int_0^{2\pi} g(re^{\mathrm{i}\theta})e^{-\mathrm{i}m\theta}\mathrm{d}\theta = \begin{cases} a_m r^m & ,m\in\mathbb{N} \\ 0 & ,n\in\mathbb{Z}_- \end{cases},$$

so by taking conjugation and adding,

$$\frac{1}{\pi}\int_0^{2\pi}\mathrm{Re}(g)(re^{\mathrm{i}\theta})e^{-\mathrm{i}n\theta}\mathrm{d}\theta = \begin{cases} a_n r^n & ,n\in\mathbb{Z}_+ \\ \mathrm{Re}(a_0) & ,n = 0 \end{cases}.$$

Then for $n\in\mathbb{Z}_+$,

$$|a_n| = \frac{1}{\pi r^n}\left|\int_0^{2\pi}[u(re^{\mathrm{i}\theta}) - Cr^\rho]e^{-\mathrm{i}n\theta}\mathrm{d}\theta\right| \leq \frac{1}{\pi r^n}\int_0^{2\pi}[Cr^\rho - u(re^{\mathrm{i}\theta})]\mathrm{d}\theta = 2Cr^{s-n} - 2\,\mathrm{Re}(a_0)r^{-n}.$$

Then letting $r = r_k\to\infty$ finishes the proof. □

Thm. (10.5.3.20) [Hadamard]. The genus h and the order λ of an entire function f satisfies

$$0 \le h \le \lambda \le h+1 \le \infty.$$

(Notice if $\lambda \in \mathbb{Z}$, it might not be able to determine h from λ).

Proof: It follows from the proof of Weierstrass theorem(10.5.3.13) that is f is of genus $h < \infty$, then $\lambda \le h+1$(taking $m_n = h$ for each n). Conversely, if f has order of growth $\lambda < \infty$, then we need to show that $h \le \lambda$. Take $h = \lfloor \lambda \rfloor$, and let (a_n) are zeros of f(counting multiplicity and ordered by modulus), then firstly, we show that the product

$$\prod_{n\in S}\Big[(1-\frac{z}{a_n})\exp(\frac{z}{a_n}+\frac{1}{2}(\frac{z}{a_n})^2+\ldots+\frac{1}{h}(\frac{z}{a_n})^h)\Big]$$

converges: For this, by the proof of Weierstrass theorem(10.5.3.13), it suffices to show that $\sum_{n\in S}|a_n|^{-h-1}$ converges, and this follows from(10.5.3.18).

Then it's left to show that the entire function $g(z)$ as in(10.5.3.13) is a polynomial of degree$\le h$. For this, firstly we prove that if $\varepsilon > 0$ is small that $\rho+\varepsilon < h+1$, and $|z-a_n| \ge |a_n|^{h+1}$ for any $n \in S$, then there exists $C \in \mathbb{R}_+$ s.t.

$$\Big|\prod_{n\in S}\Big[(1-\frac{z}{a_n})\exp(\frac{z}{a_n}+\frac{1}{2}(\frac{z}{a_n})^2+\ldots+\frac{1}{h}(\frac{z}{a_n})^h)|\Big]\Big| \ge e^{-C|z|^{\rho+\varepsilon}}.$$

Deonte $E_h(s) = (1-s)\exp(s+\frac{1}{2}s^2+\ldots+\frac{1}{h}s^h)$, we use a lemma:

Lemma (10.5.3.21). there exists constant C s.t.

- If $|s| \le 1/2$, $|E_h(s)| \ge e^{-C|z|^{h+1}}$.
- If $|s| \ge 1/2$, $|E_h(s)| \ge |(1-s)|e^{-C|z|^h}$.

Proof: For $|s| \ge 1/2$,

$$|E_h(s)| \ge |(1-s)|e^{-|s|-\frac{|s|^2}{2}-\ldots-\frac{|s|^h}{h}} \ge |(1-s)|e^{-C|z|^h}.$$

And for $|s| \le 1/2$,

$$|E_h(s)| \ge |(1-s)|e^{-\frac{|s|^{h+1}}{h+1}-\frac{|s|^{h+2}}{h+}-\cdots} \ge e^{-C|z|^{h+1}}.$$

□

Then if $|a_n| \ge 2|z|$,

$$|E_h(\frac{z}{a_n})| \ge e^{-C|z/a_n|^{h+1}} \ge e^{-C|z/a_n|^{\rho+\varepsilon}},$$

and if $|a_n| \le 2|z|$, by the hypothesis,

$$|E_h(\frac{z}{a_n})| \ge |(1-\frac{z}{a_n})|e^{-C|z/a_n|^h} \ge |a_n|^{-h-2}e^{-C|z/a_n|^{\rho+\varepsilon}}.$$

Thus by(10.5.3.18),

$$\prod_{n\in S}|E_h(\frac{z}{a_n})| \ge e^{-C'z}\prod_{|a_n|\le 2|z|}|a_n|^{-h-2} \ge e^{-C'z}|2z|^{-(h+2)N(2|z|)} \ge e^{-C''|z|^{\rho+\varepsilon'}}$$

for any $\varepsilon' > \varepsilon$.

Finally, we get

$$e^{\mathrm{Re}(g(z))} = |e^{g(z)}| = |\frac{f(z)}{\prod_{n\in S}|E_h(\frac{z}{a_n})|}| \leq Ce^{\rho+\varepsilon}$$

whenever $|z-a_n| \geq |a_n|^{h+1}$ for any $n\in S$. Then as $\sum_n |a_n|^{h+1} < \infty$, we can apply(10.5.3.19) to show that g is a polynomial of degree $\leq \rho+\varepsilon < h+1$, thus we are done. □

Cor. (10.5.3.22). For an entire function f with order $\lambda \in \mathbb{R}_+ \setminus \mathbb{Z}_+$, then $\#f^{-1}(a) = \infty$ for any $a\in\mathbb{C}$.

Proof: As f and $f-a$ has the same order, it suffices to show that such an f has i.m. zeros. Suppose it has only f.m. zeros, then we can divide a polynomial $P(z)$ and see that $F(z) = f(z)/P(z)$ also has the same order but no zero. Thus $F(z) = e^{g(z)}$ for some entire g. But then g is a polynomial of degree λ, which is impossible. □

Example (10.5.3.23) [Canonical Forms].

$$\sin(\pi z) = \pi z\prod_{n\in\mathbb{Z}^\times}[(1-\frac{z}{n})e^{z/n}] = \pi z\prod_{n=1}^\infty(1-\frac{z^2}{n^2}).$$

is of genus 1 and order of growth 1.

Proof: $|\sin(\pi z)| \leq e^{\pi|z|}$, so it has order of growth≤ 1, and it has a simple zero at $z=0$, so by Hadamard's theorem(10.5.3.20),

$$\sin(\pi z) = \pi z e^{Az+B}\prod_{n\neq 0\in\mathbb{Z}}[(1-\frac{z}{n})e^{z/n}] = \pi z e^{Az+B}\prod_{n=1}^\infty(1-\frac{z^2}{n^2})$$

for some $A,B\in\mathbb{C}$. Letting $z\to 0$ implies that $B=0$. And letting $z\to 1$ implies that

$$e^A = 2\prod_{n=1}^\infty(1-\frac{1}{n^2}) = 1,$$

so $A=0$. □

4 Analytic Continuations

Lemma (10.5.4.1) [Symmetry Principle]. If $\Omega\subset\mathbb{C}$ is a region s.t. $\mathfrak{c}(\Omega) = \Omega$, denote $\Omega^+ = \Omega\cap\mathscr{H}$, $\Omega^- = \mathfrak{c}(\Omega^+)$, $I = \Omega\cap\mathbb{R}$. Suppose $f^+\in\mathscr{O}(\overline{\Omega^+})$, $f^-\in\mathscr{O}(\overline{\Omega^-})$, and $f^+(z) = f^-(z)$ for $z\in\mathbb{R}$, then the function

$$f:\Omega\to\mathbb{C}: z\mapsto\begin{cases} f^+(z) & ,z\in\overline{\Omega^+} \\ f^-(z) & ,z\in\Omega^-\end{cases}$$

is analytic on Ω.

Proof: f is clearly continuous. Thus it is easily seen to be analytic by Morera's theorem(10.5.2.8). □

Prop. (10.5.4.2) [Schwarz Reflection Principle]. If $\Omega\subset\mathbb{C}$ is a region s.t. $\mathfrak{c}(\Omega) = \Omega$, denote $\Omega^+ = \Omega\cap\mathscr{H}$, $\Omega^- = \mathfrak{c}(\Omega^+)$, $I = \Omega\cap\mathbb{R}$. Suppose $f^+\in\mathscr{O}(\overline{\Omega^+})$ satisfies $f(I)\subset\mathbb{R}$, then f^+ can be analytically extended to an analytic function on Ω.

Proof: For $z \in \Omega^-$, define $f(z) = \overline{f(\overline{z})}$, then f is a continuous function on Ω, because for $z \in I$, $f(z) = \overline{f(\overline{z})}$. To show that f is analytic, by(10.5.4.1), it suffices to show that f is analytic on Ω^-: For any $z_0 \in \Omega^-$, if z is close to z_0, then $\overline{z}, \overline{z}_0 \in \Omega^+$. By Taylor expansion of f around $\overline{z}_0$(10.5.2.15)

$$f(z) = \overline{f(\overline{z})} = \overline{\sum_{n\in\mathbb{N}} a_n(\overline{z} - \overline{z}_0)^n} = \sum_{n\in\mathbb{N}} \overline{a}_n(z - z_0)^n.$$

And this is a power series around z_0 with the same radius of convergence as that of $\overline{z}_0$, thus f is analytic around z_0. Because z_0 is arbitrary, f is analytic on Ω^-. □

Cor. (10.5.4.3). If $\Omega \subset \mathbb{C}^\times$ is a region that is stable under the involution $\iota : z \mapsto \overline{z}^{-1}$, denote $\Omega^+ = \Omega \cap \mathcal{H}$, $\Omega^- = \iota(\Omega^+)$, $I = \Omega \cap \partial\mathbb{D}$. Suppose $f^+ \in \mathcal{O}(\overline{\Omega^+})$ satisfies $f(I) \subset \mathbb{R}$, then f^+ can be analytically extended to an analytic function on Ω.

Proof: For $z \in \Omega^-$, define $f(z) = \overline{f(\iota(z))}$, then f is a continuous function on Ω, because for $z \in I$, $f(z) = \overline{f(\iota(z))}$. To show that f is analytic, by a similar lemma as(10.5.4.1), it suffices to show that f is analytic on Ω^-: For any $z_0 \in \Omega^-$, if z is close to z_0, then $\iota(z), \iota(z_0) \in \Omega^+$. By Taylor expansion of f around $\iota(z_0)$(10.5.2.15)

$$f(z) = \overline{f(\iota(z))} = \overline{\sum_{n\in\mathbb{N}} a_n(\iota(z) - \iota(z_0))^n} = \sum_{n\in\mathbb{N}} \frac{\overline{a}_n}{z_0} \frac{(z - z_0)^n}{z^n} = g(\frac{1}{z}),$$

where $g(z) = \sum_{n\in\mathbb{N}}(-1)^n\overline{a}_n(z - \frac{1}{z_0})^n$ is a power series around z_0 with the same radius of convergence as that of $\overline{z}_0$, so analytic around z_0^{-1}. Thus f is analytic around z_0. Because z_0 is arbitrary, f is analytic on Ω^-. □

5 Theorems

Prop. (10.5.5.1) [Runge's Theorem]. Let K be a compact subset of $\overline{\mathbb{C}}$ and let f be a function which is holomorphic on an open set containing K. If A is a set containing at least one complex number from every bounded connected component of $\overline{\mathbb{C}}\backslash K$, then there exists a sequence of rational functions which converges uniformly to f on K and all the poles of the functions are in A.

Proof: □

Prop. (10.5.5.2) [Mergelyan]. If K is compact in $\mathbb{C}$ and f is a continuous function on K that is holomorphic in $\mathrm{int}(K)$, then f can be uniformly approximated by polynomials.

Prop. (10.5.5.3) [Weierstrass]. For a ascending sequence of regions $\Omega_1 \subset \Omega_2 \subset \ldots$, $\cup_n\Omega_n = \Omega$, and f_n is analytic on Ω_n, and $f_n(z)$ converges to a function $f(z)$ in the compact-open topology, then $f(z)$ is also analytic, and moreover, $f'(z)$ converges to $f'(z)$ in the compact-open topology.

Proof: The analyticity follows from Morera's theorem(10.5.2.8) as the integration on a closed curve commutes with uniform convergence, the same argument applied to the limit of equations

$$f_n'(z) = \frac{1}{2\pi\,\mathrm{i}} \int_{\partial\mathbb{D}(0,r)} \frac{f_n(\zeta)d\zeta}{(\zeta - z)^2}$$

shows that the derivative also converges, and uniformly on $\overline{\mathbb{D}(0,\rho)}$ for $\rho < r$. □

Cor. (10.5.5.4) [Hurwitz]. Cf.[Ahlfors P178].

Thm. (10.5.5.5) [Montel]. If $\Omega \subset \mathbb{C}$ is region and $\mathcal{S} = \{f_\alpha\}$ is a set of holomorphic functions on Ω bounded in the topology of $H(\Omega)$, i.e. inter convex uniform convergence, then $\mathcal{S}$ is sequentially compact in $H(\Omega)$. Equivalently, $\mathcal{O}(\Omega)$ has the Heine-Borel property.

Proof: By Arzela-Ascoli(3.3.8.8) that it suffices to show that $\mathcal{S}$ is uniformly bounded on any compact subset $K \subset \Omega$. Choose δ small s.t.

$$K_0 = \{z \in \mathbb{C} | d(z, K) \le 2\delta\} \subset \Omega,$$

then $|f_\alpha(z)| \le M$ for any $f_\alpha \in \mathcal{S}$ and $z \in K_0$ for some M. So by Cauchy's formula, $|f'_\alpha(z)| \le \frac{M}{\delta}$ for any $z \in K, f_\alpha \in \mathcal{S}$. Thus it it clear $\mathcal{S}$ are equicontinuous on K. □

Thm. (10.5.5.6) [Little Picard Theorem]. The image of a non-constant entire function $f : \mathbb{C} \to \mathbb{C}$ is either $\mathbb{C}$ or $\mathbb{C}$ with one point omitted.

Proof: The modular curve $Y(2)$ is the sphere minus three points(16.2.2.4)(16.2.4.16)(16.2.4.17), and the linear transformations of S^1 is triply transitive, thus we can assume f is a analytic map $\mathbb{C} \to Y(2)$. As $\mathbb{C}$ is simply connected, we can lift this map to the covering of $Y(2)$, which is $\mathcal{H}$. But $\mathcal{H}$ is biholomorphic to the open disk, but a bounded entire function is constant(10.5.2.10), so f is constant. □

Thm. (10.5.5.7) [Phragmén-Lindelöf]. Let f be a function that is holomorphic in the upper part of a strip $\sigma_1 \le \mathrm{Re}(s) \le \sigma_2, \mathrm{Im}(s) > c$, such that $f(\sigma + \mathrm{i}\, t) = O(e^{t^\alpha})$ for some $\alpha > 0$ uniformly for any $\sigma_1 < \sigma < \sigma_2$. Suppose further that $f(\sigma + \mathrm{i}\, t) = O(|t|^b)$ for some b and $\sigma = \sigma_1$ or σ_2, then $f(\sigma + \mathrm{i}\, t) = O(t^b)$ uniformly for $\sigma_1 \le \sigma \le \sigma_2$.

Proof: First assume that $b = 0$, thus there exists M that $|\varphi(s)| \le M$ for $\mathrm{Re}(s) = \sigma_i$. Now let $m \equiv 2 \mod 4$ and $m > \alpha$, then $\mathrm{Re}((\sigma + \mathrm{i}\, \tau)^m)$ is a polynomial of σ and τ with highest term of τ being $-\tau^m$, so we have

$$\mathrm{Re}(s^m) = -\tau^m + O(|\tau|^{m-1}), \quad |\tau| \to \infty$$

uniformly on the strip. So $\mathrm{Re}(s^m)$ has an upper bound N on the strip. Thus for any $\varepsilon > 0$,

$$|f(s)e^{\varepsilon s^m}| \le Me^{\varepsilon N}$$

on the boundary of the strip and

$$|f(s)e^{\varepsilon s^m}| = O(e^{|t|^\alpha - \varepsilon |t|^m})$$

uniformly on the strip, thus converges uniformly to 0 as $|\mathrm{Im}(s)| \to \infty$.

Then we can use maximum principle to see that

$$|f(s)e^{\varepsilon s^m}| \le Me^{\varepsilon N}$$

on the strip. Let $\varepsilon \to 0$, we get $|\varepsilon(s)| \le M$, thus the theorem.

In general, if $b \ne 0$, define $\psi(s) = (s - \sigma_1 + 1)^b$, then $|\psi(s)| = |s - \sigma_1 + 1|^b \sim |\tau|^b$ when $|\tau| \to \infty$. Thus $f_1(s) = f(s)/\psi(s)$ satisfies the same condition as φ with $b = 0$, so $f(s)/\psi(s)$ is bounded on the strip, and thus $|f(s)| = O(|\tau|^b)$. □

Remark (10.5.5.8). Some condition on the growth rate of $|f(\sigma + it)|$ is necessary, otherwise we can consider $e^{e^{iz}}$ on the strip $-\frac{\pi}{2} \le \mathrm{Re}(z) \le \frac{\pi}{2}$, then it is bounded for $\mathrm{Re}(z) = \pm\frac{\pi}{2}$, but not bounded for $-\frac{\pi}{2} < \mathrm{Re}(z) < \frac{\pi}{2}$.

6 Calculating Definite Integrals

1

Prop. (10.5.6.1). If f has a primitive F, then for any arc γ,

$$\int_\gamma f(z)\mathrm{d}z = F(\gamma(1)) - F(\gamma(0)).$$

Example (10.5.6.2). For $a > 0$, evaluate the integrals

$$\int_0^\infty e^{-ax}\cos(bx)dx, \quad \int_0^\infty e^{-ax}\sin(bx)dx.$$

Proof:

$$\int_0^\infty e^{-(a+b\,\mathrm{i})z}\mathrm{d}z = \lim_{R\to\infty}\frac{-1}{a+b\,\mathrm{i}}e^{-(a+b\,\mathrm{i})z}\Big|_0^R = \frac{1}{a+b\,\mathrm{i}} - \lim_{R\to\infty}\frac{1}{a+b\,\mathrm{i}}e^{-(a+b\,\mathrm{i})R}.$$

As $|\frac{1}{a+b\,\mathrm{i}}e^{-(a+b\,\mathrm{i})R}| = \frac{1}{\sqrt{a^2+b^2}}e^{-aR} \to 0$ as $R\to\infty$,

$$\int_0^\infty e^{-(a+b\,\mathrm{i})z}\mathrm{d}z = \frac{1}{a+b\,\mathrm{i}}.$$

Then taking the real and imaginary part, we see that

$$\int_0^\infty e^{-ax}\cos(bx)dx = \frac{a}{a^2+b^2}, \quad \int_0^\infty e^{-ax}\sin(bx)dx = \frac{b}{a^2+b^2}.$$

□

From Real to Complex

Example (10.5.6.3). Prove that for any $\xi\in\mathbb{C}$,

$$e^{-\pi\xi^2} = \int_{-\infty}^\infty e^{-\pi x^2}e^{2\pi\,\mathrm{i}\,x\xi}\mathrm{d}x.$$

Proof: Both sides are holomorphic functions in ξ, and it has been proven in Stein's book Page42 that this is true for $\xi\in\mathbb{R}$. Then as both sides are holomorphic functions in ξ, this is true for all $\xi\in\mathbb{C}$, by the uniqueness theorem.

Recall that if two holomorphic functions on a region Ω are equal on a subset $E\subset\Omega$, and E has a convergent point in Ω, then they are equal on Ω. □

Rational Functions

Prop. (10.5.6.4). Let f, g be real polynomials, and $\deg(g)\geq\deg(f)+2$, and $g(z)$ has no zeros on the real line. Then

$$\int_{-\infty}^\infty \frac{f(x)}{g(x)}\mathrm{d}x$$

can be calculated.

Proof: As the integral is absolutely convergent, we can take $R\in\mathbb{R}$, and γ to be the loop which consists of the line from $-R$ to R and the hemisphere with origin 0 and radius R from R to $-R$, then when R is large, we can assume all the zeros of $g(z)$ in $\mathscr{H}$ is enclosed by γ. Then the integral equals $2\pi\,\mathrm{i}$ times the sum of residues of $\frac{f(z)}{g(z)}$ at the zeros of $g(z)$ in $\mathscr{H}$. □

Example (10.5.6.5). Evaluate the integrals

$$\int_{-\infty}^{\infty}\frac{1}{1+x^4}\mathrm{d}x.$$

What are the poles of $1/(1+z^4)$?

Proof: $g(z)=1+z^4$ has two zeros $e^{\frac{\pi}{4}\mathrm{i}}$ and $e^{-\frac{3\pi}{4}\mathrm{i}}$ on the upper half plane, so the integral equals

$$\int_{\gamma_1}\frac{(x-e^{\frac{\pi}{4}\mathrm{i}})^{-1}(x-e^{\frac{5\pi}{4}\mathrm{i}})^{-1}(x-e^{\frac{7\pi}{4}\mathrm{i}})^{-1}}{x-e^{\frac{3\pi}{4}\mathrm{i}}}+\int_{\gamma_2}\frac{(x-e^{\frac{3\pi}{4}\mathrm{i}})^{-1}(x+-^{\frac{5\pi}{4}\mathrm{i}})^{-1}(x-e^{\frac{7\pi}{4}\mathrm{i}})^{-1}}{x-e^{\frac{\pi}{4}\mathrm{i}}}$$

which equals $2\pi\mathrm{i}$ times

$$(\frac{x^4+1}{x-e^{\frac{\pi}{4}\mathrm{i}}})^{-1}\Big|_{x=e^{\frac{\pi}{4}\mathrm{i}}}+(\frac{x^4+1}{x-e^{\frac{3\pi}{4}\mathrm{i}}})^{-1}\Big|_{x=e^{\frac{3\pi}{4}\mathrm{i}}}$$

so it equals

$$(2\pi\mathrm{i})[\frac{1}{4e^{\frac{3\pi}{4}\mathrm{i}}}+\frac{1}{4e^{\frac{9\pi}{4}\mathrm{i}}}]=\frac{\pi}{\sqrt{2}}$$

□

Prop. (10.5.6.6) [Fractional Powers]. Let f,g be real polynomials, and $\deg(g)\geq\deg(f)+2$, and $g(z)$ has at most one simple zero at the origin and no other zeros, then the integral

$$\int_0^{\infty}x^{\alpha}\frac{f(x)}{g(x)}\mathrm{d}x, 0<\alpha<1$$

can be evaluated.

Proof: The integral equals $2\int_0^\infty t^{2\alpha+1}\frac{f(t^2)}{g(t^2)}\mathrm{d}t$, and we can choose a branch of z^α that is defined on $\mathbb{C}\setminus\mathbb{R}_{\leq 0}$. Then we can integrate along the loop in $\mathscr{H}$ that consists of two hemisphere of radius ε,R centered at the origin, $[\varepsilon,R]\cup[-R,-\varepsilon]$. Then when $R\to\infty$ and $\varepsilon\to 0$, the integration on the hemisphere tends to 0, and the integration on $[\varepsilon,R]\cup[-R,-\varepsilon]$ tends to

$$\int_{-\infty}^{\infty}z^{2\alpha+1}\frac{f(z^2)}{g(z^2)}\mathrm{d}z=(1-e^{2\pi\mathrm{i}\alpha})\int_0^{\infty}t^{2\alpha+1}\frac{f(t^2)}{g(t^2)}\mathrm{d}t.$$

□

<u>4</u>

Prop. (10.5.6.7). Let f,g be real polynomials, and $\deg(g)\geq\deg(f)+1$, and $g(z)$ has no zeros on the real line, then

$$\int_{-\infty}^{\infty}\frac{f(x)}{g(x)}e^{\mathrm{i}x}\mathrm{d}x,\quad\int_{-\infty}^{\infty}\frac{f(x)}{g(x)}\cos(x)\mathrm{d}x,\quad\int_{-\infty}^{\infty}\frac{f(x)}{g(x)}\sin(x)\mathrm{d}x$$

can be calculated.

Proof: If $\deg(g)\geq\deg(f)+2$, then as before we can use the same hemisphere methods to evaluate, because on the hemisphere, we can bound

$$|\int_{\gamma}\frac{f(Re^{\mathrm{i}\theta})}{g(Re^{\mathrm{i}\theta})}\mathrm{i}Re^{\mathrm{i}z}\mathrm{d}\theta|\leq C\int_{\gamma}\frac{e^{-y}}{R}\mathrm{d}\theta\leq C\int_{\gamma}\frac{1}{R}\mathrm{d}\theta\leq\frac{2\pi C}{R}$$

which converges 0 as $R \to \infty$.

But if $\deg(g) = \deg(f)+1$, this hemisphere integral is no longer converging to 0, so we try another method: Integrate around the square with vertices

$$\{(X_1, 0), (X_1, X_1 + X_2), (-X_2, X_1 + X_2), (-X_2, 0)\}.$$

The integral on the vertical lines are bounded by

$$C\int_0^{X_1+X_2} e^{-y}\frac{\mathrm{d}y}{|z|} \le C\frac{1}{X_2}\int_0^{X_1+X_2} e^{-y}\mathrm{d}y \le \frac{C}{X_2}$$

And the same is true for the left vertical lines. And the horizontal line is bounded by

$$C\int_{-X_1}^{X_2} \frac{e^{-(X_1+X_2)}}{X_1+X_2}\mathrm{d}t = Ce^{-(X_1+X_2)}$$

and all these converge to 0 as $X_1, X_2 \to \infty$. □

Prop. (10.5.6.8). Show that

$$\int_0^\infty \frac{\sin x}{x}\mathrm{d}x = \frac{\pi}{2}.$$

Proof: To do this one, we need a variation of the technique from above. Choose the semi-contour, then it equals the half of the integral

$$\int_\gamma \frac{e^{\mathrm{i}\,z}}{z}\mathrm{d}z = 2\pi\,\mathrm{i}$$

minus the integral

$$\int_\gamma \frac{e^{\mathrm{i}\,z}}{z}\mathrm{d}z$$

where $\gamma : [0, \pi] \to \mathbb{C} : t \mapsto \varepsilon e^{\mathrm{i}\,t}$. So the integral equals

$$\int_0^\pi e^{\mathrm{i}\,z}\,\mathrm{i}\,\mathrm{d}z$$

which converges to $\pi\,\mathrm{i}$. □

7 Biholomorphisms

Def. (10.5.7.1) [Biholomorphisms]. For regions $U, V \subset \mathbb{C}$, a **biholomorphism** from U to V is a holomorphic map $f : U \to V$ s.t. there is an inverse $g : V \to U$ which is also holomorphic, and $f \circ g = \mathrm{id}_V, g \circ f = \mathrm{id}_U$.

Prop. (10.5.7.2) [Analytic Functions are Open]. Let $\Omega \subset \mathbb{C}$ be a region, then any non-constant $f \in \mathcal{O}(\Omega)$ defines an open map $\Omega \to f(\Omega)$.

Proof: Let $z_0 \in \Omega, w_0 = f(z_0)$. by(10.5.2.19), we can find $\varepsilon > 0$ s.t. $\mathbb{D}(z_0, 2\varepsilon) \subset U$, and z_0 is the only zero of $f - w_0$ in $\mathbb{D}(z_0, 2\varepsilon)$. Let γ be the circle $|z - z_0| = \varepsilon$, and $\Gamma = f(\gamma)$. Then because $w_0 \notin \Gamma$, there exists δ s.t. $\mathbb{D}(w_0, \delta) \cap \Gamma = \varnothing$. Then by Rouché's theorem(10.5.2.30), for any $w \in \mathbb{D}(w_0, \delta)$, $f - w$ has a zero $z \in \mathbb{D}(z_0, \varepsilon)$. Thus $f(\mathbb{D}(z_0, \varepsilon)) \supset \mathbb{D}(w_0, \delta)$, and this implies f is open. □

Prop. (10.5.7.3) [Local Biholomorphisms]. A holomorphic map $f : U \to V \subset \mathbb{C}$ is a local bijection iff $f'(z) \neq 0$ for any $z \in U$.

Proof: For $z_0 \in U$, by discreteness of the zeros, there exists $\delta > 0$ s.t. $\overline{\mathbb{D}(z_0,\delta)} \subset U$ and $F(z) \neq 0$ for $0 < |z - z_0| < \delta$. Because $\{F(z) : |z - z_0| = \delta\}$ is compact, there exists some $\varepsilon > 0$ s.t. $\mathbb{D}(f(z_0),\varepsilon) \subset V$ and $|F(z)| \geq \varepsilon$ for any $|z - z_0| = \delta$.

If $F(z) = f(z) - f(z_0)$ has zero of order exactly 1 at z_0, then for $\xi \in \mathbb{D}(0,\varepsilon)$, by Rouché's theorem(10.5.2.30), $F(z) - \xi$ has exactly 1 zeros in $\mathbb{D}(z_0,\delta)$, which implies $F^{-1}(\mathbb{D}(0,\varepsilon)) \xrightarrow{F} \mathbb{D}(0,\varepsilon)$ is a bijection, and $z_0 \in F^{-1}(\mathbb{D}(0,\varepsilon))$. Thus F and also f is a local bijection z_0.

If $F(z) = f(z) - f(z_0)$ has zero of order $d \geq 1$ at z_0, then for $\xi \in \mathbb{D}(0,\varepsilon)$, by Rouché's theorem(10.5.2.30), $F(z) - \xi$ has exactly d zeros in $\mathbb{D}(z_0,\delta)$, which implies $F^{-1}(\mathbb{D}(0,\varepsilon')) \xrightarrow{F} \mathbb{D}(0,\varepsilon')$ is a d-fold covering for any $\varepsilon' < \varepsilon$, so F thus also f can never be a local bijection at z_0.

Thus f is a local bijection at z_0 iff $f(z) - f(z_0)$ has zero of order exactly 1 at z_0, which is also clearly equivalent to $f'(z_0) \neq 0$. So the assertion is true. □

Cor. (10.5.7.4). If U, V are regions of $\mathbb{C}$ and $f : U \to V$ is holomorphic and bijective, then $f'(z) \neq 0$ for any $z \in U$, and the inverse of f is also holomorphic.

Proof: To show the inverse is holomorphic, notice that for $w_0 = f(z_0) \in V$, if $w = f(z)$ is close to w_0, then

$$\frac{g(w) - g(w_0)}{w - w_0} = \frac{1}{\frac{w - w_0}{g(w) - g(w_0)}} = \frac{1}{\frac{f(z) - f(z_0)}{z - z_0}}.$$

Because when $z \to z_0$, $w \to w_0$, so we conclude that g is holomorphic at w_0, and its derivative is the reciprocal of the derivative of f. □

Cor. (10.5.7.5). For regions $U, V \subset \mathbb{C}$, any holomorphic bijection from U to V is a biholomorphism.

Def. (10.5.7.6) [Univalent Functions]. A **univalent function** is a holomorphic function that is injective.

Prop. (10.5.7.7). Any C^1 conformal map in $\mathbb{C}$ is holomorphic or anti-holomorphic. In higher dimension, conformal is equivalent to $\langle df_p(v_1), df_p(v_2)\rangle = \lambda^2(p)\langle v_1, v_2\rangle$.

Proof: Cf.[Ahlfors P74]. □

Prop. (10.5.7.8) [Automorphism Groups].

- The only holomorphic automorphisms of $\mathbb{D}$ fixing the origin are the rotations.
- $\mathrm{Aut}(\mathbb{D}) = \{e^{\mathrm{i}\theta}\frac{\alpha - z}{1 - \overline{\alpha}z}, \alpha \in \mathbb{D}\}$. Moreover, we denote by ψ_α the automorphism $\psi_\alpha(z) = \frac{\alpha - z}{1 - \overline{\alpha}z}$, then $\psi_\alpha^2 = \mathrm{id}$.
- $\mathrm{Aut}(\mathscr{H}) = \mathrm{PSL}(2,\mathbb{R})$.
- $\mathrm{Aut}(\overline{\mathbb{C}}) = \mathrm{PSL}(2,\mathbb{C})$.
- $\mathrm{Aut}(\mathbb{C}) = \mathbb{C} \ltimes \mathbb{C}^\times$.

Proof: 1: g, g^{-1} are both automorphisms of $\mathbb{D}$ that fixes the origin, so by Schwartz's lemma(10.6.1.3), $|g(z)| \leq |z|, |g^{-1}(z)| \leq |z|$. Thus $|g(z)| = |z|$ for any $z \in \mathbb{D}$, and by Schwartz's lemma(10.6.1.3), g is a rotation.

2: For any $f \in \mathrm{Aut}(\mathbb{D})$, there exists some $\alpha \in \mathbb{D}$ s.t. $f(\alpha) = 0$. Then $g = f \circ \psi_\alpha$ maps 0 to 0. Then by item1, $g(z) = e^{\mathrm{i}\theta}z$, and $f(z) = e^{-\mathrm{i}\theta}\psi_\alpha(z)$.

3: Firstly $SL(2,\mathbb{R})$ acts transitively on $\mathscr{H}$ it suffices to show that any $z\in\mathscr{H}$ can be mapped to i: $\begin{bmatrix} & -c^{-1}\\ c & \end{bmatrix}(z)=\frac{1}{c^2z}$, so we may take $c\in\mathbb{R}$ s.t. $M_1=\begin{bmatrix} & -c^{-1}\\ c & \end{bmatrix}$ maps z to z_1 with $\mathrm{Im}(z_1)=1$, and then we can take some $b\in\mathbb{R}$ s.t. $M_2=\begin{bmatrix}1 & b\\ 1 & \end{bmatrix}$ maps z_1 to i.

Then for any $f\in\mathrm{Aut}(\mathscr{H})$, there exists some $\beta\in\mathscr{H}$ s.t. $f(\beta)=\mathrm{i}$. take some matrix γ s.t. $\gamma(\beta)=\mathrm{i}$, then $g=f\circ\gamma^{-1}$ preserves i. Let $F:\mathscr{H}\cong\mathbb{D}:z\mapsto\frac{z-\mathrm{i}}{z+\mathrm{i}}$ be a biholomorphism, then it can be checked that

$$F\circ\begin{bmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{bmatrix}\circ F^{-1}=e^{\mathrm{i}\,\theta}:\mathbb{D}\to\mathbb{D}.$$

Thus by Schwartz lemma(10.6.1.3), there exists some $\theta\in\mathbb{R}$ s.t. $g=\begin{bmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{bmatrix}=\kappa_\theta$, and then $f=\kappa_\theta\circ\gamma\in\mathrm{SL}(2;\mathbb{R})$.

4: For any distinct points $z_1,z_2,z_3\in\mathbb{C}\cup\{\infty\}$,

$$F_{z_1,z_2,z_3}:\mathbb{C}\cup\{\infty\}\to\mathbb{C}\cup\{\infty\}:z\mapsto\frac{z-z_2}{z-z_3}\Big/\frac{z_1-z_2}{z_1-z_3}$$

satisfies $F_{z_1,z_2,z_3}(z_1)=1,F_{z_1,z_2,z_3}(z_2)=0,F_{z_1,z_2,z_3}(z_3)=\infty$, and

$$G_{z_1,z_2,z_3}:\mathbb{C}\cup\{\infty\}\to\mathbb{C}\cup\{\infty\}:w\mapsto\frac{wz_3\frac{z_1-z_2}{z_1-z_3}-z_2}{w\frac{z_1-z_2}{z_1-z_3}-1}$$

is an inverse of f_{z_1,z_2,z_3}, so f_{z_1,z_2,z_3} is a bijection.

Now consider $h=F_{f(1),f(0),f(\infty)}\circ f$, then h is also a bijection and $h(1)=1,h(0)=0,h(\infty)=\infty$. Thus h is entire, and by(10.5.2.22) $h(z)=zL(z)$ for some $L(z)\in\mathcal{M}(\mathbb{C})$ entire and $L(1)=1,L(\infty)=0$, so by Liouville's theorem(10.5.2.10), $L=1$, and $h(z)=z$.

Thus $f(z)=G_{f(1),f(0),f(\infty)}$ is of the form $\frac{az+b}{cz+d}$. To show that $ad-bc\neq0$, notice if $ad-bc=0$, then $f(z)$ is constant, contradiction.

5: Notice $g(z)=(f(z)-f(0))/(f(1)-f(0))$ is also injective and entire, and $g(0)=0,g(1)=1$. But by Picard's great theorem, $g(z)$ is meromorphic at ∞. So $g(\infty)=\infty$, otherwise g is entire and bounded, contradicting Liouville's theorem(10.5.2.10). So $g(z)=z$, by item4. Thus $f(z)=(f(1)-f(0))z+f(0)$ is linear. □

Riemann Mapping Theorem

Lemma (10.5.7.9) [Limits of Univalent Functions are Univalent]. A limit of a sequence of univalent holomorphic functions in the compact-open topology is univalent or constant.

Proof: If $f=\lim_{n\to\infty}f_n$ is non-constant and $f(z_1)=f(z_2)$, we can take a Jordan curve γ surrounding z_1 and z_2 s.t. $0\notin f(\gamma)$. Then f_n converges uniformly to f on γ, and then it follows from Rouché's theorem(10.5.2.30) that when n is large, $f_n-f(z_1)$ has two zeros inside γ, contradiction. □

Thm. (10.5.7.10)[Riemann Mapping Theorem, Koebe]. Let $\Omega\subset\mathbb{C}$ be a simply-connected region and $\Omega\neq\mathbb{C}$, then for any $z_0\in\Omega$, there exists a unique biholomorphism $F:\Omega\to\mathbb{D}$ s.t. $F(z_0)=0$ and $F'(z_0)\in\mathbb{R}_+$.

Remark (10.5.7.11). This theorem can be generalized to other simply-connected Riemann surfaces, see(5.11.12.2).

Proof: For the uniqueness, if there are two such maps φ and φ', then $h = \varphi' \circ \varphi^{-1}$ is an automorphism of $\mathbb{D}$ s.t. $h(0) = 0$ and $h'(0) \in \mathbb{R}_+$. Then it follows from(10.5.7.8) that $h = \mathrm{id}$.

For the existence, let $\mathscr{F}$ be the space of univalent holomorphic functions on Ω with values in $\mathbb{D}$. Then $\mathscr{F} \neq 0$: Let $a \neq b \in \partial\Omega$, then by the map $g(z) = \frac{z-a}{z-b}$, we may assume that $\{0, \infty\} \subset \partial\Omega$. Then $\sqrt{\ }$ has two branches on Ω, denoted by h_+ and h_-. Suppose $w_0 \in h_-(\Omega)$ with $\mathbb{D}(w_0, \delta) \subset h_-(\Omega)$, then the function

$$f_0 : z \mapsto \frac{\delta}{h_+(z) - w_0} \in \mathscr{F}.$$

Let

$$\alpha = \sup_{f \in \mathscr{F}} |f'(z_0)|.$$

If $\mathbb{D}(z_0, \delta_1) \subset \Omega$, then by Cauchy's formula, $0 < |f'(z_0)| \leq \delta_1^{-1}$, so $\alpha \in (0, \infty)$, and there exists $f_n \in \mathscr{F}$ s.t. $|f'(z_0)| \geq \alpha - \frac{1}{n}$. Then it follows from Montel's theorem(10.5.5.5) that there is a subsequence of $\{f_n\}$ that converges to a holomorphic function f in compact-open topology, and $|f'(z_0)| = \alpha > 0$ by Weierstrass theorem(10.5.5.3). Notice f is also univalent by(10.5.7.9), so $f \in \mathscr{F}$.

It remains to show that $f(z_0) = 0$ and $f_0(\Omega) = \Delta$, as a rotation of f will satisfy the requirement. If $f(z_0) = \beta \neq 0$, then take

$$f'(z) = \psi_\beta \circ f$$

then $f' \in \mathscr{F}$, and

$$|(f')'(z_0)| = |\frac{f'(z_0)}{1 - |\beta|^2}| > |f'(z_0)|,$$

contradicting the maximality of $|f'(0)|$.

If $w \in \mathbb{D} \backslash f(\Omega)$, then $\psi(z) = \psi_\beta \circ f$ is non-vanishing on Ω, thus $\sqrt{\ }$ has a branch h on $\psi(\Omega)$. Now suppose

$$f'(z) = \psi_{h(z_0)} \circ h,$$

then

$$f = \psi_w^{-1} \circ (z \mapsto z^2) \circ \psi_{h(w)}^{-1} \circ f',$$

where $\Phi' = \psi_w^{-1} \circ (z \mapsto z^2) \circ \psi_{h(w)}^{-1}$ is an automorphism of $\mathbb{D}$ that fixes 0, so $|\Phi'(0)| < 1$ by Schwartz's lemma(10.6.1.3), and

$$|f'(0)| = |\Phi'(0)||(f')'| \leq |(f')'|,$$

contradicting the maximality of $|f'(0)|$. □

Cor. (10.5.7.12). Let $\Omega \subset \overline{\mathbb{C}}$ be a simply-connected region, then D is biholomorphic to exactly one of the following:

- $\mathbb{D}$, in which case $\#\partial\Omega > 1$, and Ω is said to be of **hyperbolic type**.
- $\mathbb{C}$, in which case $\#\partial\Omega = 1$.
- $\overline{\mathbb{C}}$, in which case $\#\partial\Omega = 0$.

Proof: If $\#\partial\Omega > 1$, by a fractional transformation, we can assume $\Omega \subset \mathbb{C}$, and $\Omega \neq \mathbb{C}$, so $\Omega \cong \mathbb{D}$ by(10.5.7.10). If $\#\partial\Omega = 1$, then clearly $\Omega = \overline{\mathbb{C}} \backslash \{z_0\} \cong \mathbb{C}$. □

Cor. (10.5.7.13). Any two simply-connected regions $\Omega, \Omega' \subset \mathbb{C}$ are homeomorphic.

Injective Holomorphic Maps

Thm. (10.5.7.14) [Bieberbach Conjecture1916, de Branges1984]. Let $f(z) = z + a_2 z^2 + \ldots \in \mathcal{O}(\mathbb{D})$ is an injective map, then $|a_n| \leq n$. And the equation holds iff f is a rotation composed with the Koebe function.

Proof: Cf.[李忠]. □

10.6 Complex Analysis II

References are [Ahl78], [S-S03], [谭-伍 06] and [李 04].

Notation (10.6.0.1).

- Use notations defined in Real Analysis(Functions on $\mathbb{R}^n$).
- Let Ω be a region(10.5.1.1).

1 Poincaré Metric

Def. (10.6.1.1) [Hyperbolic Metric]. For any region $\Omega \subset \mathbb{C}$ of hyperbolic type**??**, there exists a covering $\mathbb{D} \to \Omega$, and different coverings differ by an automorphism of $\mathbb{D}$. Thus we can define a **Poincaré metric** on Ω by pushforward of the Poincaré metric $\mathrm{d}^P s = \rho_\Omega(s)|\mathrm{d}z|$ on $\mathbb{D}$. Then this is well-defined and independent of the covering map.

Proof: It is well-defined because for any two local inverse map $\Omega \to \mathbb{D}$ differ by a Deck transformation which is an automorphism of $\mathbb{D}$ thus preserves the Poincaré metric**?**. And any two covering $\mathbb{D} \to \Omega$ differ by a covering map which is also an automorphism of $\mathbb{D}$, thus preserves the Poincaré metric. □

Prop. (10.6.1.2) [Hyperbolic Metrics].

- $\rho_{\mathcal{H}}(z) = 1/\operatorname{Im}(z)$.
- $\rho_{\mathbb{D}(0,(0,r))}(z) = 1/(|z| \log \frac{r}{|z|})$.

Proof: 1: **?**.

2: There is a covering map $\mathcal{H} \to \mathbb{D}(0,(0,r)) : z \mapsto re^{\mathrm{i}z}$, so we can plug in the inverse map $w = \mathrm{i}\log z$ into $|\mathrm{d}w|/\operatorname{Im} w$ to get the desired formula. □

Thm. (10.6.1.3)[Schwartz Lemma]. If $f \in \mathcal{O}(\mathbb{D})$ and satisfies $|f(z)| \leq 1$, $f(0) = 0$, then $|f(z)| \leq |z|$, and $|f'(0)| \leq 1$. Moreover, if $|f(z)| = |z|$ for some z or $|f'(0)| = 1$, then $f(z) = cz$ for some $|c| = 1$.

Proof: The function $g(z) = f(z)/z$ is analytic on $0 < |z| < 1$ with a removable singularity at 0(10.5.2.17) and extends to an analytic function on $|z| < 1$ with $g(0) = f'(0)$, and $\lim_{|z|\to 1} |g(z)| \leq 1$, thus by maximal principle(10.5.2.23), $|g(z)| \leq 1$ for any $|z| < 1$, thus we are done. The last assertion also follows from(10.5.2.23). □

Lemma (10.6.1.4) [Schwartz-Pick]. Let $f \in \mathcal{O}(\mathbb{D})$, and $f(\mathbb{D}) \subset \mathbb{D}, f(0) = 0$, then in the Poincaré metric, for any $z_1, z_2 \in \mathbb{D}$,

$$d^P(f(z_1), f(z_2)) \leq d^P(z_1, z_2).$$

And if the equality holds for some $z_1 \neq z_2$, then $f \in \operatorname{Aut}(\mathbb{D})$.

Proof: Cf.[李忠]P29. □

Prop. (10.6.1.5) [Generalized Schwartz Lemma]. Let Ω_1, Ω_2 be regions of hyperbolic type with Poincaré metrics $\mathrm{d}s_1 = \sigma_1(z)|\mathrm{d}z|$ and $\mathrm{d}s_2 = \sigma_2(z)|\mathrm{d}z|$, then for any holomorphic map $f : \Omega_1 \to \Omega_2$,

$$\sigma_2(f(z))|f'(z)| \leq \sigma_1(z).$$

In particular, if $\Omega_1 \subset \Omega_2$, then $\sigma_2(z) \leq \sigma_1(z)$.

Proof: Let $h_1 : \mathbb{D} \to \Omega_1, h_2 : \mathbb{D} \to \Omega_2$ be covering maps, then $f : \Omega_1 \to \Omega_2$ lifts to a holomorphic map $F : \mathbb{D} \to \mathbb{D}$. Thus Schwartz-Pick lemma implies that $\sigma_{\mathbb{D}}(F(z))|F'(z)| \leq \sigma_{\mathbb{D}}(z)$. And this implies that

$$\sigma_1(z) \geq \sigma_{\mathbb{D}}(F \circ \psi_1(z))|(F \circ \psi_1)'(z)| = \sigma_{\mathbb{D}}(\psi_2 \circ f(z))|(\psi_2 \circ f)'(z)| = \sigma_2(f(z))|f'(z)|.$$

□

Montel-Normal Family

Def. (10.6.1.6) [Montel-Normal Family]. If $\Omega \subset \mathbb{C}$ is a region, then a set $\mathcal{S} = \{f_\alpha\}$ of holomorphic functions on Ω is called a **Montel-normal family** if for any sequence of functions in $\mathcal{S}$, there exists a subsequence that converges uniformly in Ω to ∞ or to a holomorphic function.

Prop. (10.6.1.7) [Montel]. If $\Omega \subset \mathbb{C}$ is a region, and $\mathcal{S} = \{f_\alpha\}$ is a set of holomorphic functions on Ω s.t.

$$\mathcal{S}' = \{\frac{|f_\alpha'(z)|}{1 + |f_\alpha(z)|^2}\}$$

is a set of functions on Ω bounded in the compact-open topology, then $\mathcal{S}$ is a Montel-normal family.

Proof:

□

Thm. (10.6.1.8) [Montel]. If $\Omega \subset \mathbb{C}$ is a region, and $\mathcal{S} = \{f_\alpha\}$ is a set of holomorphic functions on Ω s.t. there exists $a, b \in \mathbb{C}$ s.t. $f(z) \neq a, b$ for any $f \in \mathcal{S}, z \in \Omega$, then $\mathcal{S}$ is a Montel-normal family(10.6.1.6).

Proof: We may assume $a = 0, b = 1$. And we use $\rho_{0,1}(z)|\mathrm{d}z|$ to denote the Poincaré metric on $\mathbb{D} \setminus \{0, 1\}$. For any $z_0 \in \Omega$, suppose $\mathbb{D}(z_0, \delta) \subset \Omega$, then by generalized Schwartz lemma(10.6.1.5), for any $f \in \mathcal{S}$,

$$\rho_{0,1}(f(z))|f_\alpha'(z)| \leq \frac{2\delta}{\delta^2 - |z - z_0|^2}, \quad z \in \mathbb{D}(z_0, \delta).$$

By(10.6.1.9), $\rho_{0,1}(z)$ has a minimum $m > 0$ on $\overline{\mathbb{D}} \setminus \{0, 1\}$, so if $|f_{0,1}(z)| \leq 1$,

$$m|f'(z)| \leq \frac{2\delta}{\delta^2 - |z - z_0|^2}.$$

But also when $|f_{0,1}(z)| > 1$, consider the automorphism $w \mapsto 1/w : \mathbb{C} \setminus \{0, 1\} \to \mathbb{D} \setminus \{0, 1\}$, by(10.6.1.9),

$$m|f'(z)|/|f(z)|^2 \leq \frac{2\delta}{\delta^2 - |z - z_0|^2}.$$

Thus

$$m\frac{|f'(z)|}{(1 + |f(z)|^2)} \leq \frac{2\delta}{\delta^2 - |z - z_0|^2}.$$

Then from this it is easy to show that $\{\frac{|f'(z)|}{(1+|f(z)|^2)}\}$ is bounded on compact subsets, and then by(10.6.1.7), $\mathcal{S}$ is a Montel-normal family. □

$\rho_{0,1}(z)$

Prop. (10.6.1.9) [$\rho_{0,1}$]. Suppose the Poincaré metric on $\mathbb{D}\setminus\{0,1\}$ is $\rho_{0,1}(z)|\mathrm{d}z|$, then

- $\rho_{0,1}(z)=\rho_{0,1}(1-z)$.
- $\rho_{0,1}(1/z)=\rho_{0,1}(z)/z^2$.
- $\rho_{0,1}(z)=\rho_{0,1}(1-z)>\frac{1}{4|z|}$ when $|z|$ is small.
- $\rho_{0,1}(z)\leq\frac{1}{|z|\log|\frac{1}{z}|}$.

Proof: 1, 2 follows from the uniqueness of the Poincaré metric.
3 follows from [李忠]P46.?
4: This follows from(10.6.1.2) and generalized Schwartz lemma(10.6.1.5). □

Prop. (10.6.1.10). Let $\eta=\min\{\rho_{0,1}(z):|z|=1\}$, then $\eta=\rho_{0,1}(-1)=4\pi^2/\Gamma^4(\frac{1}{4})=0.2284733$.

Proof: □

Prop. (10.6.1.11). For $0<|z|\leq 1$,

$$\rho_{0,1}(z)\geq\frac{1}{|z|(\eta^{-1}-\log|z|)},$$

where $\eta=\min\{\rho_{0,1}(z),|z|=1\}>0$ by(10.6.1.9).

Proof: □

Cor. (10.6.1.12). When $z\to 0$, $\rho_{0,1}(z)\sim\frac{1}{|z|\log|\frac{1}{z}|}$.

Thm. (10.6.1.13) [Landau]. If $f\in\mathcal{O}(\mathbb{D})$ doesn't take the values $0,1$, then

$$|f'(0)|\leq 2|f(0)|(\eta^{-1}+\Big|\log|f(0)|\Big|)\text{(10.6.1.10)}.$$

And the equality can be achieved.

Proof: Cf.[李忠]P41. □

Thm. (10.6.1.14) [Great Picard Theorem]. If an analytic function f has an essential singularity at a point w, then on any punctured nbhd of w, f takes any value infinitely often, except for at most one single exception.

Proof: We may assume $f:\mathbb{D}\setminus\{0\}\to\mathbb{C}\setminus\{0,1\}$, then by generalized Schwartz lemma(10.6.1.5) and(10.6.1.2),

$$\rho_{0,1}(f(z))|f'(z)|\leq\frac{1}{|z|\log\frac{1}{|z|}}.$$

We want to prove that for $z\in\mathbb{D}(0,e)$, there exists some C s.t.

$$-\log|f(z)|<C\log\frac{1}{|z|}.$$

When $f(z)\geq 1$, this is clearly true, so we may assume $f(z)<1$. Let $m=\max\{|f(z)|:|z|=\rho\}$, and let $z=re^{\mathrm{i}\theta}$. Consider two cases:

If $f(te^{\theta}) \in \mathbb{D}$ for any $r \le t \le e$, then by(10.6.1.11),

$$\frac{|f'(z)|}{|f(z)|}[\eta^{-1} - \log|f(te^{i\theta})|]^{-1} \le \frac{1}{|z|\log\frac{1}{|z|}}.$$

Integration on $t \in [r, \rho]$ implies that

$$\log[\eta^{-1} - \log|f(z)|] \le \log\log\frac{1}{|z|} - \log\log\frac{1}{\rho} + \log[\eta^{-1} - \log|f(\rho e^{i\theta})|] \le \log\log\frac{1}{|z|} + \log\log\frac{e^{\eta^{-1}}}{m},$$

which implies that

$$-\log|f(z)| < C\log\frac{1}{|z|}.$$

If $r_0 \in (r, e]$ is the smallest number s.t. $|f(r_0e^{i\theta})| = 1$, then integration on t from r to r_0 implies that

$$\log[\eta^{-1} - \log|f(z)|] \le \log\log\frac{1}{|z|} - \log\log\frac{1}{r_0} + \log(\eta^{-1}) \le \log\log\frac{1}{|z|},$$

which also implies that

$$-\log|f(z)| < \eta^{-1}\log\frac{1}{|z|}.$$

Now notice we can do all above for f replaced by $1/f$, so it implies that

$$\log|f(z)| < C'\log\frac{1}{|z|},$$

and then f is meromorphic at $z = 0$. □

Thm. (10.6.1.15) [Schottky]. If $f \in \mathcal{O}(\mathbb{D})$ doesn't take the values $0, 1$, then

$$\log|f(z)| \le [\eta^{-1} + \max\{\log|f(0)|, 0\}]\frac{1+|z|}{1-|z|} - \eta^{-1},$$

and the equality can be achieved.

Proof: It follows from generalized Schwartz lemma(10.6.1.5) that

$$\rho_{0,1}(f(z))|f'(z)| \le \frac{2}{1-|z|^2}.$$

For $z = re^{i\theta} \in \mathbb{D}$, if $f(te^{i\theta}) \in \mathbb{D}$ for any $t \in [0, r]$, then it follows from(10.6.1.11) that

$$\frac{|f'(z)|}{|f(z)|}[\eta^{-1} - \log|f(te^{i\theta})|]^{-1} \le \frac{2}{1-|z|^2}.$$

Integration on $t \in [0, r]$ implies that

$$\frac{\eta^{-1} - \log|f(z)|}{\eta^{-1} - \log|f(0)|} \le \frac{1+|z|}{1-|z|}.$$

If $r_0 \in (0, r]$ is the largest number s.t. $|f(r_0e^{i\theta})| = 1$, then integration on t from r_0 to r implies that

$$\eta(\eta^{-1} - \log|f(z)|) \le \frac{1+|z|}{1-|z|}\frac{1-r_0}{1+r_0} < \frac{1+|z|}{1-|z|}.$$

So in any case we get

$$\eta^{-1} - \log|f(z)| \le [\eta^{-1} + \max\{\log|f(0)|, 0\}]\frac{1+|z|}{1-|z|}.$$

And all the above applies to f replaced by $1/f$, so we get the desired formula.

To show the equality can be achieved, Cf.[李忠]P45. □

2 Harmonic Functions

Def. (10.6.2.1) [Harmonic Functions]. A real-valued function on a region $\Omega \subset \mathbb{C}$ is called **harmonic** iff it is C^1 and has second order derivatives and

$$\Delta u = (\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2})u = 4\frac{\partial}{\partial \overline{z}}\frac{\partial}{\partial z} f = 0.$$

This is an elliptic differential operator, so u is automatically smooth, by(10.13.8.4).

The vector space of Harmonic functions on Ω is denoted by $\mathscr{H}(\Omega) \subset \mathbb{C}^\infty(\Omega)$.

Prop. (10.6.2.2) [Schwarz's Theorem]. Cf.[Ahlfors P169].

Def. (10.6.2.3) [Mean-Value Property]. A real valued function u on a region Ω is said to have the **mean-value property** iff

$$u(z_0) = \frac{1}{2\pi}\int_0^{1\pi} u(z_0 + re^{\mathrm{i}\theta})d\theta$$

whenever $\mathbb{D}(z_0, r) \subset \Omega$.

Lemma (10.6.2.4) [Harmonic Mean Value]. If u is a Harmonic function between two concentric circles, then the arithmetic mean of it over circles $|z| = r$ is a linear function of $\log r$:

$$\frac{1}{2\pi}\int_{|z|=r} u\mathrm{d}\theta = \alpha \log r + \beta.$$

In particular, if u is harmonic in the disk, then by continuity, $\alpha = 0$, and the mean value is a constant.

Proof: Cf.[Ahlfors P165]. □

Prop. (10.6.2.5) [Harmonicity and Mean-Value Property]. A harmonic function satisfies the mean-value property, and conversely, and continuous function satisfying the mean-value property is harmonic.

Proof: Harmonic function satisfies the mean-value property by(10.6.2.4). Conversely, for any z_0, by Schwarz's theorem(10.6.2.2), there is a harmonic function $v(z)$ that is harmonic in $\mathbb{D}(z_0, \rho)$ and equals $u(z)$ on $\partial B(z_0, \rho)$. Now the maximal and minimal principles apply to $u - v$, thus $u = v$ is harmonic. □

Cor. (10.6.2.6) [Maximum Principle]. If u is a harmonic function, then it attains neither maximum nor minimum at its region of definition.

Prop. (10.6.2.7) [Real Part of an Analytic Function is Harmonic]. On $\mathbb{C}$, formally,

$$4\frac{\partial}{\partial z}\frac{\partial}{\partial \overline{z}} = 4\frac{\partial}{\partial \overline{z}}\frac{\partial}{\partial z} = \Delta.$$

Thus for any open subset $\Omega \subset \mathbb{C}$, if $f \in \mathcal{O}(\Omega)$, then $\operatorname{Im} f, \operatorname{Re} f \in \mathscr{H}(\Omega)$.

Proof: By(10.5.1.4),

$$4\frac{\partial}{\partial z}\frac{\partial}{\partial \overline{z}} = (\frac{\partial}{\partial x} - \mathrm{i}\frac{\partial}{\partial y})(\frac{\partial}{\partial x} + \mathrm{i}\frac{\partial}{\partial y}) = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}.$$

$$4\frac{\partial}{\partial \bar{z}}\frac{\partial}{\partial z} = (\frac{\partial}{\partial x} + \mathrm{i}\,\frac{\partial}{\partial y})(\frac{\partial}{\partial x} - \mathrm{i}\,\frac{\partial}{\partial y}) = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}.$$

If $f \in \mathcal{O}(\Omega)$, then $f \in C^\infty(\Omega)$ by(10.5.2.7), then by(10.4.3.8) the formal calculation above applies to f, and by(10.5.1.9)

$$\Delta \operatorname{Re} f + \mathrm{i}\,\Delta \operatorname{Im} f = \Delta f = \frac{\partial}{\partial z}\frac{\partial}{\partial \bar{z}} f = 0,$$

so $\Delta \operatorname{Re} f = \Delta \operatorname{Im} f = 0$, and $\operatorname{Im} f, \operatorname{Re} f \in \mathscr{H}(\Omega)$. □

Cor. (10.6.2.8). If $\Omega \subset \mathbb{C}$ is a region and $z \in \Omega$, $f \in \mathcal{O}(\Omega)$ is non-vanishing, then $\log|f| \in \mathscr{H}(\Omega)$.

Proof: Being harmonic is local, so we may look locally and assume Ω is a disk. Then by(10.5.2.32), there exists a $g \in \Omega(\Omega)$ s.t.

$$f(z) = \exp(g(z)).$$

Then it follows $\operatorname{Re}(g(z)) = \log|f(z)|$, which is harmonic by(10.6.2.7). □

Prop. (10.6.2.9) [Harmonic Functions as the Real Parts of Analytic Functions]. Let $\Omega \subset \mathbb{C}$ be a simply-connected region, $u \in \mathscr{H}(\Omega)$, then there exists $f \in \mathcal{O}(\Omega)$ s.t. $\operatorname{Re} f = u$. And any two such f differ by a purely imaginary constant.

Proof: Let $g(z) = 2\frac{\partial}{\partial z}u$, then $\frac{\partial}{\partial \bar{z}}g = 2\frac{\partial}{\partial \bar{z}}\frac{\partial}{\partial z}u = \frac{1}{2}\Delta u = 0$, so $g \in \mathcal{O}(\Omega)$. Then by(10.5.2.3), there exists $f \in \mathcal{O}(\Omega)$ s.t. $\frac{\partial}{\partial z}f = g = 2\frac{\partial}{\partial z}u$. So

$$2\frac{\partial}{\partial x}u = \frac{\partial}{\partial x}\operatorname{Re} f + \frac{\partial}{\partial y}\operatorname{Im} f = 2\frac{\partial}{\partial x}\operatorname{Re} f, \quad 2\frac{\partial}{\partial y}u = \frac{\partial}{\partial y}\operatorname{Re} f - \frac{\partial}{\partial x}\operatorname{Im} f = 2\frac{\partial}{\partial y}\operatorname{Re} f.$$

So $u - \operatorname{Re} f$ is a constant function. And we may modify f to make $\operatorname{Re} f = u$. For the last assertion, use the Cauchy-Riemann equations to show that $\frac{\partial}{\partial x}(\operatorname{Im} f - \operatorname{Im} f') = \frac{\partial}{\partial y}(\operatorname{Im} f - \operatorname{Im} f') = 0$, so $\operatorname{Im} f - \operatorname{Im} f'$ is a constant function. □

Properties

Prop. (10.6.2.10) [Poisson Formula]. For $u \in \mathscr{H}(\overline{\mathbb{D}(0,R)})$,

$$u(z) = \frac{1}{2\pi}\int_0^{2\pi} \frac{R^2 - |z|^2}{|Re^{\mathrm{i}\,\theta} - z|^2} u(Re^{\mathrm{i}\,\theta})d\theta = \operatorname{Re}\Big[\frac{1}{2\pi\,\mathrm{i}}\int_{|\zeta|=R} \frac{\zeta + z}{\zeta - z}u(\zeta)\frac{d\zeta}{\zeta}\Big].$$

for $z \in \mathbb{D}(0,R)$.

In particular, for any $f \in \mathcal{O}(\overline{\mathbb{D}(0,R)})$, there is a constant $C \in \mathbb{R}$ s.t. for any $z \in \mathbb{D}(0,R)$:

$$f(z) = \frac{1}{2\pi\,\mathrm{i}}\int_{|\zeta|=\rho} \frac{\zeta + z}{\zeta - z}\operatorname{Re}(f(\zeta))\frac{d\zeta}{\zeta} + \mathrm{i}\,C.$$

Proof: This follows from(10.6.2.9) and(10.5.2.12). □

Cor. (10.6.2.11) [Poisson-Jensen Formula]. For $f \in \Omega(\overline{\mathbb{D}(0,R)})$ with no zeros on the boundary and zeros $a_1, \ldots, a_n$ inside(counting multiplicity), then for $z \in \mathbb{D}(0,R)$ s.t. $f(z) \neq 0$,

$$\log|f(z)| = -\sum_i \log\Big|\frac{R^2 - \overline{a}_i z}{R(z - a_i)}\Big| + \frac{1}{2\pi}\int_0^{2\pi} \frac{R^2 - |z|^2}{|Re^{\mathrm{i}\,\theta} - z|^2}\log|f(Re^{\mathrm{i}\,\theta})|\mathrm{d}\theta.$$

In particular, if $f(0) \neq 0$, then

$$\log|f(0)| = -\sum_i \log\Big|\frac{R}{a_i}\Big| + \frac{1}{2\pi}\int_0^{2\pi} \log|f(Re^{\mathrm{i}\,\theta})|\mathrm{d}\theta.$$

Proof: Firstly, this is true when f is non-vanishing on $\mathbb{D}(0,\rho)$, because in this case $\log|f|$ is harmonic by(10.6.2.8) and we can use mean value theorem(10.6.2.5). In general, consider the function

$$F(z) = f(z)\prod_{i=1}^{n}\frac{R^2-\overline{a}_i z}{R(z-a_i)},$$

then it satisfies $F(z)=f(z)$ for $|z|=R$, and has no zeros on $\mathbb{D}(0,R)$, so

$$\frac{1}{2\pi}\int_0^{2\pi}\log|f(\rho e^{\mathrm{i}\theta})|\mathrm{d}\theta = \log|F(0)| = \log|f(0)| + \sum_i \log\Big|\frac{R^2-\overline{a}_i z}{R(z-a_i)}\Big|.$$

□

Prop. (10.6.2.12) [Hadamard's Three Circle Theorem]. Let $f(z)$ be analytic in the annulus $r_1 < |z| < r_2$, and continuous on the boundary, if $M(r)$ denotes the maximum of $|f(z)|$ for $|z|=r$, then:

$$M(r)\le M(r_1)^{\alpha}M(r_2)^{1-\alpha}$$

where $\alpha = \log(r_2/r):\log(r_2/r_1)$.

Proof: Apply the maximum principle(10.6.2.6) for

$$g(z) = \log|f(z)| - \log(M(r_1))(\log(r_2/|z|):\log(r_2/r_1)) - \log(M(r_2))(1-\log(r_2/|z|):\log(r_2/r_1)),$$

it is harmonic by(10.6.2.8), then $g(z)\le 0$ on $|z|=r_1$ and $|z|=r_2$, so $g(z)\le 0$ on all the annulus. □

Cor. (10.6.2.13). Let $f(z)$ be analytic in the annulus $r_1<|z|<r_2$, then the function

$$s\mapsto \max_{z=e^s}|f(z)|$$

is convex on the interval $[\log(a),\log(b)]$.

Prop. (10.6.2.14) [Reflection Principle].

Proof: □

Prop. (10.6.2.15) [Harnack's Inequality]. For a positive harmonic function u on $B(0,\rho)$,

$$\frac{\rho-|z|}{\rho+|z|}u(0)\le u(z)\le\frac{\rho+|z|}{\rho-|z|}u(0).$$

Proof: By Poisson formula,

$$u(z) = \frac{1}{2\pi}\int\frac{\rho^2-|z|^2}{|\rho e^{\mathrm{i}\theta}-z|^2}u(\rho e^{i\theta})d\theta$$

for $|z|<\rho$, so the conclusion follows from the obvious inequality

$$\frac{\rho-|z|}{\rho+|z|}\le\frac{\rho^2-|z|^2}{|\rho e^{\mathrm{i}\theta}-z|^2}\le\frac{\rho+|z|}{\rho-|z|}$$

and Mean-value property(10.6.2.5). □

Cor. (10.6.2.16). If E is a compact subset of a region Ω, there is a constant M, depending on E,Ω that for any positive harmonic function $u(z)$ on Ω, $u(z_2)\leq Mu(z_1)$ for any $z_1,z_2\in E$.

Proof: This is an easy consequence of Harnack inequality and the compactness of E. □

Cor. (10.6.2.17) [Harnack's Principle]. Consider a sequence of functions $u_n(z)$, each harmonic in a region Ω_n, and there is a region Ω that every point has a nbhd that is contained in all but f.m. Ω_n, and in this nbhd $u_n(z)\leq u_{n+1}(z)$ for n large, then either $u_n(z)$ tends to $+\infty$ in the compact open topology, or they tends to a harmonic function in compact open topology.

Proof: The uniform continuity follows easily from Harnack's inequality, and for the harmonicity of the limit function $u(z)$ is a consequence of the Poisson formula. □

Dirichlet Problem

3 Miscellaneous

Def. (10.6.3.1) [$L^2(\mathbb{D},\nu_k)$ Unit Disc]. Define a density $\nu_k=\frac{4(1-|w|^2)^{k-2}dudv}{|1-w|^{2k}}(k\geq 2)$ on $\mathbb{D}$ and define $L^2(\mathbb{D},\nu_k)$ to be the space of holomorphic functions on $\mathbb{D}$ that is $L^2(\nu_k)$ bounded. Then the space $L^2(\mathbb{D},\nu_k)$ is complete.

Proof: By(10.5.2.11), the uniform norm is bounded by the local L^1-norm hence also the local L^2-norm. Hence for a compact subset K, the uniform norm is also bounded by $L^2(\nu_k)$-norm. Thus any Cauchy sequence in $L^2(\mathbb{D},\nu_k)$ converges to a holomorphic function by Weierstrass theorem(10.5.5.3). □

Prop. (10.6.3.2). The space $L^2(\mathbb{D},\nu_k)$ has an orthogonal basis consisting of holomorphic functions

$$\{\psi_n=w^n(1-w)^k\}_{n\geq 0}.$$

Proof: Firstly, ψ_n is convergent: In the polar coordinate, $\nu_k=\frac{4(1-r^2)^{k-2}rdrd\theta}{|1-w|^{2k}}$, so

$$||\psi_n||^2=4\int_0^{2\pi}\int_0^1 r^{2n}(1-r^2)^{k-2}drd\theta<\infty.$$

And if $m\neq n$,

$$\int_{\mathbb{D}}\psi_m(w)\overline{\psi_n}(w)dw=4\int_{\mathbb{D}}w^m(\overline{w})^n(1-r^2)^{k-2}drd\theta=4\int_0^1 r^{m+n}(1-r^2)^{k-2}\int_0^{2\pi}e^{i(m-n)\theta}d\theta=0.$$

□

Def. (10.6.3.3) [Upper Half Plane $\mathscr{H}_k$]. On the upper half plane $\mathscr{H}$, we can define a density $\mu_k=y^k\frac{dxdy}{y^2}(k\geq 2)$, and define $L^2(\mathscr{H},\mu_k)$ to be the space of holomorphic functions on $\mathscr{H}$ that is $L^2(\mu_k)$ bounded. Then under the Cayley map $z\mapsto w=\frac{z-\mathrm{i}}{z+\mathrm{i}}$, this density is mapped to the density ν_k of $\mathbb{D}$ and induces an isomorphism of spaces

$$L^2(\mathscr{H},\mu_k)\cong L^2(\mathbb{D},\nu_k).$$

In particular, $L^2(\mathscr{H},\mu_k)$ is complete, and it has an orthogonal basis

$$\{\varphi_n=(\frac{z-\mathrm{i}}{z+\mathrm{i}})^n\frac{(2\,\mathrm{i})^k}{(z+\mathrm{i})^k}\}.$$

by(10.6.3.1) and(10.6.3.2).

4 Elliptic Functions

Main references are [?]Chap7, [Sil99], [Sil16].

Def. (10.6.4.1) [Doubly Periodic Function]. Let Λ be a lattice of $\mathbb{C}$, then a meromorphic function f on $\mathbb{C}$ is called **doubly periodic w.r.t.** Λ if it is invariant under Λ.

Prop. (10.6.4.2). Let f be a periodic function for Λ, not identically zero, and let D be a fundamental parallelogram for Λ that f has no zeros or poles on the boundary of D. Then

- $\sum_{P\in D}\mathrm{ord}_P(f)=0$.
- $\sum_{P\in D}\mathrm{res}_P(f)=0$.
- $\sum_{P\in D}\mathrm{ord}_P(f)\cdot P=0$.

Proof: f can be realized as meromorphic functions on the Riemann surface $\mathbb{C}/\Lambda$, so $1,2$ are direct consequences of(5.11.12.8) $1,2$. 3 is 2 applied to the meromorphic function $zf'(z)/f(z)$. □

Def. (10.6.4.3) [Order]. The order of an elliptic function f is defined to be the number of poles of f in D. Equivalently, it is the number of zeros of f in D(10.6.4.2).

Prop. (10.6.4.4). The total number of orders of a non-constant elliptic function≥ 2.

Proof: If its order is 0, then it is bounded on D and also on $\mathbb{C}$ thus constant by Liouville's theorem. If its order is 1, then it has a simple pole z_0, but then $\mathrm{Res}_{z_0}(f)\neq 0$, contradicting(10.6.4.2). □

Def. (10.6.4.5) [Weierstrass $\wp$-Function]. For a lattice $\Lambda\subset\mathbb{C}$, consider the function

$$\wp(z)=\frac{1}{z^2}+\sum_{\omega\in\Lambda\backslash\{0\}}(\frac{1}{(z-\omega)^2}-\frac{1}{\omega^2})$$

Then it is a doubly periodic meromorphic function that has a double pole at 0, and so does its derivative $\wp'$, having a triple pole at 0. Hence they descend to a rational function on $\mathbb{C}/\Lambda$.

If $\Lambda=\Lambda_\tau$, then the function $\wp(z;\tau)=\wp(z)$ is called the **Weierstrass $\wp$-function**.

Prop. (10.6.4.6). Let $G_k(\Lambda)$ be given by(16.2.5.5),

$$\wp(z)=\frac{1}{z^2}+\sum_{k\geq 1}(2k+1)G_{2k+2}(\Lambda)z^{2k}.$$

Proof: This follows from(8.5.2.1). □

Prop. (10.6.4.7) [Fields of Elliptic Functions]. The field of doubly periodic functions for Λ is just $\mathbb{C}(\wp,\wp')$. And $\wp,\wp'$ also satisfies the following equation:

$$\wp'(z)^2=4\wp(z)^3-g_2\wp(z)^2-g_3\wp(z)$$

where $g_2=60G_4(\Lambda),g_3=140G_6(\Lambda)$(16.2.5.5).

Proof: For the equational function, just notice we can calculate directly that the difference of the two sides is a holomorphic function in z without constant terms, and they are both doubly periodic, thus is zero.

For the first statement, notice that any function is a sum of an odd function and an even function. $\wp'$ is odd, thus an odd function is $\wp'$ times an even function. Thus it reduces to show that any even doubly periodic function is a rational function of $\wp$.

For any even periodic function f, f has the same order at z_0 and $-z_0$, also if $z_0 \equiv -z0 \mod \Lambda$, the order of f at z_0 must be odd. Now consider $\wp(z) - \wp(z_0)$, then it is a function with two poles at 0, so it has two zeros. If $z_0 \equiv -z_0$, then $\wp(z) - \wp(z_0)$ has a zero of order 2 at z_0, and otherwise it has simple zeros at z_0 and $-z_0$.

So for any even doubly periodic function f, we can use the product $\prod(\wp(z) - \wp(z_0))^{m_i}$ to get a function with the same order of poles and zeros as f, which implies it equals f. □

Prop. (10.6.4.8)[Uniformization Theorem]. For any complex numbers $A, B \in \mathbb{C}$ that $A^3 - 27B^2 \neq 0$, there exists a unique lattice $\Lambda \in \mathbb{C}$ that $g_2(\Lambda) = A, g_3(\Lambda) = B$(10.6.4.7).

Proof: The j-function(16.2.5.10) is surjective, thus there is a $z \in \mathbb{C}$ s.t.

$$1728\frac{1}{1 - \frac{E_6^2}{E_4^3}} = j(z) = 1728\frac{A^3}{A^3 - 27B^2}$$

And if we assume $A, B \neq 0$, then by(16.2.5.5)(19.6.4.1) and(8.5.1.12), assume this implies

$$(\frac{B}{g_3(\tau)})^2(\frac{g_2(\tau)}{A})^3 = 1.$$

Then we can scale Λ by $\Lambda' = \alpha\Lambda$ s.t. $g_3(\Lambda') = B, \quad g_2(\Lambda) = A$.

The case that $A = 0$ or $B = 0$ is similar.

The uniqueness follows from(13.5.8.6). □

5 Multi-Variable case

Basics

Should cover the part from [Complex Analytic and Differential Geometry Demailly], [Principle of Algebraic Geometry Griffith/Harris] and [Complex Geometry Daniel].

Def. (10.6.5.1). A function is called **holomorphic** in several variables iff it is holomorphic for each indeterminate.

Def. (10.6.5.2). For $a \in \mathbb{C}^n$, the **polydisc** $B(a, \varepsilon) \subset \mathbb{C}^n$ is defined to be the set $\{z||z_i - a_i| < \varepsilon_i\}$.

Prop. (10.6.5.3)[Hartog's Extension Theorem]. If K is a compact subset in an open domain Ω of $\mathbb{C}^n (n \geq 2)$ and $\Omega - K$ is connected, then any holomorphic function on $\Omega - K$ extends to a holomorphic function on Ω.

Proof: □

Prop. (10.6.5.4). Let $\varepsilon = (\delta, \ldots, \delta)$ and f be a holomorphic function on the polydisc $\overline{B_\varepsilon(0)}$. Then if f vanishes of order k at the origin and $|f(z)| \leq C$, then

$$f(z) \leq C(\frac{|z|}{\delta})^k$$

for all $z \in \overline{B_\varepsilon(0)}$.

Proof: Fix $z \in \overline{B_\varepsilon(0)} \neq= 0$, consider the one-variable function $g_z(w) = w^{-k}f(w \cdot \frac{z}{|z|})$, then g_z is holomorphic and $|g_z(w)| \leq \delta^{-k}C$ for $|w| = \delta$. So maximal principle implies that $g_z(w) \leq \delta^{-k}C$ for all $|\omega| \leq \delta$. Hence $|z|^{-k}|f(z)| = |g_z(|z|)| \leq \delta^{-k}C$. □

10.7 Special Functions

1 Gamma Function

Def. (10.7.1.1)[Gamma Function]. For a complex number s that $\mathrm{Re}(s) > 0$, the **Gamma function** is defined to be

$$\Gamma(s) = \int_0^\infty e^{-t} t^s \frac{\mathrm{d}t}{t}.$$

which is convergent for any $\mathrm{Re}(s) > 0$ thus an analytic function for $\mathrm{Re}(s) > 0$ by(10.5.2.13).

Prop. (10.7.1.2). For $\mathrm{Re}(s) > 0$, $\Gamma(s+1) = s\Gamma(s)$.

Proof: For any $\varepsilon \in \mathbb{R}_+$,

$$\int_\varepsilon^{1/\varepsilon} \frac{\partial}{\partial t}(e^{-t}t^s)\mathrm{d}t = -\int_\varepsilon^{1/\varepsilon} e^{-t}t^s \mathrm{d}t + s\int_\varepsilon^{1/\varepsilon} e^{-t}t^{s-1}\mathrm{d}t.$$

Then letting $\varepsilon \to 0$ gives the desired formula. □

Cor. (10.7.1.3). $\Gamma(s)$ extends to a meromorphic function for all $s \in \mathbb{C}$, with simple poles at $s \in \mathbb{Z}_{\leq 0}$. And for $n \in \mathbb{N}$,

$$\mathrm{res}_{s=-n}\,\Gamma(s) = \frac{(-1)^n}{n!}.$$

Proof: In fact, for $m \in \mathbb{Z}_+$,

$$F_m(s) = \frac{\Gamma(s+m)}{s(s+1)\dots(s+m-1)}$$

extends $\Gamma(s)$ meromorphically to $\mathrm{Re}(s) > -m$ with simple poles at $s = 0, -1, \dots, -m+1$, and

$$\mathrm{res}_{s=-m+1}\,F_m(s) = \frac{\Gamma(1)}{(-1)(-2)\dots(-m+1)} = \frac{(-1)^{m-1}}{(m-1)!}.$$

□

Prop. (10.7.1.4). For $t \in \mathbb{R}_+$, $\Gamma(t)$ is decreasing for $t \leq 1$, and increasing for $t \geq 1$.

Proof:

$$\frac{\partial}{\partial t}\Gamma(t) = \int_0^\infty \log t e^{-t}t^s \frac{\mathrm{d}t}{t}.$$

□

Prop. (10.7.1.5).

$$\Gamma(s)\Gamma(1-s) = \frac{\pi}{\sin(\pi s)}.$$

Proof: By uniqueness theorem, it suffices to prove for $0 < s < 1$. Then

$$\begin{aligned}\Gamma(1-s)\Gamma(s) &= \int_0^\infty e^{-t}t^{s-1}\Gamma(1-s)\mathrm{d}t = \int_0^\infty e^{-t}t^{s-1}\Big(t\int_0^\infty e^{-vt}(vt)^{-s}\mathrm{d}v\Big)\mathrm{d}t \\ &= \int_0^\infty\int_0^\infty e^{-t(v+1)}v^{-s}\mathrm{d}v\mathrm{d}t = \int_0^\infty \frac{v^{1-s}}{v(v+1)}\mathrm{d}v \\ (10.5.6.6) &= \frac{\pi}{\sin(\pi s)}\end{aligned}$$

□

Cor. (10.7.1.6). There exists constants c_1, c_2 s.t. for any $s\in\mathbb{C}$,

$$|\frac{1}{\Gamma(s)}|\leq c_1 e^{c_2|s|\log|s|}.$$

Thus $1/\Gamma(s)$ has order of growth 1.

Proof: For $\mathrm{Re}(s)>0$

$$\Gamma(s)=\int_0^1 e^{-t}t^{s-1}\mathrm{d}t+\int_1^\infty e^{-t}t^{s-1}\mathrm{d}t=\sum_{n\in\mathbb{N}}\frac{(-1)^n}{n!(n+s)}+\int_1^\infty e^{-t}t^{s-1}\mathrm{d}t,$$

and this equality holds for all $s\in\mathbb{C}$. Thus by(10.7.1.5),

$$|\frac{1}{\Gamma(s)}|=|\frac{\sin(\pi s)\Gamma(1-s)}{\pi}|\leq\Big|\sum_{n\in\mathbb{N}}\frac{(-1)^n}{n!(n+1-s)}\Big|\frac{\sin(\pi s)}{\pi}|+\Big|\int_1^\infty e^{-t}t^{-s}\mathrm{d}t\Big|.$$

Suppose $k=\lfloor\mathrm{Re}(s)+\frac{1}{2}\rfloor$, then

$$\Big|\sum_{n\in\mathbb{N}}\frac{(-1)^n}{n!(n+1-s)}\frac{\sin(\pi s)}{\pi}|\leq\sum_{n\in\mathbb{N},n\neq k}\Big|\frac{1}{n!(n+1-s)}\frac{\sin(\pi s)}{\pi}\Big|+\Big|\frac{\sin(\pi s)}{(k-1)!(s-k)\pi}\Big|$$

and the first term is bounded by $e^{\pi|s|}$, and the second term is bounded by a constant independent of k, because $\sin(\pi s)$ has a zero at $s=k$.

Also,

$$\Big|\int_1^\infty e^{-t}t^{-s}\mathrm{d}t\Big|\leq\int_1^\infty e^{-t}t^{k+1}\mathrm{d}t=(k+1)!\leq e^{(k+1)\log(k+1)}.$$

So the assertion follows. □

Prop. (10.7.1.7) [Special Values].

$$\Gamma(n+1)=n!, n\in\mathbb{N},\quad \Gamma(\frac{1}{2})=\sqrt{\pi}.$$

Proof: For the first assertion, use induction: $\Gamma(1)=\int_0^\infty e^{-t}\mathrm{d}t=1$, and the induction process follows from(10.7.1.2). The second assertion follows from(10.7.1.5). □

Thm. (10.7.1.8) [Hadamard Product]. For $s\in\mathbb{C}$,

$$\frac{1}{\Gamma(s)}=e^{\gamma s}s\prod_{n\in\mathbb{Z}_+}[(1+\frac{s}{n})e^{-s/n}],$$

where γ is the Euler's constant(10.4.5.2).

Proof: By(10.7.1.6)(10.7.1.3) and(10.5.3.20),

$$\frac{1}{\Gamma(s)}=e^{As+B}s\prod_{n\in\mathbb{Z}_+}[(1+\frac{s}{n})e^{-s/n}]$$

for some $A,B\in\mathbb{C}$. Taking $s\to 0$, we get $B=0$ by(10.7.1.3). And $\Gamma(1)=1$(10.7.1.7) implies that

$$e^{-A}=\prod_{n\in\mathbb{Z}_+}[(1+\frac{1}{n})e^{-1/n}]=\lim_{N\to\infty}e^{\log(N+1)-\sum_{n=1}^N 1/n}=e^{-\gamma}(10.4.5.2)$$

□

Cor. (10.7.1.9) [Duplication Formula].

$$\Gamma(2s-1)=\frac{4^{s-1}}{\sqrt{\pi}}\Gamma(s-\frac{1}{2})\Gamma(s).$$

Proof: □

Cor. (10.7.1.10) [Euler's Formula].

$$\frac{1}{\Gamma(s)}=\lim_{n\to\infty}\frac{s(s+1)\cdots(s+n)}{n^s n!}$$

Proof: This follows from the definition of the infinite product and the definition of Euler's constant(10.7.1.5). □

Prop. (10.7.1.11) [Mellin Inversion Formula]. By(10.12.2.16) applied to $f(x)=e^{-x}$, for any real $c>0$,

$$e^{-x}=\frac{1}{2\pi\,\mathrm{i}}\int_{c-\mathrm{i}\,\infty}^{c+\mathrm{i}\,\infty}\Gamma(s)x^{-s}ds, x>0.$$

Thm. (10.7.1.12) [Stirling's Formula]. $|\Gamma(\sigma+it)|\sim\sqrt{2\pi}|t|^{\sigma-\frac{1}{2}}e^{-\pi|t|/2}$.

Proof: □

Def. (10.7.1.13) [Archimedean L-Factors]. Define

$$L_{\mathbb{R}}(s)=\pi^{-\frac{s}{2}}\Gamma(\frac{s}{2}),\quad L_{\mathbb{C}}(s)=2(2\pi)^{-s}\Gamma(s)=\Gamma_{\mathbb{R}}(s)\Gamma_{\mathbb{R}}(s+1).$$

Notice $L_{\mathbb{R}}(1)=1, L_{\mathbb{C}}(1)=\pi^{-1}$, by(10.7.1.7).

2 Bessel Function

Def. (10.7.2.1) [Bessel Function]. The **Bessel function** is defined to be

$$B(r,s)=\int_0^1(1-y)^{r-1}y^{s-1}dy.$$

Prop. (10.7.2.2).

$$B(x,y)=\frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}.$$

3 K-Bessel Function

Def. (10.7.3.1). The **K-Bessel function** is defined to be

$$K_s(y)=\frac{1}{2}\int_0^\infty e^{-y(t+\frac{1}{t})/2}t^s\frac{dt}{t},\quad y>0.$$

it satisfies $K_{-s}(y)=K_s(y)$.

Prop. (10.7.3.2). $|K_s(y)|\leq e^{-y/2}K_{\mathrm{Re}\,s}(2)$ when $y>4$.

Proof: This is because $e^{-ab}<e^{-a}e^{-b}$ when $a,b>2$. □

Prop. (10.7.3.3).

$$\frac{\partial}{\partial y}K_s(y) = \frac{1}{2}\int_0^\infty (-(t+\frac{1}{t})/2)e^{-y(t+\frac{1}{t})/2}t^s\frac{dt}{t} = -\frac{1}{2}(K_{s+1}(y)+K_{s-1}(y))$$

Prop. (10.7.3.4). If $\mathrm{Re}(s) > 1/2$ and $r \in \mathbb{R}$,

$$(\frac{y}{\pi})^s\Gamma(s)\int_{-\infty}^\infty (x^2+y^2)^{-s}e^{2\pi\,\mathrm{i}\,rx}dx = \begin{cases} \pi^{1/2-s}\Gamma(s-\frac{1}{2})y^{1-s} & r=0 \\ 2|r|^{s-1/2}\sqrt{y}K_{s-1/2}(2\pi|r|y) & r\neq 0 \end{cases}$$

Proof: By(10.7.1.1), the LHS equals

$$\int_{-\infty}^\infty\int_0^\infty e^{-t}(\frac{ty}{\pi(x^2+y^2)})^s e^{2\pi irx}\frac{dt}{t}dx = \int_0^\infty\int_{-\infty}^\infty e^{-\pi t(x^2+y^2)/y}t^s e^{2\pi irx}dx\frac{dt}{t}$$

where we interchanged the order of integration because it is absolutely convergent, and made a change of variable. Also notice

$$\int_{-\infty}^\infty e^{-t\pi x^2/y}e^{2\pi irx}dx = \sqrt{\frac{y}{t}}e^{-y\pi r^2/t}$$

by Fourier inversion(10.12.2.3), so we get the final answer. □

Prop. (10.7.3.5). If $\mathrm{Re}(s)+k/2 > 1/2$ and r is real,

$$(\frac{y}{\pi})^s\Gamma(s)\int_{-\infty}^\infty \frac{1}{(x+yi)^k(x^2+y^2)^s}e^{-2\pi irx}dx = \begin{cases} \pi^{1/2-s}\Gamma(s-\frac{1}{2})y^{1-s} & r=0 \\ 2|r|^{s-1/2}\sqrt{y}K_{s-1/2}(2\pi|r|y) & r\neq 0 \end{cases}$$

Proof: By(10.7.1.1), the LHS equals

$$\int_{-\infty}^\infty\int_0^\infty e^{-t}(\frac{ty}{\pi(x^2+y^2)})^s e^{2\pi\,\mathrm{i}\,rx}\frac{dt}{t}dx = \int_0^\infty\int_{-\infty}^\infty e^{-\pi t(x^2+y^2)/y}t^s e^{2\pi\,\mathrm{i}\,rx}dx\frac{dt}{t}$$

where we interchanged the order of integration because it is absolutely convergent, and made a change of variable. Also notice

$$\int_{-\infty}^\infty e^{-t\pi x^2/y}e^{2\pi\,\mathrm{i}\,rx}dx = \sqrt{\frac{y}{t}}e^{-y\pi r^2/t}$$

by Fourier inversion(10.12.2.3), so we get the final answer. □

4 Dilogarithm

10.8 General Functional Analysis

Basic references are [Rudin Functional Analysis],[Nonarchimedean Functional Analysis].

This section only contains theorems that are applicable to both Archimedean and non-Archimedean valuations. For theorems specialized to non-Archimedean valuations, See12.2, for theorems specialized to Archimedean valuations, See10.9. Many propositions in Functional Analysis can be transplanted in the general case, but I haven't finish yet.

The major problem is convex is not definable, so Hahn-Banach fail, causing many to fail.

1 Topological Vector Space

Def. (10.8.1.1) [Topological Vector Spaces]. A **topological vector space**(TVS) over a complete valued field k is a k-vector space that the addition and scalar multiplication is continuous.

Remark (10.8.1.2). If the field k is not of char 0, then we fix a sequence of elements $\{a_n\}$ that $\lim |a_n| = \infty$. This will be applied for example in the proof of Banach-Steinhaus theorem, but we will just write n instead of a_n.

Prop. (10.8.1.3). For subsets K, C of a TVS X that K is compact and C is closed, there is a nbhd V that $(K+V)\cap(C+V)=\varnothing$.

Proof: For each $x\in K$, there are symmetric nbhd V_x that $(x+V_x+V_x+V_x)\cap C=\varnothing$. Then $(x+V_x+V_x)\cap(C+V_x)=\varnothing$. Because K is compact, there are f.m. x_i that $K\subset\cup(x_i+V_{x_i})$, so let $V=\cap V_{x_i}$, then $(K+V)\cap(C+V)=\varnothing$. □

Cor. (10.8.1.4) [Closed Subbasis]. Every nbhd of 0 in a TVS contains a closure of another nbhd of 0. (Apply the above proposition for $K=\{0\}$.

Def. (10.8.1.5). A subset containing 0 is called **balanced** iff $kU=U$ for each $|k|=1$.

Prop. (10.8.1.6) [Balanced Subbasis]. Every nbhd U of 0 in a TVS contains a balanced nbhd of 0. By(10.8.1.4), we can even assume $\overline{V}\subset U$.

Proof: Since scalar multiplication is continuous, there is a $\delta>0$ and a nbhd V that $\alpha V\subset U$, for each $|\alpha|<\delta$. Then let $W=\cup_{|\alpha|<\delta}\alpha V$. □

Def. (10.8.1.7)[F-Spaces and Fréchet spaces]. A space is called a **F-space** if its topology is induced by a complete invariant metric. F-space is of second Baire category by(3.3.9.2)

A locally convex F-space is called a **Fréchet space**.

Def. (10.8.1.8) [Norm]. A **seminorm** on a vector space X is a real-valued function p that $p(x+y)\leq p(x)+p(y)$, and $p(\alpha x)=|\alpha|p(x)$ for $\alpha\in k$. It is called a **norm** if moreover $p(x)=0 \iff x=0$.

A family of seminorms $\{p_i\}$ on X is called **separating** iff for each x, at least one p_i satisfies $p_i(x)\neq 0$.

Prop. (10.8.1.9). A TVS is metrizable by a translation-invariant metric iff it has a countable basis.

Proof: One direction is trivial, for the other, Cf.[Rudin P18]. □

Prop. (10.8.1.10). If a subspace Y of a TVS X is a F-space, then it is closed in it.

Proof: Choose an invariant metric d compatible with its topology, Let U_n be a nbhd of X that $U_n \cap Y = B(0,1/n)$, and choose a symmetric nbhd V_n of X that $V_n + V_n \subset U_n$, and $V_{n+1} \subset V_n$.

If $y \subset \overline{Y}$, then for any $y_n \subset Y \cap (y+V_n) = E_n$, then $y_n - y_m \subset U_{\min\{m,n\}} \cap Y = B(0,1/n)$, so it is a Cauchy sequence in Y, hence all E_n has a unique element y_0 in common. Now if we intersect each V_n by a nbhd W of X, the same argument shows that there is a unique element y_W in $Y \cap (y + W \cap V_n)$, and this must by just y_0, but $y - y_W \subset W$, so we must have $y = y_0 \subset Y$. □

Def. (10.8.1.11). A set E in a TVS is called **totally bounded** if for every nbhd V of 0, there is a finite set F that $E \subset F + V$.

2 Completeness

Prop. (10.8.2.1) [Banach-Steinhaus]. Γ is a collection of continuous linear mapping between two TVS, if the set B of x that $\Gamma(x)$ is bounded is a second category set in X, then $B = X$ and Γ is equicontinuous (thus maps bounded sets to bounded sets).

Proof: For an open balanced nbhd W of 0, choose a balanced nbhd U s.t. $\overline{U} + \overline{U} < W$(10.8.1.6), set $E = \cap_{\Lambda\in\Gamma}\Lambda^{-1}(\overline{U})$, then $B \subset \bigcup_{i=1}^{\infty} nE$, so by Baire theorem(3.3.9.2), E has a interior point thus has a nbhd V s.t. $\Gamma(V) \subset \overline{U} + \overline{U} \subset W$. Thus we are done. □

Cor. (10.8.2.2) [Uniform Boundedness Theorem]. If a set Γ of continuous linear mappings from a F-space X to Y satisfies $\Gamma(x)$ is bounded for every x, then Γ is equicontinuous.

Cor. (10.8.2.3). If A_n is a sequence of continuous linear mapping from X to Y, if X is a F-space, then $\lim A_n = A$ iff $||A_n||$ is bounded and $\lim A_n x = Ax$ for x in a dense subset of X.

Proof: One direction is immediate from Banach-Steinhaus, the converse is an easy $\varepsilon/3$-technique. □

Prop. (10.8.2.4) [Open Mapping theorem]. If a continuous linear mapping T from a F-space X to Y satisfies $R(T)$ is of second category, then it is a surjective open mapping and Y is a F-space.

In fact, we only need T be defined on a subspace $D(T)$ and it is **closed** in the sense the graph of it is closed.

Proof: $V_n = T(B(0, \frac{r}{2^n}))$ are all of second category, because $\cup_n nV_n = R(T)$, so $\overline{V_n}$ has an interior by definition. Then also it contains a nbhd of V because $\overline{V_{n+1}} + \overline{V_{n+1}} \subset \overline{V_n}$.

Now we show $\overline{V_{n+1}} \subset V_n$, this will show T is open. thus for a $y \in \overline{V_n}$ since $\overline{T(V_{n+1})}$ contains a nbhd of 0, we can consecutively choose $x_i \in B(0, \frac{r}{2^{n+i}})$ s.t. $y - \sum_{i=1}^{n} T(x_i) \in \overline{T(B(0, \frac{1}{2^{n+i+1}}))}$. So by completeness of X and closedness, $\sum x_i$ converges to some $x \in D(T)$, and $Tx = y \in V_n$.

And an open linear mapping must be surjective. hence $Y \cong X/N(T)$, so Y is also a F-space. □

Cor. (10.8.2.5) [Banach Theorem]. If a continuous map T between F-spaces is a bijection, then it has a continuous inverse.

Cor. (10.8.2.6). If a F-space is complete w.r.t two different topologies and one is stronger than the other, then they are equivalent.

Cor. (10.8.2.7). For every operator between F-spaces that has closed image, we have $X/N(T) \cong R(T)$.

Cor. (10.8.2.8) [Closed Graph Theorem]. If T is a closed linear mapping between two F-spaces, i.e. the graph of it is closed, then it is continuous, because the metric induced by the graph is stronger than the original one, and use Banach(10.8.2.5).

The graph is closed is equivalent to if $x_i \to x$ and $Tx_i \to y$, then $y = Tx$. This is very useful when proving some map is continuous.

Cor. (10.8.2.9). If A, B, C are F-spaces, and $f : A \to B, g : B \to C$, if gf, g is continuous and g is injective, then F is continuous.

Proof: Use closed graph theorem, if $x_i \to x, f(x_i) \to z$, then $gf(x_i) \to g(z)$, so $gf(x) = g(z)$, so $f(x) = z$. □

Cor. (10.8.2.10) [Finite Codimensional Image]. If the image of a continuous linear mapping T between F-spaces has finite codimensional image, then the image is closed and complemented.

Proof: It has finite codimension, so we can construct $K^n \oplus X/N(T) \to Y$, by Banach theorem(10.8.2.5) it is a homeomorphism, and the image of $X/N(T)$ corresponds to the image, so the image is closed. □

Prop. (10.8.2.11) [Separate Continuous]. If a bilinear map $B : X \times Y \to Z$ where X is a F-space is separately closed, then $B(x_n, y_n)$ converges to $B(x_0, y_0)$.

Proof: Use Banach-Steinhaus to prove $B_{y_n}(x)$ is equicontinuous, then use $B(x_n-x_0, y_n)+B(x_0, y_n-y_0)$. ? □

3 Dual Space

Prop. (10.8.3.1) [Operator Space]. If X, Y are normed spaces then $L(X, Y)$ is also a normed space with the metric $||\Lambda|| = \sup\{||\Lambda x|||x| \leq 1\}$. And if Y is Banach, then $L(X, Y)$ is also Banach. The proof is easy.

In particular, if $Y = K$, then X^* is a Banach space.

Prop. (10.8.3.2). For a bounded operator T,

$$\overline{R(T)} = N(T^*)^\perp, \text{ Thus } \overline{R(T^*)} = N(T)^\perp$$

In particular, using Hahn Banach, $R(T)$ is dense in Y iff T^* is injective, T is injective iff T^* is weak*-dense in X^*.

Prop. (10.8.3.3). Let $\Lambda_1, \ldots, \Lambda_n, \Lambda$ are linear functionals on a vector space X, let $N = \cap \ker f_i$, the following are equivalent:

1. $\Lambda = \sum \alpha_i \Lambda_i$.
2. $|\Lambda x| \leq \gamma |\Lambda_i x|$.
3. $\ker \Lambda \subset N$.

Proof: Only need to show $3 \to 1$: define $\pi : X \to k^n : x \mapsto (\Lambda_1 x, \ldots, \Lambda_n x)$, then by hypothesis $f(\pi_i(x)) = \Lambda(x)$ defined a linear functional on $\pi(X)$. This can be extended to a functional on $k^n : F(u_1, \ldots, u_n) = \sum \alpha_i u_i$, so Λ is a linear combination of Λ_i. □

Weak Convergence

Def. (10.8.3.4) [Operator Topologies]. There are three topologies on $L(X)$ for a normed space X:

- norm topology: $||T_i - T|| \to 0$.
- strong topology: $\forall x \in X, ||(T_i - T)x|| \to 0$.
- weak topology: $\forall x \in X, f \in X^*$, $\lim f(T_n x) = f(Tx)$.

Prop. (10.8.3.5) [Weak Convergence and Bounded]. In a normed space X, if $x_n \to x$ weakly iff $\{x_n\}$ is bounded and $\lim f(x_n) = f(x)$ for a dense subset $f \in M^* \subset X^*$.

Proof: This follows from(10.8.2.3), as X^* is a Banach space, by(10.8.3.1). □

4 Banach Space

Def. (10.8.4.1) [Normed(Valued) K-Spaces]. For a complete valued field K, a **normed(valued) K-space** is a TVS over K with a norm that satisfies $|kv| = |k||v|$ for $k \in K$.

Def. (10.8.4.2) [Banach Spaces]. For K complete valued field, a complete normed(valued) K-vector space(10.8.4.1) is called a **Banach space**.

A K-algebra with a complete K-algebra norm is called a **Banach algebra**.

Prop. (10.8.4.3). The dual space of a Banach space is a Banach space. (Immediate from(10.8.3.1)).

Prop. (10.8.4.4). if A is a Banach space as well as a Topological group, then there is a norm on A which induce the same topology and makes A into a Banach algebra.

Proof: embed A into $L(A)$ by left multiplication, which is injective, and $||x|| = ||xe|| = ||M_x e|| \leq ||M_x||||e||$, so its inverse is continuous. Now if we show the image $\tilde{A}$ is closed in $L(A)$, then the open mapping theorem will show that $A \cong \widetilde{A}$, and $\widetilde{A}$ is clearly a Banach algebra.

To show it is closed, if $T = \lim T_i$, notice $T_i(y) = T_i(e)y$, so take a limit, $T(y) = T(e)y = M_{T(e)}y$. □

Cor. (10.8.4.5). Every f.d. Banach algebra is isomorphic to an algebra of matrices. In particular, if $xy = e$, then $yx = e$.

Proof: Embed A into $L(A)$. □

Remark (10.8.4.6) [Inequivalent Banach Norms]. There exists two complete norm on a vector space that is inequivalent. For this, just choose a banach space X, and notice if we can choose a discontinuous bijection $X \to X$, then the induced metric is also complete, and it cannot by equivalent by Banach theorem(10.8.2.5). For this, choose a infinite dimensional Banach space over $\mathbb{C}$, and choose a $\mathbb{C}$-basis x_i for it, and choose a sequence x_n and maps x_n to nx_n, the rest are invariant, then this is not continuous.

Hilbert Space

Def. (10.8.4.7). there are different topologies in the space of operators on a Hilbert space $\mathcal{H}$.

Norm operator topology: defined by the norm $||T||$.

Strong operator topology: defined by the separating seminorms $T \mapsto ||Tu||, u \in \mathcal{H}$.

Weak operator topology: defined by the separating seminorms $T \mapsto (Tu, v), u, v \in \mathcal{H}$.

Prop. (10.8.4.8). The strong and weak operator topology coincides on the unitary operators on $\mathcal{H}$. The sets of unitary operators that is continuous in this two topology is denoted by $U(\mathcal{H})$.

Proof: If T_n converges to T in the weak operator topology, then

$$||(T_n - T)u||^2 = ||Tu||^2 + ||T_n u||^2 - 2\operatorname{Re}(T_n u, Tu).$$

The right hand side is clearly bounded by the weak seminorms, so the two topologies coincide. □

Prop. (10.8.4.9) [Hilbert Basis]. If H is a Hilbert space and $S = \{e_\alpha\}$ is an orthonormal basis in H, then the following are equivalent:

1. For any x, $x = \sum(x, e_\alpha)e_\alpha$,(notice the sum are in fact infinite sum).
2. There is a no nonzero element x that is orthogonal to all e_α.
3. **Parseval equality** holds: $||x||^2 = \sum|(x, e_\alpha)|^2$.

If these are true, then S is called a **Hilbert basis** of H, a Hilbert basis always exists, by Zorn's lemma.

Proof: $1 \to 2$: if $(x, e_\alpha) = 0$ for all e_α, then by 1, $x = \sum(x, e_\alpha)e_\alpha = 0$.
$2 \to 3$: Notice $y = x - \sum(x, e_\alpha)e_\alpha$ is orthogonal to all e_α, and

$$||y|| = ||x||^2 - \sum|(x, e_\alpha)|^2,$$

so Parseval equality holds.
$3 \to 1$: $||x - \sum(x, e_\alpha)e_\alpha|| = 0$. □

Prop. (10.8.4.10). Any symmetric operator on a Hilbert space is continuous.

Proof: Because $x_n \to 0$ implies $Tx_n \to 0$ weakly, so we can use closed graph theorem(10.8.2.8).**?**
□

Ultranormed Banach Spaces

The ultranormed Banach spaces are defined in(12.2.4.5).

Nuclear Maps and Spaces

10.9 Archimedean Functional Analysis

References are [Rud91]. [Rudin Functional Analysis Chap11,13] needs to be revisited.

This section contains functional analysis in characteristic 0. By Ostrowski theorem(10.3.3.18), the base field is just $\mathbb{R}$ or $\mathbb{C}$.

1 Topological Vector Space

Def. (10.9.1.1) [Seminorms]. A **sublinear functional** is a function p that $p(x+y) \le p(x)+p(y)$ and $p(\lambda x) = \lambda p(x)$ for $\lambda > 0$.

A **seminorm** is a non-negative function p that $p(x+y) \le p(x)+p(y)$ and $p(\alpha x) = |\alpha| p(x)$ for all complex α.

Def. (10.9.1.2). A **absorbing set** is a convex set A that $\cup_{k>0} kA = X$. A convex nbhd of 0 is clearly absorbing.

Def. (10.9.1.3) [Minkowski Functional]. For an absorbing set A, the **Minkowski functional** μ_A is defined to be $\mu_A(x) = \inf\{t > 0, x/t \in A\}$. It satisfies:

- $\mu_A(x+y) \le \mu_A(x) + \mu_A(y)$.
- $\mu_A(kx) = k\mu_A(x)$ if $k > 0$.
- μ_A is a seminorm if A is balanced.
- If $B = \{x|\mu(x) < 1\}, C = \{x|\mu(x) \le 1\}$, then $B \subset A \subset C$ and $\mu_A = \mu_B = \mu_C$.

Proof: Cf.[Rudin P27]. □

Cor. (10.9.1.4) [Seminorm and Absorbing set]. A seminorm on X is exactly the Minkowski functional of a balanced absorbing set W, but the set may not be unique. and it is uniformly continuous iff 0 is an interior point.

Proof: If p is a seminorm, then $\{x|p(x) < 1\}$ is convex, balanced and absorbing by definition(10.8.1.8). The converse is by(10.9.1.3). The last assertion is easy. □

Prop. (10.9.1.5) [Minkowski Functional and Separating Seminorms]. If $\mathfrak{B}$ is a convex local base in a TVS X, then the Minkowski functionals of elements of $\mathfrak{B}$ forms a separating family of seminorms.

Conversely, a separation family P of seminorms on a vector space defines a convex balanced local base for a topology τ that is locally convex. And in this topology, a sequence converges iff $p(x_i - x) \to 0$ for $p \in \mathfrak{P}$, a set is bounded if each p is bounded on it.

Proof: For any $V \in \mathfrak{B}$, $V = \{x \in X|\mu_V(x) < 1\}$, because V is open and convex. (10.9.1.3) shows each μ_V is a seminorm, and it is continuous because it is bounded on V. And they are separating because $\mathfrak{B}$ is a local base.

Defined $V(p,n) = \{x \in X|p(x) < 1/n\}$, and let these be a local subbasis at 0, and make it a topology by translation. This is checked to be a locally convex TVS. For the last assertion, if E is bounded, then $E \subset kV(p,1)$ for k large, so p is bounded on E, and conversely, for each nbhd U, there are p_i and M_i and $\cap V(p_i, M_i) \subset U$, so $E \subset kU$ for n large. □

Prop. (10.9.1.6). If $\mathfrak{P}$ is a family of countable separating family of semi-norms on X, then the topology defined in(10.9.1.5) is in fact metrizable, by a metric $d(x,y) = \sum \frac{1}{2^k}\frac{p_i(x-y)}{1+p_i(x-y)}$.

Finite Dimensional Subspace

Prop. (10.9.1.7)[Finite Dimensional and Locally Compact]. There is only one topological vector space structure on a finite dimensional $\mathbb{C}$-vector space and it is complete. A TVS is locally compact iff it is f.d.

Proof: Cf.[Rudin P17].

For the second assertion, if is locally compact, then 0 has a nbhd V that is precompact, so bounded, hence $2^{-n}V$ forms a local basis. the compactness of $\overline{V}$ shows there are f.m. x_i that $\overline{V} \subset \cup(x_i + \frac{1}{2}V)$. Let Y be the subspace spanned by x_i, then it is of f.d, thus closed. Now $V \subset Y + \frac{1}{2}V$, so $\frac{1}{2}V \subset Y + \frac{1}{4}V$, hence continuing this way, $V \subset \cap(Y + 2^{-n}V)$, so $V \subset \overline{Y} = Y$. But then $Y = X$. □

Cor. (10.9.1.8)[Finite Subspace Closed]. A f.d subspace in a TVS over $\mathbb{C}$ is closed, because it must be a F-space, hence it is closed by(10.8.1.10).

Prop. (10.9.1.9) [Finite Subspace in Banach Space]. For a finite dimensional space V in an Archimedean Banach space, there is a continuous projection onto it. In particular, any finite dimensional space in an Archimedean Banach space is complemented.

Also finite codimensional subspace in any Banach space is complemented by(10.8.2.10).

Proof: Choose a basis e_i for V, consider the dual basis f_i. Because a finite dimensional space only has one topology(10.9.1.7), these f_i are bounded on V. Extend them to bounded functional on X, then consider $p(x) = \sum f_i(x)e_i$, then this is a continuous projection onto V. □

2 Various Spaces and Duality

For a bounded connected open set Ω,

Prop. (10.9.2.1)[Various Spaces and Duality].

- **Sobolev Space** $W^{m,p}(\Omega)$ is the completion of a subspace of $C^\infty(\Omega)$ with the norm**?**

$$||u||_{m,p} = (\sum_{|\alpha|\leq m}\int_\Omega |\partial^\alpha u(x)|^p \mathrm{d}x)^{1/p}.$$

  for $m > 0$. And we denote $W^{m,2}(\Omega)$ by $H^m(\Omega)$. It is also a subspace of $L^p(\Omega)$ that satisfies this, without completion(10.12.4.1).

- $C_0^\infty(\Omega)$ is the subspace of $C^\infty(\Omega)$ that have compact support in Ω. Its completion $W_0^{m,p}(\Omega)$ is a closed subspace of $W^{m,p}(\Omega)$. And we denote $W_0^{m,2}(\Omega)$ by $H_0^m(\Omega)$ and the dual space of $H_0^m(\Omega)$ by $H^{-m}(\Omega)$.

- For a locally convex space X, $C(X)$ in the topology of compact convergence is a Fréchet space(10.8.1.7).

- $\mathcal{O}(\Omega) \subset C(\Omega)$ the space of holomorphic functions in Ω is a closed subspace of $C(\Omega)$ by(10.5.2.14), thus it is a Fréchet space. By Hausdorff theorem(3.3.8.7), Montel's theorem says exactly that $\mathcal{O}(\Omega)$ has the Heine-Borel property(10.8.1.7).

- $\mathcal{O}^2(D)$ the space of holomorphic functions on $\mathbb{D}$ that is also L^2. It has the L^2 norm.

- $C^\infty(\Omega)$ in the topology defined by seminorms $p_N(f) = \max\{|D^\alpha f(x)| : x \in K_N, |\alpha| \leq N\}$, is a Fréchet space thus locally convex and it has the Heine-Borel property by Arzela-Ascoli.

- For $K \subset \Omega$ closed, $D(K)$ is the closed subspace of smooth functions on Ω with support in K, thus a Fréchet space with Heine-Borel property.
- $D(\Omega)$ is the space of smooth functions with support in Ω. It has the topology generated by translation of basis consisting of convex balanced sets W that $W \cap D(K)$ is open for every compact K. This makes $D(\Omega)$ into a locally convex TVS, Cf.[Rudin P152]. It has Heine-Borel property(10.12.1.1).
- (Schwartz Functions) The space of **Schwartz functions** $\mathcal{S}(\mathbb{R}^n)$ is defined as smooth functions on $\mathbb{R}^n$ s.t.
$$\sup_{|\alpha|\leq N, x\in\mathbb{R}^n} (1+|x|^2)^N |(D_\alpha f)(x)| < \infty$$
for any $N > 0$. And it is a Fréchet space define by these seminorms.

Dual Spaces

Prop. (10.9.2.2).
- For a σ-finite measure space (X, Ω, μ) and $1 \leq p < \infty$, by(10.4.6.3),
$$L^p(X, \Omega, \mu)^* = L^q(X, \Omega, \mu).$$
- $C[0,1]^* = BV[0,1]$ and $C[X]^* = M(X)$, the space of complex measure on compact X with the norm of total variance, by Riesz representation theorem(10.11.1.10).

3 Convexity

Prop. (10.9.3.1). Every convex nbhd of 0 contains a balanced convex nbhd of 0. By(10.8.1.4), we can even assume $\overline{V} \subset U$.

Proof: If U is convex, choose W as in(10.8.1.6), then $W \subset A = \cap_{|\alpha|=1} \alpha U$ because it is balanced. Then $W \subset A^\circ$ and A° is open and balanced, satisfying the requirement. □

Prop. (10.9.3.2). For a compact convex set K in a TVS X, if a set Γ of continuous linear mapping is bounded for every $x \in K$, then Γ is equicontinuous on K.

Proof: The proof is similar to that of Banach-Steinhaus(10.8.2.1). For K compact convex, the same argument shows that there is a nbhd V that $K \cap (x_0 + V) \subset nE$, fix $p > 1$ that $K \subset x_0 + pV$, then for any $x \in K$, consider $z = (1-p^{-1})x_0 + p^{-1}x$, then $z \in K$ as K is convex and $z - x_0 = p^{-1}(x - x_0) \in V$, so $z \in nE$, and since $x = pz - (p-1)x_0$, $\Lambda x \in pnW$ for each $\Lambda \in \Gamma$, so Γ is equicontinuous. □

Hahn-Banach

Prop. (10.9.3.3) [Real Hahn]. For a sublinear functional p on a real linear space X and a subspace X_0, if a functional f satisfies $f(x) \leq p(x)$ on X_0, then it can be extended to a functional Λ on X that $|\Lambda(x)| \leq |p(x)|$.

Proof: Use Zorn's lemma, if the maximum extension is not on the whole space but on M, choose $x_1 \in X - M$, we want to define $f(x_1)$. Now let $M_1 = \{x + tx_1 | x \in M\}$. Since for $x, y \in M$, $f(x) + f(y) = f(x + y) \leq p(x + y) \leq p(x - y) + p(x_1 + y)$, so
$$f(x) - p(x - x_1) \leq p(y + x_1) - f(y)$$
for $x, y \in M$. Let the maximum of the left side be α, and define $f(x_1) = \alpha$, then it is clear $f(z) \leq p(z)$ still. □

Prop. (10.9.3.4) [Complex Hahn]. For a seminorm p (i.e. it can attain 0) on a complex linear space X and a subspace X_0, if a functional f satisfies $|f(x)| \leq p(x)$ on X_0, then it can be extended to a functional on X with the same condition.

Proof: Let $g(x) = \operatorname{Re} f(x)$ and extend it by Hahn and set $f(x) = g(x) - ig(ix)$, then f is complex linear, and for any x, for some $|\alpha| = 1$, $|f(x)| = f(\alpha x) = g(\alpha x) \leq p(\alpha x) = p(x)$. □

Cor. (10.9.3.5) [Hahn]. In a normed space X, a bounded linear functional on a subspace X_0 can be extended to a bounded functional on X with the same norm.

Cor. (10.9.3.6) [Extending Functional Preserving Norm]. If X is a normed space and N is a closed subspace, if x_0 satisfies $d = d(x_0, M) > 0$, then here is a continuous functional f that $f(x) = 0$ and $f(x_0) = d$ and $||f|| = 1$.

Proof: Define $f(m + \alpha x) = |\alpha| d$ on $\operatorname{span}\{M, x\}$, then $f(m + \alpha x) = |\alpha| d = |\alpha| d(x_0, M) \leq |\alpha| || \frac{x'}{\alpha} + x_0|| = ||x' + \alpha x|| = ||x||$. So $||f|| \leq 1$, so we can use Hahan-Banach to extend it to a functional on X. □

Prop. (10.9.3.7) [Geometric Hahn].

- If E_1 and E_2 are two convex set that $E_1 \cap E_2 = \emptyset$ and E_1 has interior point, then there is a continuous linear functional that separate them, i.e $\operatorname{Re} f(E_1) < \operatorname{Re} f(E_2)$. (The interior point is here to assure f is continuous).
- In a locally convex TVS, if E_1 is convex compact and E_2 is convex closed, then there is a real functional that separate them, i.e. $\operatorname{Re} f(E_1) < \gamma_1 < \gamma_2 < \operatorname{Re} f(E_2)$. Thus for a set E and a point x, $x \in \overline{\operatorname{span} E} \iff$ for all f that $f(E) = 0$, $f(x) = 0$.

Proof: The complex case follows from the real case, so assume it is real. Consider $a_0 \in E_1, b_0 \in E_2$, let $x_0 = a_0 - b_0$ and let $C = E_1 - E_2 + x_0$, then C is a convex nbhd of 0. Let p be the Minkowski functional of C, then p is sublinear by(10.9.1.3) and $p(x_0) \geq 1$. Let $f(tx_0) = t$ on the subspace M generated by x, then it extends to a functional Λ that≤ 1 on C, thus it is bounded by 1 on $C \cap (-C)$, hence continuous. For any $a \in E_1, b \in E_2$, because $\lambda(x_0) = 1$ and $a - b + x_0 \in C$ open, $\Lambda a < \Lambda b$.

For the second, There is a convex nbhd V of 0 that $E_1 + V \cap B = \varphi$, so the above argument applied with $E_1 + V$ and B shows that there is a f that separate them. And $f(E_1 + V)$ is open and $f(E_1)$ is compact, so the conclusion follows. □

Cor. (10.9.3.8) [Banach-Saks]. The weak closure of a convex set in a locally convex metric space equals the original closure.

Thus if a sequence $\{x_n\}$ weakly converges to x in a metrizable locally convex space, then a convex combination of $\{x_n\}$ strongly converge to x, i.e. $x \in \overline{\operatorname{co}}(\{x_n\})$, because metric space is first countable.

Proof: A weak closed set is closed, and to show the closure is weakly closed, use(10.9.3.7). □

Prop. (10.9.3.9). If A_i are compact convex sets in a TVS X, then $co(A_1 \cup \ldots \cup A_n)$ is compact.

Proof: Firstly, the image K of $S \times A_1 \times \ldots \times A_n$, $(s_1, \ldots, s_n) \times (a_1, \ldots, a_n) \mapsto \sum s_i a_i$ is closed, where $S = \{0 \leq x_i, \sum x_i = 1\}$. And we show K is just the convex closure: it contains all A_i, and it is convex because each A_i is. □

Prop. (10.9.3.10). In F-space, a closed subset is compact iff it is totally bounded by(3.3.8.7).

Prop. (10.9.3.11). In a locally convex space, if E is totally bounded, then $\operatorname{co}(E)$ is totally bounded. Thus in a Fréchet space, if K is compact, then $\overline{co}(K)$ is compact.

Proof: For a nbhd U of 0, choose a convex nbhd V that $V+V\subset U$, then $E\subset F+V$ for some finite set F, hence $co(E)\subset co(F)+V$. But $co(F)$ is compact by(10.9.3.9). So $co(F)\subset F_1+V$ for some finite set F_1, then $co(E)\subset F_1+U$.

If K is compact, then it is totally bounded, and then $co(K)$ is totally bounded and $\overline{co(K)}$ is totally bounded by(3.3.8.5), so it is compact by(10.9.3.10). □

Prop. (10.9.3.12)[Weakly Bounded and Locally Convex]. In a locally convex space, bounded $\iff$ weakly bounded.

Proof: One direction is trivial, for the other, suppose E is weakly bounded and U is a closed nbhd of 0. Because X is locally convex, there is a convex, balanced nbhd of 0 that $\overline{V}\subset U$(10.9.3.1). Now $\overline{V}=V^{**}$ the polar(10.9.4.1) by(10.9.3.8).

Now V^* is weak*-compact and $|\Lambda(x)|\leq\gamma(\Lambda)$ for each $\Lambda\in X^*$ for some $\gamma(\Lambda)$ because E is weakly bounded. So we can use(10.9.3.2) to show that $|\Lambda x|\leq\gamma$ for some γ and all $\Lambda\in V^*$. So we have $\gamma^{-1}E\subset\overline{V}\subset U$. This proves that E is bounded. □

Prop. (10.9.3.13) [Markov-Kakutani Fixed Point Theorem]. For a commuting family $\mathcal{F}$ of continuous affine maps from K to K where K is a compact convex set in a TVS, then there is a fixed point in K for all maps in $\mathcal{F}$.

Proof: Consider the semigroup $\mathcal{F}^*$ generated by these maps together with their average, it is also commutative because they are all affine. For any $f,g\in\mathcal{F}^*$, $f(K)\cap g(K)\supset f\circ g(K)$, so by finite intersection property, there is a point in $p\in K$ in all $f(K)$.

For this p, consider $p=\frac{1}{n}(I+T+t^2+\ldots+T^{n-1})(x)$, then $p-Tp=\frac{1}{n}(x-T^nx)\in\frac{1}{n}(K-K)$. as K is bounded and n is arbitrary, this means that $p=Tp$ for all T. □

Cor. (10.9.3.14)[Invariant Hahn]. For a commuting family Γ of operators on a normed space and Y an invariant space, then for any Γ-invariant continuous functional f on Y, it has a Γ-invariant Hahn extension.

Proof: We may assume $||f||=1$. Let K be all extensions of f that has norm≤ 1. K is obviously convex, and it is weak*-compact by Banach-Alaoglu. The adjoint action of T is checked to be continuous in the weak*-topology, so by(10.9.3.13), there is some $F\in K$ that is invariant under Γ. □

Krein-Milman theorem

Prop. (10.9.3.15) [Krein-Milman Theorem]. For a compact convex set in a TVS that is weak-Hausdorff(X^* separate points), then $K=\overline{\text{co}}(\text{Extreme}(K))$.

If K is a compact set in a locally convex space, then $K\subset\overline{\text{co}}(E(K))=\overline{\text{co}}(K)$.

Proof: First show that every compact extreme set S of K contains an extreme point. Notice arbitrary intersection of compact extreme sets of K is compact extreme, because compact is closed, because X is Hausdorff. And for any functional $\Lambda\in X^*$, the maximal value point in K is compact extreme. Now we use Zorn's lemma to find a minimal compact extreme set in S, then it must be a point because X^* separate points.

Now use the weak topology Hahn(10.9.4.2), if $\overline{co}(E(K))\subset K$ is not K, then it is compact, then we can find a functional that separate $\overline{co}(E(K))$ and some point of K. This is a contradiction because the extreme value point for any functional on K is an extreme set.

In the locally convex case, the convexity of K is not needed, and we can show using geometric Hahn(10.9.3.7) instead that, $K\subset\overline{co}(K)$. □

Prop. (10.9.3.16) [Milman's Theorem]. If K is a compact set in a locally convex space X and if $\overline{\text{co}}(K)$ is also compact(e.g in a Fréchet space(10.9.3.11)), then every extreme point of $\overline{\text{co}}(K)$ lies in K.

Proof: □

Def. (10.9.3.17). For a compact Hausdorff space S and an algebra in $C(S)$, a subset E is called **A-antisymmetric** iff every $f \in A$ that is real on E is constant on E. There are in fact maximal A-antisymmetric subsets of S.

Prop. (10.9.3.18) [Bishop Theorem]. If A is a closed subalgebra of $C(S)$. If $g \in C(S)$ satisfies $g|_E \in A|_E$ for every maximal A-antisymmetric set E, then $g \in A$. This theorem is a generalization of Stone-Weierstrass approximation.

Proof: The annihilator $A^\perp$ of A consists of all regular complex Borel measure μ on S that $\int f d\mu = 0$ for all $f \in A$ by Riesz representation(10.11.1.10). ?Cf.[Rudin P122]. □

Prop. (10.9.3.19)[Schauder Fixed Point Theorem]. If C is a closed convex subset in a metrizable TVS and continuous $T : C \to C$ has sequentially compact image (e.g. C is compact and X is locally convex hence X^* separate points), then T has a fixed point.

Proof: As $T(C)$ is sequentially compact, for each n, there is a $1/n$-net $N_n = \{y_i\} \subset T(C)$, let $E_n = \text{span}\{N_n\}$.

Define a map $T(C) \to co(N_n) : I_n(y) = \sum y_i\lambda_i(y)$, where $\lambda_i(y) = \frac{m_i(y)}{\sum m_i(y)}$, and $m_i(y) = 1-n||y-y_i||$ if $y \in B(y_i, 1/n)$, and 0 otherwise.

Now $||I_n(y) - y|| = ||\sum(y_i - y)\lambda_i(y)|| \leq \sum ||y_i - y||\lambda_i(y) \leq \frac{1}{n}$ for each $y \in T(C)$. As C is convex, $co(N_n) \subset C$, if we let $T_n = I_n \circ T$, then T_n has a fixed pt x_n in $co(N_n)$ by Brower fixed pt theorem(3.13.4.2).

As $T(C)$ is sequentially compact and C is closed, there is a subsequence Tx_{n_k} that converges to $x \in C$. And then

$$||x_{n_k} - x|| = ||I_nTx_{n_k} - x|| \leq ||I_nTx_{n_k} - Tx_{n_k}|| + ||Tx_{n_k} - x|| < \frac{1}{n} + ||Tx_{n_k} - x||$$

so $x_{n_k} \to x$, and then by continuity, $Tx = x$. □

Vector-valued Integration

Def. (10.9.3.20) [Vector-Valued Integration]. Given a measure space (Q, μ) and X is an Archimedean TVS on which X^* separate points. If f is a function from M to X that $\Lambda \circ f$ are integrable w.r.t μ for any $\Lambda \in X^*$. The **integration** $\int_M f d\mu$ of f w.r.t Q is an element y that

$$\Lambda y = \int_Q (\Lambda f) d\mu$$

for any $\Lambda \in X^*$.

Prop. (10.9.3.21). If X is an Archimedean TVS on which X^* separate points, (Q, μ) is a Radon measure on a locally compact Hausdorff space that μ is compactly supported, and f is continuous that $\overline{co}(f(Q))$ is compact(e.g. when X is Fréchet(10.9.3.11)), then the integral $y = \int_Q f d\mu$ exists, and belongs to the closed linear span of the range of H. Moreover if μ is positive and $\mu(Q) = 1$, then $y \in \overline{co}(f(Q))$.

Proof: Cf.[Rudin P78]. □

Cor. (10.9.3.22). If Q is Hausdorff, $d\mu$ is compactly supported, X is Archimedean Banach and $f : Q \to X$ is continuous, then
$$||\int_Q f d\mu|| \leq \int_Q ||f|| d\mu$$

Proof: Let $y = \int_Q f d\mu$. By(10.9.3.6), there is a $||\Lambda|| \leq 1$ that $\Lambda y = ||y||$, so
$$\Lambda y = ||y|| = \int_Q \Lambda f d\mu = |\int_Q \Lambda f d\mu| \leq \int_Q |\Lambda f| d\mu \leq \int_Q ||f|| d\mu$$
□

Prop. (10.9.3.23). If X is an Archimedean TVS on which X^* separate points, Q is a compact subset of X, and $\overline{co}(Q)$ is compact, then $y \in \overline{co}(Q)$ iff there is a regular Borel measure μ on Q that $y = \int_Q x d\mu(x)$.

Proof: Cf.[Rudin P79]. □

Prop. (10.9.3.24)[Continuous Action Extends to Measure]. For a fixed map $f : Q \to X$, assume X is a Fréchet space, then the integration functor in(10.9.3.21) induces a continuous map
$$Meas_c(Q) \to X : \mu \mapsto \int_\mu f$$
that maps δ_x to $f(x)$.

Proof: It suffices to verify continuity: for any seminorm ρ, by convexity,
$$\rho(\int_\mu f) \leq (\mu, \rho(f)),$$
thus for $\mu \in U$ satisfying $(\mu, \rho(f)) < 1$, $\rho(\int_\mu f) < 1$. This proves continuity. □

Prop. (10.9.3.25)[Vector Valued Integration Stronger]. If V is a Banach space and μ is a Radon measure on a locally compact Hausdorff space X. If $g \in L^1(\mu)$ and $H : X \to V$ is bounded and continuous, then $\int gH d\mu$ exists and belongs to the closed linear span of the range of H, and
$$||\int gH d\mu|| \leq \sup_{x\in X} ||H(x)|| \int |g(x)|\mu(x)$$

Proof: Clearly $\varphi(gH) \in L^1(\mu)$ for all $\varphi \in V^*$. And μ is Radon, so there is a sequence $\{g_n\} \in C_c(X)$ that converges to g in L^1, so $\int g_n H d\mu$ is integrable by(10.9.3.21), and
$$\int ||g_n(x)H(x) - g_m(x)H(x)dx|| d\mu(x) \leq \int |g_n(x) - g_m(x)| d\mu(x) \to 0$$
thus this is a Cauchy sequence, converging to some y. Now for any $\varphi \in V^*$,
$$\varphi(y) = \lim \varphi(\int g_n H d\mu(x)) = \lim \int \varphi \circ (g_n H) d\mu = \int \varphi \circ (gH) d\mu$$
The last equality uses boundedness again.

Moreover, each $\int g_n H d\mu$ belongs to the closed range of H by(10.9.3.21), hence so does $\int gH d\mu$. And last assertion is also from(10.9.3.21). □

Holomorphic Functions

Def. (10.9.3.26) [Holomorphic Functions]. Let Ω be an open set in $\mathbb{C}$, and X be a TVS over $\mathbb{C}$, then A function $f:\Omega\to X$ is called:

- **weakly holomorphic** if Λf is holomorphic for any $\Lambda\in X^*$.
- **strongly holomorphic** if $\lim_{w\to z}\frac{f(w)-f(z)}{w-z}$ exists for every $z\in\Omega$.

A strongly holomorphic function is clearly weakly holomorphic, and the converse is true when X is Fréchet space, by the following proposition(10.9.3.27).

Prop. (10.9.3.27)[Weak and Strong Holomorphic]. Let Ω be an open set in $\mathbb{C}$, and X be a Fréchet space over $\mathbb{C}$, then f is strongly continuous, and the Cauchy integral formula(10.5.2.6) holds for f, and f is strongly holomorphic.

Proof: We may assume $0\in\Omega$, then Let $B(0,2r)\subset\Omega$ and Γ the boundary of $B(0,2r)$, since Λf is holomorphic,

$$\frac{(\Lambda f)(z)-(\Lambda f)(0)}{z}=\frac{1}{2\pi i}\int_\Gamma\frac{(\Lambda f)(\zeta)}{(\zeta-z)\zeta}d\zeta\quad 0<|z|<2r.$$

Therefore $\{\frac{f(z)-f(0)}{z}|0<|z|\leq r\}$ is weakly bounded, so it is also bounded by(10.9.3.12), so f is strongly continuous.

The integral exists by(10.9.3.21), so f satisfies Cauchy integral formula because it satisfies this when acting with any functional Λ, and X^* separate points.

For the last assertion, Cf.[Rudin P84]. □

Prop. (10.9.3.28) [Liouville's Theorem]. If X is a TVS over $\mathbb{C}$ on which X^* separate points and $f:\mathbb{C}\to X$ is weakly holomorphic and $f(\mathbb{C})$ is weakly bounded, then f is constant.

Proof: Immediate from Liouville's theorem(10.5.2.10). □

4 Duality Theory

Prop. (10.9.4.1) [Banach-Alaoglu]. For a nbhd V of 0 in a TVS X, the set

$$K=\{f|\ |fx|\leq 1,\ \forall x\in V\}$$

is weak*-compact in X^*, which is called the **polar** V^* of V.

Proof: Consider the Minkowski function γ of V, then for each $\Lambda\in K$, $|\Lambda x|\leq\gamma(x)$. If we consider the space $P=\prod_{x\in X}[-\gamma(x),\gamma(x)]$, then P is compact by Tychonoff(3.3.2.5).

The point is that the weak*-topology coincides with the pointwise convergence topology on K, because they have the same generating subbasis. If we show K is a closed subspace of P, this will finish the proof that K is weak*-compact. For this, consider any f_0 in its closure, then for each $x,y\in X$, $\alpha,\beta\in K$, there is a $f\in K$ that is close to f_0 at x,y and $\alpha x+\beta y$. So f_0 is linear. Similarly we can show $|f_0(x)|\leq 1$ for $x\in V$, so $f_0\in K$. □

Prop. (10.9.4.2). If X is a TVS that X^* separate points(e.g. locally convex), then the weak topology X_w is a locally convex space, and $(X_w)^*=X^*$.

Proof: If Λ is a functional that is continuous in X_w-topology, then $|\lambda x|<1$ for some set defined by elements in X^*, so by(10.8.3.3), $\Lambda=\sum\alpha_i\Lambda_i$ which is continuous w.r.t the original topology. □

Prop. (10.9.4.3) [Hahn Weak Topology case]. If X is a TVS that X^* separate points, then if A, B are disjoint nonempty, compact convex sets in X, then there is a $\Lambda \in X^*$ that separate A and B, i.e. $\operatorname{Re} f(E_1) < \gamma_1 < \gamma_2 < \operatorname{Re} f(E_2)$.

Proof: Let X_w be X with the weak topology, then the sets A and B are compact in X_w as it's weaker. And they are also closed because X_w is Hausdorff. X_w is convex, so we can use geometric Hahn(10.9.3.7). Now $(X_w)^* = X^*$, so the chosen functional is also continuous in the original topology. □

Prop. (10.9.4.4) [Dual Banach Space]. For a normed space X, $x \in X$ can be seen as functional on X^*, of norm exactly $||x||$. And the closed ball B^* of the dual space X^* is weak*-compact.

Proof: The first assertion is because of(10.9.3.6), the last assertion is because of Banach-Alaoglu(10.9.4.1). □

Prop. (10.9.4.5) [Adjoint Norm]. For X, Y normed, the adjoint of $T : X \to Y$ satisfies $||T^*|| = ||T||$.

Proof: Use(10.9.4.4), $||T|| = \sup\{|\langle Tx, y^*\rangle| \, ||x|| \leq 1, ||y^*|| \leq 1\} = ||T^*||$. □

Prop. (10.9.4.6) [Closed Range Theorem]. Let T be continuous mapping between Banach spaces X and Y, let U, V be open balls of X, Y particularly. then the following are equivalent:

1. $||T^*y^*|| \geq \delta ||y^*||$ for some δ.
2. $\delta V \subset \overline{T(U)}$.
3. $\delta V \subset T(U)$, i.e. T^{-1} is continuous.
4. $T(X) = Y$.
5. T^* is one-to-one and $R(T^*)$ is closed in X.

Proof: $1 \to 2$: If $||T^*y^*|| \geq \delta ||y^*||$, first prove $\delta V \subset \overline{T(U)}$. If $y_0 \notin \overline{T(U)}$, since $\overline{T(U)}$ is convex closed and balanced, geometric Hahn shows that there is a y^* that $|y^*(y)| \leq 1$ for every $y \in T(U)$, and $|y^*(y_0)| > 1$. Then if follows $||T^*y^*|| \leq 1$. So

$$\delta < \delta |y^*(y_0)| \leq \delta ||y_0|| \, ||y^*|| \leq ||y_0|| \, ||T^*y^*|| \leq ||y_0||$$

This shows $\delta V \subset \overline{T(U)}$.

$2 \to 3$: may assume $\delta = 1$. Then $\overline{V} \subset \overline{T(U)}$. Then for every $y \in Y$ and every $\varepsilon > 0$, there is a x that $||x|| \leq ||y||$ and $||y - Tx|| < \varepsilon$. For any $y_1 \in V$, pick $\varepsilon_n > 0$ that $\sum \varepsilon_n < 1 - ||y_1||$, then choose $||x_n|| \leq ||y_n||$ that $||y_n - Tx_n|| < \varepsilon_n$, and let $y_{n+1} = y_n - Tx_n$. Then is verified that $x = \sum x_n \in U$ and Tx.

$3 \to 1$: $||T^*y^*|| = \sup\{|\langle x, T^*y^*\rangle| \, |x \in U\} \geq \sup\{|\langle y, y^*\rangle| \, |y \in V\} = \delta ||y^*||$.

$3 \iff 4$: By Open mapping theorem.

$4 \to 5$: T^* is injective by(10.8.3.2). By open mapping theorem, T^* is a multiple of a dilation, so $R(T^*)$ is closed by(3.3.8.10).

$5 \to 4$: $R(T)$ is dense in Y by(10.8.3.2), and it is closed by the proposition(10.9.4.7) below. □

Prop. (10.9.4.7) [Closed Range Theorem]. If X, Y are Banach spaces and $T \in L(X, Y)$, the following are equivalent:

1. $R(T)$ is closed in Y.
2. $R(T^*)$ is weak*-closed in X^*.

3. $R(T^*)$ is closed in X.

Proof: $1 \to 2$: As $N(T)^\perp$ is the weak*-closure of $R(T^*)$, it suffices to prove $N(T)^\perp \subset R(T^*)$. As $R(T)$ is complete, the open mapping theorem applies to $X \to R(T)$, showing that each $y \in R(T)$ corresponds to an element $x \in X$ that $Tx = y$ and $||x|| \leq K||y||$.

For $x^* \in N(T)^*$, define a functional Λ on $R(T)$ by $\Lambda Tx = \langle x, x^*\rangle$, this is well-defined, and $|\Lambda y| = \Lambda Tx| \leq K||y||||x^*||$. So it is continuous and by Hahan=Banach some continuous functional $y^* \in Y^*$ extends Λ. Then $\langle Tx, y^*\rangle = \Lambda Tx = \langle x, x^*\rangle$, so $x^* = T^*y^*$ is in the image of T^*, so we are done.

$3 \to 1$: let $Z = \overline{R(T)}$. RT is dense in Z, so(10.8.3.2) shows $T^* : Z^* \to X^*$ is injective. And for each $z^* \in Z*$, there is an extension y^* by Hahn-Banach, and then $\langle x, T^*y^*\rangle = \langle Tx, y^*\rangle = \langle Tx, z^*\rangle = \langle x, T^*z^*\rangle$, so $T^*(Y^*) = T^*(Z^*)$, which is closed by hypothesis.

Now use open mapping theorem for $Z^* \to R(T^*)$, then there is a c that $c||z^*|| \leq ||T^*z^*||$. So $T : X \to Z$ is surjective, by(10.9.4.6). So $R(T) = Z$ is closed. □

Prop. (10.9.4.8). In a normed space, iff $x_n \to x$ weakly, then $\underline{\lim}||x_n|| \geq ||x||$.

Proof: Choose a functional that $||f|| = 1$ and $|f(x)| = 1$ by(10.9.3.6), then use the definition of weak convergence. □

Prop. (10.9.4.9) [Eberlein-Smulian]. For a set A in a Banach space X, A is weak*-sequentially compact iff its weak precompact.

Proof: ?

We prove here that the case that the closed unit ball of a reflexive Banach space is weakly*-self sequentially compact.

To prove this, first we show that a bounded sequence has a subsequence that is weak*-convergent in X. Let $X_0 = \overline{\text{span}\{x_n\}}$, then X_0 is reflexive by(10.9.4.13), and it is separable, so X_0^* is separable by(10.9.4.11). Then the result follows from(10.9.4.14).

Finally, the weak limit x is in the closed unit ball, by(10.9.4.8). □

Reflexive and Separable

Def. (10.9.4.10)[Reflective Banach Space]. If X is a Banach space, there is an isometric immersion of X onto a closed subspace of X^{**}(closed because X is complete). X is called **reflexive** iff $X \cong X^{**}$.

Prop. (10.9.4.11) [Separability Banach]. For a normed space X, if X^* is separable, then X is separable.

Proof: Choose a countable dense set in X^*, then their projection to the unit sphere S^* $\{g_n\}$ are dense in S^*(easily checked), and choose for each of them a x_n that $||x_n|| = 1$ and $g_n(x_n) > \frac{1}{2}$.

Now I claim x_n are dense in X, i.e. $X_0 = \overline{\text{span}\{x_n\}} = X$. If this is not the case, then there is a $||x|| = 1$ not in X_0, so by(10.9.3.6), there is a f that $f(X_0) = 0$ and $||f|| = 1$ and $f(x) = 1$. Then $||g_n - f|| = \sup_{||x||=1}\{|g_n(x) - f(x)|\} \geq |g_n(x_n) - f(x_n)| = |g_n(x_n)| \geq 1/2$, contradicting the fact g_n is dense in S^*. □

Prop. (10.9.4.12) [Duality Exact]. If X is a closed subspace of a normed space Y, and Y/X is the quotient field, then $(Y/X)^*$ is a closed subspace of Y^*, and X^* is the quotient.

Proof: $(Y/X)^* \to Y^*$ is clearly injective, and the X^* are all functionals on Y modulo the functionals that vanish on X. □

Cor. (10.9.4.13) [Pettis]. Closed subspace and quotient space of a reflexive normed space is reflexive.

Proof: Use the fact that $0 \to X \to Y \to Z \to 0$ induces an exact sequence $0 \to X^{**} \to Y^{**} \to Z^{**} \to 0$, and there is a map $X \to X^{**}$, so we can use snake lemma(as modules). □

Prop. (10.9.4.14) [Separable Ball Weak*-Sequentially Compact]. If a normed space X is separable, then the closed unit ball of X^* is weak*-sequentially compact.

Proof: Let x_n be a countable dense subset of X, then by diagonal method, for each bounded sequence of $f_n \in X^*$, there is a subsequence f_{n_k} that $f_{n_k}(x_m)$ converges for each x_m. Then by(10.8.2.3), f_{n_k} converges to some $f \in X^*$. So the theorem is finished. □

Prop. (10.9.4.15) [Reflexive Ball Weak*-Sequentially Compact]. In a reflexive Banach space X, then a set in X is bounded iff it is weak*-sequentially compact.

Proof: If it is reflexive, then the unit ball is weak*-compact by Alaoglu, so it is weak*-sequentially compact by Eberlein(10.9.4.9). Conversely, if it is weak*-sequentially compact, then its closure is weak*-compact, thus bounded. □

Prop. (10.9.4.16). A closed convex set of a reflexive Banach space attains minimal norm.

Proof: By Hahn, a closed convex set is weakly closed. let $d = \inf\{||x||\}$, then if $d \leq ||x_n|| < d+q/n$, then $\{x_n\}$ is bounded, so by(10.9.4.15) it is weak-sequencially compact(10.9.4.9), thus some $x_n \to x$ weakly. and use(10.9.4.8), x must attains minimal norm d. □

5 Compact Operator & Fredholm Operator

Def. (10.9.5.1) [Compact Operators]. A **compact operator** is an operator between Banach spaces that maps bounded set to sequentially compact(equivalently precompact or totally bounded(3.3.8.7)) set. It is necessarily continuous because the norm function is continuous thus $||Tx||$ is bounded on the unit ball. The set of compact operators between X, Y is denoted by $\mathfrak{C}(X, Y)$.

Prop. (10.9.5.2) [Examples of Compact Operators].

- Let X be a compact measure space and $Lu(x) = \int_X K(x, y)u(y)dy$ for $K \in C(X \times X)$. This is a compact operator on $C(X)$ by Arzela-Ascali(3.3.8.8).
- Let Ω be a σ-finite measure space and $Lu(x) = \int_\Omega K(x, y)u(y)dy$ for $K(x, y) \in L^2(\Omega \times \Omega)$. This is a compact operator on $L^2(\Omega)$, as it is Hilbert-Schmidt(10.10.5.5)(10.10.5.3).

Prop. (10.9.5.3) [Properties of Compact Operators].

1. For a continuous operator, it has f.d. image iff it is compact and the image is closed.
2. The space of compact operator is a closed subspace of $L(X, Y)$. Thus the limit of f.d. operators is compact.
3. If one of A or B is compact and the other is continuous, then AB is compact, because continuous maps bounded to bounded and compact to compact.

Proof:

1. A finite dimensional space is closed by(10.9.1.8), and a finite dimensional space is Heine-Borel(3.3.5.2), so it maps closed ball to precompact set, as it is continuous. Conversely, if it is compact and the image is closed, then it is an open map to its image, by open mapping theorem, and the image is locally compact because T is compact, so it has finite dimension(10.9.1.7).

2. $S+T$ is continuous because sum of precompact set is precompact. To show it is closed subspace, Use totally bounded definition, for T is the closure, let $||S-T|| < r$, then if $S(x_i)$ is a r-net for $S(B(0,1))$, then $T(x_i)$ is a $3r$-net for $T(B(0,1))$.

3. Because continuous function preserves both boundedness and (pre)compactness.

□

Prop. (10.9.5.4) [Compact and Totally Convergence]. Let $x_n \to x$ weakly, if T is compact, then $Tx_n \to T_n$ strongly. The converse is true when X is reflexive. In particular, this applies to Hilbert space.

Proof: Assume the contrary, if Tx_n doesn't converge to Tx, there is a subsequence x_{n_k} that $||Tx_{n_k} - Tx|| \geq \varepsilon_0$. Now $\{x_n\}$ is bounded by(10.8.3.5), so by T compact, there is a subsubsequence $Tx_{n_k} \to z$ strongly. But because $x_{n_i} \to x$ weakly, $Tx_{n_i} \to Tx$ weakly because T is continuous, and thus $z = Tx$.

The converse is by Eberlein(10.9.4.9), because the bounded x_n has a weak convergent subsequence, and it is mapped to convergent sequence by T. □

Prop. (10.9.5.5). T is compact $\iff$ T^* is compact.

Proof: We need only to show that $T^* y_n^*$ has a uniformly convergent subsequence on the unit sphere, but for this it suffice to prove y_n^* is sequentially compact in $C(\overline{T(B(0,1))})$. And we use Arzela-Ascoli because $\overline{T(B(0,1))}$ is compact. For the other half, use the double dual space. □

Lemma (10.9.5.6). If there is a chain of closed subspaces $M_1 \subset M_2 \subset \ldots$ that $T(M_n) = M_n$ and $(T - \lambda_n I)M_n \subset M_{n-1}$ for some $\lambda_n \in \sigma(A) - B(0,r)$, then T is not compact.

Proof: There are $y_n \in M_n$ that $||y_n|| \leq 1$ and $||y_n - x_n|| \geq 1/2$ for $x \in M_{n-1}$, so if $m < n$, $||Ty_m - Ty_n|| = ||\lambda y_n - (Ty_m - (T-\lambda_n)y_n)|| \geq \frac{|\lambda_n|}{2} \geq \frac{r}{2}$, so Ty_n has no convergent subsequence. □

Lemma (10.9.5.7). If A is compact and $T = 1 - A$, then if T is not injective, then it is not surjective. And for any $r > 0$, $\sigma_p(A) - B(0,r)$ is a finite set.

Proof: We use(10.9.5.6). If $R(T) = X$, then let $M_n = N(T^n)$, then $M_0 \neq 0$ because there is a $Tx_0 = 0$, and $M_n \subset M_{n+1}$ because there is a $T^n x_{n+1} = x_0$, so $x_{n+1} \in M_{n+1} - M_n$.

If $\sigma_p(A) - B(0,r)$ is infinite, then choose M_n to be generated by n eigenvectors, then it is clear that a chain like above will be found. □

Lemma (10.9.5.8). If A is compact and $T = 1 - A$, then $R(T)$ is closed.

Proof: it suffices to show $T^{-1}: R(T) \to X/N(T)$ is continuous, if this is not the case, then there is a sequence $||x_n|| = 1$ but $Tx_n \to 0$. But A is compact, so there is a subsequence that $Ax_{n_k} \to z$, so $x_{n_k} \to z$. So $Tz = 0$ so $z = 0$, but then $x_{n_k} \to 0$, contradiction. □

Prop. (10.9.5.9) [Riesz-Fredholm]. For a compact operator $A \in L(X)$, let $T = I - A$. Then:

1. $0 \in \sigma(A)$ if X is not f.d.

2. T is Fredholm of index 0(10.9.5.17). Equivalently, $\sigma(A)\backslash\{0\} = \sigma_p(A)\backslash\{0\}$(because either T not injective or T is surjective).

3. $\sigma(A)$ has at most one convergent point 0 (it must attain 0 if X is a infinite-dimensional). Hence it has at most countable spectrum.

Proof: 1: If 0 is a regular value, then T is invertible, thus $T^{-1}T = \mathrm{id}$ is compact, thus X has f.d.(10.9.1.7).

2 : Firstly $\dim N(T) < \infty$. This is because $T|_{N(T)} = \mathrm{id}_{N(T)}$, so it is compact iff it is f.d.(10.9.5.3). by [Rudin P108]**?**.

3: By(10.9.5.7). □

Prop. (10.9.5.10) [Lomonosov's Invariant Subspace Theorem]. If X is an infinite dimensional complex Banach space, and $T \neq 0$ is a compact operator in $L(X)$, then there is a proper closed subspace M of X that is invariant under S for any S that commutes with T.

In particular, if S commutes with some compact operator T, then S has an invariant closed subspace.

Proof: If Γ is the subspace of all operators that commutes with T, then it is a subalgebra of $L(X)$, and for each $y \in X$, let $\Gamma(y) = \{Sy | S \in \Gamma\}$, then $S(\Gamma(y)) \subset \Gamma(y)$, then so does the closure of $\Gamma(y)$. So if the proposition is false, then $\Gamma(y)$ is dense in X for each y.

Pick x_0 that $Tx_0 \neq 0$, then there is an open ball B of x_0 that $||Tx|| \geq \frac{1}{2}||Tx_0||$ and $||x|| \geq \frac{1}{2}||x_0||$ for $x \in B$. Now our assumption shows that for every $y \neq 0$, there is a nbhd W of it that maps into B by some $S \in \Gamma$(notice Γ is a subspace).

Now $K = \overline{T(B)}$ is compact because T is compact, so there are f.m. open sets W_i whose union cover K, and $S_i(W_i) \in B$, where $S_i \in \Gamma$. Now let $\mu = \max\{||S_i||\}$. Consider $Tx_0 \in K$, so there is a $S_{i_1}Tx_0 \in B$, then $TS_{i_1}Tx_0 \in K$, so there is a $S_{i_2}TS_{i_1}Tx_0 \in B$. Continuing this way, we get

$$\frac{1}{2}||x_0|| \leq ||x_N|| \leq \mu^N ||T^N|| ||x0||,$$

so by Gelfand theorem(10.10.1.8), $\rho(T) > 0$, so there is a eigenvalue λ of T(by(10.9.5.9)) that $N(T - \lambda I)$ is finite dimensional, so not equal to X, and it is clearly invariant under Γ. □

Prop. (10.9.5.11) [Jordan Decomposition for Compact Operators]. For a compact operator A and all the non-zero eigenvalues λ_i, we can find a <u>subspace</u>

$$\bigoplus_{i=1}^{\infty} N((\lambda_i - A)^{p_i}), \quad \lambda_i \neq 0$$

on which A has a Jordan form.

Proof: Let $T = 1 - A$, By(2.2.4.5), we only have to prove there are some m, n that There is a p that $N(T^p) = N(T^{p+1})$ and a q that $R(T^q) = R(T^{q+1})$, because then we have a decomposition $X = N((T - \lambda I)^p) \oplus R((T - \lambda I)^p)$, and all these $N((T - \lambda I)^p)$ are pairwisely disjoint.

Now $q < \infty$, because if $R(T) \supset R(T^2) \supset \ldots$, because T^k is of the form $1 +$ compact operator, $R(T^k)$ are all closed by(10.9.5.8), so by(10.9.5.6), this is impossible.

For p, use Riesz-Fredholm(10.9.5.9),

$$\dim N(T^q) = \mathrm{codim} R(T^q) = \mathrm{codim} R(T^{q+1}) = \dim N(T^{q+1}) < \infty$$

So $p \leq q < \infty$. □

Prop. (10.9.5.12). If X, Y are Banach spaces and $T, K \in L(X, Y)$, K is compact and $R(A) \subset R(K)$, then A is compact.

Proof: Use(10.8.2.9), then we can lift the function to a map $\widetilde{T} : X \to X/N(K)$, which is also continuous, so $T = \widetilde{K} \to \widetilde{T}$ is also compact. □

Schauder Basis

Def. (10.9.5.13) [Schauder Basis]. Let X be a Banach space, a sequence e_n is called a **Schauder basis** iff for any $x \in X$, there is a unique sequence $C_n(x)$ that $x = \lim \sum_{n=1}^N C_n(x)e_n$. Notice in this case X is automatically separable.

Prop. (10.9.5.14). If X has a Schauder basis, then $C_n(x)$ are continuous functional on X.

Proof: Consider the module $||x||_1 = \sup ||S_N x||$, Firstly, it is complete, because $||x|| = \lim ||S_N x|| \leq ||x||_1$, so if there is a Cauchy sequence $\{x_i\}$ in $|\cdot|_1$, then it is a Cauchy sequence in $|\cdot|$, then it converges to some x. Now $C_N(x) = S_N(x_i) - S_{N-1}(x_i)$ are all Cauchy sequence, uniform in N, so they converges to some sequence c_N.

It is left to verify that $s_N = \sum_{i=1}^N c_n e_n$ converges to x, because then it is easy to verify that $\lim ||x_i - x||_1 = 0$. For this, choose N_1 large that $||x_n - x|| \leq \varepsilon$ for $n \geq N_1$, and choose N_2 large that $||S_k(x_n) - s_k|| \leq \varepsilon$ for all k and $n \geq N_2$. Then for $x_{N_1+N_2}$, there is a N_3 that $||S_n x_{N_1+N_2} - x_{N_1+N_2}|| \leq \varepsilon$, so $||x - s_k|| \leq ||x - x_{N_1+N_2}|| + ||S_k x_{N_1+N_2} - x_{N_1+N_2}|| + ||S_k(x_{N_1+N_2}) - s_k|| \leq 3\varepsilon$ for k large.

Now by Banach(10.8.2.6), $||x||_1 \leq M||x||$ for some M, so $|C_n(x)e_n| \leq 2M||x||$ and C_n is continuous. □

Prop. (10.9.5.15). If X has a Schauder basis, then any compact operator is a limit of operators of f.d. range.

Proof: Let $S_N(x) = \sum_{n=1}^N C_n(x)e_n$, it is continuous by(10.9.5.14). And it converges, so $||S_N|| \leq M$, by Banach-Steinhaus(10.8.2.1).

For any compact operator, we want to find f.d. range operator T_i that $T_i \to T$. For this, given any $\varepsilon > 0$, because $\overline{T(B(0,1))}$ is compact, there are operators that is a ε/M^2-net y_i, then choose N large enough that $|S_N y_i - y_i| \leq \varepsilon/M^2$, then for any x, there is a y_i that $|Tx_i - y_i| < \varepsilon/M^2$, so $|S_N T x_i - S_N y_i| < \varepsilon/M$, and then $|S_N T x - T x_i| < \varepsilon$, and notice $S_N T$ has f.d. range. □

Prop. (10.9.5.16) [Compact Operator as Limits of F.D. Operators]. Any compact operator on a Hilbert space is a limit of f.d. operators.

Proof: Cf.[Trace Classes and Hilbert-Schmidt Operators, Thm10]. □

Fredholm Operator

Def. (10.9.5.17) [Fredholm Operator]. A bounded operator between Banach space is called a **Fredholm operator** if $\dim N(T) < \infty$ and $\mathrm{codim} R(T) < \infty$. It necessarily has closed image by(10.8.2.10), so $R(T) = N(T^*)^\perp$(10.8.3.2).

The **index** of a Fredholm operator is defined as $\mathrm{ind}(T) = \dim N(T) - \mathrm{codim} R(T)$, thus for a compact operator A, $I - A$ has index 0, by(10.9.5.9).

Prop. (10.9.5.18). For a Fredholm operator between Banach space, we have

$$X = N(T) \oplus R(T) \quad Y = Y/R(T) \oplus R(T)$$

and $X/N(T) \cong R(T)$.

Proof: Because $R(T)$ and $N(T)$ are finite/cofinite hence closed and complemented by(10.9.1.9). If $X = N(T) \oplus M_1$ and $Y = R(T) \oplus M_2$, then $M_1 \cong X/N(T)$, $X/N(T) \cong R(T)$ and $M_2 \cong Y/R(T)$ by Banach theorem. □

Prop. (10.9.5.19) [Characterizating Fredholm Operator]. T is Fredholm from X to Y iff there exist a bounded S_1, S_2 from Y to X that $S_1T = I - A_1, TS_2 = I - A_2$, where A_1, A_2 is compact. If this is the case, S_1 and S_2 can be chosen the same as S, then S is called the **regulator** of T, and S is Fredholm as well.

So the Fredholm operator is the set of operators invertible 'modulo compact ones'.

Proof: By(10.9.5.18) $T : X/N(T) \cong R(T)$, and there is a projection of $\pi : Y$ onto $R(T)$. Thus we composed them to get a $S = T^{-1} \circ \pi : Y \to X$. And ST and TS are both 1 minus a projection with f.d. image, hence compact(10.9.5.3).

For the converse, $R(T) \supset R(1 - A_2)$ is of finite codimention because $1 - A_2$ is Fredholm, and $N(T) \subset N(1 - A_1)$ is of finite dimension because $1 - A_1$ is Fredholm. □

Cor. (10.9.5.20). The set of Fredholm operators is closed under composition. Index is a locally constant function on it, and $\mathrm{ind}(T_1T_2) = \mathrm{ind}(T_1) + \mathrm{Ind}(T_2)$.

Proof: There is a long exact sequence(use(3.7.5.4) in the category of vector spaces)

$$0 \to \ker T_2 \to \ker T_1T_2 \to \ker T_2 \to \mathrm{Coker}\, T_2 \to \mathrm{Coker}\, T_1T_2 \to \mathrm{Coker}\, T_1 \to 0.$$

which shows the composition and index is additive.

For the openness and locally constancy, use(10.9.5.19), when adding a small R, $S(T + R) = 1 - A_1 + SR$, and if when $||R|| < ||S||^{-1}$, $E_1 = (I + RS)^{-1}$ is bounded, so $E_1S(T+R) = I - E_1A_1$, and similarly does $(T+R)SE_2$, so $T+R$ is Fredholm. And $\mathrm{ind}\, E_1 + \mathrm{ind}\, S + \mathrm{ind}(T+R) = \mathrm{ind}(1 - E_1A_1) = 0$, and $\mathrm{ind}\, E_1 = 0$ because it is invertible, and $\mathrm{ind}\, S + \mathrm{ind}\, T = \mathrm{ind}(1 - A_1) = 0$, so $\mathrm{ind}\, T = \mathrm{ind}(T + R)$. □

Cor. (10.9.5.21). If T is Fredholm and A is compact, then $T + A$ is Fredholm, and $\mathrm{ind}(T + A) = \mathrm{ind}\, T$, so ind is in fact defined on the quotient of $L(X, Y)$ by compact operators.

Proof: It is Fredholm by(10.9.5.19), and we notice $S(T + A)$ and ST are both 1 minus compact operators, thus(10.9.5.20) and(10.9.5.9) gives the result. □

Cor. (10.9.5.22). If T is Fredholm, then T^* is Fredholm, and $\mathrm{ind}(T^*) = -\mathrm{ind}(T)$.

Proof: The first follows from(10.9.5.19) and(10.9.5.5). For the second, use the fact $R(T)$ and $N(T)$ are all closed. □

6 Unbounded Operators

10.10 Archimedean Banach Algebra

Main references are [Functional Analysis, Rudin].

1 Banach Algebra

Def. (10.10.1.1) [Spectrum]. For a bounded operator $A \in L(X)$ where X is Banach space, a $\lambda \in \mathbb{C}$ is called a:

- **point spectrum** if $\lambda I - A$ is not injective;
- **continuous spectrum** if it is not a point spectrum and $R(\lambda I - A) \neq X$ but $\overline{R(\lambda I - A)} = X$.
- **residue point** if it is not a point spectrum and $\overline{R(\lambda I - A)} \neq X$.
- **regular point** if $\lambda I - A$ is injective and $R(\lambda I - A) = X$, in which case $(\lambda I - X)^{-1}$ is continuous, by Banach.

denote $\sigma(A) = K -$ regular points of A the **spectrum** of A, and $\rho(A) = \sup\{|\lambda| | \lambda \in \sigma A\}$ is called the **spectral radius** of A.

Prop. (10.10.1.2). If A is a Banach algebra and x is invertible in A, and $h \in A$ satisfies $||h|| < \frac{1}{2}||x^{-1}||^{-1}$, then $x + h$ is also invertible and

$$||(x+h)^{-1} - x^{-1} + x^{-1}hx^{-1}|| \leq 2||x^{-1}||^3||h||^2$$

Proof: $x+h = x(e+x^{-1}h)$ and $||x^{-1}h|| < \frac{1}{2}$, so $x+h$ is invertible by(10.10.1.14), and $||(x+h)^{-1} - x^{-1} + x^{-1}hx^{-1}|| = ||[(e+x^{-1}h)^{-1} - e + x^{-1}h]x^{-1}|| \leq 2||x^{-1}||^3||h||^2$ also by(10.10.1.14). □

Cor. (10.10.1.3). If A is a Banach algebra, then the invertible elements $G(A)$ is an open subset of A, and the mapping $x \mapsto x^{-1}$ is a homeomorphism of $G(A)$ onto $G(A)$.

Prop. (10.10.1.4). For $T \in L(X)$ where X is Banach space, $\mathbb{C}\backslash\sigma(T)$ is an open set and $\lambda \to (\lambda I - T)^{-1}$ is a holomorphic function on $\mathbb{C}\backslash\sigma(T)$.

Thus for every bounded operator T on a Banach space, $\sigma(T)$ is not empty.

Proof: The first assertion is by(10.10.1.3), for the second, let $f(\lambda) = (\lambda e - x)^{-1}$ is defined on $\Omega = \mathbb{C} - \sigma(x)$ and(10.10.1.2) shows

$$||f(\mu) - f(\lambda) + (\mu - \lambda)f^2(\lambda)|| \leq 2||f(\lambda)||^3|\mu - \lambda|^2$$

so $\lim_{\mu\to\lambda} \frac{f(\mu)-f(\lambda)}{\mu-\lambda} = -f^2(\lambda)$, which means that f is strongly holomorphic in Ω.

Now if $|\lambda| > ||x||$, then $|f(\lambda)| = |\lambda^{-1}e + \lambda^{-2}x + \ldots| \leq \frac{1}{|\lambda| - ||x||}$, so $\sigma(x)$ cannot be empty by Liouville theorem(10.9.3.28). □

Cor. (10.10.1.5) [Gelfand-Mazur]. If in a Banach algebra A over $\mathbb{C}$, all the nonzero element is invertible, then it is isomorphic to $\mathbb{C}$.

Proof: Any nonzero element x has a nonempty spectrum, so there is a $\lambda(x)$ that $x - \lambda(x)e$ is not invertible, so it must be 0. That is, the mapping $\mathbb{C} \to A : \lambda \mapsto \lambda e$ is bijective, so is is isomorphism by Banach. □

Prop. (10.10.1.6). Notice $(I-T)$ is invertible for $||T||<1$ and the inverse can be calculated by definition.

In particular, for a Banach algebra A and any $x\in A$, when $\lambda>||x||$, $e-\lambda^{-1}x$ is invertible, so the spectrum of x is bounded. Now that its complement is open as the inverse image of $G(A)$ by $\lambda\mapsto\lambda e-x$, so the spectrum of x is compact.

Cor. (10.10.1.7) [Spectrum is Continuous]. The spectrum of an element of a Banach algebra is continuous, i.e. if $\sigma(x)\subset\Omega$ for some open subset $\Omega\subset\mathbb{C}$, then there is a $\delta>0$ that $\sigma(x+y)\subset\Omega$ for $||y||<\delta$.

Proof: As $||(\lambda e-x)^{-1}||$ is a continuous function of λ in the complement of σ, and since the norm tends to 0 as $\lambda\to\infty$, there is a M that $||(\lambda e-x)^{-1}||<M$ for all $\lambda\notin\Omega$. Now if $||y||<1/M$ and $\lambda\notin\Omega$, then $\lambda e-(x+y)=(\lambda e-x)[e-(\lambda e-x)^{-1}y]$ is invertible. □

Prop. (10.10.1.8) [Gelfand]. The spectrum radius $\rho(A)=\lim_{n\to\infty}||A^n||^{\frac{1}{n}}=\inf||A^n||^{\frac{1}{n}}\leq||A||$.

This formula is remarkable, as the LHS depends only on the algebraic structure, and the RHS depends on the metric structure.

Proof: For $r>\rho(x)$
$$x^n=\frac{1}{2\pi i}\int_{\Gamma_r}\lambda^n f(\lambda)d\lambda.$$
Let $M(r)=\max||f(re^{i\theta})||$, then $||x^n||\leq r^{n+1}M(r)$, hence $\limsup||x^n||^{1/n}\leq r$, so $\limsup||x^n||^{1/n}\leq\rho(x)$.

For the converse, if $\lambda\in\sigma(x)$, then $\lambda^n\in\sigma(x^n)$, because $\lambda^n e-x^n=(\lambda e-x)(\lambda^{n-1}e+\ldots+x^{n-1})$, and this two commutes. So $|\lambda^n|\leq||x^n||$, so $\rho(x)\leq\inf||x^n||^{1/n}$. □

Prop. (10.10.1.9). $\sigma(A)=\sigma(A^*)$.

Proof: It suffices to show if T is invertible iff T^* is invertible. If T is invertible, then T^* is invertible with inverse $(T^{-1})^*$. Conversely, if T^* is invertible, then T^{**} is invertible, so, as the restriction of T^{**}, T is injective and image is closed. If the image is not X, then there is a f that vanish on the image, so $T^*f=0$, but then $f=0$. □

Prop. (10.10.1.10). In a Banach algebra A, $e-xy$ is invertible iff $e-yx$ is invertible, thus $\sigma(xy)\cup\{0\}=\sigma(yx)\cup\{0\}$.

Proof: Let $z=(e-xy)^{-1}$, then we claim $e+yzx$ is just the inverse of $e-yx$: $(e-yx)(e+yzx)=e-yx+yzx-yxyzx=e$ and $(e+yzx)(e-yx)=e+yzx-yx-yzxyx=e$. □

Lemma (10.10.1.11). If A is a Banach algebra and $x_n\in G(A)$ converges to $x\notin G(A)$, then $||x_n^{-1}||\to\infty$.

Proof: If $||x_n^{-1}||<M$, choose n that $||x_n-x||<1/M$, then $||e-x_n^{-1}x||=||x_n^{-1}(x_n-x)||<1$, so $x_n^{-1}x$ is invertible, so x is invertible. □

Prop. (10.10.1.12). For Banach algebra B and its closed subalgebra A, $\sigma_A(x)$ is obtained from $\sigma_B(x)$ by filling some holes. So when $\sigma_B(x)$ doesn't separate $\overline{\mathbb{C}}$ or $\sigma(A)$ has empty interior, then $\sigma_A(x)=\sigma_B(x)$.

Proof: Cf.[Rudin P256]. □

Prop. (10.10.1.13). if A is a Banach algebra over $\mathbb{C}$ that $||x||||y|| \le M||xy||$ for some fixed M, then A is isomorphic to $\mathbb{C}$.

Proof: If y is a boundary pt of $G(A)$, $y = \lim y_n$, then $||y_n^{-1}|| \to \infty$. But $||y_n||||y_n^{-1}|| \le M||e||$, so $y_n \to 0$, so $y = 0$.

But any boundary point of $\sigma(x)$ gives a boundary point $\lambda e - x$ of $G(A)$, so $x = \lambda e$, so $A \cong \mathbb{C}$. □

Complex Homomorphism

Prop. (10.10.1.14). Suppose A is a Banach algebra over $\mathbb{C}$, $x \in A$ satisfies $||x|| < 1$, then $||(e-x)^{-1} - e - x|| \le \frac{||x||^2}{1-||x||}$, and $|\varphi(x)| < 1$ for any complex homomorphism φ on A. In particular, any complex homomorphism is continuous.

Proof: $||(e-x)^{-1} - e - x|| = ||x^2 + x^3 + \ldots|| \le \sum_{n=2}^{\infty} ||x||^n = \frac{||x||^2}{1-||x||}$.

For the second, notice $e - \lambda^{-1}x$ is invertible for each $|\lambda| \ge 1$, so $1 - \lambda\varphi(x) \ne 0$, so $\varphi(x) \ne \lambda$. □

Prop. (10.10.1.15)[Gleason-Kahane-Zelazko]. If φ is a linear functional on a Banach algebra A over $\mathbb{C}$, if $\varphi(e) = 1$ and $\varphi(x) \ne 0$ for every invertible element $x \in A$, then φ is a complex homomorphism.

Proof: Cf.[Rudin P251]. □

Symbolic Calculus

Prop. (10.10.1.16) [Symbolic Calculus]. For a Banach algebra A. For a domain Ω in $\mathbb{C}$, define A_Ω as the set of x that $\sigma(x) \in \Omega$, it is an open set by(10.10.1.7), then:

$$f \mapsto \tilde{f}(x) = \frac{1}{2\pi i}\int_\Gamma f(\lambda)(\lambda e - x)^{-1} d\lambda$$

for any contour Γ that surrounds $\sigma(x)$, is a continuous algebra isomorphism of $H(\Omega)$ into the set of A-valued functions on A_Ω with the compact-open topology.

We have $\widetilde{g \circ f} = \tilde{g} \circ \tilde{f}$.

Proof: The nontrivial part is that this map is multiplicative, but for this we can use Runge's theorem to approximate any function on $\sigma(x)$. □

This theorem makes it possible to implant complex analysis to the study of Banach Algebra.

Cor. (10.10.1.17). $\exp(x)$ is defined on A and is continuous. If $\sigma(x)$ doesn't separate 0 from ∞, then $\log(x)$ is defined but might not be continuous.

Prop. (10.10.1.18)[Spectral Mapping Theorem]. $\tilde{f}(x)$ is invertible in A iff $f(\lambda) \ne 0$ on $\sigma(x)$. Thus we have $\sigma(\tilde{f}(x)) = f(\sigma(x))$.

Prop. (10.10.1.19). If f doesn't vanish identically on any component of Ω, then $f(\sigma_p(T)) = \sigma_p(\tilde{f}(T))$. Cf.[Rudin P266].

Commutative Banach Algebra

Lemma (10.10.1.20). For A a commutative Banach algebra, the set of maximal ideals has codimension 1 corresponds to kernels of complex homomorphisms to $\mathbb{C}$. (Consider the quotient space and use Gelfand-Mazur). Note that a complex homomorphism is all continuous because $\lambda e - x$ maps to nonzero.

$\lambda \in \sigma(x)$ iff there is a complex homomorphism h s.t. $h(x) = \lambda$. (Because x is invertible iff it is not contained in any proper ideal of A.

Proof:

□

Prop. (10.10.1.21) [Gelfand Transform]. The **spectrum** Δ_A of a unital commutative Banach algebra A is defined to be the set Δ of maximal ideals of A. It is a locally compact Hausdorff space w.r.t to the weak*-topology and the Gelfand transform: $x \mapsto \widehat{x}(h) = h(x)$ is a continuous map of A into $C(\Delta)$. And the range of $\widehat{x}$ equals $\sigma(x)$, so $||\widehat{x}|| = \rho(x) \leq ||x||$.

Proof: First we prove it is compact Hausdorff: As $\sigma(A) = \{h \in \text{closed ball of } A^* | h(e) = 1, h(xy) = h(x)h(y)\}$ which is a closed subset of the closed ball of A^*, so it is compact Hausdorff. The rest is clear and follows from(10.10.1.20). □

Prop. (10.10.1.22). For $A = C(X)$ where X is compact Hausdorff, Δ is homeomorphic to X. (otherwise it has finite $f_i \neq 0$, then $\sum |f_i|^2$ is positive thus invertible but maps to 0). In fact, for a space X, $\Delta(C(X))$ is the stone-Čech compactification of X.

Prop. (10.10.1.23). For $A = L^\infty(m)$, the spectrum of f is just the essential range of f.

Lemma (10.10.1.24). If $\widehat{A} \subset C(\Delta)$ with a chosen topology that makes it compact, and A separate points, then the topology of it is the same of the weak*-topology. (Compact to Hausdorff).

Prop. (10.10.1.25). The algebra $L^1(\mathbb{R}^n) \oplus \delta$ with the multiplication by convolution has the spectrum $R^n \cap \{\infty\}$. (Use $(L^p)* = L^q$ and see when will it be homomorphism).

2 Hilbert spaces

Prop. (10.10.2.1) [Optimal Approximation]. A closed convex subset in a Hilbert space has a unique element that attains the minimum norm.

Proof: Assume $0 \notin C$, so let $d = \inf_{z \in C} ||z|| > 0$, then there are x_n that $d \leq ||x_n|| \leq d + 1/n$. It suffices to show that x_n is a Cauchy sequence, because then it has a convergent point in C. Now

$$||x_n - x_m||^2 = 2(||x_n||^2 + ||x_m||^2) - 4||\frac{x_n + x_m}{2}||^2 \leq 2[(d + 1/n)^2 + (d + 1/m)^2] - 4d^2 \to 0.$$

For the unicity, if $||x_1|| = ||x_2|| = d$, then

$$||x_1 - x_2||^2 = 2(||x_1||^2 + ||x_2||^2) - 4||\frac{x_1 + x_2}{2}||^2 \leq 4d^2 - 4d^2 = 0.$$

□

Cor. (10.10.2.2) [Orthogonal Decomposition]. The orthogonal complement of a closed subspace of a Hilbert space exists. and the projection on to a closed subspace exists. This is a good trait of Hilbert space.

Proof: For any element x, let y be the optimal approximation(10.10.2.1) of x, then $z = x - y$ is orthogonal to y. □

Prop. (10.10.2.3) [Riesz]. Linear functionals on a Hilbert space over $\mathbb{C}$ are all of the form $x \mapsto (x, z)$ (Choose an orthogonal of the kernel). In other words, Hilbert spaces are reflexive.

Proof: Choose a x_0 orthogonal to $N(f)$ by(10.10.2.2) and $||x_0|| = 1$, then any $x = \alpha x_0 + y$ where $y \in N(f)$. Inner product with x_0, we get $\alpha = (x, x_0)$, so $f(x) = \alpha f(x_0) = (x, \overline{f(x_0)} x_0)$. □

Cor. (10.10.2.4). For Hilbert spaces $\mathcal{H}, \mathcal{K}$ and $T \in \mathcal{L}(\mathcal{H}, \mathcal{K})$, $||T|| = \sup\{(Tx, y) | ||x|| \leq 1, ||y|| \leq 1\}$.

Proof: Use(10.9.3.6) to find for each x a functional f of norm 1 that $|f(Tx)| = ||Tx||$, then use Riesz theorem. In particular, if we define □

Cor. (10.10.2.5) [Reproducing Kernel]. For a Hilbert space H, if elements of H are all complex valued functions on a set S, and $J_x : f \mapsto f(x)$ is continuous functional for H, then there is a function $K(x, y)$ on $S \times S$ that $K_y(x) = K(x, y) \in H$, and $f(y) = (f, K_y)_H$, called the **reproducing kernel**.

And if e_α is a basis for H, then $K(x, y) = \sum e_\alpha(x)\overline{e_\alpha}(y)$.

Proof: For any y, there is a $K_y \in H$ that $f(y) = (f, K_y)_H$ by Riesz representation. If we let $K(x, y) = (K_y, K_x) = K_y(x)$, then this is the desired kernel.

If e_α is a basis, then $K_x = (K_x, e_n)e_n = \overline{e_n(x)} e_n$, so by Parseval equality, $K(x, y) = \sum e_\alpha(x)\overline{e_\alpha(y)}$. □

Prop. (10.10.2.6). Let $\mathcal{H}$ be a Hilbert space, then a sequence x_n converges to x iff x_n converges to x weakly and $||x||_n \to ||x||$.

Proof: One direction is trivial, for the other, notice that $||x_n - x||^2 = ||x_n||^2 + ||x||^2 - 2\operatorname{Re}(x, x_n)$ which converges to 0. □

Prop. (10.10.2.7) [Lax-Milgram Theorem]. If $a(x, y)$ is a sesquilinear form on a Hilbert space H over $\mathbb{C}$ that $|a(x, y)| \leq M||x||||y||$, then there is a unique continuous operator $A \in L(H)$ that $a(x, y) = (x, Ay)$. If moreover $|a(x, x)| \geq \delta ||x||^2$, then A is bijective and $||A^{-1}|| \leq \frac{1}{\delta}$.

Proof: For any y, $x \mapsto a(x, y)$ is a continuous functional, so by Riesz theorem(10.10.2.3), there is an element Ay that $a(x, y) = (x, Ay)$.

Now Ay depends linearly on y, and $||Ay|| = \sup |a(x, y)|/||x|| \leq M||y||$.

If $|a(x, x)| \geq \delta ||x||^2$, then A is clearly injective, and $R(A)$ is closed, because for any $z = \lim Av_n$, it is easily verified that v_n is a Cauchy sequence. And $R(A)^\perp = 0$, because if $(w, Av) = 0$ for any $v \in H$, then $\delta ||w||^2 \leq |a(w, w)| = 0$. A^{-1} exists by Banach theorem(10.8.2.5), and $\delta ||x||^2 \leq |a(x, x)| = (x, Ax)| \leq ||x||||Ax||$, so $\delta ||x|| \leq ||Ax||$. □

Cor. (10.10.2.8) [Variational Inequality]. If H is a Hilbert space that $a(x, y)$ is an anti-symmetric bilinear function that $\delta ||x||^2 \leq a(x, x) \leq M||x||^2$, then if $u_0 \in H$, and C is a closed convex subset of X, the function

$$f : x \mapsto a(x, x) - \operatorname{Re}(u_0, x)$$

attains minimum at C.

Proof: Similar to the proof of(10.10.2.1). $f(x) \geq \delta||x||^2 - ||u_0||||x||$ is bounded below on C. if x_n is a sequence that converse to the infimum d, then

$$a(x_n - x_m, x_n - x_m) = 2(a(x_n, x_n) + a(x_m, x_m)) - 4a(\frac{x_n + x_m}{2}, \frac{x_n + x_m}{2})$$
$$= 2(f(x_n) + f(x_m)) - 4f(\frac{x_n + x_m}{2}) \leq 2[(d + 1/n)^2 + (d + 1/m)^2] - 4d^2 \to 0.$$

So x_n is a Cauchy sequence by the condition, and it contains a unique minimum. □

Cor. (10.10.2.9) [Involutions]. For a Hilbert space $\mathcal{H}$ over $\mathbb{C}$, for any $T \in L(H)$, there is an operator $T^* \in L(H)$ that $(Tx, y) = (x, T^*y)$, which is called the **formal adjoint** or involution of T. Notice it is defined on H, not on H^*.

Moreover, $||T|| = ||T^*|| = ||T^*T||^{1/2}$.

Proof: Use Lax-Milgram for $a(x, y) = (Tx, y)$. For the last assertion, $|||T|| = ||T^*||$ by(10.10.2.4). And we notice

$$||Tx||^2 = (Tx, Tx) = (T^*Tx, x) \leq ||T^*T||||x||^2,$$

so $||T|| \leq ||T^*T||^{1/2}$. □

Remark (10.10.2.10) [Examples]. The dual operator of the integral operators(10.9.5.2) with kernel $K(x, y)$ is also an integral operator with kernel $K^*(x, y) = \overline{K(y, x)}$. This follows from Fubini-Tonelli theorem.

3 B^*-algebra

Def. (10.10.3.1). A **B^*-algebra** is a Banach algebra with an involution s.t. $||xx^*|| = ||x||^2$.

Any B^*-algebra is isomorphic to a closed subspace of $B(H)$ for some Hilbert space.

Proof: Cf.[Rudin P338]. □

Prop. (10.10.3.2). For a Hilbert space, the adjoint operation serves as an involution and makes $B(H)$ into a B^*-algebra by(10.10.2.9).

Prop. (10.10.3.3) [Gelfand-Naimark]. For a commutative B^*-algebra, the Gelfand transform $x \mapsto \widehat{x}$ is an isomorphism from A to $C(\Delta)$ with $||x|| = ||\widehat{x}||_\infty$ and $\widehat{x^*} = \overline{\widehat{x}}$.

Proof: First use $||xx^*|| = ||x||^2$ to prove that a Hermitian element is mapped to real function, and use Stone-Weierstrass to show that the image is dense, then let $y = xx^*$ and $||y^{2^m}|| = ||y||^{2^m}$ to prove $||\widehat{x}|| = ||x||$, so its image is closed. □

Cor. (10.10.3.4). If A is a commutative B^*-algebra that contains an element x s.t polynomials of x, x^* are dense in A, then $\widehat{x}$ is an isomorphism from Δ_A to $\sigma(x)$, in particular, the Gelfand transform is an isomorphism from $C(\sigma(x))$ to A.

Proof: Cf.[Rudin P290]. □

Now we want to apply commutative algebra methods in the non-commutative case, there are two ways.

Prop. (10.10.3.5). For a commutative set of elements S in A, its bicommutant(10.10.3.13) $B = \Gamma(\Gamma(S))$ is commutative, closed and contains S. And $\sigma_B(x) = \sigma_A(x)$ for $x \in B$.

Proof: Because $S \subset \Gamma(S)$, $\Gamma(\Gamma(S)) \subset \Gamma(S)$, thus $\Gamma(\Gamma(S))$ is commutative. And if $xy = yx$, then $x^{-1}y = yx^{-1}$, so the inverse, if exists, are in B. □

Cor. (10.10.3.6). In a Banach algebra, if x, y commutes, then

$$\sigma(x+y) \subset \sigma(x) + \sigma(y), \quad \sigma(xy) \subset \sigma(x)\sigma(y).$$

Proof: Because $\sigma(x)$ is just the range of $\widehat{x}$ on Δ_A where $A = \Gamma(\Gamma(\{x,y\}))$(10.10.3.5)(10.10.1.21). □

The second method applies to normal elements:

Def. (10.10.3.7) [Normal]. In a Banach algebra with an involution, a set S is called **normal** if it is commutative and $S^* = S$. An element x is called:

- **normal** iff x commutes with x^*.
- **unitary** iff $x^* = x^{-1}$.
- **Hermitian** iff $x^* = x$.
- **positive** iff $x = x^*$ and $\sigma(x) \subset [0, \infty)$.

Prop. (10.10.3.8). A maximal normal set B in A is a closed subalgebra and $\sigma_B(x) = \sigma_A(x)$ for $x \in B$.

Proof: Cf.[Rudin P294]. □

Cor. (10.10.3.9) [Normalness and Spectra]. In a B^*-algebra A,

- Hermitian elements have real spectra.
- If x is normal, then $\rho(x) = ||x||$.
- If $u, v \geq 0$, then $u + v \geq 0$.
- $yy^* \geq 0$. Thus $e + yy^*$ is invertible.

Proof: Cf.[Rudin P295]. □

Def. (10.10.3.10) [Positive Functional]. In a Banach algebra with an involution, a **positive functional** is such that $F(xx^*) \geq 0$. It has the following properties.

- $F(x^*) = \overline{F(x)}$ and $|F(xy^*)|^2 \leq F(xx^*)F(yy^*)$. (Use Swartz like trick).
- $|F(x)|^2 \leq F(e)F(xx^*) \leq F(e)^2\rho(xx^*)$, because $e = ee^*$. Thus $|F(x)| \leq F(e)\rho(x)$ for every normal x by(10.10.3.9), so $||F|| = F(e)$ if A is commutative.

Proof: Cf.[Rudin P297]. □

Prop. (10.10.3.11)[Positive Functional and Measure]. If A is a commutative Banach algebra with an involution that $h(x^*) = \overline{h(x)}$, then The map

$$\mu \to F(x) = \int_\Delta \widehat{x} d\mu$$

is a one-to-one correspondence between the convex set of measures μ that $\mu(\Delta) \leq 1$ to the convex set K of positive functionals on A of norm ≤ 1, i.e. $F(e) \leq 1$, so maps the extreme points, i.e. the point mass to extremes points, thus the extreme points of K is exactly Δ. This can be used to prove Bochner's theorem**??**

Proof: Use the last prop to show that there is a functional on $C(\Delta)$ and use Riesz representation. It is positive and by Stone-Weierstrass, it is unique. □

von Neumann Algebras

Def. (10.10.3.12)[von Neumann Algebra]. A **von Neumann Algebra** is a B^*-algebra of operators in $L(\mathcal{H})$ that contains the identity and is closed in the weak operator topology(10.8.3.4).

Def. (10.10.3.13) [Bicommutant]. If $\mathcal{S}$ is a subset of $L(\mathcal{H})$, then we define the **commutator** $\Gamma(\mathcal{S})$ be the algebra of operators that commutes with $S \in \mathcal{S}$, then $\Gamma(\Gamma(\mathcal{S}))$ contains $\mathcal{S}$, it is called the **bicommutant** of $\mathcal{S}S$.

If $\mathcal{A}$ is a $*$-algebra in $L(\mathcal{H})$, then $\Gamma(\Gamma(A))$ is a von-Neumann algebra.

Proof: If $\mathcal{A}$ is a $*$-algebra, then $\Gamma(\Gamma(A))$ is clearly a $*$-algebra, and it is weak-closed because if $SV_i = V_i S$ and $V_i x \to Vx$ for any x, then $SVx = VSx$ for any x. □

Prop. (10.10.3.14)[von Neumann Density Theorem]. Let $\mathcal{A}$ be a non-degenerate $*$-subalgebra of $L(\mathcal{H})$, then $\mathcal{A}$ is dense in $\Gamma(\Gamma(\mathcal{A}))$ in the strong operator topology.

Proof: For any $S \in \Gamma(\Gamma(\mathcal{A}))$ and any $x_1, \ldots, x_N \in \mathcal{H}$, $\varepsilon > 0$, we need to prove there exists $A \in \mathcal{A}$ that $\sum ||Sx_i - Ax_i|| \leq \varepsilon^2$.

For the case $N = 1$ and $x_1 = x$, consider the closure $\mathcal{X}$ of $\{Ax\}$, then the orthogonal projection P onto $\mathcal{X}$ is an operator in $\Gamma(\mathcal{A})$. This implies $A(1-P)x = (1-P)Ax = 0$, thus $x = Px$ because of non-degeneracy. Then because S commutes with P, $Sx = SPx = PSx \in \mathcal{X}$, thus there exists an $A \in \mathcal{A}$ that Ax is close to Sx.

For $N > 1$, we can just apply the result to $\mathcal{H}^N$. □

4 Spectral Theory on Hilbert Spaces

The most useful tool is the general symbolic calculus for normal operators.

Resolution of Identity

Def. (10.10.4.1). A **resolution of identity** on a Hilbert space H for a σ-algebra on a set Ω is a E that:

1. $E(\varnothing) = 0, E(\Omega) = 1$.
2. $E(\omega)$ is self-adjoint projection.
3. $E(\omega' \cap \omega) = E(\omega')E(\omega)$.
4. $E(\omega \cup \omega') = E(\omega) + E(\omega')$ for disjoint ω, ω'.
5. $E_{x,y}(\omega) = (E(\omega)x, y)$ is a complex measure on E.

Thus for any x, $\omega \to E(\omega)x$ is a countably additive H-valued measure.

This will generate an isometric*-isomorphism Ψ of the Banach algebra $L^\infty(E)$ onto a closed normal subalgebra A of $B(H)$. (Define on simple function first).

$$\Psi(f) = \int_\Omega f dE, \quad (\Psi(f)x, y) = \int_\Omega f dE_{x,y}$$

Proof: Cf.[Rudin P319]. □

Prop. (10.10.4.2)[Spectral Decomposition for Normal Algebra]. For any closed normal algebra A of $B(H)$, there is a unique resolution E of identity on the Borel subsets of Δ_A that the inverse of Gelfand transform extends to an isometric *-isomorphism Φ of the algebra $L^\infty(E)$ to a closed subalgebra B containing A.

In fact, $B = \Gamma(\Gamma(A))$ is normal by Fuglede theorem(10.10.4.10).

Proof: Cf.[Rudin P322]. □

Cor. (10.10.4.3) [Generalized Symbolic Calculus for Normal Operator]. For a normal operator T and the minimal closed commutative B^*-algebra A it generates, then the inverse of Gelfand transform gets us a map $\Psi : C(\sigma(x)) \to A$ that $\Psi(z) = x$, $\Psi(\overline{z}) = x^*$, by(10.10.3.4).

Then the above proposition says there is a resolution of identity on the Borel set of $\sigma(T)$ that Ψ extends to a function that maps $L^\infty(m)$ to $B(H)$ and $||\Psi(f)|| = ||f||_\infty$.

Cor. (10.10.4.4) [Normal and Invariant Subspace]. Any closed normal algebra A has many invariant subspaces, just choose a decomposition of Borel sets $\Delta_A = \omega \coprod \omega'$, then $R(E(\omega)) \oplus R(E(\omega')) = H$.

In particular, any normal operator has an invariant subspace.

Normal Operators on Hilbert Space

Lemma (10.10.4.5). For a Hilbert space H and $T \in L(H)$, T is defined by values (Tx, x).

Proof: If $(Tx, x) = 0$, then $(Tx, y) + (Ty, x) = 0$, so $-i(Tx, y) + i(Ty, x) = 0$, solving $(Tx, y) = 0$ for all x, y, so $T = 0$. □

Prop. (10.10.4.6) [Normal Operators].

1. An operator is normal iff $||Tx|| = ||T^*x||$. So $N(T) = N(T^*)$ thus $\sigma_p(T^*) = \overline{\sigma_p(T)}$, and $R(T)$ is dense iff T is injective. And different eigenspaces are orthogonal.
2. An operator is unitary iff $R(U) = H$ and $||Ux|| = ||x||$ for every x. (Because an operator is defined by its value (Tx, y).

Proof: $||Tx||^2 = (T^*Tx, x)$, $||T^*x|| = (TT^*x, x)$, and they are equal iff T, T^* commutes by(10.10.4.5). In particular, for different eigenvectors, $\alpha(x, y) = (Tx, y) = (xT^*y) = (x, \overline{\beta}y) = \beta(x, y)$.

For unitary, one way is obvious, for the other, if $||Ux|| = ||x||$, then $(U^*Ux, x) = (x, x)$, so $U^*U = id$ by(10.10.4.5), and U is a bijection. So it is invertible. □

Cor. (10.10.4.7). For a normal operator T on a Hilbert space T is invertible iff there is a δ that $||Tx|| = ||T^*x|| \geq \delta||x||$.

Proof: T is injective iff $R(T)$ is dense, and if $||Tx|| = ||T^*x|| \geq \delta||x||$, then $R(T)$ is closed by(3.3.8.10), so it is invertible by Banach theorem. □

Prop. (10.10.4.8). If T is normal, then

1. $||T|| = \sup\{|(Tx, x)|\ ||x|| = 1\}$.
2. T is self-adjoint iff $\sigma(T)$ is real.
3. T is unitary iff $|\sigma(T)| = 1$.

Proof: For 1, $||T|| = \rho(T) = ||z_0||$ for some $z_0 \in \rho(T)$ by Naimark(10.10.3.3), then Urysohn lemma to show $E(U) \neq 0$ for a open U near x(because otherwise there is a continuous function supported in U that are mapped to 0), then there are $||x_0|| = 1$ that $E(U)x_0 = x_0$.

Consider now $f = (z - z_0)i_U(z)$, then $f(T)(x_0) = Tx_0 - \lambda_0 x_0$, so

$$(Tx_0, x_0) - \lambda_0| = |(f(T)x_0, x_0)| \leq ||f(T)|| = ||f|| \leq \varepsilon$$

This shows that $||T|| = \sup\{|(Tx, x)|\ ||x|| = 1\}$.

For $2, 3$, by generalized symbolic calculus(10.10.4.3), $\widehat{T} = \lambda$ on σ and $\widehat{T^*} = \overline{\lambda}$ on σ, so they are equal iff $\sigma(T)$ is real, and $TT^* = I$ iff $\lambda\overline{\lambda} = 1$ on $\sigma(T)$. □

Prop. (10.10.4.9)[Decomposition of Operators]. Every operator $S \in L(\mathcal{H})$ on a Hilbert space $\mathcal{H}$ is a linear combination of two self-adjoint operator and a linear combination of four unitary operator.

Proof: The first assertion is easy as $S = (S + S^*)/2 + (S - S^*)/2$. Now any self-adjoint operator is a multiple of a self-adjoint operator of norm $||S|| \leq 1$, so $1 - S^2$ is positive, and we have $S = \frac{1}{2}(f_+(S) + f_-(S))$, where $f_\pm(s) = s \pm i\sqrt{1 - s^2}$. □

Prop. (10.10.4.10)[Fuglede]. If N_1 and N_2 are normal operators and A is a bounded linear operator on a Hilbert space such that $N_1 A = AN_2$, then $N_1^* A = AN_2^*$.

Proof: For any $S \in B(H)$, $\exp(S - S^*)$ is unitary thus $||\exp(S - S^*)|| = 1$, $\exp(N_1)A = A\exp(N_2)$. Because $\exp(M)T = T\exp(N)$, if we let $U_1 = \exp(M^* - M), U_2 = \exp(N - N^*)$, then

$$||\exp(N_1^*)T\exp(-N_2^*)|| = ||U_1 T U_2|| \leq ||T||$$

because λN_i is normal. Now

$$||\exp(\lambda N_1^*)T\exp(-\lambda N_2^*)|| = ||U_1 T U_2|| \leq ||T||$$

also holds, thus by Liouville, $\exp(\lambda N_1^*)T\exp(-\lambda N_2^*) = T$. Compare the coefficients of λ, we get the result. □

Prop. (10.10.4.11). An operator $T \in B(H)$ has the same spectrum w.r.t all the closed B^*-algebras of $B(H)$ containing it.

Proof: If T is invertible, because TT^* is self-adjoint thus has real spectrum(10.10.4.8) so doesn't separate $\mathbb{C}$ thus it is invertible in any closed B^*-algebra of $B(H)$(10.10.1.12). so does $T^{-1} = T^*(TT^*)^{-1}$. □

Prop. (10.10.4.12). For T normal and E its spectral decomposition, then if $f \in C(\sigma(T))$ and $\omega_0 = f^{-1}(0)$, then $N(f(T)) = R(E(\omega_0))$.

Proof: $\chi_{\omega_0} f = 0$, so $f(T)R(E(\omega_0)) = 0$, and if we let $\omega_n = f^{-1}([1/(n-1), 1/n))$, and let $f_n(\lambda) = 1/f(\lambda)\chi_{\omega_n}$, then $f_n(T)f(T) = E(\omega_n)$, so if $f(T) = 0$, then $E(\omega_n)x = 0$, so countable additivity shows that $E(\sigma\backslash\omega_0)x = 0$, so $E(\omega_0)x = x$. These shows the desired result. □

Cor. (10.10.4.13).

1. $N(T - \lambda I) = R(\{\lambda\})$.
2. every isolated point of $\sigma(T)$ is point spectrum, because this point is open thus is $E(\{x\}) \neq 0$ by Urysohn lemma.
3. if $\sigma(T)$ is countable, then every $x \in H$ has a unique orthogonal decomposition $x = \sum E(\lambda_i)x$ and $T(E(\lambda_i)x) = \lambda_i E(\lambda_i)x$.

Prop. (10.10.4.14)[Normal Compact Operator]. A normal operator $T \in B(H)$ is compact iff $\sigma(T)$ has no limit point except possibly 0 and $\dim N(T - \lambda I) < \infty$ for $\lambda \neq 0$.

In particular, a normal compact operator is a limit of f.d. operators

Proof: One direction is general, by(10.9.5.9), for the other, it is a limit of operators of finite dimensional range by general symbolic calculus(10.10.4.3). □

Cor. (10.10.4.15)[Spectral Theorem]. A compact normal operator (in particular a normal operator on a f.d linear space) is unitarily diagonalizable.

Proof: it suffices to find a basis of eigenvectors, but this is easy, just by(10.10.4.13). □

Cor. (10.10.4.16) [Hilbert-Schimidt]. For a self-adjoint compact operator A on a Hilbert space H, there is a set of orthonormal basis that A is diagonal on it. And of course, its eigenvalues are real and can only converges to 0(10.10.4.8).

Prop. (10.10.4.17). For a normal compact operator $T \in L(H)$, then:

1. T has an eigenvalue $|\lambda|$ that $|\lambda| = ||T||$.
2. $f(T)$ is compact if $f \in C(\sigma(T))$ and $f(0) = 0$.
3. $f(T)$ is not compact if $f \in C(\sigma(T))$ and $f(0) \neq 0$ and $\dim H = \infty$.

Proof: 1: The spectrum of maximal norm is isolated(10.9.5.9) hence a point spectrum by(10.10.4.13). And $|\lambda| = ||T||$ by symbolic calculus(10.10.4.3).

2: Cf.[Rudin P330].

3: The 2 sill show that $f(0)I - f$ is compact, If f is compact, then $f(0)I$ is compact, so $\dim H < \infty$(10.9.5.3). □

Prop. (10.10.4.18) [Freudenthal Spectral Theorem].

Prop. (10.10.4.19) [Positive Equivalent Definition]. A $T \in L(H)$ is positive, i.e. $T = T^*$ and $\sigma(T) \subset [0, \infty)$ iff $(Tx, x) \geq 0$.

Proof: If $(Tx, x) \geq 0$, then $(Tx, x) = (x, Tx) = (T^*x, x)$, so $T = T^*$ by(10.10.4.5), so $\sigma(T)$ is real(10.10.4.8), and for $\lambda > 0$,

$$\lambda||x||^2 = (\lambda x, x) \leq ((T + \lambda I)x, x) \leq ||(T + \lambda I)x||||x||,$$

so $T + \lambda I$ is invertible by(10.10.4.7), so $\sigma(T) \subset [0, \infty)$.

Conversely, if T is positive, then it is normal, so $(Tx, x) = \int_{\sigma(T)} \lambda dE_{x,x} \geq 0$. □

Prop. (10.10.4.20) [Polar Decomposition].

1. Every positive operator T has a positive square root, which is invertible if T is.
2. Polar decomposition exists in $B(H)$: Any $T \in L(H)$ invertible has a unique decomposition $T = UP$ where U is unitary and P is positive. And $||Px|| = ||Tx||$ for all x.
3. Any normal operator has commuting decomposition UP, where U, P, T commutes.

Proof: 1: Use general symbolic calculus, then $S = \sqrt{\lambda}(T)$ is the square root of T. If T is invertible, then $S^{-1} = T^{-1}S$.

2: $(T^*Tx, x) = (Tx, Tx) \geq 0$, so T^*T is positive(10.10.4.19), so let $P = \sqrt{T}$, then it is also invertible, and $U = TP^{-1}$ is unitary.

3: Use general symbolic calculus, let $p(\lambda) = |\lambda|$, $u(\lambda) = \lambda/|\lambda|$ if $\lambda \neq 0$, and $u(0) = 0$. Then $T = UP$, and they are commutative. □

Cor. (10.10.4.21) [Similar Normal Operator]. Similar normal operators are unitarily equivalent.

Proof: It suffices to show that if $M = TNT^{-1}$, and $T = UP$ is the polar decomposition, then $M = UNU^{-1}$. Fuglede(10.10.4.10) shows $M^*T = TN^*$, so $NP^2 = NT^*T = T^*MT = T^*TN = P^2N$, so N commutes with any functions $f(P)$, in particular P. Hence $M = (UP)N(UP)^{-1} = UNU^{-1}$. □

5 Hilbert-Schmidt Operators and Trace Classes

Main references are [Trace Classes and Hilbert-Schmidt Operators].

Def. (10.10.5.1) [Hilbert-Schmidt Operator]. Let $\mathcal{H},\mathcal{K}$ be Hilbert spaces and $T\in L(\mathcal{H},\mathcal{K})$. Then for any orthonormal basis $\{e_k\}$ of $\mathcal{H}$ and $\{f_k\}$ of $\mathcal{K}$,

$$\sum_j ||Te_j||^2_{\mathcal{K}} = \sum_j ||T^* f_j||^2_{\mathcal{H}}.$$

Thus we can say T is **Hilbert-Schimidt** iff

$$||T||_{HS} = (\sum_j ||Te_j||^2_{\mathcal{K}})^{1/2} < \infty$$

for some/all basis e_j of $\mathcal{H}$. The space of all Hilbert-Schimidt between $\mathcal{H},\mathcal{K}$ is denoted by $S_2(\mathcal{H},\mathcal{K})$.

Proof:

$$\sum_i ||Te_k||^2 = \sum_i\sum_j |(Te_i,f_j)|^2 = \sum_i\sum_j |(T^*f_j,e_i)|^2 = \sum_j ||T^*f_j||^2$$

□

Cor. (10.10.5.2) [Properties of $S_2(\mathcal{H},\mathcal{K})$].

- If $A\in S_2(\mathcal{H},\mathcal{K})$ then $A^*\in S_2(\mathcal{K},\mathcal{H})$ with the same HS-norm.
- For $A\in S_2(\mathcal{H},\mathcal{K})$, $||A||\le ||A||_{HS}$.
- $S_2(\mathcal{H},\mathcal{K})$ is a Banach space in the HS-norm.
- If $\mathcal{H}_1,\mathcal{K}_1$ are separable Hilbert spaces and $T\in S_2(\mathcal{H},\mathcal{K}), A\in \mathcal{L}(\mathcal{H}_1,\mathcal{H}), B\in\mathcal{L}(\mathcal{K},\mathcal{K}_1)$, then $BTA\in S_2(\mathcal{H}_1,\mathcal{K}_1)$.

Proof: 1 follows from(10.10.5.1). 2 is because we can extend u to a basis of $\mathcal{H}$.

3: $||-||_{HS}$ is clearly a semi-norm(10.8.1.8), and it is a norm by item2. To show the completeness, if A_j is an HS-Cauchy sequence, then it is a Cauchy sequence in the operator norm, thus converges to an operator A. Then for any ε, there is an N that for any $j,k\ge N$, $||A_j-A_k||_{HS}\le\varepsilon$. This implies

$$\sum_{\alpha\in S} ||(A_k-A_j)e_\alpha||^2_{\mathcal{K}}\le\varepsilon^2$$

for any finite subset $S\subset I$. Then letting $k\to\infty$ and then letting S be any subset, we get $||A-A_j||_{HS}\le\varepsilon$. Thus A is Hilbert-Schmidt and $A_j\to A$ in HS-norm.

4: it is clear that $||BT||_{HS}\le ||B||||T||_{HS}$, and because of the transpose invariance of HS-norm and operator norm(10.10.2.9). □

Prop. (10.10.5.3) [Hilbert-Schmidt Operator is Compact]. If $A\in S_2(\mathcal{H},\mathcal{K})$ and $\{f_k\}$ is an orthonormal basis of $\mathcal{K}$, and we denote π_n as the projection of $\mathcal{K}$ onto the span of $\{f_1,\ldots,f_n\}$, then

$$||\pi_n A - A||_{HS}\to 0.$$

In particular, A is compact, by(10.10.5.2) and(10.9.5.3).

Proof: By(10.10.5.2), it suffices to show that $||A^*\pi_n - A^*||_{HS}\to 0$. But this norm is just $\sum_{k>N}||A^*f_k||^2_{\mathcal{H}}$, which converges to 0. □

Prop. (10.10.5.4)[Hilbert-Schmidt Inner Product]. If $\mathcal{H}$ is a Hilbert space and $A, B \in S_2(\mathcal{H})$, then $B^*A \in S_1(\mathcal{H})$ by(10.10.5.2)(10.10.5.7), then we can define an **Hilbert-Schmidt inner product** on $S_2(\mathcal{H})$:

$$(A, B) = \mathrm{tr}(B^*A)(10.10.5.9).$$

Then this makes $S_2(\mathcal{H})$ a Hilbert space.

Proof: This follows from(10.10.5.2). □

Prop. (10.10.5.5)[Integral Operator is Hilbert-Schmidt]. Let Ω be a σ-finite measure space and $K(x, y) \in L^2(\Omega \times \Omega)$, then the operator $Lu(x) = \int_\Omega K(x, y)u(y)dy$ defined in(10.9.5.2) is a Hilbert-Schmidt operator on $L^2(\Omega)$. In fact, $||L||_2 = ||K||_{L^2}$.

Proof: Let $\mathcal{E}$ be an Hilbert basis of $L^2(\Omega)$, then we have

$$||L||_2^2 = \sum_{f_1, f_2 \in \mathcal{E}} |(Lf_1, f_2)|^2 = \sum_{f_1, f_2 \in \mathcal{E}} |\int_X \int_X \overline{f_2(y)} K(x, y) f_1(x) dx dy|^2 = \sum_{f_1, f_2 \in \mathcal{E}} (K, f_1 \otimes f_2)^2$$

But by(10.4.6.4) $\{f_i \otimes f_j\}$ form a Hilbert Basis for $L^2(\Omega \times \Omega)$, then the equation equals $||K||_2^2$ □

Trace Classes

Def. (10.10.5.6) [Trace Classes]. Let $\mathcal{H}$ be a Hilbert space, $\{e_i\}, \{f_i\}$ are two orthonormal basis, $A \in B(\mathcal{H})$. Let $|A| = (A^*A)^{1/2}$ which is positive, then

$$\sum_i (|A|e_i, e_i) = \sum_i (|A|^{1/2}e_i, |A|^{1/2}e_i) = \sum_i |||A|^{1/2} f_i|| = \sum_i (|A|f_i, f_i)$$

by(10.10.5.1), thus we can define $||A||_1 = \sum_i (|A|e_i, e_i)$, and say A is a **trace class** if $||A||_1 < \infty$. The space of trace classes is denoted by $S_1(\mathcal{H})$.

A trace-class A is clearly compact as $|A|$ is a limit of f.d. range operators.(Use diagonalization, then there are only countably many eigenvectors of $|A|$).

Prop. (10.10.5.7). If $A \in \mathcal{B}(\mathcal{H})$, then the following are equivalent:

- $A \in S_1(\mathcal{H})$.
- $|A|^{1/2} \in S_2(\mathcal{H})$.
- $|A|$ is a product of two elements in $S_2(\mathcal{H})$.
- A is a product of two elements in $S_2(\mathcal{H})$.

Proof: $1 \to 2 \to 3$ is clear, for $3 \to 4$: if $|A| = TS$, then by polar decomposition $A = U|A| = (UT)S$, and $UT \in S_2(\mathcal{H})$ by(10.10.5.2), so A is a product of two elements in $S_2(\mathcal{H})$.

$4 \to 3$ is similar to $3 \to 4$.

$3 \to 1$: if $A = BC$ where $B, C \in S_2(\mathcal{H})$, then $B^* \in S_2(\mathcal{H})$ also by(10.10.5.2), and

$$||A||_1 = \sum_i (Ae_i, e_i) = \sum_i (Ce_i, B^*e_i) \le \sum_i ||Ce_i||||B^*e_i|| \le ||C||_2||B^*||_2 < \infty$$

□

Lemma (10.10.5.8). if T is a positive trace-class and $S\in\mathcal{B}(\mathcal{H})$, then if x_i is an orthonormal basis of $\mathcal{H}$, then
$$\sum_i (STx_i,x_i)\leq ||S||||T||_1$$
is absolutely convergent, and is independent of the basis chosen.

Proof: Let e_i be the basis of eigenvectors of T of eigenvalues $\lambda_i>0$, then $\sum_i\lambda_i<\infty$ by(10.10.5.7), and
$$(STx_i,x_i)=\sum_j(x_i,e_j)(STe_j,x_i)=\sum_j\lambda_j(x_i,e_j)(Se_j,x_i)$$
And
$$\sum_i\sum_j\lambda_j|(x_i,e_j)(Se_j,x_i)|\leq\sum_j\lambda_j||e_j||||Se_j||\leq||S||\sum\lambda_\alpha<\infty.$$
Moreover:
$$\sum_i(STx_i,x_i)=\sum_i\sum_j((x_i,e_j)STe_j,x_i)=\sum_i\sum_j(STe_j,(e_j,x_i)x_i)=\sum_j(STe_j,e_j).$$
□

Prop. (10.10.5.9) [Singular Trace]. If $T\in S_1(\mathcal{H})$ and x_α is an orthonormal basis of $\mathcal{H}$, then $\sum(Tx_\alpha,x_\alpha)$ absolutely converges, and is independent of the basis chosen, called the **singular trace** $\operatorname{tr}T$ of T. The singular trace is a positive definite linear functional on $S_1(\mathcal{H})$.

Proof: Use polar decomposition $T=U|T|$(10.10.4.20) and notice $|T|$ is a positive trace class(10.10.5.7) and then use(10.10.5.8). □

Prop. (10.10.5.10) [Trace of Integral Operators]. Let A,B be L^2 integral operators on a σ-finite measure space Ω with kernel $K_1(x,y),K_2(x,y)\in L^2(\Omega\times\Omega)$, then AB is also an integral operator with kernel
$$\int K_1(x,z)K_2(z,y)dz,$$
and
$$\operatorname{tr}(AB)=\int\int K_1(x,y)K_2(y,x)dxdy.$$

Proof: The formula for integral kernel is an immediate consequence of Fubini-Tonelli theorem. For the trace, observe that A^* is the integral operator with kernel $\overline{K_1(y,x)}$(10.10.2.10), thus
$$\begin{aligned}\operatorname{tr}(AB)&=\sum_i(ABe_i,e_i)=\sum_i(Be_i,A^*e_i)\\&=\sum_i\sum_k(e_k,A^*e_i)(Be_i,e_k)\\&=\sum_i\sum_k(e_k\otimes\overline{e_i},K_1^*)(K_2,e_k\otimes\overline{e_i})\\&=(K_2,K_1^*)=\int\int K_1(x,y)K_2(y,x)dxdy\end{aligned}$$
as $\{e_i\otimes\overline{e_k}$ is a Hilbert basis for $\Omega\times\Omega$(10.4.6.4). □

Prop. (10.10.5.11) [Properties of Trace Classes].

1. $S_1(\mathcal{H})$ is a two-sided *-ideal of $\mathcal{L}(\mathcal{H})$.
2. $||\cdot||_1$ is a norm on $S_1(\mathcal{H})$.
3. If $T\in S_1(\mathcal{H})$, then $\operatorname{tr} T^* = \overline{\operatorname{tr} T}$.
4. For any $T\in S_1(\mathcal{H})$ and $S\in L(\mathcal{H})$, $\operatorname{tr}(ST)=\operatorname{tr}(TS)$, and $|\operatorname{tr}(ST)|\leq ||S||||T||_1$. In particular the singular trace is a bounded linear functional on $S_1(\mathcal{H})$.

Proof: Let $S,T\in S_1(\mathcal{H})$, $S=V|S|, T=W|T|$, $S+T=X|S+T|$ where V,W,X are unitary, then $|S+T|=X^*(S+T)$ is positive compact, so it has an orthonormal eigenbasis e_n by(10.10.4.16), so

$$\sum(|S+T|x_i,x_i)=\sum(X^*V|S|x_i,x_i)+\sum(X^*W|S|x_i,x_i)\leq ||S||_1+||T_1||$$

by(10.10.5.8). So $S+T$ is a trace class, and $||S+T||_1\leq ||S||_1+||T||_1$.

Now if U is unitary and $T\in S_1(\mathcal{H})$, then $(UT)^*UT=T^*T$, so UT is a trace class, and $(TU)^*TU=U^{-1}TU$ has $|TU|=U^{-1}|T|U$, so TU is also a trace class. Moreover, $\operatorname{tr}(TU)=\sum(TUx_i,x_i)=\sum(UTUx_i,Ux_i)=\operatorname{tr}(UT)$.

Then notice very $S\in L(\mathcal{H})$ is a linear combination of four unitary operator(10.10.4.9), so the proposition is true, and if T is a trace class, then $T=V|T|$, and $T^*=|T|V^*$ is also a trace class.

4: $|\operatorname{tr}(ST)|\leq ||SV||||T||_1=||S||||T||_1$ by(10.10.5.8). □

Prop. (10.10.5.12) [Trace Class as a Banach Space]. Let $S_0(\mathcal{H})$ be the space of operators of f.d. range, then the map

$$\rho: S_1(\mathcal{H})\to S_0(\mathcal{H})^*:\rho(A):C\mapsto \operatorname{tr}(CA)$$

is an isometric isomorphism. In particular, $S_1(\mathcal{H})$ is a Banach space, by(10.8.3.1).

Proof: Clearly ρ is a linear map as singular trace is. For $T\in S_1(\mathcal{H})$, $||\rho(T)||\leq ||T||_1$ by(10.10.5.11).

If $\Phi\in S_0(\mathcal{H})^*, g,h\in\mathcal{H}$, consider $g\otimes h^*\in S_0(\mathcal{H})$ that $g\otimes h^*(v)=(v,h)g$, then $B(g,h)=\Phi(g\otimes h^*)$ is a sesquilinear form on H that is bounded by $||\Phi||$. Thus by Lax-Milgram(10.10.2.7), there is a unique $T\in\mathcal{B}(\mathcal{H})$ that $B(g,h)=(g,Th)$.

Now let $A=T^*$ and let $A=U|A|$ be the polar decomposition, $\mathcal{E}$ an orthonormal basis of $\mathcal{H}$ and $S\subset\mathcal{E}$ a finite subset, define

$$C_S=(\sum_{e\in S}e\otimes e^*)U^*=\sum_{e\in S}e\otimes(Ue)^*.$$

Then C_S is of f.d. and $||C_S||\leq 1$. And:

$$\sum_{e\in S}(|A|e,e)=\sum_{e\in S}(U^*Ae,e)=\sum_{e\in S}(e,TUe)=\sum_{e\in S}B(e,Ue)=\sum_{e\in S}\Phi(e\otimes(Ue)^*)=\Phi(C_S).$$

So $||A||_1\leq ||\Phi||$.

If C is any operator of f.d. range that $C=\oplus g_k\otimes h_k^*$, then

$$\Phi(C)=\sum\Phi(g_k\otimes h_k^*)=\sum B(g_k,h_k)=\sum(Ag_k,h_k)=\sum\operatorname{tr}(A(g_k\otimes h_k^*))=\operatorname{tr}(AC)=\rho(A)(C)$$

so the image is A is just Φ. This shows that ρ is surjective and moreover $||A||_1=||\rho(A)||$, so we are done. □

10.11 Analysis on Locally Compact Groups

Main references are [Fol15], [Bum98].

All representations in this section are assumed to be over $\mathbb{C}$.

1 Locally Compact Groups

Def. (10.11.1.1) [Left and Right Regular Actions]. On a topological group G, the **left regular action** and **right regular action** are defined as follows: $L_y f(x) = f(y^{-1}x), R_y f(x) = f(xy)$.

Def. (10.11.1.2) [Involution]. For $f \in C_c(G)$ or $f \in L^p(G)$ for some p, let $\widetilde{f}(x) = \overline{f(x^{-1})}$.

Prop. (10.11.1.3) [Translation is Continuous]. If $f \in C_c(G)$, then f is left and right uniformly continuous. Equivalently, $G \to C_c(G) : y \mapsto R_y(f)$ and $y \mapsto L_y(f)$ are continuous group homomorphisms from G to $C_c(G)$.

Proof: Cf.[Folland Abstract Harmonic Analysis P38]. □

Prop. (10.11.1.4). Locally compact Hausdorff group is normal.

Proof: Notice that by choosing a precompact symmetric open neighbourhood U of identity, there exists a σ-compact clopen subgroup H. So H can σ-locally refine every open cover, thus G can, too. So by (3.3.7.2) G is paracompact. As a topological group, G is regular, thus G is normal by (3.3.7.6). □

Prop. (10.11.1.5) [Dirac sequence]. For a locally compact Hausdorff group G , a **Dirac sequence** is a sequence $f_n \in C_c(G)$ that $f_n \to \delta_1$ in the weak topology of $Meas_c(G)$.

Dirac sequences exist.

Proof: □

Prop. (10.11.1.6). Every locally compact group G has a subgroup G_0 that is clopen and σ-compact.

Proof: Let U be a symmetric precompact nbhd of 1 in G, then let $U_n = U^n$, then $\overline{U_n} \subset U_{n+1}$, so let $G_0 = \cup_n U^n = \cup \overline{U_n}$, then it is open because each U_n does, and compact because each $\overline{U_n}$ does. □

Prop. (10.11.1.7). If G is locally compact Hausdorff, and H is subgroup that is locally compact in the induced topology, then H is closed in G.

Proof: By hypothesis there exists an open nbhd U of $e \in G$ that $U \cap H$ has compact closure $K \subset H$. But then K is also compact in G thus closed. So K is the closure of $U \cap H$ in G. Choose a symmetric open nbhd V of $e \in G$ that $VV \subset U$, and suppose $x \in \overline{H}$, then $x^{-1} \in \overline{H}$ and $Vx^{-1} \cap H \neq \varnothing$. Let $y \in Vx^{-1} \cap H$. For any nbhd U_i of $e \in G$, choose $x' \subset xU_i \cap H$, then $yx' = yx(x^{-1}x') \in yxU_i$ and also $yx' \in H$, $yx' \in Vx^{-1}xV \subset U$. By arbitrariness of U_i, this means $yx \in \overline{U \cap H} = K \subset H$, thus $x \in H$, and H is closed. □

Integration on Locally Compact Groups

Def. (10.11.1.8)[Positive Linear Functional]. A **positive linear functional** is a linear functional I on $C_c(X)$ that $I(f) \geq 0$ whenever $f \geq 0$. How is this definition compatible with that of(10.10.3.10)**?**.

Lemma (10.11.1.9) [Positive Linear Functional is Continuous]. For a LCH space X, a positive linear functional(10.11.1.8) I on $C_c(X)$ is automatically continuous, where $C_c(X)$ is given compact convergence topology as in(10.9.2.1).

Proof: We need to prove that for any compact subset K of X, there is a constant C_K that for any $f\in C(G)$ with support in K, we have $|I(f)|\leq C_K||f||_\infty$.

Given any K, choose by Urysohn lemma a $\varphi\in C_c(X,[0,1])$ that $\varphi=1$ on K, so if $\operatorname{Supp} f\subset K$, then $|f|\leq ||f||_\infty\varphi$, thus the positivity of I shows that $|I(f)|\leq I(\varphi)||f||_\infty$. □

Prop. (10.11.1.10) [Riesz-Markov-Kakutani Representation Theorem]. Let X be a locally compact Hausdorff space.

- If I is a positive linear functional(10.11.1.8) on $C_c(X)$, there is a unique Radon measure μ on X such that $I(f)=\int f d\mu$. Moreover,
$$\mu(U)=\sup\{I(f):f<U\}\text{ for }U\text{ open},$$
$$\mu(K)=\inf\{I(f):f>\chi_K\}\text{ for }K\text{ compact}.$$
- If I is a continuous linear functional on $C_0(X)$, there is a unique regular complex Borel measure μ on X that $I(f)=\int f d\mu$.

In particular if X is compact, $M(X)$ the space of Radon measures on X is the dual space of $C(X)$.

Proof: Cf.[Real Analysis Folland P212]. □

Prop. (10.11.1.11) [Haar Measure]. A left(right) **Haar measure** on a topological group G is a nonzero Radon measure(10.4.1.9) μ on G that satisfies $\mu(xE)=\mu(E)(\mu(Ex)=\mu(E))$. A Radon measure μ is a Haar measure iff it satisfies $\int L_y f d\mu=\int f d\mu$ for any $f\in C_c^+(G)$ and $y\in G$(10.11.1.3).

Every Locally compact group G possesses a unique left Haar measure μ.

Proof: If μ is a Haar measure, then $\int L_y f d\mu=\int f d\mu$ by approximation by simple functions(10.4.8.3). Conversely, if $\int L_y f d\mu=\int f d\mu$ for any $f\in C_c(G)$, then it holds for all $f\in C_c(G)$, hence $\mu(xE)=\mu(E)$ by Riesz-Markov-Kakutani representation theorem(10.11.1.10).

For $f,\varphi\in C_c^+(G)$, define $(f:\varphi)$ to be the infimum of all finite sms $\sum_{i=1}^n c_i$ that $f\leq\sum_{i=1}^n c_i L_{x_i}\varphi$ for some $x_1,\ldots,x_n\in G$. This makes sense because f has finite support so can be covered by f.m. translation of any open set. This quantity satisfies the following properties:

- $(f:\varphi)=(L_y f:\varphi)$ for any $y\in G$.
- $(f_1+f_2:\varphi)\leq(f_1:\varphi)+(f_2:\varphi)$.
- $(cf:\varphi)=c(f:\varphi)$.
- $(f_1:\varphi)\leq(f_2:\varphi)$ for $f_1\leq f_2$.
- $(f:\varphi)\geq||f||_{sup}/||\varphi||_{sup}$.
- $(f:\varphi)\leq(f:\psi)(\psi:\varphi)$ for any $\psi\in C^+(G)$.

Now choose a $f_0\in C_c^+(G)$ and define $I_\varphi(f)=\frac{(f:\varphi)}{(f_0,\varphi)}$ for $f,\varphi\in C_c^+(G)$. Then I_φ is left-invariant, subadditive, homogeneous of degree 1, and monotone. Moreover, it satisfies $(f_0:f)^{-1}\leq I_\varphi(f)\leq(f:f_0)$.

Let X_f be the interval $[(f_0:f)^{-1},(f:f_0)]$, and let $X=\prod_{f\in C_c^+(G)}X_f$, then for each nbhd V of $1\in G$, let $K(V)$ be the closure in X of $\{I_\varphi|\operatorname{Supp}(\varphi)\subset V\}$, then these sets satisfy finite intersection property. So by compactness, there is an I contained in every $K(V)$. Which means for any nbhd V of $1\in G$ and $\varepsilon>0$ and $f_1,\ldots,f_n\in C_c^+(G)$, there exists $\varphi\in C_c^+(V)$ that $|I(f_i)-I_\varphi(f_i)|<\varepsilon$.

Then by some argument, I commutes with left translation, addition and multiplication by positive scalars. Now extend I to a positive linear functional on $C_c(G)$, and then use Riesz-Markov-Kakutani representation theorem(10.11.1.10) to finish. □

Lemma (10.11.1.12). For any $f_1, f_2 \in C_c^+(G)$ and $\varepsilon > 0$, there is a neighborhood V of $1 \in G$ that in the notation in the proof of(10.11.1.11), $I_\varphi(f_1) + I_\varphi(f_2) \leq I_\varphi(f_1 + f_2) + \varepsilon$ whenever $\mathrm{Supp}(\varphi) \subset V$.

Proof: Let $g \in C_c^+(G)$ that $g = 1$ on $\mathrm{Supp}(f_1 + f_2)$ and $\delta > 0$, let $h_i = f_i/(f_1 + f_2 + \delta g)$, then $h_i \in C_c^+(G)$ and there is a nbhd V of $1 \in G$ s.t. $|h_i(x) - h_i(y)| < \delta$ for $i = 1, 2$ and $y^{-1}x \in V$. Take $\varphi \in C_c^+(G)$ with $\mathrm{Supp}(\varphi) \subset V$. If $h \leq \sum c_i L_{x_i}\varphi$, then

$$f_i(x) = h(x)h_i(x) = \sum c_j\varphi(x_j^{-1}x)h_i(x) \leq \sum c_j\varphi(x_j^{-1}x)[h_i(x_j) + \delta]$$

because whenever $\varphi(x_j^{-1}x) \neq 0$, $|h_i(x) - h_i(x_j)| < \delta$. As $h_1 + h_2 < 1$,

$$(f_1 : \varphi) + (f_2 : \varphi) \leq \sum c_j[h_1(x_j) + \delta] + \sum c_j[h_2(x_j) + \delta] \leq \sum c_j[1 + 2\delta]$$

which implies

$$I_\varphi(f_1) + I_\varphi(f_2) \leq (1 + 2\delta)I_\varphi(h) \leq (1 + 2\delta)[I_\varphi(f_1 + f_2) + \delta I_\varphi(g)].$$

Notice δ is arbitrary, thus we can choose δ small enough that the assertion is true. □

Prop. (10.11.1.13). If G is a locally compact group and μ is a Haar measure on G, then for any open subset U of G, $\mu(U) > 0$.

Proof: By inner regularity, $\mu(K) > 0$ for some compact subset K. Suppose $\mu(U) = 0$ for an open subset U, then f.m. translates of U covers K, contradiction. □

Prop. (10.11.1.14). Integration of a nontrivial character on a compact group G w.r.t. the Haar measure is 0.

Proof: $\int f(x)d\mu(x) = \int f(yx)d\mu(yx) = f(y)\int f(x)d\mu(x)$. Now choose a y that $f(y) \neq 1$. □

Def. (10.11.1.15) [Modular Function]. For a left Haar measure μ on a locally compact group G, $\mu_x(E) = \mu(Ex)$ is also a left Haar measure, so there is a $\Delta(x)$ that $\mu_x = \Delta(x)\mu$. Then the function Δ is a group homomorphism from G to $\mathbb{R}^+$, which is called the **modular function** of G.

G is called **unimodular** iff $\Delta = 1$, i.e. a left Haar measure is also a right Haar measure. Obviously, a locally compact Abelian group is unimodular.

Prop. (10.11.1.16). Δ is a continuous group homomorphism from G to $\mathbb{R}^+$, and

$$\int R_y f d\mu = \Delta(y^{-1}) \int f d\mu.$$

equivalently, $d\mu(xy_0) = \Delta(y_0)d\mu(x)$.

Proof: For the continuity of Δ, because $y \mapsto R_y(f)$ is continuous for each f(10.11.1.3), so $y \mapsto \int R_y f d\lambda$ is continuous, as μ is Radon measure, so by the equation just proved, Δ is continuous.

Now for any measurable function E, $\chi_E(xy) = \chi_{Ey^{-1}}(x)$, thus

$$\int \chi_E(xy)d\mu = \mu(Ey^{-1}) = \Delta(y^{-1})\mu(E) = \Delta(y^{-1}) \int \chi_E(x)d\mu(x),$$

which proves the equation for $f = \chi_E$. Then the general case follows from approximating f by simple functions(10.4.8.4). □

Prop. (10.11.1.17) [Involution Measure]. If μ is a left Haar measure and ρ is defined by $\rho(E) = \mu(E^{-1})$, then ρ is a right Haar measure, and $d\rho(x) = d\mu(x^{-1}) = \Delta(x^{-1})d\mu(x)$.

Proof: Notice

$$\int R_y(f)(x)\Delta(x^{-1})d\mu(x) = \Delta(y)\int f(xy)\Delta((xy)^{-1})d\mu(x) = \int f(x)\Delta(x^{-1})d\mu(x),$$

so $\Delta(x^{-1})d\mu(x)$ is a right Haar measure, hence $cd\mu(x^{-1})$ for some c. If $c \neq 1$, we let U be a precompact symmetric nbhd U of 1 that $|\Delta(x^{-1}) - 1| \leq \frac{1}{2}|c-1|$ on U. But then $|c-1|\mu(U) = |\int_U (\Delta(x^{-1}) - 1)d\mu(x)| \leq \frac{1}{2}|c-1|\mu(U)$, contradiction. □

Prop. (10.11.1.18). For a compact group K of G, Δ is trivial on K. So compact group is unimodular, and if $G/[G,G]$ is compact, then it is also unimodular.

Proof: These all follow from(10.11.1.16) and the fact that a compact subgroup of $\mathbb{R}^+$ is $\{1\}$, and $\mathbb{R}$ is Abelian. □

Prop. (10.11.1.19) [Lie Type Case]. Suppose G is an open subset of K^N where K is a local field, and the left translation is given by

$$xy = A(x)y + b(x)$$

then the Haar measure of G is given by $|\det A(x)|^{-1}dx$, where dx is the Lebesgue measure on $\mathbb{R}^N$.

Also when we want to calculate the right Haar measure, consider the right action.

Proof: Use change of variable formula, because $A(xy) = A(x)A(y)$, and

$$|\det A(ax)|^{-1}d(ax) = |\det A(ax)|^{-1}d(A(a)x + b(x)) = |\det A(x)|^{-1}dx.$$

□

Cor. (10.11.1.20) [Examples of Lie Group Measures].

- $dx/|x|$ is the Haar measure on $\mathbb{R}^*$.
- $dxdy/x^2 + y^2$ is the Haar measure on $\mathbb{C}^*$.
- $x_{11}x_{22}^2 \ldots x_{nn}^n \prod_{i<j} dx_{ij}$(resp. $x_{11}^n x_{22}^{n-1} \ldots x_{nn} \prod_{i<j} dx_{ij}$) are the left(resp. right) Haar measure on the group of upper-triangular matrixes in $GL(n,\mathbb{R})$.
- $\prod_{i<j} dx_{ij}$ is the left and right Haar measure on the group of upper-triangular unipotent matrices in $GL(n,\mathbb{R})$.
- $|\det T|^{-n}dT$ is the left and right Haar measure on the group $GL(n,\mathbb{R})$, where dT is the Lebesgue measure on $M_n(\mathbb{R}) = \mathbb{R}^{n^2}$.
- The $ax+b$ group G of all affine (invertible)translations of $\mathbb{R}$ has left measure $dadb/a^2$ and right Haar measure $dadb/a$.

Proof: Clear. □

Prop. (10.11.1.21) [Modular Function of Lie Groups]. If G is a Lie group and Ad is the adjoint action of G on $\mathfrak{g}$, then $\Delta(x) = |\det \mathrm{Ad}(x^{-1})|$.

Proof: Let G be a Lie group of dimension m, then the Haar measure on a Lie group is given by the absolute value of a left-invariant m-form ω. Now for any $X\in\mathfrak{g}$ corresponding to a left invariant vector space L_X,

$$d(R_g)_p((L_X)_p)=(L_{\mathrm{Ad}(g^{-1})X})_{pg}$$

by(11.7.3.5), so $R_g^*\omega=\det(\mathrm{Ad}(g^{-1}))\omega$. So $\Delta(g)\omega=R_g^*|\omega|=|\det(\mathrm{Ad}(g^{-1}))||\omega|$. □

Cor. (10.11.1.22) [Unimodular Lie Groups]. Any Abelian/compact/semisimple/reductive/nilpotent Lie group is unimodular.

Proof: The nilpotent case follows directly from(10.11.1.21), as $\det\mathrm{Ad}(x)=\exp(\mathrm{tr}\,\mathrm{ad}(x))$ and $\mathrm{ad}(x)$ is nilpotent. The compact case is by(10.11.1.18). For the semisimple case, $G=[G,G]$ because $\mathfrak{g}=[\mathfrak{g},\mathfrak{g}]$(2.5.2.4) and it is connected, so we are done by(10.11.1.18). For the reductive case: Cf.[Kna96]P467. □

Convolutions

Def. (10.11.1.23)[Convolution of Measures]. If μ,ν are two complex(hence finite) Radon measures on G, the map

$$I(\varphi)=\int\int\varphi(xy)d\mu(x)d\nu(y)$$

is clearly a linear functional on $C_c(G)$ that satisfies $|I(\varphi)|\le||\varphi||_{\sup}||\mu||||\nu||$, so it defines a measure on G by Riesz representation(10.11.1.10), called the **convolution** of μ and ν, denoted by $\mu*\nu$, that $||\mu*\nu||\le||\mu||||\nu||$.

Prop. (10.11.1.24) [Measure Algebra].

- The convolution of measure is associative.
- $\delta_x*\delta_y=\delta_{xy}$.
- The convolution of measure is commutative iff G is commutative.
- The convolution makes $M(G)$ into a unital Banach algebra, called the **measure algebra** of G.

Proof: 1: If $\varphi\in C_c(G)$, then

$$\begin{aligned}\int_G\varphi d[\mu*(\nu*\sigma)]&=\int\int\varphi(xy)d\mu(x)d(\nu*\sigma)(y)\\&=\int\int\int\varphi(xyz)d\mu(x)d\nu(y)d\sigma(z)\\&=\int\int\varphi(yz)d(\mu*\nu)(y)d\sigma(z)\\&=\int\varphi d[(\mu*\nu)*\sigma]\end{aligned}$$

by Fubini theorem, which shows $\mu*(\nu*\sigma)=(\mu*\nu)*\sigma$.

2:

$$\int\int\varphi d(\delta_x*\delta_y)=\int\int\varphi(uv)d\delta_x(u)d\delta_y(v)=\varphi(xy)=\int\varphi d\delta_{xy}.$$

3: If G is commutative, then $\varphi(xy)=\varphi(yx)$, then the commutativity follows from Fubini theorem. The converse follows from item2.

4 It is a Banach algebra because $||\mu * \nu|| \leq ||\mu||||\nu||$(10.11.1.23). And the point measure δ_1 is the unit:

$$\int \varphi d(\delta * \mu) = \int\int \varphi(xy)d\delta(x)d\mu(y) = \int \varphi(y)d\mu(y)$$

shows $\delta * \mu = \mu$ for any μ, and similarly $\mu * \delta = \mu$, so δ is the identity. □

Prop. (10.11.1.25) [Involution of Measure]. $M(G)$ has a canonical involution that preserves measure:

$$\mu \mapsto \mu^* : \mu^*(E) = \overline{\mu(E^{-1})}.$$

Proof: μ^* clearly satisfies $||\mu^*|| = \mu^*(G) = \mu(G) = ||\mu||$. And for any $\varphi \in C_c(G)$,

$$\varphi d(\mu*\nu)^* = \int \varphi(x^{-1})d(\overline{\mu * \nu})(x) = \int \varphi((xy)^{-1})d\overline{\mu}(x)d\overline{\nu}(y) = \int\int \varphi(yx)d\mu^*(x)\nu^*(y) = \int \varphi d(\nu^* * \mu^*),$$

which shows $(\mu * \nu)^* = \nu^* * \mu^*$. □

Def. (10.11.1.26) [L^1 Group Algebra]. Fix a Haar measure $d\mu$ on G, $L^1(G)$ embeds into the $M(G)$ by identifying f with the measure $f(x)d\mu(x)$, and this is an isometry.

So the convolution and involution can be defined on $L^1(G)$, and the outcome turns out to be a.e. defined and in $L^1(G)$ too:

$$f * g(x) = \int f(y)g(y^{-1}x)dy$$

by Fubini-Tonelli theorem, and the involution

$$f^*(x) = \Delta(x^{-1})\overline{f(x^{-1})}.$$

Proof:

$$(f * g)(\varphi) = \int\int \varphi(xy)f(x)g(y)dxdy = \int\int \varphi(y)f(x)g(x^{-1}y)dxdy = \int \varphi(y)(\int f(x)g(x^{-1}y)dx)dy.$$

$$(fd\mu)^* = \overline{(fd\mu)(x^{-1})} = \overline{f(x^{-1})}\Delta(x^{-1})d\mu(x)\text{(10.11.1.17)}.$$

□

Prop. (10.11.1.27). The convolution $f * g$ can be calculated in multiple ways by left invariance and(10.11.1.17):

$$f*g(x) = \int f(y)g(y^{-1}x)dy = \int f(xy)g(y^{-1})dy = \int f(y^{-1})g(yx)\Delta(y^{-1})dy = \int f(xy^{-1})g(y)\Delta(y^{-1})dy.$$

In particular, if G is unimodular, then it can be calculated anyway you want.

Prop. (10.11.1.28). For $1 \leq p < \infty$, the left and right translations of G on $L^p(G)$ are all continuous.

Proof: Cf.[Fol15]P58. □

Prop. (10.11.1.29) [L^p-Estimate]. If $1 \leq p < \infty$, $f \in L^1(G)$ and $g \in L^p(G)$, then

- $f * g \in L^p(G)$, and $||f * g||_p \leq ||f||_1||g||_p \leq ||f||_p||g||_p$.
- If G is unimodular or f has compact support, then the same as above holds for $g * f$.

Proof: 1: By Minkowski's inequality(10.4.6.5),

$$||f*g||_p = |\int f(y)L_y g dy||_p \le \int |f(y)|||L_y g||_p dy = ||f||_1||g||_p.$$

2: This is similar, using(10.11.1.27). □

Prop. (10.11.1.30) [Convolution].

- Suppose G is unimodular and $f\in L^p(G), g\in L^q(G)$ with $1/p+1/q=1, 1<p<\infty$, then $f*g\in C_0(G)$, and $||f*g||_{sup}\le ||f||_p||g||_q$.
- Suppose $f\in L^1(G), g\in L^\infty(G)$, then $f*g$ is left uniformly continuous, and $g*f$ is right uniformly continuous.

Proof: Cf.[Fol15]P57, P58. □

Prop. (10.11.1.31) [Approximate Identity]. Let $\mathcal{U}$ be a neighborhood base of $1\in G$. A family of L^∞ functions $\{\varphi_U\}$ are called an **approximate identity** if:

1. $\int_0^1 \Phi_U(x)dx = 1$.
2. $\sup\int_0^1 |\Phi_U(x)|dx < \infty$.
3. For any $\delta>0, \int_{G\setminus U}|\Phi_U(x)|dx \to 0$ as $N\to+\infty$.

For any approximate identity, if $1\le p<\infty$ and $f\in L^p(G)$ for $1\le p<\infty$, or $p=\infty$ and f is left uniformly continuous, then $\Phi_U * f\to f\in L^p(G)$.

Proof: Cf.[Fol15]P58. □

Homogenous Spaces

Def. (10.11.1.32) [Notations]. If G is a locally compact group with left Haar measure dx and H is a closed subgroup with left Haar measure $d\xi$, let $q: G\to G/H$ be the quotient map.

Prop. (10.11.1.33). If G is a σ-compact locally compact group and S is a transitive G-space that is locally compact and Hausdorff, then if $s_0\in S$ and $\mathrm{Stab}(s_0)=H$, then $G/H\cong S$ as G-spaces.

Proof: Cf,[Folland P60]. □

Lemma (10.11.1.34). If $E\subset G/H$ is compact, then there is a compact $K\subset G$ that $q(K)=E$.

Proof: Choose a precompact nbhd V of 1 in G, since q is open, the set $q(xV)$ is an open cover of E, so there are f.m. x_i that $E\subset \cup q(x_iV)$. Then let $K=q^{-1}(E)\cap(\cup x_i\overline{V})$, this will suffice. □

Def. (10.11.1.35) [Fundamental Domain]. A **fundamental domain** for a group Γ acting discontinuously on a locally compact second countable Hausdorff space X is an Borel subset $F\in X$ that:

- $\cup_{\gamma\in\Gamma}\gamma F=\mathcal{H}$.
- if $\gamma\ne 1\in\Gamma$, then $\gamma F\cap F=\varnothing$.

Then fundamental domains exist.

Proof: The quotient space $G\backslash\Gamma$ is locally compact second countable, thus there is a countable set of precompact open basis $\{B_i\}$ for $G\backslash\Gamma$, and a countable set of precompact open basis $\{C_i\}$ for X. For each $\overline{x}\in G\backslash\Gamma$, choose $\overline{x}\in B_{i(\overline{x})}$ and choose a preimage $x\in X$ and a nbhd $C_{i(x)}$ that $C_{i(x)}\cap\gamma(C_{i(x)})=\varnothing$ for any $\gamma\ne 1$, then there is a nbhd $B_{j(x)}$ contained in the image of $C_{i(x)}$. Then we can take a precompact preimages of $B_{j(\overline{x})}$ in $C_{i(x)}$(by(10.11.1.34)), labeled by U_i. Then U_i maps isomorphically to their images in $G\backslash\Gamma$ and covers $G\backslash\Gamma$.

Now take $V_1 = W_1 = U_1$, and $W_{n+1} = U_{n+1} \backslash \cup_{\gamma\in\Gamma} \gamma(V_n), V_{n+1} = V_n \cup W_{n+1}$. Then $\cup V_i$ is a fundamental domain. □

Prop. (10.11.1.36) [Projection of Functions]. There is a map $P : C_c(G) \to C_c(G/H) : Pf(xH) = \int_H f(x\xi)d\mu(\xi)$. Pf is continuous and this map is well-defined and surjective.

And $\mathrm{Supp}(Pf) \subset q(\mathrm{Supp}\, f)$, and if $\varphi \in C_c(G/H)$, then $P((\varphi \circ q)f) = \varphi Pf$.

Proof: Pf is continuous because f is left uniformly continuous(10.11.1.3). By(10.11.1.37), there is a $g \geq 0 \in C_c(G)$ that $Pg = 1$ on $\mathrm{Supp}\, \varphi$. Let $f = (\varphi \circ f)g$, then $Pf = \varphi(Pg) = \varphi$. □

Lemma (10.11.1.37). If $F \in G/H$ is compact, then there is a $f \in C_c(G)$ that $f \geq 0$ and $Pf = 1$ on F.

Proof: Let E be a precompact nbhd of F in G/H, choose a compact $K \subset G$ that $q(K) = \overline{E}$ by(10.11.1.34). Choose $g \in C_c(G) \geq 0$ that is positive on K and $\varphi \in C_c(G/H)$ that is 1 on F and vanish outside E, then set

$$f = \frac{\varphi \circ q}{Pg \circ q} g$$

then $f \geq 0$ and $Pf = (\varphi/Pg)Pg = \varphi$. □

Prop. (10.11.1.38) [Quotient Measure Regular Case]. If G is a locally compact group and H is a closed subgroup, then there is a G-invariant positive Radon measure μ on G/H iff $\Delta_G|_H = \Delta_H$. And if this is the case, then this measure is unique up to constant, and if suitably chose, satisfies:

$$\int_G f(x)dx = \int_{G/H} Pf d\mu = \int_{G/H} \int_H f(x\xi)d\xi d\mu(xH).$$

for any $f \in C_c(G)$.

Proof: Cf.[Folland Abstract Analysis P62]. □

Cor. (10.11.1.39) [Decomposition of Measure]. If G is a unimodular locally compact group and P, K be closed subgroups s.t. $P \cap K$ is compact and $G = PK$. Let $d_L p, d_R k$ be the left and right Haar measure on P, K respectively, then a Haar measure on G is given by

$$\int_G f(g)dg = \int_K \int_P f(pk)d_L p d_R k.$$

Proof: Consider $H = P \times K$ and $M = P \cap K$ embedded diagonally in H, then there is a homeomorphism $H/M \cong G$ given by $(p, k) \mapsto pk^{-1}$. Then we can verify both side are H-invariant quotient measure on $G \cong H/M$, so by uniqueness in(10.11.1.38), the equation is true. □

Def. (10.11.1.40) [Rho-Functions]. If G is a locally compact subgroup and H is a closed subgroup. Let $\Delta = \Delta_G/\Delta_H$. Let $\mathcal{S}(G, \Delta)$ be the space of continuous functions on G that satisfies

- for any $h \in H$, $f(hg) = \Delta(h)f(g)$.
- f is compactly supported in $H\backslash G$.

Lemma (10.11.1.41). Let G be a locally compact group and H a closed subgroup, then there is a continuous function $f_0 : G \to [0, \infty)$ that

- $f_0^{-1}((0,\infty)) \cap Hx \neq \varnothing$ for any $x \in G$.
- Supp $f_0 \cap HK$ is compact for any compact group K of G.

Proof: Cf.[Folland, P64]. □

Lemma (10.11.1.42). If $f \in C_c(G)$ and $Pf = 0$, then $\int f\rho = 0$ for any rho-function ρ. In fact, this is true if ρ is allowed to take value 0.

Proof: Cf.[Folland P65]. □

Lemma (10.11.1.43). There is an operator $p : C_c(G) \to C(G)$ given by

$$p(f)(g) = \int_H f(hg)\Delta_G^{-1}(h)d\mu_H(h).$$

Then p is right G-invariant, and $p(ff') = fp(f')$ for any $f' \in C_c(G)$ and $f \in C(G)$ that is H-invariant.

- The image of p is $\mathcal{S}(G,\Delta)$, and if $s \geq 0 \in S(G,\Delta)$, then there is a non-negative $f \geq 0 \in C_c(G)$ that $p(f) = s$.
- If $p(f) = 0$, then $\int_G f(x)d\nu_G(x) = 0$, where $d\nu_G$ is a right Haar measure on G.

Proof: 1: It is clearly that $p(f)(gh) = \Delta(h)p(f)(g)$, and let f_0 be defined as in(10.11.1.41), then $s_0 = p(f_0)$ is positive-valued. Now for any $s \in \mathcal{S}(G,\Delta)$, $p(ss_0^{-1}f_0) = ss_0^{-1}p(f_0) = s$, and $sf_0 \in C_c(G)$ by hypothesis.

2: If $p(f) = 0$, then

$$\begin{aligned}\int_G\int_H s_0^{-1}(g)f_0(g)f(hg)\Delta_G^{-1}(h)d\mu_H(h)d\nu_G(g) &= \int_G\int_H \Delta(h)s_0^{-1}(g)f_0(h^{-1}g)f(g)d\mu_H(h)d\nu_G(g)\\ &= \int_G[\int_H f_0(hg)\Delta_G(h)^{-1}d\mu_H(h)]s_0^{-1}(g)f(g)d\nu_G(g)\\ &= \int_G f(g)d\nu_G(g)\end{aligned}$$

□

Prop. (10.11.1.44) [Haar Measure on Rho-Functions]. There exists a unique continuous positive functorial $\nu_{H\backslash G}$ on $S(G,\Delta)$ that for any $f \in C_c(G)$,

$$\int_G f(x)d\nu_G(x) = \int_{H\backslash G} p(f)(y)d\nu_{H\backslash G}(y) = \int_{H\backslash G}\int_H f(hg)\Delta_G^{-1}(h)d\mu_H(h)d\nu_{H\backslash G}.$$

and it is invariant under the right action of G. We denote $\nu_{H\backslash G}(s) = \int_{H\backslash G} s(g)d\nu_{H\backslash G}(g)$ for $s \in S(G,\Delta)$.

Proof: This follows from(10.11.1.43). □

Cor. (10.11.1.45). If G is a unimodular locally compact group and H,K be closed subgroups s.t. $H \cap K$ is compact and $G = PK$, then the the quotient measure $\mu_{H\backslash G}$ is given by

$$f \mapsto \int_K f(k)d\nu_K(k).$$

where $d\mu_K(k)$ is a right Haar measure on K, by comparison with(10.11.1.39).

Maximal Compact Subgroup

Def. (10.11.1.46) [Maximal Compact Subgroup]. A **maximal compact subgroup** of a locally compact group G is a maximal object in the set of all compact subgroup of G.

Prop. (10.11.1.47) [Cartan-Iwasawa-Malcev theorem]. Maximal compact subgroup exists for any locally compact group G.

Proof: □

Locally Profinite Groups

Def. (10.11.1.48) [Locally Profinite Group]. A **locally profinite group** is a locally profinite topological group. A profinite group is locally profinite, and any compact open subgroup of a locally profinite group is profinite.

Cor. (10.11.1.49). A closed subgroup of a locally profinite group is locally profinite, and a quotient group is locally profinite.

Proof: The proof is very similar to that of(2.1.14.4), as the result of(3.3.1.24) remains true, because any connected nbhd of e is contained in any compact open subgroup. □

Prop. (10.11.1.50) [Compact Open Subgroups Form a Basis]. If G is a locally profinite group, then the set of compact open subgroups form a basis of the nbhd of 1.

Proof: For any nbhd U of 1, choose a precompact nbhd V of 1 contained in U, then there is another compact open subgroup contained in V, by(3.11.1.24). □

Prop. (10.11.1.51) [Quotient of Locally Profinite Group]. A quotient subspace of a locally profinite group is locally profinite.

Proof: Consider the H action on G, then it is regular, because the graph is the preimage of H in the map $G \times G \to G : (g_1, g_2) \mapsto g_1^{-1} g_2$. So by(3.11.1.10) G/H is Hausdorff. But clearly $G \to G/H$ is open and G/H is locally profinite as it has a basis of locally compact subsets. □

Lemma (10.11.1.52). Let G be a locally profinite group and H a closed subgroup, then for any open compact subspace $V \subset G/H$, there is an open compact subspace $U \subset G$ that $p(U) = V$.

Proof: The preimage $p^{-1}(V)$ is open, so there is a covering of $p^{-1}(V)$ by open compact subsets U_i. Then $p(U_i)$ are open and covers V, thus there are f.m. U_i that $p(\cup U_i) = V$. □

Prop. (10.11.1.53) [Homogeneous Group]. Let G is a locally profinite group that is σ-compact. If G acts transitively on a locally profinite space X, let $x_0 \in X$ and $\mathrm{Stab}(x_0) = H$, then $G/H \to X$ is a homeomorphism. **?**Is this true for locally compact groups?

Proof: Let N be a compact open subset of N, and g_i be the left coset representatives for N, which is countable. Now $X = \cup_i \gamma(g_i N) x_0$. Because a locally profinite space is a Baire space, some $\gamma(g_i N) x_0$ contains a nbhd of $\gamma(g_i n) x$. Now left acts $(g_i n)^{-1}$, we see x_0 is an interior point of $\gamma(N) x_0$. Now N is arbitrary, thus(10.11.1.50) shows $g \mapsto \gamma(g) x$ is open, thus $G/H \to X$ is open. It is clearly continuous, thus $G/H \cong X$. □

2 Unitary Representations

Def. (10.11.2.1) [Intertwining Operators]. if π_1, π_2 are unitary representations of G, then the space $C(\pi_1, \pi_2)$ of **intertwining operators** of π_1, π_2 as:

$$C(\pi_1, \pi_2) = \{T : \mathcal{H}_{\pi_1} \to \mathcal{H}_{\pi_2} : T\pi_1(x) = \pi_2(x)T, \quad \forall x \in G\}.$$

And denote $C(\pi_1, \pi_1)$ by $C(\pi_1)$.

Lemma (10.11.2.2). The adjoint operator $S \mapsto S^*$ induces a bijection between the spaces $C(\pi_1, \pi_2) \cong C(\pi_2, \pi_1)$.

Lemma (10.11.2.3). If $\mathcal{H}_\pi$ is a representation of G, M is a closed subspace. Let P be the orthogonal projection onto M, then M is invariant under π iff $P \in C(\pi)$.

Proof: If $P \in C(\pi)$ and $v \in M$, then $\pi(x)v = \pi(x)Pv = P\pi(x)v \in M$, so M is π-invariant. Conversely if M is π-invariant, then so does $M^\perp$, so $\pi(x)Pv = \pi(x)v = P\pi(x)v$, and also for $v \in M^\perp$, so $\pi(x)P = P\pi(x)$, for any x. □

Prop. (10.11.2.4) [Schur's Lemma].

- A unitary representation π of G is irreducible iff $C(\pi)$ consists only of scalar multiples of identity.
- If π_1, π_2 are non-equivalent irreducible unitary representations of G, then $C(\pi_1, \pi_2) = 0$.

Proof: 1: if π is reducible, then it contains a non-trivial projection by lemma(10.11.2.3). Conversely, if $T \neq cI \in C(\pi)$, then we consider $A = \frac{1}{2}(T + T^*), B = \frac{1}{2i}(T - T^*)$, then at least one of them are not cI. But they are normal, thus by symbolic calculus(10.10.4.3) any $\chi_E(A)$ for some $E \subset \mathbb{R}$ Borel is non-trivial(because the spectrum of A is not a single point) and commutes with π, so $\mathcal{H}_\pi$ is reducible by(10.11.2.3) again.

2: By(10.11.2.2), for $T \in C(\pi_1, \pi_2)$, $T^* \in C(\pi_2, \pi_1)$, $TT^* = cI, T^*T = cI$. so $T = 0$ or $c^{-1/2}T$ is unitary, and it is an isomorphism between π_1, π_2. □

Cor. (10.11.2.5). if G is Abelian, then any irreducible representation of G is 1-dimensional.

Proof: If π is a representation of G, then any $\pi(x)$ commutes with π, thus $\pi(x) = c_x I$ for some c_x, so every subspace of $\mathcal{H}_\pi$ is irreducible, thus $\dim \mathcal{H} = 1$. □

Prop. (10.11.2.6) [Unitary Representation and $L^1(G)$-Representation]. Any unitary representation $(\pi, \mathcal{H})$ of G determines a representation of $L^1(G)$ by

$$f \mapsto \int f(x)\pi(x)dx$$

This is a non-degenerate *-representation of $L^1(G)$.

And conversely, any non-degenerate *-representation of $L^1(G)$ arises from a unitary representation of G.

Proof: If π is a unitary representation and $f \in L^1$, let $\pi(f)$ be defined as

$$\pi(f)u = \int f(x)\pi(x)udx,$$

where the integral is in the weak sense(10.9.3.25), and it satisfies $||\pi(f)|| \leq ||f||_1$.

For the $*$-algebra structure(10.11.1.26), it suffices to prove that

$$\pi(f*g)=\pi(f)\pi(g),\quad \pi(f^*)=\pi(f)^*,$$

which are true for formal reason:

$$\pi(f*g)=\int\int f(y)g(y^{-1}x)\pi(x)dydx=\int\int f(y)g(x)\pi(yx)dxdy=\pi(f)\pi(g),$$

$$\pi(f^*)=\int\Delta(x^{-1})\overline{f(x^{-1})}\pi(x)dx=\int\overline{f(x)}\pi(x^{-1})dx=\int(f(x)\pi(x))^*dx=\pi(f)^*.$$

and verified by supplying u,v. For the non-degeneracy, for any $u\neq 0\in\mathcal{H}$, choose a precompact nbhd V of identity that $||\pi(x)u-u||<||u||$ for $x\in V$, and let $f=|V|^{-1}\chi_V$, then it can be verified that $||\pi(f)u||\neq 0$.

For the converse, Cf.[Folland P79-81]**?** □

Prop. (10.11.2.7). We want to consider the difference of the image of $L^1(G)$ and G under these two representations: Let π be a unitary representation of G, then

- The bicommutant(10.10.3.13) of $\pi(G)$ and $\pi(L^1(G))$ are identical.
- $T\in\mathcal{L}(\mathcal{H})$ intertwines π iff it commutes with every $\pi(f)\in\pi(L^1(G))$.
- A closed subspace M of $\mathcal{H}$ is invariant under π iff $\pi(f)M\subset M$ for any $f\in L^1(G)$.

Proof: 1: Cf.[Folland, P82].

2 follows from 1 noticing the fact that T commutes with an algebra iff it commutes with its von-Neumann algebra.

3 follows from 2 and(10.11.2.3). □

Prop. (10.11.2.8) [Completion of Unitary Representation]. If $\mathcal{H}_0$ is a Hermitian inner product space that G is a topological group acting continuously on $\mathcal{H}_0$ that preserves the inner product, then if $\mathcal{H}$ is the Hilbert completion of $\mathcal{H}_0$, then the action of G extends to a continuous unitary action on $\mathcal{H}$.

Proof: The extension is clear as $||\pi(g)f||=||f||$. For the continuity, if $v\in\mathcal{H},g\in G,\varepsilon>0$, let $v_0\in\mathcal{H}_0$ that $|v-v_0|<\varepsilon/6$, then there is a nbhd W of g that if $g_1\in W$, then $|\pi(g_1)v_0-\pi(g)v_0|<\varepsilon/3$.

Then if $|v_1-v|<\varepsilon/6$ and $g_1\in W$, then

$$\begin{aligned}|\pi(g_1)v_1-\pi(g)v|&=|\pi(g_1)v_1-\pi(g_1)v_0+\pi(g_1)v_0-\pi(g)v_0+\pi(g)v_0-\pi(g)v|\\&\leq|\pi(g_1)v_1-\pi(g_1)v_0|+|\pi(g_1)v_0-\pi(g)v_0|+|\pi(g)v_0-\pi(g)v|\\&=|v_1-v_0|+|\pi(g_1)v_0-\pi(g)v_0|+|\pi(g)v_0-\pi(g)v|\\&\leq\varepsilon\end{aligned}$$

which shows the action is continuous. □

Cor. (10.11.2.9). Given a locally compact group G and a discrete subgroup Γ, the right regular action of G extends to a continuous unitary representation of G on $L^2(\Gamma\backslash G,\omega)$.

Proof: Because we can approximate $f\in L^2(\Gamma\backslash G)$ by compactly supported continuous functions(10.4.8.5), then the G action is uniformly continuous. □

Lemma (10.11.2.10) [Auxiliary Compact Supported Function Approximation]. Let G be a locally compact Lie group and K a compact subgroup. If $(\pi,\mathcal{H})$ is a unitary representation of G on a Hilbert space, and let $f\neq 0\in\mathcal{H}$, then for any $\varepsilon>0$, there is a $\varphi\in C_c^\infty(G)$ s.t. $\pi(\varphi)$ is self-adjoint and $|\varphi(\rho)f-f|<\varepsilon$.

Moreover, if $f\in\mathcal{H}^\xi$ which is the decomposition part for K, we can assume $\varphi(kg)=\varphi(gk)=\xi(k)^{-1}\varphi(g)$. In particular if $\mathcal{H}^\xi$ is f.d., we find a φ that $\pi(\varphi)f=f$.

Proof: By continuity, there is a nbhd H of 1 that $|\pi(g)f-f|<\varepsilon$, then we can choose a φ positive real valued with support in U with integral 1, then $|\pi(\varphi)f-f|<\varepsilon$ by(10.9.3.22). We can also choose $\varphi(g)=\varphi(g^{-1})$, then $\pi(\varphi)$ is self-adjoint.

For the second case, notice first there is a nbhd V of 1 that $kVk^{-1}\in U$ for any $k\in K$(3.11.1.6), so let φ_1 be a positive real valued function supported in V, and let

$$\varphi_0(g)=\int_K\varphi_1(kgk^{-1})dk$$

then φ_0 is supported in U and $\varphi(kgk^{-1})=\varphi_0(g)$ for any $k\in K$. Assume now that $\pi(k_\theta)=e^{ik\theta}f$, then we can use(10.11.1.39) for $P=G$ to see that

$$\pi(\varphi_0)f=\int_G\varphi_0(h)\pi(h)fdh=\int_G\int_K\varphi_0(hk)\pi(hk)fdkdh=\int_G\int_K\xi(k)\varphi_0(hk)dk\pi(h)fdh=\pi(\varphi)f$$

where

$$\varphi(g)=\int_K\xi(k)\varphi_0(gk)dk=\int_K\xi(k)\varphi_0(kg)dk$$

so $\varphi(k)=\varphi(gk)=\xi^{-1}(k)\varphi(g)$ as required. □

Functions of Positive Type

Def. (10.11.2.11)[Positive Type Function]. A function of **positive type** on a closed compact group G is a function $\varphi\in L^\infty(G)$ that defines a positive linear functional on the B^*-algebra $L^1(G)$. In other word,

$$\int f(x)\overline{f(y)}\varphi(y^{-1}x)dydx\geq 0,\quad\forall f\in L^1(G).$$

We denote by $P(G)$ the set of continuous functions of positive type on G.

Prop. (10.11.2.12). If φ is of positive type, then so does $\overline{\varphi}$. (Easy calculation).

Prop. (10.11.2.13). If π is a unitary representation of G and $u\in\mathcal{H}_\pi$, then $\varphi(x)=(\pi(x)u,u)\in P$.

Proof: φ is continuous by definition, so if $f\in L^1$, then

$$\int\int f(x)\overline{f(y)}\varphi(y^{-1}x)d\mu(x)d\mu(y)=\int\int(f(x)\pi(x)u,f(y)\pi(y)u)dxdy=||\pi(f)u||^2\leq 0$$

□

Prop. (10.11.2.14). If $f\in L^2(G)$, then $f*\widetilde{f}\in P(G)$(10.11.1.2).

Proof: Cf.[Folland, P84]. □

Prop. (10.11.2.15) [Cyclic Representations and Functions of Positive Type]. Any function of positive type arises from a irreducible representation and a cyclic vector ε as in(10.11.2.13)

Proof: Cf.[Folland P84-85]. □

Cor. (10.11.2.16). If φ is a function of positive type, then φ can be chosen to be continuous.

Cor. (10.11.2.17). If $\varphi \in P$, then $||\varphi||_\infty = \varphi(1)$, and $\varphi(x^{-1}) = \overline{\varphi(x)}$.

Proof: $\varphi(x) = (\pi(x)u, u)$ for some representation π and $u \in \mathcal{H}$, so $|\varphi(x)| \leq ||u||^2 = \varphi(1)$ and $\varphi(x^{-1}) = (\pi(x^{-1})u, u) = (u, \pi(x)u) = \overline{\varphi(x)}$. □

Def. (10.11.2.18). We set:

- $P_0(G) = \{\varphi | ||\varphi||_\infty \leq 1\} = \{\varphi(1) = 1\}$.
- $P_1(G) = \{\varphi | ||\varphi||_\infty = 1\} = \{0 \leq \varphi(1) \leq 1\}$.

By Banach-Alaoglu, $P_0(G)$ and $P_1(G)$ are a weak*-compact set.

Prop. (10.11.2.19) [Extreme Points of P_1]. A $\varphi \in P_1$ is an extreme point iff the representation it corresponds is irreducible. And $E(P_0) = E(P_1) \cup \{0\}$.

Proof: Cf.[Folland P86]. □

Prop. (10.11.2.20) [Two Topologies Coincide]. On P_1, the compact-open topology coincides with that of the weak*-topology.

Proof: Cf.[Folland Abstract Harmonic Analysis P80]. □

Prop. (10.11.2.21). The linear span $B(G)$ of $C_c(G) \cap P(G)$ includes all functions of the form $f * g$ where $f, g \in C_c(G)$. And it is dense in $C_c(G)$ and $L^p(G)$ for $p < \infty$.

Denote $B^p(G) = B(G) \cap L^p(G)$.

Proof: By(10.11.2.14), $P \cap C_c(G)$ includes all functions of the form $f * \widetilde{f}$ with $f \in C_c(G)$, thus its linear span includes all $f * g$ for $f, g, \in C_c(G)$ by polarization. Thus it is dense in $C_c(G)$ and $L^p(G)$ because we can use approximate identity(10.11.1.31). □

Prop. (10.11.2.22) [Gelfand-Raikov]. If G is a locally compact group, then the irreducible representations of G separate points of G.

Proof: Cf.[Folland Abstract Analysis P91]. □

3 Locally Compact Abelian Group

Dual Group

Def. (10.11.3.1) [Dual Space]. If G is locally compact, denote $\widehat{G}$ the set of all irreducible unitary representations of G, called the **dual space** of G.

Def. (10.11.3.2)[Dual Group]. If G is locally compact Abelian, the irreducible unitary representations of G are all 1-dimensional by(10.11.2.5), so it forms a group, called the **dual group** of G, denoted by $\widehat{G}$.

An element of $\widehat{G}$ is called a **character of** G, denoted by ξ. And a continuous homomorphism from G to $\mathbb{C}$ is called a **quasi-character**.

The topologies on $\widehat{G}$ that makes it into a LCA group is given in(10.11.3.6).

Remark (10.11.3.3). $\widehat{\mathbb{R}} \cong \mathbb{R}$, and the quasi-characters of $\mathbb{R}$ are all of the form $x \to e^{sx}$ for $s \in \mathbb{C}$.

Proof: If $\varphi \in \widehat{\mathbb{G}}$, then $\varphi(0) = 1$, and there is an $a > 0$ that $\int_0^a \varphi(t)dt \neq 0 = A$. Now $A\varphi(x) = \int_x^{x+a} \varphi(t)dt$, so taking derivative,

$$\varphi'(x) = \frac{\varphi(x+a) - \varphi(x)}{A} = \frac{\varphi(a) - 1}{A}\varphi(x),$$

which shows $\varphi(x) = e^{sx}$ for some $s \in \mathbb{C}$. □

Prop. (10.11.3.4) [Dual Group as Spectrum of $L^1(G)$]. The dual group $\widehat{G}$ can be regarded as the spectrum of $L^1(G)$, i.e. multiplicative homomorphism of $L^1(G)$:

$$\xi \mapsto \Big(\xi(f) = \int \overline{(x,\xi)} f(x)dx\Big).$$

Proof: First, ξ is multiplicative because

$$\xi(f * g) = \int\int f(y)g(y^{-1}x)(x,\xi)dydx = \int\int f(y)g(x)(xy,\xi)dydx = \xi(f)\xi(g).$$

Conversely, any continuous functional on L^1 is like $\varphi(f) = \int f(x)\varphi(x)dx$ for some $\varphi \in L^\infty$, and it is multiplicative, so

$$\varphi(f)\int \varphi(x)g(x) = \varphi(f)\varphi(g) = \varphi(f * g) = \int\int \varphi(y)f(yx^{-1})g(x)dxdy = \int \varphi(L_x(f))g(x)dx$$

So $\varphi(x) = \frac{\varphi(L_x(f))}{\varphi(f)}$, a.e., for any f. so $\varphi(x)$ can be chosen to be continuous, as $x \to L_x(f)$ is continuous(10.11.1.3). And clearly φ is multiplicative. □

Cor. (10.11.3.5). $\widehat{G} \subset P_1(G)$, because $\int(f^* * f)\varphi \mathrm{d}\mu = |\Phi(f)|^2 \geq 0$.

Cor. (10.11.3.6) [Dual Group as a LCA Group]. Now we can give $\widehat{G}$ the compact-open topology, then the group operation is clearly continuous, and the topology coincides with that inherited by the weak*-topology of the L^∞ by(10.11.2.20), so $\widehat{G}\cup\{0\}$ is a compact Hausdorff space because $\widehat{G} \subset P_1(G)$ and it is the subset of L^∞ that $\{h(xy) = h(x)h(y)\}$ which is weak*-closed hence weak*-compact. In particular, $\widehat{G}$ is a locally compact topological group.

Prop. (10.11.3.7) [Duality between Discrete Groups and Compact Groups]. if G is discrete, then $G^\vee$ is compact, if G is compact, then $G^\vee$ is discrete.

Proof: if G is discrete, then there is a unit δ in $L^1(G)$, which is 1 on e and 0 otherwise. So the spectrum of $L^1(G)$ is compact by(10.10.1.21).

If G is compact, then $1 \in L^1$, so $U = \{f \in L^\infty | |f| > \frac{1}{2}\}$ is weak*-open, but $U \cap \widehat{G} = \{1\}$ by(10.11.1.14), so $\widehat{G}$ is discrete. □

Fourier Transform

Prop. (10.11.3.8) [Fourier Transforms]. The **Fourier transform** on G is defined as in(10.11.3.4) to be the map

$$L^1(G) \to C(G^\vee) : f \mapsto \mathcal{F}f(\xi) = \widehat{f}(\xi) = \int f(x)\overline{(x,\xi)}.$$

It is a norm-decreasing *-homomorphism form $L^1(G)$ to $C_0(\widehat{G})$, and its range is a dense subspace of $C_0(G^\vee)$.

Equivalently, the Fourier transform is just the Gelfand transform of $L^1(G)$(10.10.1.21) composed with an inverse map.

Proof: Cf.[Folland Abstract Harmonic Analysis P102]. □

Prop. (10.11.3.9). There is another map from $M(\widehat{G})$ to bounded continuous functions on G:

$$\mu \mapsto \Big(\varphi_\mu : x \mapsto \int (x,\xi) d\mu(\xi)\Big).$$

This is a norm decreasing injection from $M(\widehat{G})$ to $L^\infty(G)$, and if μ is positive, then φ_μ is a function of positive type.

Proof: It suffices to prove injectivity, but if $\varphi_\mu = 0$, then $0 = \int\int f(x)(x,\xi)d\mu(\xi)dx = \int \widehat{f}(\xi^{-1})d\mu(\xi)$ for all $f \in L^1(G)$, so but this shows $\mu = 0$ because of(10.11.3.8) and Riesz representation.

For the positive type, notice that

$$\int\int f(x)\overline{f(y)} vp_\mu(y^{-1}x)dxdy = \int\int\int f(x)\overline{f(y)(y,\xi)}(x,\xi)d\mu(\xi)dxdy = \int |\widehat{f}(\xi)|^2 d\mu(\xi) \geq 0$$

□

Prop. (10.11.3.10) [Bochner's Theorem]. If $\varphi \in P(G)$, there is a unique positive $\mu \in M(\widehat{G})$ s.t. $\varphi = \varphi_\mu$.

Proof: We have the map defined in(10.11.3.9) injects $M(\widehat{G})$ into $P(G)$(norm-decreasing), so it suffices to prove the existence. For this, we may assume $\varphi \in P_0(G)$. Let M_0 be the set of positive measure $\mu \in M(\widehat{G})$ that $\mu(\widehat{G}) \leq 1$, then M_0 is weak*-compact in $M(\widehat{G})$. Now

$$\int f(x)\varphi_\mu(x)dx = \int\int f(x)d\mu(\xi)dx = \int \widehat{f}(\xi^{-1})\mu(x)$$

so the mapping $\mu \to P_0$ must be continuous w.r.t their weak*-topologies, so the image is a compact convex subset of P_0. But the image contains all characters and 0(by taking the point mess), which are the extreme points of P_0, by(10.11.2.19), so it contains all the P_0, by Krein-Milman(10.9.3.15). □

Cor. (10.11.3.11). $\{\varphi_\mu\} = B(G)$(10.11.2.21), by(10.11.3.10) and(10.11.3.9). Thus the inverse $B(G) \to M(\overline{G})$ is denoted by $f \mapsto d\mu_f$.

Cor. (10.11.3.12) [Herglotz]. A numerical sequence $\{a_n\}$ is positive iff there is a positive measure $\mu \in M(T)$ s.t. $a_n = \widehat{\mu}(n)$.

Prop. (10.11.3.13). The set of regular Borel probability measures on a compact X is weak*-compact in $C(X)^*$. (Use Alaoglu).

Prop. (10.11.3.14) [Fourier Inversion Formula]. (special case of(10.11.3.24)) If $f \in B^1(G)$(10.11.2.21), then $\widehat{f} \in L^1(\widehat{G})$, and if the Haar measure $d\xi$ of $\widehat{G}$ is suitably normalized w.r.t. the Haar measure of G, then $d\mu_f(\xi) = \widehat{f}(\xi)d\xi$(10.11.3.11), i.e. $f(x) = \int (x,\xi)\widehat{f}(\xi)d\xi$. This measure $d\xi$ is called the **dual measure** of dx.

Proof: Cf.[Folland Abstract Harmonic Analysis P105].? □

Cor. (10.11.3.15). If $f \in L^1(G) \cap P$, then $\widehat{f} \geq 0$, as $d\mu_f(\xi) = \widehat{f}(\xi)d\xi$ and μ_f is positive, by Bochner's theorem(10.11.3.10).

Prop. (10.11.3.16) [Dual Measure of Discrete Group]. If μ is the counting measure on a discrete group, then its dual measure satisfies $|\widehat{G}| = 1$, and if G is compact and $|G| = 1$, then the dual measure is the counting measure on $\widehat{G}$.

Proof: First(10.11.3.7) should be noticed. If G is compact and $|G| = 1$, then if $g = 1$, then $\widehat{g} = \chi_{\{1\}}$, so $g(x) = \sum(x, \xi)\widehat{g}(\xi)$, which shows the dual measure is counting measure by definition(10.11.3.14). □

Prop. (10.11.3.17)[Plancherel Theorem]. The Fourier transform on $L^1(G) \cap L^2(G)$ extends uniquely to an isomorphism from $L^2(G)$ to $L^2(\widehat{G})$ that satisfies Fourier inversion formula.

Proof: Cf.[Folland P108]. □

Cor. (10.11.3.18). If G is compact and $\mu(G) = 1$, then $\widehat{G}$ is an orthonormal basis of $L^2(G)$.

Proof: Firstly $\widehat{G}$ is an orthonormal set by(10.11.1.14). And if $f \in L^2(G)$ is orthogonal to all $\xi \in \widehat{G}$, then $\int_G f\overline{\xi} = \widehat{f}(\xi) = 0$, thus $\widehat{f} = 0$, and then $f = 0$ by Plancherel(10.11.3.17). □

Cor. (10.11.3.19) [Hausdorff-Young Inequality]. Let $1 \le p \le 2$ and $p^{-1} + q^{-1} = 1$. If $f \in L^p(G)$, then $\widehat{f} \in L^q(G)$, and $||\widehat{f}||_q \le ||f||_p$.

Proof: Cf.[Folland, P109]. □

Schrödinger Representations

Def. (10.11.3.20) [$A(G)$]. Let G be an locally compact Abelian group, denote $\mathbb{T} = \{c \in \mathbb{C} | |c| = 1\}$, $A(G) = G^* \times G \times \mathbb{T}$ with the group law

$$(v_1^*, v_1, t_1)(v_2^*, v_2, t_2) = (v_1^* + v_2^*, v_1 + v_2, t_1 t_2 \langle v_1, v_2^* \rangle).$$

Also we denote for $w, w' \in G^* \times G$, $[w, w'] = \langle v_1, v_2^* \rangle$.

Let $B(G) = \mathrm{Aut}(A(G))$, $B_0(G) \subset B(G)$ be the group of elements fixing elements in the center $Z(A(G))$.

Note the commutator

$$(v_1^*, v_1, 1)(v_2^*, v_2, 1)(v_1^*, v_1, 1)^{-1}(v_2^*, v_2, 1)^{-1} = (0, 0, \langle v_1, v_2^* \rangle \langle v_2, v_1^* \rangle^{-1}),$$

thus $\langle v_1, v_2^* \rangle \langle v_2, v_1^* \rangle^{-1}$ defines a multiplicative skew-symmetric, bilinear and perfect pairing $[\cdot, \cdot]$ of $G^* \times G$ with itself,

Prop. (10.11.3.21) [Segal-Shale-Weil]. There is an unitary representation of $A(G)$ on $L^2(G)$ given by

$$(\rho(v^*, v, t)\Phi)(u) = t\langle u, v^* \rangle \Phi(u + v),$$

called the **Schrödinger representation**. In fact, it is the induced representation $\mathrm{Ind}_{G \times \mathbb{T}}^{A(G)} \chi$, where $\chi(g, t) = t$. This representation is irreducible, and for any $\sigma \in B_0(G)$, there exists uniquely up to scalar a unitary operator $\omega(\sigma)$ on $L^2(G)$ s.t.

$$\rho(\sigma(h)) = \omega(\sigma) \circ \rho(h) \circ \omega(\sigma)^{-1}.$$

Remark (10.11.3.22). This should be a direct consequence of the Stone-Von Neumann theorem. Cf.[History of Stone Von-Newmann Theorem] or [Easy proof of the Stone-Von Neumann Theorem].?

Proof: This is clearly a unitary representation. ρ induces an action of $G^* \times G$ on $L^2(G)$ via $t = 1$, thus an action of $C_c(G^* \times G)$ on $L^2(G)$:

$$(\rho(\varphi)\Phi)(u) = \int_{G^* \times G} \varphi(w)(\rho(w,1)\Phi)(u)dw = \int_G K_\varphi(u,v)\Phi(v)dv$$

where $K_\varphi(u, u+v) = \int_{G^*} \varphi(v^*, v)\langle u, v^*\rangle dv^*$ is the Fourier transform of φ w.r.t. G^*. As Fourier transform is L^2-isometry, $\varphi \mapsto K_\varphi$ extends to an isometry $\lambda : L^2(G^* \times G) \cong L^2(G \times G)$, whose inverse is given by

$$\varphi(v^*, v) = \int_G K_\varphi(u, u+v)\langle -u, v^*\rangle du,$$

and also the action ρ extends to all $\varphi \in L^2(G^* \times G)$.

It can be verified that $\rho(\varphi_1) \circ \rho(\varphi_2) = \rho(\varphi_1 \star \varphi_2)$, where

$$(\varphi_1 \star \varphi_2)(w) = \int_{G^* \times G} \varphi_1(w_1)\varphi_2(w - w_1)[w_1, w - w_1]dw_1.$$

Then by comparison with the equation above, $K_{\varphi_1 \star \varphi_2} = K_{\varphi_1} \star K_{\varphi_2}$, where $\star$ is defined in(10.4.6.6).

$\sigma \in B_0(G)$ is of the form $\sigma(w,t) = (s(w), f(w)t)$, where $w \in G^* \times G$, $f : G^* \times G \to \mathbb{T}$ is a map satisfying

$$f(w_1 + w_2) = f(w_1)f(w_2)[s(w_1), s(w_2)][w_1, w_2]^{-1}.$$

Notice s preserves Haar measure on $G^* \times G$: it is preserved the pairing $[\cdot,\cdot]$ as it is a commutator and σ fixes $Z(A(G))$. Thus s preserves Haar measure of $G^* \times G$, by(10.11.3.34).

Now we define a unitary transformation Σ of $L^2(G^* \times G)$ by $(\Sigma\varphi)(w) = f(w)^{-1}\varphi(s(w))$, then it can be checked**?** by using the equations above that

$$\Sigma(\varphi_1 \star \varphi_2) = \Sigma(\varphi_1) \star \Sigma(\varphi_2).$$

Thus by the isomorphism $\lambda : L^2(G^* \times G) \cong L^2(G \times G)$, Σ induces a unitary transformation on $L^2(G \times G)$, also denoted by Σ and it preserves $\star$. Then by(10.4.6.7), there is a unitary map $\omega : L^2(G) \to L^2(G)$ that

$$\Sigma(P \otimes \overline{Q}) = \omega^{-1}(P) \otimes \overline{\omega^{-1}Q}.$$

Next, notice for any $(w,t) \in A(G)$,

$$\bar{t}\lambda^{-1}(P \otimes Q)(w) = \int_G P(u)\overline{tQ(u+v)\langle u, v^*\rangle}du = (P, \rho(w,t)Q)_{L^2},$$

thus

$$\begin{aligned}(P, \rho(\sigma(w,t)))_{L^2} &= (P, \rho(s(w), f(t))Q)_{L^2} = \overline{tf(w)}\lambda^{-1}(P \otimes \overline{Q})(s(w)) \\ &= \bar{t}(\Sigma\lambda^{-1}(P \otimes \overline{Q}))(w) = \bar{t}\lambda^{-1}(\omega^{-1}(P) \otimes \omega^{-1}(Q))(w) \\ &= (\omega^{-1}(P), \rho(w,t)\omega^{-1}(Q))_{L^2} \\ &= ((P), \omega\rho(w,t)\omega^{-1}(Q))_{L^2}\end{aligned}$$

Because P, Q are arbitrary, this means $\rho(\sigma(w,t)) = \omega(\sigma) \circ \rho(w,t) \circ \omega(\sigma)^{-1}$.

It remains to show that ρ is irreducible: For any endomorphism of $L^2(G)$ commuting with ρ, it commutes with $\rho(\varphi)$ for any $\varphi \in L^2(G^* \times G)$. Take $\varphi = \lambda^{-1}(P \otimes \overline{Q})$, where $P, Q \in L^2(G)$, then $\rho(\varphi)\Phi = (\Phi, Q)_{L^2}P$, so $(T\Phi, Q)_{L^2}P = (\Phi, Q)_{L^2}TP$. Then T is a scalar. $\square$

Pontryagin Duality

Prop. (10.11.3.23) [Pontryagin Duality]. For a locally compact Abelian group G, $G \to (G^\wedge)^\wedge$ is an isomorphism of topological groups.

Proof: Cf.[Folland Abstract Harmonic Analysis P110]. □

Cor. (10.11.3.24) [Fourier Inversion Theorem]. If $f \in L^1(G)$ and $\widehat{f} \in L^1(\widehat{G})$ and the measure are dual to each other(10.11.3.14), then $f(x) = \widehat{\widehat{f}}(x^{-1})$, i.e. $f(x) = \int (x,\xi)\widehat{f}(\xi)d\xi$ a.e..

Proof: As
$$\widehat{f}(\xi) = \int \overline{(x,\xi)} f(x)dx = \int (x^{-1},\xi)f(x)dx = \int (x,\xi)f(x^{-1})dx,$$
so by definition $\widehat{f} \in B^1(\widehat{G})$, and $d\mu_{\widehat{f}}(x) = f(x^{-1})dx$. Then by(10.11.3.14), $f(x^{-1}) = (f^\wedge)^\wedge(x)$. □

Cor. (10.11.3.25) [Fourier Uniqueness Theorem]. If $u, v \in M(G)$ satisfy $\widehat{u} = \widehat{v}$, then $u = v$. In particular, if $f, g \in L^1(G)$ and $\widehat{f} = \widehat{g}$, then $f = g$.

Proof: By(10.11.3.9)(norm decreasing), μ is uniquely determined by $\varphi_\mu(\xi) = \widehat{\mu}(\xi^{-1})$ by Fourier inversion. □

Lemma (10.11.3.26). If $\varphi, \psi \in C_c(\widehat{G})$, then $\varphi * \psi = \widehat{h}$ where $h \in B^1(G)$. In particular, $\mathcal{F}(B^1(G))$ is dense in $L^p(\widehat{G})$ for $p < \infty$.

Proof: Cf.[Folland, P109]. □

Prop. (10.11.3.27). $(fg)^\wedge = \widehat{f} * \widehat{g}$ is satisfied for $f, g \in L^2(G)$ also.

Proof: Cf.[Folland, P112]. □

Prop. (10.11.3.28) [Duality of Subgroups]. $(H^\perp)^\perp = H$ for closed subgroup H of a locally compact Abelian group G.

Proof: Suffices to prove $(H^\perp)^\perp \subset H$. If $x_0 \notin H$, then Gelfand-Raikov shows that there is a character η on G/H that $\eta(q(x_0)) \neq 1$, so $x_0 \notin (H^\perp)^\perp$. □

Prop. (10.11.3.29). If H is a closed subgroup of G, then there are natural isomorphisms of LCA groups:
$$\Phi : \widehat{(G/H)} \cong H^\perp, \quad \Psi : \widehat{G}/H^\perp \cong \widehat{H}$$

Proof: Φ is clearly algebraic isomorphism. If $|\eta(q(K)) - 1| < \varepsilon$, then $|\eta(K) - 1| < \varepsilon$, so Φ is continuous in the compact-open topology. Similarly, to show Φ is open, it suffices to show a compact subset of G/H has a compact inverse image in G, but this is just(10.11.1.34).

Now for Ψ, notice $\widehat{\widehat{G}/H^\perp} \cong (H^\perp)^\perp \cong H$ by(10.11.3.28), so by Pontryagin duality theorem, $\widehat{G}/H^\perp \cong \widehat{H}$. □

Cor. (10.11.3.30) [Hahn-Banach for LCA Groups]. By the surjectivity of Ψ, any character of $\widehat{H}$ extends to a character of G.

Prop. (10.11.3.31) [Poisson Summation Formula]. Suppose H is a closed subgroup of G, if $f \in L^1(G)$, define $F(xH) = \int_H f(xy)dy$ on G/H, then $F \in L^1(G/H)$ by(10.11.1.38), then:

- $\widehat{F} = \widehat{f}|_{H^\perp}$, where $\widehat{G/H}$ is identified with $H^\perp$ by(10.11.3.29).

- If $\widehat{f}|_{H^\perp} \in L^1(H^\perp)$, then with the dual measure of G/H on $H^\perp$(10.11.3.14), we have
$$\int_H f(xy)dy = \int_{H^\perp} \widehat{f}(\xi)(x,\xi)d\xi.$$
In particular, take $x = e$, then
$$\int_H f(y)dy = \int_{H^\perp} \widehat{f}(\xi)d\xi.$$

Proof: Notice for $\xi \in H^\perp$,
$$\widehat{F}(\xi) = \int_{G/H} F(xH)\overline{(x,\xi)}d(xH) = \int_{G/H}\int_H f(xy)\overline{(xy,\xi)}dyd(xH) = \int_G f(x)\overline{(x,\xi)}dx = \widehat{f}(\xi)$$
by(10.11.1.38). And 2 is just(10.11.3.24) applied to $F(xH)$ on G/H. □

Cor. (10.11.3.32). In the situation of(10.11.3.31), if H is discrete in G and G/H is compact, then both $H, H^\perp$ are discrete, then by considering the dual measure using(10.11.3.16), the Poisson summation reads:
$$\sum_H f(xy) = \frac{1}{\mu(G/H)}\sum_{H^\perp}\widehat{f}(\xi)(x,\xi).$$

Perfect Pairing

Def. (10.11.3.33) [Self-Adjoint Haar Measures]. If G is a locally compact Abelian group, and there is an isomorphism $G \cong \widehat{G}$, or a perfect bilinear pairing $G \times G \to \mathbb{C}^*$, then by Fourier inversion(10.11.3.14), a Haar measure $d\mu$ on G corresponds to a Haar measure $d\alpha$ on $\widehat{G}$, but via the isomorphism, $d\alpha$ corresponds to a measure $\widetilde{d\alpha}$ on G. Now anyway, there is a unique $d\mu$ that $d\mu = \widetilde{d\alpha}$, and this is called the **self-dual Haar measure** on G.

Via this pairing, we define the Fourier transform as an isomorphism
$$L^2(G) \cong L^2(G) : \Phi(f)(x) = \int_G f(y)\overline{\langle x,y\rangle}d\mu(y).$$
Then $d\mu$ is a self-dual measure is equivalent to $\Phi(\Phi(f))(x) = f(-x)$, or equivalently $f(y) = \int_G \widehat{f}(y)\langle x,y\rangle d\mu(y)$.

Prop. (10.11.3.34). If G is a locally compact Abelian group, and there is a perfect bilinear pairing $G \times G \to \mathbb{C}^*$ and $\sigma : G \to G$ is a group automorphism of G that preserves this pairing, then σ preserves the Haar measure on G.

Proof: It is clear that $\sigma^* d\mu = |\sigma|d\mu$ for some real constant $|\sigma| > 1$. Consider the Fourier transform w.r.t. this pairing: $\mathcal{F}\varphi(x) = \int_G \varphi(y)\langle x,y\rangle dy$, then $\mathcal{F}(\varphi\circ\sigma) = |\sigma|^{-1}\mathcal{F}(x)$. But $\mathcal{F}$ is an isomorphism $L^2(G) \cong L^2(G)$, so $|\sigma|^{-1} = |\sigma|$, thus $|\sigma| = 1$. □

Prop. (10.11.3.35) [Self Duality of Topological Fields]. Let K be a locally compact topological field. If X is a non-trivial character on the additive group K^+, then for any $\eta \in K^+$, $\xi \mapsto X(\eta\xi)$ is also a character, and
$$F_X : \eta \mapsto (\xi \to X(\eta\xi))$$
is an isomorphism of topological groups of K^+ and $\widehat{K^+}$.

Then by(10.11.3.33), we find a self-dual measure Haar measure dx on K^+ w.r.t. X.

In fact, such a character X does exist, by Gelfand-Raikov(10.11.2.22).

Proof: First this is clearly a homomorphism of groups, and it is injective, because if $X(\eta\xi)=1$ for all ξ, then $\eta K^+ \neq K^+$(because X is nontrivial), so $\eta=0$.

Now the image of F is dense, because if $X(\eta\xi)=1$ for all η, then $\xi=0$, so $\overline{\mathrm{Im}(F)}^{\perp}=1$. Now $(H^\perp)^\perp=H$ for H closed(10.11.3.28) and use Pontryagin duality(10.11.3.23), so $\mathrm{Im}\, f$ is dense in $\widehat{G}$.

Now F is open and continuous, because: for any $B\in G$ compact, there is a nbhd V of 0 that $|X(V)-1|<\varepsilon$, so there is a nbhd V' that $V'B\subset V$, so if $\eta\in V$, $|X(\eta B)-1|<\varepsilon$, so F is continuous($\widehat{K^+}$ has the compact-open topology). And if we choose ξ_0 that $X(\xi_0)\neq 1$, then choose $B=\overline{B(0,\frac{|\varepsilon_0}{\varepsilon})}$ compact, if $|X(\eta B)-1|<|X(\xi_0)-1|$, then $\xi_0\notin \eta B$, which means that $|\eta|<\varepsilon$. This means $F(B(0,\varepsilon))$ contains $V(B,|X(\xi_0)-1|)$, so F is open.

So the image of F is a locally compact subgroup of $\widehat{G}$, so by(10.11.1.7) it is closed, hence equals G as it is dense, so F is surjective, and is an isomorphism. □

4 Compact Group

Cf.[群表示论 notes] and [Fol15]Chap5.

In this subsection, we consider representations of a compact group over $\mathbb{C}$.

Unitary Representations

Prop. (10.11.4.1)[F.d. Representation is Unitary]. If V is a real/complex f.d. representation π of a compact group G, then there is an inner product on V that the action of G is orthogonal/unitary.

Proof: Choose an arbitrary inner product $(\cdot,\cdot)_0$ on V, then consider

$$(u,v)=\int_G (\pi(x)u,\pi(x)v)_0 dx.$$

where dx is a Haar measure on G. Then

$$(\pi(y)u,\pi(y)v)=\int_G(\pi(xy)u,\pi(xy)v)_0dx=\Delta(y)\int_G(\pi(x)u,\pi(x)v)_0dx=\int_G(\pi(x)u,\pi(x)v)_0dx$$

because G is compact hence unimodular(10.11.1.18). Thus this is an inner product on V that is invariant under G. □

Cor. (10.11.4.2) [F.D. Representation of Compact Groups Totally Decomposable]. Any f.d. representation of a compact group is totally decomposable.

Proof: This is because we can assume this representation is unitary by(10.11.4.1), and then for any subrepresentation we can take the orthogonal complement. □

Lemma (10.11.4.3). Suppose $(\pi,\mathcal{H})$ is a continuous unitary representation of the compact group G, let $u\neq 0\in\mathcal{H}$ be a unit vector, if the operator T on $\mathcal{H}$ is defined by

$$Tv=\int_G (v,\pi(x)u)\pi(x)udx,$$

then T is a positive, non-zero compact operator in $C(\pi)$.

Proof:

$$(Tv,v)=\int_G (v,\pi(u)u)(\pi(x)u,v)dx=\int_G |(\pi(x)u,v)|^2dx\geq 0,$$

so it is positive. Moreover, if $v=u$, then $x\mapsto |(\pi(x)u,v)|$ is a positive on a nbhd of 1, so $T\neq 0$.

Finally, because G is compact, $x\mapsto \pi(x)u$ is uniformly continuous, so for any $\varepsilon>0$, there is a disjoint partition E_i of G and $x_i\in E_i$ that if $x\in E_i$, then $||\pi(x)u-\pi(x_i)u||\leq \varepsilon/2$. Then

$$||(v,\pi(x)u)\pi(x)u-(v,\pi(x_i)u)\pi(x_i)u||\leq |(v,[\pi(x)-\pi(x_i)]u)\pi(x)u||+||(v,\pi(x_i)u)[\pi(x)-\pi(x_i)]u||<\varepsilon||v||.$$

So consider

$$T_\varepsilon(v)=\sum |E_j|(v,\pi(x_j)u)\pi(x_j)u=\sum \int_{E_i}(v,\pi(x_j)u)\pi(x_j)udx$$

then $||T-T_\varepsilon||<\varepsilon$, and T_ε has f.d image, thus T is compact, by(10.9.5.3).

Also $T\in C(\pi)$ because

$$\pi(y)Tv=\int_G (v,\pi(x)u)\pi(yx)udx=\int_G (v,\pi(y^{-1}x)u)\pi(x)udx=\int_G (\pi(y)v,\pi(x)u)\pi(x)udx=T\pi(y)v.$$

□

Prop. (10.11.4.4) [Unitary Representations of Compact Groups]. If G is compact group, then every unitary representation (ρ,V) of G is an orthogonal sum of irreducible unitary subrepresentations. Moreover, the isotopic part V^π for any irreducible representation π of G is uniquely determined. And very irreducible representation of G is of f.d.(thus unitary by(10.11.4.1)).

Proof: By taking orthogonal complements and Zorn's lemma, it suffices to show any unitary representation π has an irreducible subrepresentation. Choose T as in(10.11.4.3), then T is compact nonzero self-adjoint, so by Riesz-Fredholm(10.9.5.9) it has a finite-dimensional eigenspace, which is π-invariant, and it clearly has an irreducible subrepresentation by taking orthogonal complements.

For the orthogonality, Let V^π be the linear span of invariant subspaces isomorphic to π, for L_1,L_2 of type $\pi_1\neq\pi_2$, then consider the orthogonal projection P onto L_2, then $P|_{L_1}\in C(\pi_1,\pi_2)$, which vanishes by Schur(10.11.2.4), so they are orthogonal.

The final assertion follows from(10.11.4.19). □

Cor. (10.11.4.5). The cardinality of irreducible constituents of V that is isomorphic to π is independent of the decomposition, and it is equal to $\dim \mathrm{Hom}_G(\pi,\rho)$, and is denoted by $\mathrm{mult}(\pi,\rho)$.

Proof: Cf.[Folland, P137].**?** □

Cor. (10.11.4.6). Let G be a compact subgroup and H a closed subgroup, then G acts unitarily on $L^2(G/H)$, and it decomposes as

$$L^2(G/H)\cong \widehat{\bigoplus}_{\pi\in\widehat{G}}N_H(\pi)\pi$$

where $N_H(\pi)=\dim \pi^H$ the dimension of H-fixed vectors in V.

Proof: By(10.11.4.4), it suffices to determine the multiplicity of π in $L^(G/H)$, which is just dimension of $\mathrm{Hom}_G(\pi,L^2(G/H))$, which can be viewed as G-invariant L^2 functions on G/H with values on π^*. For any such function f, $f(1)$ is H-invariant, and for any H-invariant vector v, $g\mapsto gv$ is continuous, thus is L^2. So the dimension of this space is just $\dim\pi^H$. □

Matrix Coefficients and Peter-Weyl Theorem

Def. (10.11.4.7) [K-Finite Vectors]. Let K be compact group. For an irreducible representation ρ of K, denote $V^\rho = \rho \otimes \mathrm{Hom}_K(\rho, V)$ the ρ-isotypic component in V. And let $V^{K-\mathrm{fin}} = \oplus_\rho V^\rho$ the space of K-**finite vectors** in V(10.11.4.4).

Def. (10.11.4.8) [Matrix Coefficients]. Firstly $C(G)$ is a representation of $G \times G$ by $((g_1, g_2)f)(g) = f(g_1^{-1} g g_2)$.

For a f.d. representation (π, V) of a topological group G, we can view $\mathrm{End}(V)$ as a representation of $G \times G$ via

$$(g_1, g_2)S = \pi(g_1) S \pi(g_2^{-1})$$

There is a **matrix coefficient map**:

$$MC_V : \mathrm{End}(V) \to C(G), \quad MC_V(S)(g) = MC_{S,V}(g) = \mathrm{tr}(S\pi(g^{-1})|V)$$

is a map of $K \times K$-representations. And denote $\mathcal{E}_\pi$ the image of of MC_V, and let $L^2_{alg}(G) = \oplus_{\pi \in \widehat{G}} \mathcal{E}_\pi$.

Prop. (10.11.4.9) [Schur Orthogonality Conditions]. Let $(\pi_1, V_1), (\pi_2, V_2)$ be f.d. continuous irreducible representations of K, then

$$\int_K MC_{S_1,V_1}(k) MC_{S_2,V_2}(k) = 0$$

unless $V_2 \cong V_1^*$, in which case

$$\int_K MC_{S_1,V}(k) MC_{S_2,V^*}(k) = \frac{1}{\dim V} \mathrm{tr}(S_1 \circ S_2^* | V).$$

In particular, $\mathcal{E}_\pi$ is orthogonal to $\mathcal{E}_{\pi'}$ for $[\pi] \neq [\pi']$, and if $\{e_i\}$ is any orthonormal basis of V, $\sqrt{d_\pi}\pi_{ij}$ is an orthonormal basis of $\mathcal{E}_\pi$, and $\mathcal{E}_\pi$ is isomorphic to $\mathrm{End}(V)$ as $K \times K$-representations.

Proof: Cf.[Gaitsgory P3]. □

Cor. (10.11.4.10). $MC_{S,V}(k^{-1}) = MC_{S^*,V^*}(k)$.

Prop. (10.11.4.11). $\mathcal{E}_\pi$ is invariant under left and right translations of G, and it is a two-sided ideal in $L^1(G)$.

Proof: It can be shown that $f \star \varphi_{u,v} = \varphi_{u,\pi(\overline{f})v}$, and $\varphi_{u,v} \star f = \varphi_{\pi(\widehat{f})u,v}$, where $\widehat{f}(x) = f(x^{-1})$. □

Prop. (10.11.4.12). If ρ is an irreducible f.d representation of K and V is a continuous representation of K, then for any $S \in \mathrm{End}(\rho^*)$, the image of

$$MC_{S,\rho}\mu_{Haar} \in M(K)$$

acting on V(10.9.3.24) belongs to V^ρ.

Proof: Cf.[Gaitsgory P7]. □

Cor. (10.11.4.13). For an irreducible representation ρ of K, the element $\xi_\rho \mu_{Haar} \in Meas(K)$ acts in any continuous representation V as a projection with image equal to V^ρ.

Proof: Directly from the proposition and(10.11.4.26). □

Prop. (10.11.4.14). $\mathcal{E}$ is an algebra, Cf.[Folland, P141]. It is dense in $C(K)$, and dense in $L^p(K)$ for $p < \infty$.

Proof: □

Prop. (10.11.4.15) [Peter-Weyl]. For a compact group K,

- $\widehat{\bigotimes}_{\pi\in\widehat{G}}\mathcal{E}_\pi = L^2(K)$, where $\mathcal{E}_\pi \cong \mathrm{End}(V_\pi)$.
- $L^2_{alg}(K) = \otimes_{\pi\in\widehat{G}}\mathcal{E}_\pi$ identifies with the K-finite vectors in $L^2(K)$ w.r.t. the left translation.

Proof: 1: By(10.11.4.4), the multiplicity of π in $L^2(K)$ is just $\dim\pi$, and this is just the multiplicity of π in $\mathcal{E}_\pi$ by(10.11.4.9), so this is an surjection, thus an isomorphism.

2: Clearly every vector in $\otimes_{\pi\in\widehat{G}}\mathcal{E}_\pi$ is K-finite. Conversely, if some vector v is K-finite, then it generates a finite vector space V under the left translation action of G. Now the linear function $f \mapsto f(1)$ restricts to a linear function l on V, and then $l(L_g^* v) = v(g)$, so v is a matrix coefficient of V, so $v \in L^2_{alg}(K)$. □

Cor. (10.11.4.16) [Representations of Product Groups]. Any irreducible representation of a the product group $G \times H$ for G, H is of the form $\rho \boxtimes \psi$ where ρ and ψ are irreducible representations of G, H resp.

Proof: By orthogonality of characters(10.11.4.22), there representations are irreducible and different. They are all the representations because they already form a basis in $L^2(G \times H)$. □

Prop. (10.11.4.17). For any continuous representation K, the subset V^{K-fin} is dense in V.

Proof: For any $v \in V$, choose a Dirac sequence f_n, then $\pi(f_n)v \to v$. Then by Peter-Weyl(10.11.4.15), we can choose K-finite functions g_n that $||g_n - f_n||_{L^2} < \frac{1}{n}$. Then g_n also converges to δ_1 in the weak topology. Thus

$$\pi(g_n)v \to v$$

and(10.11.4.12) shows $\pi(g_n)v \in V^{K-fin}$. □

Cor. (10.11.4.18). Matrix coefficients of f.d. representations are dense in $C(K)$. (Immediate from the proposition and Peter-Weyl theorem(10.11.4.15).

Cor. (10.11.4.19). Every irreducible continuous representation of a compact group is of f.d..

Proof: This is because V^{K-fin} is a sub-representation of V and it is dense in V, thus $V = V^{K-fin}$ is of f.d. because it is irreducible. □

Fourier Analysis on Compact Groups

Def. (10.11.4.20)[Characters]. Let V is a f.d. continuous representation of K, let $\chi_V = MC_V(\mathrm{Id}_V) = \mathrm{tr}(g|V)$, called the **character** of V, and if V is irreducible, define $\xi_V = \dim V \cdot \chi_V$.

This definition of character is compatible the abstract definition viewed as a representation of the group algebra $\mathbb{C}[G]$.

Prop. (10.11.4.21). If we take an invariant inner product on V, and e_i an orthonormal basis, then

$$\chi_V(g) = \sum_i (ge_i, e_i),$$

and

$$\chi_{V^*}(g) = \chi_V(g^{-1}) = \overline{\chi_V(g)}, \quad \chi_{V\oplus W} = \chi_V + \chi_W, \quad \chi_{V\otimes W} = \chi_V \cdot \chi_W$$

Cor. (10.11.4.22) [Orthogonality of Characters]. Let V, W be irreducible, then

$$\int_K \chi_V(k)\chi_W(k^{-1}) = \int_K \chi_V(k)\chi_{W^*}(k) = \int_K \chi_V(k)\overline{\chi_W(k)}$$

so by(10.11.4.9) this equals 1 if $V \cong W$ and 0 otherwise.

Prop. (10.11.4.23). Let χ be a character of a representation of compact group K of dimension n, then

- $\chi(1) = n$.
- $\chi(s^{-1}) = \chi(s)^*$.
- $\chi(tst^{-1}) = \chi(s)$.

Proof: Notice the eigenvalues of $\rho(g)$ all have absolute value 1, because this representation is unitarizable(10.11.4.1) thus $\rho^*(g) = \rho(g)^*$. □

Prop. (10.11.4.24) [Fourier Transform on Compact Groups]. Let K be a compact group and $f \in L^2(K)$, then by Peter-Weyl(10.11.4.15) and(10.11.4.9),

$$f = \sum_{\pi\in\widehat{G}}\sum_{i,j=1}^{d_\pi} c_{ij}^\pi \pi_{ij}, \quad c_{ij}^\pi = d_\pi \int_G f(x)\overline{\pi_{ij}(x)}dx.$$

So

$$f(x) = \sum_{\pi\in\widehat{G}}\sum_{i,j=1}^{d_\pi} d_\pi \int_G f(y)\overline{\pi_{ij}(y)}\pi_{ij}(x)dx = \sum_{\pi\in\widehat{G}} d_\pi f(y)\,\mathrm{tr}(\pi(y^{-1}x)) = \sum_{\pi\in\widehat{G}} d_\pi (f * \chi_\pi)(y).$$

Thus

$$f = \sum_{\pi\in\widehat{G}} d_\pi f * \chi_\pi,$$

and $d_\pi f * \chi_\pi$ are the projection of f onto $\mathcal{E}_\pi$(10.11.4.9).

Cor. (10.11.4.25). $\xi_V * \xi_W = 0$ unless $W \cong V$ and $\xi_V * \xi_V = \xi_V$(10.11.4.20).

Cor. (10.11.4.26). For continuous irreducible representations V, W of K, $\pi(\xi_V) \in \mathrm{End}\, W$ equals Id_W if $W \cong V$ and zero otherwise.

Def. (10.11.4.27) [Class Functions]. A measurable function on G is called a **class function** iff $f(y^{-1}xy) = f(x)$ a.e. $(x, y) \in G \times G$. Denote $ZL^p(G)$ the space of class functions in $L^p(G)$ and $ZC(G)$ the space of continuous functions on G.

Prop. (10.11.4.28). For a compact group K and $1 \le p < \infty$, the spaces $L^p(K)$ and $C(K)$ are Banach algebras under convolution(10.11.1.26), and $ZL^p(K)$ and $ZC(K)$ are their centers.

Proof: By(10.11.1.29), $||f * g||_p \le ||f||_1||g||_p \le ||f||_p||g||_p$, for $1 \le p \le \infty$, thus $L^p(G)$ and $C(G)$ are Banach algebras.

For $f \in L^p(K)$, $f * g = g * f$ iff

$$\int_K f(xy)g(y^{-1})dy = \int_K g(y)f(y^{-1}x)dy = \int_K f(yx)g(y^{-1})dy, \quad a.e.x$$

for any $g \in L^p(K)$, which is equivalent to $f(xy) = f(yx)$ a.e. x, y. Similarly for $f \in C(K)$. □

Lemma (10.11.4.29). If $f \in ZL^1(K)$ and $\pi \in \widehat{K}$, then $d_\pi f * \chi_\pi = \int_K (f\overline{\chi_\pi})\chi_\pi$.

Proof: For $x \in G$,

$$\pi(f)\pi(x) = \int_K f(y)\pi(yx)dy = \int_K f(yx^{-1})\pi(y)dy = \int_K f(x^{-1}y)\pi(y)dy = \int_K f(y)\pi(xy)dy = \pi(x)\pi(f)$$

so $\pi(f)$ is a scalar by Schur's lemma(10.11.2.4). Notice $f'(g) = f(g^{-1}) \in ZL^1(K)$ also, so

$$d_\pi[f * \chi_\pi](x) = d_\pi \int_K f(y^{-1})(\operatorname{tr}\pi)(yx)dy = d_\pi \operatorname{tr}(\int_K f(y^{-1})\pi(yx)dy) = \operatorname{tr}\pi(f')\operatorname{tr}(\pi(x))$$

and $\operatorname{tr}\pi(f') = \int_K f(y^{-1})\operatorname{tr}\chi(y)dy = \int_K f\overline{\chi_\pi}$. □

Prop. (10.11.4.30) [Characters Orthonormal Basis]. $\{\chi_\pi | \pi \in \widehat{K}\}$ is an orthogonal basis for $ZL^2(K)$.

Proof: $\chi_\pi \in ZC(K) \subset ZL^2(K)$ by(10.11.4.23), and they are orthonormal by(10.11.4.22). They are a basis by(10.11.4.29). □

Prop. (10.11.4.31). The linear spans of $\{\chi_\pi | \pi \in \widehat{K}\}$ is dense in $ZC(K)$ and $ZL^p(K)$ for $1 \le p < \infty$.

Proof: Cf.[Fol15] P148. □

Prop. (10.11.4.32) [Real Type]. Let G be a topological group and V is a complex representation, then the following are equivalent:

- $V = U \otimes_{\mathbb{R}} \mathbb{C}$ is a complexification of a real representation U of G.
- V admits a G-invariant anti-linear endomorphism S that $S^2 = 1$.
- There is a G-invariant symmetric form B on V inducing an isomorphism $V \cong V^*$.

Proof: $1 \iff 2$ is clear.

$2 \to 3$: By averaging there is a G-invariant Hermitian form h on V, then we can define $B(u, v) = h(u, Sv)$. As $h'(u, v) = h(Sv, Su)$ is also a G-invariant Hermitian form, $h(Sv, Su) = \pm h(u, v)$, so $B(v, u) = B(u, v)$.

$3 \to 1$: h induces a G-isomorphism $\overline{\varphi}_h : \overline{V} \cong V^*$. Then $\sigma = \overline{\varphi}_h \circ \varphi_B$ is a G-isomorphism $V \to \overline{V}$. Then $\overline{\sigma} \circ \sigma : V \to V$ is a G-isomorphism, thus by Schur's lemma $\overline{\sigma} \circ \sigma = \lambda$ for some $\lambda \in \mathbb{C}$. More explicitly, $B(v, u) = H(v, \sigma(u))$ for any $u, v \in V$. Because B is symmetric or symplectic, $B(u, v) = \pm B(v, u)$, thus $H(v, \sigma(u)) = \pm H(u, \sigma(v))$, and

$$\overline{\lambda} H(v, u) = H(v, \sigma^2(u)) = \pm H(\sigma(u), \sigma(v)) = \pm \overline{H(\sigma(v), \sigma(u))} = \overline{H(u, \sigma^2(v))} = \lambda H(v, u).$$

Thus λ is real. And then we can normalize σ that $\sigma = \pm 1$. If $\sigma^2 = 1$, then consider $V_0 = \ker(\sigma - 1)$, then $iV_0 = \ker(\sigma + 1)$, and $V_0 \oplus iV_0 = V$. If $\sigma^2 = -1$, then consider the action of $\mathbb{H}$ on V given by $(\alpha + \beta j)(v) = \alpha v + \beta\sigma(v)$. It is an action because σ is anti-linear and $\sigma^2 = -1$. □

Prop. (10.11.4.33) [Quaternion Type]. Let G be a topological group and V is a complex representation, then the following are equivalent:

- $V = W_{\mathbb{C}}$ is a restriction of a quaternionic representation W of G.
- V admits a G-invariant anti-linear endomorphism S that $S^2 = -1$.
- There is a G-invariant alternating form B on V inducing an isomorphism $V \cong V^*$.

Proof: 1 $\iff$ 2 is clear. The proof of $2 \to 3 \to 1$ is the same as the proof of(10.11.4.32). □

Prop. (10.11.4.34). An irreducible complex representation V of G, then V is of real/complex/quaternionic type iff $\mathrm{End}_{\mathbb{R}[G]}(V) \cong M_2(\mathbb{R})/\mathbb{C}/\mathbb{H}$

Proof: By(10.11.4.32), if V is of real type, then $V \cong U \otimes_{\mathbb{R}} \mathbb{C} \cong V \oplus V$, then $\mathrm{End}_{\mathbb{R}[G]}(V) \cong M_2(\mathbb{R})$.

By(10.11.4.33), if V is of quaternionic type, then it is a restriction of a quaternionic representation, so $\mathbb{H} \subset \mathrm{End}_{\mathbb{R}[G]}(V)$. And for any $\mathbb{R}$-linear endomorphism f of V, $f = \frac{f+if\circ i}{2} + \frac{f-if\circ i}{2}$ is a sum of $\mathbb{C}$-linear and anti-linear endomorphisms of V. For an anti-linear endomorphism g, gj is $\mathbb{C}$-linear, thus $f \in \mathbb{H}$.

If V is of complex type, then there are no invariant anti-linear endomorphisms, thus $f = \frac{f+if\circ i}{2} + \frac{f-if\circ i}{2} = \frac{f+if\circ i}{2}$ is $\mathbb{C}$-linear, so $\mathrm{End}_{\mathbb{R}[G]}(V) \cong \mathbb{C}$. □

Prop. (10.11.4.35) [Types of Representations]. Let V be a finite-dimensional irreducible $\mathbb{C}$-representation of a compact group G. Let dg be the Haar measure on G with $\int_G dg = 1$, then:

$$\int_G \chi(g^2)dg = \begin{cases} 1 & \iff V \text{ is of real type} \\ 0 & \iff V \text{ is of complex type} \\ -1 & \iff V \text{ is of quaternionic type} \end{cases}$$

Proof: Notice that $\chi(g^2) = \chi_{\mathrm{Sym}^2(V)}(g) - \chi_{\wedge^2(V)}(g)$, so $\int_G \chi(g^2)dg = \dim \mathrm{Sym}^2(V)^G - \dim \wedge^2(V)^G$. Then it is clear by(15.1.1.6). □

5 Induced Representation

Lemma (10.11.5.1). If H is a closed subgroup of a locally compact subgroup G, $q: G \to G/H$, for any unitary representation $(\sigma, \mathcal{H})$ of H, let $\mathcal{F}_0$ be the space of continuous functions $f: G \to \mathcal{H}$ that $q(\mathrm{Supp}(f))$ is compact, and

$$f(x\xi) = \sqrt{\frac{\Delta_H(\xi)}{\Delta_G(\xi)}}\sigma(\xi^{-1})f(x).$$

Then if $\alpha: G \to \mathcal{H}$ is continuous with compact support, then

$$f_\alpha(x) = \int_H \sqrt{\frac{\Delta_G(\eta)}{\Delta_H(\eta)}}\sigma(\eta)\alpha(x\eta)d\eta \in \mathcal{F}_0$$

and is left uniformly continuous w.r.t G. Moreover, every element in $\mathcal{F}_0$ arises in this way.

Proof: Clearly $q(\mathrm{Supp}\, f_\alpha) \subset q(\mathrm{Supp}\,\alpha)$, and

$$f_\alpha(x\xi) = \int_H \sqrt{\frac{\Delta_G(\eta)}{\Delta_H(\eta)}}\sigma(\eta)\alpha(x\xi\eta)d\eta = \int_H \sqrt{\frac{\Delta_G(\xi^{-1}\eta)}{\Delta_H(\xi^{-1}\eta)}}\sigma(\xi^{-1}\eta)\alpha(x\eta)d\eta = \sqrt{\frac{\Delta_H(\xi)}{\Delta_G(\xi)}}\sigma(\xi^{-1})f_\alpha(x).$$

For left uniformly continuity, Cf.[Folland, P164].

For the surjectivity, if $f \in \mathcal{F}_0$, by(10.11.1.37), there exists $\psi \in C_c(G)$ that $\int_H \psi(x\eta)d\eta = 1$ for $x \in \mathrm{Supp}\, f$. So we can let $\alpha = \psi \cdot f$, then

$$f_\alpha(x) = \int_H \sqrt{\frac{\Delta_G(\eta)}{\Delta_H(\eta)}}\psi(x\eta)\sigma(\eta)f(x\eta)d\eta = \int_H \psi(x\eta)f(x)d\eta = f(x)$$

□

Remark (10.11.5.2)[Left and Right Compatibility]. If we consider the right action, then it suffices to consider all the functions $g(x) = f(x^{-1})$. Then g satisfied

$$g(\xi x) = \sqrt{\frac{\Delta_G(\xi)}{\Delta_H(\xi)}}\sigma(\xi)g(x).$$

Def. (10.11.5.3) [Induced Representations]. Let (σ, V) be a unitary representation of H, for any $f, f' \in \operatorname{ind}_H^G \rho$, consider the function $g \mapsto (f(g), f'(g))$, then it is a function on $\mathcal{S}(G, \mathcal{H})$(10.11.1.40), thus

$$(f, f') \mapsto \int_{H\backslash G} (f, f') d\nu_{H\backslash G}(g)$$

is a right G-invariant Hermitian inner product on $\operatorname{ind}_H^G \rho$, thus $\operatorname{ind}_H^G \rho$ is unitarizable, called the **induced representation**.

Prop. (10.11.5.4)[Induction and Restriction]. If $(\sigma, \mathcal{H})$ is a unitary representation of H and $(\pi, \mathcal{H}')$ is a unitary representation of G, then $\operatorname{ind}_H^G(\sigma \otimes \operatorname{res}(\pi)) \cong \operatorname{ind}_H^G(\sigma) \otimes \pi$.

Prop. (10.11.5.5) [Frobenius Reciprocity]. If G is compact group and H is a closed subgroup, π is an irreducible unitary representation of G, ρ is an irreducible unitary representation of H, then

$$C(\pi, \operatorname{ind}_H^G(\rho)) = C(\pi|_H, \rho), \quad \operatorname{mult}(\pi, \operatorname{ind}_H^G(\rho)) = \operatorname{mult}(\rho, \pi|_H).$$

Proof: It suffices to prove the first one, the second follows from(10.11.2.2) and(10.11.4.5).

G/H admits a G-invariant measure as $\Delta_G = \Delta_H = 1$. For the rest, it is semilar to that of(15.1.5.44), Cf.[Folland, P172]. □

10.12 Harmonic Analysis

Main reference are [Rud91], [泛函分析张恭庆] and [Harmonic Analysis: Real Variable Methods, Orthogonality, and Oscillatory Integrals, Stein]. Notice much should be rewritten in greater generality of Analysis on Locally Compact Groups.

1 Distributions

Def. (10.12.1.1) [Test Functions]. The space $D(\Omega)$ of **test functions** has the induced topology coincides with that of $D(K)$, and any bounded subsets are in some $D(K)$, thus it is complete and has Heine-Borel because $D(K)$ does.

The space of continuous linear functionals of $D(\Omega)$ is called the space of **distributions** $D'(\Omega)$. It is equivalence to the restriction to every $D(K)$ is continuous, Cf.[Rudin P155]. The **order** of a distribution Λ is the minimal N that $|\Lambda\varphi| \leq C_K||\varphi||_N$ for every $\varphi \in D(K)$, it might be ∞.

Def. (10.12.1.2) [Differentiation of Distributions]. The **differentiation of a distribution** Λ is defined as $D^\alpha\Lambda(\varphi) = (-1)^{|\alpha|}\Lambda(D^\alpha\varphi)$. The multiplication by a smooth function f is defined by $f\Lambda(\varphi) = \Lambda(f\varphi)$. Then

$$D^\alpha(f\Lambda) = \sum_{\beta\leq\alpha} C_{\alpha\beta}(D^{\alpha-\beta}f)(D^\beta\Lambda).$$

Support of a Distribution

Def. (10.12.1.3). The **support of a distribution** is the complement $\mathrm{Supp}(\Lambda)$ of the open sets U that $\Lambda(f) = 0$ for any f with support in U.

If $\mathrm{Supp}(\Lambda)$ is compact, then Λ has finite order and $|\Lambda\varphi| \leq C||\varphi||_N$ for some N, and Λ extends uniquely to a continuous linear functional on $C^\infty(\Omega)$.

Proof: This is because its support is compact so we can choose a smooth ψ that $= 1$ on $\mathrm{Supp}\,\varphi$ and has support in $W \subset \Omega$. Then by (10.12.1.1), there is a C that $|\Lambda(\psi\varphi)| < C||\psi\varphi||_N$, and Leibniz rule will give us the result. □

Prop. (10.12.1.4). If the support of a Λ is a pt p (thus has finite order m), then it is a linear combination of $D^\alpha\delta_p, |\alpha| \leq m$. (use approximate identity and show the kernel of Λ is contained in the kernel of $D^\alpha\delta_p$.

Proof: Cf.[Rudin P165]. □

Prop. (10.12.1.5). For any distribution Λ, there exist continuous functions g_α in $C^\infty(\Omega)$ that each compact K intersects support of f.m g_α and $\Lambda = \sum D^\alpha g_\alpha$. When Λ has finite order, we can use only f.m g_α.

Proof: use partition of unity. Then for a compact K, find a compact-open W, then find a bump function between $K \subset W$, thus reduce to the case of $D_{\overline{W}}$. For the rest, Cf.[Rudin P169]. □

Convolution on $\mathbb{R}^n$

Denote $\mathscr{D} = \mathscr{D}(\mathbb{R}^n), \mathscr{D}' = \mathscr{D}'(\mathbb{R}^n)$.

Def. (10.12.1.6). The **translation** of a distribution u is defined as $(\tau_x u)(\varphi) = u(\tau_{-x}\varphi)$, where $\tau_x\varphi(y) = \varphi(y-x)$.

The **convolution** of a test function with a distribution u is defined as $(u*\varphi)(x) = u(\tau_x\check{\varphi})$, where $\check{\varphi}(y) = \varphi(-y)$.

Prop. (10.12.1.7) [Special Case of (10.12.1.10)]. For $u \in D', \varphi \in D, \psi \in D$,

- $\tau_x(u*\varphi) = (\tau_x u)*\varphi = u*(\tau_x\varphi)$.
- $u*\varphi \in C^\infty$ and $D^\alpha(u*\varphi) = (D^\alpha u)*\varphi = u*(D^\alpha\varphi)$.
- $u*(\varphi*\psi) = (u*\varphi)*\psi$.

If u has compact support, then(10.12.1.3) shows that u can extend to C^∞, thus convolution is defined for $\varphi \in C^\infty$ and the first two formulae still hold, and when $\psi \in D$,

$$u*\psi \in D, \quad u*(\varphi*\psi) = (u*\varphi)*\psi = (u*\psi)*\varphi$$

Proof: Cf.[Rudin P171], [Rudin P174]. □

Cor. (10.12.1.8). $L : \varphi \mapsto u*\varphi$ is a continuous linear map into C^∞ that commutes with τ_x. And any these map comes from a $u*$:let $u = (L\check{\varphi})(0)$.

Proof: It is continuous because of of closed graph theorem(10.8.2.8), $\lim(u*\varphi_i)(x) = \lim u(\tau_x\check{\varphi}) = u(\tau_x\check{\varphi})$. □

Cor. (10.12.1.9). When $u, v \in D'$ and one of them has compact support, then similar to(10.12.1.8), $L\varphi = u*(v*\varphi)$ is a continuous linear map that commutes with τ_x, so there is a unique **convolution distribution** $u*v$ that $(u*v)*\varphi = u*(v*\varphi)$. This convolution is compatible with the previous one when $v \in D$.

Prop. (10.12.1.10) [Convolution of Distributions]. For $u, v, w \in D'$,

- if one of u, v has compact support, then $u*v = v*u$, and $\mathrm{Supp}(u*v) \subset \mathrm{Supp}(u) + \mathrm{Supp}(v)$.
- if two of three of u, v, w has compact support, then $(u*v)*w = u*(v*w)$.
- $D^\alpha u = (D^\alpha\delta)*u$.
- if one of u, v has compact support, then $D^\alpha(u*v) = (D^\alpha u)*v = u*(D^\alpha v)$.

Proof: Cf.[Rudin P177]. □

Def. (10.12.1.11). A **approximate identity** here is a $h \in D$ that $h_k(x) = k^n h(kx)$. Then we will have $\lim \varphi*h_j = \varphi$ for $\varphi \in D$, $\lim u*h_j = u$ in D'.

2 Fourier Analysis on $\mathbb{R}^n$

Def. (10.12.2.1) [Notations]. We denote the normalized notation $\mathbb{R}^n$ as $dm = (2\pi)^{-n/2}dx$ and

$$D_\alpha = \frac{1}{i^{|\alpha|}}D^\alpha = \frac{1}{i^{|\alpha|}}\frac{\partial}{\partial x^\alpha},$$

which will simplify many notations compared to D^α. The **Fourier transform** here of a function $f \in L^1(\mathbb{R}^n)$ is the function $\widehat{f}$ that $\widehat{f}(t) = \int_{\mathbb{R}^n} fe_{-t}dm_n = (f*e_t)(0)$.

See(10.12.2.12) for general Fourier transform.

Prop. (10.12.2.2). For $f \in L^1(\mathbb{R})$,

$$\widehat{\tau_x f} = e_{-x}\widehat{f}, \quad \widehat{e_{-x} f} = \tau_x \widehat{f},$$

$$\widehat{f * g} = \widehat{f}\widehat{g}, \quad \widehat{f(x/\lambda)}(t) = \lambda^n \widehat{f}(\lambda t).$$

(Note $||f * g||_1 \leq ||f||_1 ||g||_1$).

Lemma (10.12.2.3). Let $f = e^{-1/2|x|^2}$, then $f \in \mathcal{S}$, $\widehat{f} = f$ and $f(0) = \int \widehat{f}$.

Proof: Reduce to the 1 dimensional case, in which case, $f' + xy = 0$, and $\widehat{f}$ also satisfies this. □

Lemma (10.12.2.4). For $f, g \in L^1$, Fubini theorem shows $\int \widehat{f}g = \int f\widehat{g}$.

Prop. (10.12.2.5) [Classical Fourier Transform].

- $\mathcal{S}$ is a Fréchet space in the topology defined by these norms.
- multiplication by $g \in \mathcal{S}$ and derivations are continuous linear map from S to S (direct calculation).
- $\widehat{P(D)f}(t) = P(t)\widehat{f}(t)$ and $\widehat{Pf} = P(-D)\widehat{f}$.
- The Fourier transform is a continuous linear one-to-one automorphism of $\mathcal{S}$, and $\Psi^2 g = \check{g}$.

Proof: 1:

2:

3: use(10.12.1.10) for the first one, and for the second one, should use definition of derivative and dominated convergence.

4:$\Psi f \in \mathcal{S}$ by 3, and it is continuous by closed graph theorem. By(10.12.2.4) and(10.12.2.2), $\int \widehat{f}(t)g(t/\lambda) = \int f(t/\lambda)\widehat{g}(y)$. If $\widehat{f}, \widehat{g} \in L^1$, dominant convergence shows $g(0)\int \widehat{f} = f(0)\int \widehat{g}$. So we only need one f that $f(0) = \int \widehat{f}$, $f = e^{-1/2|x|^2}$ will suffice(10.12.2.3). Hence $g(0) = \int \widehat{g}$ for every such g, and the conclusion follows by translation(10.12.2.2), and(10.11.3.14) also follows. □

Cor. (10.12.2.6). If $f \in L^1(\mathbb{R}^n)$, then $\widehat{f} \in C_0(\mathbb{R}^n)$, and $||\widehat{f}||_\infty \leq ||f||_1$, because $\mathcal{S}$ is dense in $L^1(\mathbb{R}^n)$.

Prop. (10.12.2.7) [Inversion Theorem]. If $f \in L^1(\mathbb{R}^n)$ and $\widehat{f} \in L^1(\mathbb{R}^n)$, then $\check{f} = \Psi^2 f$ a.e.

Proof: In(10.12.2.4), let $g \in \mathcal{S}$ and substitute $g = \Psi g$ and use Fubini, we get $\check{f} - \Psi^2 f$ is orthogonal to every $\mathcal{S}$, then every continuous function with compact support by(10.4.8.9). Thus they equal a.e. □

Cor. (10.12.2.8). If $f, g \in \mathcal{S}$, then $\widehat{fg} = \widehat{f} * \widehat{g}$ (apply Fourier one time and use(10.12.2.2)), and thus $f * g \in \mathcal{S}$.

Prop. (10.12.2.9) [Fourier-Plancherel]. If $f, g \in \mathcal{S}$, then

$$\int f\overline{g} = \int \overline{g}(x)\widehat{f}(t)e^{ixt} = \int \widehat{f}(t)\int \overline{g}(x)e^{ixt} = \int \widehat{f}\overline{\widehat{g}}$$

by inversion formula. And $\mathcal{S}$ is dense in L^2, thus it extends to a linear isometry of $L^2(\mathbb{R}^n) \to L^2(\mathbb{R}^n)$. This coincides with the Fourier transform on $L^1 \cap L^2$.

Prop. (10.12.2.10). D injects into $\mathcal{S}$ and is dense.(Notice they both are complete, but the subspace topology are different)(Use scaling, Cf.[Rudin Functional Analysis P189]). So we call a distribution **tempered** iff it comes from a continuous functional of $\mathcal{S}$.

From(10.12.1.3), we know any distribution with compact support is tempered. By Holder, every $f\in L^p(\mathbb{R}^n), p\geq 1$ is tempered distribution, and every polynomial or functions of polynomial growth are tempered distribution.

$$D\subset\mathcal{S}\subset L^2=(L^2)^\vee\subset\mathcal{S}'\subset D'.$$

$\mathcal{S},\mathcal{S}'$ is complete(10.8.4.3).

Prop. (10.12.2.11). A $f\in\mathcal{S}'$ iff $f=\sum_{|\alpha|\leq m}D_\alpha(u_\alpha(1+|x|^2)^{m/2})$ for some m, where $u_\alpha\in L^2(\mathbb{R}^n)$.

Proof: In fact,

$$||\varphi||'_m=(\sum_{|\alpha|\leq m}\int(1+|x|^2)^m|D_\alpha\varphi|^2\,\mathrm{dx})^2$$

is an equivalent set of norms of $\mathcal{S}'$, Cf.[泛函分析张恭庆 P182]. And each of them defines a Hilbert space. So by Riesz we get the result. □

Prop. (10.12.2.12)[Generalized Fourier Transform]. For a tempered distribution $u\in\mathcal{S}'$, we define the **Fourier transformation** as the tempered distribution $\widehat{u}(\varphi)=u(\widehat{\varphi})$. It is easily verified that it is compatible with previously defined Fourier transform when seen as tempered distributions by?? In particular, this is defined for compactly supported distribution, $L^p(\mathbb{R}^n), p\geq 1$ and smooth functions of polynomial growth(10.12.2.10).

Prop. (10.12.2.13). $\widehat{P(D)u}=P\widehat{u}$ and $\widehat{Pu}=P(-D)\widehat{u}$. And The Fourier transformation is a continuous linear isometry of $\mathcal{S}'$ in the weak* topology.

Cor. (10.12.2.14). $\widehat{1}=\delta$, thus $\widehat{P}=P(-D)\delta$ and $\widehat{P(D)\delta}=P$. Now(10.12.1.4) tells us a distribution is the Fourier transform of a polynomial iff it has support in the origin.

Prop. (10.12.2.15) [Convolution of Tempered Distributions]. Let $u\in\mathcal{S}'$ and $\varphi,\psi\in\mathcal{S}$, then

- $u*\varphi\in C^\infty$ of polynomial growth and $D^\alpha(u*\varphi)=(D^\alpha u)*\varphi=u*(D^\alpha\varphi)$.
- $u*(\varphi*\psi)=(u*\varphi)*\psi$.
- $\widehat{u*\varphi}=\widehat{\varphi}\widehat{u}, \widehat{u}*\widehat{\varphi}=\widehat{\varphi u}$.
- If P is a polynomial and $g\in\mathcal{S}$, then $D^\alpha u, Pu$ and gu are all tempered.

Proof: Cf.[Rudin Functional Analysis P195] for the first 3. □

Variants

Prop. (10.12.2.16) [Mellin Inversion Formula]. Given a function $f:\mathbb{R}^+\to\mathbb{C}$ satisfying suitable conditions, its **Mellin transformation** is defined to be

$$M(f)(s)=\int_0^\infty f(t)t^s\frac{dt}{t}.$$

whenever this integral is absolutely convergent.

Notice if $\int_0^1 f(t)t^s\frac{dt}{t}$ is convergent for some s, then it converges for any bigger s, and if $\int_1^\infty f(t)t^s\frac{dt}{t}$ converges for some s, then it converges for any smaller s. So the domain of $M(f)$ if nonempty, is a vertical strip $\sigma_1<\mathrm{Re}(\sigma)<\sigma_2$ for $\sigma_1,\sigma_2\in[-\infty,\infty]$.

Then f can be recovered from $M(f)$: for any $\sigma_1 < \sigma < \sigma_2$,

$$f(x) = \frac{1}{2\pi \mathrm{i}} \int_{\sigma-\mathrm{i}\infty}^{\sigma+\mathrm{i}\infty} x^{-s} M(f)(s) ds.$$

Proof: Using the isomorphism of groups $t = e^x : \mathbb{R}^+ \to \mathbb{R}$, this is just the usual Fourier transformation on $\mathbb{R}$. □

Def. (10.12.2.17) [Laplace Transformation]. Let $h : \mathbb{R}_+ \to \mathbb{R}$ be a piecewise-continuous function, the **Laplace transformation** of h is the function

$$(\mathcal{L}h)(s) = \int_0^\infty e^{-st} h(t) \mathrm{d}t, s \in \mathbb{C}$$

whenever it is convergent. It is a holomorphic function for $\mathrm{Re}(s) > c$ if $h(t) = O(e^{ct})$.

Proof: The last assertion follows from(10.5.2.13). □

Thm. (10.12.2.18). Let $f : \mathbb{R}_{\geq 0} \to \mathbb{R}$ be a bounded piecewise-continuous function that its Laplace transform $(\mathcal{L}f)(s)$ extends to a holomorphic function on $\mathrm{Re}(s) \geq 0$, then the integral $\int_0^\infty f(t)\mathrm{d}t$ converges and equals $(\mathcal{L}f)(0)$.

Proof: Cf.[Suthurland, Number Theory1, L16].**?** □

Paley-Wiener Theory

Prop. (10.12.2.19). For $\varphi \in D(\mathbb{R}^n)$ that has support in rB, the You-Know-How defined $\widehat{\varphi}(z)$ is an entire function of several variable and satisfies:

$$|\varphi'(z)| \leq \gamma_N (1 + |z|)^{-N} e^{r|\operatorname{Im} z|}.$$

For $N \geq 0$. Conversely, any such function correspond to a $\varphi \in D(\mathbb{R}^n)$ that has support in rB.

Proof: Cf.[Rudin P198]. □

Prop. (10.12.2.20) [Fourier-Laplace transformation]. For $u \in D'(\mathbb{R}^n)$ that has support in rB, of order N, the $\widehat{u}(z) = u(e_{-z})$ is an entire function of several variable and satisfies:

$$|f(z)| \leq \gamma(1 + |z|)^N e^{r|\operatorname{Im} z|}.$$

Conversely, any such function correspond to a $u \in D'(\mathbb{R}^n)$ that has support in rB.

Proof: Cf.[Rudin P199]. □

3 Tauberian Theory

Thm. (10.12.3.1) [Wiener]. If Y is a closed translation-invariant space of $L^1(\mathbb{R}^n)$ s.t. $Z(Y) = \cap_{f\in Y}\{s \in \mathbb{R}^n : \widehat{f}(s) = 0\} = \varnothing$, then $Y = L^1(\mathbb{R}^n)$.

Proof: Cf.[Rud91]P228. □

Cor. (10.12.3.2). If $\varphi \in L^1(\mathbb{R}^n)$ and Y is the smallest closed translation-invariant subspace of $L^1(\mathbb{R}^n)$ containing φ, then $Y = L^1(\mathbb{R}^n)$ iff $\widehat{\varphi}(t) \neq 0$ for any $t \in \mathbb{R}^n$.

Proof: Notice $Z(Y) = \cap_{f\in Y}\{s \in \mathbb{R}^n : \widehat{f}(s) = 0\} = \{t \in \mathbb{R}^n : \widehat{\varphi}(t) = 0\}$. □

4 Sobolev Spaces

Def. (10.12.4.1). For $1 \le p < \infty$, the **Sobolev space** $W^{m,p}(\Omega)$ is the space of functions u that $D^\alpha u \in L^p(\Omega)$ for every $|\alpha| \le m$, with the norm $||u|| = \sum_{|\alpha|<m} \int_\Omega |D^\alpha u(x)|^2 dx$. The **Sobolev space** $W_0^{m,p}(\Omega)$ is the completion of the subspace $C_0^\infty(\Omega)$.

Prop. (10.12.4.2)[Meyers-Serrin]. The Sobolev space $W^{m,p}(\Omega)$ is the completion of $u \in C^\infty(\Omega)$ that $D^\alpha u \in L^p(\Omega)$ for every $|\alpha| \le m$.

Proof: Choose a countable partition of unity ψ_k, then as in the proof of(10.4.8.10), we can choose δ_k small enough and $||\psi u - (\psi u)_{\delta_k}|| < \varepsilon/2^k$ and $\varphi = \sum(\psi u)_{\delta_k}$ is definable. □

Prop. (10.12.4.3). We denote $H^m(\Omega) = W^{m,2}(\Omega)$ and $H_0^m(\Omega) = W_0^{m,2}(\Omega)$ and $H^{-m}(\Omega) = (H_0^m(\Omega))^*$ when m is an integer. Notice derivative is not applicable for $H^{-m}(\Omega)$ unless $\Omega = \mathbb{R}^n$.

When $\Omega = \mathbb{R}^n$, $D(\mathbb{R}^n)$ is dense in $W^{m,p}$(10.4.8.10), thus $W_0^{m,p} = W^{m,p}$. Define the **Sobolev space**

$$H^s = \{u|(1+|y|^2)^{s/2}|\widehat{u}| \in L^2\}$$

H^s is a Hilbert space and $H^s \subset \mathcal{S}'$ for every s (use Holder to show $\widehat{u} \in \mathcal{S}'$). H^m coincides with previously defined H^m when m is a positive integer thus also negative-integer. A linear operator on $H = \cup H^s$ is said to have **order** t if it maps every H^s continuously into H^{s-t}.

Proof: By Plancherel,

$$||\varphi||'_m = (\sum_{|\alpha|\le m} ||D_\alpha u||_2^2)^{1/2} \quad \text{and} \quad (\int (1+|x|^2)^m |\widehat{u}|^2)^{1/2}$$

are equivalence norms on H^m. □

Lemma (10.12.4.4) [Poincare Inequality]. For Ω bounded, on $C_0^m(\Omega)$ the $W^{m,p}$ norm is controlled by L^p norms of its mth order derivatives .

Proof: We may assume $\Omega \subset \prod_{i=1}^n [0,a]$, then for any $u \in W^{m,p}$, $u(x) = \int_0^{x_1} D^1 u(t, x_2, \ldots, x_n) dt$, so by Holder inequality,

$$|u(x)| \le a^{1/q} (\int_0^a |D^1 u|^p dx_1)^{1/p}.$$

so

$$\int_\Omega |u(x)|^p dx \le a^q \int_\Omega |D^1 u|^p dx_1.$$

Doing the same for all other derivatives, we can see the norm is controlled by the highest(m-th) order norms. □

Prop. (10.12.4.5). When $t < s$, $H^s \subset H^t$. And H^s are isometric to H^t by $\widehat{v} = (1+|y|^2)^{t/2}\widehat{u}$ and is of order t. D^α is of order $|\alpha|$. If $f \in \mathcal{S}$, then $u \to fu$ is an operator of order 0.

Every distribution of compact support is in some H^s(10.12.1.3), in particular $D(\Omega)$.

Proof: Cf.[Rudin P217]. □

Prop. (10.12.4.6)[Sobolev Embedding Theorem]. On a manifold of dimension n which is compact with Lipschitz boundary or complete of positive injective radius and bounded sectional curvature,

- if $k > l$ be integers and
$$\frac{1}{p}-\frac{k}{n}=\frac{1}{q}-\frac{l}{n}$$
then $W^{k,p}(\text{int}(M))\subset W^{l,q}(M)$ continuously.

- if
$$\frac{1}{p}-\frac{k}{n}=-\frac{r+\alpha}{n}$$
then $W^{k,p}(\text{int}(M))\subset C^{r,\alpha}(M)$ continuously.

Proof: Cf.[Evans P290]. □

Cor. (10.12.4.7) [Gagliardo–Nirenberg–Sobolev]. On a manifold of dimension n which is compact with Lipschitz boundary or a complete of positive injective radius and bounded sectional curvature, if $\frac{1}{p^*}=\frac{1}{p}-\frac{1}{n}$ (Sobolev conjugate), then $W^{1,p}(\text{int}(M))\subset L^{p^*}(M)$ continuously.

Cor. (10.12.4.8). On a manifold of dimension n which is compact with Lipschitz boundary or a complete of positive injective radius and bounded sectional curvature, if $m > n/2$, then $W^{m,2}(\text{int}(M))\subset C(\overline{\Omega})(M)$ continuously. And the functions in $W_0^{m,2}$ are continuous and vanish at the boundary, by C_0 approximation.

Proof: The $\mathbb{R}^n$ case can be directly proved: because we have the equivalent norm(10.12.4.3), $\widehat{u}\in L^2$ thus $u\in L^2$, and
$$\int|\widehat{u}|\le(\int(1+|x|^2)^m|\widehat{u}|^2)^{1/2}\cdot\Big(\int 1/(1+|x|^2)^m\Big)^{1/2}.$$
We have $\widehat{u}\in L^1$, thus inversion formula applies that u is continuous and $||u||_\infty\le||\widehat{u}||_1\le C||u||_{H^m}$. □

Cor. (10.12.4.9). $\cap_s H^s=C^\infty(M)$.

Prop. (10.12.4.10) [Rellich-Kondrechov]. On a compact manifold with C^1 boundary of dimension n, if $k > l$ and
$$\frac{1}{p}-\frac{k}{n}<\frac{1}{q}-\frac{l}{n}$$
then $W^{k,p}\subset W^{l,q}$ completely continuously.

Proof: Cf.[Distributions and Operators P199], [Evans P290]. □

Cor. (10.12.4.11). On a bounded extension domain of $\mathbb{R}^n$, $W^{1,p}\subset L^p$ completely continuously.

Proof: We prove the $p=2$ case. For a sequence u_m in $W^{1,2}$, we have $||u_m-u_p||_2=||U_m-U_p||_2=||\widehat{U}_m-\widehat{U}_p||_2$. By(10.9.4.9), there is a subsequence that $\widehat{U}_m$ pointwise converge. Notice they are uniformly bounded, Now apply two region argument, for $|x|<r$, use Lebesgue dominant convergence, and for $|x|>r$, use $\int(1+|x|^2)|\widehat{U}_m-\widehat{U}_p|^2$ is bounded to conclude $||u_m-u_p||_2\to 0$. □

Prop. (10.12.4.12). $u\in D'(\Omega)$ is a locally H^s $\iff$ $\psi u\in H^s$ for every $\psi\in D(\Omega)$ $\iff$ $D_\alpha u$ is locally L^2 for every $|\alpha|\le s$.

Thus every smooth function is locally H^s for every s.

Proof: $1\to 2$ use partition of unity, $2\to 1$ easy, and $2,3$ are all equivalent to $D_\alpha(\psi u)\in L^2$ for every $\psi\in D(\Omega)$. by Leibniz+Plancherel or (10.12.4.5). □

Prop. (10.12.4.13). If $r > p+n/2$, then if a function f on Ω has all the distribution derivative $D_i^k f$ locally L^2, $=g_{is}$, for $0\le k\le r$, then $f\in C^p(\Omega)$ a.e.

Cor. (10.12.4.14). If $u\in D'(\Omega)$ is locally H^s, then $u\in C^{s-n/2}(\Omega)$. Thus $\cap$locally $H^s=C^\infty(\Omega)$.

Holder Space

Def. (10.12.4.15). Holder space $C^{k,\alpha}(\Omega)$ is the subspace of $C^k(\Omega)$ with the norm

$$||f||_{C^{k,\alpha}} = ||f||_{C^k} + \max_{|\beta|=k} \sup_{x\neq y\in\Omega} \frac{|D^\beta f(x) - D^\beta f(y)|}{||x-y||^\alpha}.$$

5 Fourier Analysis on $\mathbb{T}^n$

Prop. (10.12.5.1). If f is a periodic function on $\mathbb{R}$ with period 2π and piecewise-differentiable, then the Fourier series of f converges to $\frac{1}{2}(f(x+) + f(x-))$ everywhere.

Proof: [武胜健 2, P264]. □

Prop. (10.12.5.2). If f is a periodic differentiable function on $\mathbb{R}$ with period 2π and f' is integrable at $[-\pi, \pi]$, then the Fourier series of f converges to f uniformly.

Proof: [武胜健 2, P281]. □

Prop. (10.12.5.3). If $f \in L^1(\mathbb{T})$ is absolutely continuous, then $\widehat{(f')}(n) = 2\pi\,\mathrm{i}\, n\cdot \widehat{f}(n)$.

Prop. (10.12.5.4). $f \in L^1(\mathbb{T})$ is determined by its Fourier coefficients.

10.13 Differential Equations

1 ODE-Fundamentals

Prop. (10.13.1.1).

$$x^{(2)} = f(x)$$

It can be solved.

Proof:

$$x^{'}x^{(2)} = f(x)x^{'}$$
$$\frac{1}{2}(x^{'})^2 = \int^x f(t)dt$$

□

Prop. (10.13.1.2) [Wronsky].

2 ODE-Theorems

Prop. (10.13.2.1) [Existence and Uniqueness of ODE of Lipschitz Type]. If $F(t,x)$ defined on $[-h,.h] \times [\eta-\delta,\eta+\delta]$ is a function that is locally Lipschitz: that is, $\exists \delta, L$, s.t. if $|t| \leq h, |x_i - \eta| \leq \delta$, then

$$|F(t,x_1) - F(t,x_2)| \leq L|x_1 - x_2|.$$

Then the initial value problem:

$$(Tx)(t) = \eta + \int_0^t F(\tau, x(\tau))d\tau$$

has a unique solution on the interval $[-h,h]$ if $h < \min\{\delta/M, 1/L\}$, where M is the maximum of F on $[-h,.h] \times [\eta-\delta,\eta+\delta]$. Because T is a contraction.

Prop. (10.13.2.2) [Existence of ODE of continuous Type (Caratheodory)]. If $F(t,x)$ defined on $[-h,.h] \times [\eta-\delta,\eta+\delta]$ is a continuous function, then

$$(Tx)(t) = \eta + \int_0^t F(\tau, x(\tau))d\tau$$

has a unique solution on the interval $[-h,h]$ if $h < \delta/M$, where M is the maximum of F on $[-h,.h] \times [\eta-\delta,\eta+\delta]$. (Use Schauder fixed point theorem and Arzela-Ascali).

Prop. (10.13.2.3) [Existence Theorem for Complex Differential Equations]. Let $f(z,\mathbf{w})$ be a holomorphic vector function in a domain $D \subset \mathbb{C}^{n+1}$, then the initial value problem

$$\mathbf{w}' = f(z,\mathbf{w}), \quad w(z_0) = w_0$$

has exactly on holomorphic solution locally (Thus on a simply connected domain).

Cor. (10.13.2.4). So a holomorphic high-order ODE for a complex variable can be solves. And luckily it can be solved even $\overline{z}$ appears (just regard it as a constant).Δ

Proof: Cf.[Ordinary Differential Equations, P110]. □

Prop. (10.13.2.5). For the equation:

$$\frac{d\mathbf{y}}{d\mathbf{x}} = \mathbf{A}\mathbf{y},$$

One solution basis is:

$$\begin{cases} e^{\lambda_1 x}\mathbf{P}_1^{(1)}(x), \cdots, e^{\lambda_1 x}\mathbf{P}_{n_1}^{(1)}(x); \\ \cdots\cdots\cdots \\ e^{\lambda_s x}\mathbf{P}_1^{(d)}(x), \cdots, e^{\lambda_s x}\mathbf{P}_{n_s}^{(1)}(x); \end{cases}$$

Where

$$\mathbf{P}_j^{(i)}(x) = \mathbf{r}_{j0}^{(i)} + \frac{x}{1!}\mathbf{r}_{j1}^{(i)} + \cdots,$$

where $\mathbf{r}_{j0}^{(i)}$ is a basis of solution of $(\mathbf{A} - \lambda_i I)^n \mathbf{x} = 0$, and $\mathbf{r}_{k+1}^{(i)} = (\mathbf{A} - \lambda_i I)\mathbf{r}_k^{(i)}$.

Proof: Cf.[常微分方程丁同仁定理 6.6]. □

Cor. (10.13.2.6). For the equation:

$$y^{(n)} + a_1 y^{(n-1)} + \cdots + a_{n-1}y' + a_n y = 0,$$

If the characteristic equation has s different roots $\lambda_1, \ldots, \lambda_s$ and corresponding multiplicities $n_1, \ldots, n_s$, then:

$$\begin{cases} e^{\lambda_1 x}, xe^{\lambda_1 x}, \cdots, x^{n_1 - 1}e^{\lambda_1 x}; \\ \cdots\cdots\cdots \\ e^{\lambda_s x}, xe^{\lambda_s x}, \cdots, x^{n_s - 1}e^{\lambda_s x}; \end{cases}$$

is a solution basis.

Proof: Cf.[常微分方程丁同仁 P198]. □

Prop. (10.13.2.7)[Lyapunov]. Consider the Lyapunov stability of an autonomous system of the form:

$$\frac{dx}{dt} = Ax + o(|x|),$$

Then:

1. If A has a eigenvalue whose real part is positive, then the trivial solution is not weak stable.
2. If all eigenvalues of A has negative real part, then the trivial solution is strong stable.

Stum-Liouville

Prop. (10.13.2.8) [Stum-Liouville]. The eigenvalue BVP problem of L-S equation:

$$Lu = (pu')' + qu = \lambda u, \quad a_1 u(a) + a_2 u'(a) = 0, b_1 u(b) + b_2 u'(b) = 0, \sigma(x) > 0.$$

can be solved by the method of Green's function. For the function:

$$G(x,s) = \begin{cases} Cu_1(x)u_2(s), & x < s \\ Cu_2(x)u_1(s), & x > s \end{cases}$$

for some C, where u_1 is a solution of the L-S equation with boundary value at a, and u_2 with boundary value at b that are linear independent (This happens when the homogenous equation has no solution). It satisfies: $LG(x,s) = \delta(x-s)$ and satisfies the boundary conditions.

Because L is self-adjoint, we have:

$$Gf(x) = \int f(s)G(x,s)ds, LG = \mathrm{id}, GL = \mathrm{id}$$

thus the eigenvalues of L is the reciprocal of the eigenvalues of G, and G is a compact self-adjoint operator on $L^2(\sigma, \mathbb{R})$, so by spectral theorem, the eigenvectors are countable and form an orthonormal basis.

And when the homogenous problem do have a solution ϕ, then we have:$Lu = f$ has a solution iff $(f, \phi) = 0$. one way is simple and the other way is because we solve the initial problem of ODE and find that it automatically satisfies the boundary condition. Cf.[Stum Liouville Theory].

Prop. (10.13.2.9). More generally, if there the boundary is mixed of $u(a), U'(a), u(b), u'(b)$, the solution of

$$Lu = (pu')' + qu = 0, B_1(u) = \alpha, B_2(u) = \beta.$$

has a unique solution for any α, β iff the homogenous equation has only non-trivial solution. (Because the solution space is of 2 dimensional.

Prop. (10.13.2.10) [Stum Seperation Theorem].

Prop. (10.13.2.11) [Stum Comparison Theorem]. If $y'' + K_i(x)y = 0$ are equations. If $y_i(0) = 0$ and $|y_1'(0)| = |y_2'(0)|$, then if $K_1(x) \geq K_2(x)$, then $y_1(x) \geq y_2(x)$ until $y_2(x)$ is zero. (directly from(11.2.4.10)).

3 Linear PDE

Def. (10.13.3.1). For a linear PDE with constant coefficients $P(D)u = v$, the **fundamental solution** is a distribution $E \in D'(\mathbb{R}^n)$ that $P(D)E = \delta$. This is important because if v is a distribution with compact support, $P(D)(E * v) = (P(D)E) * v = \delta * v = v$(10.12.1.10), so $u = E * v$ is a distribution solution.

Prop. (10.13.3.2). When $v \in D'(\mathbb{R}^n)$ has compact support, $P(D)u = v$ has a solution u with compact support iff $Pg = \widehat{v}$ has a solution g entire. In this case, $g = \widehat{u}$ for some distribution u, and u has support in the convex hull of the support of v.

Proof: Use(10.12.2.20), and some bound relation between g and Pg. Cf.[Rudin Functional Analysis P212]. □

Prop. (10.13.3.3). The fundamental solution always exist when for PDE of constant coefficients.

Proof: For a $\varphi \in D(\mathbb{R}^n)$, there is at most one ψ that $\psi = P(D)\varphi$ because $\widehat{\psi} = P\widehat{\varphi}$ and they are entire function. Thus the task is to verify the functional $u : P(D)\varphi \to \varphi(0)$ is continuous and extend to a distribution $u \in D'(\mathbb{R}^n)$. Cf.[Rudin Functional Analysis P215]. □

4 Differential Operators on Manifolds

Prop. (10.13.4.1) [Index Theorem P109]. has a nice definition of symbol of a differential operator on a manifold as a map form $\mathrm{Sym}^m T^*M \otimes \mathbb{C} \to \mathrm{Hom}(E, F)$.

5 Pseudo-Differential Operator

Def. (10.13.5.1). Denote the **Japanese bracket** $[x] = (1 + |x|^2)^{1/2} \sim 1 + |x|$.

Motivated by the formula $(\widehat{P\hat{f}})^\vee = P(D)f$ for $f \in \mathcal{S}$ and polynomial P of ξ with coefficients smooth functions of x**??** we define the **symbol class** $S^{\mu,\beta}$ as the space of smooth functions $a : \mathbb{R}^{2n} \to \mathbb{C}$ that

$$|D_{x,\alpha} D_{\xi,\beta} a(x,\xi)| \leq C_{\alpha,\beta}[x]^\mu [\xi]^{m-|\beta|}$$

and denote $S^m = S^{0,m}$.

We denote the **symbol class** $\mathcal{A}^v$ as the space of smooth functions $a : \mathbb{R}^{2n} \to C$ that $|D_\alpha a| \leq C_\alpha [x+\xi]^v$ for any α. So $S^{\mu,m} \subset \mathcal{A}^{|\mu|+|m|}$

And we define the **pseudo-differential operator of symbol** a:

$$(a(x,D)u)(x) = \int_\xi e^{ix\xi} a(x,\xi)\widehat{u}$$

Moreover, we can define the **amplitude function** $p(x,y,\xi)$ and define

$$Pu(x) = \int e^{i(x-y)\xi} p(x,y,\xi)u(y)dy.$$

Def. (10.13.5.2). We define the space S^d of **polyhomogenous symbols of degree** d as the set of all symbols in $S^d_{0,1}$ that there exists a set of p_{d-l} homogenous in ξ of degree $d-l$ that $p = \sum p_{d-l}$ modulo an operator in $S^{-\infty}$. Note that when p_{d-l} is homogenous of degree $d-l$, then it is automatically in $S^{d-l}_{0,1}$.

Def. (10.13.5.3). A ψdo operator a is called **elliptic** if $\sigma(a) \in S^m$ and $\sigma(a) \geq [\xi]^{-m}$ for ξ big enough.

Prop. (10.13.5.4) [Peetre's Inequality]. For all $v \in \mathbb{R}$, there is a constant C that

$$[X+Y]^v < C[X]^v[Y]^v.$$

Proof: For $v > 0$, just as normal. For $v < 0$, use $X = (X+Y) + (-Y)$ applied to $-v$. □

Prop. (10.13.5.5). The mapping $a(x,\xi) \times u(x) \mapsto a(x,D)u$ is continuous from $\mathcal{A}^v \times \mathcal{S} \to \mathcal{S}$, thus also continuous from $S^{\mu,m} \times \mathcal{S} \to \mathcal{S}$. Cf.[Pseudo Differential Operator P28].

Lemma (10.13.5.6) [Schur Test]. For a function K on $\mathbb{R}^{2n}$ and $u \in L^p(\mathbb{R}^n)$, let $||K||_1 = \sup_x \int |K(x,y)|dy$ and $||K(x,y)||_2 = \sup_y \int |K(x,y)|dx$. Let $Au(x) = \int K(x,y)u(y)dy$, then

$$||Au||_{l^p} \leq ||K||_1^{1-1/p} ||K||_2^{1/p} ||u||_{L^p}.$$

by Holder.

Prop. (10.13.5.7) [Calderón-Vaillancourt]. There is a constant C, N_{CV} that for $u \in \mathcal{A}^0$ and $\varphi \in \mathcal{S}$,

$$||Op(u)\varphi||_{L^2} \leq C \max_{|\alpha|+|\beta| \leq N_{CV}} ||\partial_x^\alpha D_{\beta,\xi} u||_{L^\infty} ||\varphi||_{L^2}.$$

This in particular applies to $u \in S^0$.

Proof: Cf.[Calderon-Vaillancourt]. □

Cor. (10.13.5.8). S^m maps H^s to H^{s-m}. Because by symbolic calculus(10.13.5.10), we have

$$Op([\xi]^{s-m})Op(u)Op([\xi]^{-s}) = Op(b) \in S^0,$$

thus $Op(u) = Op([\xi]^{m-s})Op(b)Op([\xi]^s)$ maps H^s into H^{s-m}.

Symbolic Calculus

Def. (10.13.5.9) [Semiclassical Operator]. For $a \in S^{\mu,m}$ and $h \in (0,1]$, we denote $a_h(x,\xi) = a(x, h\xi)$, it is also in $S^{\mu,m}$.

Prop. (10.13.5.10) [Composition]. If $a \in S^{\mu_1,m_1}$ and $b \in S^{\mu_2,m_2}$, there is a pseudo-differential operator $(a\#b)(h) \in S^{\mu_1+\mu_2,m_1+m_2}$ for every $h \in (0,1]$ that

$$Op(a_h)Op(b_h) = Op((a\#b)(h)_h)$$

and for all $J > 0$, $(a\#b)(h)$ can be written as

$$a\#b(h) = \sum_{j<J} h^j \Big(\sum_{|\alpha|=j} \frac{1}{\alpha!} \partial_\xi^\alpha a D_x^\alpha b \Big) + h^J r_J^{\#}(a,b,h)$$

where $r_J^{\#}(a,b,h) \in S^{\mu_1+\mu_2,m_1+m_2-J}$ and it is bilinear of a, b and equicontinuous independently of h.

Proof: Cf.[Pseudo Differential Operator P36]. □

Prop. (10.13.5.11) [Adjoint]. If $a \in S^{\mu,m}$ and $u, v \in \mathcal{S}$, there is a pseudo-differential operator $a * (h)$ for every $h \in (0,1]$ that

$$(u, Op(a_h)v) = (Op(a^*(h)_h)u, v)$$

in the L^2 norm and for all $J > 0$, $a^*(h)$ can be written as

$$a^*(h) = \sum_{j<J} h^j (\sum_{|\alpha|=j} \frac{1}{\alpha!} \partial_\xi^\alpha D_x^\alpha \overline{a}) + h^J r_J^*(a,h)$$

where $r_J^*(a,h) \in S^{\mu,m-J}$ and it is anti-linear of a and equicontinuous independently of h.

Proof: Cf.[Pseudo Differential Operator P30]. □

Def. (10.13.5.12). For $u \in \mathcal{S}'$, we define the action of $a(x,\xi)$ on u by

$$(Op(a_h)u)(\overline{\varphi}) = u(\overline{Op(a^*(h)_h)\varphi}).$$

This is compatible with the definition on $\mathcal{S}$.

6 General PDE

Cf.[Gilbarg, David; Trudinger, Neil S. Elliptic partial differential equations of second order. Reprint of the 1998 edition. Classics in Mathematics. Springer-Verlag, Berlin, 2001. xiv+517 pp. ISBN: 3-540-41160-7].

Direct Solution

Prop. (10.13.6.1) [Characteristic Line]. Consider a 1-dimensional parabolic equation:

$$p_t + c(p,x,t)p_x = r(p,x,t)$$

Let $P(t) = p(X(t),t)$, this equation is equivalent to

$$P_t = r(X(t),t,P(t)), \quad X_t = c(X(t),t).$$

an ODE equation.

Prop. (10.13.6.2). A set of equations:

$$\frac{\partial}{\partial x^i}\mu = A_i\mu$$

where μ is a n-vector. It has a solution iff

$$[A_i, A_j] = \frac{\partial}{\partial x^i}A_i - \frac{\partial}{\partial x^i}A_j.$$

Proof: □

Cor. (10.13.6.3). This seems to be able to derive Frobenius integrability theorem, but I cannot figure it out.

7 Analysis on Manifolds

Prop. (10.13.7.1) [Peetre's Theorem]. For a linear operator from $C^\infty(M)$ to $C^\infty(M)$ that $Supp(Lu) \subset Supp(u)$ where M is a compact manifold, then on every compact subset of a coordinate chart L looks like a differential operator of finite order.

Proof: The first thing is to prove on a chart Ω, L is continuous on $C_0^\infty(\Omega)$. In fact, it suffice to show it is continuous from $C_0^\infty(\Omega)$ to $C_0^0(\Omega)$ because we can apply to $D_\alpha L$. For this, Cf.[Pseudo Differential Operator P86].

Then we have $|Lu| \leq C\max_{|\alpha\leq m}\sup_K|D_\alpha\varphi|$ for every $\varphi \in C_0(K)$. And the functional $\varphi \to (L\varphi)(x)$ is a distribution supported on x, thus by(10.12.1.4), it is of the form

$$Lu(x) = \sum_{|\alpha|\leq m} a_\alpha(x)D_\alpha\varphi(x).$$

We need to show a_α is smooth, which we choose a bump function χ to show a_0 is smooth and then choose $x_i\chi$ applied to $L\varphi - a_0\varphi$ to show a_i is smooth, etc. □

Prop. (10.13.7.2). The property of ψdo of order d is preserved under diffeomorphism, Cf.[Distributions and Operators P195], giving us the possibility to define ψdo differential operator on manifolds, and the principal symbol variate in this way that it forms a function from the cotangent bundle to the $M_n(\mathbb{C})$. And the Sobolev space is defined by the property that all of its restrictions on a atlas are Sobolev, using the partition of unity.

Prop. (10.13.7.3). All the norms of different are commensurable up to constant factor w.r.t. each other, so it doesn't quite matter with different norms.

Prop. (10.13.7.4). The parametrix exists for an elliptic operator on manifolds. Cf.[Distributions and Operators P207].

8 Elliptic Operators

Prop. (10.13.8.1). Elliptic operator is a Fredholm operator. And the kernel and cokernel are smooth functions, so it is also a Fredholm operator on $C^\infty(\Omega)$.

Proof: It suffice to find a left and right inverse modulo compact operators, and in fact we find it module $S^{-\infty}$. Since $S^{-\infty}$ are all compact operators, i.e. it has a parametrix. Cf.[Distributions and Operators, P184]. □

Prop. (10.13.8.2) [Garding Inequality]. For an elliptic operator of order d on $\Gamma(E)$,

$$||f||_{H^s} \leq C(||f||_{H^{s-d}} + ||Pf||_{H^{s-d}})$$

Proof: □

Cor. (10.13.8.3) [Elliptic Regularity Theorem]. The inverse image of a smooth function under an elliptic operator is a smooth function, because the intersection of $H^s(E)$ is $C^\infty(E)$.

Cor. (10.13.8.4) [Elliptic Regularity Theorem]. For $L = \sum_{|\alpha|\leq N} f_\alpha D_\alpha$, where $f_\alpha \in C^\infty(\Omega)$ and the equation $Lu = v$ for distributions u and $v \in D'(\Omega)$, when v is locally H^s, u is locally H^{s+N}. Thus if $v \in C^\infty(\Omega)$, then $u \in C^\infty(\Omega)$ by(10.12.4.12)(10.12.4.14).

Proof: We prove the case when L has leading coefficients constant. For every $\varphi \in D(\Omega)$ that is 1 on some open ball B, φu has compact support thus in some H^t< and then we use a sublemma that says if ψ is 1 on the support of φ, then if ψu is in H^t, where $t \leq s + N - 1$, then $\varphi u \in H^{t+1}$. In this way, we can shrink the nbhd to reach H^{s+N}. The proof of the lemma is in [Rudin Functional Analysis P220]. □

Prop. (10.13.8.5) [Analytic Ellipticity theorem]. Suppose L is an analytic elliptic differential operator on a domain $M \subset \mathbb{R}^n$, then every solution to $L\varphi = 0$ is analytic.

Proof: □

Prop. (10.13.8.6). The formal adjoint of an elliptic operator is an elliptic operator.

Proof: □

Cor. (10.13.8.7). The index of an elliptic operator, regarded as an operator form $L_s \to L_{s-d}$ doesn't depend on s, because all the kernel of P and P^* are smooth.

Prop. (10.13.8.8). For an elliptic operator, It has a inverse, the Green function which is a compact operator, so it has countable eigenfunctions consisting of smooth functions on L^2 with eigenvalues converging to ∞. Moreover, the eigenvalues satisfy $|\lambda_n| \geq Cn^\delta$ for some δ, C.

Proof: We prove for P self-adjoint. Use(10.13.8.1), $\ker P$ is all smooth, so there is a map $P(H^{-2d}) \to P(H^{-d})$ which is bijective thus an isomorphism by Banach. So the inverse of this isomorphism composed with the Sobolev embedding $H^{-d} \to L^2$ is a compact operator G. we notice that this map has the same eigenfunctions as P, thus the result from that of compact operators.

For the second assertion, if suffice to prove $\dim N(\lambda) \leq C\lambda^M$. Using Garding inequality and Sobolev embedding, we have for $f \in N(\lambda)$, $||f||_{C^0} \leq C(1+\lambda^l)||f||_{L^2}$ for large l. So if we choose an orthonormal basis f_i, then $|a_i f_i(x)| \leq C(1+\lambda^l)|\sqrt{\sum |a_i|^2}$. Let $a_i = f_i(x)$ and integrate over M, we get the desired result. □

Cor. (10.13.8.9). For a self-adjoint elliptic operator P which is not a constant, $L^2(E)$ has a basis consisting of eigenfunctions of P.

Cor. (10.13.8.10) [Stum-Liouville]. This can be used to solve for example eigenvalue problem for Liouville's equation:

$$(pu')' + qu = \lambda\sigma u.$$

where p and σ are positive. Cf.(10.13.2.8).

Cor. (10.13.8.11). The Hermite functions $C_n e^{x^2/2}\frac{d^n}{dx^n}e^{-x^2}$, as the eigenvector of $\widehat{H}=x^2-\frac{d^2}{dx^2}$, forms a complete basis for $L^2(\mathbb{R})$. Because it is e^{-x^2} times the solution of the operator $(e^{-x^2}F')'-e^{-x^2}F$.

Prop. (10.13.8.12). For a formally self-adjoint elliptic operator P of degree d on E, $\Gamma(E)=\operatorname{Im}P\oplus P(\Gamma(E))$.

Proof: We know that $L^2(E)=P(H^dE)\oplus\ker P$, and $\ker P$ are all smooth by(10.13.8.3), so $\Gamma(E)=\ker P\oplus P(H^dE)\cap\Gamma(E)$. Now use Garding's inequality(10.13.8.2), the intersection is just $P(\Gamma(E))$, thus the result. □

Prop. (10.13.8.13) [Asymptotic Heat Equation]. In this case we have the series

$$h_t(A^*A)=\sum_\lambda e^{-\lambda t}\dim\Gamma_\lambda(E)$$

converges and h_t has an asymptotic expansion

$$h_t=\sum_{k\geq -n}t^{k/2m}U_k(A^*A)$$

where $n=\dim M$ and $U_k=\int_M\mu_k$ for a differential form on M. Cf.[Heat Equation and the Index Theorem P297].

By the proposition above, the eigenspaces of eigenvalue non-zero neutralize, so $\operatorname{Ind}A=h_t(A^*A)-h_t(AA^*)$, so

$$\operatorname{Ind}\,A=U_0(A^*A)-U_0(AA^*)=\int_M\mu_0(A^*A)-\mu_0(AA^*).$$

The proof consists of the following propositions,

Prop. (10.13.8.14). Using the fact that an elliptic operator has a countable basis, for an elliptic operator P, when $t>0$, we let $K(t,x,y)=\sum_n e^{-t\lambda_n}\Phi_n(x)\overline{\Phi}_n(y)$, then

$$e^{-tP}f(x)=\int K(t,x,y)f(y)dy.$$

$K(t,x,y)$ is smooth. and the trace of e^{-tA^*A} is exactly $h_t(A^*A)$ as in the last proposition. And the trace is just $\int_M K(t,x,x)$, as can be easily seen.

Proof: Use Garding inequality and(10.13.8.8), we can show $||K||_{C^k}$ is bounded. □

10.14 Operator Algebras

Cf.[Princeton Companion].

10.15 D-Modules

10.16 Dynamical Systems

References are [Dynamical System, Katok] and [B-S02].

1 Topological Dynamical Systems

Def. (10.16.1.1)[Topological Dynamic Systems]. A **topological dynamic system** is a topological space X and either a continuous map $f: X \to X$ or a continuous (semi)flow f^t on X.

Def. (10.16.1.2). Let $f: X \to X$ be a topological dynamic system(10.16.1.1), then

- For $x \in X$, its **ω-limit points** are defined to be
$$\omega(x) = \cap_{n\in\mathbb{N}}\overline{\cup_{i\geq n} f^i(x)}$$
- If f is invertible, for $x \in X$, its **α-limit points** are defined to be
$$\alpha(x) = \cap_{n\in\mathbb{N}}\overline{\cup_{i\leq n} f^i(x)}$$
- The set $\mathcal{R}(f)$ of **(positively)recurrent** points are the points x that $x \in \omega(x)$.
- The set $NW(f)$ of **non-wandering points** are the points x that for any nbhd U of x, there is an $n > 0$ that $f^n(U) \cap U = \varnothing$.
- Denote
$$\mathcal{O}(x) = \cup_{n\in\mathbb{Z}} f^n(x), \quad \mathcal{O}^+(x) = \cup_{n\geq 0} f^n(x).$$
- Let X be compact, then a closed non-empty forward f-invariant $Y \subset X$ is called a **minimal set** for f if there is no smaller such set.
- A point $x \in X$ is called **almost periodic** if for any nbhd U of x, $\{i | f^i(x) \in U\}$ is relatively dense in $\mathbb{N}$, i.e. appear in every k consecutive integers for some k.

Prop. (10.16.1.3).

- $NW(f)$ is closed, f-invariant, and contains $\alpha(x), \omega(x)$ for all x.
- Every recurrent point is non-wandering, thus $\overline{\mathcal{R}(f)} \subset NW(f)$.
- Let X be compact Hausdorff, then $\overline{\mathcal{O}^+(x)}$ is minimal for f iff x is almost periodic.

Proof: item1 is easy, 2 follows from1 as $x \in \omega(x)$.

For3: suppose x is almost periodic and $y \in \overline{\mathcal{O}^+(x)}$, we need to show that $x \in \overline{\mathcal{O}^+(y)}$. For any nbhd $x \in U$, there is a small nbhd $x \in U' \subset U$ and a nbhd $\Delta \subset V \subset X \times X$, that if $x_1 \in U'$ and $(x_1, x_2) \in V$, then $x_2 \in U$. Since x is periodic, there is a K that for any $j \geq 0$, there is a $f^{j+k}(x) \in U'$ for some $0 \leq k \leq K$. Let $V' = \cap_{i=0}^K f^{-1}(V)$, then V' is open and contains the diagonal. Thus there is a nbhd W of y that $W \times W \subset V'$. Now choose $f^n(x) \in W$ by almost periodicity, and $f^{n+k}(x) \in U'$ for some $0 \leq k \leq K$, then we have $(f^{n+k}(x), f^k(x)) \in V$ by the definition of V' and W, and hence $f^k(x) \in U$. This shows $x \in \overline{\mathcal{O}^+(y)}$.

Conversely, if x is not almost periodic, then there is a nbhd U of x, that there is a sequence $\{a_i\} \in \mathbb{N}$, that $f^{a_i+j}(x) \notin U$ for $j \leq i$. By convergence theorem and passing to a subsequence, we assume y is a the limit of $f^{a_i}(x)$, and $f^j(y) \notin U$ for any $j > 0$, thus $x \notin \overline{\mathcal{O}^+(y)}$, showing $\overline{\mathcal{O}^+(x)}$ is not minimal. □

Prop. (10.16.1.4) [Minimal Set Exists on Compact Dynamic System]. If f is a topological dynamic system on a compact space, then there exists a minimal set. In particular, there exists an almost periodic point, in priori positively recurrent point, by(10.16.1.3).

Proof: Use Zorn's lemma and the finite intersection property. □

Def. (10.16.1.5) [Topologically Transitive]. A topological dynamic system $f : X \to X$ is called **topologically transitive** if there is a point x that $\overline{\mathcal{O}(x)} = X$.

Prop. (10.16.1.6). Let f be a continuous map of a locally compact Hausdorff second countable space X. Suppose that for any two non-empty open set U, V, there is $n > 0$ that $f^n(U) \cap V \neq \varnothing$, then f is topologically transitive.

Proof: For any open subset V, the hypothesis says $\cup_{n>0} f^{-n}(V)$ is dense in X. Let V_i be a countable basis for the topology of X, and $Y = \cap_i \cup_{n>0} f^{-n}(V_i)$, then it is non-empty, by Baire category theorem(3.3.9.2). Now the orbit of any $y \in Y$ enters every V_i, thus its orbit is dense in X. □

Prop. (10.16.1.7). Let $f : X \to X$ be a homeomorphism of a compact metric space, and suppose X has no isolated points, then if there is a dense orbit $\mathcal{O}(x)$, there will be a dense orbit $\mathcal{O}^+(x)$.

Proof: The hypothesis that X has no isolated points shows that $\mathcal{O}(x)$ meets every open subset U infinitely many times, thus we can choose $f^{n_k}(x) \in B(x, 1/k)$ that $|n_k| \to \infty$. Thus $f^{n_k+l}(x) \to f^l(x)$ for any l.

If there are infinitely many $n_k > 0$, then we have $\mathcal{O}(x) \subset \overline{\mathcal{O}^+(x)}$, hence $\mathcal{O}^+(x)$ is dense. If there are infinitely many $n_k < 0$, then $\mathcal{O}^-(x)$ is dense. Then for any open subset U, V, we can find $i < j < 0$ that $f^i(x) \in U, f^j(x) \in V$, thus $f^{j-i}(U) \cap V \neq \varnothing$. Hence we use(10.16.1.6) to conclude f is topologically transitive. □

Def. (10.16.1.8) [Topological Mixing]. A topological dynamic system $f : X \to X$ is called **topologically mixing** if for any two non-empty open subsets U, V, there is $N > 0$ that $f^n(U) \cap V \neq \varnothing$ for any $n \geq N$.

Def. (10.16.1.9). A homeomorphism $f : X \to X$ is called **expansive** if there is a $\delta > 0$ that for any two distinct points x, y, there is some $n \in \mathbb{Z}$ that $d(f^n(x), f^n(y)) \geq \delta$. Similarly, we can define **positively expansive** for a non-invertible continuous map $f : X \to X$. This constant δ is called a **expansiveness constant** of f.

Prop. (10.16.1.10) [Compact Metric Space not positively expansive]. If f be a continuous map of an infinite compact metric space X, then it is not positively expansive.

Proof: First assume f is invertible. Fix $\varepsilon > 0$, consider all m that there are points $x \neq y$ that

$$d(f^n(x), f^n(y)) < \varepsilon, \quad 0 < n \leq m, \quad d(x, y) \geq \varepsilon.$$

If these m are infinite, then we can use convergence point theorem to find a point x, y that $d(f^n(x), f^n(y)) < \varepsilon$ for any $n > 0$, thus f is not expansive.

If these m are finite, let M be a maximal, then by absolute convergence, there is a δ that if $d(x, y) \leq \delta$, then $d(f^n(x), f^n(y)) < \varepsilon$ for any $0 \leq n \leq m$. Then by definition of M, $d(f^{-1}(x), f^{-1}(y)) < \varepsilon$, and similarly $d(f^{-n}(x), f^{-n}(y)) < \varepsilon$ for any $n < 0$.

Now choose a finite $\delta/2$-net $\{x_i\}$ of M, then for each $j \in \mathbb{Z}$, there are two $f^j(x_s), f^j(x_t)$ in the same $B(\delta/2, x_j)$, thus $d(f^n(x_s), f^n(x_t)) < \varepsilon$ for $n \leq j$. Now there are only f.m. pairs of elements in M, there are some pair (x_α, x_β) appeared infinitely many times for different $j > 0$, thus we have $d(f^n(x_\alpha), f^n(x_\beta)) < \varepsilon$ for any $n \in \mathbb{Z}$.

For the non-invertible case, the proof is the same, noticing that f^{-1} is chosen wisely when it can be defined. □

Cor. (10.16.1.11). Let f be an expansive homeomorphism of an infinite compact metric space X, then there are distinct points x_0, y_0 that $\lim_{n\to\infty} d(f^n(x_0), f^n(y_0)) = 0$.

Proof: Let δ be an expansive constant of f, then by(10.16.1.10), there are $x_0 \neq y_0 \in X$ that $d(f^n(x_0), f^n(y_0)) \leq \delta$ for all $n > 0$. Suppose $d(f^n(x), f^n(y)) \nrightarrow 0$, then by compactness in $X \times X$, there is a subsequence $\{n_k\} \in \mathbb{N}$ that $f^{n_k}(x) \to x'$, $f^{n_k}(y) \to y'$ with $x' \neq y'$. Then this will show that $d(f^m(x), f^m(y)) < \delta$ for any $m \in \mathbb{Z}$, contradicting expansiveness of f. □

Def. (10.16.1.12). Let $f : X \to X$ be a homeomorphism of compact Hausdorff space, then

- two points x, y are called **proximal** if the closure of orbits $\overline{\mathcal{O}((x, y))}$ under $f \times f$ intersect the diagonal $\Delta \subset X \times X$. It is called **distal** otherwise. f is called **distal** if every two distinct points x, y are distal.
- f is called **equicontinuous** if the family $\{f^n\}_{n\in\mathbb{Z}}$ is equicontinuous.

Prop. (10.16.1.13). A equicontinuous homeomorphism f of a compact metric space are distal.

Proof: Suppose f is not distal, then there is a proximal pair (x, y), thus there is a sequence $\{n_k\} \in \mathbb{Z}$ that $d(f^{n_k}(x), f^{n_k}(y)) \to 0$. let $d(x, y) = \varepsilon$, thus for any $\delta > 0$, there is some $d(f^{n_k}(x), f^{n_k}(y)) < \varepsilon$, thus contradicting the equicontinuity of f^{-n}. □

Def. (10.16.1.14) [Almost Periodic Set]. For a subset $A \subset X$ and a homeomorphism $f : X \to X$, denote by f_A the action of f on X^A. Then A is called **almost periodic** if every $z \in \mathrm{Mor}(A, A)$ is almost periodic for f_A. Equivalently, for any finite set of points $\{x_i\} \in A$, and nbhds $x_i \in U_i$, the set $\{k \in \mathbb{Z} | f^k(x_i) \in U_i\}$ is relatively dense in $\mathbb{Z}$. This is compatible with the previous definition of almost periodic point(10.16.1.2).

Def. (10.16.1.15). A homeomorphism of a compact Hausdorff space is called **pointwise almost periodic** if every point x is almost periodic. By(10.16.1.3), we can see that this is equivalent to X is a union of minimal sets.

Lemma (10.16.1.16). Every almost periodic set A is contained in a maximal almost periodic set in X.

Proof: It is because of the second definition of almost periodic set(10.16.1.14) that the sum of an ordered family of almost periodic sets is also almost periodic. □

Prop. (10.16.1.17). Let f be a homeomorphism of a compact Hausdorff space X, then every point $x \in X$ is proximal to an almost periodic point.

Proof: If x is almost periodic, then we are done. If not, consider a maximal almost periodic set $A \subset X$, then $x \notin A$. Then for $z \in X^A$ with range A, consider $(x, z) \in X \times X^A$, and find an almost periodic point (x_0, z_0) of $f \times f_A$ in $\overline{\mathcal{O}(x, z)}$, by(10.16.1.4). Because z is almost periodic, $z \in \overline{\mathcal{O}(z_0)}$, by(10.16.1.3). Thus we see $(x', z) \in \overline{\mathcal{O}(x_0, z_0)}$ for some x', by the compactness of X. Then (x', z) is also almost periodic, and we can forget about x_0, z_0.

Therefore, $\{x'\} \cup \mathrm{Im}(z) = \{x'\} \cup A$ is almost periodic for f, and since A is maximal, $x' \in A = \mathrm{Im}(z)$. This shows $(x', x') \in \overline{\mathcal{O}(x, x')}$, showing x is proximal to x'. □

Cor. (10.16.1.18) [Distal Homeomorphism is Pointwise Almost Periodic]. If f is a distal homeomorphism of a compact Hausdorff space, then f is pointwise almost periodic.

Prop. (10.16.1.19).
- A homeomorphism of a compact Hausdorff space is distal iff the product system $(X \times X, f \times f)$ is pointwise almost periodic.
- A factor system of a pointwise almost periodic homeomorphism is pointwise almost periodic.
- A factor system of a distal homeomorphism is distal.

Proof: 1: If f is distal, then so is $f \times f$, hence it is pointwise almost periodic, by(10.16.1.18). Conversely, if $f \times f$ is pointwise almost periodic, then if x, y is proximal, then $(z, z) \in \overline{\mathcal{O}(x, y)}$, but since $\overline{\mathcal{O}(x, y)}$ is minimal, by(10.16.1.3), $(x, y) \subset \overline{\mathcal{O}(z, z)} \subset \Delta$, hence $x = y$.

2: This is easy.

3: if f is a factor of g, then $f \times f$ is a factor of $g \times g$, but the latter is pointwise locally periodic, thus the first is also locally periodic, by2, and then f is distal, by1. □

Topological Entropy

Def. (10.16.1.20) [Definitions]. Let (X, d) be a compact metric space, and f a continuous map $X \to X$, we define
- for $x, y \in X$, $d_n(x, y) = \max_{0 \le k \le n-1} d(f^k(x), f^k(y))$.
- a subset $A \subset X$ is called (n, ε)**-spanning** if it is a ε-net in (X, d_n). Similarly, we can define (n, ε)**-separated** and $\mathrm{cov}(n, \varepsilon, f)$ the minimal number of covering of X of d_n-diameter$< \varepsilon$.

Lemma (10.16.1.21). $\mathrm{cov}(n, 2\varepsilon, f) \le \mathrm{span}(n, \varepsilon, f) \le \mathrm{sep}(n, \varepsilon, f) \le \mathrm{cov}(n, \varepsilon, f)$.

Proof: Easy. □

Prop. (10.16.1.22) [Topological Entropy]. The number

$$\lim_{n \to \infty} \frac{1}{n} \log(\mathrm{cov}(n, \varepsilon, f)) = h_\varepsilon(f)$$

is well-defined and finite. It is increasing as ε decreces, so $h(f) = \lim_{\varepsilon \to 0^+} h_\varepsilon(f)$ exists, which lies in $[0, \infty]$. It is called the **topological entropy** of f.

Notice the entropy can be calculated by either cov, span or sep, by(10.16.1.21).

Proof: For this, we need to notice if U has d_n-diameter$< \varepsilon$ and V has d_m-diameter$< \varepsilon$, then $U \cap f^{-m}(V)$ has d_{m+n}-diameter$< \varepsilon$. Hence

$$\mathrm{cov}(m + n, \varepsilon, f) \le \mathrm{cov}(m, \varepsilon, f) \cdot \mathrm{cov}(n, \varepsilon, f).$$

Thus we can use(24.1.1.1) to conclude. □

Prop. (10.16.1.23). The topological entropy doesn't depend on the metric generating the topology.

Proof: This is because d' is a continuous function on $(X \times X, d \times d)$, thus it is uniformly continuous as X is compact, so

$$\mathrm{cov}(n, \varepsilon, f) \le \mathrm{cov}(n, \delta(\varepsilon), f)$$

where $\delta(\varepsilon) \to 0$ when $\varepsilon \to 0$. This shows the topological entropies are the same. □

Cor. (10.16.1.24). Two conjugate dynamic systems have the same topological entropy.

Prop. (10.16.1.25) [Properties of Entropy]. Let $f : X \to X$ be a continuous map of a compact metric space X, $g : Y \to Y$ be a continuous map of a compact metric space Y, then

- $h(f^m) = m \cdot h(f)$ for $m > 0$.
- If f is invertible, then $h(f^{-1}) = h(f)$.
- Let A_i be a finite family closed forward f-invariant subsets of X whose union is X, then
$$h(f) = \max h(f|_{A_i}).$$
- $h(f \times g) = h(f) + h(g)$, and if f is an extension of g, then $h(f) \geq h(g)$.

Proof: 1: Use two inequalities:

$$\operatorname{span}(n, \varepsilon, f^m) \leq \operatorname{span}(mn, \varepsilon, f), \quad \operatorname{span}(n, \delta(\varepsilon), f^m) \geq \operatorname{span}(mn, \varepsilon, f)$$

where $\delta(\varepsilon) \to 0$ if $\varepsilon \to 0$, and(10.16.1.21).

2: Because (n, ε)-separated sets for f and (n, ε)-separated sets for f^{-1} corresponds via f^n.

3: Use two inequalities:

$$\operatorname{span}(n, \varepsilon, f) \leq \sum_{i=1}^{k} \operatorname{span}_i(n, \varepsilon, f) \leq k \cdot \max \operatorname{span}_i(n, \varepsilon, f),$$

$$\operatorname{sep}(n, \varepsilon, f) \geq \max \operatorname{sep}(n, \varepsilon, f).$$

4: Noticing two inequalities:

$$\operatorname{cov}(n, \varepsilon, f \times g) \geq \operatorname{cov}(n, \varepsilon, f) \cdot \operatorname{cov}(n, \varepsilon, g),$$

$$\operatorname{sep}(n, \varepsilon, f \times g) \geq \operatorname{sep}(n, \varepsilon, f) \cdot \operatorname{sep}(n, \varepsilon, g).$$

and the proof of the last assertion is similar to that of(10.16.1.23). □

Prop. (10.16.1.26). Let $f : X \to X$ be an expansive homeomorphism of a compact metric space of expansiveness constant δ, then $h(f) = h_\varepsilon(f)$ for $\varepsilon < \delta$.

Proof: For $0 < \gamma < \varepsilon < \delta$, we show that $h_{2\gamma}(f) = h_\varepsilon(f)$. For this, it suffices to prove$\leq$. By expansiveness, if $x \neq y$, then there is some $i \in \mathbb{Z}$ that $d(f^i(x), f^i(y)) \geq \delta > \varepsilon$. Since the set $\{(x, y) \in X \times X | d(x, y) \geq \gamma\}$ is compact, there is a $k = k(\gamma, \varepsilon)$ that if $d(x, y) \geq \gamma$, then $d(f^i(x), f^i(y)) > \varepsilon$ for some $|i| \leq k$. Thus if A is a (n, γ)-separated set, then $f^{-k}(A)$ is a $(n + 2k, \varepsilon)$-separated set. Hence by(10.16.1.21), $h_{2\gamma}(f) \leq h_\varepsilon(f)$. □

Application to Ramsey Theory

Def. (10.16.1.27) [IP-System]. Let $\mathcal{F}$ be the collection of all finite non-empty subset of $\mathbb{N}$. For $\alpha, \beta \in \mathcal{F}$, write $\alpha < \beta$ if every element of α is smaller than that of β.

For a commutative group G, an **IP-system** in G is a map $T : \mathcal{F} \to G$ that $T_{i_1, \ldots, i_k} = T_{i_1} \cdot \ldots \cdot T_{i_k}$.

Prop. (10.16.1.28)[Furstenberg-Weiss]. Let G be a commutative group acting minimally on a compact topological space X, then for any open subset U of X, $n > 0$ and $\alpha \in \mathcal{F}$, and any IP-systems $T^1, \ldots, T^n$ on G, there is a $\beta \in \mathcal{F}$ that $\alpha < \beta$, and

$$U \cap T^1_\beta(U) \cap \ldots \cap T^n_\beta(U) \neq \varnothing.$$

Proof: Cf.[Dynamic System, P49]. □

Cor. (10.16.1.29). Let G be a commutative group acting homeomorphically on a compact metric space X and $T^1,\dots T^n$ be IP-systems on G, then for any $\alpha\in\mathcal{F}$ and $\varepsilon>0$, there are $x\in X$ and $\beta>\alpha$ that $d(x,T^i_\beta(x))<\varepsilon$ for any i.

Proof: Just need to find a minimal closed subset of X for G, but this is easy by finite intersection theorem. □

Cor. (10.16.1.30) [Multiple Recurrence Property]. Let T be a homeomorphism of a compact metric space X, then for any $\varepsilon>0$ and $q>0$, there are $p>0$ and $x\in X$ that $d(T^{jp}(x),x)<\varepsilon$ for $0\leq j\leq q$.

Proof: This is a special case of(10.16.1.29), by taking $G=\{T^k\}$, and $T^i_\alpha=T^{i|\alpha|}$, where $|\alpha|$ is the sum of elements in α. □

Cor. (10.16.1.31)[Generalized van der Waerden Theorem]. For each finite partition $\mathbb{Z}=\cup_{i=1}^m S_k$, one of the the subset S_k contains arbitrarily long arithmetic progressions.

More generally, let A be a finite subset of $\mathbb{Z}^d$, then for each partition $\mathbb{Z}^d=\cup_{i=1}^m S_k$, there are some k, $z_0\in\mathbb{Z}^d$ and $n>0$ that $z_0+na\in S_k$ for any $a\in A$.

Proof: Consider the product space $\Sigma_m=\{1,2,\dots,m\}^{\mathbb{Z}}$ with the 2-adic metric with shifting σ. Then a partition of $\mathbb{Z}$ can be viewed as an element ξ in $\{1,2,\dots,m\}^{\mathbb{Z}}$, with $\xi_i=k$ if $i\in S_k$. Let $X=\overline{\cup_{i=-\infty}^\infty\sigma^i(\xi)}$. Let $A_k=\{\omega\in X|\omega_0=k\}$, then if $x\in A_k,y\in X$ with $d(x,y)<1$, then $y\in A_k$ also. Thus for any $q>0$, we can use(10.16.1.30) to show that there is an $\omega\in X$ that $d(\sigma^{ip}(\omega),\omega)<1$ for $0\leq i\leq q$, thus there is an $r\in\mathbb{Z}$ that $\xi_j=\omega_0$ for $j=r,r+k,\dots,r+pq$. And this proves the theorem.

The proof of the general case is similar. □

2 Symbolic Dynamics

Def. (10.16.2.1) [Subshifts]. A **subshift** is a closed subset $X\subset\Sigma_m$ that is invariant under the shift σ and σ^{-1}. A map between to subshifts of Σ_m is called a **code** if it commutes with σ.

Prop. (10.16.2.2). Let X be a subshift of Σ_m, let $W_n(X)$ be the set of words of length n that occurs in X, $\sigma|_X$ is clearly expansive of constant 1, thus we have

$$h(\sigma|_X)=\lim_{n\to\infty}\frac{1}{n}\log|W_n(X)|.$$

Proof: This is because every element in W_n appears in the first n term of some $\omega\in X$, and elements in a set of d_n-diameter<1 has first n entries the same. For the other direction, notice a $(n,1)$-separated set has the first n-entries not the same, thus contribute to different elements in $W_n(X)$, thus $\mathrm{sep}(n,1,\sigma|_X)<W_n(X)$. □

Def. (10.16.2.3) [block code]. Let X be a subshift, $k,l\geq 0,n=k+l+1$, and α be a map from $W_n(X)$ to $\{0,1,\dots,m'-1\}$, then a (k,l)-block code is a morphism from X to $\Sigma_{m'}$ that maps x to the sequence $a_\alpha(x)$ that $a_\alpha(x)_i=\alpha((x_{i-k},\dots,x_{i+l}))$.

When $\{0,1,\dots,m'-1\}$ is chosen to be $W_n(X)$ itself, then this is called a **higher block presentation** of X.

Prop. (10.16.2.4) [Curtis–Lyndon–Hedlund]. [Every Code is a block code] Every code $c : X \to Y$ is a block code.

Proof: Let $\mathcal{A}$ be the symbol set of Y, define $\widehat{c} : X \to \mathcal{A} : x \mapsto c(x)_0$. This is a continuous map, and X is compact thus it is uniformly continuous, thus there is a $\delta > 0$ that $\widehat{c}(x) = \widehat{c}(y)$ if $d(x, y) < \delta$. Thus there is a large k that $\widehat{c}$ only depends on the first $2k+1$ term, and it commutes with shifting, thus it is a block code. □

Def. (10.16.2.5) [SFT]. A **subshift of finite type** or SFT of k-step, $k > 0$ is a subshift X that are defined to be the elements in Σ_m that doesn't contain some set of words of length $k+1$. When $k = 1$, this is also called a **topological Markov chain**.

Prop. (10.16.2.6). Every SFT is isomorphic to a vertex shift.

Proof: For this SFT X of step k, construct a graph, whose vertices are $W_k(X)$, and two element of $W_k(X)$ are connected by an edge if they adjoint to an element in $W_{k+1}(X)$. □

Cor. (10.16.2.7). Every SFT is isomorphic to an edge shift. This is because every vertex shift can be 2-block isomorphic to its edge shift.

Prop. (10.16.2.8) [Perron].

<u>**Sofic Shifts and Data Transmission**</u>

Def. (10.16.2.9) [Sofic Shifts]. A subshift $X \subset \Sigma_m$ is called **sofic** if it is a factor of a subshift of finite type.

Prop. (10.16.2.10). A subshift $X \subset \Sigma_m$ is sofic iff it is isomorphic to an infinite path shift for some directed graph Γ(Notice that different edge in Γ can be labeled the same).

Proof: Clearly such a path shift is a factor of the edge shift of Γ, thus it is sofic. Conversely, A sofic shift is a factor of some edge shift $c : \Sigma_A^e \to X$, by(10.16.2.7), and c is a block code, by(10.16.2.3). Composing with the higher block code presentation, we may assume c is a $(0, 1)$-block code, □

3 Ergodic Theory

Prop. (10.16.3.1) [Poincaré's Recurrence Theorem]. Let T be a measure-preserving transformation of a finite measure space X, if A is a measurable set, then for a.e. $x \in A$, there is some $n > 0$ that $T^n(x) \in A$.

Proof: Let B be the set of points contradicting this property, $B = A \setminus \cup_{k>0} T^{-k}A$, thus all the preimages $T^{-k}B$ are disjoint, measurable and have the same measure as B, thus it must has measure 0 as X has finite measure. □

Cor. (10.16.3.2) [Derivarive Transformation]. Given a finite measurable space and a measure-preserving map $T : X \to X$ and a measurable subset A of finite measure, then the **derivative transformation** $T_A : A \to A : x \mapsto T^k(x)$, where $k > 0$ is the first integer that $T^k(x) \in A$. By Poincaré's Recurrence theorem, the derivative transformation is defined on a subset of full measure.

Prop. (10.16.3.3). Let X be a second countable metric space and μ a Borel probability measure on X, and $f : X \to X$ is a measure preserving continuous map, then a.e. point $x \in X$ is recurrent, i.e. $\operatorname{Supp} \mu \subset \mathcal{R}(f)$.

Proof: There is a countable family of basis $\{U_i\}$ of nbhds of X, and for each U_i, elements in U_i returns to U_i except for a set X_i of measure0. Then $\mathcal{R}(f) = X \setminus \bigcup_i X_i$ has full measure. □

Def. (10.16.3.4) [Ergodicity]. A measure-preserving transformation T is called **ergodic** if any essentially T-invariant measurable subset has measure 0 or full measure.

Prop. (10.16.3.5). Let T be a measure-preserving transformation on a finite measure space X and $p \in (0, \infty]$, then T is ergodic iff every essentially T-invariant function $f \in L^p(X, \mu)$ is constant.

. *Proof:*

□

Prop. (10.16.3.6). Let X be a measure space and f is an essentially invariant function for a measure-preserving map or flow Ton X, then there is a strictly invariant measurable function $\widehat{f}$ that $f = \widehat{f}$ a.e..

Proof: [Dynamic System P74]. □

Def. (10.16.3.7). A measure-preserving transformation or flow on a probability space X is called **mixing** if

$$\lim_{t\to\infty} \mu(T^{-t}A \cap B) = \mu(A)\mu(B).$$

It is called **weak mixing** if

$$\lim_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n} |\mu(T^{-i}A \cap B) - \mu(A)\mu(B)| = 0.$$

or

$$\lim_{t\to\infty} \frac{1}{t} \int_0^t |\mu(T^{-t}A \cap B) - \mu(A)\mu(B)| = 0.$$

Prop. (10.16.3.8). Mixing transformation is weak mixing, and weak mixing is ergodic.

Proof: For a weak mixing transformation, if A is essentially invariant, then $\mu(A) = \mu(A)^2$, thus $\mu(A) = 1$ or 0. □

Prop. (10.16.3.9)[Mixing and Topological Mixing]. Let X be a compact metric space, $T : X \to X$ be a continuous map and μ a T-invariant Borel measure on X, then

- If T is ergodic, then the orbit of a.e. point $x \in X$ is dense in $\operatorname{Supp}\mu$.
- If T is mixing, then T is topologically mixing on $\operatorname{Supp}\mu$.

Proof: 1: Let U be an open subset intersecting $\operatorname{Supp}\mu$, then the T-invariant subset $\cup_{k>0} T^{-k}U$ has full measure, thus the forward orbit of a.e. x intersect U. Then take a countable open basis of X, thus the forward orbit of a.e. x is dense in $\operatorname{Supp}\mu$.

2: Because $\lim_{t\to\infty} T^{-t}(A) \cap B \to \mu(A)\mu(B) > 0$, so does $\lim_{t\to\infty} A \cap T^t(B)$. □

Ergodic Theorems

Prop. (10.16.3.10) [von Neumann Ergodic Theorem]. If $U \in L(H)$ is unitary and $x \in H$, then the average $A_n x = \frac{1}{n}(x + Ux + \ldots + U^{n-1}x)$ converges to some Px, where P is the projection to the fixed space of U.

Proof: Define $a_n = \frac{1}{n}(1+\lambda+\ldots+\lambda^{n-1})$ on the unit circle, and $b(1) = \chi_{\{1\}}$, then if $y = b(U)x = P(x)$, then $||y - A_n x||^2 = \int_{\sigma(U)} |b - a_n|^2 dE_{x,x}(\lambda)$. But this integral converges to 0 by dominated convergence theorem. □

Prop. (10.16.3.11) [Birkhoff Ergodic Theorem]. If T is a measure-preserving transformation of a finite measure space (X,μ), and let $f \in L^1(X,\mu)$, then the limit

$$\overline{f}(x) = \lim_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} f(T^k(x))$$

exists for a.e. x and is μ-integrable and T-invariant, and satisfies

$$\int_X \overline{f}(x) d\mu = \int_X f(x) d\mu$$

In addition, if $f \in L^2(X,\mu)$, then $\overline{f}$ is just the projection of f to the subspace of T-invariant measures.

The same thing is true for a measure-preserving flow.

Proof: Let

$$A = \{x \in X | f(x) + f(T(x)) + \ldots + f(T^k(x)) \geq 0, \quad \exists k \geq 0\}.$$

Then firstly we have $\int_A f(x) d\mu \geq 0$: Cf.[Dynamic System, P82].**?** □

Cor. (10.16.3.12). A measure-preserving map $T : X \to X$ in a finite measure space (X,μ) is ergodic iff for each $f \in L^1(X,\mu)$,

$$\lim_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} f(T^i(x)) = \frac{1}{\mu(X)} \int_X f(x) d\mu, a.e.x.$$

I.e., the time average equals the space average for any L^1-function.

Proof: If T is ergodic, then the function $\overline{f}$ defined in(10.16.3.11) is a constant, thus the equation. Conversely, if this equation holds, then if f is T-invariant, the RHS is constant. □

Cor. (10.16.3.13). Taking a dense subset of $L^2(X,\mu)$ in the above corollary, we see that a measure-preserving map $T : X \to X$ is ergodic iff for any measurable subset A and a.e. $x \in X$,

$$\lim_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \chi_A(T^i(x)) = \frac{\mu(A)}{\mu(X)}.$$

Invariant Measure for a Transformation

4 Hyperbolic Dynamics

5 Complex Dynamics

See [Milnor, John Dynamics in one complex variable. Third edition. Annals of Mathematics Studies, 160. Princeton University Press, Princeton, NJ, 2006. viii+304 pp. ISBN: 978-0-691-12488-9; 0-691-12488-4].

Iterations

Prop. (10.16.5.1). Let $f(z)=\sum_{k\geq 1}a_k z^k$ be a power series with radius of convergence $R>0$, then the point $z=0$ is called a **stable point** of f if there exists $0\leq r_0,r\leq R$ s.t. $f^{\circ n}(z)\in\mathbb{D}(0,r)$ for any $z\in\mathbb{D}(0,r_0),n\in\mathbb{Z}_+$.

Then $z=0$ is a stable point iff $|a_1|<1$ or $|a_1|=1$ and the **Schröder functional equation**

$$\varphi(a_1\zeta)=f(\varphi(\zeta))$$

has a solution $\varphi(\zeta)=\zeta+\sum_{k=2}^\infty c_k\zeta^k$ with radius of convergence $R\in\mathbb{R}_+$.

Proof: If $|a_1|<1$, then for r small, if $z\in\mathbb{D}(0,r)$, then $|f(z)|\leq z$. So $z=0$ is clearly stable. Suppose $|a_1|\geq 1$ and $z=0$ is stable, let $\Omega=\cup_{n\in\mathbb{Z}_+}f(\mathbb{D}(0,r_0))$, then $\Omega\subset\mathbb{D}(0,r)$ and is connected. Suppose $\varphi:\mathbb{D}\to\Omega$ is a covering map that $\varphi(0)=0$ by(10.5.7.10), then the map $f:\Omega\mapsto\Omega$ lifts to a map $F:\mathbb{D}\to\mathbb{D}$ that satisfies $F(0)=0$ and $F'(0)=a_1$. Then by Schwartz lemma(10.6.1.3), $|a_1|=1$, and $F(z)=a_1 z$, and the Schröder functional equation has a solution φ. Also it is clear if $|a_1|=1$ and the Schröder functional equation has a solution φ, then $z=0$ is stable. □

Prop. (10.16.5.2) [Siegel]. Situation as in(10.16.5.1),

- If a_1 satisfies $a_1^n=1$ for some $n\in\mathbb{Z}_+$, then $z=0$ is stable for f iff $f^{\circ m}(z)=z$ for some $m\in\mathbb{Z}_+$. And if this is the case, then $f^{\circ n}=1$.
- If $a_1=e^{2\pi\mathrm{i}\omega}$ where $|\omega-\frac{m}{n}|=\Omega(n^{-\mu})$ for any $m,n\in\mathbb{Z}_+$ where $\mu\in\mathbb{R}_+$, then $z=0$ is a stable point for $f(z)$.

Proof: 1: If $z=0$ is stable, then $f^{\circ n}(z)=z$ by(10.16.5.1). Conversely, if $f^{\circ m}(z)=z$, then clearly $z=0$ is stable.

2: Use(10.16.5.1), the Schröder functional equation writes:

$$\sum_{k=2}^\infty c_k(a_1^k-a_1)\zeta^k=\sum_{l=2}^\infty a_l(\zeta+\sum_{r=2}^\infty c_r\zeta^r)^l.$$

Thus it is clear that $c_2=a_2/a_1(a_1-1)$, and c_k is determined by c_2 inductively by

$$c_k=\frac{1}{a_1^k-a_1}\sum_{l_1+\ldots+l_r=k}c_{l_1}\cdots c_{l_r}.$$

So φ is formally determined by f. Moreover, the modulus of c_k are bounded by the solution of the functional equation

$$\sum_{k=2}^\infty c_k|a_1^{k-1}-1|\zeta^k=\sum_{l=2}^\infty |a_l|(\zeta+\sum_{r=2}^\infty c_r\zeta^r)^l,$$

and the bound depends positively on $|a_l|$ and negatively on $|a_1^{k-1}-1|$.

We have $\overline{\lim}\,|a_n|^{\frac{1}{n}}=1/R$, so we have $|a_n|\geq a^{n-1}$ for some $a\in\mathbb{R}_+$ and any $n\geq 2$. Notice that the Schröder functional remains true under the transformation $f(z)\mapsto af(z/a),\varphi(\zeta)\mapsto a\varphi(\zeta/a)$, so we may assume that $|a_n|\leq 1$ for $n\geq 2$. Then it suffices to show the solution $\varphi(\zeta)=\zeta+\sum_{k=2}^\infty\tau_k\zeta^k$ of the functional equation

$$\sum_{k=2}^\infty c_k|a_1^{k-1}-1|\zeta^k=\sum_{l=2}^\infty(\zeta+\sum_{r=2}^\infty c_r\zeta^r)^l$$

has positive radius of convergence. We also denote the solution of the functional equation

$$\sum_{k=2}^{\infty} c_k \zeta^k = \sum_{l=2}^{\infty} (\zeta + \sum_{r=2}^{\infty} c_r \zeta^r)^l$$

by $\psi(\zeta) = \zeta + \sum_{k=2}^{\infty} \sigma_k \zeta^k$. Then

$$\psi(\zeta) - \zeta = \psi(\zeta)^2/(1 - \psi(\zeta)),$$

thus

$$4\psi(\zeta) = \zeta + 1 - \sqrt{1 - 6\zeta + \zeta^2}$$

has radius of convergence $R = 2 - 2\sqrt{2}$. And we can prove inductively that

$$\sigma_k \le \delta_k \tau_k,$$

where δ_k are defined as follows:

$$\delta_1 = 1, \quad \delta_k = |a_1^{k-1} - 1| \cdot \max_{l_1 + \ldots + l_r \le k} \delta_{l_1} \cdots \delta_{l_r}.$$

But then by(10.16.5.3), $\sigma_k < k^{-2\nu} 2^{(5\nu+1)(k-1)} \tau_k$. So $\varphi(\zeta)$ has radius of convergence$\ge (3 - 2\sqrt{2}) 2^{-5\nu-1}$.
□

Lemma (10.16.5.3). Situation as in(10.16.5.2), suppose $|a_1^n - 1| \le (2n)^\nu$ for $\nu \in \mathbb{R}_+$ and any $n \in \mathbb{Z}_+$, then

$$\delta_k \le k^{-2\nu} 2^{(5\nu+1)(k-1)}.$$

Proof: Cf.[Sie42]Lemma3.**?** □

Cor. (10.16.5.4). Let $f(z) = z + \sum_{k \ge 2} a_k z^k$ be a power series with radius of convergence $R > 0$, then $z = 0$ is a stable point iff $f(z) = z$.

11 Differential Geometry

11.1 Geometric Analysis

References are [Lee13], [G-P74](Good) and [Geometric Analysis Jost].

Notation (11.1.0.1).
- All manifolds in this section is assumed to be smooth over $\mathbb{R}$ or analytic over $\mathbb{C}$.

1 Smooth Manifolds

Def. (11.1.1.1) [Smooth manifolds].

Prop. (11.1.1.2) [Collar Neighborhood Theorem]. If X is a smooth paracompact manifold with boundary, then there is a nbhd of ∂X in X which is diffeomorphic to the product $\partial X \times [0, 1]$.

Proof: □

Prop. (11.1.1.3) [Rank Theorem]. Let $F : M \to N$ be a smooth map between manifolds of dimensions m and n with constant rank r. Then for any $p \in M$, there exists smooth charts centered at $p, F(p)$ that the coordinate representation of F is

$$F(x^1, \ldots, x^r, x^{r+1}, \ldots, x^m) \mapsto (x^1, \ldots, x^r, 0, \ldots, 0).$$

Proof: Cf.[Lee13]P81. □

Def. (11.1.1.4) [Immersion]. A **smooth immersion** of manifolds $f : M \to N$ is a smooth map that the differential is injective at every point.

A **smooth submersion** of manifolds $f : M \to N$ is a smooth map that the differential is surjective at every point.

Def. (11.1.1.5) [Local Diffeomorphism]. A **local diffeomorphism** $f : M \to N$ is a smooth map that for any $p \in M$, there exists an open subset U that $U \to f(U)$ is a diffeomorphism.

Prop. (11.1.1.6) [Local Section Theorem]. Let $F : M \to N$ be a smooth map between smooth manifolds, then π is a smooth submersion iff each point of M is in the image of a local section of F.

Proof: If each point of M is in the image of a local section of F, the differential is surjective at every point. Conversely, use the rank theorem(11.1.1.3). □

Prop. (11.1.1.7). A smooth submersion $F : M \to N$ is an open map, and a surjective smooth submersion is a quotient map.

Proof: Let $W \subset M$, and $q = \pi(p)$ where $p \in W$, then there is a local section $\sigma : U \to M$ that $\sigma(q) = p$(11.1.1.6), thus $\sigma^{-1}(W)$ is open in N. But for any $y \in \sigma^{-1}(W)$, $y = \pi(\sigma(y)) \subset \pi(W)$. So $p \in \sigma^{-1}(W) \subset \pi(U)$, which means $\pi(W)$ is open, and π is an open map. t The last assertion follows as any open surjective map is a quotient map(3.3.1.9). □

Prop. (11.1.1.8)[Characteristic Property of Surjective Smooth Submersions]. Let $\pi : M \to N$ be a smooth submersion of manifolds, P another smooth manifold, then

- Any map $F : N \to P$ is smooth iff $F \circ \pi$ is smooth.
- Any smooth map $\widetilde{F} : M \to P$ that is constant on the fibers of π induces a smooth map $F : N \to P$ that $\widetilde{F} = F \circ \pi$.

Proof: 1: Use local section theorem(11.1.1.6).

2: There is a constant map $F : N \to P$ that $\widetilde{F} = F \circ \pi$ by(11.1.1.7) and universal property of quotient maps, and it is smooth by item1. □

Def. (11.1.1.9) [Smooth Covering Space]. A **smooth covering space** of a smooth manifold X is a space $\widetilde{X}$ together with a smooth map $\pi : \widetilde{X} \to X$ that there is a covering U_α of X that for each α, $\pi^{-1}(U_\alpha)$ is a disjoint union of open subsets of $\widetilde{X}$, each of which is mapped diffeomorphically onto U_α.

Prop. (11.1.1.10) [Proper Free Action]. Let $\pi : E \to M$ be a smooth covering map, then with the discrete topology, $\mathrm{Aut}_\pi(E)$ is a discrete Lie group acting smoothly, freely and properly on E.

Conversely, suppose M is a smooth manifold and Γ is discrete group acting smoothly, freely and properly on a manifold, then the quotient space M/Γ is a topological manifold, and it has a unique smooth structure that the quotient map $\pi : M \to M/G$ is a smooth normal covering map.

Proof: If $\pi : E \to M$ is a smooth covering map, then the action is continuously, freely and properly by(3.14.1.28). Smoothness can be seen by applying(11.1.1.8). $\mathrm{Aut}_\pi(E)$ is a Lie group because it is countable: Let $q \in M$, and U an evenly covered nbhd of q, then $\pi^{-1}(U)$ is a union of open subsets each containing one element of $\pi^{-1}(q)$. so $|\pi^{-1}(q)|$ is countable, and because $\mathrm{Aut}_\pi(E)$ acts freely, it is also countable.

Because this action is a covering map action by(3.11.1.19), (3.14.1.31) shows this is a normal covering map. The quotient space is locally Euclidean, and also Hausdorff by(3.11.1.12)(3.11.1.10), so it is a topological manifold. The smooth structure is clear. □

Def. (11.1.1.11)[Smooth Embedding]. A **smooth embedding** of manifolds $f : M \to N$ is a smooth immersion that is also a homeomorphism onto its image.

Prop. (11.1.1.12) [Global Rank Theorem]. Let $F : M \to N$ be a smooth map of manifolds of constant tank, then:

- if it is an injection, then it is a submersion.
- if it is an surjection, then it is a submersion.
- if it is a bijection, then it is an diffeomorphism.

Proof: Cf.[Lee Smooth Manifold P83]. □

Prop. (11.1.1.13)[Local Embedding Theorem]. If $F : M \to N$ is a smooth morphism of manifolds, then it is a smooth immersion if it is locally a smooth embedding on the source.

Proof: Let $p \in M$, then there exists a nbhd U_1 of $p \in M$ that F is injective. Now choose another precompact nbhd U of p that $\overline{U} \subset V$, then $F|_{\overline{U}}$ is an injective map with compact domain, so it is a topological embedding by(3.3.2.11). Thus $F|_U$ is a smooth embedding. □

Submanifolds

Def. (11.1.1.14) [Submanifolds]. For a smooth manifold M, an **embedded submanifold** $S \subset M$ is a subset S that is a manifold in the induced topology together with a smooth structure that the inclusion is a smooth embedding of manifolds(11.1.1.11).

An **immersed submanifold** $S \subset M$ is a subset endowed with a topology and a smooth manifold structure that the inclusion is a smooth immersion(11.1.1.4).

An **weakly embedded submanifold** $S \subset M$ is an immersed submanifold that any smooth map $F : N \to M$ from some space N that has image in S is smooth as a map from N to S.

Remark (11.1.1.15). Examples of immersed submanifolds that is not an embedded submanifolds are the 8-figure and the dense curve in a torus. However, an immerse submanifold is locally embedded on the source, by(11.1.1.13).

Def. (11.1.1.16) [Slice Charts]. Let $U \subset \mathbb{R}^n$, then a k-slice of U is the set $S = \{(x^1, \ldots, x^n) \in U | x^{k+1} = \ldots = x^n = 0\}$.

Let M be a manifold, a **slice chart** of a subset $S \subset M$ is a smooth char (U, φ) that $\varphi(U \cap S)$ is a k-slice of $\varphi(U)$ for some k.

Prop. (11.1.1.17) [Local Slice Criterion for Embedded Submanifolds]. Let M be a smooth n-manifold and S an embedded k-submanifold, then each point of S is contained in the domain of a slice chart. Conversely, if $S \subset M$ is a subset that each point of S is contained in the domain of a slice chart, then the induced topology makes S a topological manifold, and there is a smooth structure on S that makes it an embedded submanifold of M.

Proof: Suppose S is an embedded submanifold, then the rank theorem(11.1.1.3) shows there exists coordinates that the image of $i(S)$ is contained in a k-slice of M. Shrinking the open subset a little bit, we get a slice chart of S.

Conversely, if each point of S is contained in the domain of a slice chart, then we can use these smooth charts to get an atlas for S, which makes S an embedded topological submanifold of M. The transition maps are also smooth because they are restrictions of the corresponding transition map of M, so S is an embedded submanifold of M. □

Prop. (11.1.1.18). If M is a compact manifold, then any injective immersion $f : M \hookrightarrow M$ is an embedding of submanifolds.

Proof: The topology of M is equivalent to the induced topology by(3.3.2.10). □

Prop. (11.1.1.19) [Immersed Submanifolds are Locally Embedded]. If $S \subset M$ is an immersed submanifold, then for any $p \in S$, there is a nbhd U of $p \in S$ that $U \subset M$ is an embedded submanifold.

Proof: This follows immediately from(11.1.1.13). Notice that the topology on U must be the induced topology, because it is a smooth embedding thus a homeomorphism onto its image(11.1.1.11). □

Lemma (11.1.1.20). If $i : S \hookrightarrow M$ is an immersed submanifold, if $F : N \to M$ is a smooth morphism of manifolds that has image in S, if $F : N \to S$ is continuous, then $N \to S$ is smooth.

Proof: Let $p \in N$ mapping to $q = F(p)$. By(11.1.1.19), there is a nbhd V of $q \in S$ that $i|_V$ is an smooth embedding. Thus there is a slice chart(11.1.1.17) (W, ψ) of M that $(V_0, \widetilde{\psi})$ is a smooth chart for V, where $V_0 = W \cap V$ and $\widetilde{\psi} = \pi \circ \psi$, where π is the projection $\mathbb{R}^n \to \mathbb{R}^k$ onto the first k coordinates, and also a smooth chart for S.

Let $U = F^{-1}(V_0)$ be open in F, then there is a smooth chart of N contained in U. Now the coordinate representation of F in the slice chart of S is just the representation of $F : N \to M$ composed with the projection π, so it is smooth. □

Remark (11.1.1.21). $N \to S$ being continuous is a necessary condition, otherwise consider the figure 8.

Prop. (11.1.1.22) [Restricting Codomain of Smooth Morphism]. If S is an embedded submanifold in M, if if $N \to M$ is a smooth that has image in S, then $N \to S$ is smooth.

Proof: Because in this case, S has the induced topology, so it is easily seen that $N \to S$ is continuous. □

Sard's Theorem

Lemma (11.1.1.23) [Invariance of Measure Zero Sets]. If $S \in \mathbb{R}^n$ has measure zero, then for any smooth map $g : \mathbb{R}^n \to \mathbb{R}^m$, $g(S)$ has measure zero.

Thus the notion of measure zero is definable for arbitrary smooth manifolds.

Lemma (11.1.1.24). Cf.[Pollack Appendix A].

Def. (11.1.1.25). For a map of schemes $f : X \to Y$, a point $y \in Y$ is called **critical** iff df_x is not surjective, for some $x \in f^{-1}(y)$, otherwise it is called a **regular value**.

Prop. (11.1.1.26) [Regular Value Theorem]. If y is a regular value for a map $f : X \to Y$, then $f^{-1}(Y)$ has a natural submanifold structure.

Proof: □

Prop. (11.1.1.27) [Stack of Records Theorem]. If y is regular value of a map $f : X \to Y$, where X is compact and $\dim X = \dim Y$, then f is a covering map locally on $f^{-1}(U)$ for some nbhd U of y.

Proof:

□

Prop. (11.1.1.28) [Sard Theorem]. For a map $X \to Y$ of smooth manifolds, the set of critical values is of measure zero Y.

Proof: Cf.[Pollack Appendix A]. □

Prop. (11.1.1.29) [Whitney Embedding Theorem]. Any k-dimensional manifold M can be embedded into $\mathbb{R}^{2k+1}$.

Proof: Cf.[Pollack P51]. □

Cor. (11.1.1.30) [Whitney Immersion Theorem]. Any smooth manifold M of dimension k can be immersed into $\mathbb{R}^{2k}$.

Proof: □

1-dimensional Smooth Manifold with Boundaries

Prop. (11.1.1.31). Any smooth manifold of dimension 1 with boundary is isomorphic to $[0,1]$ or S^1.

Proof: Cf.[Pollack Appendix]. □

Cor. (11.1.1.32). The boundary of any smooth manifold of dimension 1 consists of points of even number.

Simplifications

Prop. (11.1.1.33). For every vector field X and every point $X(p)\neq 0$, there exists a coordinate nbhd $(x_1,\ldots,x_{n-1},t)$ such that $X=\frac{\partial}{\partial t}$.

2 Smooth Vector Bundles

Def. (11.1.2.1) [Smooth Vector Bundle]. A **smooth vector bundle** over a smooth manifold is a vector bundle over X that the trivialization maps are all smooth.

Def. (11.1.2.2) [Smooth Fiber Bundle].

Tangent and Cotangent Bundles

Lemma (11.1.2.3) [Differential in Coordinates]. Let $F:U\to V$ be a smooth map where $U\subset\mathbb{R}^n$ and $V\subset R^n$, with corresponding coordinates (x^i) and (y^i), then

$$dF_p(\frac{\partial}{\partial x^i}|_p)=\sum_j\frac{\partial F^j}{\partial x^i}(p)\frac{\partial}{\partial y^j}|_{F(p)}.$$

Proof: for any smooth function f,

$$dF_p(\frac{\partial}{\partial x^i}|_p)(f)=\frac{\partial}{\partial x^i}|_p(f\circ F)=\sum\frac{\partial f}{\partial y^j}(F(p))\frac{\partial F^j}{\partial x^i}(p)=(\sum_j\frac{\partial F^j}{\partial x^i}(p)\frac{\partial}{\partial y^j}|_{F(p)})(f).$$

□

Lemma (11.1.2.4) [Change of Coordinates]. Suppose $(U,\varphi),(V,\psi)$ be two smooth charts of a smooth manifold, and the transition function on $U\cap V$ is denoted by

$$\psi\circ\varphi^{-1}(x)=(\widetilde{x}^1(x),\ldots,\widetilde{x}^n(x)),$$

then(11.1.2.3) shows

$$\begin{aligned}\frac{\partial}{\partial x^i}|_p&=d(\varphi^{-1})_{\varphi(p)}(\frac{\partial}{\partial x^i}|_{\varphi(p)})=d(\psi^{-1})_{\psi(p)}\cdot d(\psi\cdot\varphi^{-1})|_{\varphi(p)}(\frac{\partial}{\partial x^i}|_{\varphi(p)})\\&=d(\psi^{-1})_{\psi(p)}(\sum_j\frac{\partial\widetilde{x}^j}{\partial x^i}(\varphi(p))\frac{\partial}{\partial\widetilde{x}^j}|_{\psi(p)})=\sum_j\frac{\partial\widetilde{x}^j}{\partial x^i}(\varphi(p))\frac{\partial}{\partial\widetilde{x}^j}|_p\end{aligned}$$

Def. (11.1.2.5) [Tangent Vectors]. Let M be a smooth manifolds, then a **tangent vector** at a point p is a linear maps $v:C^\infty(M)\to\mathbb{R}$ satisfying:

$$v(fg)=f(p)v(g)+g(p)v(f).$$

The set of tangent vectors at p is a vector space, denoted by T_pM.

Def. (11.1.2.6) [Tangent Bundle]. Let M be a n-dimensional smooth manifold, the tangent bundle of M is defined to be the set $TM = \coprod T_pM$. It has a smooth manifold structure that makes it into a $2n$-dimensional manifold, and the projection $\pi : TM \to M$ is smooth. And it is a n-dimensional vector bundle over M.

Proof: Let (U, φ) be a smooth chart of M, with coordinate functions $\varphi^1, \ldots, \varphi^n$, then we define a map $\widetilde{\varphi} : \pi^{-1}(U) \to \mathbb{R}^{2n}$ by

$$\widetilde{\varphi}(\sum v^i \frac{\partial}{\partial x^i}|_p) = (x^1(p), \ldots, x^n(p), v^1, \ldots, v^n).$$

Then for two different open subset U, V, the transition map is

$$\widetilde{\psi} \cdot \widetilde{\varphi}^{-1}(x^1, \ldots, x^n, v^1, \ldots, v^n) = (\widetilde{x}^1(x), \ldots, \widetilde{x}^n(x), \sum_j \frac{\partial \widetilde{x}^1}{\partial x^j}(x) v^j, \ldots, \sum_j \frac{\partial \widetilde{x}^n}{\partial x^j}(x) v^j)$$

which is clearly smooth. So this defines a smooth vector bundle over M, called the **tangent bundle** of M. □

Def. (11.1.2.7) [Cotangent Bundle]. The **cotangent bundle** T^*M of a smooth manifold M is the dual of the tangent bundle TM.

Def. (11.1.2.8) [Parallelizable manifold]. A manifold is called **parallelizable** iff the tangent bundle is trivial.

Vector Fields

Def. (11.1.2.9) [Smooth Vector Field]. A **smooth vector field** on a smooth manifold is a smooth global section of the tangent bundle $TM \to M$(11.1.2.6).

Prop. (11.1.2.10) [Check Smoothness]. Let M be a smooth manifold and X be a section of the vector bundle $TM \to M$, then X is a smooth vector field iff for any $f \in C^\infty(M)$, $Xf \in C^\infty(M)$.

Proof: If for any $f \in C^\infty(M)$, $Xf \in C^\infty(M)$, let U be a trivializing nbhd of M with coordinate functions x^i, then near any point $p \in U$, we can use bump function to extend x^i to a smooth function on M. Then $X(x^i) = X^i$ near p, thus the coordinates of X in this trivialization are all smooth, so X is smooth near p, thus smooth everywhere.

Conversely, for any $f \in C^\infty(M)$, in a trivializing nbhd U of M, $Xf(x) = (\sum X^i(x) \frac{\partial}{\partial x^i}|_x)(f) = \sum X^i(x) \frac{\partial f}{\partial x^i}(x)$ is smooth. □

Def. (11.1.2.11) [Pushforward of Vector Fields]. Let $F : M \to N$ be a diffeomorphism, then for any $X \in \mathfrak{X}(M)$, there exists a $Y \in \mathfrak{X}(N)$ that $dF_p(X_p) = Y_{F(p)}$.

Proof: We just define $Y_q = dF_{F^{-1}(q)}(X_{F^{-1}(q)})$, it suffices to show this a smooth vector field. But $Y : N \to TN$ is the composition

$$N \xrightarrow{F^{-1}} M \xrightarrow{X} TM \xrightarrow{TF} TN,$$

so it is smooth. □

Def. (11.1.2.12) [Lie Bracket of Vector Fields]. Cf.[Lee13]P185.

Prop. (11.1.2.13)[Pushforward of Lie Bracket]. Let $F : M \to N$ be a diffeomorphism and $X_1, X_2 \in \mathfrak{X}(M)$, then $F_*[X_1, X_2] = [F_*X_1, F_*X_2]$(11.1.2.11).

Proof: For any $f \in C^\infty(N)$, $F_*X_i = Y_i$, then

$$[X_1, X_2](f\circ F) = X_1X_2(f\circ F)-X_2X_1(f\circ F) = X_1((Y_2(f)\circ F)-X_2((Y_1(f)\circ F) = (Y_1Y_2(f)-Y_2Y_1(f))\circ F,$$

which means exactly $F_*[X_1, X_2] = [Y_1, Y_2]$. □

Tensor Fields

Def. (11.1.2.14) [Lie Derivatives of Tensor Fields]. Cf.[Lee13]P321.

3 Differential Forms

Prop. (11.1.3.1)[Frobenius Theorem]. If X is an involutive distribution on a manifold M, then there is a unique maximal integration manifold passing through it. Where a distribution is involutive if it is closed under Lie bracket.

Proof: The key to the proof is to prove that involutive is equivalent to integrable, i.e. flat locally as $\{\frac{\partial}{\partial x_i}\}$ for some local coordinate. Cf.[李群讲义 项武义 P226] □

Cor. (11.1.3.2). X, Y in a Lie algebra commute iff their corresponding vector fields commute.

Interior and Exterior Derivatives

Lie Derivatives

Def. (11.1.3.3). The **Lie bracket** of two vector fields X, Y is defined to be $[X, Y](f) = (XY - YX)f$, then if $X = \sum a_i\partial/\partial x_i$, $Y = \sum b_i\partial/\partial x_i$, then $[X, Y] = \sum(X(b_i) - Y(a_i))\partial/\partial x_i$.

Lemma (11.1.3.4). $[X, Y] = \frac{\partial}{\partial t}(d(\phi_{-t})Y)|_{t=0}$.

Proof: For any function f,set $g(t, q) = \frac{f(\phi_t(q))-f(q)}{t}$,$g(0, q) = Xf(q)$. Then g is differentiable (because $g(t, q) = \int_0^1 Xf(\phi_{ts}(p))ds$, and:

$$\begin{aligned}\lim_{t\to 0} d(\phi_{-t})Yf(p) &= \lim \frac{Yf(p) - Y(f\phi_{-t})(\phi_t(p))}{t}\\ &= \lim \frac{Yf(p) - Yf(\phi_t p) - Y(tg(-t, \phi_t(p))}{t}\\ &= ((XY - YX)f)(p)\\ &= [X, Y]f(p)\end{aligned}$$

□

Prop. (11.1.3.5). $[fu, v] = f[u, v] - df(u)v$.

Proof: Direct from the definition(11.1.3.3). □

Prop. (11.1.3.6) [Derivative formula].

$$d\omega(X, Y) = X\omega(Y) - Y\omega(X) - \omega([X, Y]).$$

Proof: □

Prop. (11.1.3.7) [Cartan's magic formula].

$$L_X\omega = \iota_X(d\omega) + d(\iota_X\omega)$$

$$\iota([X, Y]) = [L_X, \iota_Y]$$

Proof: Notice that four of them are derivatives (check because $\iota_X(w\wedge v) = \iota_X w\wedge v + (-1)^{|w|} w\wedge \iota_X v$). So by induction, we only has to verify them on dimension 0 and 1. □

Prop. (11.1.3.8) [Stoke's theorem].

$$\oint_\Omega d\omega = \oint_{\partial\Omega} i^*\omega.$$

In a 3-dimensional Riemanian manifold, If we set:

$$df = \omega^1_{\mathrm{grad} f}, \quad d\omega^1_A = \omega^2_{\mathrm{curl} A}, \quad d\omega^2_A = (\nabla A)\omega^3,$$

Then:

$$f(y) - f(x) = \int_l \mathrm{grad} f\cdot dl.$$

$$\int_l A\cdot dl = \oint_S \mathrm{curl} A\cdot dn.$$

$$\oint_U \nabla\cdot F dV = \oint_{\partial U} F\cdot n dS.$$

Proof: □

Hodge Star

Def. (11.1.3.9) [Hodge Star Operator]. given a volume-form ω on a vector space, the Hodge star operator $*-$ is an operator from $\bigwedge^k V \to \bigwedge^{n-k} V$ such that:

$$\alpha\wedge(*\beta) = \langle\alpha, \beta\rangle\omega.$$

On a closed oriented Riemannian manifold, given a volume form ω, the star operator satisfies:

$$(\alpha, \beta) = \int_M \langle\alpha, \beta\rangle\omega = \int_M \alpha\wedge *\beta.$$

And $** = (-1)^{p(n-p)}$ on $\Omega^p M$.

Def. (11.1.3.10). For a operator d on $\Omega^* M$, we define the adjoint $d^* = (-1)^{n(p+1)+1} * d *$ on Ω^p, which satisfies the adjoint property by calculation:

$$(d^*\alpha, \beta) = (\alpha, d\beta).$$

The laplacian $\Delta = d^*d + dd^*$. It can be verified that Δ commutes with $*$ and d.

4 Differential Topology

References are [J. W. Milnor, Topology from the differentiable viewpoint. Based on notes by David W. Weaver University Press of Virginia, Charlottesville, Va. 1965 ix+65 pp.].

Transversality

Def. (11.1.4.1) [Transversality].

Prop. (11.1.4.2) [Transversal Stable under Pertabations]. The property of transversal for a map $f : X \to Y$ for a compact manifold X to a fixed submanifold Z of Y is stable under smooth deformation.

Proof: We can assume the submanifold is defined by a slice, so the transversality is in fact equivalent to locally submersion in the vertical direction. Thus it is clearly stable under deformation. □

Prop. (11.1.4.3). If a smooth map $f : X \to Y$ is transversal to a submanifold $Z \subset Y$ of codimension r, then the preimage $f^{-1}(Z)$ is a submanifold of X of codimension r.

Proof: Cf.[Pollack P28]. □

Cor. (11.1.4.4). If two submanifolds are transversal at every point is again a submanifold, and the codimension is the sum of them.

Prop. (11.1.4.5) [Parametric Transversality Theorem]. Suppose N and M are smooth manifolds, $X \subset M$ is an embedded submanifold, and F_s is a smooth family of maps from N to M. If the map $F : N \times S \to M$ is transverse to X, then for a.e. s, the map $F_s : N \to M$ is transverse to X.

Proof: Cf.[Smooth Manifold Lee T6.35]. □

Prop. (11.1.4.6) [Transversality Homotopy Theorem]. Suppose N and M are smooth manifolds and $X \subset M$ is an embedded submanifold. Every smooth map $f : N \to M$ is homotopic to a smooth map $g : N \to M$ that is transverse to X.

Proof: Embed M into an R^k and take a tubular neighbourhood, then we can construct a $N \times D^k$ transversal to M. Cf.[Smooth Manifold Lee T6.36]. □

Prop. (11.1.4.7) [Transversality Extension Theorem]. Let X is a manifold with boundary and $C \subset X$ is a closed subscheme, Z is a closed submanifold of Y. If $f : X \to Y$ is a smooth map that is transversal to Z on C and transversal to Z on $C \cap \partial X$, then there is a map $g : X \to Y$ that is homotopic to f, and $g = f$ on a nbhd of C.

Proof: Cf.[Pollack P72]. □

Intersection Numbers Modulo 2

Prop. (11.1.4.8) [Intersection Number Modulo 2]. Let X be a compact manifold, and Z is an closed submanifold of Y, where $\dim X + \dim Z = \dim Y$, then for any smooth map $f : X \to Y$ transversal to Z, define $I_2(f, Z)$ as the number of points of $f^{-1}(Z)$ modulo 2.

Prop. (11.1.4.9) [Boundary Theorem]. If X is the boundary of a smooth manifold W, Z is a closed subscheme of Y that $\dim X + \dim Z = \dim Y$. If $g : X \to Y$ is a map of smooth manifolds that can be extended to $W \to Y$, then $I_2(g, Z) = 0$.

Proof: Use extension theorem(11.1.4.7), (11.1.4.3) and(11.1.1.32). □

Cor. (11.1.4.10). Let X be a compact manifold, and Z is an closed submanifold of Y, where $\dim X + \dim Z = \dim Y$, then for any smooth maps $f, g : X \to Y$ transversal to Z. If f is homotopic to g, then $I_2(f, Z) = I_2(g, Z)$.

Proof: Immediate from boundary theorem(11.1.4.9). □

Prop. (11.1.4.11) [Mod 2 Degree of Maps]. If X, Y are manifolds of the same dimension and X is compact, then $I_2(f, \{y\})$ is the same for each $y \in Y$, called the **mod 2 degree of** f. This number is 0 for the boundary of a map, by(11.1.4.9).

Proof: Cf.[Pollack P80]. □

Orientable Intersection Numbers

Prop. (11.1.4.12) [Preimage Orientation]. Let X, Y is orientable and Z is an orientable closed subscheme in Y. If $f : X \to Y$ is transversal to Z, then the orientation of Z, Y, Z defines canonically an orientation on $f^{-1}(Z)$, called the **preimage orientation** of $f^{-1}(Z)$.

Def. (11.1.4.13) [Intersection Number]. If X is an orientable smooth manifold, Z is an orientable closed subscheme of an orientable manifold Y that $\dim X + \dim Z = \dim Y$. If $g : X \to Y$ is a map of smooth manifolds that is transversal to Z, then we defined the $I(g, Z)$ to be the sum of the orientations of $f^{-1}(Z)$.

Lemma (11.1.4.14) [Boundary Theorem]. If X is the boundary of an orientable compact smooth manifold W, Z is an orientable closed subscheme of an orientable manifold Y that $\dim X + \dim Z = \dim Y$. If $g : X \to Y$ is a map of smooth manifolds that is transversal to Z and can be extended to $W \to Y$, then $I(g, Z) = 0$.

Proof: The same as the proof of(11.1.4.9). □

Prop. (11.1.4.15). Homotopic transversal maps always have the same intersection number w.r.t Z.

Prop. (11.1.4.16) [Degree of Maps]. If X, Y are orientable manifolds of the same dimension and X is compact, then $I_2(f, \{y\})$ is the same for each $y \in Y$, called the **degree of** f. This number is 0 for a boundary map, by(11.1.4.14).

Proof: The same as that of(11.1.4.11). □

Cor. (11.1.4.17). The only finite group G that can act freely on S^{2n} is $\mathbb{Z}/2\mathbb{Z}$ or 1.

Proof: Consider the degree map, then it is a homomorphism from G to $\mathbb{Z}$, thus the image is just ± 1. Now it is by Lefschetz fixed point theorem that $\deg(g) = -1$ for $g \neq 1$, thus it is injective to $\pm$. □

Prop. (11.1.4.18) [General Intersection Number]. The intersection number can be generalized to the case that $g : Z \to Y$ is an arbitrary map of the complementary dimension, and we can define $I(f, g)$. Then:

- f, g are transversal iff $f \times g$ are transversal to Δ_Y.
- $I(f, g) = (-1)^{\dim Z}(f \times g, \Delta_Y)$.

Proof: This a simple local tangent vector calculation. □

Cor. (11.1.4.19). If $f' \sim f, g' \sim g$, then $I(f, g) = I(f', g')$ if they are definable. This is because $f \times g \sim f' \times g'$.

Prop. (11.1.4.20). $I(f, g) = (-1)^{\dim X \cdot \dim Z} I(g, f)$. This is obvious from the definition.

Cor. (11.1.4.21). This shows that the intersection number of a odd-dimensional orientable submanifold of an orientable submanifold with itself is 0. If this fails, then the ambient space is not orientable, for example the Möbius band with the central circle.

Prop. (11.1.4.22). The Euler character of an orientable compact manifold Y equals the intersection of the diagonals $I(\Delta, \Delta)$.

Proof: For this, we use the Poincare-Hopf theorem(11.1.4.24). It is clear that on a triangulation, we can place a source on the center of each face/edge/..., thus producing a smooth vector fields, thus it is clear the sum of their indices equals both the combinatorial Euler character and the defined character. □

Cor. (11.1.4.23). The Euler character of an odd dimensional compact manifold Y is 0.

Prop. (11.1.4.24) [Poincare-Hopf Index theorem]. In a compact manifold M, any vector field V with isolated zeros has sum of its index equal to $\chi(M)$. Where the index of a singularity is the mapping degree of V on a surrounding sphere.

Proof: Should use Euler character defined in(11.1.4.22), Cf.[Pollack]. □

5 Flow

Def. (11.1.5.1)[Integral Curves]. Let V be a vector field over a smooth manifold M, then an **integral curve** of V is a smooth curve $\gamma : J \to M$ that $\gamma'(t) = V_{\gamma(t)}$ for any $t \in J$.

Def. (11.1.5.2) [Flow]. Let M be a manifold, then a **flow** on M is a continuous map $\theta : D \to M$, where

- $D \in \mathbb{R} \times M$ is an open subset.
- for any $p \in M, D^p = \{t|(t,p) \in D\}$ is an open interval containing 0.
- When it is defined, $\theta(s, \theta(t,p)) = \theta(s+t,p)$.

If θ is a flow, we define $\theta_t(p) = \theta^{(p)}(t) = \theta(t,p)$.

If θ is smooth, then we can define the **infinitesimal generator** of θ to be the vector field $V_p = \theta^{(p)\prime}(0)$.

Def. (11.1.5.3)[Complete Vector Fields]. A complete vector field on a smooth manifold is a vector field that generates a global flow.

Prop. (11.1.5.4). If $\theta : D \to M$ is a smooth flow, then the infinitesimal generator V of θ is a smooth vector field, and each $\theta^{(p)}$ is an integral curve of V.

Proof: Cf.[Lee13]P212. □

Prop. (11.1.5.5) [Isotopy Extension Theorem]. Let M be a manifold and A be a compact subset. Then an isotopy $F : A \times I \to M$ can be extended to an diffeotopy of M.

Proof: Consider $F(A \times I) \subset M \times I$ is a compact set, and $TM \times I \to M \times I$ is a vector bundle. The time lines generate a section $F(A \times I) \to TM \times I$, so **??** guarantees an extension $M \times I \to TM \times I$, and because manifolds are locally compact, this section can be chosen to be compactly supported, then the flow it generates is a diffeotopy. □

6 Distributions and Foliations

Cf.[Lee13]Chap19.

7 Spin Structures

Prop. (11.1.7.1) [Spin Structure Obstruction]. For a oriented real bundle, its transformation map can be chosen to be in $SO(n)$, and constitute a Cech Cohomology $H^1(X, SO(n))$, and by exact sequence of

$$0 \to \pm 1 \to \mathrm{Spin}(n) \to SO(n),$$

this can be lifted to a $H^1(X, \mathrm{Spin}(n))$ iff its image w in $H^2(X, \mathbb{Z}/2\mathbb{Z})$ is 0. and then its inverse image will be parametrized by $H^1(X, \mathbb{Z}/2\mathbb{Z})$ (By the non-commutative spectral sequence of Čech).

We have $w = w_2$, the Whitney class, (Just need to reduce to sk_2X and in this case, check they both equivalent to the bundle can be lifted). Cf.[XieYi 几何学专题]. Or we can use the Postnikov system of $BO(n)$(3.13.5.2).

Proof: First prove that if $E \oplus R^n$ is spin, then E is spin, and then pull $H^2(X, \mathbb{Z}/2\mathbb{Z})$ into $H^2(\mathrm{sk}_2(X), \mathbb{Z}/2\mathbb{Z})$, this in a injection, and the homology is natural, so we only have to prove this for $\mathrm{sk}_2(X)$. But E on $\mathrm{sk}_2(X)$ can decompose into a E' of dimension on more than 2, and for this, we see E is Spin iff it is the square of another bundle, so w and w_2 are the same. □

Prop. (11.1.7.2). For a Spin bundle E, the Spin-principal bundle with the Spinor representation(11.7.4.17) will generate a bundle S called the **Spinor bundle**. And the Ad action of $\mathrm{Spin}(n)$ on $Cl_{n,0}$ will generate a **Clifford bundle** $Cl(E)$. The $\mathrm{Spin}(n)$ actions are compatible, so the Clifford bundle can act on the spinor bundle. bundle. The act of the chirality operator on the Spinor bundle will generate two half spinor bundles $S^{\pm}$. Then TM will maps $S^{\pm} \to S^{\mp}$ for n even,(because of anti-commutative with Γ).

Prop. (11.1.7.3) [Spin^c-structure]. The group Spin^c is the covering space of $SO(n) \times S^1$ (n>2) that corresponds to the group of elements mod 0 mod 2 in $\mathbb{Z}_2 \times \mathbb{Z}$, i.e. $\mathrm{Spin}(n) \times S^1/\{\pm 1\}$.

For example, $\mathrm{Spin}^c(4) = \{(A_1, A_2) \in U(2) \times U(2) | \det A_1 = \det A_2\}$, and $\mathrm{Spin}^C(3) = U(2)$.

Then a $SO(n)$ bundle can be lift to be a Spin^c-bundle if the line bundle determined by S^1 is determine the same w_2 as it, i.e. $w_2 = c_1(L) \bmod 2$, This is equivalent to w_2 is in the image of $H^2(X, \mathbb{Z})$, and this is equivalent to the Bockstein image of it is zero.

Use a variant of Wu's formula: $w_2(TM)[\alpha] = \alpha{\cdot}\alpha (\mathrm{mod}\ 2)$ for M orientable of dimension 4, we have any orientable manifold of dimension 4 has a Spin^c-structure. Cf.[XieYi 几何学专题 Homework3].

There is a connection on the Clifford bundle and on the Spinor bundle induced by the Levi-Civita connection of M(11.2.3.2). This is compatible with the Clifford action. and it is also metric because the connection 1-form is in $\mathfrak{so}(n)$ because the action of $SO(n)$ preserves metric.

8 Young-Mills Euqation & Seiberg-Witten Equation

[Atiyah, M. F.; Bott, R. The Yang-Mills equations over Riemann surfaces. Philos. Trans. Roy. Soc. London Ser. A 308 (1983), no. 1505, 523–615.].

Def. (11.1.8.1) [Yong-Mills]. The Young-Mills functional on connections A on a bundle E on a compact oriented space:

$$YM(A)^2 = ||F_A||^2 = -\int_X \mathrm{tr}(F_A \wedge *F_A)$$

it is a critical point when $d_A \star F_A = 0$ and $d_A F_A = 0$.

Prop. (11.1.8.2) [2-dim Case]. $\star F \in \Omega^0(su(E))$ is parallel thus its characteristic spaces is orthogonal and a stable under parallel transport. So an irreducible YM $SU(2)$-connection must by flat, thus correspond to irreducible $SU(2)$ representation of $\pi_1(X)$.

Prop. (11.1.8.3) [4-dim Case]. $** = (-1)^{2*2} = \mathrm{id}$ on $\Omega^2(E)$ on E a $SU(n)$-bundle, so $\Omega^2(E) = \Omega^+ \oplus \Omega^-$. We have

$$||F_A^+||^2 + ||F_A^-||^2 \geq ||F_A^-||^2 - ||F_A^+||^2 = \int_X \mathrm{tr}(F_A \wedge F_A) = 8\pi^2 c_2(E)$$

Cf.[谢毅 Lecture5]. So it attains minimum at the connection that $*F_A = \pm F_A$ and $d_A F_A = 0$.((Anti)self-dual((anti)instanton)) depending on the sign of $c_2(E)$.

Prop. (11.1.8.4) [Anti-Instanton Connection on Complex Line Bundle]. For a $U(1)$-bundle, $d_A F_A = dF_A$, so F_A is harmonic, thus $c_1(L) = [\frac{-1}{2\pi i}F_A] \in H^2(X,\mathbb{Z}) \cap \mathcal{H}^2_-(X,\mathbb{R})$, In fact, this is equivalent to the existence of a anti-self-dual connection on this bundle.

If this is the case, then we have the ASD-connections module Gauge equivalence is isomorphic to $H^1(X,\mathbb{R})/H^1(X,\mathbb{Z}) = T^{b_1(X)}$.

Proof: Because a gauge is just a $X \to S^1$, and its connected component thus equals $[X, S^1] = H^1(X,\mathbb{Z})$ (MacLane space), and its identity is just the map that is homotopic to id. and $d(gA) = dA - g^{-1}dg = dA - idu$, for $g = exp(iu)$, so $\Omega^1/\mathcal{G} = H^1(X, \mathbb{R}/H^!(X,\mathbb{Z}) = T^{b_1(X)}$. □

Lemma (11.1.8.5) [Weizenbock Formula]. On a Riemannian manifold M, the Laplace operator has the form:

$$\Delta = -\nabla^2_{e_i e_i} - \xi^i \wedge \iota(e_j) R(e_i, e_j)$$

where $\nabla^2_{X,Y} = \nabla_X \nabla_Y - \nabla_{\nabla_X Y}$.

$$\int |\mathcal{D}_A \varphi|^2 = \int |\nabla_A \varphi|^2 + \frac{1}{4} R|\varphi|^2 + \frac{1}{2}\langle F_A^+ \varphi, \varphi\rangle.$$

If M is a spin manifold, then the Dirac operator D satisfies:

$$D^2 = -\nabla^2_{e_i e_i} + \frac{1}{4}R$$

where R is the scalar curvature form on M. If M is a *Spin*^{c} manifold with a *Spin*^{c} connection ∇_A, then the Dirac operator satisfies

$$D_A^2 = -\nabla^2_{A, e_i e_i} + \frac{1}{4}R + \frac{1}{2}F_A$$

Cf.[Geometric Analysis Jost P143,153].

Prop. (11.1.8.6) [Seiberg-Witten]. The Seiberg-Witten equation functional for a unitary connection A on the determinant bundle of a Spin^c structure of M and a section of $\mathcal{S}^+$ is:

$$\begin{aligned} SW(\varphi, A) &= \int \Big(|\nabla_A \varphi|^2 + |F_A^+|^2 + \frac{R}{4}|\varphi|^2 + \frac{1}{8}|\varphi|^2\Big) Vol. \\ &= \int \Big(|\mathcal{D}_A \varphi|^2 + |F_A^+ - \frac{1}{4}\langle e_j e_k \varphi, \varphi\rangle e^j \wedge e^k|^2\Big) Vol \end{aligned}$$

So the Seiberg-Witten equation is the lowest topological possible value of the Seiberg-Witten functional. It writes:

$$\mathcal{D}_A \varphi = 0, \quad F_A^+ = \frac{1}{4}\langle e_j e_k \varphi, \varphi\rangle e^j \wedge e^k.$$

Cf.[Jost Chapter 7].

Cor. (11.1.8.7). If a compact oriented Spin^c manifold M has nonnegative scalar curvature, then the only possible solution is $\varphi = F_A^+ = 0$. (See from the equivalence of forms of Seiberg-Witten functional.)

9 Chern-Weil Theory

Prop. (11.1.9.1) [Chern-Weil]. An **Invariant polynomial** of a the entries of $M_n(k)$ is one that is invariant under the conjugation action(2.2.2.29).

For any connection on E, the **Chern-Weil** map CW from invariant polynomial ring to $H^*(X)$: $P \mapsto [P(\Omega)]$ is a ring homomorphism independent on the connection A.

There are relations between c_i and $\mathrm{tr}(\Omega^k)$, they can be derived formally by considering diagonal elements.

Proof: To prove $P(\Omega)$ is closed, notice by(2.2.2.29), it suffice to show $\mathrm{tr}(\Omega^k)$ is closed. By(11.2.3.7), $d\,\mathrm{tr}(\Omega^k) = \mathrm{tr}(\omega \wedge \Omega^k - \Omega^k \wedge \omega) = 0$, which is zero because Ω is of even dimension.

For the independence of connections, use(3.13.3.28). For two connection ∇_i, $\nabla = t\nabla_0 + (1-t)\nabla_1$(you can smooth it) is a connection on the vector bundle π^*E on $M \times I$, and the section 0 and 1 induces the connection ∇_0 and ∇_1. Thus s_0^* and s_1^* are the same map, thus $CW_M(p) = s_i^* CW_{M\times I}(p)$ are all the same map. □

Cor. (11.1.9.2). For a complex line bundle of degree r over a complex manifold,

$$\det(1 - \frac{1}{2\pi i}F_A) = 1 + c_1 + \ldots + c_r$$

gives out the **Chern class**, because it satisfies the axioms of Chern class (3.14.4.16). In other words, $c_k = \mathrm{tr}((-\frac{1}{2\pi i}F_A)^k)$.

For a real line bundle of degree r,

$$\det(1 - \frac{1}{2\pi i}F_A) = 1 + p_1 + \ldots + p_{\lfloor \frac{r}{2} \rfloor}$$

gives out the **Pontryagin class**, where $p_k \in H^{4k}(X)$. (Notice the ω thus Ω can be chosen to be skew-symmetric, thus for odd k the classes $\mathrm{tr}(\Omega^k) \in H^{2k}(X)$ vanish).

For an oriented real bundle of degree $2r$, the ω and thus Ω can be chosen to be skew-symmetric and the transformation matrix in $SO(2r)$, then

$$\mathrm{Pf}(\frac{1}{2\pi}\Omega) \in H^{2r}(X)$$

is well-defined and closed and gives the **Euler class** $e(E)$ (recall $e(E)^2 = p_r(E)$). (Use $\mathrm{Pf}^2 = \det$ to get that $[\dfrac{\partial \mathrm{Pf}}{\partial \Omega_{ij}}]^t$ commutes with Ω, then calculate $d\mathrm{Pf}(\Omega) = 0$).

Proof: In fact, the construction is natural w.r.t the connection because connection can be pulled back and summed. Then the only task is the normality, which is direct calculation on $\mathbb{CP}^1$. □

Cor. (11.1.9.3).
$$c_1(E) = c_1(\wedge^{\dim E} E).$$

Direct from the formula.

Cor. (11.1.9.4) [Whitney Product Formula].

$$c(E\oplus F)=c(E)c(F),\quad p(E\oplus F)=p(E)p(F)$$

Directly form the product connection on $E\oplus F$.

Prop. (11.1.9.5) [Chern Character]. The Chern character

$$ch(E)=[\operatorname{tr}\exp(\frac{i}{2\pi}F_A)]$$

satisfies $ch(E\oplus F)=ch(E)+ch(F)$ and $ch(E\otimes F)=ch(E)ch(F)$ by simple calculation. So it defines a ring homomorphism from $K(X)$ to $H^*(X)$.

Prop. (11.1.9.6) [Chern-Gauss-Bonnet]. For a $2n$-dimensional orientable manifold M,

$$\int_M e(TM)=\chi(M).$$

Prop. (11.1.9.7). For a vector bundle and a flat connection d_A on a manifold, i.e. $d_A^2=0$, we have a deRham like cohomology, and there is a sheaf of flat sections.

$$H^*(X,A)=H^*(X,E).$$

10 Index Theorems(Atiyah-Singer)

References are [Heat equation and the Index Theorem Atiyah] and [Index Theorem].

Prop. (11.1.10.1) [Gilkey]. For a natural transformation ω from the functor $p:M\to$ the Riemannian structure on M to the functor $q:M\to k$-forms on M, if it is homogenous of weight 0 w.r.t to metric g(i.e. $\omega(\lambda^2 g)=\omega(g)$) and in local coordinates it has the coefficients of $\omega(g)$ generated by g_{ij} and $\det g^{-1}$ and their derivatives , then is is a polynomial of Pontryagin classes of the given dimension. (not only up to homology).

Proof: Cf.[Heat equation and the Index Theorem Atiyah P284]. □

Prop. (11.1.10.2) [Gilkey Generalized]. For a natural transformation ω from the functor $p:M\to$ Riemannian structures on M with a Hermitian bundle E with a Hermitian connection and the functor $q:M\to k$-forms on M, if it is homogenous of weight $(0,0)$ w.r.t to metric g,h and the Hermitian structure(i.e. $\omega(\lambda^2 g,\mu^2\xi)=\omega(g,\xi)$) and in local coordinates it has the coefficients of $\omega(g,\xi)$ generated by $g_{ij},h_{ij},\det h^{-1},\det g^{-1}$ and Γ_k^{ij}(the connection form) and their derivatives, then is is a polynomial of Pontryagin classes and Chern classes of E of the given dimension. (not only up to homology).

Proof: Cf.[Heat equation and the Index Theorem Atiyah P290]. □

Cor. (11.1.10.3). For a natural transformation ω from the functor $p:M\to$ Hermitian bundle E on M with a Hermitian connection and the functor $q:M\to k$-forms on M, if it is homogenous of weight 0 w.r.t to metric h and the Hermitian structure(i.e. $\omega(\mu^2\xi)=\omega(\xi)$) and in local coordinates it has the form $\omega(g,\xi)$ generated by $h_{ij},\det h^{-1}$ and Γ_k^{ij}(the connection form) and their derivatives, then is is a polynomial of Chern classes of E of the given dimension. Because when composed with the forgetful functor, it gives a transformation as above. And it is obviously independent of g.

Prop. (11.1.10.4) [Hodge]. For any differential operator A from a vector bundle E to a vector bundle F, we form two operators AA^* and A^*A, then they are both self adjoint elliptic operators, let these corresponding eigenspace be $\Gamma_\lambda(E)$ and $\Gamma_\lambda(F)$, then A and A^* define an isomorphism between $\Gamma_\lambda(E)$ and $\Gamma_\lambda(F)$.

Proof: □

Prop. (11.1.10.5) [Hirzebruch Signature Formula]. On a $4n$-dimensional orientable manifold M, the Poincare duality defines a bilinear pairing $H^{2n}(M)\times H^{2n}(M)\to\mathbb{R}$, its signature $\sigma(M)$ is given by:

$$\sigma(M)=\int_M L_n(p_1,\ldots,p_n).$$

Where L_n is the degree n part of the Taylor expansion of $\prod_{i=1}^r \dfrac{\sqrt{x_i}}{\tanh\sqrt{x_i}}$ in terms of the symmetric polynomial.

Proof: We consider the operator $\tau:\alpha\mapsto i^{l+p(p-1)}*\alpha$, $\tau^2=1$, thus Γ^* is decomposed into two eigenspaces of τ. We define the **signature operator** A as the restriction of $\Delta=d-\tau d\tau$ to Γ_+. Δ anti commutes with τ thus maps Ω_+ to Ω_-, then we have $\ker A=\ker\Delta\cap\Omega_+$, which is the positive harmonic forms H_+. So

$$\mathrm{Ind}A=\dim H_+-\dim H_-.$$

And we notice the positive and negative harmonic forms neutralize each other unless on the $2n$-forms, so only need to consider them. In fact, if we consider $4n+2$ manifolds, then τ is pure imaginary and the conjugation neutralize even the $2n+1$ forms, so there are no signature.

Now the inner product $\alpha\to\int\alpha\wedge*\alpha$ is positive definite for a real form α, so this index of A is just the signature of the intersection form defined by cup product. □

Cor. (11.1.10.6). For a $4n$-dimensional M which is a boundary of a manifold, its signature is 0.

Proof: By Stokes theorem, if M is a boundary of a manifold, then all its Pontryagin numbers, i.e. $\int_M\prod p_i^{n_i},\sum n_i=n$, vanish. □

Prop. (11.1.10.7) [Generalized Hirzebruch Signature Formula]. Let M be a $2l$ dimensional smooth manifold and E be a Hermitian bundle over M, then The index of the generalized signature operator is giving by

$$\mathrm{Ind}A_\eta=2^l\cdot ch(E)L(p_1,\ldots,p_l).$$

where $L(M)(p_i)=\prod\dfrac{x_i/2}{\tanh x_i/2}$.

Prop. (11.1.10.8) [Hirzebruch-Riemann-Roch]. For a n-dimensional complex line bundle L over a compact Kähler manifold M,

$$\chi(M,L)=\int_M[\mathrm{ch}(E)\mathrm{td}(T^{1,0}M)]_n.$$

Where $\chi(M,L)=\sum_{q=0}^n(-1)^q\dim H^q(M,E)$, ch is the Chern character(11.1.9.5) and $\mathrm{td}(T^{1,0}M)$ is the Todd polynomial, i.e. Taylor expansion of $\prod_{i=1}^r\dfrac{t_i}{1-e^{-t_i}}$ in terms of the symmetric polynomial, applied to $c_i(T^{1,0}M)$.

Cor. (11.1.10.9) [Riemann-Roch]. For a n-dimensional complex vector bundle E over a Riemann Surface M, let $\deg E = \int_M c_1(E)$, then

$$\chi(M, E) = H^0(M, E) - \dim H^1(M, E) = \deg E + \mathrm{rk}(E)(1 - g).$$

Cf.[Index Theorem P115].

<u>**Hodge Theory**</u>

Prop. (11.1.10.10) [Hodge]. By(10.13.8.12), if we investigate the Laplace operator Δ_d on a compact orientable Riemannian manifold, we get that

$$\Omega^i = \mathcal{H}^i \oplus \mathrm{Im}\,\Delta_d = \mathcal{H}^i \oplus \mathrm{Im}\,d \oplus \mathrm{Im}\,d^*.$$

Thus H^i can be uniquely represented by elements of $\mathcal{H}^i$.

Proof: It suffice to prove Δ_d is self-adjoint elliptic.

$\mathrm{Im}\,\Delta_d \subset \mathrm{Im}\,d \oplus \mathrm{Im}\,d^*$, and the result follows if we show $\mathcal{H}^i, \mathrm{Im}\,d, \mathrm{Im}\,d^*$ are orthogonal. In fact, let ω be harmonic, then $(\omega, d^*\xi) = (d\omega, \xi) = 0$, $(\omega, d\eta) = (d^*\omega, \eta) = 0$, $(d\eta, d^*\xi) = (dd\eta, \xi) = 0$. □

Cor. (11.1.10.11) [Poincare Duality for deRham Cohomology]. If M is a n-dimensional compact orientable Riemannian manifold, then

$$H^p_{dR}(M) \cong H^{n-p}_{dR}(M)$$

Induced by $*$, because $** = \pm 1$ and $*$ commutes with Δ_d(11.1.3.10), so it induce an isomorphism $\mathcal{H}^p \cong \mathcal{H}^{n-p}$.

Moreover, $*$ in fact induces a perfect pairing:

$$H^k_{dR}(M) \times H^{n-k}(M) \to \mathbb{R}$$

induced by the map

$$* : \mathcal{H}^k(M) \times \mathcal{H}^{n-k}(M) \to \mathbb{R} : (\alpha, \beta) \mapsto \int_M \alpha \wedge *\beta$$

As $\int_M \alpha \wedge *\alpha = ||\alpha||^2 \neq 0$.

Prop. (11.1.10.12). On a compact complex manifold, the formal adjoint of $\overline{\partial}$ is $*\partial*$. (By direct calculation). Also $d^* = (-1)^{n(p+1)+1} * d* = - * d*$.

Prop. (11.1.10.13) [Hodge]. Given a compact Hermitian complex manifold (X, J, g) and a holomorphic line bundle E over it, there is a Hermitian metric on $A^{p,q}E$, and an operator $\overline{\partial}$ on it. Then $\overline{\partial}$ has a formal adjoint $\overline{\partial}^*$, and $\Delta_{\overline{\partial}_E}$ can be defined. Let $\mathcal{H}^{p,q}_E$ be the kernel of $\Delta_{\overline{\partial}}$ on $A^{p,q}E$, called the ***E*-valued (p, q)-forms**, then there is a orthonormal decomposition

$$A^{p,q}E = \mathcal{H}^{p,q}_E \oplus \mathrm{Im}\,\Delta_{\overline{\partial}_E} = \mathcal{H}^{p,q}_E \oplus \mathrm{Im}\,\overline{\partial}_E \oplus \mathrm{Im}\,\overline{\partial}^*_E$$

And thus $\mathcal{H}^{p,q}(X, E) \cong H^{p,q}_{\overline{\partial}}(X, E)$.

Proof: It suffice to prove $\Delta_{\overline{\partial}_E}$ is self-adjoint elliptic. The rest is verbatim as the proof of(11.1.10.10). □

Cor. (11.1.10.14) [Hodge]. In case $E = \mathcal{O}_X$, $\mathcal{H}^{p,q}(X) \cong H^{p,q}_{\overline{\partial}}(X)$.

Cor. (11.1.10.15) [Kodaira-Serre Duality]. For a Hermitian line bundle over a compact Hermitian complex manifold X, from Hodge theorem and(11.8.5.2), we get

$$H^p(X, \Omega^q(E)) \cong H^{n-p}(X, \Omega^{n-q}(E^*))$$

induced by $\overline{*}_E$ and $\overline{*}_{E^*}$.

11 Knots and Links

Prop. (11.1.11.1) [Linking Number]. For two knots A, B in $\mathbb{R}^n$, we can choose a $D \cong D^2$ with boundary A, then define their linking number as the intersection number of D with B.

This can be extended to higher dimensions.

12 Others

Real Algebraic Geometry

Prop. (11.1.12.1). Any compact smooth manifolds in $\mathbb{R}^n$ can be approximated by a real algebraic variety.

Proof: Cf.[Nash's work on Algebraic Geometry]. □

Prop. (11.1.12.2). Let Y be a projective variety over $\mathbb{R}$ and $Z \subset Y$ a closed subvariety, then there exists a triangulation of the pair $(Y(\mathbb{R}), Z(\mathbb{R}))$.

Proof: Cf.[Hironaka1975, Triangulations of Algebraic Sets] and [Lojasiewicz1964, Triangulation of semi-analytic sets]. □

11.2 Riemannian Geometry

Basic references are [Riemannian Geometry Do Carmo], [Geometric Analysis Jost] and [Differentia Geometry Loring Tu].

1 $\mathbb{R}^3$-Geometry

Different Coordinates

Prop. (11.2.1.1). In a polar coordinate,

$$g_{11} = 1, g_{12} = 0, g_{22} = |\frac{\partial f}{\partial \theta}|^2, \quad K = -\frac{(\sqrt{g_{22}})_{\rho\rho}}{\sqrt{g_{22}}}$$

And $\sqrt{g_{22}} \sim \rho$. (Use the formula relating Jacobi Field with curvature)

Moving Frame Method

Thm. (11.2.1.2) [Theorema Egregium, Gauss1827].

$$R_{1212} = K(g_{11}g_{22} - g_{12}^2)$$

Which is a special case of the definition of curvature.

Proof: □

Prop. (11.2.1.3) [Gauss-Bonnet]. Let M be a compact oriented 2-dimensional Riemannian manifold, then

$$\chi(M) = \frac{1}{2\pi}\int_M K \text{ Vol}.$$

Proof: Should be an direct corollary of(11.1.9.6). □

Topology and Geometry

Prop. (11.2.1.4). Every compact orientable surface of genus $p > 1$ can be provided with a metric of constant negative curvature.

Proof: □

Remark (11.2.1.5) [Hilbert Theorem]. There exist complete surfaces with $K \leq 0$ in $\mathbb{R}^3$, but the hyperbolic surface cannot be immersed into $\mathbb{R}^3$.

2 Basics

Prop. (11.2.2.1). If the metric tensor on the tangent space is g in a coordinate, then it is g^{-1} in the cotangent space. (Follows from**??**).

3 Connections

Def. (11.2.3.1) [Affine Connection]. An **affine connection** on a vector bundle E is a map $D : \Gamma(E) \to \Gamma(E) \otimes \Gamma(T^*M)$ that satisfies differential-like properties, it can be written as $D = d + \omega$, with $\omega \in \Omega^1(\mathrm{End}(E))$.

Prop. (11.2.3.2) [Transformation Law]. In two coordinates $\overline{e} = ea$ for $a : U \to GL(r, \mathbb{R})$, $d_A = d + \omega, d + \overline{\omega}$, then $\overline{\omega} = a^{-1}\omega a + a^{-1}da$.

Moreover, giving any locally compatible $d + \omega$,$\omega \in \Omega^1(\mathfrak{g})$ in the sense above, then for any G-associated bundle E, where G has lie algebra $\mathfrak{g}$, there is a connection that locally looks like $d + \omega$, (where $\mathfrak{g}$ embeds into $\mathfrak{gl}(E)$).

Cor. (11.2.3.3) [Local Nature of Connection]. From the description of connection given above, it's easy to say if the is a local connection that satisfies these transformation laws, then it generate a global connection. So by partition of unity(3.3.7.9), connection exists in any vector bundle over a manifold.

Cor. (11.2.3.4) [Simplification]. $d_{gA}(s) = gd_A(g^{-1}(s))$, So for any connection d_A and any point x_0, there is a gauge transformation that makes $d_A = d$ at x_0.

Proof: Just need to have $s(x_0) = \mathrm{id}$, $ds(x_0) = -A(x_0)$. this is possible because $A \in \Omega^1(\mathrm{Ad}E)$ which is the fiber of the frame bundle, use exp. □

Prop. (11.2.3.5) [Induced connections]. The connection action $d_A = d + \omega$ on a vector bundle E induces connection on many relevant bundles. the action on dual bundle is by

$$d_A(s^*) = ds^* - \omega^t(s^*) = ds^* - s^* \circ \omega.$$

And the connection on $\mathrm{End}\, E$ by

$$d_A(\alpha) = d\alpha + [\omega, \alpha] = [\nabla, \alpha]$$

And they act on $\Omega^*(E)$ by Leibniz rule thus the formula looks the same. (Note that the convention is section write on the left of the differential forms, so for example, $[\omega, \omega] = 2\omega \wedge \omega$).

Proof: Cf.[Jost P110]. □

Cor. (11.2.3.6). For a line bundle L, for a connection on it with curvature Ω, the induced on the dual line bundle L^* has connection $-\Omega$. (because $\Omega = d\omega$ and $\omega' = -\omega$).

Prop. (11.2.3.7) [Second Bianchi's Identity]. A affine connection on E looks locally like $d_A = d+\omega$, where $\omega \in \Omega^1(\mathrm{End}\, E)$. And $F_A = d_A \circ d_A \in \Omega^2(\mathrm{End}(E))$ satisfies

$$d_A F_A = dF_A + [\omega, F_A] = 0.$$

Proof: Notice $dF_A = dd\omega + d(\omega \wedge \omega) = d\omega \wedge \omega - \omega \wedge d\omega$, and $\omega(d\omega + \omega \wedge \omega) - (d\omega + \omega \wedge \omega)\omega = \omega \wedge d\omega - d\omega \wedge \omega$. □

Def. (11.2.3.8) [Christoffel Symbol]. The **Christoffel symbol** of a connection is defined by the equations: $\nabla_{X_i} X_j = \sum_k \Gamma^k_{ij} X_k$.

The **geodesic equations** is $\dfrac{D}{dt}(\dfrac{d\gamma}{dt}) = \ddot{x}_k + \sum_{i,j} \Gamma^k_{ij} \dot{x}_i \dot{x}_j = 0 \quad \forall k$.

Def. (11.2.3.9). The **torsion tensor** of a connection ∇ on TM is defined as $T(X,Y)=\nabla_X Y-\nabla_Y X-[X,Y]$. The connection is called **torsion-free** if $T=0$. This is equivalent to $\Gamma^k_{i,j}=\Gamma^k_{j,i}$.

A connection is called **metric** if it preserves metric. i.e. $\nabla g=0$.

Proof: T is a tensor because it is skew-symmetric, and

$$T(fX,Y)=f\nabla_X Y-f\nabla_Y X-df(Y)X-(f[X,Y]-df(Y)X)=fT(X,Y),$$

where(11.1.3.5) is used. □

Prop. (11.2.3.10). If ∇ is torsion-free connection on TM, then its induced connection on T^*M satisfies

$$(d\alpha)(v_1,\ldots,v_k)=\sum(-1)^i(D_{v_i}\alpha)(v_1,\ldots,\widehat{v}_i,\ldots,v_k).$$

Proof: □

Def. (11.2.3.11) [Curvature Tensor]. The **curvature** of a (affine) connection d_A is $F_A=d_A\circ d_A\in\Omega^2(\mathrm{End}(E))$. The curvature tensor it induced is

$$F_A(Z)(X,Y)=R(X,Y)Z=D_Y D_X Z-D_X D_Y Z+D_{[X,Y]}Z.$$

In particular, the curvature depends only on the point, and locally $F_A=d\omega+\omega\wedge\omega$

In two coordinates $\overline{e}=ea$ for $a:U\to GL(r,\mathbb{R})$,$\overline{F_A}=a^{-1}F_A a$.

The connection is called **flat** if $F_A=0$.

Proof: To verify the equation, check first the left side is pointwise, and the third component of the right side assures it is pointwise, too, thus we can check for a local coordinate vector field($[X_i,X_j]=0$), then because $\nabla s=\sum_i\nabla_i s dx_i$,

$$\nabla^2 s=\nabla(\sum_i\nabla_i s dx_i)=\sum_{ij}\nabla_j\nabla_i s dx_j dx_i=\sum_{i<j}(\nabla_i\nabla_j-\nabla_j\nabla_i)s dx_i\wedge dx_j$$

□

Prop. (11.2.3.12)[Flat coordinate]. A connection on TM assumes near every point a flat coordinate, i.e. $\nabla(\partial/\partial x^i)=0$, iff it is flat and torsion-free.

Proof: One side is easy because its Christoffels vanish. On the other side, use integrability theorems (10.13.6.2). Cf.[Jost P115]. □

Prop. (11.2.3.13).

$$\Delta\langle\varphi,\varphi\rangle=2(\langle D^*D\varphi,\varphi\rangle-\langle D\varphi,D\varphi\rangle).$$

Proof: Cf.[Jost P118]. □

Prop. (11.2.3.14). For a flat connection, there is a bundle isomorphism (Gauge transform) that transforms d_A into natural d.

Proof: Because $d_{gA}(s)=gd_A(g^{-1}(s))$,$d_{gA}=d-dg\cdot g^{-1}+g\cdot\omega\cdot g^{-1}$. Solve this PDE direvtly. (Cf.[Topics in Geometry Xie Yi week3]). □

Cor. (11.2.3.15). For a flat connection, by(11.2.3.14), the parallel transportation only depends on the homotopy type of the loop, thus gives an action of $\pi(X)$ on $SO(T_p(X))$ (or $SU(T_p(X))$. (because it is locally constant).

In this way, connections module gauge equivalence (preserving matric) equals representation of $\pi(X)$ module conjugations. The reverse map is giving by principal bundle.

Proof: □

Levi-Civita Connection

Def. (11.2.3.16) [Levi-Civita Connection]. The Levi-Civita connection is the unique connection on M that is metric and torsion-free:

$$X\langle Y,Z\rangle=\langle\nabla_X Y,Z\rangle+\langle Y,\nabla_X Z\rangle,\qquad \nabla_X Y-\nabla_Y X=[X,Y].$$

It satisfies:

$$\langle Z,\nabla_Y X\rangle=1/2\{X\langle Y,Z\rangle+Y\langle Z,X\rangle-Z\langle X,Y\rangle-\langle[X,Z],Y\rangle-\langle[Y,Z],X\rangle-\langle[X,Y],Z\rangle\}.$$

Then

$$\Gamma_{ij}^m=1/2\sum_k\{g_{jk,i}+g_{ki,j}-g_{ij,k}\}g^{km}$$

Thus geodesic is a solution that only depends on the metric(11.2.3.8), so a local isometry preserves geodesics.

Prop. (11.2.3.17). Now the Lie derivative has the form:

$$L_X(S)(Y_1,\dots,Y_p)=\nabla_X(S)(Y_1,\dots,Y_p)+\sum_{i=1}^p S(Y_1,\dots,Y_{i-1},\nabla_{Y_i}X,\dots,Y_p).$$

The exterior derivative d and its adjoint d^* has the form:

$$d\omega(Y_i)=\sum(-1)^p\nabla_{Y_i}\omega(\check{Y_p}),\quad d^*\omega(Y_i)=-\sum\nabla_{e_j}\omega(e_j,Y_i)$$

where e_i is an orthonormal basis. Cf.[Jost P140].

Prop. (11.2.3.18) [Covariant Differential Symmetry]. For a parametrized surface: $s:(u,v)\to M$,

$$\frac{D}{\partial u}\frac{\partial s}{\partial v}=\frac{D}{\partial v}\frac{\partial s}{\partial u}.$$

Proof:

$$\frac{D}{\partial u}\frac{\partial s}{\partial v}=\frac{D}{\partial u}(\sum\frac{\partial s_i}{\partial v}X_i)=\frac{\partial^2 s_i}{\partial u\partial v}+\sum\frac{\partial s_i}{\partial v}(\sum\frac{\partial s_j}{\partial u}\nabla_j X_i)=\frac{\partial^2 s_i}{\partial u\partial v}+\sum_{ij}\frac{\partial s_i}{\partial v}\frac{\partial s_j}{\partial u}\nabla_j X_i$$

But now the Levi-Civita connection is symmetric, thus $\nabla_j X_i=\nabla_i X_j$, showing the symmetry in u and v. □

Lemma (11.2.3.19) [Gauss]. Let $p\in M$ and $v\in T_pM$ s.t. $\exp_p v$ is defined, $w\in T_pM$, then

$$\langle(d\exp_p)_v(v),(d\exp_p)_v(w)\rangle=\langle v,w\rangle.$$

Proof: Cf.[Do Carmo P69]. □

Prop. (11.2.3.20) [Geodesic Locally Minimizing]. In a normal nbhd of p, the geodesic starting at p is the minimal line.

Proof: And curve $c(t)$ can be written as $\exp_p(r(t)v(t)) = f(r(t), t)$, where $f(s,t) = \exp_p(sv(t))$, so by Gauss lemma, $\langle \frac{\partial f}{\partial r}, \frac{\partial f}{\partial t} \rangle = 0$. Now $dc/dt = \partial f/\partial r r'(t) + \partial f/\partial t$, so

$$|dc/dt|^2 = |r'(t)|^2 + |\partial f/\partial t|^2 \geq |r'(t)|^2.$$

Integrate this will give us the desired result. □

Prop. (11.2.3.21) [Totally normal nbhd]. For any point p, there exists a nbhd W and a number $\delta > 0$ s.t. for every $q \in W$, $\exp_q$ is a diffeomorphism on $B_\delta(0)$ and $\exp_q(B_\delta(0)) \supset W$. Thus, fine cover exists in every smooth manifold, because Riemannian metric exists on these manifolds.

Proof: Cf.[Do Carmo P72]. □

- (**Geodesic Frame**) In a neighborhood of every point p, there exists n vector fields, orthonormal at each point, and $\nabla_{E_i} E_j(p) = 0$.(Choose normal nbhd and parallel a orthonormal basis to every point. (WARNING: this is not a flat coordinate, it only helps when dealing with point-wise properties).

Def. (11.2.3.22) [Killing Fields]. A **Killing field** is a vector field which generates an infinitesimal isometry. X is killing $\iff L_X(g) = 0 \iff \langle \nabla_Y X, Z \rangle + \langle \nabla_Z X, Y \rangle = 0$ for all Y, Z, which is called the **Killing equation**.

Proof: Use Lie formula,

$$L_X(g)(Y, Z) = X\langle Y, Z \rangle - \langle [X, Y], Z \rangle - \langle Y, [X, Z] \rangle$$

. and Levi-Civita connection is torsion-free. □

Prop. (11.2.3.23). Let M be a compact Riemannian manifold of even dimension with positive sectional curvatures, then every Killing field on M has a singularity.

Proof: Cf.[Do Carmo P104]. □

Def. (11.2.3.24) [Geometric Differential Notions].

- The **gradient** is defined to be $\langle \mathrm{grad} f(p), X \rangle = X(f)(p)$.
- The **divergence** is defined to be $\mathrm{div} X(p)$ =trace of the linear map $Y(p) \to \nabla_Y X(p) = \sum_i \langle \nabla_{E_i} X, E_i \rangle$. It measures the variation of the volume and it depends only on the point.
- The **Hessian** is defined to be $\mathrm{Hess} f$ is a self-adjoint operator that $(\mathrm{Hess} f)Y = \nabla_Y \mathrm{grad} f$ as well as a symmetric form $(\mathrm{Hess} f)(X, Y) = \langle (\mathrm{Hess} f)X, Y \rangle$.
- The **Laplacian** is defined to be $\Delta f = \mathrm{div}\ \mathrm{grad} f = \mathrm{trace}\ \mathrm{Hess} f$.

Prop. (11.2.3.25). In a geodesic frame,

$$\mathrm{grad} f(p) = \sum_{i=1}^{n} (E_i(f)) E_i$$

$$\mathrm{div} X(p) = \sum_{i=1}^{n} E_i(f_i)(p), \mathrm{where} X = \sum_i f_i E_i.$$

$$\Delta f = \sum_i E_i(E_i(f))(p).$$

Cor. (11.2.3.26).

$$\Delta(f \cdot g) = f\Delta g + g\Delta f + 2\langle \mathrm{grad} f, \mathrm{grad} g\rangle,$$

because these only depends on the point.

Prop. (11.2.3.27). $d(i(X)m) = (\mathrm{div} X)m$. where m is the volume form.

Proof: Choose a geodesic frame E_i, θ_i is a dual form of E_i, let $X = \sum f_i E_i$, then $\iota(X)m = \sum_i (-1)^{i+1} f_i\theta_i$, so

$$d(\iota(X)m) = \sum(-1)^{i+1} df_i \wedge \theta_i + \sum(-1)^{i+1} f_i \wedge d\theta = (\sum E_i(f_i))m + \sum(-1)^{i+1} f_i \wedge d\theta.$$

Notice that $d\theta_i = 0$, because $d\theta_k(E_i, E_j) = E_i\theta_k(E_j) - E_j\theta_k(E_i) - \theta_k([E_i, E_j]) = 0$(11.1.3.6), as it is a geodesic frame. And $\sum E_i(f_i) = \mathrm{div}(X)$(11.2.3.25). □

Prop. (11.2.3.28) [Hopf theorem]. If f is a differentiable function on a compact orientable manifold with $\Delta f \geq 0$, then f is constant.

Proof: Let $\mathrm{grad}(f) = X$, then

$$\int_M \Delta f dm = \int_M \mathrm{div}(X) dm = \int_M d(\iota(X)dm) = 0.$$

So $\Delta f = 0$. Now

$$0 = \int_M \Delta(f^2/2)dm = \int_M f\Delta f dm + \int_M |\mathrm{grad}(f)|^2 dm$$

by(11.2.3.26), thus $\mathrm{grad}(f) = 0$, so f is constant. □

Def. (11.2.3.29) [Riemannian Curvatures].

- The **sectional curvature** $K(X,Y) = \frac{\langle R(X,Y)X,Y\rangle}{|X\wedge Y|^2}$.
- The **Ricci curvature** $\mathrm{Ric}(x) = \mathrm{Ric}(x,x)$, where $\mathrm{Ric}(x,y)$ is the symmetric form of $\frac{1}{n}$ of trace of the map $z \to R(x,z)y$.
  Thus $\mathrm{Ric}_p(x) = \frac{1}{n-1}\sum\langle R(x,z_i)x, z_i\rangle$, for x a unit vector, where z_i is an orthonormal basis orthogonal to x.
- The **scalar curvature** $K(p) = 1/n\sum \mathrm{Ric}_p(z_i)$, where z_i is an orthonormal basis.

The curvatures only depends on the point(11.2.3.11).

Lemma (11.2.3.30).

$$\frac{D}{\partial t}\frac{D}{\partial s}V - \frac{D}{\partial s}\frac{D}{\partial t}V = R(\frac{\partial f}{\partial s}, \frac{\partial f}{\partial t})V. \quad \text{(obvious because } \frac{\partial}{\partial_s}, \frac{\partial}{\partial_t} \text{ commutes)}$$

Proof:

□

Prop. (11.2.3.31) [Sectional Curvature Define Curvature]. The curvature tensor is determined by its sectional curvature.

In particular, if M is isotropic at a point p (The sectional curvature depends only on the point), then

$$R(X,Y,W,Z) = K_0(\langle X,W\rangle\langle Y,Z\rangle - \langle X,Z\rangle\langle Y,W\rangle).$$

Proof: Cf.[Do Carmo P95], should use the cyclicity of the first three terms. □

Prop. (11.2.3.32) [Bianchi Identities]. Recall the covariant differential $\nabla R(Y_i, Z) = Z(R(Y_i)) - \sum_i R(\nabla_Z Y_i, Y_j)$(11.2.3.5).

- (Bianchi Identity)$\sum_{(X,Y,Z)} R(X,Y)Z = 0$.
- (Second Bianchi Identity)$\sum_{(Z,W,T)} \nabla R(X,Y,Z,W,T) = 0$.

Proof: 1: Cf.[Do Carmo P91], should reduce to Jacobi identity.
2: □

Prop. (11.2.3.33)[Schur's Theorem]. Let M be a manifold of dimension $n \geq 3$, suppose the sectional curvature only depends on p, then M has constant curvature.

Proof: Use the second Bianchi Identity and geodesic frame and(11.2.3.31).Cf.[Do Carmo P106]. □

Def. (11.2.3.34)[Eisenstein Curvature]. A manifold M is called a **Eisenstein manifold** iff its Ricci curvature $\lambda(p)$ only depends on the point. Then

- If M is connected and Eisenstein of dimension≥ 3, then it has constant Ricci curvatures everywhere every direction.
- If M is connected and Eisenstein of dimension3, then it has constant sectional curvatures.

Proof: 1: Cf.[Do Carmo P108].
2: Now it has constant Ricci curvature, then

$$R_{1212} + R_{1313} = \lambda = R_{1212} + R_{2323} = R_{1313} + R_{2323}.$$

So we can solve these curvatures out. □

Prop. (11.2.3.35) [Riemannian Curvature Identities].

-
- $R(X,Y,Z,W) = R(Z,W,X,Y), \quad R(X,Y,Z,W) = R(X,Y,W,Z)$.

Proof: Cf.[DO Carmo P91]. □

- $B(X,Y) = \overline{\nabla}_{\overline{X}}\overline{Y} - \nabla_X Y$. It is bilinear and symmetric.
- $H_\eta(x,y) = \langle B(x,y), \eta\rangle$. Thus $B(x,y) = \sum H_i(x,y)E_i$ for an orthonormal frame E_i in $\mathfrak{X}(U)^\perp$.
- $S_\eta(x) = -(\overline{\nabla}_x \eta)^T$. It satisfies:$\langle S_\eta(x), y\rangle = H_\eta(x,y) = \langle B(x,y), \eta\rangle$. It is self-adjoint. When codimension 1, it is the derivative of the Gauss mapping.
- (**Gauss Formula**): let x, y be orthonormal tangent vector. Then:

$$K(x,y) - \overline{K}(x,y) = \langle B(x,x), B(y,y)\rangle - |B(x,y)|^2.$$

- An immersion is called **geodesic** at p if the second fundamental form S_η is zero for all η, (which means $\nabla_X Y$ has no normal component). It is called **minimal** if the trace of S_η is zero.
- An immersion is called umbilic if there exists a normal unit field η s.t. $\langle B(X,Y), \eta\rangle(p) = \lambda(p)\langle X, Y\rangle$.
- If the ambient space has constant sectional curvature and the immersed manifold is totally umbilic, then λ is constant.

- mean curvature tensor of immersion $f = 1/n\sum_i(\mathrm{tr}\ S_i)E_i = 1/n\ \mathrm{tr}\ B$. It is zero if f is minimal.
- normal connection $\nabla^\perp_X\eta = (\overline{\nabla}_X\eta)^N = \overline{\nabla}_X\eta + S_\eta(X)$.

Prop. (11.2.3.36).
- (Gauss equation)
$$\langle\overline{R}(X,Y)Z,T\rangle = \langle R(X,Y)Z,T\rangle - \langle B(Y,T),B(X,Z)\rangle + \langle B(X,T),B(Y,Z)\rangle.$$
- (Ricci equation)
$$\langle\overline{R}(X,Y)\eta,\zeta\rangle - \langle R^\perp(X,Y)\eta,\zeta\rangle = \langle[S_\eta,S_\zeta]X,Y\rangle.$$
- (Codazzo equation)
$$\langle\overline{R}(X,Y)Z,\eta\rangle = (\overline{\nabla}_Y B)(X,Z,\eta) - (\overline{\nabla}_X B)(Y,Z,\eta). \qquad \text{(Lie bracket)}$$

Parallel Transportation

Def. (11.2.3.37) [Parallel Transportation].

Def. (11.2.3.38) [Holonomy Group]. The **holonomy group** $Hol_x(g)$ of a Riemannian manifold M w.r.t to the Levi-Civita connection is defined to be the subgroup of $O(T_x(M))$ induced by the parallel transportation along a loop. If M is connected, For different points, holonomy groups are conjugate, so holonomy group is defined up to conjugation.

Prop. (11.2.3.39) [Trivial Holonomy Group]. If M is a Riemannian manifold and the holonomy group is trivial, then for any $X,Y,Z\in X(M)$, $R(X,Y)Z=0$.

Proof: Cf.[Do Carmo P105]. □

Prop. (11.2.3.40) [Berger]. in fact, the groups that can be realized as a holonomy group of a simply connected complete Riemannian manifold can be classified.

Proof: Cf.[Complex geometry Daniel P214]. □

Def. (11.2.3.41). The **Geodesic flow** for a connection on TM is the flow on TM whose trajectories are $t\mapsto(\gamma(t),\gamma^{'}(t))$, where γ is a geodesic on M.

Prop. (11.2.3.42) [The smoothness of geodesics]. For every point p, there exists a nbhd V and a C^∞ mapping
$$\gamma:(-\delta,\delta)\times V\times B(0,\epsilon)\to M,$$
s.t. $\gamma(t,q,v)$ is the geodesic passing through p with velocity v.

Prop. (11.2.3.43) [Curvature and Metric, Cartan]. Let $M,\widetilde{M}$ be two Riemannian manifold of dimension n and let $p\in M,\widetilde{p}\in\widetilde{M}$. Choose a linear isometry $i:T_p(M)\cong T_{\widetilde{p}}(\widetilde{M})$. Let V be a normal neighbourhood of p that $\exp_{\widetilde{p}}$ is defined on $i\circ\exp_p^{-1}(V)$. Define a mapping $f:V\to\widetilde{M}$ by $f(q)=\exp_{\widetilde{p}}\circ i\circ\exp_p^{-1}(q)$.

For any $q\in V$, there is a unique normalized geodesic $\gamma:[0,t]\to M$ that $\gamma(0)=p,\gamma(t)=q$. Denote by P_t the parallel transportation along γ, and the map $\varphi_t:T_q(M)\to T_{f(q)}(\widetilde{M})$ by $\varphi_t(v)=\widetilde{P}_t\circ i\circ P_t^{-1}(v)$.

If for all $q\in V$ and all $x,y,u,v\in T_q(M)$, we have
$$\langle R(x,y)u,v\rangle = \langle\widetilde{R}(\varphi_t(x),\varphi_t(y)\varphi_t(u),\varphi_t(v)\rangle,$$
then $f:V\to f(V)\subset\widetilde{M}$ is an isometry and $df_p=i$.

Proof: Cf.[Do Carmo P157]. Use Jacobi fields. The point is that the hypothesis implies that the map of a Jacobi field is also a Jacobi field. □

Cor. (11.2.3.44). Let $M, \widetilde{M}$ be Riemannian manifolds with the same dimension n in which parallel transportation preserves sectional curvature. Let $p \in M, \widetilde{p} \in \widetilde{M}$. If there is a linear isometry $i : T_p(M) \cong T_{\widetilde{p}}(\widetilde{M})$ s.t. $K(p, E) = K(\widetilde{p}, i(E))$ for any 2-dimensional subspace $E \subset T_p(M)$, then there exist nbhd V of p, nbhd $\widetilde{V}$ of $\widetilde{p}$ and an isometry $f : V \to \widetilde{V}$ that $df_p = i$.

Cor. (11.2.3.45). If in situation(11.2.3.44), M and $\widetilde{M}$ are moreover complete and simply connected, then there is a unique isometry $f : M \to \widetilde{M}$ s.t. $f(p) = \widetilde{p}$ and $df_p = i$.

Complete manifold

Prop. (11.2.3.46) [Hopf-Rinow theorem]. The following is equivalent definition of **completeness**.

1. $\exp_p$ is defined for all of $T_p(M)$ and all $p \in M$.
2. The closed and bounded sets of M are compact.
3. M is complete as a metric space.
4. M is $\sigma-$compact and if $q_n \notin K_n$, $d(p, q_n) \to \infty$.
5. The length of any divergent (compact escaping) curve is unbounded.

and if M is complete, then for any $p, q \in M$, there exists a minimizing geodesic between p, q. In particular, any compact submanifold of a complete manifold is complete.

Proof: Cf.[Do Carmo P147]. □

- For any two manifold of the same constant curvature and any two orthogonal basis, there is a local isometry (It is locally isotropic).
- Any complete manifold with a sectional curvature is like $\tilde{M}/\Gamma$, where $\tilde{M}$ is $\mathbf{H}^n, \mathbf{R}^n$ or $\mathbf{S}^n$.

Prop. (11.2.3.47) [Cartan]. in any nontrivial homotopy class in a compact manifold , there exists a closed geodesic.

Proof: □

4 Jacobi Field and Comparison Theorems

Def. (11.2.4.1) [Jacobi Field]. The **Jacobi field equation** along a normalized geodesic γ is defined to be

$$D^2 J(t) + R(\dot{\gamma(t)}, J(t))\dot{\gamma}(t) = 0.$$

It is defined by its initial condition $J(0)$ and $J^{'}(0)$. It can be used to detect the sectional curvature, the critical point of $\exp_p$ and calculate variation of energy.

Prop. (11.2.4.2) [Constant Curvature Case]. On a manifold with constant curvature K, the Jacobi field equation for a vector field J normal to γ is equivalent to

$$D^2 J(t) + KJ(t) = 0.$$

Proof: Use(11.2.3.31), we have

$$\langle R(\gamma', J)\gamma', T\rangle = K\{\langle\gamma', \gamma'\rangle\langle J, T\rangle - \langle\gamma', T\rangle\langle J, \gamma'\rangle\} = K\langle J, T\rangle$$

So $R(\gamma', J)\gamma' = KJ$. □

Prop. (11.2.4.3). The Jacobi field along a point with initial velocity 0 all has the form

$$J(t) = (d\exp_p)_{t\dot{\gamma}(0)}(tJ^{'}(0)).$$

Proof: Cf.[Do Carmo P113]. Should use uniqueness theorem of ODE. □

Cor. (11.2.4.4)[Conjugate Points]. If two points p, q are connected by a geodesic γ, and $q = \exp_p(v_0)$, then p, q are called **conjugate** along γ, if there is a non-trivial Jacobi field on γ that $J(p) = J(q) = 0$.

Then q is conjugate to p iff v_0 is the critical point of $\exp_p$, and the multiplicity of conjugacy is equal to the kernel of $(\exp_p)_{v_0}$.

Prop. (11.2.4.5). For a Jacobi field J along γ, $\langle J(t), \gamma'(t)\rangle$ is linear in t.

Proof: Take second derivatives. □

- If J is a Jacobi field $J(t) = (d\exp_p)_{tv}(tw), |v| = |w| = 1$, then

$$|J(t)| = t - \frac{1}{6}K_p(v, w)t^3 + o(t^3).$$

Prop. (11.2.4.6). There are no conjugate points on a Riemannian manifold of non-positive curvature.

Proof: Cf.[Do Carmo P119]. □

Prop. (11.2.4.7) [Killing Field is everywhere Jacobi]. A Killing field is a Jacobi field along geodesics.

And if $X(p) = 0$, then X is tangent to the geodesic sphere near p, because X preserves length.

Proof: □

Energy Analysis

Def. (11.2.4.8) [Energy]. The **energy** of a geodesic γ is defined to be

$$E(s) = \int_0^a |\frac{\partial f}{\partial t}(s, t)|^2 dt.$$

Prop. (11.2.4.9). A minimizing geodesic must minimize energy.

- (**First Variation of Energy**)

$$1/2E^{'}(0) = -\int_0^a \langle V(t), D\dot{c}(t)\rangle dt + \langle V(a), \dot{c}(a)\rangle - \langle V(0), \dot{c}(0)\rangle.$$

  A piecewise differentiable curve is a geodesic iff every proper variation has first derivative 0.

- (**Second Variation of Energy**) If γ is a geodesic,

$$1/2E^{''}(0) = \int_0^a \{\langle DV(t), DV(t)\rangle - \langle R(\dot{\gamma}, V)\dot{\gamma}, V\rangle\}dt + \langle D_sV(a), \dot{\gamma}(a)\rangle - \langle D_sV(0), \dot{\gamma}(0)\rangle.$$

- a variation is equivalent to a vector field along the curve, and a variation that $f_s(t)$ are all piecewise geodesics corresponds to a piecewise Jacobi field(Choose a normal partition).

Prop. (11.2.4.10) [Rauch Comparison theorem]. Let M and $\tilde{M}$ be manifolds, dim$\tilde{M} \geq$ dim M. If J and $\tilde{J}$ be two normal Jacobi fields along geodesics γ and $\tilde{\gamma}$ that $|J(0)| = |J'(0)| = 0$ and $|J'(0)| = |\tilde{J}'(0)|$. If $\tilde{\gamma}$ has no conjugate point or focal point free and $\tilde{K}(\tilde{x}, \dot{\tilde{\gamma}}(t)) \geq K(x, \dot{\gamma})$ for any vector $x, \tilde{x}$, then $|\tilde{J}| \leq |J|$.

Cor. (11.2.4.11) [Injectivity Radius Estimate]. If the sectional curvature of M satisfies: $0 < L \leq K \leq H$, then the distance between any two conjugate points satisfies: $\frac{\pi}{\sqrt{H}} \leq d \leq \frac{\pi}{\sqrt{L}}$.

Prop. (11.2.4.12). If two manifold M and M' satisfy $K \leq K'$, then in a normal nbhd of a point p in M and a nbhd of p' that exp is nonsingular, the transformation of a curve c shortens length.

Note that this is not Toponogov thoerem, because if you try to map from a large curvature manifold to a small curvature, then you cannot guarantee that the mapped curve is the shortest.

Cor. (11.2.4.13). In a complete simply connected manifold of non-positive curvature,

$$A^2 + B^2 - 2AB\cos\gamma \leq C^2$$

thus $\alpha + \beta + \gamma \leq \pi$.

Prop. (11.2.4.14) [Moore theorem]. Let $\overline{M}$ be a complete simply connected manifold of sectinoal curvature $\overline{K} \leq -b \leq 0$, M a compact manifold of sectional curvature satisfying $K - \overline{K} \leq b$. If dim$\overline{M}$ < dim$M$, M cannot be immersed into $\overline{M}$.(use Hadamard theorem to choose the furthest geodesic and calculate the second variation of energy and use Gauss formula).

Cor. (11.2.4.15). Let $\overline{M}$ be a complete simply connected manifold of sectinoal curvature $\overline{K} \leq 0$, M a compact manifold of sectional curvature satisfying $K \leq \overline{K}$. If dim$\overline{M}$ < dim$M$, M cannot immerse into $\overline{M}$.

Lemma (11.2.4.16) [Klingenberg Lemma]. Let M be a complete manifold of sectional curvature $K \geq K_0$, let γ_0, γ_1 be two homotopic geodesics from p to q, then there exists a middle curve γ_s s.t.

$$l(\gamma_0) + l(\gamma_s) \geq \frac{2\pi}{\sqrt{K_0}}.$$

Proof: Assume $l(\gamma_0) < \frac{2\pi}{\sqrt{K_0}}$, otherwise we are done. Then by Rauch comparison(11.2.4.10), the $\exp_p : T_pM \to M$ has no critical point in the open ball B of radius $\pi/\sqrt{K_0}$. Now we want to lift γ_s to T_pM. It is clear that we cannot lift γ_1, because otherwise it is not a curve. Hence for every $\varepsilon > 0$, there is a curve $\alpha_{t(\varepsilon)}$ that can be lifted and has a point with distance smaller than ε to the boundary ∂B, otherwise the s that can be lifted will be open and closed in $[0, 1]$, thus containing 1.

So now if we choose a sequence of lifts curves γ_s converging to the boundary, then s has a convergent point, then we have $l(\gamma_0) + l(\gamma_{t_0}) \geq \frac{\pi}{\sqrt{K_0}}$. □

Prop. (11.2.4.17)[Klingenberg]. Let M be a simply connected compact manifold of dimension $n \geq 3$ such that $\frac{1}{4} < K \leq 1$, then $i(M)$(The infimum of distance to the cut locus)$\geq \pi$.

Cor. (11.2.4.18). If M is a compact orientable manifold of even dimension satisfying $0 < K \leq 1$, then $i(M) \geq \pi$.

Prop. (11.2.4.19) [1/4-pinch Sphere Theorem]. Let M be a compact simply connected manifold satisfying $0 < 1/4K_{\max} < K \leq K_{\max}$, then M is homeomorphic to a sphere.

(Use Klingenberg Theorem, this is a special case of diameter geodesic sphere theorem). Cf.(11.2.4.29).

It can be shown that in this case, this sphere is even diffeomorphic to S^n using Ricci flow.

Remark (11.2.4.20). $0 < 1/4K_{\max} < K$ cannot be changed to $\geq$. In fact, the Funibi-Study metric on CP^n has sectional curvature $1 \geq K \geq 4$. Cf. **??**

Hess$\rho(X, Y)$ where ρ is the distance to a fixed point, is important.

Prop. (11.2.4.21). Hess$\rho(X, Y)$ is positive definite on the tangent space of the geodesic sphere within the injective radius, and its principal value is $|\frac{J'}{J}|$ for a Jacobi field in that direction. And it is zero on the normal direction.

So there would be a Riccati comparison theorem on the eigenvalue of $\Pi_2 : \lambda' \leq -K - \lambda^2$,Hess($\rho$) is bounded.

Proof: Notice that

$$\mathrm{Hess}\rho(X, Y) = (\nabla_X \mathrm{grad}\rho, Y) = XY\rho - (\nabla_X Y)\rho$$

so if choose a normal geodesic γ of initial vector X, then

$$\mathrm{Hess}\rho(X, X) = X\langle\dot\gamma, d\rho\rangle - (\nabla_X\dot\gamma)\rho = X\langle\dot\gamma, d\rho\rangle = \langle\dot\gamma, d\langle\dot\gamma, d\rho\rangle\rangle = E''(0)$$

$$= I_q(X, X) = ((\nabla_{\dot\gamma} X)(q), X(q)) = \frac{\langle J', J\rangle}{|J|^2}$$

□

Prop. (11.2.4.22) [Toponogov]. Let$M$ be a complete manifold with $K \geq H$.

If a hinge satisfies γ_1 is minimal and $\gamma_2 \geq \frac{\pi}{\sqrt{H}}$ if $H > 0$., then on M^H the same hinge has smaller distance of endpoints than this hinge

Proof: Cf.[Cheeger Comparison Theorems in Riemannian Geometry P42]. And there is another triangle version: For a minimal geodesic triangle, the comparison triangle has smaller angles. NOTE this theorem cannot be derived from Rauch Comparison Theorem. □

Critical Point for Distance Function

Prop. (11.2.4.23). The critical point for distance function on a complete manifold is that for every direction v, there is a minimal geodesic γ s.t. $\langle\gamma'(l), v\rangle \leq \frac{\pi}{2}$.

The set of regular point is open and there exists a smooth gradient like vector field (i.e. acute angle with every minimal geodesic) on this open subset .

Prop. (11.2.4.24) [Berger's Lemma]. A maximal point for the distance function is a critical point.

Proof: If not, choose a convergent point v of the minimal geodesics with endpoint in a curve of that direction, then exp near v will generate a Jacobi field with endpoint Jacobi is the sam of that direction. So the distance will increase by $\cos\theta$ along that direction, contradiction. □

Prop. (11.2.4.25) [Soul Lemma]. Let M is a Riemannian manifold and A is a closed submanifold. If $dist(A, -)$ has no critical point on $D(A, R)\backslash A$, then $B(A, R)$ is diffeomorphic to the normal bundle of $A \to M$.

Proof: A has a normal exp radius ϵ, and we can vary the gradient-like vector field to be identical to the normal vector near A, and use Morse lemma (the flow) to get a diffeomorphism. □

Cor. (11.2.4.26) [Disk Theorem]. If A is a point then M is diffeomorphic to a disk.

Lemma (11.2.4.27) [Generalized Schoenflies Theorem]. Easy to do, just use the fact that exp is continuous to find a boundary sphere depending continuously on the direction (both p and q).

Prop. (11.2.4.28) [Sphere Theorem]. If M is a closed manifold and has a distance function with only one critical point (the furthest one), then M is homeomorphic to a twisted ball.

Proof: There exists a ϵ and r that $B(q,\epsilon)$ and $B(p,r)$ covering M, (Use the convergent point argument). Then use the generalized Schoenflies theorem. □

Prop. (11.2.4.29) [Diameter Sphere Theorem]. If a closed manifold M satisfies sec $M \geq K > 0$, and $\mathrm{diam}(M) > \frac{\pi}{2\sqrt{K}}$, then M is homeomorphic to S^n.

Proof: First, if there are two maximal distance point, then use Toponogov to show contradiction. Second, at other points x,

$$\angle pxq > \frac{\pi}{2}$$

(Regular domain) because of Toponogov and The formula

$$\cos\tilde{\alpha} = \frac{\cos l - \cos l_1 \cos l_2}{\sin l_1 \sin l_2}.$$

So the geodesic direction $\overrightarrow{xq}$ will serve as a geodesic-like vector field (might need paracompactness). □

Prop. (11.2.4.30) [Critical Principle]. In a complete manifold M of sectional curvature $> K$, if q is a critical point of p, then for any point x with $d(p,x) > d(p,q)$ and any minimal geodesic from p to x, the $\angle xpq$ is smaller than the $\cosh_K^{-1}(\frac{d(p,x)}{d(p,q)})$.

Proof: Use Toponogov for the hinge xpq. Then notice that there is a different minimal geodesic from $p \to q$ that makes the $\angle pqx < \pi/2$ by the definition of critical point, thus there is another Toponogov inequality, this two inequality contradicts. □

Cor. (11.2.4.31). For a complete open manifold whose K are lower bounded, then it is homeomorphic to the interior of a manifold with boundary. (Use Soul lemma, otherwise there will be a sequence of critical point whose angles are big).

Prop. (11.2.4.32). ray construction and Line construction?

Prop. (11.2.4.33) [Soul Theorem]. If M is an open manifold with $K \geq 0$, then there is a totally geodesic submanifold S that M is diffeomorphic to the normal bundle over S.

Proof: Use the ray construction to get a totally convex compact subset, hence it is a manifold or with boundary , if it has boundary, then find to set of maximal distance to the distance to boundary, the distance to the boundary is a convex function, so it is a smaller totally geodesic manifold. So a S without boundary must exist and this constitutes a stratification, all the level set is strongly convex. Thus all point outside S is not critical, hence the soul lemma applies. Cf.[GeJian Comparison theorems in Riemannian Geometry Lecture7]. □

Prop. (11.2.4.34) [Perelman]. There is a distance non-increasing contraction unto the soul, and it must be just the projection along the normal bundle. Moreover, for any geodesic on the soul and a parallel vector field in the normal bundle along it, it spans a flat surface (by Rauch comparison).

Cor. (11.2.4.35) [Soul Conjecture]. For an open(non-compact) complete manifold M with $K \geq 0$, if it has a point p s.t. sectional curvature at p are all positive, then M is diffeomorphic to R^n. (It's enough to show that its soul is a point, otherwise for any point, it must has a direction that is flat, $K = 0$).

5 Curvature Inequalities and Topology

Sectional Curvature

Prop. (11.2.5.1) [Hadamard theorem]. M a complete simply connected Riemann manifold of sectional curvature ≤ 0, then $\exp_p : T_pM \to M$ is an isomorphism of M to $\mathbb{R}^n$.(negative sectional curvature to show exp is a local isomorphism, complete to show it is a covering map)

Prop. (11.2.5.2) [Liouville Theorem]. Any conformal mapping for an open subset of $\mathbb{R}^n, n > 2$ is restriction of a composition of isometry, dilations and/or inversions, at most once.

Prop. (11.2.5.3) [Positive Curved, Closed Geodesic not Minimal]. If M is an even dimensional orientable Riemannian manifold with positive sectional curvature, let $\sigma : [0,1] \to M$ be a closed geodesic curve, then there exists an $\varepsilon > 0$ that parametrized closed curves $F; [0,1] \times (-\varepsilon, \varepsilon) \to M$ near σ with lengths less than that of σ.

Proof: Cf.[Solution to Yau Test Geometry Individual2013 Prob5]. □

Prop. (11.2.5.4) [Synge]. f is an isometry of a compact oriented manifold M^n of positive sectional curvature, f alter orientation by $(-1)^n$, then f has a fixed pt.

Proof: Cf.[Do Carmo P203]. □

Cor. (11.2.5.5). M a compact manifold of positive sectional curvature, then

1. If M is orientable and n is even, then M is simply connected. So If M is compact and even dimension, then $\pi(M) = 1$ or $\mathbb{Z}_2$.
2. If n is odd, then M is orientable.

(Use the universal cover and covering transformation.)

Conj. (11.2.5.6) [Hopf Conjecture]. If M is a compact Riemannian manifold of even dimension that $K > 0$, then it has positive Euler characteristic.

Morse Index

Prop. (11.2.5.7) [Index Lemma]. Among the piecewise differentiable vector fields along a geodesic without conjugate point or without focal point, with initial value 0 and fixed end value, the Jacobi field attain minimum of the index form:

$$I_a(V, V) = \int_0^a \{\langle DV(t), DV(t)\rangle - \langle R(\dot{\gamma}, V)\dot{\gamma}, V\rangle\} dt.$$

Cor. (11.2.5.8). $I_l(J, J) = \langle J, J'\rangle(l)$ for a Jacobi field.

Prop. (11.2.5.9). a focal point is a critical value of $exp^{\perp}$. For an embedded manifold, the focal point equals $x + 1/t\eta$, where η is a vertical vector and t is a principal value of S_eta.

Prop. (11.2.5.10) [Morse Index theorem]. The index of the the index form $I_a(V, W)$ on the space of vector fields 0 at the endpoints, equal to the number of points conjugate to $\gamma(0)$ in $[0, a)$.

Cor. (11.2.5.11). If γ is minimizing, γ has no conjugate points on $(0, a)$, γ has a conjugate point, it is not minimizing.

Prop. (11.2.5.12) [Morse]. If M is complete with non-negative sectional curvature, then $\pi_1(M)$ have no finite non-trivial cyclic group and $\pi_k(M) = 0$.

Proof: because universal cover of M is contractible, so the higher homotopy group vanish and $H^k(M) = H^k(\pi_1(M))$, so if a subgroup is finite cyclic, its homology is periodic, contradiction. □

Prop. (11.2.5.13) [Preissman]. For a compact manifold with $K < 0$, any nontrivial abelian subgroup of π_1 is infinite cyclic.

Prop. (11.2.5.14). If M is compact and $K < 0$, $\pi_1(M)$ is not abelian.

Assuming M complete,

- The cut point of p along γ is the maximum $\gamma(t)$ s.t. $d(p, \gamma(t)) = t$. It is either the first conjugate point of p or the intersection of two minimizing geodesics.
- Conversely, if a point is a conjugate point of p or is intersection of two geodesics of equal length, then there is a cut point before it. So, if intersection of two minimizing geodesics happens, it must happen before the occurrence of conjugate point.
- thus the cut point relation is reflexive, and if $q \in M \setminus C_m(p)$, then there exists a unique minimizing geodesic joining p and q.
- $M \setminus C_m(p)$ is homeomorphic to an open ball through exp.
- the distance of p to the cut locus is continuous, thus $C_m(p)$ is closed.
- If M is complete and there is a p which has a cut point for every geodesic, then M is compact.
- for q the closest of $C_m(p)$ to p, either there exists a minimizing geodesic and q is conjugate to p or there is to minimizing geodesic connecting at q.

Prop. (11.2.5.15). The index of a geodesic will decrease when transferred to a manifold of smaller sectional curvature K.

Prop. (11.2.5.16). In a complete manifold, if there is a sequence of points $\{p_i\}$ converging to a point p, choose for each point a minimal geodesic, then a subsequence of them will converge to a minimal geodesic to p.

Proof: The convergence is by smoothness and of exp and Hadamard. The minimality is by comparing distance. □

Ricci Curvature

Prop. (11.2.5.17) [Ricci Comparison]. Volume comparison, Laplacian Comparison, Mean Curvature comparison. Cf.[葛健 Week13].

Prop. (11.2.5.18) [Bishop-Gromov]. Let M be an open manifold with $\mathrm{Ric} \geq H$, let $\tilde{M}(H)$ be a complete simply connected manifold of constant sectional curvature H, then

$$\mathrm{Vol}(B_r(x)) \leq \mathrm{Vol}(B_r(\tilde{p})), \quad \frac{\mathrm{Vol}(B_R(x))}{\mathrm{Vol}(B_r(x))} \leq \frac{\mathrm{Vol}(B_R(\tilde{p}))}{\mathrm{Vol}(B_r(\tilde{p}))}.$$

Cf.[葛健 Week13].

Prop. (11.2.5.19) [Bonnet-Myer]. M a complete manifold of Ricci curvature $\mathrm{Ric}_p(v) \geq \frac{1}{r^2}$, Then M is compact and have diameter $\leq \pi r$.

And if the identity is achieved, $M \cong \mathbb{S}^n$.

Proof: Use Laplacian comparison $\Delta r \leq (n-1)\cot r$. Cf.[葛健 week13]. □

Cor. (11.2.5.20) [Positive Ricci Finite Fundamental Groups]. M is a complete manifold of Ricci curvature $\geq \delta > 0$, then the universal cover is compact thus $\pi_1(M)$ is finite. This can be seen as an obstruction for a compact manifold to have positive Ricci curvature.

Cor. (11.2.5.21) [Calabi-Yau]. For an open manifold with non-negative Ricci curvature, for any point, $\mathrm{Vol}(B(p,r)) \geq c_p r$.

Prop. (11.2.5.22) [Milnor]. Let M be an open manifold of non-negative Ricci curvature of dimension n, then any f.g. subgroup of $\pi_1(M)$ has polynomial growth $\leq n$. Milnor conjectured that $\pi_1(M)$ in fact is f.g..

Prop. (11.2.5.23) [First Betti Number Theorem]. There is a number $f(n,\lambda,D)$, $f(n,0,D) = n, f(n,\lambda,D) = 0$ for $\lambda > 0$ that for a manifold of diameter $\leq D$ and Ricci curvature $\geq \lambda$, $b_1(M) \leq f(n,\lambda,D)$.

Cor. (11.2.5.24) [Splitting Theorem]. The universal cover of a compact RIemannian manifold with non-negative Ricci curvature splits isometrically as a product $\widetilde{M} = N \times \mathbb{R}^k$ where N is a compact manifold manifold.

Scalar Curvature

11.3 Low Dimensional Topology

1 Morse Theory

Main references are [Supersymmetry and Morse Theory, Witten].

Morse Theory(Milnor)

Def. (11.3.1.1) [Non-Degenerate Critical Point]. For a smooth map $f : X \to \mathbb{R}$, a critical point is called a **non-degenerate critical point** iff the Hessian matrix is non-singular at x.

The notion of non-degenerate critical is independent of the coordinate chosen.

Proof: Cf.[Pollack P42]. ☐

Prop. (11.3.1.2)[Non-Degenerate Critical General]. Non-degenerate critical points are the general situation in the following sense: For a manifold $M \subset \mathbb{R}^n$, for any smooth function f on M, consider the functions $f_a = f + \sum a_i x_i$, then for almost all (a_i), all critical points of f_a is non-degenerate.

Proof: Cf.[Pollack P43] ☐

Prop. (11.3.1.3) [Morse Lemma]. In a non-degenerate critical point of f, there is a coordinate that

$$f = f(p) + x_1^2 + \cdots + x_{n-\lambda}^2 - y_1^2 - \cdots - y_\lambda^2.$$

Proof: Just extract the first order part out and reform the bilinear form one-by-one. Cf.[Milnor Morse Theory lemma 2.2]. ☐

Prop. (11.3.1.4). If f is a smooth function that $f^{-1}([a, b])$ is compact and have no critical points, then M^a is a deformation retracts of M^b using $\mathrm{grad} f/|\mathrm{grad} f|^2$.

Prop. (11.3.1.5) [Morse Main Lemma]. If f is a smooth function with p a non-degenerate critical point and λ downward pointing direction. If for some $f^{-1}([c - \epsilon, c + \epsilon])$ is compact, then $M^{c+\epsilon}$ is homotopic to $M^{c-\epsilon}$ gluing a λ dimensional cell.

Proof: Cf.[Milnor Prop3.2]. ☐

Prop. (11.3.1.6). For an embedded manifold and almost all point p, the distance to p is a morse function. (Use Sard theorem and degenerate $\iff$ p is a focal point.

Cor. (11.3.1.7). smooth manifold has CW type; on a compact manifold any vector field with discrete singular points has its index sum equal to $\chi(M)$ (Hopf-Rinow), and there exists one.

Prop. (11.3.1.8). for $\Omega(p, q)^c$ the path space of energy $< c$, the piecewise geodesic path space B (piece fixed), the energy function is smooth and B^a is compact and is the deformation contraction of $\mathrm{int}\Omega^a$ for $a < c$. E has the same critical point and same index and nullity on B and Ω^c. (Just geodesicrize any path in Ω.

So for two point not conjugate in B^a, Ω^a has a finite CW complex type and a λ-dimensional cell for every geodesic of index λ in B^a.

Prop. (11.3.1.9) [Morse Main Theorem]. If p and q are not conjugate along any geodesic, then $\Omega(p, q)$ has a countable CW complex type and has a λ-cell for every geodesic of index λ.

If M has nonnegative Ricci curvature, then M has only finite cell for every dimension.

Proof: Cf.[Milnor Morse Theory Prop17.3]. □

Cor. (11.3.1.10). The path space homotopy type only depend on the homotopy type of M (use the two homotopy to id to get a composition of homotopy of the two path space), so one can get the information of path space of M by looking at the homotopy type of M.

Prop. (11.3.1.11) [Minimal Geodesics]. If p, q in a complete manifold M has distance $\sqrt{d}$ and the minimal geodesics form a topological manifold, and if all non-minimal geodesic has index $\geq \lambda$, then for $0 \leq i < \lambda$, $\pi_i(\Omega, \Omega^d) = 0$.

Lemma (11.3.1.12). In $SU(2m)$, the minimal geodesic from I to $-I$ is homeomorphic to Grassmannian $G_m(\mathbb{C}^{2m})$ and and non-minimal geodesic has index $\geq 2m + 2$.

Similarly, The space of minimal geodesic from I to $-I$ in $O(2m)$ is homeomorphic to the space of complex structures in $\mathbb{R}^{2m}$, and any non-minimal geodesic has index $\geq 2m - 2$.

Proof: Cf.[Milnor Morse Theory Lemma23.1 Lemma24.4]. □

Lemma (11.3.1.13). Ω_{k+1} is homotopic to the space of minimal geodesics in Ω_k from J to $-J$. (The same way, calculate the index of geodesics from J to $-J$ and use (11.3.1.11)). Cf.[Milnor Morse Theory Prop24.5] for definition of Ω_{k+1}.

2 Floer Homology

Def. (11.3.2.1) [Witten Complex]. Let $M \in \mathcal{D}\mathrm{iff}_{\mathrm{cpct}}$ and $f \in C(M)$ is a Morse function, then at each critical point P of f, the Hessian $H_P(f)$ is a non-degenerate quadratic form with signature n_P^+, n_P^-. We define the **Witten complex** C as follows:

- For $0 \leq q \leq \dim M, C_q$ is the free group generated by the critical points with $n_P^- = q$.
- Choose a metric on M, define the flow generated by $\mathrm{grad}\, f$. Then for critical points P, Q with $n_P^- = q, n_Q^- = q - 1$, the number of trajectories under $\mathrm{grad}\, f$ from P to Q is finite, and this gives the boundary map coefficients $\partial_{P,Q}$.

References are [Supersymmetry and Morse Theory, Witten].

Casson Invariants

Def. (11.3.2.2) [Casson Invariants]. Let Y be a homological 3-sphere, the **Casson invariant** $\lambda(Y)$ of Y is defined to be the half of the number of isomorphism classes of irreducible representation $\pi_1(Y) \to SU(2)$.

Prop. (11.3.2.3). For a homological 3-sphere Y, let

- $\mathcal{A}$ be the space of $SU(2)$-connections for the trivial bundle on Y,
- $\mathcal{G}$ be the group of gauge transformations $Y \to SU(2)$.
- $\mathcal{C} = \mathcal{A}/\mathcal{G}$.

Then $\mathcal{C}$ is an infinite-dimensional manifold, and the connection map $F : A \mapsto F_A$ defines a 1-form F on $\mathcal{C}$.

Proof: □

Prop. (11.3.2.4) [Taubes]. Situation as in(11.3.2.3), the zeros of F, i.e. the set of flat connections, corresponds to irreducible representations $\pi_1(Y) \to SU(2)$. And we can use Fredholm perturbation to calculate the number, i.e. $2\lambda(Y)$.

Proof: ? □

Floer Homology Groups

Remark (11.3.2.5) [Relative Morse Indices]. The difficulty to construct Morse theory for Y lies in the fact that the Hessian of $f : \mathcal{C} \to \mathbb{R}/\mathbb{Z}$ at critical points has both Morse indices n^+, n^- infinite. The way around is to notice for critical points P, Q, the **relative Morse index** $n^-_{P,Q} = n^-_P - n^-_Q$ is finite.

Prop. (11.3.2.6) [Floer Homology Theory]. Using the flow generated by grad f, we can get construct a chain complex with (mod 8)-grading, which is a finite complex with the critical points of f as simplexes. The corresponding homology groups are called the **Floer homology** of Y, denoted by $HF_q(Y)$, where $q \in \mathbb{Z}/(8)$.

Notice reversing the orientation of Y induces an action on $HF_*(Y)$ corresponding to Poincaré duality.

Prop. (11.3.2.7) [Floer Homologies and Casson Invariants]. It is clear now that $2\lambda(M) = \sum_{q=0}^{7} \dim HF(Y)$. Thus the Floer homology groups form a refinement of $\lambda(Z)$.

3 Gauge Theory

4 Donaldson-Floer Theory

Main references are [Geometry of 4-Manifolds, Donaldson, ICM1987].

Prop. (11.3.4.1) [Hodge]. For an algebraic surface $S/\mathbb{C}$, the signature b_2^+ of the intersection form on $H_2(S(\mathbb{C}))$ satisfies

$$b_2^+ = 1 + 2p_g(S).$$

Def. (11.3.4.2) [Donaldson Invariants]. Let Z be an oriented simply-connected differentiable 4-manifold, let b_2^+, b_2^- be the signature of the intersection form on $H_2(Z)$. Assume $b_2^+ > 1$ is odd, the **Donaldson invariants** are a sequence of integral polynomials φ_k on $H_2(Z)$ for k sufficiently large, and $\deg(\varphi_k) = 4k = 3\frac{b_2^+ + 1}{2}$.?

Thm. (11.3.4.3). If $Z = Z_1 \# Z_2$ is a connected sum with $b_2^+(Z_i) \neq 0$, then $\varphi_k(Z) = 0$ for all k.

Proof: □

Thm. (11.3.4.4). If Z is an algebraic surface, then for k sufficiently large, $\varphi_K(Z(\mathbb{C})) \neq 0$. In particular, Z is essentially indecomposable.

Proof: □

Prop. (11.3.4.5) [Λ-Splitting]. Suppose the intersection form on $H_2(Z)$ decomposes as $H_2(Z) = A_1 \oplus A_2$, where $A_i^+ > 0$. If $\varphi_k(Z) \neq 0$ for some k, then by(11.3.4.3), Z cannot be decomposed to a connected sum $Z_1 \# Z_2$ having intersection form A_i. However, there exists such a decomposition $Z = Z_1 \coprod_Y Z_2$ where Y is a homotopy 3-sphere.

Proof: Cf.[Freeman and Taylor, Λ-Splitting 4-Manifolds]. □

Prop. (11.3.4.6). For a Λ-splitting $Z = Z_1 \coprod_Y Z_2$, the Donaldson invariant polynomials are related to the Floer homology groups of Y.?

11.4 Differential Forms in Algebraic Topology(Bott-Tu)

This section is dedicated to the analysis of algebraic geometry, using the tool of differential forms. Basic references are [Differential Forms in Algebraic Geometry Bott-Tu].

1 Basics

Prop. (11.4.1.1)[Cohomological Generator of Sphere]. Let $v : x \mapsto x/|x|$ be the outward-pointing vector field on $\mathbb{R}^n - \{0\}$, then the differential form

$$\iota(v)(dm) = \frac{1}{|x|}\sum x_i(-1)^{i-1}dx_1 \wedge dx_2 \wedge \ldots \widehat{dx_i} \wedge \ldots dx_n$$

restricts to a differential form on S^{n-1} that is a generator of $H^{n-1}(S^{n-1})$.

Proof: First we calculate $d(\iota(v)(dm)) = \mathrm{div}(v)dm = \frac{n-1}{|r|}dm$(11.2.3.27). Consider using Stoke's formula:

$$\int_{\partial B_1}\iota(v)(dm) - \int_{\partial B_\varepsilon}\iota(v)(dm) = \int_{B(0,1)-B(0,\varepsilon)}\frac{n-1}{|r|}dm = 0$$

Leting $\varepsilon \to 0$, $\int_{\partial B_\varepsilon}\iota(v)(dm)$ converges to 0 as $|\iota(v)(dm)|$ is bounded and $V(B_\varepsilon)$ converges to 0. And using the polar coordinate $dm = r^{n-1}drd\omega$, the right hand side is just

$$\int_{S^{n-1}}\int_0^1(n-1)r^{n-2}drd\omega = V(S^{n-1}).$$

□

Prop. (11.4.1.2) [Degree Formula]. If $f : X \to Y$ is an arbitrary map of two compact oriented manifolds of dimension k, then for any k-form ω on Y,

$$\int_X f^*\omega = \deg(f)\int_Y \omega.$$

Proof: deg is defined in(11.1.4.16). Cf.[Pollack P188]**?**. □

Prop. (11.4.1.3) [Hopf Invariant]. Let $n > 1$, given a map $S^{2n-1} \to S^n$, let α be a generator of $H^n)S^n$, then $f^*\alpha = d\omega$ on S^{2n-1} for some ω. Define the **Hopf invariant** of f to be $H(f) = \int_{S^{2n-1}}\omega \wedge d\omega$, then:

- The definition of Hopf invariant is independent of ω chosen.
- For odd n, the Hopf invariant is 0.
- Homotopic maps f, g have the same Hopf invariant.

Proof: 1: If $d\omega = d\omega'$, then

$$\int_{S^{2n-1}}\omega' \wedge d\omega' - \int_{S^{2n-1}}\omega \wedge d\omega = \int_{S^{2n-1}}(\omega' - \omega) \wedge d\omega = \pm\int_{S^{2n-1}}d((\omega - \omega') \wedge \omega) = 0.$$

2: If n is odd, then ω is of even dimensional, thus $\omega \wedge d\omega = \frac{1}{2}d(\omega \wedge \omega)$, so $H(f) = 0$ by Stokes.

3: If $F : S^{2n-1} \times I \to S^n$ is a homotopy of f, g, then $F^*\alpha = d\omega$ for some ω on $S^{2n-1} \times I$. Thus consider

$$H(f) - H(g) = \int_{S^{2n-1}}\omega_1 \wedge d\omega_1 - \int_{S^{2n-1}}\omega_0 \wedge d\omega_0 = \int_{\partial(S^{2n-1}\times I)}\omega \wedge d\omega = \int_{S^{2n-1}\times I}d\omega \wedge d\omega,$$

But $d\omega \wedge d\omega = F^*(\alpha \wedge \alpha)$, and $\alpha \wedge \alpha = 0$. □

11.5 Symplectic Geometry

Cf.[Methods in Classical Mechanics Arnold Chapter8],[辛几何讲义范辉军].

1 Basics

Symplectic Forms

Def. (11.5.1.1). A **symplectic form** ω is a closed 2-form that is non-degenerate on any point. A smooth manifold with a symplectic form is called a **symplectic manifold**. A symplectic manifold must be even dimensional and orientable.

Prop. (11.5.1.2). A hamiltonian phase flow preserves the symplectic form. $g^{t*}\omega = \omega$.

Proof: by Cartan's magic formula,

$$\frac{d}{dt}(g^t)^*\omega = L_X\omega = \iota_X(d\omega) + d(\iota_X\omega) = d(\iota_X\omega)$$

because ω is closed. And by definition, $d(\iota_X\omega)(\eta) = \omega(J\mathrm{d}H, \eta) = \langle dH, \eta\rangle$, so $d(\iota_X\omega) = dH$, Thus the theorem. □

For the following Cf.[辛几何讲义范辉军 lecture3].

Prop. (11.5.1.3) [Moser's Stability]. If ω_t is a smooth family of cohomologous forms on a closed manifold M, then there exists an isotopy Ψ_t s.t.

$$\Psi_t^*(\omega_t) = \omega_0.$$

Prop. (11.5.1.4) [Relative Moser Stability]. If M is a closed manifold and S is a compact submanifold, then if two closed 2-form equals on S, then there is an open neighborhood N_0, N_1 of S and a diffeomorphism $\Psi : N_0 \to N_1$ that

$$\Psi|S = \mathrm{id}, \ \Psi^*\omega_1 = \omega_0.$$

Cor. (11.5.1.5) [Darboux's Theorem]. Every symplectic form ω on M is locally diffeomorphic to the standard form ω_0 on $\mathbb{R}^{2n}$.

Proof: Choose $S = \mathrm{pt}$ and uses relative Moser stability. □

Prop. (11.5.1.6). For a compact symplectic manifold M, its even dimensional cohomology groups doesn't vanish, because ω^k are nontrivial.

Proof: This is because ω^n is a volume form on M that never vanish, so it gives M an orientation and $\int_M \omega^n \neq 0$. If ω^k is exact, then ω^n is exact, so $\int_M \omega^n = 0$ by Stokes', contradiction. □

11.6 Other Geometries

1 Hyperbolic Geometry

Prop. (11.6.1.1). Isometries of hyperbolic ball are all given by Mobius transformations, because the distance to three non-colinear point can localize a point. Cf.[双曲几何 刘毅].

Def. (11.6.1.2) [Hyperbolic Disk]. The **hyperbolic disk** is a Riemannian manifold homeomorphic to $\mathbb{D}$ endowed with the **Poincaré metric** or **hyperbolic metric**

$$\mathrm{d}^P s = \frac{|\mathrm{d}z|}{1-|z|^2} = \sigma_{\mathbb{D}}(z)|\mathrm{d}z|.$$

Prop. (11.6.1.3). The Poincaré metric on $\mathbb{D}$ is preserved by $\mathrm{Aut}(\mathbb{D})$.

Proof: Cf.[李忠, P26]. □

Prop. (11.6.1.4). For any $z_1, z_2 \in \mathbb{D}$,

$$d^P(z_1, z_2) = \log \frac{|1-\overline{z}_1 z_2| + |z_1 - z_2|}{|1-\overline{z}_1 z_2| - |z_1 - z_2|}.$$

Proof: Cf.[李忠, P27]. □

2 Metric Geometry

Def. (11.6.2.1) [Hausdorff dimension]. $\dim^H(X)$.

Def. (11.6.2.2). The **Hausdorff distance** for two subset $Y_1, Y_2 \in X$ is the

$$d^H_X(Y_1, Y_2) = \inf\{\varepsilon | Y_2 \subset B(Y_1, \varepsilon), Y_1 \subset B(Y_2, \varepsilon)\}.$$

The **Gromov-Hausdorff metric** for two metric space is

$$d^{GH}(X_1, X_2) = \inf\{d^H_Z(i_1(X_1), i_2(X_2))\}$$

where i_1, i_2 are isometry of X_1, X_2 into a metric space Z.

This metric makes the set of all compact metric space into a complete Hausdorff space $\mathcal{MET}$.

Def. (11.6.2.3). A map from X to Y is called a **ε-approximation** iff $B(f(X), \varepsilon) = Y$ and $|d(x,y) - d(f(x), f(y))| \le \varepsilon$.

We have: if there is a ε approximation, then $d^{GH}(X,Y) \le 3\varepsilon$, and if $d^{GH}(X,Y) \le \varepsilon$, there is a 3ε approximation.

Prop. (11.6.2.4). Fix a function $N : (0,1) \to \mathbb{N}$, the space $\mathcal{MET}(D,N)$ of complete metric space of diameter bounded by D and for every ε, there is a ε-net with no more then $N(\varepsilon)$ points. Then it is a compact subspace of $\mathcal{MET}$.

Proof: We show it is totally bounded and closed. It is totally bounded because the space of discrete space of no more than $N(\varepsilon)$ is compact and it ε approximate $\mathcal{MET}(D,N)$ by definition. Thus we have it is totally bounded. And □

Prop. (11.6.2.5)[Gromov Compactness Theorem]. Denote the space $\mathcal{RIC}^D_{*,-1}(n)$ of manifold with Ricci curvature bounded below by -1 and diameter bounded above by D, then it is a precompact subset of $\mathcal{MET}$.

Proof: By Bishop-Gromov(11.2.5.18), there is a $N(\varepsilon)$ that M can only have $N(\varepsilon)$ many balls of radius ε, because M has bounded diameter (Packing argument). So $\mathcal{RIC}^D_{*,-1}(n) \subset \mathcal{MET}(D, 2N)$ is precompact. □

Prop. (11.6.2.6). Any metric space X in the closure of $\mathcal{RIC}^D_{*,-1}(n)$ has Hausdorff dimension $\dim^H(X) \le n$.

Prop. (11.6.2.7)[Gromov]. If a sequence of manifold $\{M_i\}$ in $\mathcal{M}^{D,k}_{V,-k}(n)$, then they has a limit point $X \in \mathcal{MET}$. Then X is a C^∞ manifold and there is a $C^{1,\alpha}$-metric for every $\alpha < 1$. And M_i are all diffeomorphic to X for large X.

In particular, this implies that there are only finitely many diffeomorphic classes.

Prop. (11.6.2.8)[Peterson]. $\mathcal{M}^D_{*,v,k}(n)$ has only finitely many homotopy classes.

3 Spectral Geometry

11.7 Lie Groups

Main references are [Eti21], [Lee13], [Kna96].

1 Basics

Def. (11.7.1.1) [Lie Groups]. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$, a **Lie group** is a group object in the category of smooth $\mathbb{K}$-manifolds. Notice it suffices to check that multiplication is smooth. The left and right translations L_g, R_g are all smooth morphisms hence diffeomorphisms.

A **homomorphism of Lie groups** is a smooth morphism that is also a group homomorphism. By translation invariance, a group homomorphism always has constant ranks, so a homomorphism of Lie groups that is a bijection is an isomorphism by global rank theorem(11.1.1.12).

The tangent space of G at e is denoted by $\mathfrak{g}$.

Proof: We show if a topological group G that is a smooth manifold satisfies $m : G \times G \to G$ is smooth, then G is a smooth manifold: consider the map $F : G \times G \to G \times G : (g, h) \mapsto (g, gh)$, it is a smooth map that is bijective.

The tangent map of F at (g, h) is $(X, Y) \mapsto (X, (dR_h)_g(X) + (dL_g)_h(Y))$, which is surjective because L_g is a diffeomorphism by(11.1.1.12). Then $F^{-1} : G \times G \to G \times G : (g, h) \mapsto (g, g^{-1}h)$ is smooth, and $g \mapsto g^{-1}$ is smooth. □

Prop. (11.7.1.2). A connected Lie group is automatically second countable.

Proof: This follows from the fact that a connected Lie group is a manifold hence locally second-countable and it is a union of products of a nbhd of e(3.11.1.3). □

Prop. (11.7.1.3). Any homomorphism of smooth manifolds has constant rank.

Proof: F being a homomorphism means that $F \circ L_g = L_{F(g)} \circ F$. Taking derivative and noticing the fact $L_g, L_{F(g)}$ are diffeomorphisms shows dF_{g_0} and dF_e have the same rank for any g. □

Prop. (11.7.1.4) [Discrete Subgroups]. Any discrete subgroup Γ of a Lie group G is a closed Lie subgroup of dimension 0.

Proof: Firstly Γ is countable: Let U be a nbhd of e containing no other points, choose another nbhd of e that $VV \subset U$, then $\{gV\}_{g \in \Gamma}$ is a family of disjoint open subsets of G, so there are countably many because G is second countable. Secondly Γ is closed in G, because

Γ is closed in G: Let U be a nbhd of e containing no other points, choose another nbhd of e that $VV \subset U$, then $\{gV\}_{g \in \Gamma}$ is a family of disjoint open subsets of G each containing an element of Γ. Then it is clear Γ is closed. Then(11.7.1.22) shows Γ is a closed Lie subgroup of dimension 0. □

Def. (11.7.1.5)[Adjoint Representation]. For a Lie group G, the conjugation map $C_g : G \to G : h \mapsto ghg^{-1}$ is a Lie group homomorphism. Let $\mathrm{Ad}(g) : \mathfrak{g} \to \mathfrak{g}$ denote its derivative, then $\mathrm{Ad} : g \mapsto \mathrm{Ad}(g)$ is an action of G on $\mathfrak{g}$, Bbcause $C_{g_1 g_2} = C_{g_1} C_{g_2}$, $\mathrm{Ad}(g_1 g_2) = \mathrm{Ad}(g_1)\,\mathrm{Ad}(g_2)$.

Prop. (11.7.1.6). Let G be a connected Lie group, and $\Gamma \subset G$ be a discrete normal subgroup. Show that Γ is in the center of G.

Proof: For $\gamma \in \Gamma$, consider the map $G \to G : g \mapsto g\gamma g^{-1}$, then it is a map with images in Γ. But Γ is discrete, so its image must be a single point, which is γ because $e\gamma e^{-1} = \gamma$. This means γ is in the center of G. □

Prop. (11.7.1.7) [Aut($\mathfrak{g}$)]. Let $\mathfrak{g}$ be a f.d. Lie algebra, then $\mathrm{Aut}(\mathfrak{g})$ is a closed Lie subgroup of $GL(\mathfrak{g})$, and its Lie algebra is $\mathrm{Der}(\mathfrak{g})$. Denote $\mathrm{Int}(\mathfrak{g}) = \mathrm{Der}(\mathfrak{g})^0$.

Proof: For the Lie algebra, it suffices to show for $A \in \mathrm{End}(\mathfrak{g})$, $[e^{tA}X, e^{tA}Y] = e^{tA}[X, Y]$ iff $A([X, Y]) = [A(X), Y] + [X, A(Y)]$.

One direction is by taking derivative w.r.t. t, for the other, we can show $y_1(t) = [e^{tA}X, e^{tA}Y]$ and $y_2(t) = e^{tA}[X, Y]$ both satisfy the ordinary differential equation $y_i(t)' = Ay_i(t)$. □

Exponential Map

Def. (11.7.1.8) [One-Parameter Subgroup]. A **one-parameter subgroup** of a Lie group G over $\mathbb{K}$ is a Lie group homomorphism $\mathbb{K} \to G$.

Prop. (11.7.1.9). Let $X \in \mathfrak{g}$, then there exists a unique morphism of Lie groups $\gamma : \mathbb{K} \to G$ that $\gamma'(0) = X$.

Proof: If γ is such a group homomorphism, then $\gamma(s + t) = \gamma(s)\gamma(t)$. Differentiating for s, we get

$$\gamma(t)' = d(L_{\gamma(s)})_0(X).$$

Thus γ is an integral curve of the left-invariant vector field on G corresponding to X(11.7.3.3), which is unique.

Now to construct such a homomorphism, we use ODE theorems to construct a γ satisfying this for $|t| < \varepsilon$, and then check $\gamma(s + t) = \gamma(s)\gamma(t)$ because they are both integral curves for t starting at $\gamma(s)$. In particular, $d(L_{\gamma(t)})(X) = d(R_{\gamma(t)})(X)$. Now we can extend this γ to whole of $\mathbb{K}$ by defining $\gamma(2^n s) = \gamma(s)^{2^s}$, then we check by induction on n that

$$\gamma'(t) = \frac{1}{2}(d(R_{\gamma(\frac{t}{2})})\gamma'(\frac{t}{2}) + d(L_{\gamma(\frac{t}{2})})\gamma'(\frac{t}{2}))(X) = d(R_{\gamma(\frac{t}{2})})d(R_{\gamma(\frac{t}{2})})(X) = d(R_{\gamma(t)})(X).$$

□

Cor. (11.7.1.10) [One-Parameter Subgroup and Lie Algebras]. Let G be a Lie group, then the one-parameter subgroups of G correspond to maximal integral curves of left invariant vector fields starting at e. In particular, the one-parameter subgroups of G corresponds to $\mathfrak{g}$ and also $T_e(G)$.

Also, the flow of the right-invariant vector field R_X is given by $(g, t) \mapsto \exp(tX)g$, and the flow of the left-invariant vector field L_X is given by $(g, t) \mapsto g\exp(tX)$.

Def. (11.7.1.11) [Exponential Map]. Let G be a Lie group with Lie algebra $\mathfrak{g}$, then we can define an **exponential map** $\exp : \mathfrak{g} \to G$ that for any $X \in \mathfrak{g}$, $\exp(X) = \gamma_X(1)$, where γ_X is the one-parameter subgroup of G generated by X(11.7.1.10). It can be shown that $\gamma(sX)$ is the one-parameter subgroup of G generated by X.

Prop. (11.7.1.12) [Properties of Exponential Map].

1. $\exp : \mathfrak{g} \to G$ is a smooth map which is a local diffeomorphism near 0 that $\exp(0) = e, \exp_* = \mathrm{id}_{\mathfrak{g}}$.
2. $\exp(s + t) = \exp(s)\exp(t)$ for $s, t \in \mathbb{K}$.
3. For any group homomorphism $\varphi : G \to H$ and $X \in \mathfrak{g}$, $\varphi(\exp(X)) = \exp(\varphi_*(X))$.
4. $g\exp(tX)g^{-1} = \exp(\mathrm{Ad}(g)X)$. Also, $\mathrm{Ad}_* = \mathrm{ad}$, or equivalently by item3, $\mathrm{Ad}(\exp(X)) = \exp(\mathrm{ad}(x))$ as operators.

5. If we identify $\mathfrak{gl}_n(\mathbb{K})$ with $GL_n(\mathbb{K})$, then we can check directly that the exponential map of $GL_n(\mathbb{K})$ is
$$\exp(A) = \sum_{k=0}^{\infty} \frac{1}{k!} A^k.$$

Proof: 1: The smoothness follows from the smoothness of the solution of ODE. The smooth inverse theorem shows it is a local diffeomorphism at identity.

2: trivial.

3: Both $\varphi(\exp(tX))$ and $\exp(t\varphi_*(X))$ are integral curves of the vector field $L_{\varphi_*(X)}$ and have the same initial point.

4: The first assertion is just item3 applied to the conjugate action C_g. For the Lie algebra homomorphism,
$$d(Ad)(X)Y = \frac{\partial}{\partial s}\frac{\partial}{\partial t}\exp(sX)\exp(tY)\exp(-sX) = [X, Y]$$
by(11.7.1.14). □

Prop. (11.7.1.13). Let G be a Lie group with Lie algebra $\mathfrak{g}$, and $\mathfrak{g} = A \oplus B$ a decomposition as subspaces, then the map
$$F : A \oplus B \to G : (X, Y) \mapsto \exp(X)\exp(Y)$$
is a local diffeomorphism at $0 \in \mathfrak{g}$.

Proof: Identify $\mathfrak{g}$ and the tangent space of G at e, then the differential F is identity, so it is a local diffeomorphism. □

Prop. (11.7.1.14)[Baker-Campbell-Hausdorff]. Let G be a Lie group with Lie algebra $\mathfrak{g}$, $X, Y \in \mathfrak{g}$, then
$$\exp(tX)\exp(tY) = \exp(\sum_{n=1}^{\infty} \frac{t^n}{n!}\mu_n(X, Y)).$$
where $\mu_n(X, Y)$ can be written as $\mathbb{Q}$-Lie polynomials of X and Y that is invariant of G.

In particular, $\mu_1(X, Y) = X + Y$, $\mu_2(X, Y) = \frac{1}{2}t^3([X, [X, Y]] + [Y, [Y, X]])$ and so on.

Proof: By the Lie correspondence(11.7.3.15), we can first assume that G is simply-connected, then there is a mapping of G onto some subgroup of $GL(n, \mathbb{K})$ with discrete kernel. If we can prove the formula for $G = GL(n, \mathbb{K})$, then $\exp(\sum_{n=1}^{\infty} \frac{t^n}{n!}\mu_n(X, Y))\exp(tY)^{-1}\exp(tX)^{-1}$ is contained the kernel, but it is a smooth function in t, and its value is 1 for $t = 0$, thus it holds for any t.

Now let $T\mathbb{K}^2 = \mathbb{K}\langle x, y\rangle$ be the free non-commutative algebra in variables x, y, the series $\exp(x) = \sum_{n=0}^{\infty} \frac{x^n}{n!}$ can be viewed as an element in $\widehat{\mathbb{K}\langle x, y\rangle}$. Then we can define
$$\mu = \log(\exp(x)\exp(y)) \in \widehat{\mathbb{K}\langle x, y\rangle},$$
where $\log(A) = -\sum_{n=1}^{\infty} \frac{(1-A)^n}{n!}$. Then $\mu = \sum_{n=1}^{\infty} \frac{\mu_n}{n!}$, where $\mu \in \mathbb{K}\langle x, y\rangle$ are polynomials in x, y of degree n with coefficients in $\mathbb{Q}$.

Then it remains to show that μ_n can be written as Lie polynomials in x, y. Notice $\Delta(x) = x \otimes 1 + 1 \otimes x$, thus $\Delta(\exp(x)) = \exp(x) \otimes \exp(x)$, thus $\Delta(\exp(x)\exp(y)) = \exp(x)\exp(y) \otimes \exp(x)\exp(y)$, and
$$\Delta(\log(\exp(x)\exp(y))) = \log(\Delta(\exp(x)\exp(y))) = \log((\exp(x)\exp(y) \otimes 1)(1 \otimes \exp(x)\exp(y)))$$

$$= \log(\exp(x)\exp(y)) \otimes 1 + 1 \otimes \log(\exp(x)\exp(y)).$$

then by separating degrees, each μ_n is primitive(2.9.1.3), thus they are contained in the free Lie-algebra generated by x, y, by(2.5.8.15) and(2.5.8.18).

The calculation is invariant of n in $GL(n, \mathbb{R})$, thus it is invariant of G. □

Cor. (11.7.1.15). Let G be a Lie group with Lie algebra $\mathfrak{g}$, $X, Y \in \mathfrak{g}$, then

$$\lim_{n\to\infty} (\exp(\frac{1}{n}X)\exp(\frac{1}{n}Y))^n = \exp(X+Y).$$

Proof:

$$(\exp(\frac{1}{n}X)\exp(\frac{1}{n}Y))^n = (\exp(\frac{1}{n}(X+Y) + O(\frac{1}{n^2})))^n = \exp(X+Y+O(\frac{1}{n})).$$

Taking $n \to \infty$, we get the desired result. □

Prop. (11.7.1.16). Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$ and H, G be Lie groups over $\mathbb{K}$, then

- A continuous homomorphism $\gamma : \mathbb{K} \to H$ is smooth.
- A continuous homomorphism between smooth Lie groups $F : G \to H$ is smooth.
- There is at most one smooth structure on a Lie gx1x10nianshao x1x10roup G that makes it a Lie group group.

Proof: 1: Let V be a nbhd of $0 \in \mathfrak{h}$ that exp is a diffeomorphism on $2V$(11.7.1.12). Choose t_0 small that $\gamma(t) \in \exp(V)$ for any $|t| \le t_0$, and let $X \in V$ that $\exp(X) = \gamma(t_0)$, then we can show $\gamma(t) = \exp(tX)$ for any $t = \frac{m}{2^n}$, so this holds for any t by continuity/analyticity, and γ is smooth.

2: By the proof of 1, we can construct a map(not necessary continuous) $F_* : \mathfrak{g} \to \mathfrak{h}$ with commutative diagram $\begin{array}{ccc} \mathfrak{g} & \xrightarrow{F_*} & \mathfrak{h} \\ \downarrow{\scriptstyle\exp} & & \downarrow{\scriptstyle\exp} \\ G & \xrightarrow{F} & H \end{array}$. Now using(11.7.1.15) and the continuity of F, we can show F_* is linear:

$$\begin{aligned} \exp(F_*(X+Y)) = F(\exp(X+Y)) &= F(\lim_{n\to\infty} \exp(\frac{1}{n}X)\exp(\frac{1}{n}Y))^n] \\ &= \lim_{n\to\infty} (\exp(\frac{1}{n}F_*X)\exp(\frac{1}{n}F_*Y))^n = \exp(F_*(X+Y)) \end{aligned}$$

Thus F is smooth at a nbhd of G, and smooth everywhere by translation. □

Group Aspects

Def. (11.7.1.17) [Lie Subgroup]. A **Lie subgroup** of a Lie group G is a subgroup that is also an immersed submanifold(11.1.1.14).

An **embedded Lie subgroup** of a Lie group G is a subgroup that is also an immerse submanifold(11.1.1.14).

Prop. (11.7.1.18) [Lie subgroup is Weakly Embedded]. Any Lie subgroup of a Lie group G is weakly embedded.

Proof: Cf.[Lee13]P506. □

Lemma (11.7.1.19). Let G be a Lie group and H a subgroup that is also an embedded submanifold, then H is an embedded Lie subgroup.

Proof: We need to show the multiplication and inverse on H is smooth: $H\times H\to G$ is smooth and has image in H, thus $H\times H\to H$ is also smooth, by(11.1.1.22). □

Lemma (11.7.1.20). Let G be a Lie group and $H\subset G$ a Lie subgroup, if H is an embedded submanifold of G, then H is closed in G.

Proof: Assume H is an embedded submanifold of G, then it is locally compact in the induced topology, so(10.11.1.7) shows H is closed in G. □

Lemma (11.7.1.21). Let G be a Lie group and H a subgroup of G that is also a closed subset of G, then H is an embedded Lie subgroup.

Proof: By(11.7.1.20), it suffices to show that H is an embedded submanifold of G. Let $\mathfrak{g}$ be the Lie algebra of G, and define a subspace $\mathfrak{h}\subset\mathfrak{g}$ that $\mathfrak{h}=\{X\in\mathfrak{g}|\exp(tX)\in H,\forall t\in\mathbb{R}\}$. By(11.7.1.15) and the fact H is closed in G, $\mathfrak{h}$ is a linear subspace of $\mathfrak{g}$.

Next we show that there exists a nbhd U of $0\in\mathfrak{g}$ that exp is a diffeomorphism and also $\exp(U\cap\mathfrak{h})=\exp(U)\cap H$: Let U be any open nbhd of $0\in\mathfrak{g}$ that exp is a diffeomorphism $U\to\exp(U)$, then $\exp(U\cap\mathfrak{h})\subset\exp(U)\cap H$ by definition.

Let $\mathfrak{b}\subset\mathfrak{g}$ be chosen s.t. $\mathfrak{h}\oplus\mathfrak{b}=\mathfrak{h}$, then $F:\mathfrak{h}\oplus\mathfrak{b}\to G:(X,Y)\mapsto\exp(X)\exp(Y)$ is a local diffeomorphism. Choose nbhd U of $0\in\mathfrak{g}$ and $\widetilde{U}$ of $0\in\mathfrak{h}\oplus\mathfrak{b}$ that both $\exp|_U$ and $F|_{\widetilde{U}}$ are diffeomorphisms, and choose a countable nbhd basis $\{U_i\}$ of $0\in\mathfrak{g}$. Denote $V_i=\exp(U_i)$ and $\widetilde{U}_i=F^{-1}(V_i)$, then V_i is a nbhd basis of $e\in G$ and $\widetilde{U}_i$ is a nbhd basis of $0\in\mathfrak{h}\oplus\mathfrak{b}$. We may assume $U_i\subset U$ and $\widetilde{U}_i\subset\widetilde{U}$.

If $\exp(U_i\cap\mathfrak{h})\subset\exp(U_i)\cap H$ for any i, then we can choose $h_i=\exp(Z_i)\in H$ that $h_i\notin\exp(U_i\cap\mathfrak{h})$. Because $\exp(U_i)=F(\widetilde{U}_i)$, set $h_i=\exp(X_i)\exp(Y_i)$, where $(X_i,Y_i)\in\widetilde{U}_i$. Now $Y_i\neq 0$, otherwise $\exp(Z_i)=\exp(X_i)$, which implies $Z_i=X_i$ and $h\in\exp(U_i\cap\mathfrak{h})$. Notice $\exp(Y_i)=\exp(X_i)^{-1}h_i\in H$.

Because $\widetilde{U}_i$ is a basis of $\mathfrak{h}\oplus\mathfrak{b}$, $Y_i\to 0$, Choose an inner product on $\mathfrak{b}$, and let $c_i=|Y_i|$, then $c_i^{-1}Y_i$ lies on the unit sphere of $\mathfrak{b}$. Replacing by a subsequence, we can assume $c_i^{-1}Y_i\to Y$ for some $Y\in\mathfrak{b}$. Then $|Y|=1$ by continuity.

For any $t\in\mathbb{R}$, let $n_i=[\frac{t}{c_i}]$, then $|nc_i-t|\leq c_i\to 0$, which means $n_iY_i\to tY$, so $\exp(n_iY_i)\to\exp(tY)$. But $\exp(n_iY_i)=\exp(Y_i)^{n_i}\in H$, so $\exp(tY)\in H$ because H is closed. Thus $Y\in\mathfrak{h}$, contradiction.

Thus in this way we can construct a slice chart φ of H at e, and for any $h\in H$, because

$$L_h((\exp(U)\cap H))=L_h(\exp(U))\cap H,$$

$\varphi\circ L_{h^{-1}}$ is a slice chart of H at h. Thus H is an embedded submanifold of G by(11.1.1.17). □

Prop. (11.7.1.22)[Closed Subgroup Theorem]. Let G be a Lie group and H a subgroup of G, then the following are equivalent:

- H is closed in G.
- H is an embedded submanifold.
- H is an embedded Lie subgroup.

Proof: $3\to 2$ is trivial, $3\to 1$ is(11.7.1.20). $1\to 3$ is(11.7.1.21), $2\to 3$ is(11.7.1.19). □

Remark (11.7.1.23). The dense line of the torus is a Lie subgroup that is not a closed Lie subgroup.

Lemma (11.7.1.24) [One-Parameter subgroup of Subgroups]. Let $H \subset G$ be a Lie subgroup, then the one-parameter subgroups of H are exactly those of G with initial velocity in $T_e(H)$.

Proof: This is because a one-parameter subgroup of H is naturally a one-parameter subgroup of G, and two one-parameter subgroups with the same initial velocity is identical. □

Prop. (11.7.1.25). Let $H \subset G$ be a Lie subgroup, then the exponential map of H is the exponential map of G restricted to $\mathfrak{h}$, and

$$\mathfrak{h} = \{X \in \mathfrak{g} | \exp(tX) \in H, \forall t \in \mathbb{R}\}.$$

Proof: The first assertion is an immediate corollary of(11.7.1.24). Now if $X \in \mathfrak{h}$, then the first assertion shows $\exp(tX) \in H$ for all t. Conversely, if $\exp(tX) \in H$ for all t, then $\exp(tX)$ is a smooth map to H, by(11.7.1.18), thus its derivative at e is in $\mathfrak{h}$, which means $X \in H$. □

Prop. (11.7.1.26) [Semidirect Product]. Let G acts via τ on H, then the Lie algebra of $G \ltimes_\tau H$ is $\mathfrak{g} \ltimes_{d\tau} \mathfrak{h}$.

Proof: Notice the differential of the action $\tau(g)$ on H defines a map $G \to GL(\mathfrak{h})$, and then the differential of this map gives a map $d\tau : \mathfrak{g} \to \mathrm{Der}(\mathfrak{h})$, so we can form $\mathfrak{g} \ltimes_{d\tau} \mathfrak{h}$(2.5.1.6).

For the rest, Cf.[Knapp, P60]. □

Prop. (11.7.1.27). Let G, H be simply-connected Lie groups with Lie algebra $\mathfrak{g}, \mathfrak{h}$, and let $\pi : \mathfrak{g} \to \mathrm{Der}(\mathfrak{h})$ be a Lie algebra homomorphism, then there is an action τ of G on H by automorphisms that $d\overline{\tau} = \pi$, and $G \ltimes_\tau H$ is a simply-connected Lie group with Lie algebra $\mathfrak{g} \ltimes_\pi \mathfrak{h}$.

Proof: Cf.[Knapp, P60]. □

Prop. (11.7.1.28) [Quotient Theorem for Lie Groups]. Let G be a Lie group and H a normal closed Lie subgroup, then the quotient G/H is a Lie group, and the quotient map π is a surjective Lie group homomorphism with kernel H.

Proof: By(11.7.2.6), G/H is a smooth manifold that the quotient map is surjective, smooth, and is a group homomorphism with kernel H. It suffices to show the multiplication of G/H is smooth, which is easy by(11.1.1.8). □

Prop. (11.7.1.29) [First Isomorphism Theorem for Lie Groups]. Let $\varphi : G \to H$ be a Lie group homomorphism, then there kernel of F is an closed Lie subgroup of G with Lie algebra $\ker(\varphi_*)$. The image of φ has a unique smooth structure making it a Lie subgroup of H that $G/\ker(F) \to \mathrm{Im}(\varphi)$ is a diffeomorphism, and it is a closed Lie subgroup when it is embedded in H, e.g. when φ induces a proper action(11.7.2.3).

Proof: This follows from(11.7.2.2) and(11.7.1.22). □

Def. (11.7.1.30) [Adjoint Group]. For a Lie group G, the center $Z(G)$ of G is a closed Lie subgroup because it the kernel of Ad(11.7.1.29). We call the group $G/Z(G)$ the **adjoint group** of G, which is an immersed subgroup of $GL(\mathfrak{g})$ by(11.7.1.29).

Lie Groups and Analytic Groups

Prop. (11.7.1.31). What condition makes a Lie group a complex Lie group?

Prop. (11.7.1.32). Any connected Lie group has a compact subgroup as deformation retraction.

Proof: □

Prop. (11.7.1.33) [Gleason; Montgomery-Zippin]. A real topological group G admits a (unique) Lie group structure iff the underlying topological space G is a topological manifold.

Proof: Cf.https://terrytao.wordpress.com/2011/06/17/hilberts-fifth-problem-and-gleason-metrics/
□

Prop. (11.7.1.34) [Lie Groups and Analytic Groups]. A real Lie group admits a unique real analytic structure, So it is not important to distinguish between a Lie group and an analytic Lie group, and call it **analytic group** if it is a connected Lie group. The uniqueness follows from(11.7.1.16).

Proof: Use(11.7.1.14) to show that in a local exp char (U,φ) of 1, $U\times U\to U$ is analytic, then we can choose an analytic atlas on G given by $\{(gU,\varphi\circ L_{g^{-1}})$. This is an analytic atlas, because the transition function is $\varphi L_{g^{-1}h}\varphi^{-1}$ on $U\cap h^{-1}gU$. Because $hU\cap gU\neq\varnothing$, let $x=hu_1=gu_2$, then $L_{g^{-1}h}=L_{u_2u_1^{-1}}$, which is analytic.

To show multiplication is analytic w.r.t. this atlas: ? □

Cor. (11.7.1.35). The proof above can be used to show that any C^k-group manifold be upgraded uniquely to a Lie group structure. So basically the study of C^0-Group manifold and analytic groups are the same.

2 Homogeneous Spaces

Actions of Lie Groups

Prop. (11.7.2.1) [Fundamental Theorem on Lie Group Actions]. Let θ be a right smooth action of a Lie group G on a smooth manifold M, then we can define a complete Lie algebra homomorphism

$$\widetilde{\theta}:\mathfrak{g}\to\mathfrak{X}(M):\theta(X)_p=\frac{d}{dt}|_{t=0}p\cdot\exp(tX)=d(\theta^{(p)})_e(X_e),$$

called the **infinitesimal generator** of θ. where a Lie homomorphism $\widetilde{\theta}:\mathfrak{g}\to\mathfrak{X}(M)$ is called complete iff for any $X\in\mathfrak{g}$, $\widetilde{\theta}(X)$ is a complete vector field(11.1.5.3).

Conversely, if G is simply-connected and $\widetilde{\theta}:\mathfrak{g}\to\mathfrak{X}(M)$ is a complete Lie algebra homomorphism, then there exists a unique smooth right action θ of G on M with infinitesimal generator $\widetilde{\theta}$.

Proof: $\theta(X)$ is smooth because it is the infinitesimal generator of the smooth flow $\mathbb{R}\times M\to M$: $(t,p)\mapsto p\exp(tX)$(11.1.5.4). $\widetilde{\theta}$ is a Lie algebra homomorphism by(11.1.2.13).? □

Prop. (11.7.2.2) [Isotropy Group and Orbits]. Let θ be an action of G on a manifold M, let $\widetilde{\theta}_x:\mathfrak{g}\to T_xM$ be given by $\widetilde{\theta}_x(X)=\widetilde{\theta}(X)_x$. Then

- The stabilizer G_x is a closed subgroup of G with Lie subalgebra $\mathfrak{g}_x=\ker(\widetilde{\theta}_x)$.
- Gx has a unique smooth structure making it an immersed subgroup of M that $G/G_x\to Gx$ is a diffeomorphism, and $T_x(Gx)\cong\operatorname{Im}(\widetilde{\theta}_x)\cong\mathfrak{g}/\mathfrak{g}_x$.

Proof: Cf.[Eti21]P48. □

Prop. (11.7.2.3). If a Lie group G acts properly on a manifold M, then each orbit is a closed submanifold of M, and each isotropy group is compact, by(3.11.1.15) and(3.11.1.17).

Prop. (11.7.2.4) [Quotient Map Theorem]. Let G be a Lie group that acts smoothly, freely and properly on a manifold M, then the quotient space M/G is a topological manifold with dimension $\dim M - \dim G$, and it has a unique smooth structure that $M \to M/G$ is a smooth submersion.

Proof: Cf.[Lee13]P544. □

Homogeneous Spaces and Fiber Bundles

Def. (11.7.2.5) [Homogeneous Spaces]. Let G be a Lie group, then a **homogeneous space** for G is a smooth manifold M with a smooth transitive G-action.

Prop. (11.7.2.6) [Characterizing Homogeneous Spaces]. Let G be a Lie group.

- if H is a closed subgroup of G, then the left coset space G/H is a topological manifold of dimension $\dim G - \dim H$, and has a unique smooth structure that the quotient map $G \to G/H$ is a smooth submersion. With this smooth structure, the left action of G on G/H turns it into a homogeneous space.
- If M is a homogeneous G-space, and $p \in M$, then the isotropy group G_p of M is a closed subgroup of G, and $G/G_p \to M$ is a diffeomorphism of G-spaces.

Proof: Cf.[Lee13]P551, P552. □

Cor. (11.7.2.7) [Homogeneous Space Structure on Sets]. Suppose X is a set with a transitive action of a Lie group G that for some point $p \in X$, the isotropy group G_p is closed in G. Then X has a unique smooth manifold structure with respect to which the given action is smooth. With this structure, $\dim X = \dim G - \dim G_p$.

Proof: This is because G/G_p is a smooth manifold that is G-equivariantly isomorphism to X, and the uniqueness also follows from the proposition. □

Prop. (11.7.2.8) [Quotients of Lie Groups by Discrete Subgroups]. Let G be a Lie group and Γ a discrete subgroup of G, then G/Γ is a smooth manifold, and the quotient map $G \to G/\Gamma$ is a smooth normal covering.

Proof: (11.7.1.4) and the proof of(11.7.2.6) shows Γ acts smoothly, freely, and properly on G on the right. Then the theorem is a consequence of(11.1.1.10). □

Prop. (11.7.2.9) [Contractible Homogeneous Space]. If X is a homogeneous G-manifold that is contractible, $x \in X$, then G is diffeomorphic to $G_x \times X$.

Proof: □

Prop. (11.7.2.10) [Orientability of Homogenous Spaces]. Let G be a Lie group and X be a homogeneous manifold of G. Let $x \in X$ and $H = \mathrm{Stab}_G(x)$.

1. X is orientable iff values of $\mathrm{Ad}(h_i)$ are of the same sign for any two element $h_1, h_2 \in H$ lying in a same connected component of G.
2. Show that when H is connected, X is orientable.

3. There exist a G-invariant volume form on X iff $\mathrm{Ad}(H) \subset SL(\mathfrak{g}/\mathfrak{h})$.

Prop. (11.7.2.11) [Fiber Bundle of Homogenous Spaces]. Let $G \in \mathcal{L}\mathrm{ie}\mathcal{G}\mathrm{rp}_{\mathrm{cpct}}$, $K \le H \le G$ be closed subgroups, then the map $G/K \to G/H$ is a G- locally trivial fiber bundle.

Proof: ? □

Prop. (11.7.2.12) [Examples of Homogeneous Spaces]. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$.

- The **Grassmannian manifold** $\mathrm{Gra}(k, \mathbb{K}^n)$ is defined to be the set of k-dimensional spaces in $\mathbb{K}^n$. $U(n, \mathbb{K})$ acts transitively on $\mathrm{Gra}(k, \mathbb{K}^n)$, and the stabilizer is $U(k, \mathbb{K}) \times U(n-k, \mathbb{K})$. Thus $\mathrm{Gra}(k, \mathbb{K}^n)$ is a homogeneous $U(n, \mathbb{K})$-space by(11.7.2.7), and $U(n, \mathbb{K}) \to \mathrm{Gra}(k, \mathbb{K}^n)$ is a fiber bundle with fiber $U(k, \mathbb{K}) \times U(n-k, \mathbb{K})$ by(11.7.2.11).
- The **Stiefel manifold** $V_k(\mathbb{K}^n)$ of orthonormal k-frames in $\mathbb{K}^n$ is defined to be the set of tuples $(v_1, \ldots, v_n)$ in $\mathbb{K}^n$ that $(v_i, v_j) = \delta_{ij}$. $U(n, \mathbb{K})$ acts transitively on $V_k(\mathbb{K}^n)$ with stabilizer $U(n-k, \mathbb{K})$, Thus $V_k(\mathbb{K}^n)$ is a homogeneous $U(n, \mathbb{K})$-space by(11.7.2.7), and $U(n, \mathbb{K}) \to V_k(\mathbb{K}^n)$ is a fiber bundle with fiber $U(n-k, \mathbb{K})$, and $V_k(\mathbb{K}^n) \to \mathrm{Gra}(k, \mathbb{K}^n)$ is a fiber bundle with fiber $U(k, \mathbb{K})$.
- The **flag Variety**.

Proof: 1: Let $\dim X = n$. X is orientable iff there is a non-vanishing n-form on X. Because $o_x : G \to X$ is submersive, choose n left invariant vector fields $X_1, \ldots, X_n$ that $(do_x)_e(v_i)$ generate $T_x(X)$, then by homogeneity, $(do_x)_g(X_{ig})$ generate $T_gx(X)$ for any $g \in G$. Thus X is orientable iff there is a n-form ω on G that satisfies $r_h^*\omega = \omega$, $\omega_g = \Delta(g) l_{g^{-1}}^* \omega_e$ for some $\Delta(g) \in \mathbb{R}*$, and for any $h \in H$, and $\omega(X_1, \ldots, X_n) \neq 0$.

If such a form exists, then $\Delta(gh) l_{(gh)^{-1}}^* \omega_e = r_h^* l_{g^{-1}}^* \omega_e$, which is equivalent to $\Delta(g) \mathrm{Ad}(h)^* \omega_e = \Delta(gh)\omega_e$ for any $h \in H$, thus values of $\mathrm{Ad}(h_i)$ are of the same sign for any two element $h_1, h_2 \in H$ lying in a same connected component of G.

Conversely, if values of $\mathrm{Ad}(h_i)$ are of the same sign for any two element $h_1, h_2 \in H$ lying in a same connected component of G, then we can define ω as above, where $\Delta(h) = \det(\mathrm{Ad}(h)|(\mathfrak{g}/\mathfrak{h}))$, and extend Δ to G that satisfy $\Delta(gh) = \Delta(g)\Delta(h)$. This can be because G is a fiber bundle over G/H.

2: When H is connected, clearly the values of $\mathrm{Ad}(H)$ are of the same sign.

3: The proof is the same as that of item1. In this case, all $\Delta(g) = 1$, thus the existence of G-invariant volume form on X is equivalent to $\mathrm{Ad}(H) \subset SL(\mathfrak{g}/\mathfrak{h})$. □

3 Lie Theory

Lie Algebras of Lie Groups

Def. (11.7.3.1) [Invariant Vector Fields]. Let G be a Lie group, then a smooth vector field X on G is called left-invariant if $d(L_g)_{g'}(X_{g'}) = X_{gg'}$ for any $g, g' \in G$. The set of left-invariant vector fields on G is denoted by $\mathrm{Lie}(G)$.

Prop. (11.7.3.2). If $X.Y$ are left-invariant vector fields over G, then $[X, Y]$ is also left-invariant, by(11.1.2.13).

Prop. (11.7.3.3) [Invariant Vector Fields and Tangent Spaces]. Let G be a Lie group, then the evaluation map $\mathrm{Lie}(G) \to \mathfrak{g} : X \mapsto X_e$ is a vector space isomorphism.

Proof: The inverse map is given by $X \mapsto (L_X)_g = d(L_g)_e(X)$. This is clearly a left-invariant vector field. It suffices to show that this $\tilde{X}$ is smooth. By(11.1.2.10), it suffices to show $L_X(f)$ is smooth for any smooth function f.

$$L_X(f)(g) = d(L_g)_e(X)(f)(g) = X(L_g f)(0) = \frac{d}{dt}|_0 f(g\exp(tX))$$

which is a differential of a smooth map $\mathbb{R} \times G \to GL : (t, g) \mapsto f(g\exp(tX))$, so it is smooth in g. □

Cor. (11.7.3.4) [Lie Group is Parallelizable]. Every Lie group admits a left-invariant smooth global frame, thus any Lie group is parallelizable.

Prop. (11.7.3.5). If $X \in \mathfrak{g}$ corresponds to a left-invariant vector field L_X, then for any $g \in G$,

$$d(R_g)_p((L_X)_p) = (L_{\mathrm{Ad}(g^{-1})X})_{pg}.$$

Proof:

$$\begin{aligned} d(R_g)_p((L_X)_p)(f)(pg) &= (L_X)_p(R_g f) = d(L_p)_e(X)(R_g f) \\ &= X(L_p R_g(f)) = \frac{d}{dt}|_0 f(p\exp(tX)g) \\ &= \frac{d}{dt}|_0 f(p\exp(t\,\mathrm{Ad}(g^{-1})X)) = (\mathrm{Ad}(g^{-1}X)(L_p(f)) \\ &= (L_{\mathrm{Ad}(g^{-1})X})_{pg}(f)(pg) \end{aligned}$$

□

Def. (11.7.3.6) [Lie Algebra of a Lie Group]. If G is a Lie group, $\mathrm{Lie}(G)$ is a Lie algebra w.r.t. the Lie bracket(11.1.2.12). It is called the **Lie algebra associated to** G.

Proof: This is clear from the definition $[X, Y](f) = XY(f) - YX(f)$. □

Prop. (11.7.3.7) [Induced Map of Lie Algebras]. A homomorphism $F : G \to H$ of Lie groups induces a morphism of their Lie algebras via the tangent space.

Proof: For any $X \in \mathrm{Lie}(G)$, define $F_*(X)_g = (dL_g)_e(dF_e(X_e))$, then this is a left-invariant vector field, and it clearly corresponds to the tangent map via isomorphism in(11.7.3.3). This map is a Lie algebra map by a variant of(11.1.2.13). □

Cor. (11.7.3.8). If $H \subset G$ is a Lie subgroup, then there is a natural isomorphism

$$\mathfrak{h} \cong \{X \in \mathrm{Lie}(G) | X_e \in T_e H\}.$$

In particular, the tangent space $\mathfrak{h}$ of H is a Lie subalgebra of $\mathfrak{g}$.

Proof: There is a commutative diagram $\begin{array}{ccc} \mathrm{Lie}(H) & \xrightarrow{X \mapsto X_e} & \mathfrak{h} \\ \downarrow \iota_* & & \downarrow (\iota_*)_e \\ \mathrm{Lie}(G) & \xrightarrow{X \mapsto X_e} & \mathfrak{g} \end{array}$. □

Prop. (11.7.3.9) [Covering of Lie Groups]. Let $F : G \to H$ be a homomorphism of connected Lie groups, then the following are equivalent:

- F is surjective with discrete kernel.
- F is a smooth covering map.
- F is a local diffeomorphism.
- The induced homomorphism $F_* : \mathfrak{g} \to \mathfrak{h}$ is an isomorphism.

Proof: $1 \to 2$: F is surjective thus H is a homogeneous G-space, so(11.7.2.6) shows $H \cong G/\ker(F)$. And $G \to G/\ker(F)$ is a smooth covering map by(11.7.2.8).

$2 \to 3$ is trivial.

$3 \to 1$: If F is a local diffeomorphism, then $\ker(F)$ is discrete, and F is open. Thus $F(G)$ is an open subgroup of H, thus all of H because H is connected(3.11.1.3).

$3 \to 4$ is trivial. $4 \to 3$ is by inverse function theorem. □

Cor. (11.7.3.10)[Homomorphism with Discrete Kernel]. Let $G \to H$ be a homomorphism of Lie groups of the same dimension with discrete kernel and H connected, then it is a covering space map, and the kernel is in the center of G, by(11.7.1.6).

Proof: This homomorphism is locally injective at 1, so it has rank $\dim G = \dim H$, so it is local diffeomorphism. In particular, the image contains a nbhd of 1 in H, thus it contains all H by(3.11.1.3). □

Prop. (11.7.3.11)[Universal Covering Lie Group]. If G is a connected Lie group, then its universal covering space $\widetilde{G}$ can be given a Lie group structure that the covering map is a group homomorphism. Moreover, the group structure is unique up to isomorphism over G. Moreover, the kernel of $\widetilde{G} \to G$ is a discrete central subgroup of $\widetilde{G}$.

Proof: Because $\widetilde{G}$ is simply connected, so does $\widetilde{G} \times \widetilde{G}$, let $\widetilde{e}$ be an element over e, we can lift the map $\widetilde{G} \times \widetilde{G} \to G \times G \xrightarrow{m} G$ to a map $\widetilde{m} : \widetilde{G} \times \widetilde{G} \to \widetilde{G}$ that $\widetilde{m}(\widetilde{e}, \widetilde{e}) = \widetilde{e}$. Similar we can lift an inverse map $\widetilde{i}$ that $\widetilde{i}(\widetilde{e}) = \widetilde{e}$. These maps are smooth because $\pi : \widetilde{G} \to G$ is a local diffeomorphism.

It's left to show that $(\widetilde{m}, \widetilde{i})$ makes $\widetilde{G}$ into a Lie group: For example, the map $L_{\widetilde{e}} : \widetilde{G} \to \widetilde{G}$ is a lift of id_G and it coincides with $\mathrm{id}_{\widetilde{G}}$ on a point $\widetilde{e}$, thus it is just $\mathrm{id}_{\widetilde{G}}$, which means $\widetilde{e}$ is a left identity. The rest is easy.

For the uniqueness: By the universal property of covering, if there are two coverings, we can lift it to a map connecting them that maps identity to identity, then show it is a group homomorphism.

The last assertion follows from(11.7.3.10). □

Prop. (11.7.3.12) [Lie Subalgebras and Subgroups]. For a Lie group G, for any lie subalgebra $\mathfrak{h} \subset \mathfrak{g}$, there exists uniquely a connected Lie subgroup H s.t. $\mathfrak{h}$ is the lie algebra of H.

Proof: By (11.1.3.1), there is a maximal connected manifold H corresponding to $\mathfrak{h}$, we only need to show that it is a group. But the left invariance of $\mathfrak{h}$ shows that $HH \subset H$ because H is maximal. Cf.[Lee13]P506.? □

Cor. (11.7.3.13). If G_1 is a simply connected Lie group and G_2 is a connected Lie group, then any Lie algebra homomorphism $\widetilde{h} : \mathfrak{g}_1 \to \mathfrak{g}_2$ can be lifted to a unique Lie group homomorphism.

Proof: Consider the image of $\widetilde{h}$: $\Gamma(\widetilde{h}) \subset \mathfrak{g}_1 \times \mathfrak{g}_2$, which is a Lie subalgebra. First notice a Lie group homomorphism h is equivalent to a Lie subgroup G_h of $G_1 \times G_2$ that $\pi_1|_{G_h}$ is a diffeomorphism onto G_1. And this Lie homomorphism induces the desired Lie algebra homomorphism iff the Lie algebra of G_h is just $\widetilde{h}$.

(11.7.3.12) shows that there exists a unique Lie group G in $G_1 \times G_2$ with Lie subalgebra $\Gamma(\widetilde{h})$. The projection $\pi_1|_G$ is a diffeomorphism onto G_1, because the tangent map at e is an isomorphism, thus a local diffeomorphism and by(11.7.3.10) a covering map, so it must be an isomorphism because G_1 is simply connected and G is connected. □

Cor. (11.7.3.14) [Representations of Simply-Connected Lie Groups]. The category of representations of s simply-connected Lie groups is equivalent to the category of representations of its Lie algebra.

Thm. (11.7.3.15) [The Lie Correspondence].

- The category of finite dimensional Lie algebras is equivalent to the category of simply connected Lie groups.
- For a f.d. Lie algebra $\mathfrak{g}$, the connected Lie groups with Lie algebras isomorphic to $\mathfrak{g}$ corresponds to G/Γ, where G is a simply connected subgroup with Lie algebra $\mathfrak{g}$, and Γ is a discrete central subgroup of G.

Proof: 1: By(11.7.3.12)(11.7.3.13) together with Ado's theorem**??**.

2: (11.7.3.11) and(11.7.3.9) shows any Lie group is a quotient of its universal covering Lie group by a discrete central subgroup. Conversely, for any discrete central subgroup, G/Γ is a Lie subgroup and $\pi : G \to G/\Gamma$ is a homomorphism with kernel Γ by(11.7.1.4) and(11.7.1.28), thus $\mathrm{Lie}(G) = \mathrm{Lie}(G/\Gamma) \cong \mathfrak{g}$(11.7.1.28). □

Prop. (11.7.3.16) [Ideals and Normal Subgroups]. Let G be a connected Lie group and H a connected Lie subgroup, then H is a normal subgroup of G iff $\mathfrak{h}$ is an ideal of $\mathfrak{g}$.

Proof: Because G, H are both connected, (3.11.1.3) shows H is normal in G iff for any $X \in \mathfrak{g}, Y \in \mathfrak{h}$, $\exp(X)\exp(Y)\exp(X)^{-1} \in H$. Taking derivative w.r.t. Y, this is equivalent to $d(\mathrm{Ad}(\exp(X)))(Y) = \mathrm{ad}(X)Y \in \mathfrak{h}$(11.7.1.12), by(11.7.1.25), which is equivalent to $\mathfrak{h}$ being an ideal of $\mathfrak{g}$. □

Prop. (11.7.3.17) [Center]. Let G be a connected subgroup with Lie algebra $\mathfrak{g}$ and Z the center of G, $\mathfrak{z}$ the center of $\mathfrak{g}$, then Z is a closed Lie subgroup of G with Lie algebra $\mathfrak{z}$.

Proof: Because G is connected, $g \in Z$ iff g commutes with all $\exp(tX), X \in \mathfrak{g}$. Thus $Z = \ker \mathrm{Ad}$. Now the assertion follows from(11.7.1.29). □

Prop. (11.7.3.18) [Chevalley's Theorem]. Let G be a complex connected Lie group and $\mathfrak{g}$ the Lie algebra of G, $\mathfrak{h}$ the Cartan subalgebra of $\mathfrak{g}$, and W the Weyl group, then the restriction of functions induces a graded algebra isomorphism

$$\mathbb{C}[\mathfrak{g}]^G \cong \mathbb{C}[\mathfrak{h}]^W.$$

Proof: **?** □

Classifications

Prop. (11.7.3.19) [Simply-Connected Compact Lie Groups]. Any simply connected compact Lie groups is a product of the following types:

- $\mathrm{Spin}(n)$ for $n \geq 3$.
- $\mathrm{SU}(2)$ for $n \geq 2$.
- $\mathrm{Sp}(n)$ for $n \geq 1$.
- E_6, E_7, E_8, F_4, G_2.

Proof: **?** □

4 Classical Groups

In this subsection, Archimedean points of classical groups(8.3.5.1) are studied.
For more classical groups, Cf.[Classical Groups Baker].

Def. (11.7.4.1) [Examples of Classical Groups]. Let $\mathbb{K}$ be either $\mathbb{R},\mathbb{C}$,

- For any associative algebra $\mathbb{K}$ over a field, the **general linear group** $GL(n,\mathbb{K})$ is the subgroup of $M_n(\mathbb{K})$ consisting of invertible matrices.
- The **unitary group** $U(n)$ is the subgroup of $GL_n(\mathbb{C})$ consisting of matrices fixing a non-degenerate Hermitian form.
- The **special unitary group** $SU(n) = U(n) \cap SL_n(\mathbb{C})$.
- The **pseudo-unitary groups** $U(p,q,\mathbb{K})$: If $\mathbb{K}=\mathbb{R}$, it is the subgroup of $GL(n,\mathbb{R})$ consisting of matrices preserving a bilinear form of signature (p,q). If $\mathbb{K}=\mathbb{C}$, it is the subgroup of $GL(n,\mathbb{C})$ consisting of matrices preserving a Hermitian form of signature (p,q). If $\mathbb{K}=\mathbb{H}$, it is the subgroup of $GL(n,\mathbb{H})$ consisting of matrices preserving a non-degenerate quoternionic Hermitian form of signature (p,q)(2.3.11.7).
- The **quoternionic orthogonal group** $O^*(2n)$ is the subgroup of $GL(n,\mathbb{H})$ consisting of matrices preserving a non-degenerate quoternionic skew-Hermitian form(2.3.11.7). $SO^*(2n)$ is the subgroup of $O^*(2n)$ consisting of elements of determinant 1.
- $PU(n)$ is the quotient group of $SU(n)$(or $U(n)$) by scalar matrices.

Proof: $GL_n(\mathbb{K})$ has a natural smooth structure as an open subset of $\mathbb{K}^{n^2}$, and the multiplication map is clearly smooth, so it is a Lie group by(11.7.1.1). The other groups are closed subgroups of $GL_n(\mathbb{K})$, so they have unique smooth manifold structure making them Lie subgroups of $GL_n(\mathbb{K})$, by(11.7.1.22)(11.7.1.16). Finally the quotient group by normal closed subgroups have natural Lie group structure by(11.7.1.28). □

Prop. (11.7.4.2) [Classification of Transformations]. Let $\alpha \in SL(2,\mathbb{R})$ and $\alpha \neq \mathbf{I}$, then by Jordan decomposition, α is conjugate to a matrix of one the two following types:

$$\begin{bmatrix} \lambda & 1 \\ & \lambda \end{bmatrix}, \quad \begin{bmatrix} \lambda & \\ & \mu \end{bmatrix}, \lambda \neq \mu$$

according as it has repeated eigenvalues or distinct eigenvalues. In the first case, α is called **parabolic**, and in the second case, if $|\lambda/\mu| = 1$, it is called **elliptic**, If λ/μ is real and positive, it is called **parabolic**, and called **loxodromic** otherwise.

- If $\alpha \in SL_2(\mathbb{R})$ is parabolic, then it has a unique real eigenvector, which means it has a unique fixed point in $\mathbb{R}\cup\infty$.
- If $\alpha \in SL_2(\mathbb{R})$ is elliptic, then α has two conjugate eigenvectors, which means it has exactly one fixed point z in $\mathscr{H}$, and a second fixed point, namely $\overline{z}$, in the lower half plane.
- If $\alpha \in SL_2(\mathbb{R})$ is hyperbolic, then it has two real eigenvectors, which means it has two distinct fixed points in $\mathbb{R}\cup\infty$.

Prop. (11.7.4.3) [Iwasawa-Decomposition]. Any element of $GL(2,\mathbb{R})^+$ has a unique representation of the form(11.7.6.4):

$$g = \begin{bmatrix} u & \\ & u \end{bmatrix} \begin{bmatrix} y^{1/2} & xy^{-1/2} \\ & y^{-1/2} \end{bmatrix} k_\theta$$

where $k_\theta = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}$. So by(10.11.1.39) and(10.11.1.19) the Haar measure is calculated to be $\mathrm{d}g = \frac{1}{2\pi}\frac{\mathrm{d}u}{u}\frac{\mathrm{d}x\mathrm{d}y}{y^2}\mathrm{d}\theta$, and it is unimodular by(10.11.1.22). (Notice the upper triangular matrix group $B \subset GL(2,\mathbb{R})^+$ is not unimodular).

Proof: For the calculation of Haar measure, notice that it suffices to calculate for u, x, y and it is

$$\frac{\mathrm{d}(uy^{1/2})\mathrm{d}(uy^{-1/2})\mathrm{d}(uxy^{-1/2})}{(uy^{1/2})^2 uy^{-1/2}} = \frac{\mathrm{d}x\mathrm{d}(uy^{1/2})\mathrm{d}(uy^{-1/2})}{u^2 y} = \frac{\mathrm{d}x\mathrm{d}y\mathrm{d}u}{uy^2}$$

□

Cor. (11.7.4.4). Any element of $SL(2,\mathbb{R})$ has a unique representation of the form

$$g = \begin{bmatrix} e^{\frac{u}{2}} & 0 \\ 0 & e^{-\frac{u}{2}} \end{bmatrix}\begin{bmatrix} 1 & x \\ & 1 \end{bmatrix} k_\theta.$$

And the Haar measure is given by $\mathrm{d}g = \frac{1}{2\pi}\mathrm{d}u\mathrm{d}x\mathrm{d}\theta$ by similar calculation, which is unimodular.

Prop. (11.7.4.5). $\mathscr{H}$ is a homogenous space for $\mathrm{PGL}(2,\mathbb{R})$, and $\mathrm{Stab}_{\mathrm{PGL}(2,\mathbb{R})}(\mathrm{i}) = SO(2,\mathbb{R})$. Also it fixes the hyperbolic metric $\mathrm{d}s^2 = y^{-2}\mathrm{d}x\mathrm{d}y$.

Proof: This follows from the Iwasawa decomposition(11.7.4.3). □

Prop. (11.7.4.6) [$SU(2)$].

$$SU(2) = \{A_{\alpha,\beta} = \begin{bmatrix} \alpha & \beta \\ -\overline{\beta} & \overline{\alpha} \end{bmatrix}, \alpha, \beta \in \mathbb{C}, |\alpha|^2 + |\beta|^2 = 1\}$$

is isomorphic to the group of unit quaternions and diffeomorphic to S^3. The Lie algebra of $SU(2)$ is isomorphic to $\mathfrak{sl}_2(\mathbb{R})$.

Proof: Let $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \in SU(2)$, then

$$a\overline{a} + b\overline{b} = 1, \quad a\overline{c} + b\overline{d} = 0, \quad c\overline{c} + d\overline{d} = 1, ac - bd = 1.$$

So $(c,d) = \lambda.(-\overline{b}, \overline{a})$, and we can calculate $\lambda = 1$. So the first assertion follows.

By(2.3.11.4), $SU(2)$ is isomorphic to the group of unit quaternions, which is clearly isomorphic to S^3. □

Prop. (11.7.4.7) [Actions of $SU(2)$].

- There is a double covering of Lie groups $SU(2) \to SO(3)$ with kernel $\{\pm 1\}$.
- There is a double covering of Lie groups $SU(2) \times SU(2) \to SO(4)$ with kernel $\{\pm 1\}$.

Proof: 1: Regard $SU(2)$ as the unit quaternions and $SO(3)$ the transformation group of pure unit quaternions, then $SU(2) \to SO(3)$ is given by

$$u \mapsto (v \mapsto uv\overline{u}).$$

Because $u \cdot \overline{u}$ preserves orthogonality relations, it preserves the space of pure quaternions, so it has image in $O(3)$. But it has image in $SO(3)$ because $SU(2) \cong S^3$ is connected. Its kernel is in the center of $\mathbb{H}$, so must be ± 1. Now(11.7.3.10) shows this is a covering space map.

2: Consider the action $SU(2) \times SU(2)$ on the section of unit vectors of $\mathbb{H}$: $(u,v)(z) = uzv^{-1}$. if (u,v) is in the kernel of this map, then $uv^{-1} = 1$, so $u = v$,and u is in the center of $\mathbb{H}$, so $u = v = \pm 1$. Because $\dim SU(2) = 3$ and $\dim SO(4) = 6$, (11.7.3.10) shows this is a double cover. □

Prop. (11.7.4.8).

- There is a double cover $SU(4)\to SO(6,\mathbb{R})$ with kernel $\{\pm 1\}$.
- There is a double cover $SL(4,\mathbb{C})\to SO(6,\mathbb{C})$ with kernel $\{\pm 1\}$.
- There is a double cover $Sp(4,\mathbb{C})\to SO(5,\mathbb{C})$ with kernel $\{\pm 1\}$.

Proof: 1: $SU(4)$ acts on a 4-dimensional Hermitian space V. Then it acts on the Hermitian space $\wedge^2 V$. Consider the Hodge star operator $*:\wedge^2 V\to\wedge^2 V$(11.1.3.9), it is an anti-linear operator, $*^2=\mathrm{id}$ and $*$ commutes with $SU(4)$ action. Then $W=\ker(*-\mathrm{id})$ is a real vector space of dimension 6 that $SU(4)$ acts on. This kernel of this action is the same as the kernel of the action $\wedge^2 V$, which is $\{\pm 1\}$.

The Hermitian form induces a symmetric form on W: Take a conjugation on V, because $V=W\oplus iW$, $W=\mathrm{Im}(*+\mathrm{id})V$. So for $a,b\in W$, let $a=*c+c, b=*d+d$, then $(a,b)\omega=((*a,*b)+(*a,b)+(a,*b)+(a,b))\omega=*a\wedge b+\overline{a\wedge b}+a\wedge b+\overline{*a\wedge b}$ is a real form. Then this representation induces a map $SU(4)\to SO(6)$(because $SU(4)$ is connected). Because $\dim SU(4)=\dim SO(6)=6$, it is a double cover by(11.7.3.10).

2: $SL(4,\mathbb{C})$ acts on a 4-dimensional complex vector space V, then it acts on the space $W=\wedge^2 V^*$. We construct a non-degenerate bilinear form on W given by $\wedge: W\times W\to\wedge^4 V^*\cong\mathbb{C}$. Then $SL(4,\mathbb{C})$ preserves this bilinear form, thus induces a map $SL(4,\mathbb{C})\to SO(6,\mathbb{C})$. The kernel of this map is $\{\pm 1\}$, because if A preserves all $v_1^*\wedge v_2^*$, then $Av_1^*\wedge Av_2^*=v_1^*\wedge v_2^*$, so $Av_1^*\wedge Av_2^*\wedge v_i^*=0$, so $Av_1^*\in\{v_1^*,v_2^*\}$, or $Av_2^*\subset\{Av_1^*,v_1^*\}\cap\{Av_1^*,v_2^*\}=Av_1^*$, then $Av_1^*\wedge Av_2^*=0$, contradiction. So $Av_1^*\subset\{v_1^*,v_2^*\}$. v_1,v_2 is arbitrary, thus A is diagonal, and it is clear $A=\pm 1$. Finally, $SL(4,\mathbb{C})\to SO(6,\mathbb{C})$ is a double cover by(11.7.3.10).

3: The representation of $SL(4,\mathbb{C})$ on $W=\wedge^2 V^*$ restricts to a representation of $Sp(4,\mathbb{C})$, and it fixes the vector $\sigma=v_1^*\wedge v_2^*+v_3^*\wedge v_4^*$ by definition, so it also fixes the orthogonal $\{\sigma\}^\perp$, thus inducing a map $Sp(4,\mathbb{C})\to SO(5,\mathbb{C})$ with kernel $\{\pm 1\}$, which is a double cover by(11.7.3.10). □

Prop. (11.7.4.9) [$SU(1,1)$ and $SL(2,\mathbb{R})$]. Let $SL(2,\mathbb{C})$ act continuously on $\mathbb{P}^1(\mathbb{C})$ by $\gamma(z)=\frac{az+b}{cz+d}$ where $\gamma=\begin{bmatrix}a & b\\ c & d\end{bmatrix}$, then

- The stabilizer of the unit disk $\mathbb{D}$ is
$$SU(1,1)=\{\begin{bmatrix}a & b\\ \overline{b} & \overline{a}\end{bmatrix}\,||a|^2-|b|^2=1\}.$$
- $SU(1,1)$ is conjugate to $SL(2,\mathbb{R})$ in $SL(2,\mathbb{C})$.
- The subgroup of $SU(1,1)$ fixing $0\in\mathbb{D}$ is the subgroup of rotations $\{\mathrm{diag}(e^{\mathrm{i}\theta/2},e^{-\mathrm{i}\theta/2})\}$.

Proof: 3: This follows from Schwartz lemma(10.6.1.3).

1, 2: We first describe $SU(1,1)$:
$$SU(1,1)=\{\begin{bmatrix}a & b\\ c & d\end{bmatrix}:|a|^2-|c|^2=1,\quad a\overline{b}-c\overline{d}=0,\quad |b|^2-|d|^2=-1,\quad ad-bc=1\}$$
which means $(b,d)=\lambda(\overline{c},\overline{a})$, and $\lambda=1$.

Let $C=\frac{1}{\sqrt{2}e^{2\pi i/4}}\begin{bmatrix}1 & -i\\ 1 & i\end{bmatrix}$, then C induces an isomorphism between $\mathscr{H}$ and $\mathbb{D}$, because $\frac{z-i}{z+i}\in\mathbb{D}$ iff $|z-i|<|z+i|$ iff z is in the upper half plane. By this isomorphism and item 3, the element of $SL(2,\mathbb{C})$ stabilizing $\mathbb{D}$ and fixing i is of the group $SO(2,\mathbb{R})\subset SL(2,\mathbb{R})$.

Notice that $SL(2,\mathbb{R})$ preserves $\mathcal{H}$ by(10.5.1.8), and it acts transitively on it because $\sqrt{y}\begin{bmatrix} y & x \\ & 1 \end{bmatrix}$ maps i to $x+iy\in\mathcal{H}$. Now if $\gamma\in SL(2,\mathbb{C})$ stabilizes $\mathscr{H}$, then γg fixes i for some $g\in SL(2,\mathbb{R})$, thus $\gamma g\in SL(2,\mathbb{R})$, thus $\gamma\in SL(2,\mathbb{R})$. Thus we have shown the stabilizer of $\mathcal{H}$ is $SL(2,\mathbb{R})$. Then the stabilizer of $\mathbb{D}$ is

$$\begin{aligned} C\cdot SL(2,\mathbb{R})C^{-1} &= \{\frac{1}{2i}\begin{bmatrix} 1 & -i \\ 1 & i \end{bmatrix}\begin{bmatrix} a & b \\ c & d \end{bmatrix}\begin{bmatrix} i & i \\ -1 & 1 \end{bmatrix} \mid a,b,c,d\in\mathbb{R}, ad-bc=1\} \\ &= \{\frac{1}{2}\begin{bmatrix} a+d+(b-c)i & a-d-(b+c)i \\ a-d+(b+c)i & a+d-(b-c)i \end{bmatrix} \mid a,b,c,d\in\mathbb{R}, ad-bc=1\} \end{aligned}$$

which is exactly $SU(1,1)$. So we get 1 and 2. □

Cor. (11.7.4.10)[Upper Half Plane $\mathscr{H}$]. By(10.5.7.8), the groups $GL(2,\mathbb{R})$ preserves the upper plane $\mathscr{H}$, by(10.5.1.8). The action of SL(2; $\mathbb{R}$) on $\mathscr{H}$ is transitive and the stabilizer of i is $SO(2,\mathbb{R})$, thus we have $\mathcal{H}\cong SL(2;\mathbb{R})/SO(2;\mathbb{R})$.

Prop. (11.7.4.11)[$Sp(2,\mathbb{K})$ and $SL(2,\mathbb{K})$]. For any field $\mathbb{K}$, $Sp(2,\mathbb{K})\cong SL(2,\mathbb{K})$: They both consists of linear maps preserving the differential form $dx\wedge dy$.

Prop. (11.7.4.12)[Center of $SU(p,q)$]. $Z_{U(p,q)}(SU(p,q))$ are all scalar matrices.

Proof: Firstly we consider $Z_{U(2)}(SU(2))$, if $A\in Z(SU(2))$, then it commutes with $\mathrm{diag}(i,-i)$, so A is a scalar. Similarly, If $A\in Z_{U(1,1)}(SU(1,1))$, then A commutes with $\mathrm{diag}(i,-i)$, thus A is a scalar.

If $X\in Z(SU(p,q))$ is not a scalar matrix, then it has two eigenvectors s,t with different eigenvalues. Consider the space V generated by s,t and its orthogonal complement, then X restricted to this space is in the center of $U(V)$. Now $SU(V)\cong SU(1,1)$ or $SU(2)$, both have the set of scalar matrices as center, so X cannot have different eigenvalue, contradiction. Thus X is a scaler matrix. □

Prop. (11.7.4.13)[$PGL(2,\mathbb{C})\cong SO(3,\mathbb{C})$]. $V\cong\mathbb{C}^2$ has a natural symmetric form $(x,y)\mapsto x\wedge y\cong\mathbb{C}$, and this form is preserved by $SL(2,\mathbb{C})$ by definition. The kernel of this map is $\{\pm 1\}$. Thus $SL(2,\mathbb{C})$ acts on $\mathrm{Sym}^2(V)$, thus induces a map $PGL(2,\mathbb{C})\to SO(3)$, which an isomorphism by(11.7.3.10).

Prop. (11.7.4.14) [Real and Complex Matrices]. $GL_n(\mathbb{C})$ can be embedded into $GL_{2n}(\mathbb{R})$, with determinant $|\det|^2$. And in this way, $U(n)$ is mapped into $O(2n,\mathbb{R})$. Also, $O(n,\mathbb{R})$ embeds into $U(n)$ diagonally.

Proof:

$$X+iY\mapsto\begin{bmatrix} X & -Y \\ Y & X \end{bmatrix}\sim\begin{bmatrix} X & -Y \\ iX+Y & X-iY \end{bmatrix}\sim\begin{bmatrix} X+iY & Y \\ 0 & X-iY \end{bmatrix}$$

□

Prop. (11.7.4.15) [Symplectic Groups].

- $U(p,q,\mathbb{H}) = Sp(2n,\mathbb{C})\cap U(2p,2q,\mathbb{C})$. $U(n,\mathbb{H}) = U(n,0,\mathbb{H})$ is also denoted by $Sp(n)$, called the **compact symplectic group**.
- $O^*(2n) = U(n,n)\cap O(2n,\mathbb{C})$.
- $Sp(2n,\mathbb{C}) = SL(n,\mathbb{H})$.

- $Sp(2n,\mathbb{R}) \cap O(2n,\mathbb{R}) = Sp(2n,\mathbb{R}) \cap GL(n,\mathbb{C}) = O(2n,\mathbb{R}) \cap GL(n,\mathbb{C}) = U(n) = \{\begin{bmatrix} X & -Y \\ Y & X \end{bmatrix}, \quad X+iY \in U(n)\}$.

Proof: 1: By(2.3.11.9), notice that any $\mathbb{C}$-linear automorphism preserving B_1 and B_2 is $\mathbb{H}$-linear.

2: By(2.3.11.9), notice that any $\mathbb{C}$-linear automorphism preserving B_1 and B_2 is $\mathbb{H}$-linear.

3: If $A \in Sp(2n,\mathbb{R}) \cap O(2n,\mathbb{R})$, then $AA^t = A^tA = 1, A^tJA = 1$, then $AJ = JA$. The rest and the other identities are easy by(11.7.4.14). □

Spin Groups

Prop. (11.7.4.16). Let $\mathrm{Cl}_{r,s}$ denote the real Clifford algebra of signature $r-s$, then

$$\mathrm{Cl}_{1,0} \cong \mathbb{C}, \quad Cl_{0,1} \cong \mathbb{R}\oplus\mathbb{R}, \quad \mathrm{Cl}_{2,0} \cong \mathbb{H} \subset M(2,\mathbb{C}), \quad Cl_{0,2} \cong R(2) = M(2,\mathbb{R}),$$

And we have

$$Cl_{n+2,0} \cong Cl_{0,n} \otimes Cl_{2,0}, \quad Cl_{0,n+2} \cong Cl_{n,0} \otimes Cl_{0,2}.$$

by the mapping $e_i \to e_i \otimes e_1'e_2'$, $e_{n+j} \to 1 \otimes e_j'$.

So we have

$$Cl_{n+8,0} \cong Cl_n \otimes \mathbb{R}(16), \quad \mathbb{C}l_{n+2,0} = Cl_{n+2,0} \otimes \mathbb{C} = \mathbb{C}l_{n,0} \otimes \mathbb{C}(2).$$

because $\mathbb{H}\otimes\mathbb{C} = \mathbb{C}(2)$, and

$$\begin{bmatrix} n & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ Cl_{n,0} & \mathbb{R} & \mathbb{C} & \mathbb{H} & \mathbb{H}\oplus\mathbb{H} & \mathbb{H}(2) & \mathbb{C}(4) & \mathbb{R}(8) & \mathbb{R}(8)\oplus\mathbb{R}(8) \\ \mathbb{C}l_{n,0} & \mathbb{C} & \mathbb{C}\oplus\mathbb{C} & & & & & & \end{bmatrix}$$

The Clifford algebra is a $\mathbb{Z}_2$-graded algebra, $Cl = Cl^0 \otimes Cl^1$ and $Cl_{n-1} \cong Cl_n^0$ by the mapping $e_i \to e_i \otimes e_{n+1}$. This is in fact the decomposition of the chirality operator $\Gamma = (-1)^{\lfloor \frac{n+1}{2} \rfloor} e_1e_2\ldots e_n, \Gamma^2 = 1$.

Prop. (11.7.4.17). For n even, $\mathbb{C}(V)$ is naturally isomorphic to $\mathrm{End}_{\mathbb{C}}(\Lambda^*W)$, where $W = \{\frac{1}{\sqrt{2}}(e_{2i-1} - ie_{2i})\}$. This isomorphism is not obvious and restrict to a Spinor representation of $\mathrm{Spin}(n)$ and $\rho(\Gamma)^2 = 1$ induce two representations of $Cl(n)^0$, in particular $\mathrm{Spin}(n)$, called the **(half Spinor representations)**. This has a unique extension to representation of Spin^c. $\wedge^*W$ comes with a Hermitian metric which is preserved by the action of $\mathrm{Pin}(n)$ (check). So the image is $\mathrm{SO}(n)$ is in $SO(\wedge^*W)$. Cf.[Jost Geometric analysis P72].

Def. (11.7.4.18) [Spin(n)]. denote $\mathrm{Pin}(n)$ as the group in Cl_n generated by v_i of norm 1. Because $v_i \cdot v_i = -1$, it is a group. And denote $\mathrm{Spin}(n)$ as the subgroup of $\mathrm{Pin}(n)$ generated by even number of v_is.

Prop. (11.7.4.19) [Action of Spin(n)]. The conjugation action $Ad(v) = v(-)v$ =reflection w.r.t v, maps $\mathrm{Pin}(n)$ to $O(n)$ and $\mathrm{Spin}(n)$ to $SO(n)$. The kernel of this mapping is $\{\pm1\}$ when n is even. This is a double covering of $SO(n)$ and $O(n)$, it is nontrivial because $1, -1$ is connected by $(\cos te_1 + \sin te_2)(\cos te_1 - \sin te_2)$.

In particular, $\mathrm{Spin}(n)$ is a universal covering of $SO(n)$ and thus simply-connected for $n \geq 3$.

Proof: Let $\alpha = e_i\beta + \gamma$, then $\beta,\gamma \in Cl^0$ and so $\alpha = ce_1\ldots e_n + d$, and c can happen only when n is odd. □

Prop. (11.7.4.20) [Center of $\mathrm{Spin}(n)$**].** $Z(\mathrm{Spin}(n)) = \begin{cases} S^1 & n=2 \\ \mathbb{Z}/2\mathbb{Z} & n=2k+1, \\ \mathbb{Z}/2\mathbb{Z}\oplus\mathbb{Z}/2\mathbb{Z} & n=4k, \\ \mathbb{Z}/4\mathbb{Z} & n=4k+2, \end{cases}$.

Proof: □

Prop. (11.7.4.21) [Low Dimensional Accidental Isomorphisms].

- $\mathrm{Spin}(2)\cong SO(2)\cong U(1)$.
- $\mathrm{Spin}(3)\cong SU(2)\cong Sp(1)$
- $\mathrm{Spin}(4)\cong SU(2)\times SU(2)$ because they are both universal coverings of $SO(4)$, by(11.7.4.22) and(11.7.4.19).
- $\mathrm{Spin}(5)\cong \mathrm{Sp}(2)$.
- $\mathrm{Spin}(6)\cong SU(4)$.

Proof: 2: because $\mathrm{Spin}(3), SU(2)$ are both universal covering of $SO(3)$, by(11.7.4.22) and(11.7.4.19), and $Sp(1)$ acts transitively on the set of unit vectors in $\mathbb{H}$ with trivial kernel. □

Fundamental Groups

Prop. (11.7.4.22).

- $SU(n-1)\to SU(n)\to S^{2n-1}$ shows $SU(n)$ are connected and simply connected. Also $\pi_2(SU(n))\cong\pi_2(SU(2))\cong\pi_2(S^3)=0$.
- $SO(n-1)\to SO(n)\to S^{n-1}$ shows $SO(n)$ are connected and $\pi_1(SO(n))\cong\pi_1(SO(3))=\mathbb{Z}/2\mathbb{Z}$ for $n\geq 3$ by(11.7.4.7)and(11.7.4.6). And $\pi_1(SO(2))=\mathbb{Z}$.
- $U(n-1)\to U(n)\to S^{2n-1}$ shows $U(n)$ are connected and $\pi_1(U(n))\cong\mathbb{Z}$.
- $SO(n,\mathbb{R})$ is a deformation retraction of $SL(n,\mathbb{R})$, and $SU(n)$ is a deformation retraction of $SL(n,\mathbb{C})$.
- $\pi_1(PSO(n)) = \begin{cases} \mathbb{Z} & n=2 \\ \mathbb{Z}/2\mathbb{Z} & n=2k+1, \\ \mathbb{Z}/2\mathbb{Z}\oplus\mathbb{Z}/2\mathbb{Z} & n=4k, \\ \mathbb{Z}/4\mathbb{Z} & n=4k+2, \end{cases}$. Because for $n\geq 3$, its universal covering is $\mathrm{Spin}(n)$, so $\pi_1(PS(n))=Z(\mathrm{Spin}(n))$(11.7.4.20).
- $\pi_1(PU(n))=\mathbb{Z}/n\mathbb{Z}$.
- $Sp(n-1)\to Sp(n)\to S^{4n-1}$ shows $Sp(n)$ are connected and simply connected.
- $\pi_1(Sp(2n,\mathbb{R}))=\pi_1(U(n))=\mathbb{Z}$ and the determinant induces an isomorphism onto $\pi_1(S^1)$. In fact, this is used to define the Maslov index.

Generals

Prop. (11.7.4.23) [Finite Subgroups of $SO(3,\mathbb{R})$**].** Every finite subgroup of $SO(3,\mathbb{R})$ is conjugate to one of the following:

- the cyclic group C_n generated by rotation.

- the dihedral group D_{2n} generated by adjoining a reflection to the rotation.
- the group A_4 of rotation of the tetrahedron.
- the group S_4 of rotations of the octahedron.
- the group A_5 of rotations of the icosahedron.

Proof: Cf.[Dornhoff, Group Representation Theory, 1971 Part A, Chap26]. □

Prop. (11.7.4.24) [Image of Exponential Maps].

- The exponential map for $GL_n(\mathbb{C})$ is surjective.
- The image of the exponential map for $GL_n(\mathbb{R})$ is $GL_n(\mathbb{R})^2$.
- The image of exponential map for B_+ which is the subgroup of $GL(n,\mathbb{R})$ consisting of upper-triangular matrices with positive entries, is surjective.
- The exponential defines a diffeomorphism from the space of Hermitian(symmetric) matrices to positive definite Hermitian(symmetric) matrices in $GL(n,\mathbb{C})(GL(n,\mathbb{R}))$.
- The exponential for a compact Lie group is surjective, by(11.7.8.6) and(11.7.8.2).

Proof: 1: Use Jordan forms. Notice the logarithm of $(cI+N), c\neq 0$ is definable for N nilpotent, and it is a polynomial function of the matrix itself.

2: It is clear the image is contained in $GL(n,\mathbb{R})^2$, conversely, we see from the complex case that any $B\in GL(n,\mathbb{R})$ is of the form $\exp(P(B))$ for some polynomial $P\in\mathbb{C}[X]$, then $T=B^2=\exp(P(B)+\overline{P}(B))\in\exp(GL(n,\mathbb{R}))$.

3: Use Jordan forms. Notice the logarithm of $(cI+N), c\neq 0$ is definable for N nilpotent and $c>0$, and it is a polynomial function of the matrix itself, so it is also upper-triangular.

4: By(2.3.8.3) it is clearly surjective. For injectivity, consider $\exp(X)=\exp(Y)$, then at least X,Y are both unitarily conjugate to the same diagonal matrix $\mathrm{diag}(d_1,\ldots,d_n)$, and we may assume $Y=\mathrm{diag}(d_1,\ldots,d_n)$, then

$$X=\tau^{-1}Y\tau,\quad \mathrm{diag}(D_1,\ldots,D_n)=\tau^{-1}\,\mathrm{diag}(D_1,\ldots,D_n)\tau$$

where $D_i=e^{d_i}$. Consequently, $\mathrm{diag}(D_1^k,\ldots,D_n^k)=\tau^{-1}\,\mathrm{diag}(D_1^k,\ldots,D_n^k)\tau$, and we can choose c_i that $\sum c_iD_j^i=d_j$ for any j, because the Vandermonde matrix is nonsingular. Hence $\mathrm{diag}(d_1,\ldots,d_n)=\tau^{-1}\,\mathrm{diag}(d_1,\ldots,d_n)\tau$, so $X=Y$. □

5 Compact Lie Groups and Representations

Prop. (11.7.5.1). Any compact connected complex Lie group is Abelian. And it is a complex tori. So we only consider only compact real Lie groups.

Proof: Mimic the proof that Abelian variety is commutative(13.5.1.5), using a similar rigidity lemma. □

Cor. (11.7.5.2). $U(n)$ is not a complex Lie group, in particular not a complex algebraic variety.

Prop. (11.7.5.3). Let G be a compact connected Lie group with Lie algebra $\mathfrak{g}$ and center Z. Let G_{ss} be the connected subgroup of G corresponding to the Lie subalgebra $[\mathfrak{g},\mathfrak{g}]$(11.7.3.12), then G_{ss} has finite center, and Z^0, G_{ss} are closed in G, and $G=Z^0G_{ss}$.

Proof: Cf.[Kna96]P198. □

Prop. (11.7.5.4) [Compact Lie Group and Representations]. A compact topological group G is a real Lie group iff it has a faithful real f.d. representation. And in this case, it is a closed subgroup of $U(n)$ for some n.

Proof: If it has a faithful f.d. representation, then $G\subset GL(n,\mathbb{R})$ compact hence closed, thus a Lie subgroup by(11.7.1.22).

Conversely, if G is a Lie group, then we can choose a small nbhd U of $e\in G$ that contains no non-trivial subgroup of G(choose $\exp(\frac{1}{2}V)$ where exp is an diffeomorphism on V). Consider kernel K_π for irreducible representations π of G, then $\cap_\pi K_\pi=\varnothing$ by Gelfand-Raikov(10.11.2.22), in particular $\cap_\pi(K_\pi-U)=\varnothing$. But $G-U$ is compact, hence there are f.m. π_i that $\cap_i K_{\pi_i}\in U$, but by definition of U, $\cap_i K_{\pi_i}=\{e\}$, which gives a f.d. faithful representation of G, by(10.11.4.4). □

Prop. (11.7.5.5) [Reduction to Faithful Representations]. Let V be a faithful f.d. representation of a compact Lie group G and Y is an irreducible f.d. representation of G, then Y is a direct summand of $V^{\otimes n}\otimes V^{*\otimes m}$ for some $m,n\geq 0$. Moreover, if G is unimodular, we can take $m=0$.

Proof: Cf.[Etingof, P175]. □

Remark (11.7.5.6). Theory of Representations of compact Lie groups are a special case of abstract harmonic analysis10.11.

<u>**Maximal Tori**</u>

Prop. (11.7.5.7) [Tori]. Any connected compact Abelian real Lie group is a torus.

Proof: By(11.7.4.24), the exponential map realizes $\mathfrak{g}$ as the universal cover of G, and the kernel is then a complete lattice Λ in $\mathbb{R}^n$, so $G\cong\mathbb{R}^n/\Lambda\cong(S^1)^n$. □

Prop. (11.7.5.8). The maximal tori in a compact Lie group G corresponds to the maximal Abelian subalgebras of $\mathfrak{g}$.

Proof: Let T be a maximal tori, then $\mathfrak{t}$ is maximal Abelian by fundamental theorem of Lie(11.7.3.12). Conversely, if $\mathfrak{t}$ is a maximal tori, then the corresponding Lie subgroup T is Abelian, and $\overline{T}$ is also Abelian. The Lie algebra of $T,\overline{T}$ are the same by maximality of $\mathfrak{t}$, so $T=\overline{T}$, and it is a torus by(11.7.5.7), and it is clearly maximal. □

Prop. (11.7.5.9). Let G be a compact connected Lie group with Lie algebra $\mathfrak{g}$, then any two maximal Abelian subalgebra of $\mathfrak{g}$ are conjugate via $\mathrm{Ad}(G)$.

Proof: Let $\mathfrak{t},\mathfrak{t}'$ be two maximal Abelian subalgebra of $\mathfrak{g}$. As $\mathfrak{g}$ is reductive(2.5.5.3), if we choose $X\in\mathfrak{t},X'\in\mathfrak{t}'$ that are not zero for any roots, then $Z_\mathfrak{g}(X)=T,Z_\mathfrak{g}(X')=T'$. Let $(\cdot,\cdot)$ be a invariant inner product on $\mathfrak{g}$ defined in(11.7.8.2), choose a $g_0\in G$ that $(\mathrm{Ad}(g_0)X,X')$ is maximal, then $0=([Z,\mathrm{Ad}(g_0)X,X')=(Z,[\mathrm{Ad}(g_0)X,X'])$ for any $Z\in\mathfrak{g}$, so $\mathrm{Ad}(g_0)X\in Z_\mathfrak{g}(X')=\mathfrak{t}'$. Thus $\mathfrak{t}'\subset Z_\mathfrak{g}(\mathrm{Ad}(\mathfrak{g}_0)X)=\mathrm{Ad}(g_0)Z_\mathfrak{g}(X)=\mathrm{Ad}(g_0)\mathfrak{t}$, and the equality holds as $\mathfrak{t}'$ is maximal. □

Cor. (11.7.5.10) [Maximal Tori are Conjugate]. Let G be a compact connected Lie group, then any two maximal tori of G are conjugate via $\mathrm{Ad}(G)$.

Prop. (11.7.5.11). Let G be a compact connected Lie group, then any element of G is connected in a maximal torus.

Proof: By(11.7.4.24), this element is contained in a 1-parameter subgroup T of G, and $\overline{T}$ is also Abelian, so is a torus by(11.7.5.7). Then choose a maximal torus containing $\overline{T}$. □

Cor. (11.7.5.12). The center of G is contained in any maximal torus, by(11.7.5.10).

Prop. (11.7.5.13). Let S be a torus in a compact Lie group G and $g\in G$ that commutes with elements in S, then there is a torus containing both S and g.

Proof: Let A be the closure of $\cup_{i\in\mathbb{Z}}g^iS$, and A_0 the identity component of A, then as A is compact, A_0 is open in A and compact, so $\cup_{i\in\mathbb{Z}}g^iA_0=A$, and also A/A_0 is a cyclic group. As A_0 is a torus, we can find $a\in A$ that the closure of $\{a^n|n\in\mathbb{Z}\}$ is A. By(11.7.4.24), let $a=\exp_G(X)$, then the closure of the 1-parameter group generated by X is a torus containing both S and g. □

Cor. (11.7.5.14). In a compact connected Lie group G, then centralizer of a torus T is connected. In fact, it is the union of maximal tori containing T. In particular, a maximal torus is self-centralizing.

Highest Weight Theory

Cf.[Compact Lie Groups, Sepanski].Chap7.

Examples of Representations

Prop. (11.7.5.15) [Representations of $SU(2)$]. $SU(2)\cong S^3$ is simply connected with Lie algebra $\mathfrak{sl}_2(\mathbb{R})$(11.7.4.6), thus we can use(11.7.3.14) and(15.8.1.14) to see that the representations of $SU(2)$ are all of the form W_n, where W_n is the representation of $SU(2)$ on the space of homogenous polynomials of degree n in two variables x,y induced by $\begin{bmatrix}a&b\\c&d\end{bmatrix}\begin{bmatrix}x\\y\end{bmatrix}=\begin{bmatrix}ax+by\\cx+dy\end{bmatrix}$.

Proof: Check the central character of the induced representations of Lie algebra. □

Prop. (11.7.5.16). Let $G=SO(n)$ for $n\not\equiv 2 \mod 4$. Show that:

1. For any element $g\in G$, g and g^{-1} are conjugate in $SO(n)$.
2. Any irreducible finite-dimensional $\mathbb{C}$-representation V of G is isomorphic to its dual.

Proof: 1: By(2.3.8.16), if $n=2m+1$, g is orthogonally diagonal to a matrix of the form $\mathrm{diag}\{SO(2,\mathbb{R}),\ldots,SO(2,\mathbb{R}),1\}$. Notice $SO(2,\mathbb{R})=\{k_\theta,\theta\in(0,2\pi]\}$, where $k_\theta=\begin{bmatrix}\cos\theta&\sin\theta\\-\sin\theta&\cos\theta\end{bmatrix}$, and $k_\theta^{-1}=k_{-\theta}=k_\theta^t$. If we take $W=\mathrm{diag}\{\begin{bmatrix}&1\\1&\end{bmatrix},\ldots,\begin{bmatrix}&1\\1&\end{bmatrix},(-1)^m\}$, then $W\in SO(n,\mathbb{R})$ and $WgW^{-1}=g^{-1}$.

If $n=4k$, then g is orthogonally diagonal to a matrix of the form $\mathrm{diag}\{SO(2,\mathbb{R}),\ldots,SO(2,\mathbb{R})\}$. If we take $W=\mathrm{diag}\{\begin{bmatrix}&1\\1&\end{bmatrix},\ldots,\begin{bmatrix}&1\\1&\end{bmatrix}\}$, then $W\in SO(n,\mathbb{R})$ and $WgW^{-1}=g^{-1}$.

2: Because $\chi_{V^*}(g)=\chi_V(g^{-1})=\chi_V(g)$ as g,g' are in the same conjugacy class, V and V^* are isomorphic, because f.d. representations are determined by characters(2.4.1.13)(applied to the group algebra $\mathbb{C}[G]$). □

Maximal Compact Subgroup

For maximal compact subgroup of general locally compact subgroups, Cf.1.

Prop. (11.7.5.17) [Uniqueness for Semisimple Lie group]. Maximal compact subgroup exists by(10.11.1.47), and for a semisimple Lie group G, the maximal compact subgroup is unique up to conjugation.

Proof: Cf.[Wiki]. □

Prop. (11.7.5.18) [Examples of Maximal Subgroups].

- $O(n)$ is the maximal compact subgroup of $GL(n,\mathbb{R})$.
- $SO(n)$ is the maximal compact subgroup of $SL(n,\mathbb{R})$.
- $SO(m,n)$ is the maximal compact subgroup of $S(O(m)\times O(n))$.
- $SO(n)$ is the maximal compact subgroup of $SL(n,\mathbb{R})$.
- $SU(n)$ is the maximal compact subgroup of $SL(n,\mathbb{C})$.
- $SU(m,n)$ is the maximal compact subgroup of $S(U(m)\times U(n))$.
- $SO(n)$ is the maximal compact subgroup of $SO(n,\mathbb{C})$.
- $U(n)$ is the maximal compact subgroup of $GL(n,\mathbb{C})$.
- $SU(n)$ is the maximal compact subgroup of $SL(n,\mathbb{C})$.
- $Sp(n)$ is the maximal compact subgroup of $Sp(n,\mathbb{C})$, by(11.7.4.15).
- $Sp(m,n)$ is the maximal compact subgroup of $Sp(m)\times Sp(n)$.
- $Sp(n)$ is the maximal compact subgroup of $SL(n,\mathbb{H})$, by(11.7.4.15).
- $U(n)$ is the maximal compact subgroup of $O^*(n)$, by(11.7.4.15).

And the above maximal compact subgroups are also deformation retractions.

Proof: This follows from polar decomposition(11.7.6.2), notice that the projection of a compact group is a compact group in $\mathbb{R}^n$, so it is trivial. □

6 Decompositions

Prop. (11.7.6.1) [Cartan Decomposition]. Let $G=GL(n,\mathbb{R}),K=O(n)$ or $G=GL(n,\mathbb{R})^+,K=SO(n)$, then every double coset $K\backslash G/K$ has a unique representation of diagonal matrix D with decreasing positive entries.

Proof: For the existence, given g, consider $S=g^tg=k_1^{-1}\operatorname{diag}(\lambda_1,\ldots,\lambda_n)k_1$, where $k_1\in SO(n)$(2.3.8.3). Then consider

$$k_2=gk_1^{-1}\operatorname{diag}(\lambda_1^{-1/2},\ldots,\lambda_n^{-1/2})$$

it is orthogonal and $g=k_2\operatorname{diag}(\lambda_1^{1/2},\ldots,\lambda_n^{1/2})k_1$.

For the uniqueness, consider $gk_1^{-1}\operatorname{diag}(\lambda_1^{-1/2},\ldots,\lambda_n^{-1/2})$ is orthogonal, thus $k_1Sk_1^{-1}$ is diagonal with decreasing positive entries, thus uniquely defined. □

Prop. (11.7.6.2) [Polar Decomposition for Linear Groups]. Let $G\subset GL(n,\mathbb{C})$ be a closed linear group that is defined by the a family of real valued polynomials in the real and imaginary parts of entries of G, and G is closed under conjugation. Let $K=G\cap U(n)$, and let $\mathfrak{p}$ be the subspace of Hermitian matrices in $\mathfrak{g}$, then the map $K\times\mathfrak{p}\to G:(k,X)\mapsto k\exp(X)$ is a homeomorphism. In particular, G has K as deformation retracts.

Proof: The $GL(n,\mathbb{C})$ case follows from(10.10.4.20) and(11.7.4.24), and for the general case, it suffices to show if $g\in G$ and $g=k\exp(X)$, then $X\in\mathfrak{g}$: By hypothesis, $g^*g=e^{2X}\in G$. Take a basis that $2X=\mathrm{diag}(a_1,\ldots,a_n)$ with a_i real, then $e^{2kX}=\mathrm{diag}(e^{ka_1},\ldots,e^{ka_n})$ are all in G. Then it can be easily shown any polynomial that vanishes at all such e^{2kX} vanishes on all e^{2tX}, thus $X\in\mathfrak{g}$. □

Cor. (11.7.6.3). $GL(n,\mathbb{R})\cong P\cdot O(n)$, where P is the set of positive symmetric matrix, by(11.7.4.24).

Prop. (11.7.6.4) [QR-Decomposition].

- Any real matrix A has the form $A=QR$ where Q is orthogonal and R is upper triangular with positive diagonal entries. Moreover, if A is invertible, then the decomposition is unique.
- Any complex matrix A has the form $A=QR$ where Q is unitary and R is upper triangular with positive diagonal entries. Moreover, if A is invertible, then the decomposition is unique.
- Any Quaternion matrix A has the form $A=QR$ where $Q\in U(n,\mathbb{H})$(11.7.4.15) and R is upper triangular with positive diagonal entries. Moreover, if A is invertible, then the decomposition is unique.

Proof: We only prove for $GL(n,\mathbb{R})$, the rest is similar. Use Gram-Schmidt orthogonalization: choose a basis $v=\{v_1,\ldots,v_n\}$ of V and A acts on V, then A maps $\{v_1,\ldots,v_n\}$ to a set $\{w_1,\ldots,w_n\}$. Then we can define an orthonormal basis $\{e_1,\ldots,e_n\}$ that $v_k\in span\{e_1,\ldots,e_k\}$. Now let $\{w_1,\ldots,w_n\}=\{e_1,\ldots,e_n\}R$, then R is upper triangular, and $Q=[e_1,\ldots,e_n]_v$ is orthogonal, and $A=QR$. We can make diagonal entries of R positive by left multiplying a diagonal orthogonal matrix.

To show the uniqueness when A is invertible, let $A=Q_1R_1=Q_2R_2$, then $A^tA=R_1^tR_1=R_2^tR_2$. Then $(R_2)^{-t}R_1^t=R_2R_1^{-1}$, where the LHS is lower-triangular and the RHS is upper-triangular, which means both of them are diagonal. Then if α_i are the diagonal entries of R_1 and β_i are the diagonal entries of R_2, then $\alpha_i/\beta_i=\beta_i=\alpha_i$, which means $\alpha_i=\beta_i$, and $R_2R_1^{-1}=1$. □

Prop. (11.7.6.5) [Bruhat Decomposition]. Let K be a field, B be the set of upper-triangular matrices, N be the set of unipotent upper-triangular matrices, then

$$GL(n,K)=BWB=BWN$$

where W is the set of permutation matrices, B is the invertible upper triangular matrices, and the decomposition is a disjoint union w.r.t. W.

Moreover, if K is a topological field, there is a lexicographical stratification $0=W_0\subset W_1\subset\ldots\subset W_{n!}$ of $GL(n,K)$ that W_k is closed in W_{k+1} and each $W_{k+1}\backslash W_k$ is a double coset BwB.

Proof: For any matrix $M\in GL(n,K)$, consider the first column, then there is a lowest term a_{i_11} that are not zero, then we can left multiply an upper triangular matrix b_1 s.t. the first column of b_1M has only one nonzero entry $a_{i_11}=1$, then consider the second column but ignore the k-th row, we can find a lowest term a_{i_22} that is non-zero, then left multiply an upper triangular matrix b_2 that the second column of b_2b_1M has only one non-zero entry $a_{2i_2}=1$. Now continuing this way, we find a permutation σ that only the entries a_{ij} that $j \geq \sigma^{-1}(i)$ are non-zero. Then we can find an upper triangular matrix c that $b_n b_{n-1} \dots b_1 M c$ is a permutation matrix $M_{\sigma^{-1}}$.

So we proved $BWB = GL(n, K)$. Now it suffices to show if $M_{\sigma_1}^{-1} b M_{\sigma_2} \in B$ for some $b \in B$, then $\sigma_1 = \sigma_2$: Because $M_\sigma = \sum_i e_{\sigma(i)i} = \sum_i e_{i\sigma^{-1}(i)}$,

$$M_{\sigma_1^{-1}} b M_{\sigma_2} = \sum_{ij} b_{\sigma_1(i)\sigma_2(j)} e_{ij}.$$

This is an element in B, both its $(\sigma_1^{-1}(k), \sigma_2^{-1}(k))$-entry is $b_{kk} \neq 0$, thus $\sigma_1^{-1}(k) \leq \sigma_2^{-1}(k)$, which implies $\sigma_1 = \sigma_2$. □

Cor. (11.7.6.6). If N is the group of unipotent upper triangular matrices, then $GL(n, L) = BWN$.

Prop. (11.7.6.7)[Smith Normal Form]. Let R be a PID, and K its fraction field. Choose a representative $\mathcal{P}$ for associativity classes of any prime in R(to eliminate the distraction of units), then there is complete set of representatives for the double cosets of $GL(n, R) \backslash GL(n, K) / GL(n, R)$ consisting of diagonal matrices $\text{diag}(f_1, \dots, f_n)$, where $f_i \in K$ are products of elements in $\mathcal{P}$, and f_k divides f_{k+1}. Notice $GL(n, R)$ is the matrices with unit determinants in R.

Proof: For the uniqueness, clearly the row operators doesn't change the greatest common divisor of $k \times k$ minors of M for any k(change by a scalar but the diagonal entries are monic), thus the entries are determined by the minors of M.

For the existence, for any $g \in GL(n, K)$ there is an $r \in R$, that rg has coefficients in R, and also r is a product of elements in $\mathcal{P}$. let M be the submodule of R^n generated by the rows of rg, then by the elementary divisor theorem(2.2.4.24), there exists a basis ξ_i for R^n and $d_i \in R$ that $d_i | d_{i+1}$, and $\{d_i \xi_i\}$ form a basis of M. we may assume d_i are products of elements in $\mathcal{P}$. Then the matrix ξ with rows ξ_i are in $GL(n, R)$, and the rows of the matrix $\text{diag}(d_1, \dots, d_n)\xi$ span the same module as rg. Then

$$K_1 rg = \text{diag}(d_1, \dots, d_n)\xi$$

for some $K_1 \in GL(n, R)$, so g are in the same double coset as $\text{diag}(r^{-1}d_1, \dots, r^{-1}d_n)$. □

Prop. (11.7.6.8) [Iwasawa Decomposition].

7 Semisimple Lie Groups

Def. (11.7.7.1) [Semisimple Lie Group]. A **semisimple/solvable/nilpotent/simple Lie group** is a Lie group with a semisimple/solvable/nilpotent/simple Lie algebra.

Def. (11.7.7.2) [Adjoint Lie Group]. An **adjoint Lie group** is a semisimple real Lie group(11.7.7.1) with trivial center.

Prop. (11.7.7.3). Let G be a semisimple complex Lie group, then the center Z of G is contained in G^c, thus the restriction of f.d. representations of G to G^c is an equivalence of categories.

Proof: Cf.[Etingof, P209] □

Maximal Tori

Prop. (11.7.7.4). Let G be a complex semisimple Lie group with Lie algebra $\mathfrak{g}$, compact form $\mathfrak{g}^c$ and compact part G^c, then

8 Analysis

Lemma (11.7.8.1). Let H be a Lie subgroup of G and $g \notin H$, then there is a smooth function Φ on G that $\Phi(xh) = \Phi(x)$ for any $x \in G, h \in H$, and $\Phi(H) = 0$, yet $\Phi(g) \neq 0$.

Proof: Because H is closed, there is a nbhd U of g disjoint from H and a function φ supported in U. Then $\Phi(x) = \int_H \varphi(xh)dh$ satisfies the desired condition. □

Bi-Invariant Metric

Lemma (11.7.8.2). Bi-invariant metric exists in a compact Lie group.

Proof: Because the Haar measure on a compact metric is bi-invariant. Choose a Riemann metric and set

$$\langle V, W\rangle = \int_{G\times G} \langle L_{\sigma *}R_{\tau *}(V), L_{\sigma *}R_{\tau *}(W)\rangle d\mu(\sigma)d\mu(\tau).$$

Note that L_* and R_* commute. □

Prop. (11.7.8.3). For a left-invariant metric on a connected Lie group G, if it is bi-invariant, then the inner product at the origin e is invariant under $\mathfrak{g}$(2.5.1.13), and the converse is also true if G is connected.

Proof: If the metric is invariant, then for any $X, Y, Z \in \mathfrak{g}$, $\langle \mathrm{Ad}(\exp(tX))Y, \mathrm{Ad}(\exp(tX))Z\rangle = \langle X, Y\rangle$, so we take derivation w.r.t. t to get

$$\langle \mathrm{ad}(X)Y, Z\rangle + \langle Y, \mathrm{ad}(X)Z\rangle = 0$$

by(11.7.1.12).

Conversely, if this is invariant, then using $\exp(tX) = \exp((t-t_0)X)\exp(t_0X)$, we get $\partial(\langle \mathrm{Ad}(\exp(tX))Y, \mathrm{Ad}(\exp(tX))Z\rangle)/\partial t = 0$ for all t, thus $\langle \mathrm{Ad}(\exp(tX))Y, \mathrm{Ad}(\exp(tX))Z\rangle = \langle X, Y\rangle$, and it is invariant under right actions by $\exp(tX)$ also. As G is generated by the elements $\exp(X)$(3.11.1.3), it is right-invariant under G. □

Prop. (11.7.8.4). If G is a Lie group with a bi-invariant metric, then

$$\nabla_X Y = 1/2[X, Y], \quad R(X, Y)Z = 1/4[[X, Y], Z], \quad K(\sigma) = 1/4\Big|[X, Y]\Big|^2.$$

So it has non-positive sectional curvature, and its curvature is non-negative, and all 1-parameter subgroups are geodesics from e.

Proof: It suffices to show that $\langle Z, \nabla_X Y\rangle = 1/2\langle Z, [X, Y]\rangle$ for any Z, and this follows from(11.2.3.16). The second follows from the first and the definition(11.2.3.11). □

Cor. (11.7.8.5). A bi-invariant Lie group with $\mathfrak{g}$ having trivial center is compact and $\pi_1(G)$ finite.

Proof: The Ricci curvature has a positive lower bound, otherwise for some X, $[X, Y] = 0$ for all Y, thus X is in the center. Hence we use Myer theorem(11.2.5.20). □

Cor. (11.7.8.6). If G has a bi-invariant metric, then the exp map $\mathfrak{g} \to G$ is surjective.

Proof: Because exp is defined for any $X \in \mathfrak{g}$, and for any $g \in G$ and $v \in T_g(G)$, $\exp_p(v) = L_g(\exp(dL_{g^{-1}})_g(v))$ because L_g is an isomorphism of Riemann manifolds. So by Hopf-Rinow(11.2.3.46), G is complete. Thus for any q, there is a geodesic connecting e, q, which is a 1-parameter subgroup, thus $q = \exp(X)$ for some $X \in \mathfrak{g}$. □

Prop. (11.7.8.7) [Structure of bi-invariant Lie groups]. A simply-connected Lie group with a bi-invariant metric is equal to $G^{'} \times R^k$, $G^{'}$ compact.

Proof: Because the orthogonal complement of the center of $\mathfrak{g}$ is a Lie algebra, G is like $G^{'} \times R^k$, and a simply connected abelian Lie group is R^k **?**. □

11.8 Complex Geometry

Basic References are [Voi02], [Principle of Algebraic Geometry Griffith/Harris], more advanced stuffs to add from [Kähler Geometry] and [Huy05]. Even more advanced is [Demailly Complex Analytic and Differential Geometry].

1 Complex Manifolds

Def. (11.8.1.1) [Complex Manifold]. A **complex manifold** is an even dimensional manifold that the transformation matrices are holomorphic. The category of complex manifolds are denoted by $\mathbb{C}$-$\mathfrak{Mani}$.

Prop. (11.8.1.2) [Andreotti-Franlcel]. Let $M^n \subset \mathbb{C}^n \in \mathbb{C}\text{-}\mathfrak{Mani}^n$, then M is homotopic to a CW complex of real dimension$\leq n$.

Proof: □

Prop. (11.8.1.3) [Adjunction Formula]. The normal sheaf of a submanifold $Y \subset X$ is defined the same as the case of nonsingular varieties(5.10.1.17), then the same is true of the adjunction formula:

$$\mathcal{K}_Y \cong \mathcal{K}_X \otimes \det \mathcal{N}_{Y/X}$$

In case Y is of codimension 1, $\mathcal{N}_{Y/X} \cong \mathcal{L}(Y)|_Y = \mathcal{O}_Y(Y)$.

Prop. (11.8.1.4) [Remmert]. A non-compact complex manifold admits a proper holomorphic embedding into $\mathbb{C}^N$ for some N iff it is a Stein manifold.

Proof: **?** □

Prop. (11.8.1.5) [Siegel]. Let $X \in \mathbb{C}\text{-}\mathfrak{Mani}^n$, then the field $R(X)$ of meromorphic functions on X has transcendence degree$\leq n$ over $\mathbb{C}$. And in case $\mathrm{tr.deg}[R(X) : \mathbb{C}] = n$, it is a f.g. field extension of $\mathbb{C}$. Then we define the **algebraic dimension** of a compact connected complex manifold X to be $\dim^{\mathrm{alg}}(X) = \mathrm{tr.deg}\, R(X)$.

Proof: It suffices to show that given any meromorphic functions $f_1, \ldots, f_{n+1}$, there is an algebraic relation between them.

Now for each x, there is a nbhd U_x that any f_i writes as the quotient of two holomorphic functions $\frac{g_{i,x}}{h_{i,x}}$. And assume $W_x \subset V_x \subset \overline{V_x} \subset U_x$ are the metric balls $B(x, \frac{1}{2}) \subset B(x, 1)$. As X is compact, there are N x_k that $X = \cup W_{x_k}$.

As on the intersections, $\frac{g_{i,k}}{h_{i,k}} = \frac{g_{i,l}}{h_{i,l}}$, any we can assume they are all prime, so $\frac{g_{i,k}}{g_{i,l}} = \varphi_{i,kl}$ is a unit. Let $\varphi_{kl} = \prod_i \varphi_{i,kl}$, as X is compact, let $C = \max_{k,l} \varphi_{kl} \geq 1$.

For any homogenous polynomial $F \in \mathbb{C}[X_1, \ldots, X_{n+1}]$ of deg m, let $G_k = F(\frac{g_{1,k}}{h_{1,k}}, \ldots, \frac{g_{n,k}}{h_{n,k}})(\prod_i h_{ik})^m$. Then G_k are holomorphic and $G_k = \varphi_{lk}^m G_l$ on the intersection. Now I claim for any $M > 0$, there is a F that G_k vanishes vanishes up to at least order M at x_k.

For this, just consider the dimension of all homogenous polynomials of degree m is C^m_{m+n+1}, and the number of desired equations of elements needs to be vanish is $N \cdot C^{m'-1}_{m'-1+n}$, so this always can be achieved when m is sufficiently large.

By Schwartz lemma(10.6.5.4), $|G_k(x)| \leq (\frac{1}{2})^{m'} C'$, where $C' = \max\{|G_k(x)||k = 1, \ldots, n, x \in \overline{V_k}\}$.

If $C' = |G_k(x)|$, and $x \in W_l$, then $C' = |G_l(x)||\varphi_{lk}^m(x)| \leq \frac{C'}{2^{m'}} \cdot C^m$. If for some m, m', $C^m < 2^{m'}$, then this shows $C' = 0$ which will finish the proof.

Look back at the condition of m, m', $C^m_{m+n+1} > N \cdot C^{m'-1}_{m'-1+n}$ can be achieved together with $m < \lambda m'$ for any λ, because the left hand is degree $n+1$ in m and the right hand is degree n in m'. □

Almost Complex Structure

Def. (11.8.1.6) [Almost Complex Structures]. For M a real orientable manifold of dimension $2n$, an **almost complex structure** is a real bundle map $J : T_{\mathbb{C}}M \to T_{\mathbb{C}}M$ satisfying $J^2 = -1$. A manifold with an almost complex structure is called an **almost complex manifold**.

A complex manifold has an almost complex structure, just define

$$J(\frac{\partial}{\partial x_i}) = \frac{\partial}{\partial y_i}, \quad J(\frac{\partial}{\partial y_i}) = -\frac{\partial}{\partial x_i}.$$

Def. (11.8.1.7) [Complex Differentials]. Situation as in(11.8.1.6), J will define a bundle map $J : T^*M \to T^*M$, and it has two eigenvalues $\pm\mathrm{i}$, denoted by $T^{*1,0}M$ and $T^{*0,1}M$. The **formal differential forms** $\wedge^k T^*M \cong \oplus_{0\le p\le k} \wedge^{p,k-p} T^*M$.

Define $\partial = \mathrm{pr}_{p+1,q} \circ \mathrm{d}$ on $\wedge^{p,q}T^*M$, and $\overline{\partial} = \mathrm{pr}_{p,q+1} \circ \mathrm{d}$ on $\wedge^{p,q}T^*M$.

Def. (11.8.1.8)[Integrability]. An almost complex structure (M, J) is called **integrable** iff it satisfies the following equivalent conditions:

- $d\alpha = \partial\alpha + \overline{\partial}\alpha$.
- $d\alpha = \partial\alpha + \overline{\partial}\alpha$ is true for $\alpha \in \Omega^{1,0}(M)$
- $[T^{0,1}X, T^{0,1}X] \subset T^{0,1}X$.
- $\overline{\partial}^2 f = 0$ for functions f.

Proof: 1 $\iff$ 3 is because by(11.1.3.6), if $u, v \in T^{0,1}X$,

$$d\alpha(u, v) = u(\alpha(v)) - v(\alpha(u)) - \alpha([u, v]) = -\alpha([u, v]).$$

3 $\iff$ 4 is because by(11.1.3.6), if $\alpha = \overline{\partial} f$ and $u, v \in T^{0,1}X$, then

$$\overline{\partial}^2 f(u, v) = u(\overline{\partial} f(v)) - v(\overline{\partial} f(u)) - \overline{\partial} f([u, v]) = u(df(v)) - v(df(u)) - \overline{\partial} f([u, v]) = \partial f([u, v])$$

□

Thm. (11.8.1.9)[Nirenberg-Newlander]. Given an almost complex manifold (M, J), it is integrable iff it comes from a complex structure.

Proof: Cf.[Foundation of Differential Geometry Kobayashi Chap9.2]. □

Cor. (11.8.1.10). For $M \in \mathbb{C}$-$\mathfrak{Mani}$,

$$\overline{\partial}^2 = 0, \quad \partial\overline{\partial} + \overline{\partial}\partial = 0, \quad \partial^2 = 0.$$

2 Deformation of Complex Structures

Cf.[Kähler Geometry] and [Complex Geometry, Daniel Chap6], should be completed as soon as possible.

3 Analytic Spaces and Coherence Sheaves

Cf.[Demailly] and [GAGA Serre].

Analytic Subvarieties

Def. (11.8.3.1) [Analytic subvariety]. An **analytic subvariety** is a closed subset of a complex manifold that is locally defined by f.m. holomorphic functions. The **regular points** of an analytic subvatiety locally defined by k functions is the points that $\mathrm{rank}((\frac{\partial}{\partial z_j}f_i)_{i\leq k, j\leq n}) = k$.

Prop. (11.8.3.2) [Proper Mapping Theorem]. If U, M are complex manifolds and $M \subset U$ is an analytic subvariety, then if $f : U \to N$ is a holomorphic mapping whose restriction on M is proper, then $f(M)$ is an analytic subvariety of N.

Proof: Cf.[Griffith/harris P395]. □

Def. (11.8.3.3) [Local Analytic Spaces]. An **analytic space of** $\mathbb{C}^n$ is an analytic subvariety of $\mathbb{C}^n$. On an analytic space, there is a sheaf of holomorphic functions $\mathcal{O}_U$. So we can define **holomorphic map** φ as continuous functions that maps holomorphic germs to holomorphic germs, which is equivalent to the coordinates of φ are all holomorphic.

Def. (11.8.3.4) [Analytic Spaces]. An **analytic space** is a Hausdorff space X with a structure sheaf $\mathcal{O}_X$ that is locally isomorphic to an analytic space of $\mathbb{C}^n$(11.8.3.3). Morphisms are continuous maps that are locally holomorphic. Sub-analytic spaces are defined as usual.

The products of analytic spaces can be defined, and it has the product topology, unlike the case of schemes.

Prop. (11.8.3.5) [Analytic Modules]. Let $(X, \mathcal{O}_X)$ be an analytic space(11.8.3.4), an **analytic module** over X is just an $\mathcal{O}_X$-module. For a sub-analytic space Y, we have a sheaf of ideals $\mathcal{I}_Y$ which is the sheaf of germs vanishing at Y, and $\mathcal{O}_X/\mathcal{I}_Y$ is a sheaf on X that is zero outside Y, and we identify it with $\mathcal{O}_Y$.

Def. (11.8.3.6) [Coherent Analytic Sheaves]. ?

Prop. (11.8.3.7) [Coherence of Structure Sheaf]. If $(X, \mathcal{O}_X)$ is an analytic space, then $\mathcal{O}_X$ is coherent?, and the sheaf of ideals $\mathcal{I}_Y$ of any sub-analytic-space Y is also coherent.

Proof: First prove for X is an open subset of $\mathbb{C}^n$, Cf.[GAGA Serre P4]. And by definition $\mathcal{O}_X$ is a $\mathcal{O}_X$-module of f.t., and it is also coherent?, so $\mathcal{O}_X$ is coherent. $\mathcal{I}_Y$ is coherent because it is a kernel of $\mathcal{H}_X \to \mathcal{H}_Y$. □

4 Positive Current

5 Hermitian Vector Bundles

Def. (11.8.5.1) [Holomorphic and Hermitian Vector Bundles]. H A **holomorphic vector bundle** is a vector bundle on a complex manifold that the transition functions are holomorphic. A **Hermitian vector bundle** is a holomorphic vector bundle endowed with a Hermitian metric?. Any holomorphic vector bundle has a Hermitian structure, by partition of unity method.

Prop. (11.8.5.2) [Hodge Star for Hermitian bundles]. If $\mathcal{E}$ is a Hermitian vector bundle over a compact complex manifold X of complex dimension n, we define a conjugate-linear operator $\overline{*}$: $A^{p,q}(\mathcal{E}) \to A^{n-p,n-q}(\mathcal{E}) : \eta \mapsto *\overline{\eta}$, and a conjugate-linear functor $\tau E \to E^*$ induced by the Hermitian metric on E.

Then we can define $\overline{*}_E : A^{p,q}(E) \to A^{n-p,n-q}E : \eta \otimes s \mapsto \overline{*}(\eta) \otimes \tau(s)$. It can be checked that

$$(\alpha, \beta) * 1 = \alpha \wedge *_E \beta,$$

$$\overline{\partial}_E^* = -\overline{*}_{E^*}\overline{\partial}_{E^*}\overline{*}_E, \quad \overline{*}_E \Delta_{\overline{\partial}_E} = \Delta_{\overline{\partial}_{E^*}}\overline{*}_{E^*}, \quad \overline{*}_{E^*}\overline{*}_E = (-1)^{p+1} \text{ on } \Omega^{p,q}(E).$$

Hermitian Manifold

Def. (11.8.5.3) [Holomorphic Tangent Bundle]. Let M be a complex manifold, the complexified tangent bundle $T_{\mathbb{C}}M$ is defined as $TM \otimes_{\mathbb{R}} \mathbb{C}$, the **holomorphic tangent bundle** $T^{1,0}M$ and anti-holomorphic bundle $T^{0,1}M$ are defined to be the vectors generated resp. by $\frac{\partial}{\partial z_i}$ and $\frac{\partial}{\partial \overline{z}_i}$. The **holomorphic cotangent bundle** and anti-holomorphic cotangent bundle is defined to be the covectors generated by $\mathrm{d}z_i$ and $\mathrm{d}\overline{z}_i$.

Def. (11.8.5.4)[Hermitian Metric]. Let M be an almost complex manifold, a **Hermitian metric** on $T_{\mathbb{C}}M$ is a metric that is J-invariant, that is $g(Ju, Jv) = g(u, v)$. Notice(2.3.8.1) shows a Hermitian metric is equivalent to a non-degenerate Hermitian form on $T_{\mathbb{C}}M$, where g appears as the real part of the Hermitian form.

Def. (11.8.5.5) [Hermitian Manifolds]. A complex manifold with a Hermitian metric is called a **Hermitian manifold**.

Def. (11.8.5.6) [the Kähler Form]. Given a Hermitian manifold M, define the **Kahler form** ω_g as $\omega_g(u, v) = g(Ju, v)$. Then it is a real 2-form on M.

Notice $g(u, v) = \omega_g(u, Jv)$, so g can be constructed by ω_g, iff ω_g is positive(11.9.6.1).

Analytic Picard Groups

Def. (11.8.5.7) [Analytic Picard Groups]. The group of isomorphisms of holomorphic line bundles on a complex manifold X is denoted by $\mathrm{Pic}_{\mathbb{C}}(X)$, called the **analytic Picard group** of X.

Prop. (11.8.5.8) [First Chern Class]. For a connected space X, there is an exact sequence

$$0 \to \mathbb{Z} \to \mathcal{O}_X \xrightarrow{f \to e^{2\pi i f}} \mathcal{O}_X^* \to 0,$$

and it induces a map $\mathrm{Pic}_{\mathbb{C}}(X) = H^1(X, \mathcal{O}_X^*) \to H^2(X, \mathbb{Z})$, which is a just the first Chern class(same proof as in(3.14.4.19)).

WARNING: in this case it is not necessarily isomorphism, not as in the case of topological line bundles.

in particular, The image of the first Chern class is trivial in $H^2(X, \mathcal{O}_X)$.

Def. (11.8.5.9). The dual of the universal line bundle on $\mathbb{CP}^n$ is called the **hyperplane line bundle**, denoted by H or $\mathcal{O}(1)$.

Prop. (11.8.5.10). $\mathrm{Pic}_{\mathbb{C}}(\mathbb{CP}^n) \cong \mathbb{Z}$, with $\mathcal{O}(1)$ as a generator.

Proof: As $\mathbb{CP}^n$ is Kähler, use(11.10.2.5), then $H^{0,k}(X,\mathbb{C}) \cong H^k(X,\mathcal{O}_X) = H^k(X,\mathcal{K}_X\otimes\mathcal{O}(2)) = 0$ for $k\geq 1$ by Kodaira vanishing(11.9.7.3), and then $\mathrm{NS}(X) = H^{1,1}(X) = H^2(X,\mathbb{Z}) = \mathbb{Z}$ by Lefschetz $(1,1)$-form theorem(11.10.2.6). It remains to prove $c_1(\mathcal{O}(1))$ is the generator, for this, Cf.[Demailly P280]. □

Prop. (11.8.5.11). Let S_d be the set of homogenous polynomials of degree d, then

$$H^0(\mathbb{CP}^n,\mathcal{O}(d)) = \begin{cases} S_d & d\geq 0\\ 0 & d<0\end{cases}$$

Proof: This is because it is sections that satisfy $f_\alpha([z]) = (\frac{z_\beta}{z_\alpha})^k f_\beta([z])$, which says f_α glue together to give a holomorphic function homogenous of degree k on $\mathbb{C}^n\setminus\{0\}$, which extends to a function on $\mathbb{C}^n$ by(10.6.5.3), then it is easy to see it is a homogenous polynomial using the power series expansion. □

Def. (11.8.5.12) [Neron-Severi Group]. For a compact complex manifold X, the **Néron-Severi group** $\mathrm{NS}(X)$ is the image of $\mathrm{Pic}_{\mathbb{C}}(X)\to H^2(X,\mathbb{Z})$. $\mathrm{rank}(\mathrm{NS}(X))$ is called the **Picard number** of X.

There is a good description of $\mathrm{NS}(X)$ in case X is Kähler , See Lefschetz theorem(11.10.2.6).

This is compatible with the the algebraic Néron-Severi group(8.7.3.38), Cf.[G-H78]P457, [Vak17]P484.

Chern Connection

Prop. (11.8.5.13)[Chern Connection]. Given a Hermitian holomorphic bundle $E\to M$ on a complex manifold, there is a unique **Chern connection** ∇ on E, that ∇ is holomorphic(i.e. the connection matrix is holomorphic w.r.t a homomorphic frame), and it is compatible with the Hermitian metric.

Proof: Write out the requirement: if $H = h_{ij}$ is the matrix of the Hermitian metric, so H is Hermitian, and we need $dh_{ij} = (\nabla e_i, e_j) + (e_i,\nabla e_j) = \sum_k \omega_{ik}h_{kj} + \sum \overline{\omega_{jk}}h_{ik}.\omega$ is holomorphic, so must

$$\partial H = \theta H,\quad \overline{\partial} H = H\overline{\theta}^t.$$

But $H^t = \overline{H}$ so these two equations are equivalent and $\theta = \partial H H^{-1}$. □

Cor. (11.8.5.14). The curvature of the Chern connection is $\Omega = \overline{\partial}(\partial(h)h^{-1})$. In particular, it is a skew-symmetric matrix of $(1,1)$-forms. If it is of dimension 1, then $\Omega = \overline{\partial}\partial\log h$.

Proof: Ω is locally $d\omega+\omega\wedge\omega$, so if we choose a unitary basis, then ω is skew-symmetric by definition and $\omega\wedge\omega$ is also skew-symmetric, so Ω is skew-symmetric. The calculation is direct calculation. □

Prop. (11.8.5.15). The transformation matrix of a complex manifold is holomorphic, so it is possible to define globally $\overline{\partial}$ operator. And locally on a nbhd, ∂ is defined as $d-\overline{\partial}$.

Prop. (11.8.5.16) [Normal Coordinate]. For a Hermitian vector bundle E over a complex manifold X, given any coordinate frame (z_j), there exists a holomorphic frame (e_λ) that

$$\langle e_\lambda, e_\mu\rangle = \delta_{\lambda,\mu} - \sum c_{jk\lambda\mu}z_j\overline{z}_k + O(|z|^3)$$

where $c_{ij\lambda\mu}$ is the coefficient of the Chern connection Ω. Such a coordinate is called the **normal coordinate frame** of E at x.

Proof: Cf.[Demailly P270]. □

6 Cohomology

Lemma (11.8.6.1) [Dolbeault Complex, $\overline{\partial}$-Poincaré Lemma]. If X is a complex manifold of dimension n, and $\mathcal{E}$ a holomorphic vector bundle, then there is an exact sequence:

$$0 \to \Omega^{p,0}(\mathcal{E}) \xrightarrow{\overline{\partial}_{\mathcal{E}}} \Omega^{p,1}(\mathcal{E}) \xrightarrow{\overline{\partial}_{\mathcal{E}}} \ldots \xrightarrow{\overline{\partial}_{\mathcal{E}}} \Omega^{p,n-p}(\mathcal{E}) \to 0$$

If $p=0$, it is called the **Dolbeault complex** of $\mathcal{E}$.

Proof: Because tensoring $\mathcal{E}$ is exact, it suffices to show for $\mathcal{E} = \underline{\mathbb{C}}_X$. As $\overline{\partial}^2 = 0$(11.8.1.10), and the sequence is clearly exact at $\Omega^{p,0}(\mathcal{E})$, it suffices to show that if $\alpha \in \Omega^{p,q}(X), q > 0$ satisfies $\overline{\partial}\alpha = 0$, then $\alpha = \overline{\partial}\beta$ for some $\beta \in \Omega^{p,q-1}(X)$. Let

$$\alpha = \sum_I \sum_J \alpha_{I,J} \mathrm{d}z_I \wedge \mathrm{d}\overline{z}_J = \sum_I \mathrm{d}z_I (\sum_J \alpha_{I,J} \wedge \mathrm{d}\overline{z}_J),$$

then it is clear it suffices to prove for $(\sum_J \alpha_{I,J} \wedge \mathrm{d}\overline{z}_J)$, and the question is reduced to the case $p=0$.

Suppose $\alpha = \sum_J \alpha_J \wedge \mathrm{d}\overline{z}_J$, then we use induction on k which equals the maximal number s.t. there is a J with $k \in J$ and $\alpha_J \neq 0$. Notice $k \geq q$. If $k = q$, then

$$\alpha = f\mathrm{d}\overline{z}_1 \wedge \ldots \wedge \mathrm{d}\overline{z}_q,$$

and f is holomorphic in the variables $z_l, l > q$. Then the proof of(10.5.1.11) gives us a smooth function g s.t. $\frac{\partial}{\partial \overline{z}_q} g = f$ that is holomorphic in the variables $z_l, l > q$. So

$$\overline{\partial}((-1)^{q-1} g\mathrm{d}\overline{z}_1 \wedge \ldots \wedge \mathrm{d}\overline{z}_{q-1}) = f\mathrm{d}\overline{z}_1 \wedge \ldots \wedge \mathrm{d}\overline{z}_q.$$

So the case $k = q$ is proved. Suppose the assertion is true for $k-1 \geq q$, suppose

$$\alpha = \alpha_1 + \alpha_2 \wedge \mathrm{d}\overline{z}_k,$$

where only the coordinates of index$< k$ appear in α_i. Then α_2 is holomorphic in the same argument as above shows that for each J, $\alpha_{2,J} = \frac{\partial}{\partial \overline{z}_k}\beta_{2,J}$ that each $\beta_{2,J}$ is holomorphic in the variables $z_l, l > q$. Then

$$\overline{\partial}(\sum_J \beta_{2,J} \mathrm{d}\overline{z}_J) = (-1)^{q-1}\alpha_2 \wedge \mathrm{d}\overline{z}_k + \alpha_1'$$

where α_1' involves only the coordinates z_l for $l < k$. Then we eliminated $\mathrm{d}\overline{z}_k$ and can use induction hypothesis from now. □

Def. (11.8.6.2) [Dolbeault Cohomology]. The **Dolbeault cohomology group** $H^{p,q}_{\overline{\partial}}(X, \mathcal{E})$ of a holomorphic vector bundle $\mathcal{E}$ over a complex manifold X is defined to be the q-th cohomology group of the complex

$$0 \to \Omega^{p,0}(\mathcal{E}) \xrightarrow{\overline{\partial}_{\mathcal{E}}} \Omega^{p,1}(\mathcal{E}) \xrightarrow{\overline{\partial}_{\mathcal{E}}} \ldots \xrightarrow{\overline{\partial}_{\mathcal{E}}} \Omega^{p,n-p}(\mathcal{E}) \to 0$$

and $H^{p,q}_{\overline{\partial}}(X)$ is defined to be $H^{p,q}_{\overline{\partial}}(X, \underline{\mathbb{C}}_X)$. By(11.8.6.5), $H^{p,q}_{\overline{\partial}}(X, \mathcal{E}) \cong H^q_{\overline{\partial}}(M, \Omega^p_{\mathrm{hol}} \otimes_{\mathcal{O}_X} \mathcal{E})$.

Cor. (11.8.6.3). If X is a complex manifold of dimension n, there are exact sequences:

$$0 \to \underline{\mathbb{C}}_X \xrightarrow{\partial} \mathcal{O}_X \xrightarrow{\partial} \Omega^1_{\mathrm{hol}} \xrightarrow{\partial} \ldots \xrightarrow{\partial} \Omega^n_{\mathrm{hol}} \to 0$$

Proof: This follows from the Poincaré lemma(5.3.5.10) and $\overline{\partial}$-Poincare lemma(11.8.6.1), by applying the spectral sequence(I mean in the category of sheaves).**?** □

Prop. (11.8.6.4) [Holomorphic Cohomology]. For $X \in \mathbb{C}$-$\mathcal{M}$ani,

$$H^p(X, \underline{\mathbb{C}}) = H^p(X, \Omega^\bullet_{\text{hol}}).$$

Prop. (11.8.6.5) [Dolbeault]. For $X \in \mathbb{C}$-$\mathcal{M}$ani and $\mathcal{E}$ a holomorphic bundle,

$$H^{p,q}_{\overline{\partial}}(X, \mathcal{E}) \cong H^q(M, \Omega^p_{\text{hol}} \otimes_{\mathcal{O}_X} \mathcal{E}),$$

where the left is Dolbeault cohomology and the right is sheaf cohomology. (Use the fact that smooth sheaf is fine so adapted to sheaf cohomology(5.3.5.4), and $\overline{\partial}$-Poincare lemma(11.8.6.1)).

Moreover, there is a spectral sequence of

$$E_1^{p,q} = H^{p,q}_{\overline{\partial}}(X) \Rightarrow E^n = H^n_{dR}(X, \mathbb{R}) \times_{\mathbb{R}} \mathbb{C}.$$

Prop. (11.8.6.6) [Cartan]. The class of Coh-Acyclic subsets of an analytic space is exactly the class of Stein manifolds.

Proof: □

De.Rham Cohomology

Prop. (11.8.6.7). The Frölicher spectral sequence of a compact Kähler manifold generates at E_1.

Proof: □

7 GAGA

Main references are [Ser55].

Analytification of Algebraic Varieties and Sheaves

Prop. (11.8.7.1) [Analytification]. For any variety over $\mathbb{C}$, any open affine subset is isomorphic to an analytic space of $\mathbb{C}^n$, hence can be given an analytic structure X^{an} called the **analytification of** X. It is a locally ringed space, together with a map $X^{\text{an}} \to X$ of local ringed spaces.

This construction extends to a functor

$$\mathcal{S}\text{ch}^{\text{loc.ft},sep}/\mathbb{C} \to \text{AnSpa}/\mathbb{C}.$$

An **algebraic analytic space** is an analytic space that is in the essential image of this functor.

Notice X^{an} and X have in fact the same underlying sets.

Remark (11.8.7.2). There is in fact a more general analytification for any scheme locally of finite type over $\mathbb{C}$. That is, we define it as the right adjoint to the forgetful functor from analytic spaces to local ringed spaces. Where an analytic space is a local ringed space that locally has immersions into $\mathbb{C}^n$. Should consult [Grothendieck EGA1-7].

Proof: Notice the schemes that have an analytification is stable under open subscheme, closed subscheme and products, and we can make a glue a large space from open subschemes by the unicity. So we only need to consider $\operatorname{Spec} \mathbb{C}[T]$, whose analytification is $\mathbb{C}$. □

Def. (11.8.7.3) [Betti Cohomologies]. For any variety defined over $\mathbb{C}$, and $\mathbb{R}$ a ring, let $H^i_{Betti}(X,R) = H^i(X^{\mathrm{an}},R)$ be the **Betti cohomology** of X with coefficients in R.

Prop. (11.8.7.4) [Transfer of Properties].

- X^{an} is locally compact and σ-compact.
- X^{an} is Hausdorff
- A morphism $f : X \to Y$ is smooth/étaleiff f^{an} is smooth/a local isomorphism. X is smooth over $\mathbb{C}$ iff X^{an} is a complex manifold.
- A morphism $f : X \to Y$ is proper iff $X^{\mathrm{an}} \to Y^{\mathrm{an}}$ is proper. In particular, X is complete(proper) iff X^{an} is compact.
- If X is projective and connected, then X^{an} is connected iff X is connected.

Proof: 1: X is qc hence covered by f.m. affine subsets hence second-countable and use(3.3.2.23). X^{an}/X is flat because completion of Noetherian rings are flat(4.2.3.14).

2: Because analytification preserves products and morphisms, and separatedness of X shows that $\Delta(X)$ is closed in $X \times X$, hence it is also closed in the analytification.

3: This follows from the Jacobian criterion(4.4.5.24).

4: Cf.[GAGA Serre P8].

5: This follows from(11.8.7.16), as $H^0(X,\mathcal{O}_X) = H^0(X^{\mathrm{an}},\mathcal{O}_X)$. □

Prop. (11.8.7.5). There is a natural map from $\mathcal{O}_x$ to $\mathcal{H}_x$ that maps $\mathfrak{m}_x$ to $\mathfrak{m}_x\mathcal{H}_x$, thus inducing a map $\widehat{\theta} : \widehat{\mathcal{O}}_x \to \widehat{\mathcal{H}}_x$. This is an isomorphism. In particular, $\theta : \Omega_x \to \mathcal{H}_x$ is injective.

Moreover, if Y is a locally closed subscheme of X, then the local ideal of functions vanishing at Y maps to $\mathcal{A}_x(Y)$, and $\mathcal{A}_x(Y)$ is generated by $\theta(\mathcal{I}_x(Y))$. Moreover, $\mathcal{H}_{x,Y} = \mathcal{H}_x/\mathcal{I}_x(Y)$.

Proof: [GAGA Serre P6]. □

Cor. (11.8.7.6). The inclusion $\mathcal{O}_x \subset \mathcal{H}_x$ is flat ring extension, by(4.4.1.20) and the fact $\widehat{A}/A$ is flat. And $\dim \mathcal{O}_x = \dim \mathcal{H}_x$ because $\dim A = \dim \widehat{A}$(4.2.4.16).

Cor. (11.8.7.7). Given an open and dense subscheme U of an algebraic variety X over $\mathbb{C}$, U^{an} is dense in X^{an}.

Proof: Consider the complement Y, if U^{an} is not dense in X^{an}, then there exists a x that $\mathcal{A}_x(Y) = 0$, so by(11.8.7.5), $\mathcal{I}_x(Y) = 0$, so Y is not dense near x, contradiciton. □

Cor. (11.8.7.8). For a morphism f of algebraic varieties over $\mathbb{C}$, $\overline{f(X)^{\mathrm{an}}} = \overline{f(X)}^{\mathrm{an}}$.

Proof: By Chevalley theorem(5.6.1.6), there is a open dense subscheme U of $\overline{f(X)}$ that is contained in $f(X)$, then(11.8.7.7) shows U^{an} is dense in $\overline{f(X)}^{\mathrm{an}}$, so $\overline{f(X)}^{\mathrm{an}} \subset \overline{f(X)^{\mathrm{an}}}$. The converse is obvious. □

Def. (11.8.7.9) [Analytification of Sheaves]. Denote for a sheaf $\mathcal{F}$ over X $\mathcal{F}'$ the inverse image sheaf over X^{an} pulled back along $X^{\mathrm{an}} \to X$. Define $\mathcal{F}^{\mathrm{an}}$ the **analytification of** $\mathcal{F}$ as the sheaf $\mathcal{F}' \otimes_{\mathcal{O}_X} \mathcal{H}_X$.

Prop. (11.8.7.10). $\mathcal{F} \to \mathcal{F}^{\mathrm{an}}$ is exact from the category of sheaves on X to the category of analytic sheaves on X^{an}, $\mathcal{F}' \to \mathcal{F}^{\mathrm{an}}$ is injective, and it maps coherent sheaves to coherent analytic sheaves.

Proof: The first two follows from the fact that $\mathcal{H}_X$ is flat over $X^{\mathrm{an}} \to X$(11.8.7.6). For the last assertion, notice if $\mathcal{O}_X^p \to \mathcal{O}_X^q \to \mathcal{F} \to 0$, then $\mathcal{H}_X^p \to \mathcal{H}_X^q \to \mathcal{F}^{\mathrm{an}} \to 0$, so it is coherent because $\mathcal{H}_X$ is coherent(11.8.3.7)(5.2.2.28). □

Prop. (11.8.7.11). Let $i : Y \to X$ be a closed subscheme, then for a coherent sheaf $\mathcal{F}$ on Y, $(i^{\mathrm{an}})_*\mathcal{F}^{\mathrm{an}} \cong (i_*\mathcal{F})^{\mathrm{an}}$.

Proof: These two sheaves are both 0 outside Y^{an}, consider a point of Y, their stalks are respectively $\mathcal{F}_x \otimes_{\mathcal{O}_{x,X}} \mathcal{H}_{x,X}$ and $\mathcal{F}_x \otimes_{\mathcal{O}_{x,Y}} \mathcal{H}_{x,Y}$. By(11.8.7.5) we notice

$$\mathcal{H}_{x,Y} = \mathcal{H}_{x,X}/\mathcal{I}_x(Y)\mathcal{H}_{x,X} = \mathcal{H}_{x,X} \otimes_{\mathcal{O}_{x,X}} \mathcal{O}_{x,Y}.$$

So this two are equal by associativity of tensor product. □

Prop. (11.8.7.12). By Leray Spectral sequence(5.3.1.9), for an analytic sheaf $\mathcal{G}$, there is a boundary map $H^k(X,\mathcal{G})H^k(X^{\mathrm{an}},\mathcal{G})$. So for a sheaf $\mathcal{F}$ on X, there is a map

$$\varepsilon : H^k(X,\mathcal{F}) \to H^k(X, an_*\mathcal{F}^{\mathrm{an}}) \to H^k(X^{\mathrm{an}},\mathcal{F}^{\mathrm{an}})$$

<u>**Equivalence between Algebraic Variety and Analytic Spaces**</u>

Remark (11.8.7.13) [GAGA Principle]. In principal, any complete analytic object in $\mathbb{CP}^n$ is algebraic.

Prop. (11.8.7.14). Let X, Y be algebraic varieties over $\mathbb{C}$ and $f : X \to Y$ is morphism that is bijective, if f^{an} is an analytic isomorphism, then f is an isomorphism.

Proof: Cf.[GAGA Serre P9]. □

Cor. (11.8.7.15). Let X, Y be algebraic varieties over $\mathbb{C}$, iff $f : X^{\mathrm{an}} \to Y^{\mathrm{an}}$ is holomorphic map and the image of f in $X^{\mathrm{an}} \times Y^{\mathrm{an}} = (X \times Y)^{\mathrm{an}}$ comes from an algebraic subscheme, then f comes from an algebraic morphism. (Because $X^{\mathrm{an}} \to \Gamma(X)$ is an analytic isomorphism).

Prop. (11.8.7.16) [GAGA on $\mathfrak{Coh}(X)$]. Let X be a proper scheme over $\mathbb{C}$, then $\mathcal{F} \to \mathcal{F}^{\mathrm{an}}$ defines an equivalence of categories between $\mathfrak{Coh}(X)$ and $\mathfrak{Coh}^{\mathrm{an}}(X^{\mathrm{an}})$.

Proof: Cf.[GAGA Serre P13], [SGA1,Chap12].. □

Prop. (11.8.7.17) [GAGA on Projective Varieties].

- (Chow)Any analytic subvariety of $\mathbb{CP}^n$ is algebraic.
- Any meromorphic function on an algebraic variety $V \subset \mathbb{CP}^n$ is rational.
- Any meromorphic differential form on a smooth variety is algebraic.
- Any holomorphic map between smooth varieties can be given by rational maps.
- Any holomorphic vector bundle on a smooth variety is algebraic, i.e. transition function can be made rational.

Cf.[Griffith/Harris P168,170].?

Cor. (11.8.7.18). If the analytification of a variety X is a compact complex manifold, i.e. X is smooth(11.8.7.4), then $K(X) = K(X^{\mathrm{an}})$, as they are both morphism to $\mathbb{P}^1$.

Applications

Prop. (11.8.7.19) [Generalized Riemann Existence Theorem]. Let X be a normal scheme of finite type over $\mathbb{C}$. Given any finite morphism of analytic spaces(i.e. proper and has finite fibers) form a normal complex analytic space $f : X' \to X^{\text{an}}$, then there is a unique normal scheme X' and a finite morphism $g : X' \to X$ that $g^{\text{an}} = f$.

Proof: Cf.[SGA1, Chap12], using resolution of singularities. □

Cor. (11.8.7.20) [Algebraic Fundamental Group].

8 Algebraic Compact Complex Manifolds

Def. (11.8.8.1) [Moishezon Manifolds]. A compact complex manifold is called a **Moishezon manifold** iff $\operatorname{tr.deg.} K(X) = \dim X$, by(11.8.1.5) this is the highest degree it can have. When X is an analytification of an algebraic variety X^{an}, $K(X^{\text{an}}) = K(X)$ by(11.8.7.18), so Moishezon is a necessary condition for a compact complex manifold to be algebraic.

Prop. (11.8.8.2) [Chow-Kodaira]. Any Moishezon manifold of dimension2 is algebraic and projective.

Proof: □

Prop. (11.8.8.3) [Moishezon]. Any Moishezon manifold becomes algebraic and projective after a finite number of monoidal transformations with non-singular centers.

Proof: □

Prop. (11.8.8.4) [Artin]. The category of smooth proper algebraic spaces over $\mathbb{C}$ is equivalent to the category of Moishezon manifolds.

In particular, there are non-algebraic Moishezon manifolds in dimension≥ 3. Examples are given in[Har77]P444.

Proof: □

Prop. (11.8.8.5) [Moishezon]. Every Moishezon manifold that is Kähler is projective and algebraic.

Proof: Cf.[Moishezon On n-dimensional compact varieties with n algebraically independent meromorphic functions]. □

11.9 Kähler Geometry

Basic References are [Voi02], [Principle of Algebraic Geometry Griffith/Harris], more advanced stuffs to add from [Kähler Geometry] and [Huy05]. Even more advanced is [Demailly Complex Analytic and Differential Geometry].

Notation (11.9.0.1).

- Use notations as in Complex Geometry.

1 Kähler Metric

Def. (11.9.1.1) [Kähler Manifolds]. A metric g on a manifold M is called a **Kähler metric** if the metric form ω_g is closed. In which case, it is called the **Kähler class** or Kähler form of g in $H^2_{\mathrm{dR}}(M)$. A complex manifold with a Kähler metric is called a **Kähler manifold**.

If $g_{ij} = g(\frac{\partial}{\partial z_i}, \frac{\partial}{\partial \overline{z}_j})$, then $\omega_g = \sum_{ij} g_{ij} dz_i \wedge d\overline{z}_j$. Then the condition of ω_g being closed can in fact be written in derivatives of g.

Prop. (11.9.1.2). If g is Hermitian, then ω_g is real, non-degenerate and $\frac{1}{n!}\omega^n$ is a volume form on M. In particular, if ω is Kähler, then it is a symplectic form.

Proof: If $g = \sum \varphi_i \otimes \overline{\varphi}_i$, then $\omega = \mathrm{i} \sum \varphi_i \wedge \overline{\varphi}_i$, so it is clear that $\overline{\omega} = \omega$. ω is non-degenerate as g is. The last assertion follows from(2.3.8.7). □

Cor. (11.9.1.3). If M is a compact Kähler manifold, then its even dimensional cohomology group doesn't vanish(11.5.1.6).

Remark (11.9.1.4). Notice there are notions like almost Hermitian and almost Kähler, similar to the definition of Hermitian and Kähler, but they are just defined using an almost complex structure on M. And an almost Kähler structure is Kähler iff $\nabla J = 0$, Cf.[Foundation of Differential Geometry Kobayashi].

Example (11.9.1.5) [Kähler Manifolds].

- If $M = \mathbb{R}^{2n}$, $g = \sum dx_i \wedge dx_i + \sum dy_i \wedge dy_i$, then $\omega_g = \frac{\mathrm{i}}{2} \sum dz_i \wedge d\overline{z}_i$ is Kähler.
- The metric $\omega_g = \sum dz_i \wedge dz_i$ on a complex tori $\mathbb{C}^n/\Lambda$ is Kähler.
- Any Riemann surface is Kähler , because $d\omega$ is a 3-form so vanish.
- if $M = B(0,1) \subset \mathbb{C}^n$ and $\omega_g = \mathrm{i}\,\partial\overline{\partial} \log \frac{1}{1-|z|^2}$, then it is Kähler.
- The product metric on the product space $M \times N$ of two Kähler manifold is Kähler.
- A submanifold of a Kähler manifold is Kähler, as the Kähler form is the pullback of the Kähler form of the large manifold.

Prop. (11.9.1.6) [Fubini-Study Metric]. The **Fubini-Study metric** form on $\mathbb{CP}^n$ is defined locally to be $\mathrm{i}\,\partial\overline{\partial}|s|^2$, for any local lifting s of the projection $\mathbb{C}^n \backslash \{0\} \to \mathbb{CP}^n$. This doesn't depend on the lifting, as $\partial\overline{\partial}(\log f + \log \overline{f}) = 0$, so they glue together to be a global form on $\mathbb{CP}^n$. It can be checked, ω is translation invariant and on the coordinate $(1, w_1, \ldots, w_n) \to (w_1, \ldots, w_n)$, $\omega|_{(0,\ldots,0)} = \sum dw_i \wedge dw_i$, so it is positive definite.

Cor. (11.9.1.7). Any projective manifold is Kähler.

Prop. (11.9.1.8). the Fubini-Study metric on $\mathbb{CP}^n$ has sectional curvature $1 \le K \le 4$.

Proof: Cf.[Do Carmo P188].**?** ☐

Prop. (11.9.1.9) [Kähler Normal Coordinate]. For a Hermitian metric g on M, g is Kähler iff for any point p of M, there is a holomorphic coordinate centered at p, $\omega_g = \sum g_{ij} dz_i \wedge d\overline{z}_j$ satisfying $g_{ij}(p) = 0$ and $dg_{ij}(p) = 0$. This coordinate is called **Kähler normal coordinate**. (Notice this is different from Darboux theorem, because this coordinate should be holomorphic).

Proof: Cf.[Complex Geometry P210]. ☐

2 Geometry of Kähler Manifolds

Prop. (11.9.2.1). Let (M, J, g) be a Kähler manifold, then the complexification of the Levi-Civita connection of g restricts to the Chern connection on $T^{1,0}M$.

Proof: Cf.[Complex Geometry note 石亚龙 48] and [Complex geometry Daniel Chap4.A]. ☐

Prop. (11.9.2.2). For a Kähler manifold, $\nabla J = 0$.

Proof: The problem depends only on first derivative, so choosing a Kähler normal nbhd(11.9.1.9), we may choose J to be constant, so obviously $\nabla J(p) = 0$, P is arbitrary, so $\nabla J = 0$. ☐

Cor. (11.9.2.3). $\nabla(JX) = J\nabla X$, so $R(X,Y)JZ = JR(X,Y)Z$, thus

$$\langle R(JX, JY)Z, W\rangle = \langle R(Z, W)JX, JY\rangle = \langle R(Z, W)X, Y\rangle = \langle R(X, Y)Z, W\rangle,$$

so $R(JX, JY)Z = R(X, Y)Z$.

Prop. (11.9.2.4). The curvature tensor of the complexified Levi-Civita connection on a Kähler manifold can be calculated in terms of $\partial_i, \overline{\partial}_j$, Cf.[Complex Geometry note 石亚龙 50].

3 Kähler Identities

Let X be a compact complex Kähler manifold.

Def. (11.9.3.1). Introduce some operators:

- $d^c = i(\overline{\partial} - \partial)$, then $dd^c = 2i\partial\overline{\partial}$.
- The **Lefschetz operator** $L(\eta) = \omega \wedge \eta$. Λ is defined as the formal adjoint of L as $A^{p,q}$ is an inner space. In fact, $\Lambda = \pm * L *$.
- $h = (k - n)$ on $\mathcal{A}^k(X)$.

Prop. (11.9.3.2). $[L, \Lambda] = p + q - n$ on (p, q)-forms.

Proof: The problem doesn't depends on the derivatives, so using the Kähler normal coordinate(11.9.1.9), it suffice to prove for $\mathbb{C}^n$, for this, Cf.[Griffith/Harris P120] or [Complex Geometry P34]. ☐

Prop. (11.9.3.3) [Kähler Identities].

$$[\Lambda, \partial] = i\overline{\partial}^*, \quad [\Lambda, \overline{\partial}] = -i\partial^*.$$

Proof: The second one follows from the first because ω is a real form. For the first, notice only first derivation are involved, so by using the Kähler normal coordinate, it suffice to prove for $\mathbb{C}^n$, and this is by [Complex Geometry 石亚龙 P61]. ☐

Cor. (11.9.3.4).

$$[\Lambda, d^c] = d^*, \quad [\Lambda, d] = -d^{c*}.$$

Prop. (11.9.3.5). Δ_d commutes with both L and Λ.

Proof: L commutes with d because ω is closed, so taking adjoints, Λ commutes with d^*. Now by Kähler identities,

$$\Lambda\Delta_d = \Lambda(dd^* + d^*d) = -d^{c*}d^* + dd^*\Lambda - dd^{*c} + d^*d\Lambda = \Delta_d\Lambda.$$

So taking adjoints, Δ_d also commutes with L. □

Prop. (11.9.3.6). In the Kähler case, $\Delta_\partial = \Delta_{\overline{\partial}} = \frac{1}{2}\Delta_d$.

Proof:

$$\Delta_d = (\partial + \overline{\partial})(\partial^* + \overline{\partial}^*) + (\partial^* + \overline{\partial}^*)(\partial + \overline{\partial}) = \Delta_\partial + \Delta_{\overline{\partial}} + (\partial\overline{\partial}^* + \overline{\partial}^*\partial) + (\overline{\partial}\partial^* + \partial^*\overline{\partial})$$

So it suffice to prove $\partial\overline{\partial}^* + \overline{\partial}^*\partial = 0$(so $\overline{\partial}\partial^* + \partial^*\overline{\partial} = 0$ by conjugation), and $\Delta_\partial = \Delta_{\overline{\partial}}$. For the first, use Kähler identities, then

$$i(\partial\overline{\partial}^* + \overline{\partial}^*\partial) = \partial[\Lambda, \partial] + [\Lambda, \partial]\partial = 0$$

For the second, using Kähler identities,

$$i\Delta_{\overline{\partial}} = \overline{\partial}[\Lambda, \partial] + [\Lambda, \partial]\overline{\partial} = \overline{\partial}\Lambda\partial + \partial\overline{\partial} - \Lambda\overline{\partial}\partial - \partial\Lambda\overline{\partial}$$

and the same is miraculous true for Δ_∂, so the result is true. □

4 Hodge Theory

Thm. (11.9.4.1) [Hodge Decomposition for compact Kähler Manifolds]. For a compact Kähler manifold X,

$$H^r_{\mathrm{dR}}(X, \mathbb{C}) = \bigoplus_{p+q=r} H^{p,q}_{\overline{\partial}}(X) \cong \bigoplus_{p+q=r} H^q(X, \Omega^p)$$

and $\overline{H^{p,q}_{\overline{\partial}}(X)} \cong H^{q,p}_{\overline{\partial}}(X)$. Moreover, this decomposition doesn't depends on the Kähler metric.

Proof: (11.9.3.6) shows that Δ_d maps $A^{p,q}$ to $A^{p,q}$, so $\mathscr{H}^{p+q}_d \cap A^{p,q} = H^{p,q}_{\overline{\partial}}(X)$. The last assertion is seen using the Δ_d definition.

If chosen two different Kähler metric g, g', there $\mathcal{H}^{p,q}(X, g) \cong H^{p,q}(X) \cong H^{p,q}(X, g')$. If α, α' be g, g' $\overline{\partial}$-harmonic respectively, so by definition $\alpha - \alpha' = \overline{\partial}\gamma$ for some γ, and they are both d-harmonic, so $d\overline{\partial}\gamma = 0$, and $\overline{\partial}\gamma$ is g-orthogonal to $\mathcal{H}^k(X, g)$ by Hodge decomposition for $\overline{\partial}$ with metric g, so by Hodge theorem for d with metric g, $\partial\gamma$ is d-exact, so $[\alpha] = [\alpha']$. □

Cor. (11.9.4.2). Betti number $b_r = \sum_{p+q=r} h^{p,q}$, $h^{p,q} = h^{q,p}$. In particular, b_{2k+1} is always even.

Cor. (11.9.4.3) [Holomorphic Forms on Kähler Manifolds are Closed]. $\mathscr{H}^{p,0}_{\overline{\partial}}(X) = H^0(X, \Omega^p)$. Now a $(p, 0)$-form is automatically $\overline{\partial}^*$-closed, so it is $\overline{\partial}$-harmonic iff it is holomorphic. So we conclude any holomorphic p-form on a Kähler manifold is d-closed, even d-harmonic.

Lemma (11.9.4.4) [$\partial\overline{\partial}$-lemma]. A closed differential form η on a compact Kähler manifold M is d-exact iff it is ∂-exact iff it is $\overline{\partial}$-exact iff it is $\partial\overline{\partial}$-exact.

Proof: Now $\Delta_d, \Delta_{\overline{\partial}}, \Delta_\partial$ are all the same, By Hodge theorem, it suffice to prove, if a form is orthogonal to $\mathcal{H}^{p,q}(X)$, then it is $\partial\overline{\partial}$-exact(this implies other exactness).

Noe η is d-closed hence ∂ and $\overline{\partial}$-closed, then $\eta = \partial\gamma$ for some γ, and then $\gamma = \overline{\partial}\beta + \overline{\partial}^*\beta' + \beta''$ for β'' harmonic. So $\eta = \partial\overline{\partial}\beta + \partial\overline{\partial}^*\beta'$, and then $\overline{\partial}\eta = \overline{\partial}\overline{\partial}^*\partial\beta = 0$, but then inner product with $\partial\beta$ shows $\overline{\partial}^*\partial\beta = 0$, so $\eta = \partial\overline{\partial}\beta$. □

Cor. (11.9.4.5)[Kodaira-Serre Duality]. By(11.1.10.15), For a Hermitian line bundle over a compact Hermitian complex manifold X, from Hodge theorem and(11.8.5.2), we get

$$H^p(X, \Omega^q(E)) \cong H^{n-p}(X, \Omega^{n-q}(E^*))$$

induced by $\overline{*}_E$ and $\overline{*}_{E^*}$. Moreover, there is a perfect pairing

$$H^p(X, \Omega^q(E)) \times H^{n-p}(X, \Omega^{n-q}(E^*)) \to \mathbb{C}$$

induced by

$$\mathcal{H}^{p,q}(X, E) \times \mathcal{H}^{n-p,n-q}(X, E^*) \to \mathbb{C} : (\alpha, \beta) \mapsto \int_X \alpha \wedge \overline{*}_E\beta$$

In fact, $\int_X \alpha \wedge \overline{*}_E\alpha = ||\alpha||^2 \neq 0$.

Prop. (11.9.4.6). Holomorphic 1-forms on a compact complex surface is closed.?

Prop. (11.9.4.7) [Hard Lefschetz Theorem]. For a compact Kähler manifold M, the map

$$L^k : H^{n-k}(M) \to H^{n+k}(M)(11.9.3.1)$$

is an isomorphism,(notice it is defined because L commutes with Δ_d(11.9.3.5)).

Define the **primitive cohomology class** $H^{n-k}_{\text{prm}}(M) = \ker(L^{k+1}|_{H^{n-k}})$, then

$$H^m(M) = \oplus_k L^k H^{m-2k}_{\text{prm}}(M).$$

Proof: Cf.[Griffith/Harris P122], using representation theory of $\mathfrak{sl}_2$. □

Thm. (11.9.4.8) [Hodge-Riemann Bilinear Relation]. Let (X, ω) be a Kähler manifold of dimension n, then for $k \leq n$, we can define a Hermitian form

$$H(\alpha, \beta) = \mathrm{i}^k \int_X \omega^{n-k} \wedge \alpha \wedge \beta = \mathrm{i}^k \langle L^{n-k}\alpha, \beta \rangle$$

on $H^k(X; \mathbb{R})$. Then it satisfies:

- The Hodge decomposition(11.9.4.1) is orthogonal for H.
- If $\alpha \neq 0 \in H^{p,q}_{\text{prm}}(X)$, then
$$i^{p-q-k}(-1)^{\frac{k(k-1)}{2}} H(\alpha) > 0$$

Proof: Cf.[Griffith/Harris] or [Complex Geometry Daniel P138] or[Hodge Theory, Chap6.3.2]. □

Cor. (11.9.4.9). For a compact Kähler manifold of complex dimension $2m$,

$$\text{sgn}(X) = \sum_{p,q=0}^{m} (-1)^p h^{p,q}(m)$$

Proof: Cf.[Complex Geometry Daniel P140]. □

Prop. (11.9.4.10) [Hirzebruch-Riemann-Roch]. By(11.1.10.8), for a n-dimensional complex line bundle L over a compact Kähler manifold M,

$$\chi(M,L)=\int_M[\mathrm{ch}(E)\mathrm{td}(T^{1,0}M)]_n.$$

Where $\chi(M,L)=\sum_{q=0}^n(-1)^q\dim H^q(M,E)$, ch is the Chern character(11.1.9.5) and $\mathrm{td}(T^{1,0}M)$ is the Todd polynomial, i.e. Taylor expansion of $\prod_{i=1}^r\dfrac{t_i}{1-e^{-t_i}}$ in terms of the symmetric polynomial, applied to $c_i(T^{1,0}M)$.

Cor. (11.9.4.11) [Riemann-Roch]. By(11.1.10.9), for a complex vector bundle E over a Riemann surface M, let $\deg E=\int_M c_1(E)$, then

$$\chi(M,E)=H^0(M,E)-\dim H^1(M,E)=\deg E+\mathrm{rk}(E)(1-g).$$

Cor. (11.9.4.12). For other examples of corollaries of Hirzebruch-Riemann-Roch theorem, Cf.[Complex Geometry P232].

5 Complex Tori

Def. (11.9.5.1) [Complex Tori]. A **complex torus** is a pointed complex manifold isomorphic to the complex manifold V/Λ, where V is a f.d. vector space over $\mathbb{C}$ and Λ is a complete lattice in V.

Prop. (11.9.5.2). Let $X=V/\Lambda, X'=V'/\Lambda'$ be complex tori, then any $\mathbb{C}$-linear map $\alpha:V\to V'$ s.t. $\alpha(\Lambda)\subset\Lambda'$ defines a holomorphic map $X\to X'$ sending 0 to 0. And any holomorphic map $X\to X'$ sending 0 to 0 is of this form.

Proof: Any $\varphi:X\to X'$ lifts to a continuous map $\psi:V\to V'$, and it is holomorphic because the morphisms $V\to X,V'\to X'$ are locally biholomorphic, ψ is also holomorphic. For any $\omega\in\Lambda$, $\psi(z+\omega)-\psi(z)$ has value in Λ' for any z, so $\psi(z+\omega)=\psi(z)+a(\omega)$. From here it is easy to see that ψ is linear. □

Def. (11.9.5.3) [Riemann Pairs]. A **Riemann pair** is a pair (Λ,J) where Λ is a finite $\mathbb{Z}$-module of finite rank, and J is a complex structure on $\Lambda\otimes\mathbb{R}$. A homomorphism of Riemann pairs is a group homomorphism $\Lambda\to\Lambda'$ that preserves the complex structure.

Prop. (11.9.5.4) [Riemann Pairs and Abelian Varieties]. There is an equivalence of the category of Riemann pairs with $\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/\mathbb{C}$ by

$$(\Lambda,J)\mapsto(\Lambda\otimes\mathbb{R})/\Lambda.$$

Proof: It is fully faithful by(11.9.5.2), and it is clearly essentially surjective. □

Prop. (11.9.5.5) [Cohomology of Complex Tori]. For any complex torus $X=V/\Lambda$, $H_1(X,\mathbb{Z})\cong\Lambda$, so $H^1(X,\mathbb{Z})\cong\mathrm{Hom}(\Lambda,\mathbb{Z})$, and by Künneth formula,

$$H^n(X,\mathbb{Z})\cong\wedge^n H^1(X,\mathbb{Z})\cong\wedge^n\mathrm{Hom}(\Lambda,\mathbb{Z}).$$

Then

$$H^n(X,\mathbb{C}) \cong \wedge^n \operatorname{Hom}_{\mathbb{R}}(V,\mathbb{C}) \cong \wedge^n(\operatorname{Hom}_{\mathbb{C}}(V,\mathbb{C}) \oplus \operatorname{Hom}_{\mathbb{C}}(\overline{V},\mathbb{C})) = \bigoplus_{p+q=n} \wedge^p V^* \otimes \wedge^q \overline{V}^*$$

and

$$H_1(X,\mathbb{C}) \cong \Lambda \otimes_{\mathbb{Z}} \mathbb{C} \cong V \otimes_{\mathbb{R}} \mathbb{C} \cong V \otimes V^* = \mathrm{Tgt}_0(X) \oplus \overline{\mathrm{Tgt}_0(X)}.$$

Cor. (11.9.5.6) [Complex Tori are Kähler]. A complex torus(11.9.5.1) $X = V/\Gamma$ is a Kähler manifold. And $H^2(X,\mathbb{R}) \cong \wedge^2 \operatorname{Hom}_{\mathbb{R}}(V,\mathbb{R})$, by(11.9.5.5).

Prop. (11.9.5.7) [Hodge Theory of Complex Tori]. Let $X = V/\Lambda$ be a complex torus, as X is Kähler(11.9.5.6), there is a decomposition

$$H^n_{\mathrm{dR}}(X,\mathbb{C}) \cong \bigoplus_{p+q=n} H^q(X,\Omega^p)$$

by(11.9.4.1). Then this decomposition corresponds to the decomposition in(11.9.5.5) via the isomorphism $H^n_{\mathrm{dR}}(X,\mathbb{C}) \cong H^n(X,\mathbb{C})$. In particular, there is a canonical isomorphism

$$H^q(X,\Omega^p) \cong \wedge^p V^* \otimes \wedge^q \overline{V}^*.$$

Proof: □

Def. (11.9.5.8) [Dual Complex Tori]. Let $X = V/\Lambda$ be a complex torus with a Riemann form, then we can define the **dual complex torus** as

$$X^\vee = V^*/\Lambda^*$$

where $V^* = \operatorname{Hom}_{\mathbb{C}}(V,\mathbb{C})$ and $\Lambda^* = \{f \in V^* | f(\Lambda) \subset \mathbb{Z}\}$.

Riemann Forms

Prop. (11.9.5.9) [Riemann Forms]. For a complex torus V/Λ, it is projective iff there is a **Riemann form** on V, which is an alternating bilinear form $\omega : V \times V \to \mathbb{R}$ that:

- $\omega(\mathrm{i}\,u, \mathrm{i}\,v) = \omega(u,v)$.
- $\omega(v, \mathrm{i}\,v) > 0$ for $v \neq 0$.
- $\omega(u,v) \in \mathbb{Z}$ for $u, v \in \Gamma$.

Notice ω is clearly non-degenerate.

Proof: Use(11.9.5.6). The conditions are just equivalent to ω being an integral positive Kähler form(11.9.8.6). □

Prop. (11.9.5.10) [Dual Riemann Forms]. If $X = V/\Lambda$ is a complex torus with a Riemann form, then the dual complex torus(11.9.5.8) $X^\vee$ also has a Riemann form defined as follows: any $f \in V^*$ corresponds to an element v_f s.t. $f(u) = \omega(u, v_f)$. Thus we can define $\omega'(f,g) = \omega(v_f, v_g)$. And there is an isogeny(i.e. surjective isomorphism with finite kernel)

$$A \to A^\vee : \overline{a} \mapsto [x \mapsto \omega(x,a)]$$

which is compatible with the Riemann forms.

6 Positivity

Def. (11.9.6.1) [Positive Line Bundle]. A 2-form ω on a Hermitian complex manifold M is called **positive** iff $\omega(u, Ju) \geq 0$ for $u \neq 0 \in TM$, which is equivalent to $-i\omega(v, \overline{v}) > 0$ for all $v \in T^{1,0}X$.

A holomorphic vector bundle is called **(Griffith-)positive** iff there exists a Hermitian metric on it that the curvature form Ω for the Chern connection(11.8.5.13) satisfies $h(\Omega(s), s)(v, \overline{v}) > 0$ for all $s \in E$ and $v \in T^{1,0}X$.

The pullback of a positive line bundle along an immersion is positive.

Prop. (11.9.6.2) [Positivity on Kähler Manifolds]. On a compact Kähler manifold, being positive is a topological property for line bundles. It is equivalent to the first Chern class of L can be represented by a positive form in $H^2_{dR}(M)$.

Proof: $c_1(L) = [\frac{i}{2\pi}\Omega]$, so one direction is trivial, and if $c_1(L) = [\frac{i}{2\pi}\theta]$, choose an arbitrary Hermitian metric h on L, then by $\partial\overline{\partial}$-lemma(11.9.4.4), $\theta = \Omega + \overline{\partial}\partial\rho$ for some smooth function ρ. Then $e^\rho h$ has $\Omega = \theta$ by formula(11.8.5.14). □

Cor. (11.9.6.3). On a compact Kähler manifold, if L is positive, then for any other Hermitian line bundle L', $kL + L'$ is positive.

Prop. (11.9.6.4). The hyperplane line bundle $\mathcal{O}(1)$(11.8.5.9) is positive.

Proof: The hyperplane line bundle is dual to the tautological line bundle. The metric on the tautological line bundle is given by locally $g_i = \frac{1}{|z_i|^2}\sum |z_i|^2$. It is compatible with the transition map, and then by(11.8.5.14), the Chern curvature is

$$\overline{\partial}\partial(\frac{1}{|z_i|^2}\sum |z_i|^2) = \overline{\partial}\partial(\sum |z_i|^2).$$

So by(11.2.3.6) the curvature of the hyperplane line bundle times i is just the Fubini-Study metric form(11.9.1.6), so it is positive. □

Prop. (11.9.6.5). For $\widetilde{X} \to X$ the blowing-up of X at a point x, If L is a positive line bundle on X, then for any integer n, there exists a $k > 0$ that $\pi^* L^k - nE$ is a positive line bundle on $\widetilde{X}$, where E is the exceptional divisor.

Proof: Involves explicit metric calculation, Cf.[Kodaira Embedding Theorem P11] and [Complex Geometry P249].. □

7 Kodaira Vanishing Theorem

Prop. (11.9.7.1) [Nakano Identities]. For a holomorphic vector bundle over a compact Kähler manifold (M, ω) with Hermitian metric h, introduce operators L and Λ as before. If we denote the $(1,0)$ and $(0,1)$-part of the Chern connection on E by D' and $D'' = \overline{\partial}$, then

$$[\Lambda, \overline{\partial}] = -iD'^*, \quad [\Lambda, D'] = i\overline{\partial}^*$$

Proof: The question is local, choose normal coordinate frame at x(11.8.5.16), then by the formula of Chern connection(11.8.5.14), $\nabla_E = d + A$, $A(x) = 0$, and $\nabla_{E^*} = d + B$, $B(x) = 0$. so

$$[\Lambda, \overline{\partial}_E] + iD'^* = [\Lambda, \partial] + i\partial^* + [\Lambda, A^{0,1}] + iB^{0,1}$$

where the usual Kähler identities(11.9.3.3) are used. Then it is zero when evaluated at x, Cf.[Demailly Complex Analytic and Differential Geometry P329]. □

Cor. (11.9.7.2) [Bochner-Kodaira-Nakano Identity].

$$\Delta_{\overline{\partial},E} - \Delta_{D',E} = i[\Omega, \Lambda]$$

Proof:

$$-i\Delta_{D',E} = D'[\Lambda, \overline{\partial}] + [\Lambda, \overline{\partial}]D' = D'\Lambda\overline{\partial} - D'\overline{\partial}\Lambda + \Lambda\overline{\partial}D' - \overline{\partial}\Lambda D'$$

and similar calculation for $i\Delta_{\overline{\partial},E}$, so

$$i\Delta_{\overline{\partial},E} - i\Delta_{D',E} = \Lambda(\overline{\partial}D' + D'\overline{\partial}) - (\overline{\partial}D' + D'\overline{\partial})\Lambda = -[\Omega, \Lambda].$$

□

Prop. (11.9.7.3) [Kodaira-Akizuki-Nakano Vanishing Theorem]. If L is a positive line bundle on a compact Kähler manifold M, then

$$H^p(M, \Omega^q(\mathcal{L})) = 0$$

for $p + q > n$. In particular, $H^p(M, \mathcal{K}_M \otimes \mathcal{L}) = 0$ for $p > 0$.

Proof: By Hodge theorem(11.1.10.13), it suffice to prove there are no harmonic (p, q)-forms$\in \mathcal{H}^{p,q}(X, L)$ on L.

As $i\Omega = \omega$ is positive, we may endow M with the metric ω, then by(11.9.7.2) and(11.9.3.2), $\Delta_{\overline{\partial}} - \Delta_{D'} = [L, \Lambda] = p + q - n$ on $A^{p,q}$.

So if $s \in \mathcal{H}^{p,q}(X, L)$, then $(\Delta_{\overline{\partial}}s - \Delta_{D'}s, s) = (p + q - n)||s||^2 \geq 0$, but $(\Delta_{\overline{\partial}}s - \Delta_{D'}s, s) = -(\Delta_{D'}s, s) = -||D's||^2 - ||D'^*s||^2 \leq 0$, so $s = 0$. □

Cor. (11.9.7.4) [Serre's Theorem]. Let $\mathcal{L}$ be a positive line bundle on a compact complex Kähler manifold M, then for any holomorphic vector bundle $\mathcal{E}$, for m large, $H^q(M, \mathcal{L}^m \otimes \mathcal{E}) = 0$.

Proof: Same notation as in the proof of(11.9.7.3), choose Hermitian structure on E and L and their Chern connections by ∇_E, ∇_L, the corresponding Chern connection on $E \otimes L^m$ is denoted by ∇, and make sure $\frac{i}{2\pi}F_{\nabla_L}$ is the Kähler form ω, then for any harmonic form $\alpha \in \mathcal{H}^{p,q}(X, E \otimes L^m)$, by(11.9.7.2), $\frac{i}{2\pi}([\Lambda, F_\nabla](\alpha), \alpha) \geq 0$, but $\frac{i}{2\pi}F_\nabla = \frac{i}{2\pi}F_{\nabla_E} + m\omega$, so

$$0 \leq \frac{i}{2\pi}([\Lambda, F_{\nabla_E}](\alpha), \alpha) + m(n - p - q)||\alpha||^2$$

Notice $|([\Lambda, F_{\nabla_E}](\alpha), \alpha)|$ has a bound by Schwartz inequality, then if $p + q > n$ and m sufficiently large, α must by 0. In this case $\mathcal{H}^{p,q}(X, E \otimes L^m) = 0$, but $\mathcal{H}^{0,q}(X, \mathcal{K}_X \otimes E \otimes L^m) \subset \mathcal{H}^{n,q}(X, E \otimes L^m)$, so it is 0. Now we've proved $H^q(X, \mathcal{K}_X \otimes E \otimes L^m) = 0$ for any E if m is large. But E is arbitrary, so the conclusion is true. □

Cor. (11.9.7.5) [Grothendieck's Lemma]. Every holomorphic vector bundle E over $\mathbb{CP}^1$ is uniquely isomorphic to a finite direct sum of $\mathcal{O}(a_i)$.

Proof: If E has rank 1, this is the content of(11.8.5.10), so use induction on rank of E. Choose a maximal a that $\mathrm{Hom}(\mathcal{O}(a), E) = H^0(CP^1, E(-a)) \neq 0$. This a exists because Serre's Theorem(11.9.7.4) shows that $H^1(\mathbb{CP}^1, E(-a)) = 0$ for a sufficiently small, and Riemann-Roch(11.1.10.9) shows that $\chi(\mathbb{CP}^1, E(-a)) = \deg E + \mathrm{rk}(E)(1 - a)$ is positive for a sufficiently small, so $H^0(CP^1, E(-a)) \neq 0$. Conversely, if a is sufficiently large, then $H^0(\mathbb{CP}^1, E(-a)) \cong H^1(\mathbb{CP}^1, E^*(a - 2)) = 0$(Notice $\mathcal{K}_{\mathbb{CP}^n} = \mathcal{O}(-n - 1)$).

So now there is an exact sequence of sheaves

$$0 \to \mathcal{O}(a) \xrightarrow{s} E \to E_1 \to 0$$

I claim E_1 is also a vector bundle, because s never vanishes, otherwise if it vanish at some x, then we can divide by a linear factor $s_x \in H^0(\mathbb{CP}^1, \mathcal{O}(1))$ to get a map $\mathcal{O}(a+1) \to E$, contradicting the maximality. So by induction $E_1 = \oplus\mathcal{O}(a_i)$, then I claim $a_i \leq a$, because otherwise $H^0(\mathbb{CP}^1, E_1(-a-1)) \neq 0$, and by the exact sequence $0 \to \mathcal{O}(-1) \to E(-a-1) \to E_1(-a-1) \to 0$, $H^0(\mathbb{CP}^1, E(-a-1)) \neq 0$, contradiction.

Then we want to show the above sequence splits, this is equivalent to

$$0 \to E_1^*(a) \to E^*(a) \to \mathcal{O} \to 0$$

splits, and his follows from the fact $H^1(\mathbb{CP}^1, E_1^*(a)) = H^1(\mathbb{CP}^1, \oplus\mathcal{O}(a-a_i)) = 0$, by Serre duality. So there is a section lifting $\mathcal{O} \to E^*(a)$, which splits the sequence. □

Prop. (11.9.7.6) [Weak Lefschetz Theorem]. Let X be a compact Kähler manifold and Y be a submanifold that the line bundle $\mathcal{L}(Y)$ is positive, then the canonical restriction map $H^k(X, \mathbb{C}) \to H^k(Y, \mathbb{C})$ is isomorphism for $k \leq n-2$ and injective for $k = n-1$.

Proof: In fact, using Hodge decomposition, it suffices to prove on the level of $H^q(X, \Omega_X^p)$. Tensoring the exact sequence

$$0 \to \mathcal{O}_X(-Y) \to \mathcal{O}_X \to i_* i_Y^* O_X \to 0$$

with Ω_X^p and taking the cohomology. By Serre duality and Kodaira vanishing(11.9.7.3), the map $H^q(X, \Omega_X^p) \to H^q(X, \Omega^p i_* i_Y^* O_X)$ is isomorphism for $p+q < n-1$ and injection for $p+q = n-1$.

Next consider the exact sequence $0 \to TY \to TX \to \mathcal{N}_{Y/X} \to 0$. By(5.5.1.26) there is an exact sequence

$$0 \to \wedge^p TY \to \wedge^p TX|_Y \to \wedge^{q-1} TY \mathcal{N}_{Y/X} \to 0$$

Taking dual and applying adjunction formula(11.8.1.3), it becomes:

$$0 \to \Omega_Y^{q-1} \otimes \mathcal{O}(-N) \to \Omega_X^q|Y \to \Omega_Y^q \to 0$$

Taking cohomology and use Serre duality and Kodaira vanishing as before, the result follows, and the composition is also true. □

Remark (11.9.7.7). There is a topological proof of weak Lefschetz theorem in [Bott, On a Theorem of Lefschetz].

8 Kodaira Embedding

Prop. (11.9.8.1)[Kodaira map]. For a holomorphic line bundle L on a compact complex manifold M, if $s_0, \ldots, s_n$ be a basis of $H^0(X, L)$, we try to define a map from M to $\mathbb{CP}^n : x \to [s_0(x), \ldots, s_n(x)]$. This is independent of the change of coordinates because $g_{\alpha\beta}$ is invertible, and it is definable iff L is basepoint-free. This map is holomorphic where it is definable.

Def. (11.9.8.2) [Ample Holomorphic Line Bundles]. A holomorphic line bundle $\mathcal{L}$ on a compact complex manifold X is called a

- **semi-ample holomorphic line bundle** iff for m large, $\mathcal{L}^m$ is basepoint-free.

- **very ample holomorphic line bundle** iff L is basepoint-free and the Kodaira map $\iota_L : X \to \mathbb{CP}^N$ is a holomorphic embedding.
- **ample holomorphism line bundle** iff for m large, L^m is very ample.

Lemma (11.9.8.3) [Cohomological Method for Very Ampleness]. For the above Kodaira map to be a holomorphic embedding, it suffice to show that the map is definable, injective and surjective on cotangent space. For these, it is equivalent to $H^0(X,L) \to L_x$ surjective, $H^0(X,L) \to L_x \oplus L_y$ surjective, and $L \otimes \mathcal{I}_x \to L_x \otimes T^{1,0*}(X)_x$ surjective. And they are true if

$$H^1(X, L\otimes \mathcal{I}_x) = 0, \quad H^1(X, L\otimes \mathcal{I}_{x,y}) = 0, \quad H^1(X, L\otimes \mathcal{I}_x^2) = 0.$$

respectively.

Proof: Basepoint-free at x is easily seen to be equivalent to $H^0(X,L) \to L_x$ surjective. And there is an exact sequence of sheaves:

$$0 \to L\otimes \mathcal{I}_x \to L \to L_x \to 0$$

where L_x means the skyscraper sheaf. So $H^1(X, L\otimes \mathcal{I}_x^2) = 0$ induces the result.

Injective is easily seen to be equivalent to $H^0(X,L) \to L_x \oplus L_y$ surjective. And there is an exact sequence of sheaves:

$$0 \to L\otimes \mathcal{I}_{x,y} \to L \to L_x \oplus L_y \to 0$$

where $\mathcal{I}_{x,y}$ is the sheave of functions vanishing at x and y, and $L_x \oplus L_y$ means the skyscraper sheaf. So $H^1(X, L\otimes \mathcal{I}_{x,y}) = 0$ induces the result.

For the surjection on cotangent spaces, given any point x, choose a basis $s_1, \ldots, s_n$ of sections in $H^0(X,L)$ vanishing at x, and by basepoint-free, there is a s_0 not vanishing at x, then on a coordinate, the Kodaira map is given by $x \to (s_1/s_0, \ldots, s_n/s_0)$, then it need to be checked $d_x(s_i/s_0) = d_x(x_i)/s_0$ span $T^{1,0*}(X)_x$. But there are exact sequences of sheaves:

$$0 \to L\otimes \mathcal{I}_x^2 \to L\otimes \mathcal{I}_x \xrightarrow{d_x} L_x \otimes T_x^{1,0*} \to 0$$

where d_x is given by $d_x(s\otimes f) = s(x)\otimes d_x(f)$(by the universal property of skyscraper sheaf), it suffice to give a map $(L\otimes \mathcal{I}_x \to L_x \otimes T_x^{1,0*})$, notice this is independent of the coordinate because $d_x(s_\alpha) = d_x(g_{\alpha\beta}s_\beta) = g_{\alpha\beta}d_x(s_\beta)$, as s_α vanishes at x, so this is truly a sheaf map, and its kernel is $L\otimes \mathcal{I}_x^2$. So $H^1(X, L\otimes \mathcal{I}_x^2) = 0$ induces the result. □

Prop. (11.9.8.4) [Ampleness and Positivity]. A holomorphic line bundle $\mathcal{L}$ on a compact Kähler manifold is ample iff it is positive.

Proof: If L is ample, then L^m is the pullback of the hyperplane bundle by the Kodaira map. The hyperplane line bundle is positive by(11.9.6.4), so L^m is positive with the induced metric, so L is also positive given the m-th roots of the induced metric (notice the metric of line bundle is just locally a number compatible with transition map).

Conversely, using(11.9.8.3), we want to find a L^k that $H^1(X, L^k\otimes \mathcal{I}_x) = 0, H^1(X, L^k\otimes \mathcal{I}_{x,y}) = 0, H^1(X, L^k\otimes \mathcal{I}_x^2) = 0$. First notice it suffice to prove for single points when k is sufficiently large, because the holomorphic embedding is an open property and X is compact so a sufficiently large k will suffice.

Consider the blowing-up $\widetilde{X}$ at a point x, there is a commutative diagram

$$\begin{array}{ccc} H^0(X, L^k) & \longrightarrow & L_x^k \\ \downarrow{\scriptstyle \pi^*} & & \downarrow{\scriptstyle \cong} \\ H^0(\widetilde{X}, \pi^* L^k \otimes L_x^k) & \longrightarrow & H^0(E, \mathcal{O}_E) \otimes L_x^k \end{array}$$

The right vertical map is isomorphism as $E \cong \mathbb{CP}^n$, so $H^0(E, \mathcal{O}_E) = \mathbb{C}$. The left exact sequence is also isomorphism: it is injective because π is surjective, and it is surjective because: if $\dim X = 1$, then $\pi = \mathrm{id}$ so trivially true, and if $\dim X \geq 2$, then because $\pi : \widetilde{X} - E \cong X - \{x\}$, any holomorphic function on $\widetilde{X}$ induces a holomorphic function on $X - \{x\}$ and by Hartog's theorem(10.6.5.3), it comes from a holomorphic function on X.

Now the second horizontal line is part of the cohomology exact sequence of(5.5.3.15)

$$0 \to \pi^* L^k \otimes \mathcal{O}_{\widetilde{X}}(-E) \to \pi^* L^k \to \pi^* L^k|_E \to 0$$

So it is reduced to prove $H^1(\widetilde{X}, \pi^* L^k \otimes \mathcal{O}(-E)) = 0$, but by(5.8.2.8), $\pi^* L^k - E = \pi^* L^k - E + \mathcal{K}_{\widetilde{X}} - \pi^* \mathcal{K}_X - (n-1)E = \mathcal{K}_{\widetilde{X}} + (\pi^* L^k - E) + \pi^*(L^k - \mathcal{K}_X)$, and by(11.9.6.5)(11.9.6.3) the last two are positive when k is large, so the conclusion follows from Kodaira vanishing(11.9.7.3).

The proof of $H^1(X, L^k \otimes \mathcal{I}_{x,y}) = 0$ is verbatim, just use blowing-up at two different points.

To prove $H^1(X, L^k \otimes \mathcal{I}_x^2) = 0$, consider the blowing-up $\widetilde{X}$ at a point x, notice there is a commutative diagram

$$\begin{array}{ccc} H^0(X, L^k \otimes \mathcal{I}_x) & \xrightarrow{d_x} & L_x^k \otimes T^{1,0*} X_x \\ \downarrow{\scriptstyle \pi^*} & & \downarrow{\scriptstyle \cong} \\ H^0(\widetilde{X}, \pi^* L^k - E) & \longrightarrow & L_x^k \otimes H^0(E, -E) \end{array}$$

In fact this comes from the two commuting exact sequences twisted with $\pi^* L^k$:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \pi^* \mathcal{I}_x^2 & \longrightarrow & \pi^* \mathcal{I}_x & \xrightarrow{d_x} & \pi^* T^{1,0*} X_x & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathcal{O}(-2E) & \longrightarrow & \mathcal{O}(-E) & \longrightarrow & \mathcal{O}_E(-E) & \longrightarrow & 0 \end{array}$$

The second line is(5.5.3.15) and the fact a section vanishing at x lifts to a section vanishing at E thus equivalent to a section in the twisted sheaf $- \otimes \mathcal{O}(-E)$. These two exact sequences commutes because

Back to the commutative diagram, the above argument also shows that the first vertical map is isomorphism. To show the second vertical map is isomorphism, notice by(5.8.2.7) $\mathcal{O}(-E)$ is just the hyperplane line bundle on E, so $H^0(E, -E) \cong T^{1,0*} X_x$, we need to know the vertical map is the natural map $V^* \to H^0(\mathbb{P}(V), \mathcal{O}(1))$. This in fact need some careful calculation using coordinates in(5.8.2.7).?

Now the map d_x is surjective iff the second horizontal map is surjective, with is part of the cohomology exact sequence of

$$0 \to \pi^* L^k \otimes \mathcal{O}_{\widetilde{X}}(-2E) \to \pi^* L^k \mathcal{O}_{\widetilde{X}}(-E) \to \pi^* L^k|_E \to 0$$

So it is reduced to prove $H^1(\widetilde{X}, \pi^* L^k \otimes \mathcal{O}(-wE)) = 0$, which is by Kodaira vanishing theorem the same reason as before. $\square$

Cor. (11.9.8.5) [Kodaira Embedding Theorem]. If a compact complex manifold M has a positive line bundle, then it is projective.

Def. (11.9.8.6) [Hodge Manifolds]. A compact Kähler manifold X is projective iff it has a closed positive $(1,1)$-form ω whose cohomology class $[\omega]$ is rational(resp. integral)(i.e. in $H^2(X,\mathbb{Q})$(resp. $H^2(X,\mathbb{Z})$)). In fact, a compact Kähler manifold with a Hodge metric is called a **Hodge manifold**. A pair $(X,[\omega])$ where X is a compact Kähler manifold and $[\omega]\in H^2(X,\mathbb{Z})$ is called a **polarized manifold**.

So compact Hodge manifolds are just those compact Kähler manifolds together with an ample line bundle class.

Proof: if ω is rational, then a multiple of it is integral, then there is a L that $c_1(L)=k[\omega]$ by Lefschetz theorem on $(1,1)$-forms(11.10.2.6), so L is positive by(11.9.6.2), which is equivalent to ampleness by(11.9.8.4), so X is projective. Conversely, the Chern class of the pullback of the hyperplane line bundle is positive and rational(11.9.6.4)(11.10.2.6). □

Cor. (11.9.8.7) [Compact Riemann Surfaces are Hodge Manifolds]. A **Riemann surface** is a complex variety of dimension 1. Any compact Riemann surface is a compact Hodge manifold.

Proof: This is because $H^2(X,\mathbb{C})=H^2(X,\mathbb{Q})\otimes_{\mathbb{Q}}\mathbb{C}\cong\mathbb{C}$ is generated by the metric form ω, so there must be a multiple of ω that is integral. □

Cor. (11.9.8.8). if $\widetilde{X}$ is the blowing-up of a Kähler manifold X at a point x, then if X is projective, then $\widetilde{X}$ is also projective, because by(11.9.6.5) $\pi^*L^k\backslash E$ is positive for k large.

Cor. (11.9.8.9). For a finite unbranched cover of compact Kähler manifolds $\widetilde{X}\to X$, $\widetilde{X}$ is projective iff X is projective.

Proof: A positive rational closed $(1,1)$-form on X pull backs to a positive rational closed $(1,1)$-form on $\widetilde{X}$, and it can even be pulled forward: $\omega'=\sum_{y\in\pi^{-1}(x)}(\pi^{-1})^*\omega(y)$, then it is also positive closed. It is rational because $\int_X\omega'\wedge\eta=\frac{1}{d}\int_{X'}\omega\wedge\pi^*\eta$, where $\widetilde{X}\to X$ is branched of degree d. □

Def. (11.9.8.10) [the Kähler Cone]. For a Kähler manifold X, the **Kähler cone** K_X is defined to be the set of closed real positive $(1,1)$-forms. Then K_X is an open convex cone in $H^{1,1}(X)\cap H^2(X,\mathbb{R})$. Then(11.9.8.6) says X is projective iff $K_X\cap H^2(X,\mathbb{Z})\neq 0$.

9 Fujiki Manifolds

11.10 Hodge Theory

1 Hodge-Structures and Polarization

Cf.[Complex Geometry Daniel Chap3.A].

Def. (11.10.1.1) [Integral Hodge Structures]. An **integral Hodge structure** of weight $k \in \mathbb{Z}$ is given by a a finite free Abelian group Λ together with a **Hodge decomposition**

$$\Lambda_{\mathbb{C}} = \oplus_{p+q=k} V^{p,q}.$$

satisfying $\overline{V^{p,q}} = V^{q,p}$.

Given an integral Hodge structure, we can associate a **Hodge filtration** $F^\bullet V : F^p V = \oplus_{r \geq p} V^{r,k-r}$. It satisfies

$$V_{\mathbb{C}} = F^p\Lambda \oplus \overline{F^{k-p+1}\Lambda}$$

for any p, and for any $p+q=k$,

$$V^{p,q} = F^p\Lambda \cap \overline{F^q\Lambda}.$$

Thus giving the Hodge decomposition is equivalent to giving the Hodge filtration.

Def. (11.10.1.2) [K-Hodge-deRham Structures]. For a subfield $\iota : K \subset \mathbb{C}$, a **$K$-Hodge-deRham structure** is a 4-tuple $V = (V_{\mathbb{Q}}, V_K, u, (V^{p,q})_{p,q\in\mathbb{Z}})$ where

- $V_{\mathbb{Q}} \in \mathcal{V}\mathrm{ect}_{\mathbb{Q}}$, $V_K \in \mathcal{V}\mathrm{ect}_K$,
- u is an isomorphism
$$u : V_K \otimes_K \mathbb{C} \cong V_{\mathbb{Q}} \otimes_{\mathbb{Q}} \mathbb{C},$$
endowing $V_K \otimes_K \mathbb{C}$ with a real structure,
- $(V_{p,q})$ is a finite disjoint family of subspaces of $V_K \otimes_{\mathbb{C}}$ s.t.
$$V_K \otimes_K \mathbb{C} = \bigoplus_{p,q} V^{p,q}, \overline{V^{p,q}} = V^{q,p}$$

and V is called **pure of weight** i iff $V^{p,q} = 0$ unless $p+q=i$.

Def. (11.10.1.3) [Primitive Parts].

Def. (11.10.1.4) [Hodge Classes]. If Λ is an integral Hodge structure of weight $2p$, define the **Hodge classes** of degree $2p$ to be the

$$\mathrm{Hdg}^{2p}(\Lambda, \mathbb{Z}) = \Lambda \cap V^{p,p} = \ker(\Lambda \to \Lambda_{\mathbb{C}}/F^p V).$$

Def. (11.10.1.5) [Polarizations]. An **integral polarized Hodge structure** of weight $k \in \mathbb{Z}$ is given by a Hodge structure $(\Lambda, F^p\Lambda)$ of weight k together with a Hermitian form H s.t.

- The Hodge decomposition is orthogonal for H.
- If $\alpha \neq 0 \in H^{p,q}(X)$, then
$$i^{p-q-k}(-1)^{\frac{k(k-1)}{2}} H(\alpha) > 0$$

2 Abel-Jacobi map

Intermediate Jacobians

Def. (11.10.2.1) [Intermediate Jacobians]. For any integral Hodge structure of weight $2k-1$, we can define

$$J^{2k-1}(\Lambda) = \Lambda_{\mathbb{C}}/(F^k\Lambda \oplus H^{2k-1}(X,\mathbb{Z})).$$

This is a complex torus.

Proof: We have a decomposition

$$\Lambda_{\mathbb{C}} = F^k\Lambda \oplus \overline{F^k\Lambda},$$

so $F^k\Lambda \cap \Lambda_{\mathbb{R}} = \{0\}$, thus the map

$$\Lambda_{\mathbb{R}} \to \Lambda_{\mathbb{C}}/F^k\Lambda$$

is an isomorphism of $\mathbb{R}$-vector spaces. □

Prop. (11.10.2.2). If $(\Lambda, F^\bullet\Lambda) \to (\Lambda', F^\bullet\Lambda')$ is a morphism of Hodge-structure of bidegree (r,r), then it induces a morphism of complex tori

$$J^{2p-1}(\Lambda) \to J^{2(p+r)-1}(\Lambda').$$

Def. (11.10.2.3) [Jacobian and Albanese Varieties]. If X is a compact Kähler manifold of dimension n, then $J^1(X)$ is also denoted by $\mathrm{Jac}(X)$, called the **Jacobian variety of** X, and $J^{2n-1}(X)$ is denoted by $\mathrm{Alb}(X)$, called the **Albanese variety** of X.

Prop. (11.10.2.4) [Jacobian]. The **Jacobian** $\mathrm{Jac}(X)$ of a compact Kähler manifold X is defined to be $H^1(X,\mathcal{O}_X)/H^1(X,\mathbb{Z})$, so it is a complex torus of dimension $b_1(X)$ by(11.10.2.1), it is also the kernel of the first Chern class map by the long exact seqence(11.8.5.8), i.e.

$$0 \to \mathrm{Jac}(X) \to \mathrm{Pic}(X) \xrightarrow{c} \mathrm{NS}(X) \to 0$$

Lemma (11.10.2.5). if X is compact Kähler , then the natural map $H^k(X,\mathbb{C}) \to H^k(X,\mathcal{O}_X)$ is just the projection onto the $(0,k)$-part. In particular, the image is in $H^{0,k}(X)$.

Proof: By Hodge decomposition, the definition of Dolbeault cohomology and the commutative diagram

$$\begin{array}{ccccccc}
\mathbb{C} & \longrightarrow & \mathcal{A}^0(X) & \xrightarrow{d} & \mathcal{A}^1(X) & \xrightarrow{d} & \mathcal{A}^2(X)\ldots \\
\downarrow & & \downarrow = & & \downarrow \pi_{0,1} & & \downarrow \pi_{0,2} \\
\mathcal{O}_X & \longrightarrow & \mathcal{A}^0(X) & \xrightarrow{\bar\partial} & \mathcal{A}^1(X) & \xrightarrow{\bar\partial} & \mathcal{A}^2(X)\ldots
\end{array}$$

□

Prop. (11.10.2.6) [Lefschetz theorem on $(1,1)$-forms]. By(11.8.5.8), the image of $\mathrm{Pic}_{\mathbb{C}}(X) \to H^2(X,\mathbb{Z})$ is trivial in $H^2(X,\mathcal{O}_X)$. And if X is compact Kähler , there is Hodge decomposition(11.9.4.1) $H^2(X,\mathcal{O}_X) = H^{2,0}(X) \oplus H^{1,1}(X) \oplus H^{0,2}(X)$.

So the image of $\mathrm{Pic}_{\mathbb{C}}(X)$ is contained in $H^{1,1}(X,\mathbb{Z}) = H^2(X,\mathbb{Z}) \cap H^{1,1}(X)$ by(11.10.2.5) and daulity. Then it is also surjective, this is to say, $\mathrm{NS}(X) = H^{1,1}(X)$

Proof: Because by the long exact sequence of(11.8.5.8) and(11.10.2.5) again, an $\alpha \in H^2(X,\mathbb{C})$ is in $H^{1,1}(X,\mathbb{Z})$ iff α is in the image of $\mathrm{Pic}_{\mathbb{C}}(X) \to H^{1,1}(X,\mathbb{Z})$. □

Abel-Jacobi Maps

Def. (11.10.2.7) [Abel-Jacobi Map]. For any $k \in \mathbb{Z}_+$, there is an **Abel-Jacobi map**

$$\Phi_X^k : Z^k(X)_{\mathrm{hom}} \to J^{2k-1}(X).$$

Proof: Cf.[Voison, P292].**?** □

Thm. (11.10.2.8) [Griffith1968]. Let X is a compact Kähler manifold, Y be a connected complex manifold and $y_0 \in Y$, $Z \subset Y \times X$ a cycle of codimension k s.t. each component Z_i of Z is smooth and the projection $Z_i \to Y$ is a submersion. Then the map

$$Y \to J^{2k-1}(X) : y \mapsto \Phi_X^k(Z_y - Z_{y_0})$$

is holomorphic.

Proof: Cf.[Voison, P294].**?** □

Def. (11.10.2.9) [Albanese Maps]. Fix a base point x_0 of X, by Griffith's theorem(11.10.2.8) applied to $\Delta \subset X \times X$, we get an **Albanese map**

$$\mathrm{Alb}_X : X \to \mathrm{Alb}(X) : x \mapsto \Phi_X^{2n-1}(x - x_0)$$

that is holomorphic and functorial in (X, x_0).

Prop. (11.10.2.10). if T is a torus, then the Albanese map $\mathrm{Alb}_T : T \to \mathrm{Alb}(T)$ is an isomorphism.

Proof: □

Prop. (11.10.2.11) [Universal Properties]. The Albanese map satisfies the following universal property: Any complex torus T and a map $f : X \to T$ s.t. $f(x_0) = 0$ factors through the Albanese map.

Proof:

□

Lemma (11.10.2.12). For $k \in \mathbb{Z}_+$ sufficiently large,

$$\mathrm{Alb}^k : X^k \to \mathrm{Alb}(X)$$

is surjective.

Proof: Cf.[Voison, P298].**?** □

Prop. (11.10.2.13). If $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\,/\mathbb{C}$, then $\mathrm{Alb}(X) \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}\,/\mathbb{C}$.

Proof: Cf.[Voison, P300].**?** The factorized map is

$$g : \mathrm{Alb}(X) = H^0(X, \Omega_X)^*/H_1(X, \mathbb{Z}) \to T = H^0(T, \Omega_T)^*/H_1(T, \mathbb{Z}).$$

□

3 Deligne Cohomology

Cf.[Voisin1, 2] and [Esnault-Viehweg, Deligne-Beilinson Cohomology].

Def. (11.10.3.1) [Deligne Complex]. Let X be a complex manifold and $p \in \mathbb{Z}_+$, the (real)**Deligne complex** $\mathbb{R}_{\mathrm{Del}}(p)$ is the complex

$$0 \to \mathbb{R}[0] \xrightarrow{(2\pi\,\mathrm{i})^p} \mathcal{O}_X \xrightarrow{d} \Omega_X \xrightarrow{d} \dots \xrightarrow{d} \Omega_X^{p-1} \to 0.$$

Similarly we can define the Deligne complex with coefficients in A for any ring $A \subset \mathbb{R}$.

Def. (11.10.3.2) [Deligne Cohomologies]. Let X be a complex manifold and $p \in \mathbb{Z}, k \in \mathbb{N}$, the **Deligne cohomology** $H^k_{\mathrm{Del}}(X, \mathbb{R}(p))$ is defined to be the hypercohomology $\mathbb{H}^k(X, \mathbb{R}_{\mathrm{Del}}(p))$(11.10.3.1). Similarly we can define the Deligne cohomology with coefficients in A for any ring $A \subset \mathbb{R}$.

Example (11.10.3.3). For $p = 1$, $\mathbb{Z}_{\mathrm{Del}}(1)$ is quasi-isomorphic to $\mathcal{O}_X^*[-1]$, so $H^{k+1}_{\mathrm{Del}}(X, \mathbb{Z}(1)) \cong H^k(X, \mathcal{O}_X^*)$.

For $p = 2$, there is a quasi-isomorphism

$$\begin{array}{ccccc}
(2\pi\,\mathrm{i})^2\mathbb{Z} & \longrightarrow & \mathcal{O}_X & \longrightarrow & \Omega_X^1 \\
 & & \Big\downarrow{\scriptstyle \exp((2\pi\,\mathrm{i})^{-1}(-))} & & \Big\downarrow{\scriptstyle (2\pi\,\mathrm{i})^{-1}} \\
 & & \mathcal{O}_X^* & \xrightarrow{f \mapsto d\log(f)} & \Omega_X^1
\end{array},$$

so $H^1_{\mathrm{Del}}(X, \mathbb{Z}(2)) = \mathbb{C}^\times$, and $H^2_{\mathrm{Del}}(X, \mathbb{Z}(2))$ corresponds to holomorphic line bundles with a holomorphic connection.

Prop. (11.10.3.4). If X is a compact Kähler manifold and $A \subset \mathbb{R}$, then there is a long exact sequence

$$\dots \to H^k_{\mathrm{Del}}(X, A(p)) \to H^k(X, A) \to H^k(X, \mathbb{C})/\operatorname{Fil}^p H^k(X, \mathbb{C}) \to H^{k+1}_{\mathrm{Del}}(X, A(p)) \to \dots$$

Proof: There is an exact sequence of complexes

$$0 \to \Omega_X^{\leq p-1}[-1] \to A_{\mathrm{Del}}(p) \to A(p) \to 0,$$

which induces a long exact sequence

$$\dots \to H^k_{\mathrm{Del}}(X, A(p)) \to H^k(X, A(p)) \to \mathbb{H}^k(X, \Omega_X^{\leq p-1}) \to H^{k+1}_{\mathrm{Del}}(X, A(p)) \to \dots.$$

And the exact sequence of complexes

$$0 \to \Omega_X^{\geq p} \to \Omega_X^\bullet \to \Omega_X^{\leq p-1} \to 0$$

and the fact $\mathbb{H}^k(X, \Omega_X^{\geq p}) \cong \operatorname{Fil}^p H^k(X, \mathbb{C}) \subset H^k(X, \mathbb{C})$**?** implies that $\mathbb{H}^k(X, \Omega_X^{\leq p-1}) \cong H^k(X, \mathbb{C})/F^p H^k(X, \mathbb{C})$. □

Cor. (11.10.3.5). There is an exact sequence

$$0 \to J^{2p-1}(X) \to H^{2p}_{\mathrm{Del}}(X, \mathbb{Z}(p)) \to \mathrm{Hdg}^{2p}(X, \mathbb{Z}) \to 0.$$(11.10.2.1)(11.10.1.4)

Prop. (11.10.3.6). Let X be compact Kähler of dimension p and $i < 2p$, then

$$H^i(X, \mathbb{R}(i)) \hookrightarrow H^k(X, \mathbb{C})/\operatorname{Fil}^p H^k(X, \mathbb{C}).$$

So there are exact sequences

$$0 \to H^{i-1}(X, \mathbb{R}(p)) \to H^{i-1}(X, \mathbb{C})/\operatorname{Fil}^p H^{i-1}(X, \mathbb{C}) \to H^i_{\mathrm{Del}}(X, \mathbb{R}(p)) \to 0.$$

And because $\mathbb{C} = \mathbb{R}(p) \oplus \mathbb{R}(p-1)$, there are exact sequences

$$0 \to \operatorname{Fil}^p H^{i-1}(X, \mathbb{C}) \to H^{i-1}(X, \mathbb{R}(p-1)) \to H^i_{\mathrm{Del}}(X, \mathbb{R}(p)) \to 0$$

is injective.

Proof: This is because $\mathfrak{c}$ acts as multiplication by $(-1)^p$ on the LHS, and $\operatorname{Fil}^p H^k(X, \mathbb{C}) \cap \overline{\operatorname{Fil}^p H^k(X, \mathbb{C})} = \oplus_{r,s \geq p} H^{r,s}(X)$, so the kernel is $\{0\}$. □

Prop. (11.10.3.7) [Comparison of Complex Conjugations]. For $X \in \mathcal{S}m\mathcal{P}roj/\mathbb{R}$, the canonical isomorphism

$$H_{\mathrm{Betti}}(X, \mathbb{R}) \otimes_{\mathbb{R}} \mathbb{C} = H_{\mathrm{Betti}}(X, \mathbb{C}) \xrightarrow{I_{\mathrm{dR}}} H^i_{\mathrm{dR}}(X^{\mathrm{an}}) \xrightarrow{GAGA} H^i_{\mathrm{dR}}(X) \otimes_{\mathbb{R}} \mathbb{C}$$

is an isomorphism that identifies the complex conjugation $\mathfrak{c}^* \otimes \mathfrak{c}$ on the LHS with $\mathfrak{c}$ on the RHS, so

Proof: Deligne, Prop1.4. □

Cor. (11.10.3.8). By taking the complex conjugation fixed part, we get an exact sequence

$$0 \to \operatorname{Fil}^p H^{i-1}_{\mathrm{Betti}}(X, \mathbb{R}) \to H^{i-1}_{\mathrm{Betti}}(X, \mathbb{R}(p-1))^{\mathfrak{c}^* = (-1)^{p-1}} \to H^i_{\mathrm{Del}}(X/\mathbb{R}, \mathbb{R}(p)) \to 0$$

Differential Characters

Def. (11.10.3.9)[Differential Characters]. Let X be a differential manifold and Z_l^∞ be the subgroup of closed singular differentiable chains, and $\Xi^l_\infty(X) \subset \operatorname{Hom}(Z_l^\infty, \mathbb{R}/\mathbb{Z})$ consisting of characters χ s.t. there exists $\omega \in \Omega^{l+1}(X)$ s.t.

$$\chi(\partial\varphi) = \int_{\Delta_{l+1}} \varphi^*\omega \in \mathbb{R}/\mathbb{Z}, \quad \forall \varphi \in C^\infty_{l+1}(X).$$

Such an ω is clearly uniquely determined by χ.

Prop. (11.10.3.10). For any $\chi \in \Xi^l_\infty(X)$, ω_χ is an integral closed form.

Proof: Cf.[Voisin, P306].? □

Prop. (11.10.3.11). If X is a complex manifold, and $\mu \in \Omega^{l-1}_{\mathbb{R}}(X)$, then for any closed chain $\varphi \in C^\infty_l(X)$,

$$\overline{\int_{\Delta_l} \varphi^*(\mathrm{i}\,\partial\mu)} = \int_{\Delta_l} \varphi^*(-i\overline{\partial}\mu) = \int_{\Delta_l} \varphi^*(-\mathrm{i}\,d\mu + \mathrm{i}\,\partial\mu) = \int_{\Delta_l} \varphi^*(\mathrm{i}\,\partial u),$$

so $\int_{\Delta_l} \varphi^*(\mathrm{i}\,\partial u) \in \mathbb{R}$, and we can define a differential character

$$\int \mathrm{i}\,\partial\mu \in \Xi^l_\infty(X) : \varphi \mapsto \int_{\Delta_l} \varphi^*(\mathrm{i}\,\partial u).$$

Prop. (11.10.3.12). For a compact Kähler manifold X and $p \in \mathbb{N}$, consider the subgroup $\Xi^{2p-1}_\infty(X)^{p,p} \subset \Xi^{2p}_\infty(X)$ consisting of differential characters χ s.t. ω_χ is of the type (p,p). Then

$$H^{2p-1}_{\mathrm{Del}}(X)^{p,p} \cong K^{2p-1}_\infty(X) = \Xi^{2p-1}_\infty(X)^{p,p}/\{\int \mathrm{i}\,\partial\mu | \mu \in \Omega^{p-1,p-1}(X)\}.$$

Proof: Cf.[Voisin, P307].? □

Properties of the Deligne Cohomology

Prop. (11.10.3.13) [Cup Products]. There are cup products

$$H^p_{\mathrm{Del}}(X, \mathbb{Z}(q)) \times H^{p'}_{\mathrm{Del}}(X, \mathbb{Z}(q')) \to H^{p+p'}_{\mathrm{Del}}(X, \mathbb{Z}(q+q')).$$

Proof: □

Prop. (11.10.3.14) [Cycle Class Maps]. For $X \in \mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}/\mathbb{C}$ and $p \in \mathbb{N}$, there are class maps

$$\mathrm{CH}^p(X) \to H^{2p}_{\mathrm{Del}}(X, \mathbb{Z})$$

that lifts the class $[Z] \in H^{2p}(X, \mathbb{Z})$(11.10.3.4), and commutes with products and cup products.

Proof: Cf.[Voisin, P311].**?** □

4 Coiveau

Def. (11.10.4.1) [Coniveau]. The **coniveau** of $\alpha \in H^\bullet_{\mathrm{Betti}}(X, \mathbb{Q})$ is the smallest number c s.t. there is a closed algebraic subscheme $Y \subset X$ s.t. $\alpha|_{X \setminus Y} = 0 \in H^\bullet_{\mathrm{Betti}}(X \setminus Y, \mathbb{Q})$.

Thm. (11.10.4.2) [Deligne]. If $\alpha \in H^\bullet_{\mathrm{Betti}}(X, \mathbb{Q})$ is mapped to $0 \in H^\bullet_{\mathrm{Betti}}(X \setminus Y, \mathbb{Q})$ where Y is pure of codimension c, then $\alpha = j_*\beta$, where $j : \overline{Y} \to Y \to X$ is a resolution of singularities of Y and $\beta \in H^{\bullet-2c}_{\mathrm{Betti}}(\widetilde{Y}, \mathbb{Q})$.

11.11 Locally Symmetric Spaces

1 Symmetric Spaces

Main references are[Hel78], [Mil17b] and [Lan20].

Def. (11.11.1.1) [Symmetric Spaces]. A Riemannian manifold is called **locally symmetric** at p if $\nabla R(p) = 0$. Locally symmetric is equivalent to the fact that every local reversing map is an isometry.

A **symmetric space** is a Riemannian manifold that $\nabla R = 0$ everywhere.

A symmetric space is complete because two folding is an extension of geodesics. In particular, a symmetric space is homogenous, and to check symmetrically, it suffices to show it is homogenous and locally symmetric at a point.

Proof: □

Prop. (11.11.1.2). A Lie group with a bi-invariant metric is a symmetric space.

Proof:

□

Prop. (11.11.1.3). The conjugate points in a symmetric space is easy to calculate, they are $\exp(\frac{\pi k}{\sqrt{e_i}}V)$, counting multiplicity, where e_i is the eigenvalue of the self-adjoint operator $K_V(W) = R(V,W)V$ at p.

Prop. (11.11.1.4) [Lie Group of Isometries]. Let M be a symmetric space, then the group of isometries $\mathrm{Isom}(M^\infty, g)$ of M has a natural structure of a Lie group.

Proof: Cf.[Helgason, homogenous Spaces, 4.3.2]. □

Prop. (11.11.1.5) [Symmetric Space is a Homogenous Space]. Let (M,g) be a symmetric space, and $p \in M$, then the subgroup $K_p \subset \mathrm{Aut}(M,g)^0$ fixing p is compact, and the natural map

$$\mathrm{Isom}(M,g)^0/K_p \to M^\infty$$

is an isomorphism of smooth manifolds, where $\mathrm{Isom}(M,g)^0/K_p$ is given the homogenous space structure(11.11.1.4). In particular, $\mathrm{Isom}(M,g)^0$ acts transitively on M.

Proof: Cf.[Mil17c]P12. □

2 Decompositions of Symmetric Spaces

3 Non-Compact Type

4 Compact Type

5 Hermitian Symmetric Spaces

Def. (11.11.5.1) [Hermitian Symmetric Spaces]. A **Hermitian symmetric space** is a Hermitian manifold that is a symmetric space(11.11.1.1) and that the local symmetries are all holomorphic.

Prop. (11.11.5.2) [Lie Group of Isometries]. For a Hermitian symmetric space, the group of holomorphic symmetries $\mathrm{Aut}(M,g)$ is closed in the group of isometries $\mathrm{Aut}(M^\infty, g)$, which is a Lie group by(11.11.1.4), so it is also a Lie group.

Prop. (11.11.5.3) [Basic Hermitian Symmetric Spaces]. There are three different families of Hermitian symmetric spaces(but not complete):

- (Non-compact Type): These spaces are non-compact and simply connected, with negative curvatures, and $\mathrm{Isom}(M,g)^0$ is adjoint and non-compact.
- (Compact Type): These spaces are compact and simply-connected, with positive curvatures, and $\mathrm{Isom}(M,g)^0$ is adjoint and compact.
- (Euclidean Type): These spaces have constant curvature 0.

Proof: Cf.Helgason 1978, Chap8. □

Prop. (11.11.5.4) [Decomposition]. Any Hermitian symmetric space M decomposes into a product $M^0 \times M^+ \times M^-$ of Hermitian symmetric spaces with M^0 Euclidean, M^- of non-compact type and M^+ of compact type.

Proof: □

Prop. (11.11.5.5). Any Hermitian symmetric space of Euclidean type is a quotient of $\mathbb{C}^g$ by a discrete subgroup of translations.

Proof: □

Example (11.11.5.6). The projective space $\mathbb{P}^n(\mathbb{C})$ with the Fubini-Study metric is a Hermitian symmetric space. For any p, the (descent of) the rotation through π about the axis through p and its polar opposite is the geodesic isomorphism at p.

Proof: See(11.9.1.6). □

6 Hermitian Symmetric Domains

Def. (11.11.6.1) [Hermitian Symmetric Domain]. A Hermitian symmetric space of non-compact type(11.11.5.3) is called a **Hermitian symmetric domain**. A **bounded symmetric domain** is a bounded open connected symmetric subset of $\mathbb{C}^n$.

Prop. (11.11.6.2). Every Hermitian symmetric domain can be embedded into $\mathbb{C}^n$ for some n, and the image is bounded.

Proof:

□

Prop. (11.11.6.3) [Bergman Metric]. Every bounded symmetric domain has a canonical Hermitian metric called the **Bergman metric**, it is invariant under holomorphic automorphisms, and it has negative curvatures.

Proof: Cf.[Mil17]P11 and [Hel78]8.3.3. □

Cor. (11.11.6.4). Every Hermitian symmetric domain D has a unique Hermitian metric that maps to the Bergman metric under any isomorphism of D onto a bounded symmetric domain.

Cor. (11.11.6.5). A complex manifold is a a symmetric Hermitian domain iff it is biholomorphic to a bounded symmetric domain.

Proof: □

Def. (11.11.6.6) [Siegal Upper Half Plane $\mathscr{H}_g$]. The **Siegal upper half space** $\mathscr{H}_g$ consists of symmetric complex $g \times g$ matrices $Z = X + iY$ with Y positive definite. It is identified with an open subset of $\mathbb{C}^{g(g+1)/2}$. The symplectic group $\mathrm{Sp}(2g;\mathbb{R})$(11.7.4.1) acts transitively on $\mathscr{H}_g$ via

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} Z = (AZ+B)(CZ+D)^{-1}$$

The matrix $\begin{bmatrix} 0 & -I \\ I & 0 \end{bmatrix}$ acts as an involution on $\mathscr{H}_g$, and has iI_g has its fixed point, so $\mathscr{H}_g$ is homogenous and symmetric.

The injection into $\mathbb{C}^g$ is not holomorphic, so we cannot see from this that $\mathscr{H}_g$ is holomorphic, but we can see from**?**

Proof: **?** □

Cor. (11.11.6.7) [Upper Half Plane]. By(11.7.4.10), the group $GL(2;\mathbb{R})$ acts continuously on $\mathbb{C}$ by $\gamma(z) = \frac{az+b}{cz+d}$ where $\gamma = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$.

The groups $GL(2,\mathbb{R})$ preserves the upper plane $\mathscr{H}$, by(10.5.1.8). The action of $\mathrm{SL}(2;\mathbb{R})$ on $\mathscr{H}$ is transitive and the stabilizer of i is $SO(2,\mathbb{R})$, thus we have $\mathcal{H} \cong SL(2;\mathbb{R})/SO(2;\mathbb{R})$, and $\mathrm{PSL}(2;\mathbb{R})$ is the group of holomorphic automorphisms of $\mathcal{H}$ by(10.5.7.8).

Also, the Riemannian metric $\frac{\mathrm{d}x\mathrm{d}y}{y^2}$ on $\mathscr{H}$ is fixed by the action of $GL(2;\mathbb{R})$.

Def. (11.11.6.8) [Siegal Unit Disk $\mathbb{D}_g$]. Let $\mathbb{D}_g$ be the set of symmetric complex matrixes that $I - Z^*Z$ is positive definite, then it is identified with an open subset of $\mathbb{C}^{g(g+1)/2}$, this is a holomorphic embedding.

There is an isomorphism from $\mathcal{H}_g$(11.11.6.6) to $\mathcal{D}_g$:

$$Z \mapsto (Z - iI_g)(Z + iI_g)^{-1}.$$

This is an isomorphic, so D_g is symmetric, and $\mathcal{H}_g$ has an invariant metric, so they are both Hermitian symmetric domains**?**.

Proof: **?**. □

Prop. (11.11.6.9). Let (M, g) be a Hermitian symmetric domain, then the inclusions

$$\mathrm{Aut}(M^\infty, g) \supset \mathrm{Aut}(M, g) \subset \mathrm{Aut}^{\mathrm{Hol}}(M)$$

induce equalities

$$\mathrm{Aut}(M^\infty, g)^0 = \mathrm{Aut}(M, g)^0 = \mathrm{Hol}(M)^0$$

Then $\mathrm{Hol}(M)^0$ acts transitively on M, the stabilizer K_p of p in $\mathrm{Aut}^{\mathrm{Hol}}(M)^0$ is compact, and

$$\mathrm{Hol}(D)^0/K_p \cong M^\infty.$$

Proof: Cf.[Mil17b]P12. □

Prop. (11.11.6.10). The Lie group $\mathrm{Aut}^{\mathrm{Hol}}(M)$ in(11.11.6.9) is a real semisimple Lie group with only f.m. connected components and trivial center.**?**

If G is a connected simple real algebraic group with trivial center s.t. $D = G(\mathbb{R})^0/K$ for some maximal compact subgroup $K \subset G(\mathbb{R})^0$, then $\mathrm{Aut}(D) \cap G(\mathbb{R}) = G(\mathbb{R})^0$, and $G(\mathbb{R})$ has one or two connected components.

Proof: ? □

Prop. (11.11.6.11) [Rotation at a Point]. Let D be a Hermitian symmetric domain and $p \in D$, then there is a unique homomorphism $u_p : U_1 \to \mathrm{Hol}(D)$ that $u_p(z)$ fixes p and acts on $T_p(D)$ as multiplication by z.

Prop. (11.11.6.12) [Classification of Hermitian Symmetric Domains]. The isomorphism classes of irreducible Hermitian symmetric domains are classified by the special nodes on connected Dynkin diagrams.

Proof: Cf.[Mil17]P20. □

7 Locally Symmetric Varieties

Prop. (11.11.7.1) [$D(\Gamma)$]. Let D be a Hermitian symmetric domain, and let Γ be a discrete subgroup of $\mathrm{Aut}^{\mathrm{Hol}}(D)^0$. If Γ is torsion-free, then Γ acts freely on D, and there is a unique complex manifold structure on $\Gamma\backslash D$ that the quotient map $\pi : D \to \Gamma\backslash D$ is a holomorphic covering space.

In this case, denote $D(\Gamma) = \Gamma\backslash D$, and D is a universal covering of $D(\Gamma)$, by(11.11.5.3) and(11.11.6.1).

Proof: Cf.[Mil17b]P32. □

Prop. (11.11.7.2). Let D be a Hermitian symmetric domain and $\Gamma \subset \mathrm{Hol}(D)^0$ is a discrete subgroup, then by(11.11.6.9), Γ has finite covolume in $\mathrm{Hol}(D)^0$ iff $\Gamma\backslash D$ has finite covolume,

Proof: □

Prop. (11.11.7.3). $D(\Gamma)$ has only f.m. automorphisms, as a complex manifold.

Proof: Cf.[Mil17b]P41. □

Thm. (11.11.7.4) [Satake-Baily-Borel Compactifications]. Let D be a locally symmetric Hermitian space and $\Gamma \subset \mathrm{Hol}(D)^0$ an arithmetic subgroup(13.4.2.1), then $D(\Gamma)$ can be realized as an open subset of a projective variety $\overline{D(\Gamma)}$ over $\mathbb{C}$, and it is a normal algebraic variety. If moreover Γ is torsion-free, then it is smooth, by(11.11.7.1).

Such a projective variety $D(\Gamma)$ is called a **locally symmetric variety**.

Proof: Cf. [BAILY-BOREL, Compactification of arithmetic quotients of bounded symmetric domains. 84:442–528. 1966] and [CASSELMAN, Geometric rationality of Satake compactifications, pp. 81–103.1997].

Cf.[Mil17b]P38 for a history. □

Thm. (11.11.7.5) [Borel]. Let $D(\Gamma)$ be a quotient variety(11.11.7.4) of a Hermitian symmetric domain by a torsion-free arithmetic subgroup Γ in $\mathrm{Aut}^{\mathrm{Hol}}(D)^0$, then for any other smooth quasi-projective variety V over $\mathbb{C}$, any holomorphism map $V^{\mathrm{an}} \to D(\Gamma)^{\mathrm{an}}$ comes from a morphism.

Proof: □

Cor. (11.11.7.6) [Algebraic Structure is Unique]. The algebraic variety structure on $D(\Gamma)$ is unique. Any variety of the form is called a **locally symmetric variety**.

Proof: If there is another structure, then by GAGA it is a smooth variety, then the holomorphic map extends to a bijective morphism, which must be an isomorphism, by [Milne, Algebraic Geometry, P188]**?**. □

Cor. (11.11.7.7) [Borel]. The Satake-Baily-Borel compactification(11.11.7.4) $\overline{D(\Gamma)}$ is minimal in the sense that it factors through any compactification $D(\Gamma) \subset V$ s.t. $V \backslash D(\Gamma)$ is a divisor with only normal crossings as singularities.

Proof: Cf.[Borel 1972]**?** □

11.12 Compactifications of Locally Symmetric Spaces

Main references are [Smooth compactifications of locally symmetric varieties, Rapoport-Scholze](contains a lot of references), [Toroidal Compactification of Siegel Spaces (1980).pdf], [Goresky, M. 2005. Compactifications and cohomology of modular varieties, pp. 551–582. In Harmonic analysis, the trace formula, and Shimura varieties] and [SATAKE, 2001. Compactifications, old and new].

Def. (11.12.0.1) [Toroidal Compactifications]. Cf. [BOREL, A. AND JI, L. 2006. Compactifications of symmetric and locally symmetric spaces].

For Siegel modular varieties, there is a short note in [Conrad, Mordell conjecture seminar].

Cf.[Princeton Companion].

12 Algebraic Number Theory

12.1 Additive Number Theory

References are [Introduction to the theory of numbers, Hardy-Wright]. [Some Results in the Additive prime-number theory, Long-Keng Hua].

1 Circle Methods

Prop. (12.1.1.1). For any $\alpha \in \mathbb{R} \setminus \mathbb{Z}$ and $M \in \mathbb{Z}_+$,

$$\sum_{n=1}^{M} e^{2\pi\,\mathrm{i}\,\alpha n} \leq \frac{1}{2\{\{\alpha\}\}}.$$

Proof:

$$|\sum_{n=1}^{M} e^{2\pi\,\mathrm{i}\,\alpha n}| = |\frac{e^{2\pi\,\mathrm{i}\,\alpha M}-1}{e^{2\pi\,\mathrm{i}\,\alpha}-1}| \leq |\frac{2}{2\sin(\pi\alpha)}| \leq \frac{1}{2\{\{\alpha\}\}} \text{(10.4.7.2)}$$

□

12.2 p-adic Analysis

References are [Non-Archimedean Analysis Part A].

This section should only contain theorems that are only applicable to non-Archimedean valuations. Theorems that are applicable to both Archimedean and non-Archimedean valuations should be put into10.8.

As far as I know, all properties proved in Functional Analysis independent of complex analysis is applicable to the non-Archimedean case, and in fact, the goal of this section is to build an analytic theory parallel to complex analysis.

1 (Ultranormed) Valuation Theory

Ultranormed Rings

Def. (12.2.1.1) [Normed Groups]. A **semi-normed group** is a group with a non-Archimedean valuation, it is called a **normed group** iff the valuation has kernel 0, which is equivalent to Hausdorff.

A normed group is totally connected, because open balls at 0 are subgroups hence closed.

Def. (12.2.1.2) [Normed Ring]. A **(semi-)normed ring** is a (semi-)normed additive group that

- $|1| = 1$. or the valuation is trivial.
- $|ab| \le |a||b|$.

A **valued ring** is a normed ring with $|ab| = |a||b|$. It is called **degenerate** if all non-zero valuation value≥ 1.

Prop. (12.2.1.3). A valuation on a ring is non-Archimedean iff $\{|n|\}$ is bounded. Thus any valuation on a field with finite characteristic is non-Archimedian.

Prop. (12.2.1.4). In a normed ring, every triangle is an acute isosceles triangle. (This is because the biggest is smaller than the maximal of the other two, thus the biggest two are equal). Hence we have, for a circle $B(O, r)$, any interior point P is a center of circle, because $OP < r$.

Def. (12.2.1.5) [Bald Rings]. A normed ring R is call a **B-ring** if elements of valuation 1 is invertible, it is called **bald** if there is a ε that no elements has valuation in $(1-\varepsilon, 1)$.

Def. (12.2.1.6) [Uniform Rings]. A non-Archimedean ring A is called **uniform** if the set of topologically nilpotent elements are bounded in A.

Prop. (12.2.1.7). If K is a normed field with valuation ring R, the smallest subring containing a zero sequence $a_0, a_1, \ldots$ is bald(12.2.1.5).

Proof: Cf.[Formal and Rigid Geometry P25]. □

Def. (12.2.1.8) [Topologically Nilpotent Elements]. An element a in a normed ring A is called **topologically nilpotent** iff $\lim a^n = 0$. The set of all topological nilpotent elements in A are denoted by $\check{A}$ or A^0.

Prop. (12.2.1.9). $\check{A}$ is a subgroup of A^+, which is multiplicatively closed, then $\check{A}$ is clopen in A. In particular, $\check{A}$ is complete if A is complete.

Proof: Cf.[Non-Archimedean analysis P27]. □

Prop. (12.2.1.10) [Nakayama's Lemma]. If A is complete normed ring and M is a A-module, if there are f.m. elements x_i of M that $M = N + \sum x_i M$, then $M = N$.

Proof: The proof is verbatim as the proof of the usual Nakayama lemma. □

Normed Modules

Def. (12.2.1.11) [Ultranormed Module]. A module M over a normed ring A is called **normed module** iff it is a normed additive group and $|ax| \leq |a||x|$ for $a \in A, x \in M$. If A is valued and the equality always holds, we call it **faithfully normed** or **valued module**.

If A is a valued field, any normed module is valued.

Prop. (12.2.1.12) [Ultranormed Algebra]. A normed algebra is an A algebra B with $A \to B$ bounded of norm 1.

Prop. (12.2.1.13). For two valued module over A, if A is non-degenerate, a morphisms is bounded iff it is continuous. This is because we can multiply by elements of A to reduce to a nbhd of 0.

This applies to the case when A contains a field where the valuation is non-trivial, because we can use(12.2.1.11).

Def. (12.2.1.14) [Completed Tensor Product]. For two normed modules over a normed ring R, there is a complete normed R-module $M\widehat{\otimes}N$ called the **completed tensor product**, satisfying the following universal properties: $M \times N \to M\widehat{\otimes}N$ is bounded by 1, and for any complete normed R-module T and a R-map $M \times N \to T$ bounded by a, then it factor through a R-map $M\widehat{\otimes}N \to T$ bounded by a.

It satisfies many universal properties as you can imagine.

Proof: Cf.[Formal and Rigid Geometry P238]. □

Cor. (12.2.1.15). By(12.2.1.13), when A is non-degenerate, then the amalgamated sum is just the fibered pushout when restricted to the category of complete valued module over A with continuous maps as morphisms, because it satisfies the universal property.

Prop. (12.2.1.16)[Amalgamated Sum]. For two normed R-algebras there is an operation of **amalgamated sum** which satisfies universal properties similar to(12.2.1.14). In fact, it is just the completed tensor product when seen as modules.

Proof: Cf.[Formal and Rigid Geometry P242]. □

Weakly Cartesian Space

Def. (12.2.1.17) [Weakly Cartesian Vector Spaces]. A normed K-vector space over a valued field K is called **weakly Cartesian** if**?**

Prop. (12.2.1.18). If K is a complete valued field, then each normed K-vector space V is weakly Cartesian.

Proof: Cf.[Non-Archimedean Analysis P92]. □

Completeness

Prop. (12.2.1.19) [Cauchy Sequence of Non-Archimedean field]. For a sequence $\sum a_i$ in a non-Archimedean field, it is a Cauchy sequence iff $\lim |a_i| = 0$.

In particular, convergent sequence are all absolutely convergent and for a Cauchy sequence not converging to 0, the valuations of the terms stabilize.

Proof: One way is easy, the other way, notice $|\sum_{v=i}^{j} a_i| \leq \max_{i,i+1,\ldots j} |a_v| < \varepsilon$. □

Prop. (12.2.1.20) [Completion of a Field]. The completion of a non-Archimedean field is preferred to choose the definition of Cauchy sequence, so we see by(12.2.1.19) that $v(\widehat{K}) = v(K)$.

Prop. (12.2.1.21). For a complete field K and any finite vector space L, L has only one norm up to equivalence and it is complete.

Proof: Cf.[Formal and Rigid Geometry P230]. □

Prop. (12.2.1.22). A complete valuation on a field can extend uniquely to a valuation on its alg.closure. And in the finite case, it is $|\alpha| = |N(\alpha)|^{\frac{1}{d}}$. This is an immediate consequence of(12.2.1.33) and(12.2.1.30), and $|\alpha| \leq 1$ iff it is integral over valuation ring R of K.

Prop. (12.2.1.23). Any infinite separable algebraic extension of a complete field is never complete.

Proof: We use Krasner's lemma(12.2.1.34). By Ostrowski theorem(10.3.3.18), we can assume it is non-Achimedean, otherwise it cannot by infinite dimensional. Choose an infinite linearly independent basis of decreasing value rapidly enough, then we can see the field generated by the limit contains all the partial sums, contradiction. □

Prop. (12.2.1.24). If $K = \overline{K}$, then $\widehat{K} = \overline{\widehat{K}}$.

Proof: Let $L = \overline{\widehat{K}}$, then we can extend to a valuation on L, now let f be a monic polynomial with coefficients in $\widehat{K}$, we show its root $\alpha \in L$ can be approximated by elements in K, now let g monic in $K[X]$ be an approximation of f that $|g(\alpha)| \leq \varepsilon^n$, then there is a root β of g that $|\alpha - \beta| < \varepsilon$, and $\beta \in K$ by alg.closedness. □

Prop. (12.2.1.25). If K is a complete, then K^{sep} is dense in $\overline{K}$.

Proof: Assume F is non-Archimedean, then for $y \in F^{alg}$, there is a n that $y^{p^n} = \alpha \in F^{sep}$. We may assume $|\alpha| \leq 1$, then let π be an element that $|\pi| < 1$, then if y_i is a root of the separable polynomial $Y^{p^n} - \pi^i Y - \alpha = 0$, then $(y - y_i)^{p^n} = \pi^i y_i$. So $|y - y_i| \to 0$. □

Def. (12.2.1.26) [$\mathbb{Q}_p$, Hensel1897]. For $p \in \mathbf{P}$, $\mathbb{Q}_p$ is defined to be the p-adic completion of $\mathbb{Q}$, called the **field of p-adic numbers**. Its ring of integer is $\mathbb{Z}_p$, which equals the p-adic completion of $\mathbb{Z}$, called the **ring of p-adic integers**.

Prop. (12.2.1.27). There is a non-canonical isomorphism $\overline{\mathbb{Q}_p} \cong \mathbb{C}$, not compatible the topology.

Proof: This follows from(2.2.6.5) and the fact they both have the same cardinality $\aleph_1$. □

Cor. (12.2.1.28). The p-adic valuation on $\mathbb{Q}$ can be extended to $\mathbb{C}$ non-canonically.

Henselian Valued Fields

Def. (12.2.1.29) [Henselian Valued Field]. A **Henselian valued field** is a valued field K that the valuation ring $\mathcal{O}_K$ is a Henselian local ring(4.3.10.1).

Prop. (12.2.1.30). A valued field K is Henselian(12.2.1.29) iff the valuation of K has a unique extension to any finite extension L/K.

Proof: Cf.[Algebraic Number Theory Neukirch P144]. □

Def. (12.2.1.31) [Ramification Degrees]. If L/K is a finite extension of valued field of degree n, then v extends uniquely to $w(\alpha) = \frac{1}{n}v(N_{L/K}(\alpha))$, now we define the **ramification degree** as $[w(L^*) : v(K^*)]$, and the **inertia degree** as the degree of the residue field extension.

Thus for a normal extension, x and $\sigma(x)$ has the same valuation. Hence any polynomial in $K[X]$ has a decomposition into polynomials where all their roots has the same valuation.

Prop. (12.2.1.32) [Hensel's Lemma Generalized]. Let K be a complete valued non-Archimedean field and $\mathcal{O}_K$ be the valuation ring. If $P, Q, R \in \mathcal{O}_K[X]$ and $0 \leq \lambda < 1$ that $\deg P = m + n, \deg Q = n, \deg R = m$, and

$$\deg(P - QR) \leq m + n - 1, \quad |P - QR|_G \leq \lambda |\operatorname{res}(Q, R)|^2$$

Where $|-|_G$ is the induced Gauss norm on $K[X]$. Then there exist polynomials U, V that

$$|U|_G, |V|_G \leq \lambda |\operatorname{res}(Q, R)|^2, \deg U \leq n - 1, \deg V \leq m - 1$$

and $P = (Q + U)(R + V)$.

Proof: If $\rho = |\operatorname{res}(Q, R)| = 0$, then $P = QR$. Otherwise, the map $\theta_{Q,R} : W_m \oplus W_n \to W_{m+n}$ is invertible(2.2.2.9). Then we let $\varphi(U, V) = \theta_{Q,R}^{-1}(P - QR - UV)$, then If $U, V \in B(0, \lambda\rho)$, then $|\varphi(U, V)|_G \leq \lambda\rho$. And it can be proved φ is a contraction map from $B(0, \lambda\rho)^2$ to itself with contraction factor λ, so it has a fixed point (U, V) by(3.3.8.9). So $QU + RV = P - QR - UV$. □

Cor. (12.2.1.33) [Hensel's Lemma]. If K be a complete and A be the valuation ring. Suppose $P(X) \in A[X]$ and α_0 is an element of A s.t. $|P(\alpha_0)/P'(\alpha_0)^2| = \varepsilon < 1$, then there exists a $\alpha \in A$ that $P(\alpha) = 0$ and $|\alpha - \alpha_0| \leq |P(\alpha_0)/P'(\alpha_0)|$.

The usual form is when $|P'(\alpha_0)| = 1$, in which case we can pass to the residue field. Equivalently, a complete valued field is Henselian(12.2.1.29).

Proof: Let $\lambda = |P(\alpha_0)/P'(\alpha_0)|$ and $\operatorname{res} = |P'(\alpha_0)$. Notice If $P(X) = Q(X)(X - \alpha_0) + P(\alpha)$, then $\operatorname{res}(Q(X), X - \alpha_0) = Q(\alpha_0) = P'(\alpha_0)$(2.2.2.11). □

Prop. (12.2.1.34) [Krasner's Lemma]. If $\alpha, \beta \in \overline{K}$ that $|\alpha - \beta| < |\alpha - \sigma(\alpha)|$ for all σ, then $K(\alpha, \beta)/K(\beta)$ is purely inseparable. So when α is separable over K, $K(\alpha) \in K(\beta)$.

Proof: It suffice to prove that for all field morphism $\tau : K(\alpha, \beta) \to \overline{K}$ fixing $K(\beta)$, $\tau(\alpha) = \alpha$. This is because $|\tau(\alpha) - \beta| = |\alpha - \beta| < |\alpha - \sigma(\alpha)|$, thus $|\tau(\alpha) - \alpha| \leq \max\{|\tau(\alpha) - \beta|, |\beta - \alpha|\} < |\alpha - \sigma(\alpha)|$. □

Cor. (12.2.1.35). If f is a separable irreducible polynomial and α is a root, then for g closed enough to f, there is a root β of g that $K(\beta) = K(\alpha)$. (Immediate consequence of(10.3.3.19)).

Cor. (12.2.1.36). Any finite separable extension $\mathcal{L}/\widehat{K}$ is of the form $L_0\widehat{K}$ for some finite separable extension L_0/K. (Because of primitive element theorem**?**).

Cor. (12.2.1.37). $K \subset \overline{K}$ is dense, then $K = \overline{K}$.

2 Extensions of Henselian Valued Fields

Notation (12.2.2.1).

- Let $(K, v, \mathcal{O}_K, \mathfrak{p}_v, \varpi, k)$ be a Henselian non-Archimedean valued field of residue characteristic p, and $\varpi \in K^\times, |\varpi| < 1$ a uniformizer. If $\mathcal{O}_K$ is DVR, assume $(\pi) = \mathfrak{p}_v$.

Lemma (12.2.2.2) [Extension is Monogenous]. For a finite extension of CDVR, if the residue field extension λ/k is separable, then there exists a $x \in \mathcal{O}_L$ that $\mathcal{O}_K[x] = \mathcal{O}_L$.

Proof: If $\overline{x}$ is an element of λ that generate λ over k, by primitive element theorem, then let $\overline{f}$ be the minipoly of $\overline{x}$, then let f, x be lifting of them, then $f(x)$ is a uniformizer, otherwise $f'(x)$ has valuation 0, so $f(x + \pi_L)$ is a uniformizer. Now we see that $x^i f(x)^j$ is a basis of $\mathcal{O}_L$ over $\mathcal{O}_K$, □

Prop. (12.2.2.3). If L/K is a finite separable extension and if I is an ideal of $\mathcal{O}_L$, then $v_K(\mathrm{tr}_{L/K}(I)) = \lfloor v_K(I.\mathfrak{D}_{L/K}) \rfloor$.

Proof: By definition, $\mathrm{tr}_{L/K}(x\mathcal{O}_L) \subset \mathcal{O}_K$ iff $x \in \mathcal{D}_{L/K}^{-1}$, thus $\mathrm{tr}_{L/K}(I) \subset J$ iff $I \subset \mathcal{D}_{L/K}^{-1} J$, i.e. $\mathrm{tr}_{L/K}(I)$ is the smallest ideal J of $\mathcal{O}_K$ that contains $I \cdot \mathcal{D}_{L/K}$, thus the result. □

Unramified Extensions

Def. (12.2.2.4) [Unramified Extensions]. A finite extension L/K is called **unramified extension** if the residue field extension λ/k is separable and $[L : K] = [\lambda : k]$. Any algebraic extension is called **unramified** iff any finite extension is unramified.

This is compatible because unramified extensions form a distinguished class. So we can talk about the **maximal unramified extension** T of K, and a field extension L/K is called **unramified** if all finite subextensions are unramified.

Proof: It is faithfully transitive because the field extension degree is transitive, and for base change, as the residue field is separable, we let $\lambda = k[\overline{\alpha}]$, and choose a lift $\alpha \in \mathcal{O}_L$, the minipoly of α is $f(X) \in \mathcal{O}_K[X]$. Then we have

$$[\lambda : k] \leq \deg \overline{f} = \deg f = [K(\alpha) : K] \leq [L : K] = [\lambda : k]$$

So $L = K(\alpha)$ and $\overline{f}$ is the minipoly of $\overline{\alpha}$. Then $L' = K'(\alpha)$, and let $g(X)$ be the minipoly of α over K', then $\overline{g}$ is a factor of $\overline{f}$ so separable, hence irreducible by Hensel's lemma. Noe:

$$[\lambda' : k'] \leq [L' : K'] = \deg g = \deg \overline{g} = [k'(\alpha) : k'] \leq [\lambda' : k].$$

So $[\lambda' : k'] = [L' : K']$. □

Prop. (12.2.2.5) [Maximal Unramified Extension]. The residue field of the maximal unramified extension K^{ur}/K is $\overline{k}$, and the value group is the same as K.

Proof: The first assertion is because for any separable polynomial, it has a lift which is irreducible has a root lifting $\overline{\alpha}$, contradicting the maximality. For the second, look at finite subextensions, then it results from the fundamental inequality(10.3.3.20). □

Tamely Ramified Extensions

Def. (12.2.2.6) [Tamely Ramified Extension]. For K a Henselian non-Archimedean valued field, a finite field extension L/K is called a **tamely ramified extension** if the residue field extension is separable and $([L:T],p)=1$, where T is the maximal unramified subextension.

Prop. (12.2.2.7). Tamely unramified extensions form a distinguished class, so we can talk about the maximal tamely unramified extensions, and a field extension L/K is called **tamely ramified** if all finite subextensions are tamely unramified.

Proof: Cf.[Algebraic Number Theory Neukirch P156]. □

Prop. (12.2.2.8). A finite extension L/K is tamely ramified iff the extension is generated by radicals over the maximal unramified extension: $L=K^{\mathrm{ur}}(\sqrt[m]{a_i}),(m,p)=1$, where $a_i\in K^{\mathrm{ur}}$, (WARNING: make sure if $a_i\in K$ or not?).

Proof: Cf.[Algebraic Number Theory Neukirch P155]. □

Prop. (12.2.2.9). The value field of tamely ramified extensions. Cf.[Neukirch P157].

Totally Ramified Extensions

Def. (12.2.2.10) [Eisenstein Polynomial]. Let $(R,\mathfrak{m})$ be a DVR, an **Eisenstein polynomial** in $R[T]$ is a polynomial of the form

$$f(T)=T^n+a_{n-1}T^{n-1}+\ldots+a_1T+a_0$$

where $a_i\in\mathfrak{m}$ for any i and $a_0\in\mathfrak{m}\backslash\mathfrak{m}^2$.

Prop. (12.2.2.11)[Totally Ramified Extensions via Eisenstein Polynomials]. If $e(T)$ is an Eisenstein polynomial in $\mathcal{O}_K[T]$ and Π is a root of $e(T)$ in $\overline{K}$, then $L=K(\Pi)$ is a totally ramified extension of K with uniformizer Π. Conversely, if L/K is a totally ramified and $\Pi\in L$ is a uniformizer, then $L=K(\Pi)$ and the minimal polynomial of Π is an Eisenstein polynomial.

Proof:

□

Remark (12.2.2.12). More about totally ramified extensions are discussed in Totally Ramified Extensions.

Ramification Groups

Def. (12.2.2.13)[Ramification Groups]. For a Galois extension L/K of CVDRs, denote λ/k residue fields extension of $w|v$, and denote $\mathfrak{p}_w,\mathfrak{p}_v$ by $\mathfrak{P},\mathfrak{p}$. Define:
The **inertia group** is $I(L/K)=\{\sigma\in\mathrm{Gal}(L/K)|\sigma(x)\equiv x \mod \mathfrak{P}\}$.
The **ramification group** is $R(L/K)=\{\sigma\in\mathrm{Gal}(L/K)|\sigma(x)/x\equiv 1 \mod \mathfrak{P}\}$.

Prop. (12.2.2.14). For local fields, the ramification degree e equals the order of inertia group $|I_{L/K}|$.

Prop. (12.2.2.15). The residue field extension λ/k is normal and there is an exact sequence

$$1\to I(L/K)\to\mathrm{Gal}(L/K)\to\mathrm{Gal}(\lambda/k)\to 1.$$

Proof: Cf.[Neukirch P172]. □

Prop. (12.2.2.16). $R(L/K)$ is the unique pro-p-Sylow subgroup of $\mathrm{Gal}(L/K)$(2.1.14.11).

Proof: Cf.[Neukirch P174]. □

Prop. (12.2.2.17). There is an exact sequence

$$1 \to R(L/K) \to I(L/K) \to \chi(L/K) \to 0$$

where $\chi_v(L/K) = \mathrm{Hom}(\Delta/\Gamma, \lambda^\times)$ and $\Delta = w(L^\times), \Gamma = v(K^\times)$. Moreover, in case L/K is a finite extension, this exact sequence splits.

Proof: For any $\sigma \in I_w$, define the map $\chi_\sigma : \Delta/\Gamma \to \lambda^*$ as follows: for any $\delta \in \Delta/\Gamma$, let $\delta = w(x)$ for some $x \in L^*$, let $\chi_\sigma(\bar{\delta}) = \frac{\sigma(x)}{x} \mod \mathfrak{P}_w$. This is independent of x chosen, because if $w(x) \equiv w(x') \mod \Gamma$, then $w(x) = w(ax)$ for some $a \in K^*$, thus $x = axu$ for some $u \in \mathcal{O}_w^*$. Now $\frac{\sigma(u)}{u} \equiv 1 \mod \mathfrak{P}$ as $\sigma \in I_w$, so $\frac{\sigma(x)}{x} = \frac{\sigma(x')}{x'} \in \lambda^*$. And the kernel of this map is R_w by definition.

The sequence is exact on the right by [Neukirch P175].**?** □

Higher Ramification Groups

Notation (12.2.2.18).

- Let L/K be a finite Galois extension of CDVRs.

Def. (12.2.2.19) [Higher Ramifications]. For $s \in \mathbb{R}_+$, define the ***s*-th ramification group** $G_s(L/K) = \{\sigma \in G | v_L(\sigma(x) - x) \geq s+1 \text{ for all } a \in \mathcal{O}_L\}$.

Then we have $G = G_{-1} \supset G_0 \supset G_1 \supset \ldots$. And G_0 is the inertia group.

Prop. (12.2.2.20). When K has finite residue field, G_1 is the ramification group R_w(12.4.2.15). In this case, we have

$$G_s(L/K) = \{\sigma \in G_0 | \frac{\sigma(\pi_L)}{\pi_L} \in U_L^s\}, \text{ for } s \geq 0.$$

So there are injective morphism $G_s/G_{s+1} \to U_L^s/U_L^{s+1} : \sigma \mapsto \sigma(\pi_L)/\pi_L$ for $s \geq 0$.(This is independent of π_L chosen because units are mapped mod U_L^{s+1}).

Proof: $G_1 = R_w$: one direction is trivial, for the other, we use Teichmüller representatives, then R_w preserves all them, and $\sigma(x) - x \equiv 0 \mod \mathfrak{P}^2$ is true for π, so it is true for all. □

Prop. (12.2.2.21). For local fields L/K, if σ is in the inertia group, then

$$v_L(\frac{\sigma(x)}{x} - 1) \geq v_L(\frac{\sigma(\pi_L)}{\pi_L} - 1) + \delta_{v_L(x),0}$$

for any $x \in \mathcal{O}_L$ and a uniformizer π_L. Equality holds when $v_L(x) = 1$.

Proof: if L has residue field $\mathbb{F}_q$, then any element of $\mathcal{L}$ can be written as $\sum \xi_n \pi_L^n$, where ξ_n are all $q-1$-th roots of unity. And because σ is inertia group, all $q-1$-th roots of unity are preserved, so $\sigma(\xi_n\pi_L^n) - \xi_n\pi_L^n = \xi_n\pi_L(\frac{\sigma(\pi_L)}{\pi_L} - 1)(\sigma(\pi_L)^{n-1} + \sigma(\pi_L)^{n-2}\pi_L + \ldots + \pi_L^{n-1})$ has valuation $\geq v(\frac{\sigma(\pi_L)}{\pi_L} - 1) + n$. Thus the result. □

In the sequel, we assume that the residue field extension is separable, as to use the proposition(12.2.2.2).

Lemma (12.2.2.22). We define $i_{L/K}(\sigma) = v_L(\sigma x - x)$, where x is the generator of $\mathcal{O}_L/\mathcal{O}_K$.
If $L/L'/K$ are Galois extensions that e is the ramification index of L/L'. Then

$$i_{L'/K}(\sigma') = \frac{1}{e}\sum_{\sigma|_{L'}=\sigma'} i_{L/K}(\sigma).$$

Proof: Cf.[Neukirch Algebraic Number Theory P178]. □

Def. (12.2.2.23) [Upper Numbering]. We define the **Herbrand function** $\varphi_{L/K}(u) = \int_0^u \frac{\mathrm{dx}}{(G_0:G_x)}$. It maps $\{x \geq 1\}$ to itself and is strictly increasing.

If $m \leq s < m+1$, then it is just $\varphi_{L/K}(s) = \frac{1}{g_0}(g_1 + g_2 + \ldots + g_m + (s-m)g_{m+1})$, where $g_i = |G_i|$. By a double counting, it is

$$\varphi_{L/K}(s) = \frac{1}{g_0}\sum_{\sigma\in G}\min\{i_{L/K}(\sigma), s+1\} - 1.$$

The derivative of $\varphi_{L/K}$ is $\varphi'_{L/K}(s) = \dfrac{|G_s|}{g_0}$.

Let $\psi_{L/K}$ be the inverse function of We define $G^t = G_{\psi_{L/K}(t)}$, this is called the **upper numbering**.

Lemma (12.2.2.24). For $L/L'/K$ Galois extensions, one has $G_s(L/K)H/H = G_t(L'/K)$, where $t = \varphi_{L/L'}(s)$. Equivalently, $G_s/H_s = (G/H)_{\varphi_{L/L'}(s)}$.

Proof: For $\sigma' \in G(L'/K)$, we choose a inverse image $\sigma \in G(L/K)$ of maximal $i_{L/K}(\sigma)$, then $i_{L'/K}(\sigma') - 1 = \varphi_{L/L'}(i_{L/K}(\sigma) - 1)$. To prove this, let $i_{L/K}(\sigma) = m$, then we see $i_{L/K}(\sigma\tau) = \min\{i_{L/K}(\tau), m\}$, so by(12.2.2.22), $i_{L'/K}(\sigma') = \frac{1}{e}\sum_{\tau\in H}\min\{i_{L/K}(\tau), m\}$. And $e = |H_0|$ by(12.2.2.14). So the assertion follows from(12.2.2.23).

Now σ' is in the image of G_s is equivalent to $i_{L/K}(\sigma) - 1 \geq s \iff \varphi_{L/L'}(i_{L/K}(\sigma) - 1) \geq \varphi_{L/L'}(s)$, which by what proved is equivalent to $\sigma' \in G_t(L'/K)$. □

Cor. (12.2.2.25). For $L/L'/K$ Galois extensions, $\varphi_{L/K} = \varphi_{L'/K}\circ\varphi_{L/L'}$, hence similar formula holds for ψ.

Proof: By the proposition and multiplicity of ramification index e, we get

$$\frac{1}{e_{L/K}}|G_s| = \frac{1}{e_{L'/K}}|(G/H)_t|\frac{1}{e_{L/L'}}|H_s|.$$

where $t = \varphi_{L/L'}(s)$, which is equivalent to the derivative $\varphi'_{L/K}(s) = \varphi'_{L'/K}(t)\varphi'_{L/L'}(s) = (\varphi_{L'/K}\circ\varphi_{L/L'})'(s)$, and they are equal at 0, so the conclusion follows. □

Prop. (12.2.2.26) [Herbrand's Theorem]. For $L/L'/K$ Galois extensions, $G^t(L'/K)$ is the image of $G^t(L/K)$ under the quotient.

Proof: Let $r = \varphi_{L'/K}(t)$, by the above lemme and corollary,

$$G^t H/H = G_{\varphi_{L/K}(t)}H/H = G'_{\varphi_{L/L'}(\psi_{L/K}(t))} = G'_{\varphi_{L/L'}(\psi_{L/L'}(r))} = G_r(L'/K) = G^t(L'/K)$$

□

Prop. (12.2.2.27) [Hasse-Arf]. For an Abelian extension of CDVRs L/K that the residue field extension is separable, the jump in the upper numbering of higher ramification group G^v must happen at integers. (Note: The proof in the case where K is a local field is much easier by Lubin-Tate group, See(12.6.2.30)).

Proof: The theorem is just saying that if $G_s \neq G_{s+1}$ for s integer, then $\varphi_{L/K}(s)$ is an integer.

This follows follows from the following lemma, because if G is not totally ramified, then we can change it to the Galois field of G_0, this didn't change anything by the definition of(12.2.2.23), and the fact $\varphi(0) = 0$. And when $G^v \neq G^{v+}$, then we consider splitting G/G^{v+} into product of cyclic groups, thus there is one cyclic group H that the projection of G^v into H is not trivial. Now H is a Galois group of some L'/K, and Herbrand's theorem shows that $H^v \neq H^{v+}$, hence v is an integer by the following lemma. □

Lemma (12.2.2.28). For a cyclic totally ramified extension of CDVRs L/K s.t. the residue field extension is separable, if μ is the maximal integer that $G_\mu \neq 1$, then $\varphi_{L/K}(G_\mu)$ is an integer.

Proof: Cf.[Serre Local Fields P94]. □

Example (12.2.2.29). If $K_n = \mathbb{Q}_p(\zeta_{p^n})$, then

$$\mathrm{Gal}_s(K_n/\mathbb{Q}_p) = \mathrm{Gal}(F_n/F_t) \quad \text{for } p^t - 1 \leq s < p^{t+1} - 2.$$

Thus $\mathrm{Gal}^i(K_n/\mathbb{Q}_p) = \mathrm{Gal}(K_n/K_i)$.

Proof: This is because $\zeta_{p^n} - 1$ is a uniformizer of K_n(12.2.3.21). □

3 Local Fields

Notation (12.2.3.1).

- Let $p \in \mathbf{P}$ and $(K, \mathfrak{m}, \kappa) \in p\text{-}\mathtt{LField}$(12.2.3.5).

Def. (12.2.3.2) [Local Fields]. A **local field** is a locally compact valued field. A local field is clearly complete. The category of local fields is denoted by `LField`.

Prop. (12.2.3.3) [Complete Valued Fields]. A complete Archimedean valued field must be $\mathbb{R}$ or $\mathbb{C}$, by(10.3.3.18).

Any complete non-Archimedean valued field is discretely valued, and has finite residue fields of characteristic $p \in \mathbf{P}$. Such a field is called a ***p*-adic local fields**. The category of p-adic local fields is denoted by p-`LField`.

Proof: Cf.[Sutherland, L9].**?** □

Remark (12.2.3.4). The valuation ring of a p-adic local field is a DVR, thus the theory of Dedekind domains7 applies to this case.

Prop. (12.2.3.5) [*p*-adic Local Fields]. p-adic local fields are precisely the finite extensions of the field $\mathbb{Q}_p$ or $\mathbb{F}_p((t))$, called ***p*-adic number field** and ***p*-adic function field** respectively.

The category of p-adic number fields are denoted by p-`NField`, and the category of p-adic function fields are denoted by p-`FField`.

Proof: Cf.[Neukirch Algebraic Number Theory P135]. □

The Group Structure of Local Fields

Prop. (12.2.3.6). For $m > 0$, there is an isomorphism $(-)^m : U^n \cong U^{n+v(m)}$ when n is sufficiently large.

Proof: Let $m = u\pi^{v(m)}$. For surjectivity, we need to find x, that $1 + a\pi^{n+v(m)} = -(1 + x\pi^n)^m$. i.e.

$$-a + ux + \pi^{n-v(m)} f(x) = 0.$$

This has a solution x by Hensel's lemma. □

Cor. (12.2.3.7). $(K^*)^m$ is an open subgroup of K^*, and $\bigcap_m (K^*)^m = 1$. (Because if $a \in \bigcap_m (K^*)^m = 1$, then a is a unit, thus $a \in \bigcap_m (U)^m = 1$, thus $a \in U^n$ for every n thus $a = 1$).

Prop. (12.2.3.8). $[K^\times : (K^\times)^m] = m \cdot |m|_{\mathfrak{p}}^{-1} \cdot |\mu_m(K)|$.

Proof: Use the multiplicative Herbrand quotient(3.7.5.7), $(K^* : (K^*)^m) = q_{0,m}(K^*)|\mu_m(K)|$. $q_{0,m}$ is additive, thus

$$q_{0,m}(K^*) = q_{0,m}(K/U) q_{0,m}(U/U^n) q_{0,m}(U^n).$$

$q_{0,m}(K/U) = m$, $q_{0,m}(U/U^n) = 1$ as U/U^n is finite(3.7.5.9). It For $q_{0,m}(U^n)$, when n is large, it equals $(U^n : U^{n+v(m)})$ by(12.2.3.6), which is $|m|_{\mathfrak{p}}^{-1}$. □

Prop. (12.2.3.9)[p-adic Logarithm]. For a p-adic umber field K, there is a unique **p-adic logarithm** function $\log : K^* \to K$ that $\log(p) = 0$, and for $x \in \mathfrak{p}$, it is defined to be

$$\log(1 + x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \ldots.$$

Moreover, for $n > \frac{e_K}{p-1}$, there is a map $\exp : \mathfrak{p}^n \to U^n$: which is an inverse to log on U^n, so $U^n \cong \mathfrak{p}^n$.

Proof: This follows from(8.5.4.8). □

Remark (12.2.3.10). In fact, this map can be extended to a function from $\mathbb{C}_p^*$ to $\mathbb{C}_p$.

Cor. (12.2.3.11). For a local field K, $\mathcal{O}_K^*$ thus also $K^\times$ are locally compact.

Proof: For n large, $U^n \cong \mathfrak{p}^n$ is compact. □

Prop. (12.2.3.12) [Multiplicative Group Structure]. For $K \in p$-`LField`,

- If char $K = 0$, then $\mathcal{O}_K^* \cong \mathbb{Z}/(p-1) \oplus \mathbb{Z}/(p^a) \oplus \mathbb{Z}_p^d$, where $d = [K : \mathbb{Q}_p]$ and $a \in \mathbb{N}$.
- If char $K = p$, then $\mathcal{O}_K^* \cong \mathbb{Z}/(p-1) \oplus \mathbb{Z}_p^{\mathbb{N}}$.

Proof: Cf.[Neukirch P140]. □

Prop. (12.2.3.13). Any automorphism of $\mathbb{R}$ or a p-adic number field is identity.

Proof: It suffices to show that an automorphism is continuous. For $\mathbb{R}$, this is because $a > 0 \iff a = b^2 \iff \sigma(a) = \sigma(b)^2 \iff \sigma(a) > 0$, and $\mathbb{Q}$ is dense in $\mathbb{R}$.

For a local field, we prove that $\sigma(\mathcal{O}_K^*) \subset \mathcal{O}_K^*$. $\mathcal{O}_K^*$ is characterized by the property that $\{n | y^n = x\}$ are infinite. This is because $x^p = a$ has a root for $a \in \mathcal{O}_K^*$ for p large prime, by Henselian lemma. □

Def. (12.2.3.14)[Norm Groups]. For any extension of local fields L/K, $\mathrm{Nm}_{L/K}$ is open, and $\mathcal{N}_{L/K} = \mathrm{Nm}_{L/K} L^\times \subset K^\times$ is called the **norm group** of L/K.

Extension Fields

Prop. (12.2.3.15). $[\mathbb{Q}_p^{\text{ab,tame}} : \mathbb{Q}_p^{\text{ab,ur}}] < \infty$.

Proof:

□

Prop. (12.2.3.16). The maximal unramified extension of $\mathbb{F}_p((t))$ is $T = \overline{\mathbb{F}}_p((t))$, and the maximal tamely unramified extension of $\mathbb{F}_p((t))$ is $T(\sqrt[m]{t}|m \geq 1, (m,p) = 1\})$.

Proof:

□

Prop. (12.2.3.17). Any finite quotient group of Gal_K is solvable.

Proof: This follows from(12.2.2.16)(12.2.2.15)(12.2.2.17) and(2.1.14.12) and(2.1.7.2). □

Def. (12.2.3.18) [Tame Characters]. There is an isomorphism

$$\hat{t} : I_K/R_K \cong \mathrm{Gal}(K^{\text{tame}}/K^{\text{ur}}) \cong \prod_{\ell \neq p} \mathbb{Z}_\ell$$

and the projection to $\mathbb{Z}_\ell$ is called the ℓ-adic (additive)**tame character** of I_K.

Equivalently, if $\ell \in \mathbf{P}\backslash\{p\}$, for any compatible system of ℓ^∞-th roots $\{\varpi_{\ell^n}\}$ of ϖ in $\overline{K}$, it is the character t_ℓ of Gal_K that $\sigma(\varpi_{\ell^n}) = \varpi_{\ell^n}^{t_\ell(\sigma)}$.

Ramifications of Cyclotomic Fields

Prop. (12.2.3.19) [Unramified cases]. Let $\#\kappa = q$ and $n \in \mathbb{Z}_+ \setminus (p)$, consider $L = K(\zeta_n)$. Then L/K is unramified of inertia degree f where f is the minimal number that $q^f \equiv 1 \mod n$. And $\mathcal{O}_L = \mathcal{O}_K[\zeta_n]$.

Proof: ζ_n is a root of $\Psi_n(X)|X^n - 1$, which is separable in k, so Ψ and $\overline{\Psi}$ are both irreducible of the same degree by Hensel's lemma, so it is unramified, and λ is the minimal extension of $\mathbb{F}_q$ that contains the n-th roots and are generated by it, thus the result by the theory of finite fields.

For the last assertion, notice it is unramified so $\mathcal{O}_L = \mathcal{O}_K[\zeta_n] + p\mathcal{O}_L$ hence the result follows from Nakayama. □

Cor. (12.2.3.20). The maximal unramified extension of K is generated by adjoining all n-th roots where $(n,p) = 1$. This is because there is an inclusion relation and their residue field $\overline{\mathbb{F}}_p$ is already generated by roots of unity.

Prop. (12.2.3.21)[Totally Ramified cases]. Consider $\mathbb{Q}_p$(other local fields behave different), we have the $\mathbb{Q}(\zeta_{p^n})/\mathbb{Q}$ is totally ramified of degree $\varphi(p^n)$ the Galois group is $(\mathbb{Z}/(p^n))^*$. The ring of valuation of $\mathbb{Q}_p(\zeta_{p^n})$ is $\mathbb{Z}_p[\zeta_{p^n}]$ and $1 - \zeta_{p^n}$ is a uniformizer.

Proof: Notice

$$\Psi_{p^n}(X) = \frac{X^{p^n} - 1}{X^{p^{n-1}} - 1} \equiv (X-1)^{p^{n-1}(p-1)} (\mathrm{mod}\ p)$$

and $\Phi(1) = p$. So $\mathrm{Nm}(1 - \zeta_{p^n}) = \prod(1 - \sigma(\zeta_{p^n})) = \Phi(1) = p$. Thus $\mathbb{Q}(\zeta_{p^n})/\mathbb{Q}$ is totally ramified of degree $p^{n-1}(p-1)$ and $1 - \zeta_{p^n}$ is a uniformizer. The ring of integer is generated by a uniformizer by(10.3.3.20) as the extension is totally ramified. □

Prop. (12.2.3.22) [Infinite Cyclotomic Field]. Let $K_n = K(\zeta_{p^n})$ and $K_\infty = \cup K_n$ and $F = \mathbb{Q}_p$. Let χ be the cyclotomic character, then $\chi(\mathrm{Gal}_K)$ is an open subgroup of $\mathbb{Z}_p^*$, thus contains a U_n for some n. Thus there is an isomorphism of groups: $\chi^{-1}(U_n)\cap \mathrm{Gal}_K / \chi^{-1}(U_n+1)\cap \mathrm{Gal}_K \cong U_n/U_{n+1}$ which has order p, for n large.

So K_{n+1}/K_n is totally ramified of degree p, because $K_n = K\cdot F_n$, and its value group extension is of degree p, too.

And $|\{K_n : F_n\}|$ is decreasing and eventually equals to $[K_\infty : F_\infty]$. This is because its order equals $\chi^{-1}(U_n)/\chi^{-1}(U_n)\cap \mathrm{Gal}_K \cong \chi^{-1}(U_n)\,\mathrm{Gal}_K / \mathrm{Gal}_K$, which is eventually $\ker(\chi)\,\mathrm{Gal}_K / \mathrm{Gal}_K$, because $U_n \subset \chi(\mathrm{Gal}_K)$.

Cor. (12.2.3.23). For n large, if x_i is a set of basis of $\mathcal{O}_{K_n}$ over $\mathcal{O}_{F_n}$, then they form a basis of K_N over F_N for all $N \geq n$. This is because it generate K_N over F_N and $[K_N : F_N] = [K_n : F_n]$.

Prop. (12.2.3.24). $p^n v_p(\mathfrak{D}_{K_n/F_n})$ is bounded and eventually constant. In particular $v_p(\mathfrak{D}_{K_n/F_n})$ converges to 0.

Proof: Cf.[Galois representation Berger P20]. □

Cor. (12.2.3.25). If L/K is a finite extension, then $\mathrm{tr}_{L_\infty/K_\infty}(\mathfrak{m}_{L_\infty}) = \mathfrak{m}_{K_\infty}$.

Proof: By(12.2.2.3) and the fact $\mathrm{Gal}(L_\infty/K_\infty) \cong \mathrm{Gal}(L_n/K_n)$ for n large by(12.2.3.22), we have $\mathrm{tr}_{L_\infty/K_\infty}(\mathfrak{m}_{L_n}) = \mathfrak{m}_{K_n}^{c_n}$, where $c_n = \lfloor v_{K_n}(\mathfrak{m}_{L_n}\mathcal{D}_{L_n/K_n})\rfloor$. By the above proposition, c_n is bounded by a c. But if $x \in \mathfrak{m}_{K_\infty}$, $x \in \mathfrak{m}_{K_n}^c$ for n large, so $x \in \mathrm{tr}_{L_\infty/K_\infty}(\mathfrak{m}_{L_\infty})$. □

Lemma (12.2.3.26). For any $\delta > 0$, when n is large, if $x \in \mathcal{O}_{K_{n+1}}$ and $g \in G(K_{n+1}/K_n)$, $v_p(g(x)-x) \geq \frac{1}{p-1} - \delta$. In particular, $v(N_{K_{n+1}/K_n}(x) - x^p) \geq \frac{1}{p-1} - \delta$.

Proof: Choose a basis e_i of $\mathcal{O}_{K_n}/\mathcal{O}_{F_n}$, then e_i^* is a basis for $\mathcal{D}_{K_n/F_n}$, and if $x_i = \mathrm{tr}_{K_{n+1}/F_{n+1}}(xe_i)$, then $x_i \in \mathcal{O}_{F_{n+1}}$ and $x = \sum x_i e_i$, by(12.2.3.23), and we have by(12.2.2.29), $v(g(x_i) - x_i) \geq 1/(p-1)$, so when n is large, by(12.2.3.24), $v(x_i) \geq -\delta$, so the require is satisfied. □

Prop. (12.2.3.27). if $\delta > 0$ and I is the ideal of elements of valuation$\geq 1/(p-1) - \delta$, then for n large, there is a map $x \mapsto x^p : \mathcal{O}_{K_{n+1}}/I \cap \mathcal{O}_{K_{n+1}} \to \mathcal{O}_{K_n}/I \cap \mathcal{O}_{K_n}$, and it is surjective.

Proof: For n large, choose a uniformizer π_{n+1} of K_{n+1}, then $\pi_n = N_{K_{n+1}/K_n}(\pi_{n+1})$ is the uniformizer of K_n because it is totally ramified(12.2.3.22), so any element $x \in \mathcal{O}_{K_{n+1}}$ can be written as $\sum \pi_{n+1}^i [x_i]$, where $x_i \in k_{K_{n+1}} = k_{K_\infty}$. Then $x^p \equiv \sum \pi_{n+1}^{pi}[x_i]^p \equiv \sum \pi_n^i [x_i^p] \mod I$ by the above proposition. And the surjection is verbatim. □

Def. (12.2.3.28) [Tate's Normalized Trace]. The function $R_n(x) = p^{-k}\,\mathrm{tr}_{F_{n+k}/F_n}(x)$ is compatible with k and defines a F_n-linear projection from F_∞ to F_n, and it commutes with G_F action, called the **Tate's normalized trace**.

From(12.2.3.29) it's easily verified that $R_n(\mathcal{O}_{F_{n+k}}) \subset \mathcal{O}_{F_n}$, thus $R_n(\pi_n^j \mathcal{O}_{F_{n+k}}) \subset \pi_n^j \mathcal{O}_{F_n}$. So we have $v(R_n(x)) > v(x) - v(\pi_n)$. So R_n extends by continuity to a map $R_n : \widehat{F}_\infty \to F_n$. If $x \in F_\infty$, then $R_n(x) = x$ for n large, thus $R_n(x) \to x$ for any $x \in \widehat{F}_\infty$.

Now for a finite extension $K/\mathbb{Q}_p$, for n large, if e_i is a set of basis of $\mathcal{O}_{K_n}/\mathcal{O}_{F_n}$, then for any $x \in \mathcal{O}_{K_{n+k}}$, $x = \sum x_i e_i^*$, where $x_i = \mathrm{tr}_{K_{n+k}/F_{n+k}}(xe_i) \in \mathcal{O}_{F_{n+k}}$, as in the proof of(12.2.3.26). So we can define $R_n(x) = \sum R_n(x_i)e_i^*$. Notice this is defined only for n large, and is independent of e_i chosen, and by the following lemma, it is continuous and extends to a K_n-linear projection $R_n : \widehat{K_\infty}$ to K_n.

Lemma (12.2.3.29). Let $k \geq 0$ and $n \geq 1$, then $R_n(\zeta^j_{p^{n+k}}) = 1$ for $j = 0$ and vanishes otherwise.

Proof: This is clear from the fact $\mathrm{tr}_{F_{n+k}/F_n}(\zeta^j_{p^{n+k}}) = \zeta^j_{p^{n+k}} \sum_{\eta^{p^k}=1} \eta^j$. □

Lemma (12.2.3.30). for any $\delta > 0$, when n is large, $v(R_n(x)) \geq v(x) - \delta$.

Proof: We have $v(x_i) > v(x) - v(\pi_{n+k})$ by F_{n+k}-linearity, and $v(R_n(x_i)) > v(x_i) - v(\pi_n)$ as in(12.2.3.28), and $v(e_i^*) \geq -\delta$ when n is large, by(12.2.3.24). Thus the result. □

Prop. (12.2.3.31) [Refinement of Hilbert's Theorem90]. There is a decomposition of $\widehat{K_\infty} = K_n \oplus X_n$, where $X_n = \ker R_n$. If $\delta > 0$, then for n large, $\alpha \in \mathbb{Z}_p^*$ and γ_n that $\chi(\gamma_n)$ is a topological generator of Γ_{F_n}, $1 - \alpha\gamma_n : X_n \to X_n$ (because γ_n commutes with R_n) is invertible and

$$v_p((1 - \alpha\gamma_n)^{-1}x) \geq v_p(x) - 1/(p-1) - \delta,$$

unless $\alpha = -1$ and $p = 2$, in which case it is only invertible on X_{n+1}.

Proof: As usual, x_i is a basis of $\mathcal{O}_{K_n/F_n}$, then $x = \sum x_i e_i^*$, $x_i = \mathrm{tr}_{K_\infty/F_\infty}(xe_i) \in \widehat{F}_\infty$, and $R_n(x) = 0$. Then $(1 - \alpha\gamma_n)$ acts on x_i, so it reduce to the case $K = \mathbb{Q}_p$.

Injectivity: If $\alpha = 1$, this is Ax-Sen-Tate theorem. In other situations, $(1-\alpha\gamma_n)(R_{n+k}(x)) = 0$ for all $k \geq 0$, so $R_{n+k}(x) = \alpha^{p^k}\gamma_n^{p^k}(R_{n+k}(x)) = \alpha^{p^k}R_{n+k}(x)$, so $R_{n+k}(x) = 0$, hence $x = 0$ by continuity.

Surjectivity: Let $F^*_{n+k} = \oplus_{j=1,p\nmid j}^{p^k-1} F_n\zeta^j_{p^{n+k}}$, then $F_{n+k} = F_n^* \oplus F^*_{n+1} \oplus \ldots \oplus F^*_{n+k}$, and $F_{n+k} \cap X_n = F^*_{n+1} \oplus \ldots \oplus F^*_{n+k}$. Now if $x = \sum_{j=1,p\nmid j}^{p^k-1} x_j\zeta^j_{p^{n+k}}$ with $x_j \in \mathcal{O}_{F_n}$, then

$$x = (1 - \alpha^{p^{k-1}}\gamma_n^{p^{k-1}}) \sum_{j=1,p\nmid j}^{p^{k-1}} x_j \frac{\zeta^j_{p^{n+k}}}{1 - \alpha^{p^{k-1}}\zeta_p^j}.$$

Now $v_p(1 - \alpha^{p^{k-1}}\zeta_p^j) \leq 1/(p-1)$, and

$$(1 - \alpha\gamma_n)^{-1} = \frac{1 - \alpha^{p^{k-1}}\gamma_n^{p^{k-1}}}{1 - \alpha\gamma_n}(1 - \alpha^{p^{k-1}}\gamma_n^{p^{k-1}})^{-1},$$

so $\alpha_n : 1 - \alpha\gamma_n : F^*_{n+k} \to F^*_{n+k}$ is invertible and

$$v_p((1 - \alpha\gamma_n)^{-1}x) \geq v_p(x) - 1/(p-1) - v_p(\zeta_{p^n} - 1)$$

holds. And the assertion holds by uniform continuity. □

<u>**Miscellaneous**</u>

Def. (12.2.3.32) [Lattices]. If $K \in$ `LField` and $V \in \mathcal{V}\mathrm{ect}^{\mathrm{fd}}/K$, then a **lattice in** V is

- a compact open $\mathcal{O}_K$-submodule of V if K is non-Archimedean. Equivalently, it is a f.g. $\mathcal{O}_K$-submodule that contains a K-basis of V.
- a discrete subgroup Λ of V s.t. V/Λ is compact if K is Archimedean.

Prop. (12.2.3.33). Let V be a f.d. vector space over a non-Archimedean local field K and Λ be an $\mathcal{O}_K$-submodule of V, then Λ is a lattice in V iff it is a finite $\mathcal{O}_K$-module and generate V as a K-vector space.

Proof: If Λ is an $\mathcal{O}_K$-submodule, then it clearly generates V as a K-vector space, and the f.g. $\mathcal{O}_K$-submodules of Λ is a cover of Λ, which has a finite subcover as Λ is compact open, thus Λ is f.g. over $\mathcal{O}_K$.

Conversely, if Λ is a f.g. $\mathcal{O}_K$-submodule that generate V as a K-vector space, then it is a quotient of $\mathcal{O}_K^n$ for some n, thus compact. And let S be a K-basis of V contained in Λ, then $\mathcal{O}_K S$ is an open nbhd of $0 \subset \Lambda$, which means it is open. □

Prop. (12.2.3.34). Let Λ be a subgroup of a f.d. real or complex vector space V, then the following are equivalent:

- Λ is a lattice in V.
- Λ is discrete and contains an $\mathbb{R}$-basis of V.
- Λ has a $\mathbb{Z}$-basis that is also an $\mathbb{R}$-basis of V.

Remark (12.2.3.35). WARNING: This is not equivalent to Λ is a f.g. $\mathbb{Z}$-module and generated V as an $\mathbb{R}$-vector space: Consider $\mathbb{Z}\{1, \alpha\} \subset \mathbb{R}$.

Proof: $1 \to 2$: Let W be a complementary subspace of $\Lambda \otimes_{\mathbb{Z}} \mathbb{R} \subset V$, then $W \cong \overline{W}$ is closed thus compact in V/Λ, which implies $W = 0$.

$2 \to 3$: We may assume $V = \mathbb{R}^n$ and Λ contains the canonical basis $e_1, \ldots, e_n$, then Λ is generated by $S = \{\lambda \in \Lambda | \max_i |\lambda_i| \leq 1\}$. Because Λ is discrete thus closed in V, S is finite. Thus Λ is a f.g. $\mathbb{Z}$-module, and has no torsion, thus a free Abelian group. But $\Lambda/\mathbb{Z}\{e_i\}$ is finite, thus $\Lambda \cong \mathbb{Z}^n$. Hence a basis of Λ must also be a basis of V.

$3 \to 1$ is clear. □

Def. (12.2.3.36) [Dual Lattice]. If $K \in \texttt{p-Field}$ and V is a f.d. vector space over K, B is a non-degenerate bilinear form on V and ψ is a non-trivial character of K, then for any lattice $L \subset V$, the **dual lattice** $L' = \{u \in V | \psi(2(B(u, v))) = 1, \forall v \in L\}$ is also a lattice in V.

Proof: It is an open group by no-small-subgroup argument, as ψ, B are continuous. it is compact because take any basis $\{v_1, \ldots, v_n\}$ of V that $v_i \in L$, $\{u \in V | \psi(2(B(u, v_i))) = 1, \forall i\}$ is compact. □

4 Ultranormed Banach Spaces

Notation (12.2.4.1).

- Let $(K, v, \mathcal{O}_K, \mathfrak{p}_v, \varpi, k)$ be a complete non-Archimedean valued field(of rank 1), $K^0 = \mathfrak{p}_v$, and $\varpi \in K^\times, |\varpi| < 1$ a uniformizer. If $\mathcal{O}_K$ is DVR, assume $(\varpi) = \mathfrak{p}_v$.

Ultranormed K-modules

Prop. (12.2.4.2). Any normed K-module is weakly-Cartesian.

Proof: Cf.[Non-Archimedean Analysis P92]. □

Cor. (12.2.4.3). Any two valuation on a finite K-vector space are equivalent.

Proof: Cf.[Non-Archimedean Analysis P93]. □

Prop. (12.2.4.4). If V is a normed $\mathbb{Q}_p$ vector space and $V_0 = \{x \in V | |x| \leq 1\}$, then $V^\wedge \cong (V_0)_p^\wedge[p^{-1}]$.

Ultranormed Banach Spaces

Def. (12.2.4.5) [Ultranormed Banach Spaces]. In the non-Archimedean case, an **ultranormed Banach algebra** is defined as in(10.8.4.2), but additionally $|a+b| \leq \max\{|a|,|b|\}$.

Def. (12.2.4.6) [Uniform Banach Space]. For a complete non-Archimedean field K and a Banach algebra R, define R^0 to be the ring of **power bounded elements**. Then it is a subring, and it is open, as it contains the closed ball $\overline{\mathbb{D}(0,1)}$.

Recall R is called uniform if R^0 is itself bounded in R(12.2.1.6). Notice a uniform Banach space must be reduced, because a nilpotent element is clearly power bounded, and any scalar multiple of it is nilpotent.

Lemma (12.2.4.7). Fix a uniformizer t in a non-Archimedean complete field K, if $|K^*|$ is discrete, then if A is a t-adically complete and t-torsion-free K^0-algebra, let $R = A[t^{-1}]$, then the norm

$$|f| = \inf\{|t|^n | f \in t^n A\},$$

then this makes R into a K-Banach space that the t-adic topology of A is the same as the metric topology of A, so $A \subset R_{\leq 1} \subset R^0$.

Notice if $|K^*|$ is not discrete but there is a pseudo-uniformizer t that has a compatible system of p^n-th roots, if A is a t-adically complete and t-torsion-free K^0-algebra, let $R = A[t^{-1}]$, then the norm

$$|f| = \inf\{|t|^{\frac{n}{p^k}} | f \in t^{\frac{n}{p^k}} A\},$$

then this makes R into a K-Banach space that the t-adic topology of A is the same as the metric topology of A, so $A \subset R_{\leq 1} \subset R^0$, and in this case $R^0 = A_* = \mathrm{Hom}((t^{\frac{1}{p^\infty}}), A)$(4.7.2.2).

Prop. (12.2.4.8) [Uniform K-Banach Space and K^0-Algebra]. Fix a pseudo uniformizer t in a non-Archimedean complete field K, the following category are equivalent:

- The category $\mathcal{C}$ of uniform Banach K-algebras R.
- The category $\mathcal{D}_{tic}$ of t-adically complete and t-torsionfree K^0-algebras A with A totally integrally closed(4.2.1.1) in $A[t^{-1}]$.

Proof: The functor $F : \mathcal{C} \to \mathcal{D}_{tic}$: if R is uniform Banach space, then $F(R) = R^0$: R^0 is open subring by(12.2.4.6), and $R^0 \in B(0,r]$ for some $r > 0$ by uniformity. As R is K-Banach, $\cap t^n B(0,r] = 0$, so R^0 is t-adically separated, and also it is complete. If $f^{\mathbb{N}} \in t^{-k}R^0 \subset t^{-k}B(0,r]$, then clearly f is power bounded thus $f \in R^0$, so R^0 is totally integrally closed in R. $R \to R^0$ is preserved by continuous mappings, so F is truly a functor.

Conversely, lemma above(12.2.4.7) shows $R = A[t^{-1}]$ is a K-Banach algebra, this is a functor $G : \mathcal{D}_{tic} \to \mathcal{C}$, and $A \subset R^0$. We show $A = R^0$, as this is equivalent to $FG \cong \mathrm{id}$: as the t-adic topology and metric topology are the same(12.2.4.7), if $t^c f^{\mathbb{N}} \subset A$ for some c, thus f is totally integral over A, thus $f \in A$ by tic.

Finally, we need to show $GF \cong \mathrm{id}$, which in fact that the given Banach algebra norm on R is equivalent to the norm $|\cdot|'$ given in(12.2.4.7) w.r.t R^0. $R'_{<1} \subset R^0 \subset R_{\leq c}$ by uniformity, and conversely, $R_{\leq 1} \subset R^0 \subset R'_{\leq 1}$, thus this two norms are equivalent. □

Prop. (12.2.4.9). Let $\varphi : A \to B$ be a k-homomorphism between k-Banach algebras that there is a family $\mathfrak{B}$ of ideals of B that for each $b \in \mathfrak{B}$:

- B is closed and $\varphi^{-1}(b)$ is closed in A.

- $\dim_k B/b < \infty$.
- $\cap_{b\in\mathfrak{B}} b = (0)$.

Then φ is continuous.

Proof: Consider the map $A/\varphi^{-1}(b) \to B/b$ with the residue norms, Cf.[non-Archimedean analysis P167]. □

Cor. (12.2.4.10). Let $\varphi : A \to B$ be a k-homomorphism between Noetherian k-Banach algebras that there is a family $\mathfrak{B}$ of ideals of B that for each $b \in \mathfrak{B}$, $\dim_k B/b < \infty$ and $\cap_{b\in\mathfrak{B}} b = (0)$, then φ is continuous. (Because the closedness condition is automatic by(12.2.4.13)).

Cor. (12.2.4.11). All complete k-algebra norms on a Noetherian k-algebra B satisfying the condition of(12.2.4.10) are equivalent.

Modules over K-Banach Spaces

Prop. (12.2.4.12). If M is a normed module over a k-Banach algebra A, if the completion of M is a finite A-module, then M is complete.

Proof: There are morphism $\pi : A^n \to \widehat{M}$ that are surjective continuous, so by open mapping theorem(10.8.2.4), this map is open, so $\sum \check{A}x_i = \pi(A^n)$ is a nbhd of 0 in $\widehat{M}$, because $\check{A}$ is open(12.2.1.9) and then $\widehat{M} = M + \sum \check{A}x_i$, because M is dense in $\check{M}$, then we are done by(12.2.1.10). □

Cor. (12.2.4.13) [Noetherian and Submodule Closed]. For a complete normed module over a k-Banach algebra A, M is Noetherian iff all submodules of M are closed. In particular, A is Noetherian iff all ideals of A are closed.

Proof: If M is Noetherian, then the completion of any submodule is finite over A, so it is complete hence closed by(12.2.4.12). Conversely, if any ideal of M is closed, then for a chain of ideals of $M : \cup M_i = M'$, M' is complete hence Baire space by(3.3.9.2), so some M_i must contain a nbhd of M', because it is an ideal, but then $M_i = M'$. □

5 p-adic Analysis

Main References are [p-adic Analysis Robert].

p-adic Fields

Def. (12.2.5.1) [p-adic Fields]. For $p \in \mathbf{P}$, a **p-adic field** is a CDVR $(K, v, \mathcal{O}_K, \mathfrak{p}_v, k)$ s.t. $\operatorname{char} K = 0, \operatorname{char} k = p, k = k^{\mathrm{perf}}$. A p-adic local field is a p-adic field(12.2.5.1).

Prop. (12.2.5.2). For $b \in \mathbb{Z}_p$, we can define a power series in $\mathbb{Z}_p[[T]]$ as the limit of $(1+a)^{b_n}$ for $b_n \to b$ in $\mathbb{Z}_p$. So for $a \in \mathbb{C}_p$ with $v(a) > 0$, there can be defined an element $(1+a)^b \in \mathbb{C}_p$, and we have $(1+a)^b = \sum C_b^k a^k$.

Def. (12.2.5.3) [Topological Completion]. If $p \in \mathbf{P}$ and K is a p-adic field, then we can define $\mathbb{C}_K = \widehat{\overline{K}}$, which is an alg.closed complete valued field, by(12.2.1.33)(12.2.1.30) and(12.2.1.24). Also denote $\mathbb{C}_p = \mathbb{C}_{\mathbb{Q}_p}$.

Lemma (12.2.5.4). If K a p-adic field and $P(X) \in \overline{K}[X]$ is a monic polynomial of degree n, and all of its roots satisfied $v_p(\alpha) \geq c$ for some constant c. Let $q = p^k$ if $n = p^k d, d \neq 1$ or $n = p^{k+1}$.

Then the derivative $P^{(q)}(X)$ has a root β with $v_p(\beta) \geq c$ or in case $n = p^{k+1}$, $v_p(\beta) \geq c - \frac{1}{p^k(p-1)}$.

Proof: Let $P = X^n + a_{n-1}X^{n-1} + \ldots + a_0$, then $v_p(a_i) \geq (n-i)c$. And

$$1/q! \cdot P^{(q)}(X) = \sum_{i=0}^{n-1} C_{n-i}^{q} a_{n-i} X^{-i-q}.$$

So at lest one root β satisfies

$$v_p(\beta) \geq \frac{1}{n-q}((n-q)c - v_p(C_n^q)) = c - \frac{1}{p^k(p-1)}.$$

□

Lemma (12.2.5.5). If K is a p-adic field and $\alpha \in \overline{K}$, let $\Delta_K(\alpha) = \inf_{g \in \mathrm{Gal}_K} v_p(g(\alpha) - \alpha)$, then there exists a $\delta \in K$ that $v_p(\alpha - \delta) \geq \Delta_K(\alpha) - p/(p-1)^2$.

Proof: We strengthen the assertion and use induction on $n = [K(\alpha) : K]$ to prove that there is a δ that $v_p(\alpha - \delta) \geq \Delta_K(\alpha) - \sum_{k=0}^{m} \frac{1}{p^k(p-1)}$, where p^{m+1} is the largest power of p that $\leq n$.

$n = 1$ is sure, let the minipoly of α over K be $P(X)$. By lemma(12.2.5.4), there is a root β of $P^{(q)}$ that $v_p(\beta - \alpha) \geq v_p(\alpha)$ or minus a factor when $n = p^{k+1}$. Then for any σ, $v_p(\sigma(\beta) - \beta) \geq v_p(\sigma(\alpha) - \alpha)$ or minus a factor. Then $\Delta(\beta) \geq \Delta(\alpha)$ or minus a factor. Now $[K(\beta) : K] < [K(\alpha) : K] = n$, so we can use induction hypothesis to get the result. □

Remark (12.2.5.6). The constant $p/(p-1)^2$ can be replaced by $1/(p-1)$, and it is optimal: this is a theorem of Le Borgne in[Bor10].

Prop. (12.2.5.7) [Ax-Sen-Tate]. If F is a p-adic field and if $K \subset \overline{F}$, then $\widehat{\overline{F}}^{\mathrm{Gal}_K} = \widehat{K}$. Thus $\widehat{L}^{\mathrm{Gal}(L/K)} = \widehat{K}$ for any alg.ext L/K.

Proof: Any $\alpha \in \widehat{\overline{F}}$ can be written as $\sum \alpha_n$ with $\alpha_n \in \overline{F}$. Then $\Delta_K(\alpha_n) \to \infty$, and α_n can be approximated by $\delta_n \in K$ by lemma(12.2.5.5), thus $\alpha \in \widehat{K}$. □

Holomorphic functions

Def. (12.2.5.8). For a p-adic field L, denote by $\mathcal{L}_L$ the set of Laurent series with coefficients in $\mathcal{L}$, then the set of valuations that a Laurent series converges $Conv(f)$ is an interval of $[-\infty, +\infty]$. Let $\mathcal{A}(I)$ denote the set of elements in L of valuation in I.

If f is bounded at r_1, r_2, then it is convergent on (r_1, r_2).

Def. (12.2.5.9). Denote $\mathcal{L}_L[r_1, r_2] = \{f | f \text{ is convergent on } [r_1, r_2]\}$.

$\mathcal{L}_L(r_1, r_2] = \{f | f \text{ is convergent on } (r_1, r_2]\}$.

$\mathcal{L}_L]r_1, r_2] = \{f | f \text{ is convergent on } (r_1, r_2] \text{ and bounded at } r_1\}$.

$\mathcal{B}_L(I)$ is the subset of bounded functions. These are all rings under addition and multiplication. And if we define $v^{(r)}(f)$ as the minimum of $v(a_n) + nr$, then it is a valuation on these rings.

Proof: Cf.[Foundations of Theory of (φ, Γ)-modules over the Robba Ring P31]. □

Def. (12.2.5.10). If we set for $\mathcal{L}_L]r_1, r_2]$ the the valuation $v^{[r_1,r_2]}(f) = \min\{v^{(r_1)}(f), v^{(r_2)}(f)\}$, then this is a valuation on it.

Prop. (12.2.5.11). $\mathcal{L}_L(\{r\})$ is complete under valuation $v^{(r)}$. Similarly the valuation $v^{[r_1,r_2]}(f)$ makes $\mathcal{L}_L[r_1, r_2]$ a Banach space unless $r_1 = r_2 = \infty$.

Proof: We let $r=0$. For a Cauchy sequence of Laurent series, we see that each coefficient is a Cauchy sequence, hence converge to some element in L, so it converge term-wise to a Laurent series f, so it converse to f in $v^{(r)}$. □

Cor. (12.2.5.12). We consider $\mathcal{L}_L(0,r]$, then it has a countable sequence of norms $v^{1/n,r}$, which makes it a locally convex space, and the last proposition shows that these valuations are complete, and a Cauchy sequence must converge to the term-wise limit, so $\mathcal{L}_L(0,r]$ is a complete Fréchet space in the Fréchet topology.

Cor. (12.2.5.13). The same method shows that $\mathcal{L}_L(I)$ is a Fréchet space for any interval I.

Def. (12.2.5.14) [Robba Ring and Overconvergent Elements]. We define $\mathcal{E}$ as the Laurent sequences that are bounded at 0 and $\lim_{n\to-\infty} v(a_n)=\infty$, and we define the **overconvergent elements** $\mathcal{E}^\dagger$ and **Robba ring** $\mathcal{R}$ as

$$\mathcal{E}^\dagger=\bigcup_{r>0}\mathcal{L}_L]0,r],\quad \mathcal{R}=\bigcup_{r>0}\mathcal{L}_L(0,r],\quad \mathcal{E}^\dagger\subset\mathcal{R}$$

and equip them with the final topology w.r.t. the Fréchet topologies on $\mathcal{L}_L(0,r]$. And denote by $\mathcal{E}^+=\mathcal{E}^\dagger\cap L[[T]]$ and $\mathcal{R}^+=\mathcal{R}\cap L[[T]]$.

For more properties of Robba ring, See [Foundations of Theory of (φ,Γ)-modules over the Robba Ring Chap4].

Def. (12.2.5.15) [Newton Polygon]. For a non-Archimedean valued field K and a polynomial or power series $P(X)=a_0+a_1X+\cdots+a_dX^d\in K[X]$, we denote by **Newton polygon** as the lower convex hull of the set of points $(0,v(a_0)),(1,v(a_1)),\ldots,(d,v(a_d))$.

Prop. (12.2.5.16)[Roots and Newton Polygon]. Foe a non-Archimedean valued field K the number of roots of P in $\overline{K}$ with valuation λ equals the horizontal width of the segment of Newton polynomial of P of slope $-\lambda$.

Proof: We may assume P is monic, then its coefficients are elementary polynomials of roots of P. And the conclusion follows as K is non-Archimedean. □

For Newton polynomial of power series, see[Berger Galois Representations Chap3] and Reference [Zeros of Power Series over complete Valued Field Lazard].

Prop. (12.2.5.17). . If $I=]0,+\infty]$ and $f(X)\in\mathcal{H}(I)$, then the number of zeros of $f(X)$ in $\mathcal{A}(I)$ equals the length of the segment of $NP(f)$ whose slope is $-s$, and these roots gives a $P_s(X)\in K[X]$ that $f(X)=P_s(X)G(X)$, $G(X)\in\mathcal{H}(I)$.

Proof: Cf.[Zeros of Power Series over complete Valued Field Lazard]. □

Cor. (12.2.5.18). If $f(X)\in\mathcal{H}(I)$, then $f(X)\in\mathcal{B}_L(I)$ iff it has f.m. zeros in $\mathcal{A}(I)$.

Proof: Let $r=\inf I$ and $s=\sup I$. First notice that $f\in\mathcal{L}_L(I)$ is in $\mathcal{B}(I)$ iff $v(a_n)+nr$ is bounded from below as $n\to+\infty$ and $v(a_n)+ns$ is bounded below as $n\to-\infty$. And from the graph of $NP(f)$, this is equivalent to f has f.m. zeros in $\mathcal{A}(I)$. □

Prop. (12.2.5.19). $\mathcal{H}(I)$ is a Bezout domain.

Formal Power Series

Cor. (12.2.5.20)[Convergence of Power Series]. Let $(R, \mathfrak{m})$ be a CDVR of characteristic0 of residue characteristic p, then

- If $f(T) = \sum_{n\geq 1}^{\infty} \frac{a_n}{n} T^n \in (R\otimes \mathbb{Q})[[T]]$ with $a_i \in R$, then $f(x)$ converges in R for $x \in \mathfrak{m}$.
- If $g(T) = \sum_{n\geq 1}^{\infty} \frac{b_n}{n!} T^n \in (R\otimes \mathbb{Q})[[T]]$ with $b_i \in R$, then $f(x)$ converges in R for $v(x) > v(p)/(p-1)$.

Proof: 1: $v(a_n x^n/n) \geq nv(x) - v(n) \geq nv(x) - \log_p(n)v(p)$ converges to ∞ for $n \to \infty$ when $v(x) > 0$.

2: $v(b_n x^n/n!) \geq nv(x) - v(n!) \geq nv(x) - (n-1)v(p)/(p-1)$(24.1.3.17) converges to ∞ for $n \to \infty$ when $v(x) > v(p)/(p-1)$ □

12.4 Global Fields

Main references are [Neu99], [Sen80], [R-V99], [Cox89], https://math.mit.edu/classes/18.785/2015fa/lectures.html, http://www.math.columbia.edu/~chaoli/docs/ClassFieldTheory.html#thm:CFTlocalnorm, should also consult notes of Pete. L. Clark.

Notation (12.4.0.1).

- Use notations defined in Commutative Algebra II.
- Use notations defined in Valuations of Rank 1, all valuations are of rank1.
- Use notations defined in More on (Non-Commutative)Algebras.
- Use notations defined in p-adic Analysis.
- Let $(K, \mathcal{O}_K) \in$ `LField`.
- Let $(F, \mathcal{O}_F) \in$ `GField`(12.4.2.1)(12.4.2.2).

1 Classical Problems

Remark (12.4.1.1). Propositions in this section must be stated without the language of global or local fields.

Prop. (12.4.1.2). Let $p \in \mathbf{P}$, then

- p can be written as the form $x^2 + y^2$ iff $p = 2$ or $p \equiv 1 \mod 4$.
- p can be written as the form $x^2 + 2y^2$ iff $p = 2$ or $p \equiv 1, 3 \mod 8$.

Proof:

□

2 Global Fields

Def. (12.4.2.1) [Global Fields]. A **global field** is a finite extension of $\mathbb{Q}$ or $\mathbb{F}_p((t))$, without a valuation. The former is called a **number field** and the latter a **function field**. The set of global fields is denoted by `GField`. The set of number fields is denoted by `NField`. The set of function fields is denoted by `FField`.

Def. (12.4.2.2) [Ring of Integers]. $\mathbb{Z} \subset \mathbb{Q}$ and $\mathbb{F}_p[t] \subset F_p((t))$ are PIDs, thus Dedekind domains, thus for a global field F(12.4.2.1), we can define the **ring of integers** $\mathcal{O}_F$ of F to be the integral closure of $\mathbb{Z}$ or $\mathbb{F}_p[t]$ in F, which is an Dedekind domain, by(4.2.7.12) and(2.2.3.16).

Remark (12.4.2.3). The section Dedekind Domains applies to the ring of integers $\mathcal{O}_F$ for $F \in$ `GField`.

Def. (12.4.2.4) [Roots of Unity]. Denote $\mu(F)$ be the set of roots of unity in F, which is a finite group.

Def. (12.4.2.5) [Places].

- Σ_F^{fin} is the equivalent classes of (non-Archimedean)valuations of F, called the **finite places** of F.
- Σ_F^{∞} is the equivalent classes of (Archimedean valuations)$|\cdot|_v = -\log|\tau(\cdot)|$ of F corresponding to embeddings $\tau : K \to \mathbb{C}$(10.3.3.16), called the **infinite places** of F.

- $\Sigma_F^{\mathbb{R}}$ is the set of infinite places v of F corresponding to embeddings $F \to \mathbb{R}$, called the set of **real places** of F. Denote $r_1 = \#\Sigma_F^{\mathbb{R}}$ if it is finite.
- $\Sigma_F^{\mathbb{C}}$ is the set of infinite places v of F that is non-real, called the set of **complex places** of F. Notice two embeddings corresponds to the same place iff they are conjugate. Denote $r_2 = \#\Sigma_F^{\mathbb{C}}$ if it is finite.
- For a maximal ideal $\mathfrak{p} \subset \mathcal{O}_F$, $v_{\mathfrak{p}}$ is the valuation of F corresponding to F. Most of the time we will not distinguish between a maximal prime $\mathfrak{p}$ and its corresponding valuation.
- For a finite extension L/F and $v \in \Sigma_F$, Σ_L^v is the set of finite places over L over v.
- For $v \in \Sigma_F$, denote F_v the completion of F w.r.t. v.

Def. (12.4.2.6) [Constant Fields].

Prop. (12.4.2.7) [Valuations]. Let F be a global field, for any $v \in \Sigma_F$, let $\wp \in \mathbf{P} \cup \{\infty\}$ s.t. $v|\wp$, then define the **inertia degree**

$$f_v = \begin{cases} [\kappa(v) : \kappa(\wp)] & , v \in \Sigma_F^{\text{fin}} \\ [F_v : F_\wp] & , v \in \Sigma_F^{\infty} \end{cases}, \quad ||v|| = \begin{cases} \wp^{f_v} & , v \in \Sigma_F^{\text{fin}} \\ e^{f_v} & , v \in \Sigma_F^{\infty} \end{cases}, \quad |\cdot|_v = ||v||^{-v(a)}$$

This is compatible with the definition in(4.2.7.20) when $v \in \Sigma_F^{\text{fin}}$.

Prop. (12.4.2.8) [Product Formula]. Let F be a global field and $a \in F^\times$, then $|a|_w = 1$ for a.e. $w \in \Sigma_F$, and

$$\prod_{w \in \Sigma_F} |a|_w = 1.$$

Proof: Let $F_0 = \mathbb{Q}$ or $\mathbb{F}_p(t)$ be the constant field of F, then the assertion is easy to verify for F_0, and

$$\prod_{w \in \Sigma_F} |a|_w = \prod_{v \in F_0} \prod_{w|v} |a|_w = \prod_{v \in F_0} |\operatorname{Nm}_{F/F_0}(a)|_v = 1.$$

□

Prop. (12.4.2.9) [Artin-Whaples]. Let F be a field and Σ_F the set of places of F, then F is a global field iff

- There exists representatives $|\cdot|_v$ for $v \in \Sigma_F$ s.t. the product formula $\prod_{v \in \Sigma_F} |a|_v = 1$ for any $a \in F^\times$.
- For any $v \in \Sigma_F$, F_v is a local field(12.2.3.2).

Proof: □

Prop. (12.4.2.10) [Global and Local]. Let $F \in \texttt{GField}$, $v \in \Sigma_F$, then for any extension L^w/F_v, there exists a global field L/F extension s.t. $L^w = LF_v$, and $[L : F] = [L^w : F_v]$.

Proof: Cf.[Sutherland, L11]. □

Def. (12.4.2.11) [Algebraic Integers]. An element $\alpha \in \overline{\mathbb{Q}}$ is called an **algebraic number**. It is called an **algebraic integer** iff it satisfies a monic polynomial equation $p(X) \in \mathbb{Z}[T]$. Notice the set of algebraic integers equals

$$\mathcal{O}_{\overline{\mathbb{Q}}} = \bigcup_{F \subset \mathbb{C}} \mathcal{O}_F.$$

where the union is taken over all number fields F.

Prop. (12.4.2.12). If α is an algebraic integer s.t. any of its conjugate has absolute value 1, then α is a root of unity.

Proof: For any power α^r of α, its minimal polynomial over $\mathbb{Q}$ has bounded degree and bounded coefficients independent of r, so there are only f.m. such polynomial and f.m. such roots. Thus $\alpha^i = \alpha^j$ for some $i \neq j \in \mathbb{Z}_+$, and $\alpha \in \mu(\overline{\mathbb{Q}})$. □

Def. (12.4.2.13)[Weil Numbers]. For $p \in \mathbf{P}, q \in p^{\mathbb{Z}}$, a q-adic **Weil number** of weight w is a number $\alpha \in \mathcal{O}_{\overline{\mathbb{Q}}}$ that for any embedding $\iota : \mathbb{Q} \to \mathbb{C}$, $|\iota(\alpha)| = q^{w/2}$. The set of Weil q-numbers of weight w is denoted by $\mathrm{Weil}(q^{w/2})$.

Prop. (12.4.2.14)[Sign of Discriminants]. If $F \in \mathtt{NField}$. then $d(F) \in (-1)^{r_2}\mathbb{Z}_+$.

Proof: $d(F) \neq 0$ by(2.2.5.34), and by definition, $d(F) = \det((\sigma\alpha_i)_{\sigma,i})^2$, where σ runs through embeddings $F \hookrightarrow \mathbb{C}$, and $\alpha_1, \ldots, \alpha_n$ is a $\mathbb{Z}$-basis of $\mathcal{O}_F$. Then notice

$$\overline{\det((\sigma\alpha_i)_{\sigma,i})} = (-1)^{r_2} \det((\sigma\alpha_i)_{\sigma,i}),$$

so if r_2 is odd, then $\det((\sigma\alpha_i)_{\sigma,i})$ is purely imaginary, and if r_2 is even, $\det((\sigma\alpha_i)_{\sigma,i})$ is real. Thus the assertion follows. □

Galois Theory of Extensions

Def. (12.4.2.15)[Ramification Groups]. For a Galois extension of global fields L/K and a valuation extension $w|v$, denote λ/k residue fields extension of $w|v$, and denote $\mathfrak{p}_w, \mathfrak{p}_v$ by $\mathfrak{P}, \mathfrak{p}$.

Then the **decomposition group** is $G_w(L/K) = \{\sigma \in G(L/K) | w \circ \sigma = w\}$. The **decomposition field** Z_w is the fixed field of G_w.

When w is non-Archimedean, we further define:

The **inertia group** is $I_w(L/K) = \{\sigma \in G_w(L/K) | \sigma(x) \equiv x \mod \mathfrak{P}\}$. The **inertia field** T_w is the fixed field of I_w.

The **ramification group** is $R_w(L/K) = \{\sigma \in G_w(L/K) | \sigma(x)/x \equiv 1 \mod \mathfrak{P}\}$. The **ramification field** V_w is the fixed field of R_w.

Similarly we can define for higher ramification groups $G_{w,s}(L/F)$.

Prop. (12.4.2.16) [Local and Global Ramification Groups]. Let L/F be a Galois extension of global fields, $v \in \Sigma_F, w \in \Sigma_L^v$, then any embedding $L \to \overline{F}_v$ induces isomorphisms

$$G_{w,s}(L/F) \cong G_s(L_w/F_v)$$

by natural restriction.

Proof: Cf.[ANT, Neukirch]. □

Cor. (12.4.2.17) [Local and Global Galois Groups]. There is an embedding $\mathrm{Gal}(L_w/F_v) \hookrightarrow \mathrm{Gal}(L/F)$ that is determined up to conjugation. In particular, there is an embedding

$$\mathrm{Gal}_{F_v} \hookrightarrow \mathrm{Gal}_F$$

determined up to conjugation.

Proof: It is determined up to conjugation because $\mathrm{Gal}(L/F)$ acts transitively on the places over v: For finite places this follows from(4.2.7.22), and for infinite places this means $\mathrm{Gal}(L/F)$ acts transitively on the extension of embedding to $\mathbb{C}$, which is clearly true. □

Prop. (12.4.2.18) [Z_w].

- The restriction w_Z of w to Z_w extends uniquely to L.
- If v is non-Archimedean, w_Z has the same residue field and value group as v.
- $Z_w = L \cap K_v \subset L_w$.

Proof: Cf.[Neukirch P171]. □

Prop. (12.4.2.19). T_w/Z_w is the maximal unramified subextension of L/Z_w.

Proof: Cf.[Neukirch P173]. □

Prop. (12.4.2.20). V_w/Z_w is the maximal tamely ramified subextension of L/Z_w.

Proof: Cf.[Neukirch P175]. □

Minkowski Theory

Def. (12.4.2.21) [Global Lattices]. If $F \in \texttt{GField}$ and $V \in \mathcal{V}\mathrm{ect}/F$, then an $\mathcal{O}_F$-**lattice** in V is a f.g. $\mathcal{O}_F$-module Λ s.t. that generates V as a F-vector space.

In general, $\Lambda = \mathcal{O}_F x_1 \oplus \mathcal{O}_F x_2 \oplus \ldots \oplus \mathcal{O}_F x_{n-1} \oplus \mathfrak{a} x_n$ where $\mathfrak{a} \in \mathrm{Ideal}(\mathcal{O}_F)$(Cf. [?]P42, may have to do with(4.2.7.15)?), and it is called a **free lattice** if $L \cong \mathcal{O}_F^n$. Notice this is always the case if $\mathrm{cl}(\mathcal{O}_F) = 1$, e.g. when $F = \mathbb{Q}$.

Prop. (12.4.2.22) [Local to Global Compatibility for Lattices]. Let $F \in \texttt{NField}$, then

- If Λ is an $\mathcal{O}_F$-lattice in F^n, then for any $v \in \Sigma_F$, its completion in F_v is an $\mathcal{O}_{F_v}$-lattice in F_v^n, and for a.e. place v, $\Lambda_v = \mathcal{O}_{F,v}^n$.
- Conversely, if for any $v \in \Sigma_F^f$, Λ_v is an $\mathcal{O}_{F_v}$-lattice in F_v^n, and $\Lambda_v = \mathcal{O}_{F,v}^n$ for a.e. v, then there is a unique F-lattice $\Lambda \in F^n$ s.t. Λ_v is the closure of Λ in F_v. In fact, $\Lambda = \cap_{v\in\Sigma_F^f}(F^n \cap \Lambda_v)$.
- Λ is determined by Λ_v for each $v \in \Sigma_F^f$.

Proof: 1 is easy. For 2, notice that $\mathcal{O} = \cap_{v\in\Sigma_F^f}(\mathcal{O}_{F_v})$, so Λ defined as above is commensurable with $\mathcal{O}_F^n$, so it is clearly a lattice, because $\mathcal{O}_F$ is Noetherian. 3 follows from 2. (I think this argument also holds for global function fields?) □

Prop. (12.4.2.23) [Minkowski]. Let $\mathfrak{a} \neq 0 \in \mathrm{Ideal}(\mathcal{O}_F)$ and for each $\tau \in \mathrm{Hom}(F, \mathbb{C})$, let $c_\tau > 0$ s.t. $c_\tau = c_{\overline{\tau}}$ and

$$\prod_\tau c_\tau > (\frac{2}{\pi})^s |d_K|^{1/2} (\mathcal{O}_K : \mathfrak{a}),$$

then there exists $a \in \mathfrak{a}^\times$ s.t. for any $\tau \in \Sigma_F^\infty$,

$$|\tau(a)| < c_\tau$$

Proof: Cf.[Neu99]P32. □

Cor. (12.4.2.24). For $\mathfrak{a} \neq 0 \in \mathrm{Ideal}(\mathcal{O}_F)$, there exists $a \in \mathfrak{a}^\times$ s.t

$$|\tau(a)| < (\frac{2}{\pi})^{s/n} |d_K|^{1/2n} (\mathcal{O}_K : \mathfrak{a})^{1/n}$$

for any $\tau \in \mathrm{Hom}(F, \mathbb{C})$.

Prop. (12.4.2.25) [Regulator Map]. There is a **regulator map**

$$\mathrm{Reg}_F : \mathcal{O}_F^* \to [\prod_{\tau\in\Sigma_F^\infty} \mathbb{R}]^+$$

such that the kernel is $\mu(F)$, and the image is a complete lattice in $H = \{(x_i)|\sum x_i = 0\}$.

Proof: Cf.[Neukirch, P43]. □

Cor. (12.4.2.26) [Regulators]. Let $\{\varepsilon_1, \ldots, \varepsilon_t\}_{t=r_1+r_2-1}$ be a system of fundamental units in F, define $\mathrm{Reg}(F)$ the **regular of** F to be the absolute value of any $t \times t$ minor of the following matrix

$$\begin{bmatrix} \mathrm{Reg}^{(1)}(\varepsilon_1) & \ldots & \mathrm{Reg}^{(1)}(\varepsilon_t) \\ \vdots & & \vdots \\ \mathrm{Reg}^{(t+1)}(\varepsilon_1) & \ldots & \mathrm{Reg}^{(t+1)}(\varepsilon_t) \end{bmatrix},$$

then the volume of $\mathrm{Reg}(\mathcal{O}_F^*) \subset H$ is

$$\mathrm{Vol}(\mathrm{Reg}(\mathcal{O}_F^*)) = \sqrt{r_1 + r_2}\,\mathrm{Reg}(F).$$

Proof: Cf.[Neukirch, P43]. □

Thm. (12.4.2.27) [Bounded Ramifications are Rare]. Let $\Sigma_F^\infty \subset S \subset \Sigma_F$, $\#S < \infty$, then there are only f.m. field extensions L/F of a given degree n that are unramified outside S.

Proof: The power of a prime $\mathfrak{P}$ in the discriminant is controlled by n by(4.2.7.35). Together with(4.2.7.37), thus shows the power of $\mathfrak{p}$ in the discriminant of the extension is controlled by n, independent of the field. Also we can assume $\sqrt{-1} \in F$, because it changes the discriminant by a bounded factor, by(4.2.7.38). So it suffices to prove there are only f.m. field extension with fixed degree and discriminant. By(4.2.7.38), we can assume $K = \mathbb{Q}$.

For the rest, we use Minkowski's theorem, Cf.[Neukirch, P203]?. □

Prop. (12.4.2.28) [Lower Bounds for Discriminant]. The discriminant of F satisfies

$$|d_F|^{1/2} \geq \frac{n^n}{n!}(\frac{\pi}{4})^{n/2}.$$

Proof: Cf.[Neukirch, P204]. □

Cor. (12.4.2.29) [Hermit's Theorem]. There are only f.m. number fields with a given discriminant.

Proof: (12.4.2.28) shows the degree is controlled by the discriminant, thus the theorem follows from(12.4.2.27). □

Cor. (12.4.2.30) [Minkowski's Theorem]. For $F \neq \mathbb{Q} \in \mathtt{NField}$, $d_F \neq \pm 1$.

Cor. (12.4.2.31). $\mathbb{Q}$ doesn't have any non-trivial unramified extensions, by(4.2.7.39).

Orders

References are [Neu99]Chap1.12 and [?]P42.

Def. (12.4.2.32) [Orders]. An **order** is a Noetherian integral domain $\mathcal{O}$ of dimension 1 whose conductor(4.2.7.17) is non-zero, or equivalently its integral closure in fraction field is finite over $\mathcal{O}$ by(4.2.7.18). A Dedekind domain is an order.

Def. (12.4.2.33)[A-Orders]. If A is Noetherian domain with fraction field k and $B \in \mathcal{R}\mathrm{ing}^{\mathrm{fd}}/K$, then an **$A$-order** in B is an A-lattice(12.4.2.21) in B that is also a subring.

Prop. (12.4.2.34)[Orders in Number Fields]. Situation as in(4.2.7.13), if L/K is separable, then a subring $\mathcal{O}$ of L is an $\mathcal{O}_K$-order iff it is an order in L(12.4.2.32) with integral closure $\mathcal{O}_L$. in particular, $\mathcal{O}_L$ is the maximal $\mathcal{O}_K$-order in L.

In particular, if $F \in \texttt{NField}$, then the $\mathbb{Z}$-orders of F are exactly subrings of $\mathcal{O}_F$ that contains a basis of F.

Proof: If $\mathcal{O}$ is an $\mathcal{O}_K$-order, then every element of $\mathcal{O}$ is integral over $\mathcal{O}_K$, by acting on $\mathcal{O}$. $\mathcal{O}_K$ is contained in $\mathcal{O}$, and $\mathcal{O} \otimes_{\mathcal{O}_K} K = L$, so the fraction field of $\mathcal{O}$ is L. Thus the integral closure of $\mathcal{O}$ in L is $\mathcal{O}_L$. Then $\dim \mathcal{O} = 1$ as $\dim \mathcal{O}_L = 1$(4.2.4.14), and it is Noetherian because it is f.g. over A(4.1.1.40). And $\mathcal{O}_L$ is finite over $\mathcal{O}_K$ by(4.2.7.21), thus is also f.g. over $\mathcal{O}$. Thus $\mathcal{O}$ is an order.

If $\mathcal{O}$ is an order with integral closure $\mathcal{O}_L$, then it is f.g. over $\mathcal{O}_K$ as it is contained in the f.g. $\mathcal{O}_K$-module $\mathcal{O}_L$. And it contains a K-basis of L because $L = K\mathcal{O}_L$ and $a\mathcal{O}_L \subset \mathcal{O}$ for some $a \in \mathcal{O}^\times$ because $\mathcal{O}$ is an order. Thus $\mathcal{O}$ is an A-lattice in L that is a ring, so it is an A-order.

For the last assertion, notice that one direction is clear, and if $\mathcal{O}_F$ contains a basis of F and is contained in $\mathcal{O}_F$, then it must be a $\mathbb{Z}$-lattice of F, as $\mathcal{O}_F$ is free because it is finite over $\mathbb{Z}$(4.2.7.21). Then it is clear $\mathcal{O}$ is an order with integral closure $\mathcal{O}_F$. □

Cor. (12.4.2.35). If $F \in \texttt{NField}$ and $L = F(\alpha_i)$ where $\alpha_i \in \mathcal{O}_L$, then $\mathcal{O} = \mathcal{O}_F[\alpha_i]$ is an $\mathcal{O}_K$-order in L.

Prop. (12.4.2.36). Let $F \in \texttt{NField}$ and Λ is a $\mathbb{Z}$-lattice in F, then the ring of multipliers

$$\mathcal{O} = \{\alpha \in \mathcal{O}_F | \alpha\Lambda \subset \Lambda\}$$

is an order in F.

Proof: $\mathcal{O}$ contains (d) for some $d \in \mathbb{Z}_+$, because for any $\alpha \in \mathcal{O}_F$, $\alpha\Lambda \subset F = \Lambda \otimes \mathbb{Q}$, so for some $d_\alpha \in \mathbb{Z}_+$, $d_\alpha\Lambda \subset \Lambda$.

Thus $\mathcal{O}$ contains a basis of F. And $\mathcal{O}$ is contained in $\mathcal{O}_F$: if $\alpha\Lambda \subset \Lambda$, then α satisfies the equation of its characteristic polynomial, which has coefficients in $\mathbb{Z}$. So $\alpha \in \mathcal{O}_F$. Thus $\mathcal{O}$ is an order, by(12.4.2.34). □

Prop. (12.4.2.37). Let $F \in \texttt{NField}$ and $B \in \mathcal{R}\mathrm{ing}^{\mathrm{fd}}/F$, then an order $\mathcal{O} \leq B$ is maximal iff for each $v \in \Sigma_F^f$, $\mathcal{O}_v \subset B_{F_v}$ is maximal.

Proof: This is clear from(12.4.2.22) and the definition(12.4.2.33). □

Lemma (12.4.2.38). For $K \in p\text{-}\texttt{LField}$,

- $\mathrm{Mat}(n; \mathcal{O}_K)$ is a maximal order in $\mathrm{Mat}(n; K)$.
- Any two maximal orders in $\mathrm{Mat}(n; K)$ are conjugate.

- Any order $\mathcal{O}\subset \mathrm{Mat}(n;K)$ is contained in some maximal order. And it is contained in f.m. maximal orders.

Proof: 1: If another order contains $\mathrm{Mat}(n;\mathcal{O}_K)$ and also an element x, then we can clearly see that it contains an element of the form $A=\mathrm{diag}(x_1,\ldots,x_n)$ s.t. $x_1\notin\mathcal{O}_K$. Then $\{A^{\mathbb{Z}}\}$ is not bounded.

3: As $\mathcal{O}$ is compact and $\mathrm{Mat}(n;\mathcal{O}_K)$ is open, there exists f.m. x_i s.t. $B\subset\cup_i(x_i+\mathrm{Mat}(n;\mathcal{O}_K))$. Then it follows that $\Lambda=\oplus\mathcal{O}_K^n x_i$ is a lattice stable under $\mathcal{O}$, thus $\mathcal{O}\subset\mathrm{Stab}(\Lambda)$ is conjugate to $\mathrm{Mat}(n;\mathcal{O}_K)$ thus maximal.

Next we show $\mathcal{O}$ is contained in f.m. maximal orders: Suppose $\mathcal{O}\subset C=\mathrm{Stab}(\Lambda)$ and $\mathcal{O}\subset C'=\mathrm{Stab}(\Lambda')$, then there exists some α that $\varpi^\alpha\,\mathrm{Stab}(\Lambda)\subset\mathcal{O}\subset\mathrm{Stab}(\Lambda')$. Replacing Λ by a constant doesn't change stabilizer, so we may assume $\Lambda\subset\Lambda'$, and assume $\Lambda=\mathcal{O}_K\{e_1,\ldots,e_n\}$ and $\Lambda'=\mathcal{O}_K\{e_1,\varpi^{\alpha_2}e_2,\ldots,\varpi^{\alpha_n}e_n\}$. Since $\varpi^\alpha\,\mathrm{Stab}(\Lambda)\subset\mathrm{Stab}(\Lambda')$, $\mathrm{Stab}(\lambda)(\Lambda')\subset\varpi^{-\alpha}\Lambda'$. Also by using the matrices permuting e_1 and e_i, we see $\alpha_i<\alpha$ for each i, so $\varpi^\alpha\Lambda\subset\Lambda'$, and then $\varpi^n\,\mathrm{Stab}(\Lambda')(\Lambda)\subset\mathrm{Stab}(\Lambda')(\Lambda')=\Lambda'\subset L$. This implies $\varpi^\alpha\,\mathrm{Stab}(\Lambda')\subset\mathrm{Stab}(\Lambda)$. From this it is clear that there are only f.m. maximal orders containing $\mathcal{O}$.

2: It follows from the proof of item3 that any order is contained in a stabilizer, then it suffices to show that if $\mathrm{Stab}(\Lambda)=\mathrm{Stab}(\Lambda')$, then $\Lambda=\Lambda'$. But this is already implicit in the proof of item2: In this case, $\alpha=0$. □

Thm. (12.4.2.39) [Maximal Orders in Semisimple Algebras over Local Fields]. If $K\in$ p-`LField` and B is a semisimple algebra over K, then any $\mathcal{O}_K$-order $\mathcal{O}\subset B$ is contained in a maximal order. And there are only f.m. maximal orders containing it.

Proof: Writing B as a product of simple algebras, it suffices to prove for B simple, and by base change to the center L of B, it suffices to show for B central simple: This is because if two orders are isomorphic after extension by $\mathcal{O}_L$, then their transformation matrix has coefficients in $\mathcal{O}_L\cap K=\mathcal{O}_K$. Then we need to show that there are only f.m. orders containing $\mathcal{O}$. Choose a splitting field L/K for B, it reduces to prove for $B=\mathrm{Mat}(n;K)$: This reason is the same as above. Then the assertion follows from(12.4.2.38). □

Thm. (12.4.2.40)[Maximal Orders in Semisimple Algebras over Global Fields]. If $F\in$ `NField` and B is a semisimple algebra over F, then any order $\mathcal{O}\subset B$ is contained in some maximal order. And there are only f.m. maximal orders containing it.

Proof: Writing B as a product of simple algebras, it suffices to prove for B simple, and by base change to the center L of B, it suffices to show for B central simple: This is because if two orders are isomorphic after extension by $\mathcal{O}_L$, then their transformation matrix has coefficients in $\mathcal{O}_L\cap F=\mathcal{O}_F$. Then we need to show that there are only f.m. orders containing $\mathcal{O}$. Choose a splitting field L/F for B, it reduces to prove for $B=\mathrm{Mat}(n;F)$: This reason is the same as above.

And for $B=\mathrm{Mat}(n;F)$, by(12.4.2.38) and(12.4.2.22), $\mathcal{O}$ is already maximal at a.e. place, so the assertion follows from(12.4.2.22) and the local case(12.4.2.39). □

Orders in Imaginary Quadratic Fields

Def. (12.4.2.41) [$\mathcal{O}_D$]. For $D\in\mathbb{Z}$ s.t. $D\equiv 0,1 \pmod 4$, denote $\mathcal{O}_D=\mathbb{Z}[\frac{D+\sqrt{D}}{2}]$, which is an order in $\mathbb{Q}(\sqrt{D})$.

Def. (12.4.2.42) [Imaginary Quadratic Orders].

- $\mathbb{Z}[\mathrm{i}]$ is called the ring of **Gaussian integers**.

- $\mathbb{Z}[\frac{1+\sqrt{-3}}{2}]$ is called the ring of **Eisenstein integers**.
- $\mathbb{Z}[\frac{1+\sqrt{-7}}{2}]$ is called the ring of **Kleinian Integers**.

These are all PIDs.

3 Cyclotomic Fields

Def. (12.4.3.1) [Cyclotomic Units]. A **compatible system of roots of unity** is a system $\{\zeta_n, n \in \mathbb{Z}_+\} \subset \overline{\mathbb{Q}}$ s.t.

- $\zeta_m \neq 1$ for $m > 1$.
- For $k, n \in \mathbb{Z}_+$, $\zeta_{kn}^k = \zeta_n$.
- $\zeta_4 = \mathrm{i}$.

We fix a choice of compatible system of unity throughout this book.

Prop. (12.4.3.2). $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \cong (\mathbb{Z}/(n))^*$.

Proof: We choose a prime p prime to n and show that ζ_n^p is conjugate to ζ_n.

Let $X^n - 1 = f(X)h(X)$ with f(X) minimal polynomial of ζ_n.If $f(\zeta_n^p) \neq 0$, then $h(\zeta_n^p) = 0$,thus $h(X^p) = f(X)g(X)$. So modulo p, $X^n - 1$ has a multi root, which is impossible. □

Lemma (12.4.3.3). For $p \in \mathbf{P}, r \in \mathbf{Z}_+$, consider $\mathbb{Q}(\zeta_{p^r})$, then $(p) = (1 - \zeta_{p^r})^{p^{r-1}(p-1)}$, and

$$d(1, \zeta_{p^r}, \ldots, \zeta_{p^r}^{p^{r-1}(p-1)-1}) = \pm p^{p^{r-1}(r(p-1)-1)},$$

where the sign is positive if $p^r = 4$ or $p \equiv 3 (\mathrm{mod}\ 4)$.

Proof: As $\Psi_{p^r}(X) = X^{p^{r-1}(p-1)} + X^{p^{r-1}(p-2)} + \ldots + X^{p^{r-1}} + 1$, by taking $X = 1$, we get

$$p = \prod_{g \in (\mathbb{Z}/(n))^*} (1 - \zeta_{p^r}^g).$$

But it is easy to see that for any $g, g \in (\mathbb{Z}/(n))^*$, $1 - \zeta_{p^r}^g$ and $1 - \zeta_{p^r}^{g'}$ differ by a unit, so by(2.2.5.35), if ζ_i are the conjugates of ζ_{p^r}, then

$$d(1, \ldots, \theta^{p^{r-1}(p-1)-1}) = \prod_{i<j} (\zeta_i - \zeta_j)^2 = \pm \prod_i \Psi'_{p^r}(\zeta_i) = \pm \mathrm{Nm}_{\mathbb{Q}(\zeta_{p^r})/\mathbb{Q}}(\Psi'_{p^r}(\zeta_{p^r})).$$

Differentiating the equation

$$(X^{p^{r-1}} - 1)\Psi_{p^r}(X) = X^{p^r} - 1,$$

we get

$$(\zeta_p - 1)\Psi'_{p^r}(\zeta_{p^r}) = p^r \zeta_{p^r}^{-1}.$$

Then notice as p is totally ramified in $\mathbb{Q}(\zeta_p)$(12.2.3.21),

$$\mathrm{Nm}_{\mathbb{Q}(\zeta_{p^r})/\mathbb{Q}}(\zeta_p - 1) = (\mathrm{Nm}_{\mathbb{Q}(\zeta_p)/\mathbb{Q}}(\zeta_p - 1))^{p^{r-1}} = \pm p^{p^{r-1}},$$

and the assertion follows. The last assertion follows from(12.4.2.14). □

Prop. (12.4.3.4). For $n \in \mathbb{Z}_+$, $\mathcal{O}_{\mathbb{Q}(\zeta_n)} = \mathbb{Z}[\zeta_n]$.

Proof: First consider the case $n = p^r$ a prime power. By(12.4.3.3), $d(1, \zeta_{p^r}, \ldots, \zeta_{p^r}^{p^{r-1}(p-1)-1}) = \pm p^s$ for some $s \in \mathbb{Z}_+$, so $p^s\mathcal{O} \subset \mathbb{Z}[\zeta_{p^r}] \subset \mathcal{O}$. Because p totally ramifies by(12.2.3.21), $\mathcal{O} = \mathbb{Z}[\zeta_{p^r}] + (1 - \zeta_{p^r})\mathcal{O}$, thus $\mathcal{O} = \mathbb{Z}[\zeta]$ by Nakayama.

In general, if $n = \prod_i p_i^{r_i}$, for different p_i, and $\mathbb{Q}(\zeta_n) = \prod \mathbb{Q}(\zeta_{p_i^{r_i}})$ by Chinese remainder theorem, and the fields $\mathbb{Q}(\zeta_{p_i^{r_i}})$ are disjoint and the discriminant are pairwisely coprime, thus by(4.2.7.16), the products of the integral basis form an integral basis. □

Cor. (12.4.3.5). $\mathcal{O}_{\mathbb{Q}(\zeta_n+\zeta_n^{-1})} = \mathbb{Z}[\zeta_n + \zeta_n^{-1}]$.

Prop. (12.4.3.6) [Ring of Integers]. Let n be an integer with no repeated primes, then

- If $n \equiv 3 \mod 4$, the ring of integers in $\mathbb{Q}(\sqrt{n})$ is $\mathbb{Z}[\sqrt{n}]$.
- If $n \equiv 1 \mod 4$, the ring of integers in $\mathbb{Q}(\sqrt{n})$ is $\mathbb{Z}[\frac{1+\sqrt{n}}{2}]$.

Proof: 1: the minimal polynomial of $\sqrt{n}$ is $X^2 - n$, whose different is $4n$, which doesn't have a proper divisor β that $4n/\beta$ is a square and $\beta \equiv 0, 1 \mod 4$, so $\mathbb{Z}[\sqrt{n}]$ is the ring of integers.

2: the minimal polynomial of $\frac{1+\sqrt{n}}{2}$ is $X^2 - X + \frac{1-n}{4}$, whose different is n, which doesn't have a proper divisor β that $4n/\beta$ is a square, so $\mathbb{Z}[\frac{1+\sqrt{n}}{2}]$ is the ring of integers. □

Prop. (12.4.3.7). By(19.3.2.8), for $p \geq 3 \in \mathbf{P}$, $\mathbb{Q}(\sqrt{(-1)^{\frac{p-1}{2}}p}) \subset \mathbb{Q}(\zeta_p)$.

Prop. (12.4.3.8). For $p \in \mathbf{P}$, if $\varepsilon \in (\mathbb{Z}[\zeta_p])^*$, then there exists $\varepsilon_1 \in \mathbb{Q}(\zeta_p + \zeta_p^{-1})$ and $r \in \mathbb{Z}$ s.t. $\varepsilon = \zeta_p^r \varepsilon_1$.

Proof: The case $p = 2$ is clear. Assume $p \geq 3$, and $\alpha = \overline{\varepsilon}/\varepsilon$, then any conjugate of α has absolute value 1. Thus α is a root of unity(12.4.2.12), Assume $\alpha = \pm\zeta_p^a$**?**. Let $\varepsilon = b_0 + b_1\zeta_p + \ldots + b_{p-2}\zeta_p^{p-2}$, if $\alpha = -\zeta_p^a$, then

$$\overline{\varepsilon} = b_0 + b_1\zeta_p^{-1} + \ldots \equiv b_0 + b_1 + \ldots \equiv \varepsilon = -\zeta_p^a\overline{\varepsilon} \equiv \overline{\varepsilon} (\mathrm{mod}\ 1 - \zeta_p).$$

Then $2\overline{\varepsilon} \in (1 - \zeta_p)$, which is not possible.

Thus $\alpha = \zeta_p^a$. Assume $a \equiv 2r (\mathrm{mod}\ p)$, and $\varepsilon_1 = \zeta^{-r}\varepsilon$, then $\overline{\varepsilon}_1 = \varepsilon_1$, and $\varepsilon = \varepsilon_1\zeta_p^r$. □

Prop. (12.4.3.9). $p \in \mathbf{P}$ splits in $\mathbb{Q}(\zeta_n)$ iff $p \equiv 1 \mod n$.

Proof: First, if it splits, then $f_p = 1$. Because the ring of integers is $\mathbb{Z}[\zeta_n]$, so $X^n - 1$ splits in $\mathbb{F}_p$(12.4.3.4), thus $p \equiv 1 \mod n$. And if $p \equiv 1 \mod n$, it is unramified and $X^n - 1$ splits in $\mathbb{F}_p$, so $f_p = 1$. □

Prop. (12.4.3.10). $p \in \mathbf{P}$ is ramified in $\mathbb{Q}(\zeta_n)$ iff $p|n$.

Proof: This follows from(12.2.3.19) and(12.2.3.21). □

Cor. (12.4.3.11). If $m, n \in \mathbb{Z}_+$ are coprime, then $\mathbb{Q}(\zeta_m) \cap \mathbb{Q}(\zeta_n) = \mathbb{Q}$.

Proof: This follows from Minkowski's theorem(12.4.2.30). □

Prop. (12.4.3.12). If $n \in \mathbb{Z}_+$ has at least two prime divisors, then $1 - \zeta_n$ is a unit in $\mathbb{Q}(\zeta_n)$.

Proof: By(2.2.2.24), $\mathrm{Nm}(1 - \zeta_n) = \Psi_n(1) = 1$. □

Prop. (12.4.3.13).

- If $n \in \mathbb{Z}_+$ is not of the form p^r or $2p^r$ for $p \in \mathbf{P}$, then $\mathbb{Q}(\zeta_n)/\mathbb{Q}(\zeta_n + \zeta_n^{-1})$ is unramified at finite places.
- If $p \in \mathbf{P}$ and $n \in p^{\mathbb{Z}_+}$ or $n \in 2p^{\mathbb{Z}_+}$, then $\mathbb{Q}(\zeta_n)/\mathbb{Q}(\zeta_n + \zeta_n^{-1})$ is ramified at any places above p, and unramified at other finite places.

Proof: For the first case, let p, q are two prime divisors of n(or $q = 2$, in which case take $q = 4$). Then ζ_p, ζ_q are not in $\mathbb{Q}(\zeta_n + \zeta_n^{-1})$, so $\mathbb{Q}(\zeta_n) = \mathbb{Q}(\zeta_n + \zeta_n^{-1}, \zeta_p) = \mathbb{Q}(\zeta_n + \zeta_n^{-1}, \zeta_q)$. But then $\mathbb{Q}(\zeta_n)/\mathbb{Q}(\zeta_n + \zeta_n^{-1})$ can only ramify at finite places that are both over p and over q, so it is unramified at all finite places.

For the second case, use the fact that $\mathbb{Q}(\zeta_n)/\mathbb{Q}$ is totally ramified at p and unramified at other places(12.2.3.19) and(12.2.3.21). □

$\mathbb{Z}_p$-Extensions

Def. (12.4.3.14)[$\mathrm{cycl}_p(K)$]**.** For $p \in \mathbf{P}$ and $K \in$ p-`Field` or $K \in$ `GField`, Denote $K_{p^\infty} = K(\zeta_{p^\infty})$. Then by(12.4.3.2) and(12.2.3.12), $\mathrm{Gal}(K_{p^\infty}/K) \subset \mathbb{Z}_p^* \cong \mathbb{Z}_p \oplus G$ is a subgroup of finite index, where G is a finite group. So there is a unique subextension $\mathrm{cycl}_p(K) \subset K(\mu_{p^\infty})$ with $\mathrm{Gal}(\mathrm{cycl}_p(K)/K) \cong \mathbb{Z}_p$, called the **cyclotomic $\mathbb{Z}_p$-extension** of K.

Also denote $\mathrm{cycl}_{p,n}(K) \subset \mathrm{cycl}_p(K)$ the subextension of degree p^n.

Prop. (12.4.3.15). If ℓ is a p is totally ramified in $\mathrm{cycl}_p(\mathbb{Q})$, and any $\ell \in \mathbf{P} \setminus \{p\}$ is unramified in $\mathrm{cycl}_p(\mathbb{Q})$.

Proof: Cf.[Washington, P265]. □

Others

Prop. (12.4.3.16). For $n \in \mathbb{Z}_+$, the sum of primitive n-th roots of unity equals $\mu(n)$(24.1.3.14).

Proof: ? Prove that the assertion is multiplicative, and then prove for prime powers. □

Prop. (12.4.3.17). Find all $n \in \mathbb{Z}_+$ and primitive n-th roots of unity $\zeta_1, \ldots, \zeta_4$ s.t.

$$\zeta_1 + \zeta_2 + \zeta_3 + \zeta_4 = 1.$$

Proof: By(12.4.3.16),

$$4\mu(n) = \sum_{k \in (\mathbb{Z}/(n))^*} \sum_{i=1}^{4} \zeta_i^k = \phi(n).$$

Thus $\varphi(n) = 4$ and $\mu(n) = 1$. Then n can only be 5, 8, 10, 12, and n can only be 10.

Now $\Psi_{10}(X) = X^4 - X^3 + X^2 - X + 1$, so the identity $\zeta_1 + \zeta_2 + \zeta_3 + \zeta_4 = 1$ must be essentially identical to this one. So the only possibility is

$$\{\zeta_1, \zeta_2, \zeta_3, \zeta_4\} = \{e^{2\pi\mathrm{i}\frac{1}{10}}, e^{2\pi\mathrm{i}\frac{3}{10}}, e^{2\pi\mathrm{i}\frac{7}{10}}, e^{2\pi\mathrm{i}\frac{9}{10}}\}.$$

□

4 Class Numbers

Def. (12.4.4.1) [Class Groups]. For $F \in \texttt{GField}$, the **class group of** F is defined to be the class group $\mathrm{Cl}(\mathcal{O}_F)$ of $\mathcal{O}_F$. It is denoted by $\mathrm{Cl}(F)$. The cardinality of $\mathrm{Cl}(F)$ is called the **class number of** F, denoted by $\mathrm{cl}(F)$.

Conj. (12.4.4.2). There are infinitely many number fields with class number 1.

Proof: □

Class Number of Complex Quadratic Fields

References are [Gol85], [Sta67].

Prop. (12.4.4.3). Let $\ell \equiv 3(\mathrm{mod}\ 4) \in \mathbf{P}$, then for $D = -\ell$ or -4ℓ, $h(\mathcal{O}_D)$(12.4.2.41) is odd.

Proof: Cf.[Cox, Prop3.11 and Thm7.7(ii)].? □

Prop. (12.4.4.4)[Gauss Class Number Problem1801, Siegel/Goldfeld-Gross-Zagier/Zhang]. There exists an effectively computable constant $C > 0$ s.t. for any complex quadratic field $\mathbb{Q}(\sqrt{D})$ with discriminant $D < 0$,

$$h(\mathbb{Q}(\sqrt{D})) > C\frac{|D|^{1/2}}{(\log|D|)^{2022}}.$$

Proof: This follows from(19.3.4.3) and(19.3.3.12). □

Cor. (12.4.4.5) [Baker-Heegner-Stark]. For $d \in \mathbb{Z}_+$ squarefree, $\mathrm{cl}(\mathbb{Q}(\sqrt{-d})) = 1$ iff

$$d \in \{1, 2, 3, 7, 11, 19, 43, 67, 163\}.$$

These numbers are called the **Heegner numbers**.

Proof: Cf.[Cox, P247]? □

Class Number of Cyclotomic Fields

Prop. (12.4.4.6). For $p \geq 3 \in \mathbf{P}$, $p | \mathrm{cl}(\mathbb{Q}(\zeta_p))$ iff there exists some $k \in \mathbb{Z}_+$ s.t. $k \leq \frac{p-3}{2}$ and p divides the denominator of B_{2k}(8.5.1.12).

Proof: ? □

Prop. (12.4.4.7) [Montgomery/Uchida]. For $p \in \mathbf{P}$, $\mathrm{cl}(\mathbb{Q}(\zeta_p)) = 1$ iff $p \leq 19$.

Proof: □

5 Adeles and Ideles

Restricted Direct Products

Def. (12.4.5.1) [Restricted Direct Products]. Let $\{\mathfrak{p}\}$ be a set of indices and given a family of locally compact Abelian groups $G_\mathfrak{p}$, and for a.e. $\mathfrak{p}$ an open compact subgroup $H_\mathfrak{p}\subset G_\mathfrak{p}$. Then the **restricted direct product** is defined to be

$$G=\prod{}'(G_\mathfrak{p},H_\mathfrak{p})=\varinjlim_{S\in\{\mathfrak{p}\},|S|<\infty}\prod_{\mathfrak{p}\in S}G_\mathfrak{p}\times\prod_{\mathfrak{p}\notin S}H_\mathfrak{p}$$

given the colimit space topology. And we denote $\prod_{\mathfrak{p}\in S}G_\mathfrak{p}\times\prod_{\mathfrak{p}\notin S}H_\mathfrak{p}=G_S,\prod_{\mathfrak{p}\notin S}H_\mathfrak{p}=G^S$.

This topology is stronger than the product topology of $\prod_\mathfrak{p}G_\mathfrak{p}$. It has an open basis $N=\prod_\mathfrak{p}N_\mathfrak{p}$, where $N_\mathfrak{p}$ is open in $G_\mathfrak{p}$ and $N_\mathfrak{p}=H_\mathfrak{p}$ for a.e. $\mathfrak{p}$. It is locally compact because every G_S does.

Prop. (12.4.5.2). Every compact subset N of G is contained in some $\prod_\mathfrak{p}N_\mathfrak{p}$, where $N_\mathfrak{p}$ is compact and $N_\mathfrak{p}=H_\mathfrak{p}$ for a.e. $\mathfrak{p}$.

Proof: This is because G_S is an open covering of G, and the union of f.m. G_{S_i} is also of the form G_S. So N is contained in some G_S, thus its projection in the S-coordinates is compact. □

Prop. (12.4.5.3) [Quasi-Characters on G]. Quasi-characters on G are all of the form $\otimes_\mathfrak{p}c_\mathfrak{p}$ that $c_\mathfrak{p}$ is trivial on $H_\mathfrak{p}$ for a.e. $\mathfrak{p}$.

Proof: Let c be a quasi-character, choose a nbhd of $1\in U\subset\mathbb{C}$ that contains no subgroup, then $c^{-1}(U)$ has contains an open basis $\prod_{\mathfrak{p}\in S}N_\mathfrak{p}\times G^S$, where $N_\mathfrak{p}$ are open nbhds of 1, so $c(G^S)=1$. Thus $c(\mathfrak{a})=\prod_\mathfrak{p}c_\mathfrak{p}(a_\mathfrak{p})$ is true for any $\mathfrak{a}\in G$.

Conversely, clearly $\otimes_\mathfrak{p}c_\mathfrak{p}$ is a quasi-character on G, it is continuous. □

Prop. (12.4.5.4)[Dual of G]. In each $G_\mathfrak{p}^\vee$, by(10.11.3.7) $H_\mathfrak{p}$ are compact, so $H_\mathfrak{p}^\vee=G_\mathfrak{p}^\vee/H_\mathfrak{p}^\perp$ are discrete, so $H_\mathfrak{p}^\perp$ is open; $H_\mathfrak{p}$ are open, so $H_\mathfrak{p}^\perp=(G_\mathfrak{p}/H_\mathfrak{p})^\vee$ are compact. So we can define the space $\prod'(G_\mathfrak{p}^\vee,H_\mathfrak{p}^\perp)$.

Then the dual group $G^\vee\cong\prod'(G_\mathfrak{p}^\vee,H_\mathfrak{p}^\perp)$ as a topological group.

Proof: (12.4.5.3) shows that this is an algebraic isomorphism, so it suffices to prove this is a topological homeomorphism(10.11.3.6):

For any compact $B\in G_1=\prod_{\mathfrak{p}\in S}N_\mathfrak{p}\times\prod_{\mathfrak{p}\notin S}H_\mathfrak{p}$, for any $\varepsilon>0$, if $c\in\prod_{\mathfrak{p}\in S}N'_\mathfrak{p}\times\prod_{\mathfrak{p}\notin S}H_\mathfrak{p}^\perp$, where $N'_\mathfrak{p}=\{c_\mathfrak{p}||c_\mathfrak{p}(N_\mathfrak{p}-1)|<\varepsilon/|S|\}$, then $|c(B)-1|<\varepsilon$.

Conversely, if ε is small enough, then if $c(\prod_{\mathfrak{p}\in S}N_\mathfrak{p}\times\prod_{\mathfrak{p}\notin S}H_\mathfrak{p})-1|<\varepsilon$, then $c\in\prod_{\mathfrak{p}\in S}N'_\mathfrak{p}\times\prod_{\mathfrak{p}\notin S}H_\mathfrak{p}^\perp$, where $N'_\mathfrak{p}=\{c_\mathfrak{p}||c_\mathfrak{p}(N_\mathfrak{p}-1)|<\varepsilon\}$ □

Prop. (12.4.5.5)[Restricted Product Measure]. Let measures $d\alpha_\mathfrak{p}$ be given on $G_\mathfrak{p}$ that $\alpha_\mathfrak{p}(H_\mathfrak{p})=1$ for a.e. $\mathfrak{p}$, define a Haar measure on G as follows:

On G_S, $d\alpha_S=\prod_{\mathfrak{p}\in S}d\alpha_\mathfrak{p}\cdot d\alpha^S$, where α^S is the product measure on G^S.

Then these can define a functional a positive left-invariant functional I that $|I(f)|\leq||f||$ for any f that depends only on f.m. coordinates $\mathfrak{p}\in S$. Then Stone-Weierstrass theorem shows these functions are dense in $C(G)$, thus I can be uniquely extended to a functional on $C(G)$, and this defines a Haar measure on G by Riesz representation(10.11.1.10), denoted by $d\alpha=\prod'_\mathfrak{p}d\alpha_\mathfrak{p}$, called the **restricted product measure**.

Prop. (12.4.5.6). For a function f on $G=\prod'(G_\mathfrak{p},H_\mathfrak{p})$ measurable, if either $f\geq 0$ or $f\in L^1(G)$, then
$$\int_G f(\mathfrak{a})d\mathfrak{a}=\varinjlim_S\int_{G_S}f(\mathfrak{a})d\mathfrak{a}$$
as a net limit.

Proof: The second case follows from the first case, as $\int_G f=\varinjlim_{B\text{ compact}}\int_B f$ by monotone convergence theorem, and any B compact is contained in some G_S(12.4.5.2). □

Cor. (12.4.5.7). If $f(\mathfrak{a})=\prod_\mathfrak{p} f_\mathfrak{p}(\mathfrak{a}_\mathfrak{p})$, where $f_\mathfrak{p}\in L_1(G_\mathfrak{p})$ and $f_\mathfrak{p}=\chi_{H_\mathfrak{p}}$ a.e. p, then if
$$\prod_\mathfrak{p}\int_{G_\mathfrak{p}}|f_\mathfrak{p}(\mathfrak{a}_\mathfrak{p})|d\mathfrak{a}_\mathfrak{p}<\infty,$$
then $f\in L^1(G)$, and
$$\int_G f(\mathfrak{a})\mathrm{d}\mathfrak{a}=\prod_\mathfrak{p}(\int f_\mathfrak{p}(\mathfrak{a}_\mathfrak{p})\mathrm{d}\mathfrak{a}_\mathfrak{p}).$$

Def. (12.4.5.8) [Dual Measure]. Notice if $f_\mathfrak{p}=\chi_{H_\mathfrak{p}}$, then
$$f_\mathfrak{p}^\vee(c_\mathfrak{p})=\int_{H_\mathfrak{p}}\overline{c_\mathfrak{p}(\alpha_\mathfrak{p})}d\mathfrak{a}_\mathfrak{p}=d\mathfrak{a}_\mathfrak{p}(H_\mathfrak{p})\chi_{H_\mathfrak{p}^\perp}(c_\mathfrak{p}).$$
So by Fourier transform(10.11.3.24), if $\mathrm{d}c_\mathfrak{p}$ is the dual measure on $G_\mathfrak{p}^\vee$, then $\chi_{H_\mathfrak{p}^\perp}=\mathrm{d}c_\mathfrak{p}(H_\mathfrak{p}^\perp)d\mathfrak{a}_\mathfrak{p}(H)\chi_{H_\mathfrak{p}^\perp}$, which means $\mathrm{d}c_\mathfrak{p}(H_\mathfrak{p}^\perp)=1, a.e.\mathfrak{p}$, thus we can define a measure on $G^\vee$ as $dc=\prod' dc_\mathfrak{p}$.

Then $\mathrm{d}c$ is the measure on $\widehat{G}$ dual to $\mathrm{d}\mathfrak{a}$ on G.

Proof: The duality is by the lemma below(12.4.5.9), applied to both f and $\widehat{f}$. □

Lemma (12.4.5.9) [Fourier Transform on Product]. if $f_\mathfrak{p}\in B_1(G_\mathfrak{p})$ and $f_\mathfrak{p}=\chi_{H_\mathfrak{p}}$ a.e. $\mathfrak{p}$, then $f(\mathfrak{a})=\prod f_\mathfrak{p}(\mathfrak{a}_\mathfrak{p})\in B_1(G)$, and $f^\vee(c)=\prod f_\mathfrak{p}^\vee(c_\mathfrak{p})$.

Proof: For any character c, because
$$f(\mathfrak{a})\overline{c}(\mathfrak{a})=\prod f_\mathfrak{p}(\mathfrak{a}_\mathfrak{p})\overline{c}_\mathfrak{p}(\mathfrak{a}_\mathfrak{p})$$
and every $f_\mathfrak{p}(\mathfrak{a}_\mathfrak{p})\overline{c}_\mathfrak{p}(\mathfrak{a}_\mathfrak{p})\in L^1(G_\mathfrak{p})$. So(12.4.5.7) applies and shows the equations. Similarly, because $\widehat{f}_\mathfrak{p}=\chi_{H_\mathfrak{p}^\perp}$ a.e. $\mathfrak{p}$, we have $\widehat{f}\in L_1(\widehat{G})$, so $f(\mathfrak{a})\in B_1(G)$. □

Adeles

Notation (12.4.5.10) [Adeles]. For $S\in\Sigma_F$, $\#S<\infty$,

- The **adele group**(adele=additive element) of F is defined to be $\mathbf{A}_F=\prod'_v(F_v,\mathcal{O}_v)$(12.4.5.1).
- $\mathbf{A}_{S,F}=\prod_{v\in S}F_v$.
- $\mathbf{A}_F^S=\prod'_{v\notin S}(F_v,\mathcal{O}_v)$, called the group of S-**adeles** of F.
- The **finite adeles** $\mathbf{A}_F^f=\mathbf{A}_F^{S_\infty}=\prod'_{v\notin S_\infty}(F_v,\mathcal{O}_v)$.
- The **infinite adeles** $\mathbf{A}_{F,\infty}=\mathbf{A}_{F,S_\infty}=\prod_{v\in S_\infty}F_v$.

- For $v \in \Sigma_F, x \in F_v$, let $[x]_{\mathfrak{p}}^{\oplus}$ be the image of x under the map $F_{\mathfrak{p}} \to A_F$.

Prop. (12.4.5.11) [Extension of Adeles]. If $L/F \in \texttt{GField}$ is separable, then

$$\mathbf{A}_F \otimes_F L \cong \mathbf{A}_L$$

by diagonal embedding.

Proof: $\mathbf{A}_K \otimes_F L \cong \prod_v'(F_v, \mathcal{O}_v \otimes_{\mathcal{O}_F} \mathcal{O}_L)$, because for any element $x \in L$, $|\operatorname{Nm}_{L/F}(x)|_v \neq 0$ for only f.m. v. And there are isomorphisms by diagonal maps.

$$F_v \otimes_F L \cong \prod_{w|v} L_w, \quad \mathcal{O}_v \otimes_{\mathcal{O}_F} \mathcal{O}_L \cong \prod_{w|v} \mathcal{O}_w (4.2.7.26).$$

□

Prop. (12.4.5.12) [K Cocompact in Adele]. F is discrete in $\mathbf{A}_F$ and $\mathbf{A}_F/F$ is compact.

Proof: Let ∞ be any prime, consider $U = \{\mathfrak{a} \in A_F||a|_\infty < 1, |a|_v \leq 1\}$, then $U \cap K = 0$ by(12.4.5.16).

Now we show A_F/F is compact. By(12.4.5.11), it suffices to prove for $F = \mathbb{Q}$ or $\mathbb{F}_p(t)$. Let $U_\infty = \{x \in F_\infty||x|_\infty \leq 1\}$, and Cf.[MIT notes, 22.12].**?** □

Lemma (12.4.5.13) [Strong Approximation for $\mathbb{G}_a$]. For any $S \neq \varnothing \in \Sigma_F$, strong approximation holds for S. In other words, the image of F is dense in $\mathbf{A}_F^S$, or equivalently, $FF_vU = \mathbf{A}_F$ for any non-empty open subset $U \subset \mathbf{A}_F^S$.

Remark (12.4.5.14). See(13.3.3.9) for more general strong approximation theorems.

Proof: Cf.[MIT notes, 22.14].**?** □

Ideles

Notation (12.4.5.15) [Ideles]. For $S \in \Sigma_F$, $\#S < \infty$,

- The **idele group**(idele=ideal element) of F is defined to be $\mathbf{I}_F = \prod_v'(F_v^\times, \mathcal{O}_{F_v}^*)$(12.4.5.1), which is set-theoretically just $\mathbf{A}_F^\times$. Notice the topology on $\mathbf{I}_K$ is stronger than the subspace topology induced from $\mathbf{A}_K$.
- The **ideal class group** $C_F = \mathbf{I}_F/F^\times$.
- $\mathbf{I}_F$ is naturally a valuation ring with valuation $|\cdot|$, called the **idelic norm**.
- $\mathbf{I}_F^1 \subset I_F$ is the subgroup consisting of elements of idelic norm 1, called the set of **unit ideles**.
- $\mathbf{I}_F^S = \prod_{\mathfrak{p}\in S} F_{\mathfrak{p}}^\times \times \prod_{\mathfrak{p}\notin S} \mathcal{O}_{F,\mathfrak{p}}^*$, called the group of S-**ideles** of F.
- $\mathbf{I}_{F,S} = \prod_{v\in S} F_v^\times$.
- $F^S = \mathcal{O}_{F,S}^* = F^\times \cap \mathbf{I}_F^S$ is the set of S-units of F(4.2.7.10).
- The **finite ideles** $\mathbf{I}_F^f = \mathbf{I}_F^{\Sigma_F^\infty} = \prod_{v\notin\Sigma^\infty}'(F_v^\times, \mathcal{O}_v^*)$.
- The **infinite ideles** $\mathbf{I}_{F,\infty} = \mathbf{I}_{F,S_\infty} = \prod_{v\in S_\infty} F_v^\times$.
- For $v \in \Sigma_F, x \in F_v^\times$, let $[x]_v$ be the image of x under the map $F_v^\times \to \mathbf{I}_F$ or the map $F_{\mathfrak{p}}^\times \to \mathbf{A}_F$.

Prop. (12.4.5.16) [Product Formula]. If $\mathfrak{a} \in F^\times \subset \mathbf{I}_F$, then $|\mathfrak{a}|_F = 1$. In other words, $F^\times \subset \mathbf{I}_F^1$.

Proof: Consider the restricted product measure $d\mu$ on A_F, then clearly $d\mu(\mathfrak{a}x) = |\mathfrak{a}|d\mu(x)$, and multiplying by $\mathfrak{a}$ induces an isomorphism of $\mathbf{A}_F$, but preserves the counting measure on F. But A_F is compact(12.4.5.12) thus has finite volume, so $|\mathfrak{a}| = 1$. □

Prop. (12.4.5.17). If $F \in$ `FField`, the norm group $|\mathbf{I}_F|$ of the Adelic norm is $|\mathbf{I}_F| = q^{\mathbb{Z}}$, where $q = \#F_0$ and F_0 is the maximal finite field contained in F.

Proof: This is because in this case, F corresponds to smooth curve over F_0**?**. Then by Weil conjecture(19.1.4.3), there exists a point of F_0 with residue order q^n for any n large. Then their quotient gives q. □

Prop. (12.4.5.18) [Splitting of $\mathbf{I}_F$].

- If $F \in$ `NField`, take $v \in \Sigma_F^\infty$, then the exact sequence $1 \to I_F^1 \to I_F \xrightarrow{v} \mathbb{R}_+ \to 1$ splits, so there are a non-canonical isomorphisms

$$I_F \cong I_F^1 \times \mathbb{R}_+, \quad I_F/F^\times \cong I_F^1/F^\times \times \mathbb{R}_+.$$

- If $F \in$ `FField`, take $v \in \Sigma_F$, then for some $q = (\operatorname{char} k)^r$, the exact sequence $1 \to \mathbf{I}_F^1 \to \mathbf{I}_F \xrightarrow{v} q^{\mathbb{Z}} \to 1$ splits, so there are a non-canonical isomorphisms

$$I_F \cong \mathbf{I}_F^1 \times q^{\mathbb{Z}}, \quad \mathbf{I}_F/F^\times \cong I_F^1/F^\times \times q^{\mathbb{Z}}.$$

Lemma (12.4.5.19). $\mathbf{I}_F^1$ is closed in $\mathbf{A}_F$, and the subspace topologies from $\mathbf{A}_F$ and $\mathbf{I}_F$ are the same on $\mathbf{I}_F^1$.

Proof: **?** □

Lemma (12.4.5.20) [Blichfeldt-Minkowski]. For $F \in$ `GField`, there exists $C > 0$ s.t. for any $x \in \mathbf{I}_F$ s.t. $|x|_F \geq C$, let

$$W(x) = \{y \in \mathbf{I}_F : |y_v|_v \leq |x_v|_v, \forall v \in \Sigma_F\}.$$

Then $W(x) \cap F^\times \neq \varnothing$.

Proof: **?** □

Prop. (12.4.5.21) [$F^\times$ Cocompact in $\mathbf{I}_F^1$]. $F^\times$ is discrete in $\mathbf{I}_F$, and $\mathbf{I}_F^1/F^\times$ is compact. Thus $C_F = \mathbf{I}_F/F^\times$ is Hausdorff and locally compact.

Proof: $F^\times$ is discrete in $\mathbf{I}_F$ because it is already discrete in $\mathbf{A}_F$(12.4.5.12). By(12.4.5.19), use Minkowski(12.4.5.20), it suffices to show that for $||x||_F \geq C$, $W(x) \cap I_F^1 \to I_F^1/F^\times$ is surjective: If $y \in I_F^1$, then $||x/y|| = ||x|| \geq C$, thus there exists $z \in K^\times \cap W(x/y)$, thus $zy \in W(x)$, and y is in the image of $W(x) \cap I_F^1$. □

Prop. (12.4.5.22). For $L/F \in$ `GField`, $\mathbf{I}_F \subset \mathbf{I}_L$, and $\mathbf{I}_L^G = \mathbf{I}_K$, this is be the diagonal inclusion to all the primes above a given prime, and the action is by $(\sigma\mathfrak{a})_{\mathfrak{P}} = \sigma\mathfrak{a}_{\sigma^{-1}\mathfrak{P}}$. This induces an inclusion $C_K \subset C_L$ and $C_L^G = C_K$. The last assertion uses long exact sequence and $H^1(G, L^*) = 0$.

Lemma (12.4.5.23). The map $\mathbf{I}_F \to \mathbf{A}_F \times \mathbf{A}_F : x \mapsto (x, x^{-1})$ is a homeomorphism of $\mathbf{I}_F$ onto a closed subspace of $\mathbf{A}_F \times \mathbf{A}_F$.

Proof: Compare their topological basis. □

Prop. (12.4.5.24) [Idele Groups and Extensions]. For an extension of global fields L/F,

- the diagonal embedding $\mathbf{A}_F \to \mathbf{A}_L$ induces a closed embedding, and also a closed embedding $\mathbf{I}_F \to \mathbf{I}_L$ by(12.4.5.23), thus also a closed embedding $I_F/F^\times \to I_L/L^\times$.
- A_L is a finite A_K-module, thus there is a norm map $\mathrm{Nm}_{L/K} : A_L \to A_F$, which restricts to $\mathrm{Nm}_{L/K} : \mathbf{I}_L \to \mathbf{I}_F$, which is compatible with $\mathrm{Nm}_{L/K} : L^\times \to K^\times$, thus inducing a map $\mathrm{Nm}_{L/K} : C_L \to C_F$. Then this map is continuous, open and proper.
- $[n] : C_F \to C_F$ is continuous and proper.

Proof: 2: It is continuous because it is compatible with the local norms $\mathrm{Nm}_{L_\mathfrak{P}/F_\mathfrak{p}}$, and $\mathrm{Nm}^{-1}_{L_\mathfrak{P}/F_\mathfrak{p}}(\mathcal{O}^\times_{F,\mathfrak{p}}) = \mathcal{O}^\times_{L,\mathfrak{P}}$. To show it is open, use the fact the local norms are open and for unramified places $\mathrm{Nm}_{L_\mathfrak{P}/F_\mathfrak{p}} \mathcal{O}_{L,\mathfrak{P}} = \mathcal{O}_{F,\mathfrak{p}}$(12.2.3.14)(12.6.2.5). To show it is proper, use the splitting $C_F \cong \mathbf{I}^1_F/F^\times \times q^\mathbb{Z}$(12.4.5.18) and the fact $I^1_F/F^\times$ is proper(12.4.5.21).

3: Use the splitting(12.4.5.18). □

<u>C_F</u>

Def. (12.4.5.25) [Hecke Character]. A **Hecke character** over F is a character of C_F.

Def. (12.4.5.26) [Unramified Places]. Let χ be a Hecke character of C_F, then for a.e. $v \in \Sigma^{\mathrm{fin}}_F$, the conductor of χ_v is $\mathcal{O}^*_v$. For these v, χ is said to be **unramified** at v.

Prop. (12.4.5.27). Let $p \in \mathfrak{P}, F \in p$-`FField`, and $\ell \in \mathbf{P}\backslash p, E \in \ell$-`NField`, then any continuous homomorphism $\chi : C_F \to \mathcal{O}^*_E$ that is unramified outside a finite set of places is of the form $\chi = \chi_1 \cdot c^{\deg(\cdot)}$, where $\chi_1 : C_F \to \mathcal{O}^*_E$ is of finite order and $c \in \mathcal{O}^*_E$.

Proof: Let $\sigma \in C^{\mathrm{ab}}_F$ s.t. $\deg(\sigma) = 1$, let $c = \chi(\sigma)$, and $\chi_1 = \chi \cdot c^{-\deg(\cdot)}$, then $\chi_1(C_F) = \chi_1(I_F)$. But as $\#\,\mathrm{Cl}(F) < \infty$, by(12.6.4.7), it suffices to show that $\chi_1(F^\times U^\mathbb{1}/F^\times)$ is finite. Then it suffices to show that $\#\chi(U^\mathbb{1}) < \infty$. But if χ is unramified outside a finite set S of places, then it suffices to show that $\#\chi(\prod_{v\in S}\mathcal{O}^*_v) < \infty$. But this is because $\prod_{v\in S}\mathcal{O}^*_v$ has a pro-p-group of finite index and $\mathcal{O}^*_E$ has a pro-ℓ-group of finite index. □

Def. (12.4.5.28) [Norm Groups]. For an extension of global fields L/F, let $\mathcal{N}_{L/F} = \mathrm{Nm}_{L/F} C_L$, called the **norm group** of L/F.

Prop. (12.4.5.29) [Connected Component of identity of C_F]. If F is a number field, let $I^0_{F,\infty} \cong \mathbb{R}^{r_1}_+ \times (\mathbb{C}^\times)^{r_2}$ be the connected component of identity of $I_{F,\infty}$, $D_F \subset C_F$ the closure of $I^0_{F,\infty} \subset C_F$, then

- D_F is the connected component of identity of C_F.
- $D_F = \cap_{n\in\mathbb{Z}_+} C^n_F$ is the group of divisible elements of C_F.
- C_F/D_F is a profinite group.(which will be isomorphic to Gal^{ab}_F, as we will see in(12.6.3.27)).

Proof: $I^0_{F,\infty}$ is divisible, thus so does its image in C_F. Then D_F is also divisible as $[n] : C_F \to C_F$ is continuous and proper(12.4.5.24).

Consider the map $\prod_{v\in\Sigma^{\mathrm{fin}}_F}\mathcal{O}^*_{F,v} \to C_F/D_F$, its cokernel is finite because $C_F/\prod_{v\in\Sigma^{\mathrm{fin}}_F} I_{F,\infty} \cong \mathrm{Cl}(\mathcal{O}_F)$ is finite and $I_{F,\infty}/I^0_{F,\infty}$ is finite. But $\prod_{v\in\Sigma^{\mathrm{fin}}_F}\mathcal{O}^*_{F,v}$ is a profinite group, thus C_F/D_F is also a profinite group.

To show $D_F = C_F^0$, firstly $C_F^0 \subset D_F$ by the fact C_F/D_F is connected thus totally disconnected, and the reverse is true because D_F is connected.

To show $D_F = \cap_{n\in\mathbb{Z}_+} C_F^n$, notice any divisible element is in D_F as a profinite group C_F/D_F doesn't contain non-trivial divisible elements. □

Thm. (12.4.5.30) [Class Numbers and Unit Theorems]. If $\Sigma_F^\infty \subset S \subset \Sigma_F$,

- The S-class group $\mathrm{Cl}(\mathcal{O}_{F,S}) \cong \mathbf{I}_F / F^\times \mathbf{I}_F^S$ is finite. In particular, $\mathbf{I}_\mathbb{Q} = \mathbb{Q}^\times \times \mathbb{R}_+^\times \times \prod_{p\in\mathbf{P}} \mathbb{Z}_p^\times$.
- The S-unit group(4.2.7.10) $\mathcal{O}_{F,S}^* \cong \mathbb{Z}^{\#S-1}$.
- For any $x \in F$, if $|x|_v = 1$ for any $v \in \Sigma_F$, then $x \in \mu(F)$.

Proof: 1: Let $(\mathbf{I}_F^S)^1 = \mathbf{I}_F^1 \cap I_F^S$. As $\mathcal{O}_{F,S}^* = F^\times \cap \mathbf{I}_F^S$, there is an exact sequence

$$1 \to (I_F^S)^1/F^S \cong F^\times (I_F^S)^1/F^\times \to I_F^1/F^\times \to (I_F^S)^1/F^\times (I_F^S)^1 \to 1.$$

The first term is an open subset, and $\mathbf{I}_F^1/F^\times$ is compact by(12.4.5.21), thus $(I_F^S)^1/F^\times(I_F^S)^1$ is finite and $(I_F^S)^1/F^S$ is compact. There is also an exact sequence

$$1 \to (I_F^S)^1/F^\times(I_F^S)^1 \to I_F^S/F^\times I_F^S \cong \mathrm{Cl}(\mathcal{O}_{F,S}) \to ||I_F||_F/||I_F^S||_F \to 1$$

and $||I_F||_F/||I_F^S||_F$ is always finite, so $\#\,\mathrm{Cl}(\mathcal{O}_{F,S}) < \infty$.

2, 3: Consider the regulator map

$$\mathrm{Reg}^S : \prod_{v\in S} F_v^\times \to \mathbb{R}^{\#S} : (x_v) \mapsto (-\log |x_v|_v).$$

Then this map restricted to F^S has image a discrete subset of the hyperplane $H = \{\sum x_i = 0\}$. In fact the image is a full lattice in H: let n_1 be the number of infinite places in S and n_2 the number of finite places in S, then $\mathrm{Reg}^S((\prod_{v\in S} F_v^\times)^1) \cong \mathbb{R}^{n_1-1} \times \mathbb{Z}^{n_2}$ if $n_1 > 0$ and $\mathbb{Z}^{\#S-1}$ if $n_1 = 0$. Then notice $(\prod_{v\in S} F_v)^1/F^S$ is finite, which is true as $(\mathbf{I}_F^S)^1/F^S$ is compact, so The image of F^S is a full lattice of H.

Also notice if x is in the kernel, then $|x|_v = 1$ for any $v \in \Sigma_F$, so $\{x^n | n \in \mathbb{Z}\}$ is a bounded subset in the lattice $\prod_{v\in S} F_v^\times$, but it is also contained in the discrete subset F^S, thus it a finite subset, so x is a root of unity. □

Cor. (12.4.5.31). If $S \subset \Sigma_F$ is sufficiently large, then $\mathbf{I}_F = \mathbf{I}_F^S \cdot F^\times$ hence $C_F = \mathbf{I}_F^S . F^\times/F^\times$.

Proof: The ideal class group is finite, hence we can find a finite set of representative for it. Only finite set of primes are involved in it, thus we let S contain all these primes and infinite primes, then for any $\mathfrak{a}$, $\prod_{\mathfrak{p}\nmid\infty} a_\mathfrak{p} = A_i \cdot (x)$, and $A_i \in I_K^S$, hence $\mathfrak{a} \in I_K^S \cdot K^*$. □

Cor. (12.4.5.32) [Dirichlet Characters and Hecke Characters for $\mathbb{Q}$]. Hecke characters of $\mathbb{Q}$ are exactly of the form $\chi(x) = \chi_1(x)|x|^\lambda$ for some $\lambda \in i\mathbb{R}$, where χ_1 a Hecke character of finite order corresponding to a primitive Dirichlet character χ_0 via(12.4.5.30).

To transit between these two, we need to use $\mathbb{Q}^\times$ to "clear the denominators". For example, for p prime to the conductor of χ_0, $\chi_1(p_v) = \chi_0(p)$.

6 Fourier Analysis on Adeles

Main references are [Poo15], [R-V99] and [Tat65].

Local Notations

Def. (12.4.6.1) [Normalized Valuations]. Let $\mathrm{d}\mu$ a Haar measure on K, let the valuation on K be given by $d\mu(\alpha\xi) = |\alpha| d\mu(\xi)$. Then for $k \in K$,

$$|k| = \begin{cases} |k| & K = \mathbb{R} \\ |k|^2 & K = \mathbb{C} \\ \frac{1}{||\mathfrak{p}||^{v(k)}} & K \in p\text{-}\texttt{LField} \end{cases}.$$

Proof: If $K = \mathbb{R}, \mathbb{C}$, this is routine calculation. If K is non-Archimedean , then by the translation invariance of μ, $\mu(\alpha\mathcal{O}) = \frac{\mu(\mathcal{O})}{N(\alpha)} = |\alpha|\mu(\mathcal{O})$. □

Def. (12.4.6.2) [Unramified Quasi-Character]. The multiplicative group $K^\times$ is also a locally compact group. For a quasi-character χ of $K^\times$, it is called **unramified** iff $\chi(\mathcal{O}_K^*) = 1$.

An unramified quasi-character on $K^\times$ is all of the form $|\cdot|^s$ for $s \in \mathbb{C}$.

Proof: An unramified quasi-character is equivalent to a continuous group homomorphism from $\mathrm{val}(K^\times) \to \mathbb{Z}$. But $\mathrm{val}(K^\times)$ must be isomorphic to $\mathbb{Z}$ or $\mathbb{R}$, so the assertion follows from(10.11.3.3). □

Lemma (12.4.6.3) [Canonical Character of Local Fields]. Consider k the closure of the base field of K, which is $\mathbb{R}, \mathbb{Q}_p$ or $\mathbb{F}_p((t))$ by Ostrowski(10.3.3.18). Now let

$$\lambda(x) = \begin{cases} x (\mathrm{mod}\ 1) & k = \mathbb{R} \\ \text{a rational number } \lambda(x) \text{ that } \lambda(x) - x \in \mathbb{Z}_p \text{ in } \mathbb{Q}/\mathbb{Z} & k = \mathbb{Q}_p \\ a_{-1}/p = \mathrm{res}(x)/p & k = \mathbb{F}_p((t)) \end{cases}$$

Then λ is a continuous additive function on k. Now let

$$\Lambda(x) = \begin{cases} \lambda(\mathrm{tr}_{K/k}(x)) & \text{number field case} \\ \lambda(\mathrm{tr}_{K_v/k_v}(x\omega_v)) & \text{function field case, where } \omega \text{ is a chosen global meromorphic form on } X. \end{cases}$$

And $X(x) = e^{2\pi i\Lambda(x)}$. Notice that this is just a rigorous definition of the character $e^{2\pi\,\mathrm{i}\,\mathrm{tr}_{K/k}(x)}$.

Cor. (12.4.6.4). $F(\eta) = e^{2\pi\,\mathrm{i}\,\Lambda(\eta\xi)}$ is trivial on $\mathcal{O}_K$ is equivalent to $\xi \in \mathfrak{d}^{-1}$, where $\mathfrak{d} = \mathfrak{d}_{K/k}$. In other words, adopting the isomorphism of(10.11.3.35), $\mathcal{O}^\perp = \mathfrak{d}^{-1}, (\mathfrak{d}^{-1})^\perp = \mathcal{O}$.

Proof: Because $\Lambda(\eta\mathcal{O}) = 0$ iff $\mathrm{tr}_{K/k}(\eta\mathcal{O}) \subset \mathcal{O}_k$, which is equivalent to $\eta \in \delta^{-1}$. □

Prop. (12.4.6.5) [Canonical Self-Adjoint Haar Measures]. We can calculate the self-adjoint Haar measure w.r.t. the canonical character on K^+(12.4.6.3) as follows:

$$d\mu = \begin{cases} \mathrm{dm} & K = \mathbb{R} \\ 2\,\mathrm{dm} & K = \mathbb{C} \\ \text{the measure that } \mu(\mathcal{O}) = \frac{1}{||\mathfrak{d}||^{1/2}} & \text{others} \end{cases}$$

Proof: We only calculate for the p-adic fields**?**.

Let $f=\mathbb{1}_{\mathcal{O}}$, then

$$\widehat{f}(\eta)=\int_{\mathcal{O}}e^{-2\pi i\Lambda(\xi\eta)}d\mu(\xi)=\begin{cases}\mu(\mathcal{O}) & \eta\in\mathfrak{d}^{-1}\\ 0 & \text{otherwise}\end{cases}=\mu(\mathcal{O})\mathbb{1}_{\mathfrak{d}^{-1}}(\eta)$$

By(12.4.6.4) and(10.11.1.14). So

$$I_{\mathcal{O}}(\xi)=\int_G\widehat{f}(F(\eta))(\xi,F(\eta))d\mu(\eta)=\int_{\delta^{-1}}\mu(\mathcal{O})e^{2\pi i\Lambda(\eta\xi)}d\mu(\eta)=\mu(\mathcal{O})\mu(\delta^{-1})I_{\mathcal{O}}(\eta).$$

So $\mu(\mathcal{O})\mu(\delta^{-1})=N(\delta)\mu(\mathcal{O})^2=1$, which shows the desired result. □

Remark (12.4.6.6). In fact, if we use other characters ψ, then $\mu(\mathcal{O}_K)=||\mathfrak{c}_\psi||^{1/2}$.

Cor. (12.4.6.7) [Quasi-Character of $K^\times$]. There is a continuous morphism from $K^\times\to\mathcal{O}_K^*$: $\widetilde{\alpha}=\alpha/\pi^{v(\alpha)}$ when α is non-Archimedean or $\widetilde{\alpha}=\alpha/|\alpha|$ if K is Archimedean. So any quasi-character c is of the form $c(\alpha)=c(\widetilde{\alpha})$ times an unramified quasi-character, which is of the form $|\cdot|^s$, where $\mathrm{Re}(s)$ is called the **exponent** of c. Now $\mathcal{O}_K^*$ is a compact group, so continuous quasi-characters $\widetilde{c}$ on it must be a character.

Def. (12.4.6.8) [Haar Measure on $K^\times$]. Notice that if $g(\alpha)\in C_c(K^\times)$, then $\frac{g(\alpha)}{|\alpha|}\in C_c(K^+\backslash 0)$, so if we define $\Phi(g)=\int_{K^+\backslash\{0\}}g(\xi)|\xi|^{-1}d\xi$, then

$$\Phi(ag)=\int_{K^+\backslash 0}g(a\xi)|a\xi|^{-1}|a|d\xi=\int_{K^+\backslash 0}g(a\xi)|a\xi|^{-1}da\xi=\Phi(g).$$

By(12.4.6.1). So By Riesz representation, there is a Haar measure $d_1^\times\alpha$ on $K^\times$ that $\int_{K^\times}g(\alpha)d_1^\times\alpha=\int_{K^+\backslash 0}g(\xi)|\xi|^{-1}d\xi$, for any $g\in C_c(K^\times)$.

But when K is non-Archimedean, renormalize $d^\times\alpha=(1-\frac{1}{N\mathfrak{p}})^{-1}d_1^\times\alpha$.

Remark (12.4.6.9). The reason behind this normalization is when $d\mu$ is the canonical measure(12.4.6.5), we want to make $\mathrm{d}^\times\alpha(\mathcal{O}^*)=||\mathfrak{d}||^{-1/2}$:

$$\int_{\mathcal{O}\backslash 0}d\xi=\sum_{k=0}^{\infty}\int_{\pi^k\mathcal{O}^*}d\xi=(1+\frac{1}{N\mathfrak{p}}+\frac{1}{N\mathfrak{p}^2}+\ldots)\int_{\mathcal{O}^*}d\xi=\frac{1}{1-\frac{1}{N\mathfrak{p}}}\int_{\mathcal{O}^*}d\xi$$

so

$$\int_{\mathcal{O}^*}d_1^\times\alpha=\int_{\mathcal{O}^*}|\xi|^{-1}d\xi=\frac{||\mathfrak{p}||-1}{||\mathfrak{p}||}\int_{\mathcal{O}\backslash 0}d\xi=\frac{||\mathfrak{p}||-1}{||\mathfrak{p}||}||\mathfrak{d}||^{-1/2}\text{(12.4.6.5)}$$

Def. (12.4.6.10)[Schwartz-Bruhat Function]. Define the set $\mathcal{S}(K)$ of **Schwartz-Bruhat function** on K as Schwartz functions on K if $F=\mathbb{R},\mathbb{C}$(10.9.2.1) and locally constant functions with compact support if $K\in p$-`LField`.

Prop. (12.4.6.11) [Local Schwarz Functions]. The space $\mathcal{S}(K)$ of Schwartz functions satisfy the following properties: If $f\in\mathcal{S}(K)$,

- $f,f^\vee\in L^1(K^+)$.
- $f(\alpha)|\alpha|^\sigma,f^\vee(\alpha)|\alpha|^\sigma\in L^1(K^\times)$ for $\sigma>0$.
- $f^\vee\in\mathcal{S}(K)$ too.

Proof: 3: p-adic case: Let $\mathfrak{p}^n$ be the conductor of ψ, then the Fourier transform of $\chi_{\mathfrak{p}^{-k}}$ is $V(\mathfrak{p}^{-k})\chi_{\mathfrak{p}^{n+k}}$. Then for k large, $\chi_{\mathfrak{p}^{-k}}v=V(\mathfrak{p}^{-k})V(\mathfrak{p}^{n+k})v$, thus $v\in C_c^\infty(F)$.

Archimedean case:(10.12.2.5). □

Global notations

Notation (12.4.6.12).

- There are natural Haar measures $\mathrm{d}\mu_K, \mathrm{d}^\times\mu_K$ on $\mathbf{A}_F$ and $\mathbf{I}_F$ defined by(12.4.5.5) and(12.4.6.5)(12.4.6.8). They satisfy $\mathrm{d}^\times\mu_K = \frac{1}{|-|_K}\mathrm{d}\mu_K$.
- Let $\mathfrak{d} = \mathfrak{d}_{F/\mathbb{Q}}$ when $F \in \texttt{NField}$, or $\mathfrak{d} = \{x|\operatorname{tr}(\operatorname{res}(x\mathcal{O})) = 0\}^{-1}$ when $F \in \texttt{FField}$.
- Fix $\psi = \prod_v \psi_v$ an additive character of $\mathbf{A}_F/F$, then

Def. (12.4.6.13) [Global Fourier Transform]. (10.11.3.35) shows ψ induces a canonical isomorphism

$$\mathbf{A}_F \cong \mathbf{A}_F^\vee : \eta \mapsto (\xi \to \psi(\eta\xi)),$$

and we choose the corresponding self-dual Haar measure $\mathrm{d}\mu$, then the Fourier transform and inversion formula on $\mathbf{A}_F$ is then written as:

$$f^\vee(y) = \int_{\mathbf{A}_F} f(x)\overline{\psi(xy)}dx, \quad f(x) = \int_{\mathbf{A}_F} f^\vee(y)\psi(xy)dy.$$

In fact $\mathrm{d}x = \prod x_\mathfrak{p}$ is the restricted product measure on $\mathbf{A}_F$(12.4.5.5), where $\mathrm{d}x_\mathfrak{p}$ is the self-dual measure w.r.t ψ_p in(12.4.6.5), then $\mathrm{d}x$ is the self-dual Haar measure w.r.t the global canonical character ψ by(12.4.5.8), called the **Tamagawa measure** on $\mathbf{A}_F$.

Def. (12.4.6.14) [Global Schwartz-Bruhat Functions]. For a global field F, the set $\mathcal{S}(F)$ of global **Schwartz-Bruhat functions** is defined to be

$$\mathcal{S}(F) = \bigotimes_{v\in\Sigma_F}{}' \mathcal{S}(F_v)(2.4.4.13).$$

Prop. (12.4.6.15) [Schwartz-Bruhat Functions]. A Schwartz-Bruhat function $f \in \mathcal{S}(\mathbf{A}_F)$(12.4.6.14) satisfies:

- $f(x) \in L^1(A), f^\vee(x) \in L^1(\mathbf{A}_F)$ and $f, f^\vee$ is continuous.
- $\sum_{\xi\in K} f(\mathfrak{a}(x+\xi))$ and $\sum_{\xi\in K} \widehat{f}(\mathfrak{a}(x+\xi))$ converges uniformly absolutely on compact sets of A.
- $f(\mathfrak{a})|\mathfrak{a}|^\sigma, \widehat{f}(\mathfrak{a})|\mathfrak{a}|^\sigma \in L^1(I_F)$ for $\sigma > 1$.

Proof: $1, 2$ is the same as in(12.4.6.23), for 3: $\int_{\mathbf{I}_F} |f||\mathfrak{a}|^\sigma d\mathfrak{a} = \prod_\mathfrak{p} \int_{F_\mathfrak{p}^\times} |f_\mathfrak{p}||\mathfrak{a}|^\sigma d\mathfrak{a}_\mathfrak{p}$, and for a.e. $\mathfrak{p}$,

$$\int_{F_\mathfrak{p}^\times} |f_\mathfrak{p}||\mathfrak{a}|^\sigma d\mathfrak{a}_\mathfrak{p} = \int_{\mathcal{O}_\mathfrak{p}^\times} |\mathfrak{a}_\mathfrak{p}|_\mathfrak{p}^\sigma d\mathfrak{a}_\mathfrak{p} = \frac{1}{1-\frac{1}{||\mathfrak{p}||^\sigma}} \int_{\mathcal{O}_\mathfrak{p}^*} d\mathfrak{a}_\mathfrak{p} = \frac{1}{1-\frac{1}{||\mathfrak{p}||^\sigma}}.$$

Thus the global integral converges by comparison with the Dedekind Zeta function(19.2.2.1). □

Def. (12.4.6.16) [Global Canonical Character]. Define the **global canonical character**

$$X : \mathbf{A}_F \to \mathbb{C}^\times : x \mapsto e^{2\pi\,\mathrm{i}\,\Lambda(x)}, \quad \Lambda(x) = \sum_{\mathfrak{p}\in\Sigma_F} \Lambda_\mathfrak{p}(x_\mathfrak{p})(12.4.6.3).$$

Notice this is definable because $x_\mathfrak{p} \in \mathcal{O}_\mathfrak{p}$ a.e. $\mathfrak{p}$, thus $\Lambda_\mathfrak{p}(x_\mathfrak{p}) = 1$ a.e..

Then $X(F) = 1$.

Proof: In the number field case,

$$\Lambda(\xi) = \sum_p \sum_{\mathfrak{p}|p} \lambda_p(\mathrm{tr}_{\mathfrak{p}/p}(\xi)) = \sum_p \lambda_p(\mathrm{tr}_{K/\mathbb{Q}}(\xi))$$

so to show λ is an integer, it suffices to show $\Lambda(a)$ is a q-adic integer for any q and any $a \in \mathbb{Q}$, but for this, notice

$$\sum \lambda_{\mathfrak{p}}(x) = \sum_{p \neq q,\infty} \lambda_p(x) + \lambda_q(x) - x$$

is a q-adic integer, by definition(12.4.6.3).

In the function field case, this follows from the fact that the sum of residues of a meromorphic 1-form is 0**?**. □

Prop. (12.4.6.17). $F^\perp = F$, i.e. $X(xy) = 0, \forall y \in F \iff x \in K$.

Proof: Because $K^\perp \cong \widehat{A/K}$ and A/K is compact(12.4.5.12), $K^\perp$ is discrete(10.11.3.7) and contains K. So $K^\perp/K$ is discrete hence finite in A/K. But $K^\perp$ is clearly a vector space over K, thus $K^\perp = K$ must be true, because $|K| = \infty$. □

Cor. (12.4.6.18). By(10.11.3.35) and(12.4.6.17), any non-trivial character on A_F/F is of the form $\mathfrak{a} \mapsto X(k\mathfrak{a})$ for some $k \in K$.

In particular, for any such character ψ, ψ_v is non-trivial.

Def. (12.4.6.19) [Unramified Places]. Let χ be a Hecke character of F, then $v \in \Sigma_F$ is called **unramified** if $v \in \Sigma_F^{\mathrm{fin}}$, $\mathfrak{d}_v = 1$, $\mathfrak{c}(\psi_v) = \mathcal{O}_v$, χ_v is unramified(12.4.6.2). Notice a.e. place v is unramified.

Proof: To show that for any unramified character ψ, the conductor of φ_v is $\mathcal{O}_v$, consider the canonical character X defined(12.4.6.16), it can be verified the conductor of X_v is $\mathcal{O}_v$ for a.e. v, and ψ must be of the form $\psi(x) = X(ax)$ for some $a \in K$ by(12.4.6.13) and(12.4.6.17), thus this is also true for ψ. □

Prop. (12.4.6.20).

$$V(\mathbf{I}_F^1/F^\times) = \frac{2^{r_1}(2\pi)^{r_2}}{w_F\sqrt{|d_F|}} h_F \,\mathrm{Reg}(F)$$

where $w_F = \#F_{\mathrm{tor}}^\times$, h_F is the class number, and $\mathrm{Reg}(F)$ is the regulator(12.4.2.26).

Proof: Cf.[Tate Thesis, P337] or[GTM186, P281].**?** □

Lemma (12.4.6.21) [Poisson Formula]. If $F \in L^1(\mathbf{A}_F)$ and $\sum_{\xi\in F} |f^\vee(\xi)| < \infty$, then in the self-dual Haar measure

$$\sum_{\xi\in F} f^\vee(\xi) = \sum_{\xi\in F} f(\xi).$$

and $V(\mathbf{A}_F/F) = 1$.

Proof: By(12.4.6.17), this is a special case of(10.11.3.31). In fact, we know it is true for a constant $V(\mathbf{A}_F/F)$, but it is symmetric, so $V(\mathbf{A}_F/F)^2 = 1$. □

Prop. (12.4.6.22) [Riemann-Roch]. If $f(\mathfrak{a}x) \in L^1(\mathbf{A}_F)$ and $\sum_{\xi\in F} |\widehat{f}(\mathfrak{a}\xi)| < \infty$ for any idele $\mathfrak{a} \in I_F$, then for any $\mathfrak{a} \in \mathbf{I}_F$,

$$\frac{1}{|\mathfrak{a}|}\sum_{\xi\in F}\widehat{f}(\frac{\xi}{\mathfrak{a}}) = \sum_{\xi\in F} f(\mathfrak{a}\xi).$$

Proof: Consider $g(x) = f(\mathfrak{a}x)$, then

$$g^\vee(x) = \int_{\mathbf{A}_F} f(\mathfrak{a}\eta)e^{-2\pi i\lambda(x\eta)}d\eta = \frac{1}{|\mathfrak{a}|}\int_{\mathbf{A}_F} f(\eta)e^{-2\pi i\Lambda(x\eta/\mathfrak{a})}d\eta = \frac{1}{|\mathfrak{a}|}f^\vee(x/\mathfrak{a}).$$

Then apply Poisson formula(12.4.6.21) to g. □

Prop. (12.4.6.23). Schwartz-Bruhat functions(12.4.6.14) satisfy the condition in(12.4.6.22).

Proof: $\int_A |f| = \prod_v \int_{F_v}\int |f_v| dx_v < \infty$, noticing(12.4.6.5) and $N(\mathfrak{d}_v) = 1$ for a.e. v. And for any Schwartz function f and any x, the set of k that $f_v(x_v + k_v) \neq 0$ is v-bounded for v non-Archimedean and $|k|_v \leq 1$ a.e., so in the function case, these k are finite because F is discrete in $\mathbf{A}_F$.

And in the number field case, these k is contained in some fractional ideal I, but I is then a lattice in F_∞ by Minkowski theory, so

$$\sum_{\xi\in K}|f(x+\xi)| \leq C\sum_{x\in K}|\prod_{\mathfrak{p}\in S_\infty}|f_{\mathfrak{p}}(x+\xi)|$$

but $f_{\mathfrak{p}}$ is an Archimedean Schwartz function, thus this is absolutely convergent.

Now we showed that $\int_{\xi\in F} f^\vee(\xi) < \infty$, because $f^\vee \in \mathcal{S}(\mathbf{A}_F)$, by(12.4.6.11). □

Prop. (12.4.6.24) [True Riemann-Roch For Function Fields]. Cf.[Fourier Analysis on Number Fields, P267].?

12.5 Quadratic Forms over Fields

Basic references are [Lam05], [Quadratic Forms Clark] and [Algebraic and Geometric Theory of Quadratic Forms].

All fields K in this section has char$\neq 2$.

1 Quadratic Forms

This subsection should be regarded as a continuation of Bilinear & Hermitian Forms. In fact, must materials in this subsection are trivial facts.

Def. (12.5.1.1). Given a field K of char$\neq 2$, a **quadratic form** over K is a bilinear form on K^n for some K. It is represented by a symmetric matrix.

The reason that char$K \neq 2$ is because only in this case, a quadratic form q is equivalent to a symmetric bilinear form B, and I will use this equivalence freely.

The determinant det is a function from the set of quadratic forms to $K^\times/(K^\times)^2$ that is invariant under congruence.

Def. (12.5.1.2) [Quadratically Closed]. A field is called **quadratically closed** iff $(K^\times)^2 = K^\times$, or equivalently K has no quadratic field extensions.

Def. (12.5.1.3). The category of **quadratic spaces** is a category with objects as finite dimensional spaces with a quadratic form, and its morphisms are isometric embeddings.

Def. (12.5.1.4) [Universal Quadratic Form]. For a quadratic form A, let $D_F(A)$ be the set of elements representable by A. A **universal quadratic form** is a quadratic form that represents every element of K^*.

Prop. (12.5.1.5). If every binary quadratic form over K is universal, then any two non-degenerate quadratic forms over K are isomorphic iff they have the same rank and determinant.

Proof: This is because $\langle a, b\rangle \cong \langle 1, ab\rangle$ and then use induction. □

<u>Non-Degeneracy</u>

Def. (12.5.1.6) [Non-degeneracy]. A quadratic space is called **non-degenerate** if $v \mapsto B(v,\cdot)$ is an isomorphism from V to V^*. Notice if $\dim V = \infty$, this cannot happen, because $\dim V^* > \dim V$(2.3.3.9). And in case $\dim V < \infty$, $\dim V = \dim V^*$, so it suffices to show $v \mapsto B(v,\cdot)$ is injective, i.e. if $v \neq 0$, then there is a w that $B(v,w) \neq 0$.

Prop. (12.5.1.7)[Radical Splitting]. The **radical** of a quadratic space is defined to be $\mathrm{rad}(V) = V^\perp$. Then for any quadratic form V, there is an orthogonal decomposition $V = \mathrm{rad}(Y) \oplus W$, where W is a non-degenerate form.

Proof: In fact, by the definition, any complement space of $\mathrm{rad}(V)$ in V can be chosen as the orthogonal complement W. □

Prop. (12.5.1.8). If W is a non-degenerate sub-quadratic space of V, then $W \oplus W^\perp = V$.

Proof: Since W is non-degenerate, $W \cap W^\perp = 0$. and for any $v \in V$, $B(v,\cdot) \in W^*$, so by degeneracy, there is a $w \in W$ that $B(v,\cdot) = B(w,\cdot)$, then $z = v - w \in W^\perp$ and $v = w + z$. □

Prop. (12.5.1.9) [Orthogonal Complement and Non-Degeneracy]. If V is a non-degenerate quadratic space, then for any non-degenerate subspace W, $\dim W + \dim W^\perp = \dim V$, and $(W^\perp)^\perp = W$.

Proof: The first is immediate from the fact $\dim\ker + \dim\operatorname{Coker} = \dim V$. The second is by dimensional reason. □

Cor. (12.5.1.10). A subspace W of a non-degenerate quadratic space V is a non-degenerate quadratic space iff $W \cap W^\perp = 0$.

Remark (12.5.1.11). We basically only care about non-degenerate forms, so from now on, we only care about non-degenerate forms.

Diagonalizability

Prop. (12.5.1.12) [Quadratic Form Representable]. Any quadratic forms over K of char$\neq 2$ is diagonalizable, and if $\alpha \in K^*$ is represented by K, then it is diagonalizable to a matrix with first entry α.

We will use the notation $\langle \alpha_1, \ldots, \alpha_n \rangle$ for the diagonal quadratic form $\sum \alpha_i x_i^2$.

Proof: Use(2.3.8.5), since in this case, a quadratic form is equivalent to a symmetric form. And if $\alpha = B(v, v)$, then we can choose v in the first place in the proof of(2.3.8.5). □

Cor. (12.5.1.13). Over a quadratically closed field K of char$\neq$ 2, any non-degenerate quadratic form is congruent to $x_1^2 + \ldots + x_n^2$.

Proof: Because in this case, we can make $\sum a_i x_i^2$ into $\sum(\sqrt{a_i} x_i)^2$. □

Isotropic and Hyperbolic Spaces

Def. (12.5.1.14) [Isotropic]. Given a non-degenerate quadratic space V, a vector v is called **isotropic** if $B(v, v) = 0$. V is itself called **isotropic** if it is non-degenerate and there exists an isotropic vector, otherwise it is called **anisotropic**.

Def. (12.5.1.15) [Hyperbolic]. The **hyperbolic plane** $\mathbb{H}$ is the 2-dimensional space with quadratic form $H(x, y) = xy$, which is congruent to $\frac{1}{2}(x^2 - y^2)$.

A quadratic space is called **hyperbolic** if it is isomorphic to a direct sum of hyperbolic planes.

Lemma (12.5.1.16). If V is a non-degenerate isotropic space, then there is an isometric imbedding of the hyperbolic plane into V.

Proof: There is a $u \in V$ that $B(u, w) = 0$. By non-degeneracy, there is a w that $B(u, w) \neq 0$. We may assume $B(u, w) = 1$. Now I claim there is an α that $q(\alpha u + w) = 0$: in fact, $q(\alpha u + w) = 2\alpha B(u, w) + q(w)$, so take $\alpha = -q(w)/2$. Let $v = \alpha u + w$, then $q(u) = q(v) = 0$, and $B(u, v) = 1$, so it is isomorphic to $\mathbb{H}$. □

Prop. (12.5.1.17) [Isotropic Complement]. If V is a non-degenerate quadratic space, and $W \subset V$ is an isotropic space with basis $u_1, \ldots, u_m$, then there is another isotropic space W' with basis $v_1, \ldots, v_m$ that $B(u_i, v_j) = \delta_{ij}$.

Proof: Use induction on m. The $m = 1$ case is lemma(12.5.1.16) above. If this is true for $n < m$, let $W = \{u_2, \ldots, u_m\}$, then if $W^\perp \subset \{u_1\}^\perp$, then $u_1 \in W$ by(12.5.1.9), contradiction, so there is a $v \in W^\perp$ that $B(u_1, v) \neq 0$, so by the same proof as(12.5.1.16), there is a $\alpha u_1 + v$ that is isotropic, and a $\mathbb{H} \subset W^\perp$, so by(12.5.1.9), $W \subset \mathbb{H}^\perp$, so by induction, we can find in $\mathbb{H}^\perp$ elements $v_2, \ldots, v_m$ that satisfies the requirement. □

Cor. (12.5.1.18). $\langle a, -a\rangle \cong \mathbb{H}$, because it is isotropic, and it has dimension 2.

Cor. (12.5.1.19) [Isotropic Form is Universal]. A non-degenerate isotropic space is universal, because hyperbolic plane does.

Cor. (12.5.1.20). A maximal totally isotropic space in a non-degenerate quadratic space V has dimension at most $\frac{1}{2}\dim V$, and equality holds if V is hyperbolic.

Prop. (12.5.1.21) [First Representation Theorem]. If q is a non-degenerate quadratic form, then q represents $\alpha \in K^*$ iff $q \oplus \langle -\alpha\rangle$ is isotropic.

Proof: If q represent α, then by(12.5.1.12) shows that q is equivalent to $\langle \alpha, \alpha_1, \ldots, \alpha_n\rangle$, so $q \oplus \langle -\alpha\rangle$ contains a $\langle \alpha, -\alpha\rangle$ which is isomorphic to $\mathbb{H}$ by(12.5.1.16).

Conversely, if $q \oplus \langle -\alpha\rangle$ is isotropic, then there is a $-\alpha x_0^2 + \sum \alpha_i x_i^2 = 0$. If $x_0 \neq 0$, then q represent α, and if $x_0 = 0$, then q is isotropic, thus represent any element(12.5.1.19). □

Cor. (12.5.1.22). The following are equivalent:

- Any n-quadratic form over K is universal.
- Any $(n + 1)$-quadratic form over K is isotropic.

Cor. (12.5.1.23) [Transform of Binary Forms]. For any $a, b \in F^*$ that $a + b \in F^*$, $\langle a, b\rangle \cong \langle a + b, (a + b)ab\rangle$.

Prop. (12.5.1.24) [Isotropy Criterion]. For two non-degenerate forms f, g over K, $h = \langle f, -g\rangle$ is isotropic iff there is an $\alpha \in K^*$ that is represented by both f and g.

Proof: Easy, notice to use isotropic form is universal(12.5.1.19). □

2 Witt Theory

Prop. (12.5.2.1) [Witt Cancellation Theorem]. If U_1, U_2, V_1, V_2 are quadratic spaces and $V_1 \cong V_2$, $V_1 \oplus U_1 \cong V_2 \cong U_2$, then $U_1 \cong U_2$.

Proof: We may identify $V_1 = V_2 = V$, and $W = U_1 \oplus V = U_2 \oplus V$.

First if V is totally isotropic and U_1 is non-degenerate, then there is a matrix $M = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$ that

$$M^t \begin{bmatrix} 0 & 0 \\ 0 & B_2 \end{bmatrix} M = \begin{bmatrix} 0 & 0 \\ 0 & B_1 \end{bmatrix}$$

So $B_1 = D^t B_2 D$. As B_1 is non-singular, so is D, thus $U_1 \cong U_2$.

Now if V is isotropic but U_1, U_2 are not non-degenerate, then we may assume in their diagonalization, U_1 has less 0s, it has r 0s, then we can extract from both U_i a zero part, thus reducing to the above case.

Now if $\dim V = 1$, $V = \langle a\rangle$, if $a = 0$, then we are done by the above argument, and if $a = 0$, then find $q(x) = a$, then by(12.5.2.13), we can find a $\tau \in O(W)$ that $\tau(V_1) = V_2$, so now U_1, U_2 as the orthogonal complement of V_1, V_2, they are isometric under the map τ.

So now in general, we can cancel V out by moving its diagonal part once a time. □

Cor. (12.5.2.2). If X is a quadratic space and V_1, V_2 are non-degenerate subspaces of X, then any isometry $V_1 \cong V_2$ extends to an isometry of X.

Proof: $V_i \oplus V_i^\perp = X$ by(12.5.1.8). □

Cor. (12.5.2.3) [Witt's Extension Theorem]. If X is a non-degenerate quadratic space and $f : W_1 \to W_2$ is an isometry of two subspaces of X, then f extends to an isometry of X.

Notice this also holds for symplectic spaces X, by the same method of proof.

Proof: If W_1 is non-degenerate, then so does W_2, and we can use(12.5.2.2). By(12.5.1.7), we can write $W_i = U_i \oplus V_i$ where U_i is totally isotropic and V_i is non-degenerate. Now X, V_i are non-degenerate, $V_i^\perp$ is non-degenerate also, so there is an isotropic complement $U_i' \subset V_i^\perp$(12.5.1.17). Let $T_i = \langle U_i, U_i'\rangle V_i$, then T_i is non-degenerate and $W \subset T$. As U_i is the radical of W_i, $U_1 \cong U_2$, and then $\langle U_1, U_1'\rangle \cong \langle U_2, U_2'\rangle$. By Witt cancellation, $W_1 \cong W_2$. So we reduced to the non-degenerate case. □

Cor. (12.5.2.4). If V is a non-degenerate quadratic space, then the group of isometries of X acts transitively on the set of all totally isotropic subspaces of a fixed dimension d.

Prop. (12.5.2.5)[Witt's Decomposition Theorem]. For any quadratic space V, there is an orthogonal decomposition

$$V \cong \mathrm{rad}(V) \oplus \bigoplus_1^k \mathbb{H} \oplus V'$$

where V' is anisotropic(12.5.1.14). Moreover the number $k = I(V)$ which is called the **Witt index** of V and the isometry class of $V' = w(V)$ which is called the **non-isotropic kernel** is independent of the decomposition.

Proof: The existence of the decomposition follows from(12.5.1.7) and an easy induction using(12.5.1.16). The uniqueness is an easy corollary of(12.5.1.16) and Witt's cancellation theorem. □

Cor. (12.5.2.6). The Witt index equals the maximal dimension of a maximal totally isotropic subspace of W, by(12.5.1.17).

Remark (12.5.2.7). This is a good reason that <u>we will only consider non-degenerate quadratic forms from now on.</u>

Cor. (12.5.2.8) [Sylvester's Law of Nullity]. Let $q_{r,s} = [r]\langle 1\rangle \oplus [s]\langle 1\rangle$, then any non-degenerate quadratic form q over $\mathbb{R}$ is congruent to exactly one of $q_{r,s}$, and $r - s$ is called the **signature** of q.

Def. (12.5.2.9). Two quadratic forms $q_1 = \langle a_1, \ldots, a_n\rangle$ and $q_2 = \langle b_1, \ldots, b_n\rangle$ are called **simply equivalent** iff there are two indices that $\langle a_i, a_j\rangle \cong \langle b_i, b_j\rangle$. Two quadratic forms are called **chain equivalent** iff there is a chain of simply equivalence between them.

Prop. (12.5.2.10) [Witt's Chain Equivalence Theorem]. Two diagonal quadratic forms over K are equivalent iff they are chain equivalent.

Proof: Chain equivalent is clearly equivalent, Conversely, by Witt's decomposition theorem, it is easy to reduce to the non-degenerate case.

Now if $q = \langle\alpha_1, \ldots, \alpha_n\rangle \cong q' = \langle\beta_1, \ldots, \beta_n\rangle$, any form $q = \langle\gamma_1, \ldots, \gamma_n\rangle$ that is chain equivalent to q is equivalent to q', so β_1 is represented by it, choose a form that there is a minimal l that β_1 is represented by $\langle\gamma_1, \ldots, \gamma_l\rangle$, we prove that $l = 1$:

if the minimal l is not 1, then $d = \gamma_1 a_1^2 + \gamma_2 a_2^2 \neq 0$(otherwise l can be smaller), so $\langle\gamma_1, \gamma_2\rangle \cong \langle d, \gamma_1\gamma_2 d\rangle$ by(12.5.1.12) and invariance of det. so $q \cong \langle d, \gamma_3, \ldots, \gamma_n, d\gamma_1\gamma_2\rangle$(notice permutation is chain equivalence), and this is smaller, contradiction.

Now $l = 1$, so we may assume $\alpha_1 = \beta_1$, and then Witt's cancellation(12.5.2.1) shows that $\langle\alpha_2, \ldots, \alpha_n\rangle \cong \langle\beta_2, \ldots, \beta_n\rangle$, so we win by induction. □

Orthogonal Group

Prop. (12.5.2.11). The **orthogonal group** of a quadratic form q is the set of matrixes M that $g(Mx) = q(x)$. And it is clear $\det M = \pm 1$, so we can also define $O^+(V)$ and $O^-(V)$.

Def. (12.5.2.12). A **hyperplane reflection** for a non-isotropic vector v is defines by $x \mapsto x - \frac{2B(x,v)}{q(v)} v$, it is an element in $O(V)$.

Prop. (12.5.2.13). If x, y are two non-isotropic vectors that $q(x) = q(y)$, then there is a $\tau \in O(V)$ that $\tau(x) = y$.

Proof: First notice $q(x + y) + q(x - y) = 2q(x) + 2q(y) = 4q(x) \neq 0$, so one of $x + y, x - y$ is non-isotropic. And it can be easily calculated that $\tau_{x-y}(x) = y$ or $-\tau_{x+y}(x) = y$. □

Prop. (12.5.2.14) [Cartan-Dieudonné]. Let V be a non-degenerate quadratic form of dimension n, then every element of the orthogonal group $O(V)$ can be represented as a product of n reflections.

Proof: Cf.[Quadratic Forms Clark P22]. □

3 Witt Ring

References are [Quadratic Forms 2, Clark].

Def. (12.5.3.1)[Witt Ring]. The **Witt ring** $W(K)$ of K is a free commutative ring over $\mathbb{Z}$ generated by equivalent classes of anisotropic(12.5.1.14) quadratic forms over K, modulo the the relations $[q_1] + [q_2] - [q_1 \oplus q_2]$ and $[q_1] \cdot [q_2] - [q_1 \otimes q_2]$.

There is another ring, the **Grothendieck-Witt ring** $\widehat{W}(K)$ which is defined as the ring generated by all non-degenerate quadratic forms over K.

Cor. (12.5.3.2)[Rank Functor]. There are rank functors from $\widehat{W}(K) \to \mathbb{Z}$, which is a ring homomorphism. In particular, two elements of the same rank are equal in $\widehat{W}(K)$ iff they are equal in $W(F)$, by Witt's cancelation theorem(12.5.2.1).

Prop. (12.5.3.3). The rank functor is an isomorphism $\widehat{W}(K) \to \mathbb{Z}$ iff K is quadratically closed. In this case, $W(K) \cong \mathbb{Z}/2\mathbb{Z}$.

Proof: This is equivalent to $\langle a\rangle \cong \langle 1\rangle$ for any $a \in K^*$, which means K is quadratically closed. □

Prop. (12.5.3.4). The subgroup $[\mathbb{H}]$ generated by the hyperbolic plane is an ideal of $\widehat{W}(K)$. And $\widehat{W}(K)/\mathbb{Z}[\mathbb{H}] \cong W(K)$.

Proof: $\mathbb{Z}[\mathbb{H}]$ is an ideal because $[\mathbb{H}]\cdot[\langle a_1,\ldots,a_n\rangle]\cong\sum\langle a_i,-a_i\rangle$ which is a multiple of $[\mathbb{H}]$, by(12.5.1.18). The last assertion follows from Witt's decomposition(12.5.2.5). □

Cor. (12.5.3.5). $[\langle a_1,\ldots,a_n\rangle]+[\langle -a_1,\ldots,-a_n\rangle]=0\in W(F)$, by(12.5.1.18).

Prop. (12.5.3.6) [Presentation of the Witt Ring]. $\widehat{W}(F)$ is isomorphic to the quotient of the free commutative ring generated by $\{[a]|a\in F^*\}$ module the following relations:

- $[1]-1$.
- $[ab]-[a]-[b]$.
- $[a]+[b]-[a+b](1+[ab])$, $a,b,a+b\in F^*$.

Proof: Cf.[Lam, P39]. □

4 Quaternion Algebras

References are [Quaternion Algebras].

Notation (12.5.4.1).

- In this subsection, let $k,F\in\texttt{Field}$.

Def. (12.5.4.2) [Quaternion Algebras]. Let $a,b\in F^\times$, define a **Quaternion algebra** $Q(a,b)$ as

$$Q_F(a,b)=Q\langle X,Y\rangle/(X^2-a,Y^2-b,XY+YX).$$

Denote $\overline{X}=i,\overline{Y}=j,\overline{XY}=k$.

Prop. (12.5.4.3). Let $a,b\in F^\times$, then

- $\dim_F Q_F(a,b)=4$, thus any element of $Q_F(a,b)$ is of the form $x+yi+zj+wk$.
- $Q_F(ax^2,by^2)\cong Q_F(a,b)$ for $x,y\in F^*$.
- $Q_F(-1,1)\cong M(2,F)$.
- $Q_F(a,b)$ is a simple algebra with center F.

Proof: 1: $Q_F(a,b)\otimes_F\overline{F}=Q_{\overline{F}}(a,b)\cong Q_{\overline{F}}(-1,1)\cong M_2(\overline{F})$ has dimension 4 over $\overline{F}$, by item2 and3.

2: trivial.

3: The map is given by $\varphi:Q_F(-1,1)\to M(2,F):i\mapsto\begin{bmatrix} & 1\\ -1 & \end{bmatrix},j\mapsto\begin{bmatrix} & 1\\ 1 & \end{bmatrix}$. The verification is straightforward.

4: Consider $Q_F(a,b)\otimes_F\overline{F}\cong\mathrm{Mat}(2,\overline{F})$ is simple with center $\overline{F}$, the center of $Q_F(a,b)$ has to be F, and also simple. □

Def. (12.5.4.4) [Pure Tensors]. A quaternion element of the form $yi+zj+wk$ is called a **pure tensor**. The space of pure tensor is denoted by A_0.

Let $v\neq 0\in Q_F(a,b)$, then $v\in A_0$ iff $v\notin F$ but $v^2\in F$.

Proof: By direct calculation,

$$(x+yi+zj+wk)^2=(x^2+ay^2+bz^2-abw)+2x(yi+zj+wk).$$

□

Def. (12.5.4.5) [Bar Involution]. There is an anti-involution of $Q_F(a,b) = Q\langle X,Y\rangle/(X^2-a, Y^2-b, XY+YX)$ given by $X\mapsto -X, Y\mapsto -Y$(thus $XY\mapsto(-Y)(-X)=YX$), called the **bar involution**.

Thus if we define the **norm** and **trace** $N: x\mapsto x\overline{x}, \mathrm{tr}: x\mapsto x+\overline{x}$, then they have images in F. If $\alpha = x+yi+zj+wk$, then $\mathrm{tr}(\alpha)=2x, N(\alpha)=x^2-ay^2-bz^2+abw^2$.

Cor. (12.5.4.6). Notice the Bar involution can be defined intrinsically, by defining a pure vector to be a vector x s.t. $x^2\in\mathbb{F}$ but $x\notin F$.

Cor. (12.5.4.7). For $x\in Q_F(a,b)$, if we let $T(x)$ be the left(or right) multiplication by x on $Q_F(a,b)$, then the determinant of $T(x)$ equals $N(x)^2$.

Proof: After base change, all the values won't change, thus it suffices to prove for $M(2,F)$, in which case, it can be verified by(12.5.4.3) that $\det(A)=N(A)$, and the $T(A)$ has determinant $\det(A)^2$. □

Prop. (12.5.4.8) [Norm Form]. Define a symmetric bilinear form on $Q_F(a,b)$: $B(x,y)=\mathrm{tr}(x\overline{y})/2$. Its norm form is just $N(x)$.

Thus this symmetric space has $\{1,i,j,k\}$ as an orthonormal basis. It is non-degenerate and isomorphic to

$$\langle 1,-a,-b,ab\rangle\cong\langle 1,-a\rangle\otimes\langle 1,-b\rangle.$$

Prop. (12.5.4.9). Let A,A' be two quaternion algebras over F, then the following are equivalent:

- A,A' are isomorphic as quaternion algebras.
- A,A' are isomorphic as quadratic spaces.
- A_0,A_0'(12.5.4.4) are isomorphic as quadratic spaces.

Proof: Cf.[Lam, P57]. □

Cor. (12.5.4.10). $Q_F(a,-1)\cong Q_F(a,a)$.

Proof: These algebras have norm forms $\langle 1,-a,-1,-a\rangle$ and $\langle 1,-a,-a,a^2\rangle$, which are clearly isometric quadratic spaces. □

Prop. (12.5.4.11) [Split or Division Ring]. Let $A=Q_F(a,b)$, then the following are equivalent:

1. $A\cong\mathrm{Mat}(2,F)$.
2. A is not a division algebra.
3. A is isotropic as a quadratic space.
4. A is hyperbolic as a quadratic space.
5. A_0 is isotropic as a quadratic space.
6. $(\langle a\rangle-1)(\langle b\rangle-1)=0$ in $W(F)$(or $\widehat{W}(F)$, by(12.5.3.2)).
7. (Hilbert's Criterion)The binary form $\langle a,b\rangle$ represents 1.
8. $a\in\mathrm{Nm}_{E/F}(E^*)$, where $E=F(\sqrt{b})$.

Proof: $4\to5\to3$ is clear. As $Q_F(-1,1)\cong M(2,F)$, $1,4,6,7$ are equivalent by(12.5.1.12) and(12.5.4.9). Also $3\iff4$ as the the norm form of A has determinant in $(F^*)^2$. Also $1\to2\to3$ is clear, as $x\in A$ is invertible iff $N(x)\neq0$. Thus 1 to 7 are all equivalent.

Now we show $7\iff8$: Firstly assume $b\notin(F^*)^2$, otherwise both are true. Let $E=F(\sqrt{b})$, then $N_{E/F}(x+y\sqrt{b})=x^2-by^2$, thus 8 says $a\in D_F(\langle 1,-b\rangle)$, which is equivalent to $\langle 1,-b,-a\rangle$ isotropic, which is equivalent to $\langle a,b\rangle$ represents 1, by representation theorem(12.5.1.21). □

Cor. (12.5.4.12). Let $a \in F^*$,

- $Q_F(1,-a) \cong Q_F(a,-a) \cong M(2,F)$.
- If $a \neq 1$, then $Q_F(a, 1-a)$ splits.
- $Q_F(-1,a)$ splits iff a is a sum of two squares in F.

Proof: These follows from Hilbert's criterion and representation theorem(12.5.1.21). □

Prop. (12.5.4.13) [Characterizing Quaternion Algebras].

- If $A \neq F$ is a simple algebra over F of dimension≤ 4 with center F, then A is isomorphic to a quaternion algebra over F.
- If $B \neq F$ is a f.d. simple F-algebra with center F equipped with an F-algebra involution $x \mapsto \overline{x}$ s.t. $x+\overline{x} \in F, x\overline{x} \in F$ for any $x \in B$, then B is isomorphic to a quaternion algebra over F.

Proof: 1: Use Wedderburn's theorem, then $A \cong M(n,D)$ where D is a division ring over F with center F. Then $A = M(2,F) \cong Q_F(1,-1)$ or D. If $A = D$, choose $i \notin F$, and $K = F(i)$ a subfield of D. Then $F \subset K \subset D$, thus $\dim K = 2$, thus we may modify i that $i^2 = a \in F$. The conjugation of i on D satisfies $(\mathrm{ad}(i))^2 = \mathrm{id}$, thus $A = A^+ \oplus A^-$ where $\mathrm{ad}(i)$ acts by 1 and -1 resp.. Let $j \neq 0 \in A^-$, then $ij = -ji$, $j^2 i = ij^2$, thus $j^2 \in A^+$. Now $K(j)$ is also a quadratic field over F, thus $j^2 + cj - b = 0$ for $c, b \in F$. Then $cj = b - j^2 \in A^+ \cap A^- = 0$ shows $c = 0$. Then $A = F \oplus Fi \oplus Fj \oplus Fij$ is the quaternion algebra $Q_F(a,b)$.

2: Use Wedderburn's theorem, then $A \cong \mathrm{Mat}(n,D)$ where D is a central division ring over F. The hypothesis shows every element of B satisfies a degree 2 equation $x^2 - (x+\overline{x})x + x\overline{x} = 0$, thus $n \leq 2$. If $n = 2$, then consider the diagonal elements, then we get $D = F$. If $B = D$, then the same argument as above shows we can find i, j that $ij = -ji$ and $i^2 = a, j^2 = b, a, b \in F^*$. Then j induces an isomorphism $A^+ \cong A^-$. If there are some $l \in A^+ \backslash F(i)$, then $\overline{il} = \overline{l}\overline{i} = il$, thus $il + \overline{il} = 2il \in F$, contradiction. Thus $A^+ = F(i)$, and $D = Q_F(a,b)$. □

Prop. (12.5.4.14) [Classifying Binary Forms]. Let $q = \langle a, b\rangle, q' = \langle a', b'\rangle$ be non-singular binary forms, then they are isomorphic iff $\det(q) = \det(q')$ and $Q_F(a,b) \cong Q_F(a',b')$.

Proof: If $q \cong q'$, then $ab = a'b' \in F^\times/(F^\times)^2$, thus $\langle 1, -a, -b, ab\rangle \cong \langle 1, -a', -b', a'b'\rangle$, thus $Q_F(a,b) \cong Q_F(a',b')$ by(12.5.4.11). The converse follows the same way by cancellation theorem(12.5.2.1). □

Def. (12.5.4.15) [Hilbert Symbol]. For $a, b \in k^\times$, define the **Hilbert symbol**

$$\{a,b\}_k = \begin{cases} 1 & Q_k(a,b) \cong \mathrm{Mat}(2;k) \\ -1 & \text{otherwise} \end{cases}.$$

Splitting Fields

Def. (12.5.4.16) [Splitting Fields]. A quaternion algebra A over F is said to **split** in a field extension K/F if $A \otimes_F K \cong \mathrm{Mat}(2,K)$. K is said to be a **splitting field** for A.

Prop. (12.5.4.17). Let $A = Q_F(a,b)$ and $K = F(\sqrt{c}), c \in F^\times$, then the following are equivalent:

- A splits over K.
- $A \cong Q_F(c,d)$ for some $d \in F^\times$.
- K is a subalgebra of A over F.

Proof: 1 → 2: Consider the pure tensor space $A_0 \cong \langle -a, -b, ab\rangle$. If it is isotropic, then $A_0 \cong \langle -c, -d, cd\rangle$ for some $d \in F^\times$. If it is anisotropic, then because $A_K \cong \mathrm{Mat}(2, K)$, by(12.5.4.11), there exists x_i, y_i not all zero s.t.

$$-a(x_1 + \sqrt{a}y_1)^2 - b(x_2 + \sqrt{a}y_2)^2 + ab(x_3 + \sqrt{a}y_3)^2 = 0$$

Thus $\mathtt{x}$ is orthogonal to $\mathtt{y}$ and $N(\mathtt{x}) + cN(\mathtt{y}) = 0$. $\mathtt{y} \neq 0$, because otherwise $N(\mathtt{x}) = 0$ and $\mathtt{x} = 0$. Thus there is an orthogonal basis $\{x, y, z\}$, and

$$A_0 \cong \langle N(z), N(y), -cN(y)\rangle,$$

and because $\det(A_0) = 1$, $N(z) \in c(K^\times)^2$, thus item2 holds.

2 → 3: In fact, if $i^2 = c \in A$, then $F(i) \cong K$.

3 → 1: This follows from(2.4.3.17). □

Prop. (12.5.4.18).

5 over Local or Finite Fields

References are [Quadratic Forms 3, Clark]

In this subsection, Let F be a local field or a finite field, of char$\neq 2$ with a non-trivial character ψ.

Prop. (12.5.5.1) [$W(\mathbb{F}_q)$].

- If $q \equiv 1 \mod 4$, then $W(\mathbb{F}_q)$ is isomorphic to $\mathbb{Z}/2\mathbb{Z}[F^*/(F^*)^2] \cong \mathbb{Z}/2\mathbb{Z}[\mathbb{F}_2]$ as rings.
- If $q \equiv 3 \mod 4$, then $W(\mathbb{F}_q)$ is isomorphic to $\mathbb{Z}/4\mathbb{Z}$ as rings.

Proof: 1: In this case, -1 is a square, let s be a non-square, then there are only three anisotropic forms: $\langle 1\rangle, \langle s\rangle, \langle 1, s\rangle$. Thus the assertion is clear.

2: In this case, we can take $s = -1$, thus any anisotropic form must be of the form $\langle 1, \dots, 1\rangle$ or $\langle -1, \dots, -1\rangle$. As $\langle 1, 1\rangle$ is universal by(23.1.5.2), $\langle 1, 1, 1\rangle \cong \langle -1\rangle$ by representation theorem(12.5.1.21), thus $4[\langle 1\rangle] = 0$. □

Prop. (12.5.5.2). Every binary quadratic form over a finite field $\mathbb{F}_q$ is universal.

Proof: By(12.5.5.1), if s is a non-square, there are essentially three quadratic forms, $\langle 1, 1\rangle, \langle s, s\rangle, \langle 1, s\rangle$. By(23.1.5.2), these are all universal. □

Cor. (12.5.5.3). Any quaternion algebra over a finite field splits, by Hilbert's criterion(12.5.4.11).

Prop. (12.5.5.4) [$W(\mathbb{R})$].

- There exists two anisotripic forms at each rank n: $\langle 1, \dots, 1\rangle$ and $\langle -1, \dots, -1\rangle$.
- $W(\mathbb{R}) \cong \mathbb{Z}$.
- (Sylvester's Law of Inertia)Two non-degenerate forms over $\mathbb{R}$ are equivalent iff they have the same rank and signature.
- $\widehat{W}(\mathbb{R}) \cong \mathbb{Z}[\mathbb{F}_2]$ as a ring.

Proof: Only 4 need a proof: It suffices to show $[\langle 1\rangle]$ and $[\langle -1\rangle]$ are linearly independent in $\widehat{W}(\mathbb{R})$, because they generate all other rings. But if $a[\langle 1\rangle] + b[\langle -1\rangle] = 0$, then $a + b = 0$ by rank reason, but when pass to $W(F)$, $a - b = 0$, thus $a = b = 0$. □

Prop. (12.5.5.5). Let $\langle a_1,\ldots,a_n\rangle_F$ be a quadratic space over a non-Archimedean local field F, we may assume $a_i\in\mathcal{O}_F$. If $\langle a_1,\ldots,a_n\rangle_{\mathcal{O}_F/\mathfrak{p}^n}$ is isotropic for all n, then $\langle a_1,\ldots,a_n\rangle_F$ is isotropic.

Proof: This is because we can find non-zero elements $v_n\in(\mathcal{O}_F/\mathfrak{p}^n)^d$ that $q(v_n)=0\in\mathcal{O}_F/\mathfrak{p}^n$, thus we can find elements $v\in\mathcal{O}_F^d$ that $q(v)=0$. □

Prop. (12.5.5.6) [Unique Quaternion Algebra]. If $F\ncong\mathbb{C}$ is a local field, then there is a unique non-split quadratic algebra over F.

Proof: Cf.[Lam, P156]. □

Cor. (12.5.5.7). For this unique quaternion algebra A, the valuation $|N(x)|$ is a valuation of A, i.e. defines the topology.

Proof: This is because $|N(\cdot)|$ is bounded on the compact subset $\{x||x|=1\}$. □

Prop. (12.5.5.8)[Hilbert Symbol]. Let F be a local or finite field, then the Hilbert symbol(12.5.4.15) $(\cdot,\cdot)_F: F^*/(F^*)^2\times F^*/(F^*)^2\to\{\pm1\}$ satisfies

- It is symmetric and bi-multiplicative for both terms.
- It is non-degenerate: if $F\ncong\mathbb{C}$ is a local field, for any $y\in F^*\backslash(F^*)^2$, then there exists a $z\in F^*$ that $(y,z)_F=-1$.
- $(a,-a)=1$.
- If $a(a-1)\neq0$, $(a,1-a)=1$.

Proof: 1: To show it is multiplicative, by(12.5.4.11), $(a,b)_F=1$ iff $a\in N_{E/F}(E^*)$, where $E=F(\sqrt{b})$. Notice $N_{E/F}(E^*)$ has index 1 or 2 in F^* by class field theory(12.6.2.10), thus $a\mapsto(a,b)_F$ is a character of a in any case.

2: Cf.[Lam, P160].**?**

3: By(12.5.4.12). □

Prop. (12.5.5.9) [Weil]. Let (V,B) be a quadratic space over a local or finite field F of dimension d, ψ a non-trivial character of F. Let V be identified with V^* via $(v,v^*)\mapsto\psi(-2B(v,v^*))$, denote the Fourier transform $\mathcal{F}$ to be compatible with this identification.

Let $F_B(v)=\psi(B(v,v))$, then for any $a\in F^*$, then $\varphi*F_{aB}\in\mathcal{S}(V)$ for any $\varphi\in\mathcal{S}(V)$, and there is a complex number $\gamma(aB)$ with norm 1 that for any $\varphi\in\mathcal{S}(V)$,

$$\mathcal{F}(\varphi*F_{aB})=|a|^{-d/2}\gamma(aB)\mathcal{F}(\varphi)F_{-a^{-1}B}.$$

which means $|a|^{-d/2}\gamma(aB)F_{-a^{-1}B}$ is formally the Fourier transform of F_{aB}.

Proof: We only prove for $a=1$:

$$(\Phi*F_B)(v)=\int_V\Phi(u)\psi(B(v-u,v-u))du=F_B(v)\mathcal{F}(\Phi\cdot F_B)(-v)$$

is an element of $\mathcal{S}(V)$, as $\mathcal{F}(\mathcal{S}(V))=\mathcal{S}(V)$(12.4.6.11). Now use the last equation of(2.1.6.8) for $z=1$ and the projective unitary representation ω_1 of $SL(2,F)$ on $L^2(V)$(16.5.4.2),

$$\omega_1(w_1)\omega_1(n(1))\omega_1(w_1)\omega_1(n(1))\omega_1(-1)\Phi=\gamma(B)\omega_1(n(-1))\omega_1(w_1)\Phi$$

for some $|\gamma(B)|=1$. Then it can be computed that the LHS equals $\widehat{\Phi*F_B}$, and the RHS equals $F_B\cdot\widehat{\Phi}$, thus we are done. □

Cor. (12.5.5.10) [Analytic Interpretation of Isotropy].

- If (V_1, B_1), (V_2, B_2) are quadratic spaces, then $\gamma(B_1 \oplus B_2) = \gamma(B_1)\gamma(B_2)$.
- If (V, B) is a quadratic space, then $\gamma(-B) = \gamma(B)^{-1}$.
- If (V, B) is a hyperbolic quadratic space(12.5.1.15), then $\gamma(B) = 1$.
- γ is a group homomorphism $W(F) \to \mathbb{C}^*$(12.5.3.1).

Proof: 1, 2 follow from taking test functions φ to be $\varphi_1 \otimes \varphi_2$ or $\overline{\varphi}$. 3 follows from the fact $\gamma(\langle -1, 1\rangle) = \gamma(\langle 1\rangle)\gamma(\langle -1\rangle) = 1$. 4 follows from 1 and 3. □

Prop. (12.5.5.11). Situation as in(12.5.5.9),

- For any $\Phi \in \mathcal{S}(V)$, $\int_V (\Phi * F_B)(v)dv = \gamma(B)\int_V \Phi(v)dv$.
- If F is non-Archimedean , then for any lattice in V(12.2.3.32) sufficiently large, $\gamma(B) = \int_L F_B(v)dv$.
- If F is finite, then $\gamma(B) = \int_V F_B(v)dv$.

Proof: 1 follows from(12.5.5.9) evaluated at $a = 1$ and $v = 0$.

2: Consider the dual lattice L'(12.2.3.36), if L is sufficiently large, then L' is sufficiently small, s.t. $F_B(u) = 1$ for all $u \in L'$. Then

$$(\chi_{L'} * F_B)(v) = \int_{L'} F_B(v - u)du = \psi(B(v, v))\int_{L'} \psi(-2B(u, v))du,$$

which equals $V(L')\chi_L F_B$. Then let $\Phi = \chi_{L'}$ in item1, we get the desired assertion.

3: This is the same as 2, take $\Phi = 1$. □

Prop. (12.5.5.12) [Weil's Characterization of Hilbert Symbol]. Let $Q_F(a, b)$ be a quadratic algebra over a local field F of characteristic$\neq 2$, let $q : Q_F(a, b) \to F$ be the norm form, then $\gamma(q) = (a, b)_F$(12.5.4.15).

In particular, $(a, b)_F = \gamma(\langle 1, -a, -b, ab\rangle)$.

Proof: By(12.5.5.10) and(12.5.5.8), it suffices to show for a non-split $Q_F(a, b)$, $\gamma(\langle 1, -a, -b, ab\rangle) = -1$.

If F is Archimedean or finite, then the existence of a non-split $Q_F(a, b)$ over A shows $F = \mathbb{R}$, and $a = b = -1$, and $\gamma(\langle 1, 1, 1, 1\rangle) = (\gamma(\langle 1\rangle))^4$. Let $\psi : \mathbb{R} \to \mathbb{C} : x \mapsto e^{2\pi i x}$ as in(12.4.6.3), and $\Phi(x) = e^{-\pi x^2}$, then it can be calculated using(12.5.5.9) that $\gamma(B)$ is an 8-th roots of unity, thus we are done.

If F is non-Archimedean, denote the Haar measure on $A = Q_F(a, b)$ by dz, and then by(12.5.4.7) and(10.11.1.19), the Haar measure on A^* is of the form $d^\times z = |N(z)|^{-2}dz$. By(12.5.5.7), for large n, $L = N^{-1}(\mathfrak{p}^{-n})$ is a sufficiently large lattice in V, thus we can use(12.5.5.11) to evaluate the sign of

$$\gamma(N) = \int_{L\backslash\{0\}} \psi(N(z))|N(z)|^2 d^\times z.$$

But this integrand factors through $N : L\backslash 0 \to \mathfrak{p}^{-n}$, thus it suffices to evaluate the sign of

$$\int_{\mathfrak{p}^{-n}\backslash 0} \psi(x)|x|^2 d^\times x = \int_{\mathfrak{p}^{-n}} \psi(x)|x|dx,$$

which is $-q^{1-2r}(1 - q^{-1})^{-1}$, where the conductor of ψ is $\mathfrak{p}^r$. So $\gamma(N) = -1$. □

Cor. (12.5.5.13). Let $r_i \in F^*$, then $\gamma(\langle ar_1, \ldots, ar_{2n}\rangle) = ((-1)^n r_1 \ldots r_{2n}, a)_F \gamma(\langle r_1, \ldots, r_{2n}\rangle)$.

Proof: By(12.5.5.12), it suffices to show for $n = 1$. $\gamma(\langle r_1, r_2\rangle) = (r_1, r_2)_F \gamma(\langle 1, r_1 r_2\rangle)$, thus also $\gamma(\langle ar_1, ar_2\rangle) = (ar_1, ar_2)_F \gamma(\langle 1, a^2 r_1 r_2\rangle)$, so

$$\gamma(\langle ar_1, ar_2\rangle)/\gamma(\langle r_1, r_2\rangle) = (ar_1, ar_2)_F/(r_1, r_2)_F = (a, -r_1 r_2)$$

by(12.5.5.8). □

Cor. (12.5.5.14). Let (V, B) has dimension $2n$, then $\gamma(B)^2 = ((-1)^n \det(B), -1)_F$.

Proof: It reduces to $n = 1$, in which case, it suffices to show that $\gamma(\langle r_1, r_2\rangle)^2 = (-1, -r_1 r_2)_F$. But $(-1, -r_1 r_2)_F = \gamma(\langle 1, 1, r_1 r_2, r_1 r_2\rangle) = \gamma(\langle 1, r_1 r_2\rangle)^2$. By(12.5.5.12), $\gamma(\langle 1, -r_1, -r_2, r_1 r_2\rangle)^2 = 1$, thus $\gamma(\langle 1, r_1 r_2\rangle)^2 = \gamma(\langle r_1, r_2\rangle)^2$. □

6 over Global Fields

References are [Quadratic Forms over Global Fields, Clark].

Prop. (12.5.6.1). Let $F = k(t)$ where k is alg.closed, then any binary quadratic form Q over F is universal.

Proof: We may assume $Q = \langle 1, f\rangle$, where $f \in F^*$. We can assume $f \notin -(F^*)^2$, otherwise this is clearly universal. It is easy to see that the $\mathbb{F}_2$ vector space $F^*/(F^*)^2$ has a basis $\{t - a | a \in k\}$. Notice $D_F(Q)$ is a subgroup of F^* as it is the norm group of $F(\sqrt{-f})$, it suffices to show that $t - a \in D_F(Q)$. After a change of variable, it suffices to show that $t \in D_F(Q)$, or $\langle 1, f, -t\rangle$ is isotropic, or equivalently $-f \in \langle 1, -t\rangle$ for any f. The same argument show that it suffices to show that $\langle 1, -t, t - a\rangle$ is isotropic. But $t - a + (-t) + (\sqrt{a})^2 = 0$. □

Cor. (12.5.6.2). Any quaternion algebra over $\overline{k}(t)$ splits, by Hilbert's criterion(12.5.4.11).

Prop. (12.5.6.3) [Examples].

- $Q_{\mathbb{Q}}(-1, -1) \cong Q_{\mathbb{Q}}(-2, -3)$.
- $Q_{\mathbb{Q}}(-1, -1) \ncong Q_{\mathbb{Q}}(-2, -5)$.
- Let p be a prime number, $Q_{\mathbb{Q}}(-1, p)$ splits iff $p = 2$ or $p \equiv 1 \mod 4$.
- Let p be a prime number, $Q_{\mathbb{Q}}(-2, p)$ splits iff $p = 2$ or $p \equiv 1, 3 \mod 8$.
- $Q_{\mathbb{Q}}(-3, 5)$ is a division ring, but splits over $K = \mathbb{Q}(\sqrt{17})$.

Proof: 1: By(12.5.1.23), $Q_{\mathbb{Q}}(1, 1, 1, 1) \cong (1, 1, 2, 2) \cong (1, 3, 6, 2)$, thus $Q_{\mathbb{Q}}(-1, -1) \cong Q_{\mathbb{Q}}(-2, -3)$ by(12.5.4.11).

2: if they are isomorphic, then $\langle 2, 5, 10\rangle \cong \langle 1, 1, 1\rangle \cong \langle 2, 2, 1\rangle$, thus $\langle 5, 10\rangle \cong 1, 2$, which is impossible as 1 is not representable by $\langle 5, 10\rangle$.

3: By Hilbert's criterion(12.5.1.23), if $Q_{\mathbb{Q}}(-1, p)$ splits, then $-x^2 + py^2 = z^2$ for some $x, y, z \in \mathbb{Z}$ that $(x, y, z) = 1$, thus -1 is a square in $\mathbb{F}_p$, which means $p \equiv 1 \mod 4$ or $p = 2$. Conversely, if $p \equiv 1 \mod 4$, then by(12.4.1.2), $p = x^2 + y^2$ for some $x, y \in \mathbb{Z}$, thus $\langle -1, p\rangle$ represents 1, so $Q_{\mathbb{Q}}(-1, p)$ splits. if $p = 2$, then $\langle -1, 2\rangle$ represents 1, thus it splits.

4: By Hilbert's criterion(12.5.1.23), if $Q_{\mathbb{Q}}(-1, p)$ splits, then $-2x^2 + py^2 = z^2$ for some $x, y, z \in \mathbb{Z}$ that $(x, y, z) = 1$, thus -2 is a square in $\mathbb{F}_p$, which means $p \equiv 1, 3 \mod 8$ or $p = 2$. Conversely, if $p \equiv 1 \mod 4$, then by(12.4.1.2), $p = x^2 + y^2$ for some $x, y \in \mathbb{Z}$, thus $\langle -1, p\rangle$ represents 1, so $Q_{\mathbb{Q}}(-1, p)$ splits. If $p = 2$, then it splits as above.

5: If it splits, then $-3x^2 + 5y^2 = z^2$ for some $x, y, z \in \mathbb{Z}$ that $(x, y, z) = 1$. This is a contradiction modulo3. In $K = \mathbb{Q}(\sqrt{17})$, however, $5 \cdot 2^2 - 3 = 17$, thus $Q_{\mathbb{Q}(\sqrt{13})}(-3, 5)$ splits. □

Prop. (12.5.6.4)[Hasse-Minkowski Principle]. If $F \in \texttt{GField}$ and char $F \neq 2$, and Q is a quadratic form over F, then q is isotropic over F iff Q is isotropic over $F_{\mathfrak{p}}$ for all place $\mathfrak{p}$.

Proof: Cf.[Lam, P170].**?** □

12.6 Cohomology of Arithmetic Fields

Main references are [Neu15], [Cohomology of Number Fields, Neukirch], `http://www.math.columbia.edu/~chaoli/docs/ClassFieldTheory.html#sec28` and [Mil20] and [Arithmetic Duality Theory, Milne].

Notation (12.6.0.1).

- Use notations from Global Fields

1 Abstract Class Field Theory

Def. (12.6.1.1) [Class Formations]. A **profinite formation** consists of a profinite group G regarded as a Galois group of a field Gal_K and $A \in T_G$. It is called a **field formation** iff for any normal extension L/K, $H^1(L/K, A^L) = 0$.

For a field extension, by(10.1.1.13), inf is an injection on H^2. We denote $H^2(K)$ as the profinite cohomology group $H^2(G, A) = \mathrm{Br}(K)$. Inflation should be thought of as inclusions.

It is called a **class formation** if moreover for every normal extension L/K, there is an canonical isomorphism

$$\mathrm{inv}_{L/K} : H^2(L/K) \to \frac{1}{[L:K]}\mathbb{Z}/\mathbb{Z}$$

that is compatible with inflation and restriction in the sense that:

- If $N/L/K$ with N/K and L/K normal, then $\mathrm{inv}_{L/K} = \mathrm{inv}_{N/K}|_{H^2(L/K)}$ via inflation.
- If $N/L/K$ with N/L and N/K normal, then $\mathrm{inv}_{N/L} \circ \mathrm{res}_L = [L:K] \cdot \mathrm{inv}_{N/K}$.

$\mathrm{inv}^{-1}_{L/K}(\frac{1}{[L:K]} + \mathbb{Z}) \in H^2(L/K)$ is called the **fundamental class** $u_{L/K}$.

Prop. (12.6.1.2). inv also commutes with cor and conjugation:

$$\mathrm{inv}_{N/K}(\mathrm{cor}_K c) = \mathrm{inv}_{N/L} c, \quad \mathrm{inv}_{\sigma N/\sigma K}(\sigma^* c) = \mathrm{inv}(c).$$

The first is because inv commutes with res thus res is surjective, thus there is a c' that $c = \mathrm{res}\, c'$. Because of cor res=$[L:k]$, we have $\mathrm{cor}_K(c) = c'^{[L:K]}$. Thus $\mathrm{inv}_{N/K}(\mathrm{cor}_K c) = [L:K]\mathrm{inv}_{N/K}(c') = \mathrm{inv}_{N/L}(\mathrm{res}_L c') = \mathrm{inv}_{N/L}(c)$.

For the conjugation, Cf.[Neu15]P69**?**.

Cor. (12.6.1.3). From this we easily get that

$$u_{L/K} = (u_{N/K})^{[N:L]}, \quad \mathrm{res}_L(u_{N/K}) = u_{L/K}$$

$$\mathrm{cor}_K(u_{N/L}) = (u_{N/K})^{[L:K]}, \quad \sigma^*(u_{N/K}) = u_{\sigma N/\sigma K}.$$

Prop. (12.6.1.4) [Class Formation Main Theorem]. Tate's theorem(10.1.1.24) tells us for a class formation, for L/K normal extension, there is a **Nakayama isomorphism**

$$\theta_{L/K} = u_{L/K} \cup - : H^q(\mathrm{Gal}(L/K), \mathbb{Z}) \cong H^{q+2}(L/K).$$

Especially, for $q = -2$, there is a canonical isomorphism $\mathrm{Gal}^{ab}(L/K) \cong A_K/\mathrm{Nm}_{L/K} A_L$. Its inverse is called the **Artin reciprocity isomorphism** and induces a **norm residue symbol** map $(-, L/K)$

$$1 \to \mathrm{Nm}_{L/K} A_L \to A_K \xrightarrow{(-,L/K)} \mathrm{Gal}^{ab}(L/K) \to 1.$$

This norm residue symbols induce an **Artin map**

$$\mathrm{Art}_K = (-, K) : A_K \to \mathrm{Gal}_K^{\mathrm{ab}} = \varprojlim_{L/K} \mathrm{Gal}^{\mathrm{ab}}(L/K)$$

that has dense image.

Lemma (12.6.1.5). Let L/K be a normal extension, $a \in A_K$ and $\chi \in \mathrm{Gal}^{\mathrm{ab}}(L/K)^\vee = H^1(G(L/K), \mathbb{Q}/\mathbb{Z})$ is a character, then

$$\chi((a, L/K)) = \mathrm{inv}_{L/K}(a \smile \delta\chi) \in \frac{1}{[L:K]}\mathbb{Z}/\mathbb{Z}.$$

Proof: Cf.[Neukirch CFT P71]. □

Prop. (12.6.1.6)[Properties of Norm Residue Symbols]. For formal field extensions $N/L/K$ with N/K normal, there are commutative diagrams:

$$\begin{array}{ccc} A_K & \xrightarrow{(-,N/K)} & \mathrm{Gal}(N/K)^{\mathrm{ab}} \\ \downarrow \mathrm{id} & & \downarrow \mathrm{pr} \\ A_K & \xrightarrow{(-,L/K)} & \mathrm{Gal}(L/K)^{\mathrm{ab}} \end{array} \qquad \begin{array}{ccc} A_K & \xrightarrow{(-,N/K)} & \mathrm{Gal}(N/K)^{\mathrm{ab}} \\ \mathrm{Nm}_{L/K}\uparrow\downarrow i & & i\uparrow\downarrow \mathrm{Ver} \\ A_L & \xrightarrow{(-,N/L)} & \mathrm{Gal}(N/L)^{\mathrm{ab}} \end{array} \qquad \begin{array}{ccc} A_L & \xrightarrow{(-,N/L)} & \mathrm{Gal}(N/L)^{\mathrm{ab}} \\ \downarrow \sigma & & \downarrow \sigma^* \\ A_{\sigma L} & \xrightarrow{(-,\sigma N/\sigma L)} & \mathrm{Gal}(\sigma N/\sigma L)^{\mathrm{ab}} \end{array}$$

Where Ver is the transfer map defined in**??**.

Proof: Cf.[Neukirch CFT P72].**?** □

Remark (12.6.1.7) [Non-Abelian Problems]. For a finite normal extension L/K, $\mathrm{Nm}_{L/K} A_L = \mathrm{Nm}_{L^{\mathrm{ab}}/K} A_{L^{\mathrm{ab}}}$. This is because the quotient both correspond to $G(L/K)^{\mathrm{ab}}$. So class field theory doesn't tell about non-Abelian extension.

Prop. (12.6.1.8) [Norm Groups and Abelian Extension]. The map $L \mapsto \mathcal{N}_{L/K} = \mathrm{Nm}_{L/K} A_L$ defines a inclusion reversing isomorphism between the lattice of Abelian extension L of K and the lattice of norm groups of A_K, i.e.:

$$\mathcal{N}_{L_1L_2/K} = \mathcal{N}_{L_1/K} \cap \mathcal{N}_{L_2/K}, \quad \mathcal{N}_{L_1\cap L_2/K} = \mathcal{N}_{L_1/K} \cdot \mathcal{N}_{L_2/K}.$$

And any group that contains a norm group is a norm group.

Proof: By the first commutative diagram of inv, if $(a, L_i/K) = 0$, then $(a, L_1L_2/K)$ is trivial on $G_{L_i/K}$, thus trivial on $G_{L_1L_2/K}$, thus $a \in I_{L_1L_2}$. so $I_{L_1} \cap I_{L_2} \subset I_{L_1L_2}$, the other side is easy. the second is because $|I_{L_1\cap L_2}/I_{L_1}| = |G_{L_1/L_1\cap L_2}| = |G_{L_1L_2/L_2}| = |I_{L_1}I_{L_2}/I_{L_1}|$. Also we deduce $I_{L_1} \subset I_{L_2} \iff L_2 \subset L_1$, thus by canonical isomorphism, groups containing $\mathrm{Nm}_{L/K} A_L$ are one-to-one correspondence with middle fields of L/K by counting numbers. □

Remark (12.6.1.9). This shows the philosophy of CFT, i.e. the property of Abelian extensions of a field is can be read from its multiplicative group structure. Of course, determining and characterizing these norm groups requires some work.

Weil Groups

Main references are[A-T67].

2 Local Class Field Theory

Notation (12.6.2.1).

- Let $K \in p$-`LField`.
- Let L/K be a finite extension field.

Unramified Extensions

Lemma (12.6.2.2). If L/K is unramified, then $H^q(G_{L/K}, \mathcal{O}_L^*) = 0$ for all q.

Proof: Cf.[Neukirch P83]. □

Prop. (12.6.2.3) [Witt Residues]. The unramified extensions of K form a class formation.

Proof: We first define the inv map: use the exact sequence $1 \to \mathcal{O}_L^* \to L^\times \xrightarrow{v_L} \mathbb{Z} \to 0$, using the lemma(12.6.2.2), we have an isomorphism

$$H^2(\mathrm{Gal}(L/K), L^\times) \xrightarrow{v_L} H^2(\mathrm{Gal}(L/K), \mathbb{Z}) \xrightarrow{\delta^{-1}} H^1(\mathrm{Gal}(L/K), \mathbb{Q}/\mathbb{Z}) = \mathrm{Gal}(L/K)^\vee.$$

And there is an isomorphism

$$\varphi : \mathrm{Gal}(L/K)^\vee \cong \frac{1}{[L;K]}\mathbb{Z}/\mathbb{Z}, \quad \varphi(\chi) = \chi(\varphi_{L/K})$$

where $\varphi_{L/K}$ is the Frobenius which generates $\mathrm{Gal}(L/K)$. Then define

$$\mathrm{inv}_{L/K} = \varphi \circ \delta^{-1} \circ v_L : H^2(\mathrm{Gal}(L/K), L^\times) \cong \frac{1}{[L:K]}\mathbb{Z}/\mathbb{Z}$$

To verify this is a class formation, we should verify(12.6.1.1), Cf.[Neukirch P85]**?**. □

Prop. (12.6.2.4) [Local Norm Symbol is given by Frobenius]. If L/K is unramified, then $(a, L/K) = \varphi_{L/K}^{v_K(a)}$. The same holds for L replaces by K^{ur}, in which case

$$1 \to \mathcal{O}_K^* \to K^\times \to \mathrm{Gal}(K^{\mathrm{ur}}/K) \to 0$$

is exact. Cf[Neukirch P88].

Proof: We use(12.6.1.5), then $\chi(a, L/K) = \mathrm{inv}_{L/K}(\overline{a} \cup \delta\chi) = \varphi \circ \delta^{-1} \circ v_K(\overline{A} \smile \delta\chi) = \varphi(\delta^{-1}(v_K(a)\delta\chi)) = \varphi(v_K(a)\chi) = v_K(a)\chi(\varphi_{L/K}) = \chi(\varphi_{L/K}^{v_K(a)})$, for any χ. The second assertion follows from the last prop(12.6.2.5). □

Cor. (12.6.2.5) [Norm Group of Unramified Extensions]. The norm group of an unramified extension of degree f is

$$\mathcal{O}_K^* \times (\varpi_K^f)^{\mathbb{Z}}.$$

In particular, L/K is unramified iff $\mathcal{O}_K^* \subset \mathcal{N}_{L/K}$.

Ramified Extensions

Lemma (12.6.2.6). If L/K is normal, then $\#H^2(L/K)\Big|[L:K]$.

Proof: Cf.[Neukirch CFT P89]. Should use the fact that $G_{L/K}$ is solvable and Herbrand quotient. □

Lemma (12.6.2.7) [Invariant Maps]. If L/K is normal and L'/K is another unramified extension of the same degree, then $H^2(L/K) = H^2(L'/K) \subset \mathrm{Br}(K)$. In particular, we can define an invariant map $\mathrm{inv} : \mathrm{Br}(K) \to \mathbb{Q}/\mathbb{Z}$.

Proof: In view of(12.6.2.6) and(12.6.2.3), we only need to prove $H^2(L'/K) \subset H^2(L/K)$. For this, we let $N = LL'$, then there is an exact sequence(10.1.1.13)

$$1 \to H^2(L/K) \to H^2(N/K) \xrightarrow{\mathrm{res}_L} H^2(N/L)$$

then we only need to prove $\mathrm{res}_L(c) = 0$, and this follows from $\mathrm{inv}_{N/L}(\mathrm{res}_L\, c) = 0$. This will follow, if we have

$$\mathrm{inv}_{N/L}(\mathrm{res}_L\, c) = [L:K]\cdot \mathrm{inv}_{L'/K}\, c.$$

This follows from(12.6.2.8). □

Lemma (12.6.2.8). For two subextensions L/K, L'/K in M/L normal with L'/K unramified extension, $N = LL'$, for $c \in H^2(L'/K)$,

$$\mathrm{inv}_{N/L}(\mathrm{res}_L c) = [L:K]\cdot \mathrm{inv}_{L'/K} c.$$

Proof: Cf[Neukirch CFT P90]. □

Lemma (12.6.2.9). $(\mathrm{Gal}_K, (K^{\mathrm{sep}})^\times, \mathrm{inv}_K)$ forms a class formation.

Proof: This almost follows from that of unramified extensions(12.6.2.3). We verify axioms(12.6.1.1) that inf is natural and commutes with res. It is natural because it is natural on unramified extensions, it commutes with res because we can assume $c \in H^2(L'/K)$ unramified and use(12.6.2.8). □

Cor. (12.6.2.10) [Local Artin's Reciprocity Law]. Let L/K be a normal extension, then the homomorphism

$$u_{L/K} \cup - : H^q(\mathrm{Gal}(L/K), \mathbb{Z}) \cong H^{q+2}(L/K)$$

is an isomorphism.

Cor. (12.6.2.11). $H^3(L/K) = 1, H^4(L/K) = \mathrm{Gal}^{\mathrm{ab}}(L/K)^\vee$, by(10.1.1.6).

Thm. (12.6.2.12) [Artin's Reciprocity Law]. By(12.6.1.4), cup product with the fundamental class in $H^2(L/F)$ define an isomorphism

$$\theta_{L/K} : \mathrm{Gal}^{\mathrm{ab}}(L/K) \cong H^{-2}(\mathrm{Gal}(L/K), \mathbb{Z}) \to H^0(L/K) = K^\times / \mathrm{Nm}_{L/K} L^\times,$$

called the **Nakayama map**. And the reverse map is called the **norm residue symbol**$(-, L/K)$

$$1 \to \mathrm{Nm}_{L/K} L^\times \to K^\times \xrightarrow{(-,L/K)} \mathrm{Gal}^{\mathrm{ab}}(L/K) \to 1.$$

This norm residue symbols induce an **Artin map**

$$\mathrm{Art}_K = (-, K) : K^\times \to \mathrm{Gal}_K^{\mathrm{ab}}$$

with dense image.

Cor. (12.6.2.13). By(12.6.1.6), there are commutative diagrams

$$\begin{array}{ccc} K^\times & \xrightarrow{(-,N/K)} & \mathrm{Gal}(N/K)^{\mathrm{ab}} \\ \downarrow \mathrm{id} & & \downarrow \mathrm{pr} \\ K^\times & \xrightarrow{(-,L/K)} & \mathrm{Gal}(L/K)^{\mathrm{ab}} \end{array} \qquad \begin{array}{ccc} K^\times & \xrightarrow{(-,N/K)} & \mathrm{Gal}(N/K)^{\mathrm{ab}} \\ \mathrm{Nm}_{L/K}\uparrow\downarrow i & & i\uparrow\downarrow \mathrm{Ver} \\ L^\times & \xrightarrow{(-,N/L)} & \mathrm{Gal}(N/L)^{\mathrm{ab}} \end{array} \qquad \begin{array}{ccc} L^\times & \xrightarrow{(-,N/L)} & \mathrm{Gal}(N/L)^{\mathrm{ab}} \\ \downarrow \sigma & & \downarrow \sigma^* \\ \sigma L^\times & \xrightarrow{(-,\sigma N/\sigma L)} & \mathrm{Gal}(\sigma N/\sigma L)^{\mathrm{ab}} \end{array}$$

Where Ver is the transfer map defined in**??**.

Cor. (12.6.2.14) [Quadratic Character]. If L/K is a quadratic extension, then $\mathcal{N}_{L/K}$ is a subgroup of $K^\times$ of order 2. Let χ be the non-trivial character of $K^\times$ that is trivial on $\mathcal{N}_{L/K}$, called the **quadratic character** of $K^\times$ attached to L/K.

Prop. (12.6.2.15) [Higher Ramification Groups]. For an Abelian extension L/K, the higher principal units U_K^n are mapped under the higher ramification groups of $G_{L/K}$ under the upper numbering. **?**

Proof: □

Def. (12.6.2.16) [Conductors]. If L/K is Abelian, define the **conductor** $\mathfrak{f}_{L/K}$ to be the smallest positive integer n s.t. $U_K^n \subset \mathcal{N}_{L/K}$.

Cor. (12.6.2.17). For an Abelian extension L/K, $\mathfrak{f}_{L/K} = 1$ iff L/K is unramified, by(12.6.2.5).

Characterize the Norm Groups of $K^\times$

Prop. (12.6.2.18) [Norm Group and Abelian Extension]. The map $L \mapsto \mathcal{N}_{L/K}$ defines a inclusion reversing isomorphism between the lattice of Abelian extension L of K and the lattice of norm groups of $K^\times$, i.e.:

$$\mathcal{N}_{L_1L_2/F} = \mathcal{N}_{L_1/K} \cap \mathcal{N}_{L_2/K}, \quad \mathcal{N}_{L_1\cap L_2/K} = \mathcal{N}_{L_1/K} \cdot \mathcal{N}_{L_2/K}.$$

And any group that contains a norm group is a norm group. This follows from(12.6.1.8) and (12.6.2.9).

Prop. (12.6.2.19). The norm groups are precisely the open(closed) subgroups of finite index in K^*. In fact finite index are itself open because it contains $(K^\times)^n$ which is open.

Proof: One part follows from(12.6.2.18) and the fact that $(K^*)^m$ is open(12.2.3.7). For the converse, we only need to prove $(K^*)^m$ is a norm group. This uses Kummer theory and Cf.[Neukirch CFT P96]. □

Prop. (12.6.2.20) [Norm Groups of Local Fields]. The norm groups of K^* are exactly the groups containing $U_K^n \times (\pi^f)$ for some n, f.

Proof: $U_K^n \times (\pi^f)$ is a norm group because it is closed of finite index. Conversely, any norm group contains some U_K^n because it is open and contains some (π^f) because it is of finite index. □

Local Weil Groups

Prop. (12.6.2.21) [Weil Groups]. The Artin map $\mathrm{Art}_K : K^\times \to \mathrm{Gal}_K^{\mathrm{ab}}$ is injective because $(K^\times)^n$ are all norm groups by(12.6.2.19), so the kernel is their intersection with is 1 by(12.2.3.7). It image is just W_K^{ab}.

Prop. (12.6.2.22) [Norm on Weil Groups]. The Artin map(12.6.2.21) gives a norm $|x| = |\,\mathrm{Art}^{-1}(x)|$ on W_K^{ab}, which maps a lift of the geometric Frobenius in Gal_κ to q^{-1}.

Totally Ramified Extensions

References are [L-T65].

Notation (12.6.2.23).

- Use notations defined in Lubin-Tate Formal Group Law.

Prop. (12.6.2.24) [Tate Modules]. There is an isomorphism of $\mathcal{O}$-modules $\Lambda_{f,n} \cong \mathcal{O}/\pi^n\mathcal{O}$, Cf.[Neukirch CFT P101]. Thus the automorphism of $\Lambda_{f,n}$ is all of the form u_f for units, isomorphic to U_K/U_K^n.

So we can define a **Tate module** $TG = \varprojlim \ker[\pi_K^n]$, it is a free $\mathcal{O}_K$-module of rank 1.

Def. (12.6.2.25)[Lubin-Tate Character]. As TG is a free $\mathcal{O}_G$-module of dimension 1, and Gal_K acts on TG, there can be attached a **Lubin-Tate character** $\chi_K : \mathrm{Gal}_K \to \mathcal{O}_K^*$ by $g(\alpha) = [\chi_K(g)](\alpha)$, this depends on π_K, but its restriction on I_K doesn't depend on π_K, and is just the local CFT isomorphism composed with $x \to x^{-1}$.

Proof: $[\chi_K(g)]$ is, by definition, the morphism that is id on K^{ur} and g on L_π. So it equals g on all K^{ab} iff g is id on K^{ur}, that is, $g \in I_K$. So if $g \in I_K$, by local CFT, $(\chi(g))^{-1}$ corresponds to g, uniquely. □

Prop. (12.6.2.26). $G_{\pi,n} \cong \mathcal{O}_K^*/U_K^n$, thus we have $G_\pi \cong \mathcal{O}_K^*$. $L_{\pi,n}/K$(8.5.3.26) is Abelian totally ramified of degree $p^{n-1}(p-1)$ generated by a Eisenstein polynomial with constant coefficient ϖ. In particular, ϖ is in the norm group.

Proof: For this, first note Galois action induce an isomorphism on $\Lambda_{f,n}$, thus correspond to an element of U_K/U_K^n by(12.6.2.24), this is an injection because $\Lambda_{f,n}$ generate $L_{\pi,n}$. Then we use the canonical polynomial $f(Z) = \pi Z + Z^q$, $f^n = f^{n-1}\varphi(n)$, where $\varphi(n)$ is a Eisenstein polynomial, thus $L_{\pi,n}/K$ is totally ramifies with $|G_{\pi,n}| = q^{n-1}(q-1) = |U_K/U_K^n|$, thus the result. □

Prop. (12.6.2.27)[Explicit Local Norm Residue Symbol]. Now we can write the universal residue symbol little bit more explicitly. For $a = u\varpi^m$, (a, K) acts as φ^m on K^{ur}, and on $L_{\pi,n}$, its action is generated by the action $(u^{-1})_f$ on the generating set $\Lambda_{f,n}$.

Thus the norm group of $L_{\pi,n}$ is just U_K^n by(12.6.2.26).

Proof: Cf.[Neukirch CFT P106].**?** □

Cor. (12.6.2.28)[Norm Groups of Totally Ramified Extensions]. The norm groups of the totally ramified Abelian extension are precisely the groups that contains some $U_K^n \times \varpi^{\mathbb{Z}}$ for some uniformizer π. And every totally ramified Abelian extension L/K is contained in some $L_{\varpi,n}$.

Proof: For any totally ramified extension, choose a uniformizer, then its norm is a uniformizer ϖ of K. And $\mathrm{Nm}_{L/K}$ is open, thus it contains some U^n. The rest follows from local CFT(12.6.2.18). □

Cor. (12.6.2.29)[Maximal Abelian Extension of p-adic Local Fields]. Let $L_\pi = \cup L_{\pi,n} = K(\Lambda_f)$, where $\Lambda_f = \cup\Lambda_{f,n}$, then $T \cdot L_\pi$ is the maximal Abelian extension of K. Hence $G_K^{\mathrm{ab}} = G_{T,K} \times G_\pi$.

Proof: This follows immediately from(12.6.2.20). □

Cor. (12.6.2.30)[Hasse-Arf]. We can prove Hasse-Arf(12.2.2.27) in the case where K is a local field. This is because we already know the maximal Abelian extension, and $G(K^{\mathrm{ab}}/T) \cong G(L_\pi/K) \cong \mathbb{Z}_p$ for which we know the Galois action well(12.6.2.24)(12.6.2.26), so $i(\sigma) = v(\sigma(\alpha_n) - \alpha_n) = v([\sigma - 1](\alpha))$, which jumps at U_K^n(the same pattern as $K = \mathbb{Q}_p$(12.2.2.29)), thus the result.

Example (12.6.2.31) [Cyclotomic Fields]. When $K=\mathbb{Q}_p$, we can choose $f(T)=(1+T)^p-1$, thus $L_{\varpi,n}$ is just $\mathbb{Q}_p(\zeta_{p^n})$. And we have $r_f=(1+T)^r-1$, thus we have

$$(a,\mathbb{Q}_p(\zeta_{p^n})/\mathbb{Q}_p)(\zeta_{p^n})=\zeta_{p^n}^r$$

where $a=up^m$, and $r\equiv u^{-1}(\mathrm{mod}\ p^n)$.

3 Global Class Field Theory

Notation (12.6.3.1).
- Let $F\in\mathtt{GField}$.

Prop. (12.6.3.2). Let $\mathfrak{P}$ be a prime of L lying over $\mathfrak{p}$, then $H^q(G,I_L^{\mathfrak{p}})\cong H^q(G_{\mathfrak{P}},L_{\mathfrak{P}}^*)$. If $\mathfrak{p}$ is a finite unramified prime of L, then $H^q(G,U_L^{\mathfrak{p}})=1$ for all q.

Proof: Notice $I_L^{\mathfrak{p}}=\prod_{\sigma\in G/G_{\mathfrak{P}}}L_{\sigma\mathfrak{P}}^*=\prod_{\sigma\in G/G_{\mathfrak{P}}}\sigma L_{\mathfrak{P}}^*$ is an induced module, so by(10.1.2.7), we have $H^q(G_{\mathfrak{P}},L_{\mathfrak{P}}^*)$, and similarly for $U_{\mathfrak{p}}$, which vanish by(12.6.2.2). □

Cor. (12.6.3.3).

$$H^q(G,I_L^S)=\bigoplus_{p\in S}H^q(G_{\mathfrak{P}/\mathfrak{p}},L_{\mathfrak{P}}^*),\quad H^q(G,I_L)=\bigoplus_{p}H^q(G_{\mathfrak{P}},L_{\mathfrak{P}}^*).$$

And the isomorphism is natural, by restriction to components.

Proof: For this, just notice $I_L=\cup_S I_L^S$, then use the last proposition, notice group cohomology commutes with colimits(10.1.2.2). □

Cor. (12.6.3.4). $H^1(G,\mathbf{I}_L)=H^3(G,\mathbf{I}_L)=0$, by(12.6.2.11).

Cor. (12.6.3.5). An idele $\mathfrak{a}\in\mathbf{I}_F$ is the norm of an idele $\mathfrak{b}$ in $\mathbf{I}_L$ if each component $\mathfrak{a}_{\mathfrak{p}}$ is the norm of an element $b_{\mathfrak{P}}\in L_{\mathfrak{P}}^*$.

Prop. (12.6.3.6). The decomposition commutes with inf, res and cor. Cf.[Neukirch CFT P125].

Cyclic Class Formations

Lemma (12.6.3.7). For a cyclic extension L/F of order p, C_L is a Herbrand module with Herbrand quotient $h(C_L)=p$.

Proof: □

Prop. (12.6.3.8) [First Fundamental Inequality]. $[C_F:\mathrm{Nm}_{L/F}C_L]\geq p$

Proof: □

Prop. (12.6.3.9). If $\mathbb{Q}(\zeta_p)\subset F$ and L/F is a cyclic extension of order p, then $[C_F:\mathrm{Nm}_{L/F}C_L]\leq p$.

Proof: □

Cor. (12.6.3.10) [Second Fundamental Inequality]. If L/F is a cyclic extension of order p, then $[C_F:\mathrm{Nm}_{L/F}C_L]=p$.

Proof: □

Cor. (12.6.3.11) [Hasse Norm Principle]. For a cyclic extension L/F and $a \in F^\times$, $a \in \mathrm{Nm}_{L/F} L^\times$ iff $a \in \mathrm{Nm}_{L/F}(\mathbf{I}_L)$.

Proof: Use the long exact sequence for $1 \to L^\times \to \mathbf{I}_L \to C_L \to 1$, we see that $H^0(G, L^\times) \to H^0(G, \mathbf{I}_L)$ is an injection, which is

$$F^\times / \mathrm{Nm}_{L/F} L^\times \hookrightarrow \bigoplus_p F_\mathfrak{p}^\times / \mathrm{Nm}_{L_\mathfrak{P}/F_\mathfrak{p}} L_\mathfrak{P}^\times.$$

In fact, by(12.6.3.4), we say that this is equivalent to $H^1(\mathrm{Gal}(L/K), C_L) = 1$, which is equivalent to second fundamental inequality. □

Remark (12.6.3.12). WARNING: the Hasse norm principle is not true for non-cyclic Galois extensions, for examples $\mathbb{Q}(\sqrt{13}, \sqrt{17})/\mathbb{Q}$.

General Class Formations

Prop. (12.6.3.13). For L/F normal, $\#H^2(G, C_L)|[L : F]$.

Proof: Cf.[Neukirch P137]. □

Prop. (12.6.3.14).

$$\mathrm{Br}(F) = \bigcup_{L/F \text{ cyclic}} H^2(\mathrm{Gal}(L/F), L^\times), \quad H^2(\mathrm{Gal}_K, \mathbf{I}_{\overline{K}}) = \bigcup_{L/K \text{ cyclic}} H^2(\mathrm{Gal}(L/K), \mathbf{I}_L).$$

Proof: Cf,[Neukirch P127]. □

Def. (12.6.3.15) [Invariant Maps]. For $c = (c_\mathfrak{p}) \in H^2(G_{L/K}, I_L)$, define the **invariant map**

$$\mathrm{inv}_{L/K} c = \sum_\mathfrak{p} \mathrm{inv}_{L_\mathfrak{P}/K_\mathfrak{p}} c_\mathfrak{p} \text{(12.6.2.9)}.$$

Prop. (12.6.3.16). If $c \in H^2(G_{L/K}, L^\times)$, then $\mathrm{inv}_{L/K}\, c = 0$.

Proof: Cf.[Neukirch P141]. □

Cor. (12.6.3.17). Now we can define the inv map for C_K. By the exact sequence $1 \to L^* \to I_L \to C_K \to 1$, we have

$$1 \to H^2(\mathrm{Gal}(L/K), L^*) \to H^2(\mathrm{Gal}(L/K), I_L) \to H^2(\mathrm{Gal}(L/K), C_L) \to H^3(G_{L/K}, L^*)$$

The last one is 1 if L/K is cyclic, thus tby this proposition, inv is defined for $H^2(G_{L/K}, C_L)$.

Prop. (12.6.3.18) [Reduce to Cyclic Case]. If L/K is normal and L'/K is cyclic with the same degree, then $H^2(L'/K) = H^2(L/K) \subset H^2(\overline{K}/K)$.

Proof: □

Cor. (12.6.3.19). $H^2(\overline{K}/K) = \cup_{L/K \text{ cyclic}} H^2(L/K)$, thus the homomorphism $H^2(\mathrm{Gal}_K, I_{\overline{K}}) \to H^2(\overline{K}/K)$ is surjective by(12.6.3.17).

Proof: Why can always find such a cyclic extension**?**. □

Cor. (12.6.3.20). The inv map is defined for $H^2(\overline{K}/K)$, and $\mathrm{inv}_{L/K} : H^2(L/K) \to \frac{1}{[L:K]}\mathbb{Z}/\mathbb{Z}$ is an isomorphism for every normal extension L/K.

Lemma (12.6.3.21) [Main Lemma]. The formation $(\mathrm{Gal}_F, C_{F^{\mathrm{sep}}}, \mathrm{inv}_F)$ is a class formation(12.6.1.1).

Proof: □

Thm. (12.6.3.22) [Artin's Reciprocity Law, Artin1927]. By(12.6.1.4), cup product with fundamental classes $u_{L/F} \in H^2(L/F)$ define an isomorphism

$$\theta_{L/F} : \mathrm{Gal}^{\mathrm{ab}}(L/F) \cong H^{-2}(\mathrm{Gal}(L/F), \mathbb{Z}) \to H^0(L/F) = C_F/\,\mathrm{Nm}_{L/F} C_L,$$

called the **Nakayama isomorphism**. And the reverse map is called the **norm residue symbol** map $(-, L/F)$

$$1 \to \mathrm{Nm}_{L/F} C_L \to C_F \xrightarrow{(-,L/F)} \mathrm{Gal}^{\mathrm{ab}}(L/F) \to 1.$$

This norm residue symbols induce an **Artin map**

$$\mathrm{Art}_F = (-, F) : C_F \to \mathrm{Gal}_F^{\mathrm{ab}}$$

Prop. (12.6.3.23) [Local-Global Compatibility]. For L/F and $\mathfrak{a} \in I_F$:

$$(\mathfrak{a}, L/F) = \prod_{\mathfrak{p}} (a_{\mathfrak{p}}, L_{\mathfrak{P}}/K_{\mathfrak{p}}) \in \mathrm{Gal}^{\mathrm{ab}}(L/F)(12.6.2.12).$$

In particular, if $v \in \Sigma_F^{\mathrm{fin}}$ is unramified in L, then

$$([\varpi_{\mathfrak{p}}]_{\mathfrak{p}}, L/F) = \varphi_{L_{\mathfrak{P}}/F_{\mathfrak{p}}} \in \mathrm{Gal}_{L_{\mathfrak{P}}/F_{\mathfrak{p}}} \subset \mathrm{Gal}_F\,.$$

Proof: Cf.[Neukirch CFT P154]. □

Prop. (12.6.3.24). There are commutative diagrams:

$$\begin{array}{ccc} C_F & \xrightarrow{(-,N/F)} & \mathrm{Gal}(N/F)^{\mathrm{ab}} \\ \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle \mathrm{pr}} \\ C_F & \xrightarrow{(-,L/F)} & \mathrm{Gal}(L/F)^{\mathrm{ab}} \end{array} \qquad \begin{array}{ccc} C_F & \xrightarrow{(-,N/F)} & \mathrm{Gal}(N/F)^{\mathrm{ab}} \\ {\scriptstyle \mathrm{Nm}_{L/F}}\uparrow\downarrow{\scriptstyle i} & & {\scriptstyle i}\uparrow\downarrow{\scriptstyle \mathrm{Ver}} \\ C_L & \xrightarrow{(-,N/L)} & \mathrm{Gal}(N/L)^{\mathrm{ab}} \end{array} \qquad \begin{array}{ccc} C_L & \xrightarrow{(-,N/L)} & \mathrm{Gal}(N/L)^{\mathrm{ab}} \\ \downarrow{\scriptstyle \sigma} & & \downarrow{\scriptstyle \sigma^*} \\ C_{\sigma L} & \xrightarrow{(-,\sigma N/\sigma L)} & \mathrm{Gal}(\sigma N/\sigma L)^{\mathrm{ab}} \end{array}$$

Where Ver is the transfer map defined in**??**.

Proof: □

Cor. (12.6.3.25). By(12.6.1.8), the map $L \mapsto \mathcal{N}_{L/F} = \mathrm{Nm}_{L/F} C_L$ defines a inclusion reversing isomorphism between the lattice of Abelian extension L/K and the lattice of norm groups of C_F, i.e.:

$$\mathcal{N}_{L_1L_2/F} = \mathcal{N}_{L_1/F} \cap \mathcal{N}_{L_2/F}, \quad \mathcal{N}_{L_1\cap L_2/F} = \mathcal{N}_{L_1/F} \cdot \mathcal{N}_{L_2/F}.$$

And any group that contains a norm group is a norm group.

Prop. (12.6.3.26) [Existence Theorem]. The norm groups of C_F are precisely the (open)closed subgroups of finite index.

Proof: Cf.[Neukirch P162] or notes taken by Chao Li.? □

Cor. (12.6.3.27) [The Kernel of Art_F].

- If F is a number field, the kernel $\cap_{L/F}\mathcal{N}_{L/F}$ of Art_F is exactly the connected component D_F of $1 \in C_K$, which is the group of divisible elements in C_K(12.4.5.29). Moreover, $\mathrm{Art}_F : C_F/D_F \to \mathrm{Gal}_F^{\mathrm{ab}}$ is an isomorphism.
- If F is a global function field, then $(-, F)$ is injective but not surjective. In fact, there is an exact sequence(? by etale fundamental group)

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathbf{I}_F^1/F^\times & \longrightarrow & \mathbf{I}_F/F^\times & \longrightarrow & q^{\mathbb{Z}} & \longrightarrow & 0 \\ & & \downarrow\cong & & \downarrow(-,F) & & \downarrow & & \\ 0 & \longrightarrow & I_F^{\mathrm{ab}} & \longrightarrow & \mathrm{Gal}_F^{\mathrm{ab}} & \longrightarrow & \mathrm{Gal}_k \cong \widehat{\mathbb{Z}} & \longrightarrow & 0 \end{array}$$

thus C_F can be regarded as the Weil group of F.

Proof: 1: As $\mathrm{Gal}_F^{\mathrm{ab}}$ is totally disconnected, it must factors through D_F. But C_F/D_F is a profinite group, thus D_F is an intersection of open subgroups of finite index, thus it is in the kernel, by(12.6.3.26).

2: The map is injective because by splitting it is a product of $q^{\mathbb{Z}}$ and a profinite group, thus the intersection of open subgroups of finite index is trivial(12.6.3.26). To show the diagram is commutative, it suffices to show that (x, F) acts as $\mathrm{Frob}_k^{|x|_F}$ on $\overline{k}$: This is because on any finite unramified Abelian extension L/F, (x, F) acts via $\varphi_{L_w/F_v}^{|x_v|_v}$ by definition(12.6.2.4), and these add up to $|x|_v$ as L/F is cyclic. □

Cor. (12.6.3.28). 1: If F is a number field, there is an inclusion reversing isomorphism between the lattice of Abelian extensions L/F and the lattice of closed subgroups of C_F containing the image of $(I_{F,\infty}^0)$, by(12.6.1.8) and(12.4.5.29). To show it is surjective, notice that

4 Decomposition Law

Prop. (12.6.4.1). If L/F is an Abelian extension, then $\mathcal{N}_{L/K} \cap K_{\mathfrak{p}}^\times = \mathcal{N}_{L_{\mathfrak{P}}/K_{\mathfrak{p}}}$.

Proof: For the non-trivial part, notice if $\mathfrak{a} \in N_{\mathfrak{P}}L_{\mathfrak{P}}^*$ is a norm times a $a \in K^*$, then it is a norm at all primes except $\mathfrak{p}$, thus it is also norm at $\mathfrak{p}$ by the multiplicative definition of the inv map(12.6.3.15). □

Cor. (12.6.4.2)[Ramifications]. Let L/K be an Abelian extension of global fields and $\mathcal{N} = \mathrm{Nm}_{L/K} C_L$ be the norm group, then

- $\mathfrak{p}$ is unramified in L iff $\mathcal{O}_{F,\mathfrak{p}}^* \subset \mathcal{N}_{L/F}$.
- $\mathfrak{p}$ splits completely in L iff $F_{\mathfrak{p}}^\times \subset \mathcal{N}_{L/F}$.

Proof: □

Prop. (12.6.4.3) [Decomposition Law]. Let L/F is an Abelian extension of degree n and $\mathfrak{p} \in \Sigma_F$ is an unramified place of F and $\varpi_{\mathfrak{p}}$ is a uniformizer, then if f is the smallest positive integer s.t. $[\varpi_{\mathfrak{p}}]_{\mathfrak{p}}^f \in \mathcal{N}_{L/F}$, then $\mathfrak{p}$ factors in the extension L into $r = n/f$ distinct primes of degree f.

Notice to determine whether a place is ramified or not, we use conductors(12.6.4.17).

Proof: The degree the extension of $\mathfrak{p}$ is just the order of the Frobenius automorphism of $G_{\mathfrak{P}/\mathfrak{p}}$, which is just the order in $\mathrm{Gal}(L/F) \cong C_F/\mathrm{Nm}_{L/F} C_L$. The Frobenius of $\mathfrak{p}$ correspond exactly to $(\ldots, 1, \pi, 1, \ldots)$ by(12.6.3.23) and(12.6.2.4), so the result follows. □

Prop. (12.6.4.4) [Unramified Kummer Extensions are Rare]. Let F be a global field or the function field of a smooth curve over an alg.closed field k, and $S \subset \Sigma_F$ be a finite set of places, and $m \in \mathbb{Z} \cap F^*$, then there are only f.m. Kummer extensions over F that have Galois group of exponent m and are unramified at all finite places outside S.

Proof: We may add all the m-th roots of unity to F. Then by Kummer theory(2.2.7.9), Kummer extensions of exponent m over F corresponds to $F(\sqrt[m]{a})$, where $a \in F$. But we can only add those a s.t. $\mathrm{ord}_v(a) \equiv 0 \mod m$ in order to get unramified extensions, so the desired Kummer extensions correspond to

$$T_S = \{a \in F^\times/(F^\times)^n | \mathrm{ord}_v(a) \equiv 0 \mod m, \forall v \in \Sigma_K^0 \backslash S\}.$$

If F is a global field, after enlarging S, we may assume $\mathcal{O}_{K,S}$ is PID, then this group is a quotient of $\mathcal{O}_{K,S}^*/\mathcal{O}_{K,S}^m$, which is finite by unit theorem(12.4.5.30). If $F = K(C)$, where C is a complete non-singular curve, then by Riemann-Roch there is an exact sequence

$$0 \to T_\varnothing \to T_S \to (\mathbb{Z}/(m))^{\# S} \to 0$$

And for $f \in T_\varnothing$, $\mathrm{div}(f) = mD_f$ for some $D_f \in \mathrm{Pic}(C)[m]$. Notice $\#\mathrm{Pic}(C)[m] < \infty$ by(5.11.2.18), thus the theorem follows. □

Ray Class Fields

Def. (12.6.4.5) [Notations].

- A **modulus** $\mathfrak{m}$ is a a formal product $\prod_{\mathfrak{p} \in \Sigma_F} \mathfrak{p}^{e_\mathfrak{p}}$ where $e_\mathfrak{p} \geq 0$, and $e_\mathfrak{p} = 0$ if $\mathfrak{p} \in \Sigma_F^{\mathbb{C}}$, and $e_\mathfrak{p} = 0, 1$ if $\mathfrak{p} \in \Sigma_F^{\mathbb{R}}$.
- For a modulus $\mathfrak{m}$,

$$U^\mathfrak{m} = \prod_{v \in \Sigma_F^\infty, e_v = 0} F_v^\times \times \prod_{v \in \Sigma_F^\mathbb{R}, e_v = 1} \mathbb{R}_+^\times \times \prod_{\mathfrak{p} \in \Sigma_F^{\mathrm{fin}}, e_\mathfrak{p} = 0} F_\mathfrak{p} \times \prod_{\mathfrak{p} \in \Sigma_F^{\mathrm{fin}}, e_\mathfrak{p} > 0} (1 + \mathfrak{p}^{e_\mathfrak{p}}) \subset \mathbf{I}_F$$

  and $C^\mathfrak{m}$ is the image of $U^\mathfrak{m}$ in C_F, which is an open subgroup of finite index.

Def. (12.6.4.6) [Ray Class Fields]. For a modulus $\mathfrak{m}$,

- $F_\mathfrak{m}$ is defined to be the Abelian extension corresponding to $C^\mathfrak{m}$(12.6.3.26), called the **ray class field** of $\mathfrak{m}$. in particular, $\mathrm{Gal}(F_\mathfrak{m}/F) \cong C_F/C^\mathfrak{m}$.
- $J^\mathfrak{m}$ is defined to be the group of all ideals of $\mathcal{O}_F$ relatively prime to $\mathfrak{m}$, $P^\mathfrak{m} = F^\times \cap U^\mathfrak{m}$, called the **ray mod** $\mathfrak{m}$.

Def. (12.6.4.7) [Ray Class Groups]. For a modulus $\mathfrak{m}$,

$$\mathrm{Cl}_\mathfrak{m}(F) = J^\mathfrak{m}/P^\mathfrak{m} \cong C_F/C^\mathfrak{m} \cong \mathrm{Gal}(F^\mathfrak{m}/F)$$

is finite, called the **ray class group** of $\mathfrak{m}$.

Proof: This is because $\mathrm{Cl}_{\mathfrak{m}}(F)$ is a quotient group of $I_F/U^{\mathfrak{m}}$, which is finite. □

Prop. (12.6.4.8). Any finite Abelian extension is contained in a finite

Cor. (12.6.4.9) [Cyclotomic Fields]. When $F=\mathbb{Q}, m\in\mathbb{Z}_+$ and $\mathfrak{m}=m\cdot\infty$, $\mathbb{Q}_{\mathfrak{m}}=\mathbb{Q}(\zeta_m)$.

In particular, we can think of the ray classes fields for general function fields as "generalized cyclotomic fields".

Proof: For any $p\in\mathbf{P}$, let $m=\mathfrak{p}^{e_p}\times m'$, then $\mathbb{Q}(\zeta_m)=\mathbb{Q}(\zeta_{p^{e_p}})\mathbb{Q}(\zeta_{m'})$. Notice both $\mathcal{N}_{\mathbb{Q}(\zeta_{p^{e_p}})/\mathbb{Q}}$ and $\mathcal{N}_{\mathbb{Q}(\zeta_{m'})/\mathbb{Q}}$ contains $(1+\mathfrak{p}^{e_p})$ by(12.6.2.31)(12.6.2.27) and(12.6.2.5). Thus by(12.6.3.25), the $\mathcal{N}_{\mathbb{Q}(\zeta_m)/\mathbb{Q}}$ als contains $(1+\mathfrak{p}^{e_p})$. Thus $U^{\mathfrak{m}}$ is contained in $\mathrm{Nm}_{\mathbb{Q}(\zeta_m)/\mathbb{Q}} I_{\mathbb{Q}(\zeta_m)}$.

To show the reverse inclusion, we calculate $(C_{\mathbb{Q}}:C^{\mathfrak{m}})$. As $(C_{\mathbb{Q}}:C^1_{\mathbb{Q}})=\mathrm{Cl}(\mathbb{Q})=1$,

$$(C_{\mathbb{Q}}:C^{\mathfrak{m}})=(U^1_{\mathbb{Q}}\mathbb{Q}^\times:U^{m\infty}_{\mathbb{Q}}\mathbb{Q}^\times)=(U^1_{\mathbb{Q}}:U^{m\infty}_{\mathbb{Q}})(U^1_{\mathbb{Q}}\cap\mathbb{Q}^\times:U^{m\infty}_{\mathbb{Q}}\cap\mathbb{Q}^\times)=\varphi(m)=[\mathbb{Q}(\zeta_m):\mathbb{Q}].$$

□

Cor. (12.6.4.10) [Kronecker]. Every Abelian extension $F/\mathbb{Q}$ is a subfield of $\mathbb{Q}(\zeta_m)$ for some $m\in\mathbb{Z}_+$.

Def. (12.6.4.11) [Hilbert Class Fields]. The ray class field mod 1 is important, it is the **Hilbert class field** of F, denoted by F_1. Its Galois group is isomorphic to $C_K/C^1_K\cong J_K/P_K$(12.6.4.7). In particular, $[F_1:F]=h(F)$.

Conductors

Def. (12.6.4.12) [Admissible Modulus].

- For an Abelian extension of global fields L/F, an **admissible modulus** for L/F is a modulus $\mathfrak{m}$ s.t. $C^{\mathfrak{m}}\subset\mathrm{Nm}_{L/F} C_L$ or equivalently $L\subset F_{\mathfrak{m}}$(12.6.4.6).
- All subgroups of $\mathrm{Cl}_{\mathfrak{m}}(F)$(12.6.4.7) are called **ideal groups defined mod** $\mathfrak{m}$.
- If L/F is an Abelian extension with an admissible modulus $\mathfrak{m}$, then $H^{\mathfrak{m}}_{L/F}=\mathrm{Nm}_{L/F} J^{\mathfrak{m}}_L\cdot P^{\mathfrak{m}}_F$ is called the **ideal group defined mod** $\mathfrak{m}$.

Prop. (12.6.4.13). For an Abelian extension L/F, a modulus $\mathfrak{m}$ is admissible for L/F iff $U^{\mathfrak{m}}\subset N_{L/F}(I_L)$.

Proof: This is because $\mathcal{N}_{L/F}\cap K_p=\mathcal{N}_{L_{\mathfrak{P}}/K_{\mathfrak{p}}}$ by(12.6.4.1). □

Cor. (12.6.4.14). The norm subgroups of C_F are exactly those containing some $C^{\mathfrak{m}}$.

Proof: This is because $\mathcal{N}_{L/F}A_L$ is open in A_K, by(12.4.5.24), so it must contain some $U^{\mathfrak{m}}$. The converse is also clear. □

Def. (12.6.4.15) [Conductors]. For an Abelian extension of global fields L/F, by(12.6.4.14), there is a minimal admissible modulus for L/F, called the **conductor of** L/F, denoted by $\mathfrak{f}_{L/F}$.

Prop. (12.6.4.16) [Local and Global Conductors]. For an Abelian extension L/F,

$$\mathfrak{f}_{L/F}=\prod_{\mathfrak{p}\in\Sigma_F}\mathfrak{f}_{L_{\mathfrak{P}}/F_{\mathfrak{p}}}(12.6.2.16).$$

Proof: This follows from(12.4.5.24). □

Cor. (12.6.4.17) [Conductor Detects Ramifications]. Let L/F be an Abelian extension, then $\mathfrak{p} \in \Sigma_F$ is ramified in L/F iff $\mathfrak{p} \mid \mathfrak{f}_{L/F}$, by(12.6.2.16).

In particular, $\mathrm{Ram}(F_{\mathfrak{m}}/F) = S(\mathfrak{m})$.

Prop. (12.6.4.18). For a field K, if S is a finite set of primes that contains all the infinite primes and all the primes lying above the primes dividing n, and $I_K = I_K^S \cdot K^*$, then $C_K^n \cdot U_K^S$ is a norm group. If K contains the n-th roots of unity, then it corresponds to the Kummer extension $T = K(\sqrt[n]{K^S}/K)$.

Hilbert Class Fields

Prop. (12.6.4.19). The Hilbert class field F_1(12.6.4.11) is the maximal unramified Abelian extension of F, by(12.6.4.17).

Def. (12.6.4.20) [Hilbert Class Field Tower]. Let F be a global field, then let F_1 be the Hilbert class field of F, and for any $n \in \mathbb{Z}_+$, let F_{n+1} be the Hilbert class field of F_n, then such a series of extensions is called the **Hilbert class field tower** of F.

Similarly for $p \in \mathbf{P}$, we can consider the maximal Abelian p-extensions of F, which gives us a series

$$F \subset F_1^{(p)} \subset F_2(p) \subset \ldots \subset F_\infty^{(p)}.$$

Prop. (12.6.4.21). Let F be a global field, then each F_n is Galois over F, and F_1 is the largest Abelian subfield of F_2/F.

Proof: For the last assertion, notice that that largest Abelian subfield of F_2/F is unramified Abelian over F, then use(12.6.4.19). □

Prop. (12.6.4.22) [Principal Ideal Theorem]. In the Hilbert class field over F, every ideal $\mathfrak{a}$ of F becomes a principal ideal.

Proof: As $J_F/P_F \cong C_F/C_F^1$, It suffices to show that the map $i : C_F \to C_{F_1}$ has image in $C_{F_1}^1$. By the commutative diagram(12.6.3.24)

$$\begin{array}{ccccccccc} & & & & C_K & \xrightarrow{(-,F_2/F)} & \mathrm{Gal}(F_2/F)^{\mathrm{ab}} & & \\ & & & & \downarrow i & & \downarrow \mathrm{Ver} & & \\ 0 & \longrightarrow & C_{F_1}^1 & \longrightarrow & C_{F_1} & \xrightarrow{(-,F_2/F_1)} & \mathrm{Gal}(F_2/F_1)^{\mathrm{ab}} & \longrightarrow & 0 \end{array}$$

It suffices to show that Ver is trivial. Then this follows from(12.6.4.21) and(2.1.10.3). □

Thm. (12.6.4.23) [Brumer]. Let $F \in \mathtt{NField}, p \in \mathbf{P}$, and $t_F^{(p)}$ be the number of primes $\ell \in \mathbf{P}$ s.t. $p | e_{\mathfrak{L}/\ell}$ for any prime $\mathfrak{L}$ above ℓ, then

$$\dim_{\mathbb{F}_p} \mathrm{Cl}(F)/(p) \geq t_F^{(p)} - 2(d-1)$$

Proof: □

Prop. (12.6.4.24)[Golod-Šafarevič]. Let F be a number field of degree d and $p \in \mathbf{P}$, if $[F_\infty^{(p)} : F] < \infty$, then

$$\dim_{\mathbb{F}_p} \mathrm{Cl}(F)/p\,\mathrm{Cl}(F) \leq 1 + 2\sqrt{d+1}.$$

Proof: □

Cor. (12.6.4.25). By(12.6.4.23), if $t_F^{(p)} \geq 2d + 2\sqrt{d+1}$, then $[F_\infty^{(p)} : F] = \infty$.

For example, if we take $F = \mathbb{Q}(\sqrt{d})$ where d is square-free with at least 8 different prime factors, then $[F_\infty^{(p)} : F] = \infty$.

Classical Formulation

Def. (12.6.4.26) [Artin Symbols]. There is a homomorphism $J^\mathfrak{m} \to \mathrm{Gal}(L/K)$ called the **Artin symbol** $(\frac{L/K}{-})$. On primes $\mathfrak{p}$, it maps a prime $\mathfrak{p}$ which is unramified by(12.6.4.12) to its local Frobenius $\mathrm{Frob}_\mathfrak{p} \in G_{\mathfrak{P}/\mathfrak{p}} \subset G_{L/K}$. This is well-defined only up to conjugacy in $\mathrm{Gal}(L/K)$, and thus well-defined when L/K is Abelian.

Lemma (12.6.4.27). If $\mathfrak{m}$ is an admissible modulus for L/K, the restriction to finite part defines isomorphism $\mathcal{N}_{L/F}/C^\mathfrak{m} \cong H^\mathfrak{m}_{L/F}/P^\mathfrak{m}$.

Proof: Cf.[Neukirch CFT P176]. □

Prop. (12.6.4.28) [Classical Artin Reciprocity Law]. If L/K is an Abelian extension and $\mathfrak{m}$ is an admissible modulus, then there is a commutative diagram

$$\begin{array}{ccccccccc} 1 & \longrightarrow & \mathcal{N}_{L/K} & \longrightarrow & C_K & \xrightarrow{(-,L/K)} & G_{L/K} & \longrightarrow & 1 \\ & & \downarrow & & \downarrow & & \| & & \\ 1 & \longrightarrow & H^\mathfrak{m}_{L/K}/P^\mathfrak{m} & \longrightarrow & J^\mathfrak{m}/P^\mathfrak{m} & \xrightarrow{(\frac{L/K}{-})} & G_{L/K} & \longrightarrow & 1 \end{array}$$

Thus the second row is exact by(12.6.3.22), and $\mathrm{Gal}(L/K) \cong J^\mathfrak{m}/H^\mathfrak{m}_{L/K}$.

Proof: Cf.[Neukirch CFT, P178]. □

Prop. (12.6.4.29) [Decomposition Law]. Let L/F is an Abelian extension of degree n with an admissible modulus $\mathfrak{m}$(e.g. the conductor) and $\mathfrak{p} \nmid \mathfrak{m}$. then if f is the smallest number that $\mathfrak{p}^f \in H^\mathfrak{m}_{L/F}$, then $\mathfrak{p}$ factors in the extension L into $r = n/f$ distinct primes of degree f.

Proof: The degree the extension of $\mathfrak{p}$ is just the order of the Frobenius automorphism of $G_{\mathfrak{P}/\mathfrak{p}}$, which is just the order in $G_{L/K} \cong J^\mathfrak{m}/H^\mathfrak{m}$. The Frobenius of $\mathfrak{p}$ correspond exactly to $\mathfrak{p}$ by(12.6.2.4), so the result follows. □

n-th Powers

Cf.[A-T67]Chap9,10.

Prop. (12.6.4.30) [Grünwald-Wang]. Let $F \in \texttt{GField}$, $n = 2^t \cdot m \in \mathbb{Z}_+$, and assume $F \in \texttt{FField}$ or $F(\zeta_{2^t})/F$ is cyclic. Then $a \in F$ is in F^n iff $a \in F_v^n$ for a.e. $v \in \Sigma_F$.

Proof: Cf.[Chao Li's notes] or [Mil20]P229. □

Thm. (12.6.4.31) [Grünwald-Wang]. Let $F \in \texttt{GField}$, then for any $S \subset \Sigma_F$ finite, if for each $v \in S$, χ'_v is a continuous character of $F_v^\times$ of finite order n_v, then there exists a Hecke character χ of F with the $\chi_v = \chi'_v$. Moreover, if $n = \mathrm{lcm}(n_v), t = \mathrm{ord}_2(n)$, and assume $F \in \texttt{FField}$ or $F(\zeta_{2^t})/F$ is cyclic, then χ can be taken to be of order n.

Proof: Cf.[Chao Li's notes] or [Artin-Tate, Class Field Theory, Thm10.5].**?** □

Cor. (12.6.4.32) [Local-Global Compatibility for Cyclic Extensions]. Let $F \in \texttt{GField}$ and for each $v \in \Sigma_F$, a positive integer n_v is given s.t.

- For a.e. v, $n_v = 1$.
- For $v \in \Sigma_F^{\mathbb{R}}$, $n_v \in \{1, 2\}$.
- For $v \in \Sigma_F^{\mathbb{C}}$, $n_v = 1$.

Proof: The point is that we can choose χ_v s.t. the exceptions in(12.6.4.31) can be avoided, and then get a Hecke character χ of F or order n which corresponds to a cyclic extension via cyclic class formation. **?**Cf.[Artin-Tate, Class Field Theory, Thm10.5, P105].**?** □

Higher Reciprocity Law

Cf.[Mil20]Chap8.

Prop. (12.6.4.33) [Quadratic Reciprocity].

Prop. (12.6.4.34) [Cubic Reciprocity].

Prop. (12.6.4.35) [Quadric Reciprocity].

5 L-Series and Dirichlet Density

Def. (12.6.5.1). In this subsection, for two functions $f(s), g(s) : (1, \infty) \to \mathbb{C}$, write $f \overset{1}{\sim} g$ iff $f - g$ is bounded on $(1, 1 + \varepsilon)$ for some $\varepsilon > 0$.

Def. (12.6.5.2) [Densities]. Let F be a number field and $T \subset \Sigma_K^{\text{fin}}$, then T is said to have

- **polar density** $m/n \in \mathbb{Q}$ if
$$\zeta_{F,T} = \prod_{v \in T} \frac{1}{1 - ||v||^{-s}}$$
satisfies $\zeta_{F,T}^n$ extends to a nbhd of $s = 1$ with a pole of order n.
- **Dirichlet density** δ iff
$$\sum_{\mathfrak{p} \in T} \frac{1}{(N\mathfrak{p})^s} \overset{1}{\sim} \frac{\delta}{s - 1}.$$
- **natural density** δ if
$$\lim_{x \to \infty} \frac{\# T \cap \{\mathfrak{p} \in \Sigma_F^0 | N\mathfrak{p} \leq x\}}{\#\{\mathfrak{p} \in \Sigma_F^0 | N\mathfrak{p} \leq x\}} = \delta.$$

Prop. (12.6.5.3). If the polar density exists, then so does the Dirichlet density, and they are equal. If the natural density exists, then so does the Dirichlet density, and they are equal.

Proof: Cf.[Mil20]P194. □

Thm. (12.6.5.4) [Effective Chebotarev]. Let L/F be a finite Galois extension of number fields, then for any subset $C \subset \mathrm{Gal}(L/F)$ that is stable under conjugation, for $X > 0$, let
$$\pi_C(X) = \{\mathfrak{p} \in \Sigma_F | (\mathfrak{p}, L/F) \in C, ||\mathfrak{p}|| \leq C\},$$
then
$$\#\pi_C(x) = \frac{\# C}{\#\,\mathrm{Gal}(L/F)} \frac{X}{\log X} + O(\frac{X}{\log X}).$$

Proof: Cf.[Lagarias and Odlysko (Algebraic Number Fields, Ed. Frohlich, 1977)]. Cf.[Mil20]P259. □

Cor. (12.6.5.5) [Chebotarev]. Let L/F be a finite Galois extension of number fields, then for any subset $C \subset \mathrm{Gal}(L/F)$ that is stable under conjugation, let

$$T = \{\mathfrak{p} \in \Sigma_K^0 | \mathfrak{p} \text{ unramified in } L, (\mathfrak{p}, L/F) \subset C\},$$

then T has Dirichlet density $\delta(T) = \#C/\#\mathrm{Gal}(L/F)$.

Proof: This follows from(12.6.5.4) and the prime number theorem**?**. □

Prop. (12.6.5.6) [Chebotarev for Function Fields]. Cf.[Sta].

Splitting of Primes

Def. (12.6.5.7) [Splitting Sets]. Let L/F be a finite separable extension of global fields, let $\mathrm{Spl}(L/F) \subset \Sigma_F^{\mathrm{fin}}$ be the set of finite places of F that splits completely in L. By(4.2.7.28), If N/F is the Galois closure of L/F, then $\mathrm{Spl}(N/F) = \mathrm{Spl}(L/F)$.

Prop. (12.6.5.8) [Splitting in Cyclotomic Fields]. Let $L/\mathbb{Q}$ be Galois, then $L \in \mathbb{Q}(\zeta_m)$ for some $m \in \mathbb{Z}_+$ by(12.6.4.10), and let $\Lambda = \mathcal{N}_{L/\mathbb{Q}}/C^{\mathfrak{m}} \subset (\mathbb{Z}/(m))^*$ corresponds to L, then $p \in \mathbf{P}$ splits in L iff $p(\mathrm{mod}\ m) \in \Lambda$.

Cor. (12.6.5.9) [Dirichlet's Problem]. By(12.6.5.4) and(12.6.5.8), for any $m \in \mathbb{Z}_+$ and $[a] \in (\mathbb{Z}/(m))^\times$, there exists i.m. $p \in \mathbf{P}$ s.t. $p \equiv a(\mathrm{mod}\ m)$.

Prop. (12.6.5.10) [Frobenius]. If L/K is a finite Galois extension of global fields, then $\mathrm{Spl}(L/K)$ has Dirichlet density $1/[L:K]$.

Proof: For $v \in \Sigma_F^{\mathrm{fin}}$ unramified, it splits in L iff $(\mathfrak{p}_v, L/F) = \mathrm{id}$, by(12.6.3.23). So we can use Chebotarev theorem(12.6.5.5) for $C = \{\mathrm{id}\}$. □

Cor. (12.6.5.11). If $L/F, L/F'$ satisfies $\mathrm{Spl}(L/F) = \mathrm{Spl}(L'/F)$, then $L = L'$.

Proof: The hypothesis implies that $\mathrm{Spl}(L/F) = \mathrm{Spl}(LL'/F) = \mathrm{Spl}(L'/F)$, which then implies $L = LL' = L'$, by(12.6.5.10). □

Cor. (12.6.5.12). If L/K is a finite separable extension of global fields s.t. $\mathrm{Spl}(L/K)$ has Dirichlet density $[L:K]$, then L/K is Galois, by(12.6.5.7).

Cor. (12.6.5.13). If L/K is a finite separable extension of global fields s.t. $\mathrm{Spl}(L/K)$ has Dirichlet density 1, then $L = K$, by(12.6.5.7).

6 Explicit Construction of Class Fields

The explicit class field theory is the subject that tries to write the maximal Abelian extension of a field K as splitting field of polynomials.

Prop. (12.6.6.1) [Known Cases].

- $\mathbb{Q}^{ab} = \mathbb{Q}(\zeta_\infty)$(12.6.4.10).
- If $F \in$ `FField`, the theory of Drinfeld modules gives most Abelian extensions of F**?**.

- If $K \in p$-NField, K^{ab} is given by adjoining all torsion points of Lubin-Tate formal groups over K(12.6.2.29).
- If $F \in$ NField is a CM field, then by Kronecker's Jugendtraum(13.6.6.9), the Abelian extensions of F are given by j-invariants and torsion points of elliptic curves over F with CM.
- If $F \in$ NField is totally real, the conjecture of Stark gives all the Abelian extensions.?

7 Classical problems

$p = x^2 + ny^2$

References are [Primes of the form $x^2 + ny^2$, Cox].

Thm. (12.6.7.1). For $n \in \mathbb{Z}_+$, there is a monic irreducible polynomial $f_n(T) \in \mathbb{Z}[T]$ of degree $h(-4n)$ s.t.:

For $p > 2 \in \mathbf{P}$ dividing neither n nor the discriminant of $f_n(T)$,

$$p \in \{x^2 + ny^2 | x, y \in \mathbb{Z}\} \iff \left(\frac{-n}{p}\right) = 1 \vee \{x \in \mathbb{Z} | f_n(x) = 0 \in \mathbb{F}_p\} \neq \varnothing.$$

Moreover, $f_n(T)$ is the minimal polynomial of a real algebraic integer α s.t. $L = K(\alpha)$ is ring class field of the order $\mathbb{Z}[\sqrt{-n}] \in K = \mathbb{Q}(\sqrt{-n})$, and any such f is of this form.

Proof: Cf.[Cox, $p = x^2 + ny^2$]P163.? □

8 Local Field cases

Poitou-Tate Duality

Artin-Verdier Duality

9 Global Field cases

Poitou-Tate Duality

Artin-Verdier Duality

10 Inverse Galois Problem

p-adic Case

Prop. (12.6.10.1) [Abhyankar's conjecture, Raynaud]. A finite group Γ is the Galois group of an unramified Galois covering of $\mathbb{A}^1_{\overline{\mathbb{F}}_p}$ iff it is generated by its p-Sylow subgroups.

Proof: □

Solvable Groups

Thm. (12.6.10.2) [Šafarevič]. For $F \in$ GField and $G \in \mathcal{A}b^{\text{fin}}$ is solvable, then there exists a Galois extension L/F s.t. $\text{Gal}(L/F) \cong G$.

Proof: Cf.[Cohomology of Number Fields, Neukirch]. □

Arithmetic Statistics

Thm. (12.6.10.3). For $\xi, \eta \in \mathbb{R}$, let $N_3(\xi, \eta)$ be the isomorphism classes of cubic fields $\mathcal{K}$ s.t. $d_{\mathcal{K}} \in (\xi, \eta)$. Then

$$\lim_{X\to\infty} \frac{N_3(0,X)}{X} = \frac{1}{12\zeta(3)}, \quad \lim_{X\to\infty} \frac{N_3(-X,0)}{X} = \frac{1}{4\zeta(3)}.$$

Proof: Cf.[On the density of discriminants of cubic fields, Davenport-Heilbronn]. □

Thm. (12.6.10.4) [Bhargava]. For $\xi, \eta \in \mathbb{R}$, let $N_n(\xi, \eta)$ be the isomorphism classes of cubic fields $\mathcal{K}$ s.t. $d_{\mathcal{K}} \in (\xi, \eta)$. Then for $n = 4$ or 5,

$$\lim_{X\to\infty} \frac{N_n(-X,X)}{X}$$

exists.

Proof: Cf.[The density of discriminants of quartic rings and fields], [The density of discriminants of quintic rings and fields]. □

12.7 Transcendental Number Theory

1 Transcendental Numbers

Prop. (12.7.1.1) [Lindemann1882]. If $\alpha \in \overline{\mathbb{Q}}$, then $e^\alpha \notin \overline{\mathbb{Q}}$.

Proof: □

Cor. (12.7.1.2). π and e are not in $\overline{\mathbb{Q}}$.

Proof: $e^{2\pi\mathrm{i}} = 1$, and $e^1 = e$. □

Prop. (12.7.1.3). If $\alpha, \beta \in \overline{\mathbb{Q}}$ with $\alpha \neq 0, 1$ and $\beta \notin \overline{\mathbb{Q}}$, then $\alpha^\beta \notin \overline{\mathbb{Q}}$.

Proof: Cf.[Sil16]P286. □

Cor. (12.7.1.4). $(\sqrt{2})^{\sqrt{2}} \notin \overline{\mathbb{Q}}$.

2 Periods

Main references are [Periods, Zagier].

Def. (12.7.2.1) [Algebraic Functions]. Let F be a field contained in $\mathbb{C}$, then an **algebraic function** of degree $d \in \mathbb{Z}_+$ in n variable over F is a function $f(\underline{X}) \in C(\mathbb{R}^n)$ that is continuous in its domain and satisfies an equation $P(\underline{X}, f(\underline{X})) = 0$ where $P \in F[\underline{X}, T]$ that is of degree d in T.

Def. (12.7.2.2) [Periods]. A **period number** is a complex number that is an integral combinations of real numbers of the form $\int_U f(x)dx$ where f is an algebraic function over $\mathbb{Q}$(12.7.2.1) and U is a precompact connected open domain of $\mathbb{R}^n$ defined by polynomial inequalities with rational coefficients, for some $n \in N$. The set of periods is denoted by $\mathbb{P}$. The **extended Period ring** is defined to be $\widehat{\mathbb{P}} = \mathbb{P}[\frac{1}{2\pi i}]$.

Clearly $\overline{\mathbb{Q}} \subset \mathbb{P} \subset \mathbb{C}$, and they form an algebra. Also, $\#\mathbb{P} = \aleph_1$.

Prop. (12.7.2.3). In defining periods, we can even consider domains defined by inequalities by algebraic functions over $\mathbb{Q}$(12.7.2.1) defined on a larger open subset.

Proof: If U satisfies $f < a$ and f satisfies a polynomial function $P(\underline{X}, f(\underline{X})) = 0$, then U satisfies $P(\underline{X}, a) > 0$ or $P(\underline{X}, a) < 0$. We can assume the first one holds, and we can isolate the part $P(\underline{X}, a) > 0, f(\underline{X}) < a$ and the part $P(\underline{X}, a) > 0, f(\underline{X}) > a$ by segments, so we are reduced to the polynomial case. □

Prop. (12.7.2.4) [Algebraic Varieties]. If X is a smooth variety of dimension d over $\mathbb{Q}$ and $D \subset X$ a divisor with normal crossing, $\omega \in \Omega^d(X)$ vanishing on D, and $\gamma \in H_d(X(\mathbb{C}), D(\mathbb{C}), \mathbb{Q})$ is a singular n-chain with boundary in $Y(\mathbb{C})$, then the integral $\int_C \omega \in \mathbb{P}$.

In fact, any integration on a variety over $\mathbb{Q}$ can be reduced to this case, by resolution of singularity and restriction of divisors, and any period number comes from these.?

Proof: Roughly because we can represent γ by a semi-algebraic chain.? □

Example (12.7.2.5).

- $\sqrt{2} = \int_{2x^2<1} dx \in \mathbb{P}$.
- $\pi = \int_{x^2+y^2<1} dxdy \in \mathbb{P}$.

- $\log 2 = \int_1^2 \frac{dx}{x} \in \mathbb{P}$.

Prop. (12.7.2.6). For $n \in \mathbb{Z}_+, n \geq 2$, $\zeta(n) \in \mathbb{P}$.

Conj. (12.7.2.7) [Non-Examples]. There are no natural examples of numbers proven to be non-period. e, $1/\pi$ and Euler-Mascheroni constant γ are conjectured to be non-periods. Notice e is known to be transcendental but γ is not known to be rational or not yet!

Remark (12.7.2.8) [How to Distinguish Different Periods]. There may be numbers that can be written in different ways, such as

$$\sqrt{11+2\sqrt{29}}+\sqrt{16-2\sqrt{29}+2\sqrt{55-10\sqrt{29}}}=\sqrt{5}+\sqrt{22+2\sqrt{5}}.$$

But as they are both algebraic numbers we can check this by brutal force:

1. Find polynomials satisfied by them and use Euclidean division to find their common divisor, and use inequalities to bound its roots.
2. Calculate these two numbers to sufficiently high precision and use the fact two algebraic numbers of bounded degree cannot be too close to each other by Diophantine geometry.

But how to do this for periods?

Proof: They are both equal to the expression

$$\sqrt{11+2\sqrt{29}}+\sqrt{11-2\sqrt{29}}+\sqrt{5}$$

by using the equality $\sqrt{a}+\sqrt{b}=\sqrt{a+b+\sqrt{ab}}$. □

Conj. (12.7.2.9) [Periods Conjecture]. Any two integral representations of a period can be transformed to each other by means of , cut-and-paste, change of variables and Stoke's formula.

Prop. (12.7.2.10) [Calabi]. We give one indication of this conjecture by proving $\zeta(2) = \pi^2/6$:

$$(1-\frac{1}{4})\zeta(2) = 1^{-2}+3^{-2}+5^{-2}+\cdots = \int_{(0,1)^2}\frac{1}{(1-x^2y^2)}dxdy.$$

But the change of variables

$$(x,y) = (\frac{\sin u}{\cos v}, \frac{\sin v}{\cos u})$$

has Jacobian $(1-x^2y^2)$ and maps the triangle $T = \{u, v > 0, u + v < \pi/2\}$ bijectively to $(0,1)^2$, so

$$\int_{(0,1)^2}\frac{1}{(1-x^2y^2)}dxdy = \int_T dudv = \mathrm{Vol}(T) = \pi^2/8$$

Def. (12.7.2.11) [Exponential Periods]. An **exponential period number** is a complex number that is an integral combinations of real numbers of the form $\int_U f(x)\exp(g(x))dx$ where f, g are algebraic functions over $\mathbb{Q}$(12.7.2.1) and U is a precompact connected open domain of $\mathbb{R}^n$ defined by polynomial inequalities with rational coefficients, for some $n \in N$. The set of periods is denoted by $\mathbb{P}_{\exp}$.

13 Arithmetic Geometry

13.1 Pseudo-Algebraically Closed Fields

References are [Field Arithmetic].

1 Pseudo-Algebraically Closed Fields

Def. (13.1.1.1). $k \in \texttt{Field}$ is called a **pseudo-algebraically closed field** or **PAC field** if every variety over k has a k-point.

Example (13.1.1.2) [PAC Fields].

- Separably closed fields are PAC.
- Infinite algebraic extensions of finite fields are PAC.
- Ultraproducts of distinct finite fields are PAC.

Proof: □

2 Hilbertian Fields

Cf.[Field Arithmetics] or [Mordell-Weil Theorem notes, Serre, 1997].

Hilbert Subsets

Def. (13.1.2.1) [Hilbert Subsets]. For $k \in \texttt{Field}$ and two set of variables $T_1, \ldots, T_r$ an $X_1, \ldots, X_n$, let $f_1(\underline{T}, \underline{X}), \ldots f_m(\underline{T}, \underline{X}) \in k[\underline{X}, \underline{X}]$ that is irreducible in $k(\underline{T})[\underline{X}]$, and let $g \in j[\underline{T}]$. Then a **Hilbert subset** of k^r is a subset of the form

$$\{(a_1, \ldots, a_r) \in k^r | g(\underline{a}) \neq 0, f(\underline{a}, \underline{X}) \text{ are irreducible in } k[\underline{X}]\}.$$

A **separable Hilbert subset** is a Hilbert set of this form s.t. $n = 1$ and each f_i is separable in X.

Def. (13.1.2.2) [Hilbertian Fields]. $k \in \texttt{Field}$ is called a **Hilbertian field** if each separable Hilbert subset of k is non-empty. Thus a Hilbert field must be infinite.

Prop. (13.1.2.3) [Separable Extensions]. If L/K is a finite separable extension, then any Hilbert subset of L^r contains a Hilbert subset of K^r. In particular, if K is Hilbertian, then so is L.

Proof: Cf.[Field Arithmetic, P223]. □

Remark (13.1.2.4). The converse is false, Cf.[Field Arithmetic, 13.9.5].

Examples of Hilbertian Fields

Example (13.1.2.5) [Hilbertian Fields].

- Global fields are Hilbertian.
- If $k \in \texttt{Field}$ and K is a f.g. transcendental extension of k, then K is Hilbertian.

Proof: Cf.[Field Arithmetic, Chap13]. □

13.2 Diophantine Geometry

References are [Galois Cohomology, Serre]Chap2.4.5, [B-G06], [Fundamentals of Diophantine Geometry, Lang], [Weil50].

Arithmetic of varieties(i.e. varieties over absolutely f.g. fields) that are not necessarily Abelian varieties are studied in this section. The Abelian variety case is studied in Arithmetic of Abelian Varieties.

1 Geometry of Numbers

Minkowski's Second Theorem

Cf.[B-G06].

Prop. (13.2.1.1) [Minkowski's Second Theorem]. Let F be a global number field of degree d, V a f.d. F-vector space of dimension n, and Λ a lattice in V. For any $v|\infty$, let S_v be a non-empty open convex symmetric bounded subset S_v of V_v. For $\lambda > 0 \in \mathbb{R}$, denote $\lambda S = \prod_{v|\infty} \lambda S_v \times \prod_{v\nmid\infty} \lambda\Lambda_v$. For $n \geq 1$, denote the n**-th succesive minimum** of S to be

$$\lambda_n = \inf\{t > 0 | tS \text{ contains } n \text{ linearly independent vectors of } \Lambda \text{ over } K\}.$$

Then

$$(\prod_{i=1}^n \lambda_i) \operatorname{Vol}(S)^{1/d} \leq 2^N,$$

where the volume is calculated w.r.t. the Adele measure given by(12.4.6.5).

Moreover, if S_v are totally symmetric, then

$$\frac{2^{dn}\pi^{sn}}{(n!)^r((2n)!)^s} N(d_{K/\mathbb{Q}})^{n/2} \leq (\prod_i \lambda_i)^d \operatorname{Vol}(S).$$

Proof: Cf.[B-G06]P611. □

2 Conjectures

Weak Approximation

Prop. (13.2.2.1). If X is a smooth complete intersection of two quadrics in $\mathbb{P}^N_F$ for $N \geq 5$, and $X(F) \neq \varnothing$, then X satisfies weak approximation.

Proof: Cf.[Colliot-Thelene-Skorobogatov1987, R-equivalence on cubic bundles of degree 4]. □

Mazur's Conjecture

Conj. (13.2.2.2) [Mazur]. Let $X/\mathbb{Q}$ be a smooth algebraic scheme over a field, then the topological closure of $X(\mathbb{Q})$ in $X(\mathbb{R})$ consist of a finite union of connected components.

Proof: □

Remark (13.2.2.3). As the kernel of the Brauer-pairing(9.2.6.1) vanishes on all the infinite places, when the Brauer-Manin obstruction is sufficient, Mazur's conjecture holds.

Artin's Conjecture

Def. (13.2.2.4) [C_d-Fields]. A field K is called C_k or for any homogenous polynomial $F(X_1,\ldots,X_n)$ of degree d with coefficient in K that $d^k<n$ has a non-zero solution in K^n.

C_0 fields are just alg.closed fields, C_1 fields are also called **quasi-algebraically closed**.

Prop. (13.2.2.5). Algebraic extensions of a quasi-alg.closed field is quasi-alg.closed.

Proof: For a homogenous polynomial $F(X_1,\ldots,X_n)$, its coefficient lies in a finite extension of K contained in L, so we may assume L/K is finite. Then choose a basis $\{e_1,\ldots,e_m\}$ of L over K, then consider the function

$$f(x_{11},\ldots,x_{1m},\ldots,x_{n1},\ldots,x_{nm})=\mathrm{Nm}_{L/K}(F(x_{11}e_1+\ldots+x_{1m}e_m,\ldots,x_{n1}e_1+\ldots+x_{nm}e_m)),$$

which is a homogenous polynomial of degree nm with coefficient in K, because it has values all in K. So it has a nonzero solution in K^{nm} by(5.10.2.3), Krull's height theorem and k is alg.closed. □

Prop. (13.2.2.6) [Chevalley-Warning]. Any finite field $\mathbb{F}_q$ is quasi-algebraically closed. In fact, for any system of homogenous polynomials f_i of n variables, if $\sum_{i=1}^r \deg f_i<d$, then the number of solutions to this equation on $\mathbb{F}_q$ is divisible by p, where q is a p-power.

Proof: The number of solutions to this system is equivalent to

$$\sum_{x\in\mathbb{F}_q^n}\prod(1-f_i^{q-1}(x))$$

modulo p.

But notice that if $i<q-1$, then $\sum_{x\in\mathbb{F}_q}x^i=0$ in $\mathbb{F}_q$ by(24.1.3.5), but as the degree of the highest term of $\sum_{x\in\mathbb{F}_q^n}\prod(1-f_i^{q-1}(x))$ modulo p is smaller than $n(q-1)$, some x_i has power smaller than $q-1$, thus when summed over $\mathbb{F}_q$, it vanishes. □

Remark (13.2.2.7). This may follow from the fact any smooth projective Fano variety over $\mathbb{F}_q$ has a rational point(13.2.6.3).

Prop. (13.2.2.8) [Tsen]. Algebraic function fields of dimension 1 over an alg.closed field K is quasi-alg.closed.

Proof: By(13.2.2.5), it suffice to consider the case $K=k(t)$ purely transcendental. for a polynomial F with coefficient in $k(t)$, we can assume it has coefficient in $k[t]$, then let δ be their maximal degree. If substituted with $X_i=\sum_{i=0}^N a_ijt^j$, the function becomes a system of $\delta+dN+1$ homogenous equation with $n(N+1)$ unknowns a_{ij}, since $d<n$, $\delta+dN+1<n(N+1)$ for N large. In this case, □

Prop. (13.2.2.9). If K is quasi-alg.closed, then $H^2(G(K_s/K),K_s^*)=0$.

Proof: Cf.[Etale Cohomology Fulei 5.7.15]. □

Cor. (13.2.2.10). By this and(13.2.2.5), the condition of(10.1.2.17) are satisfied. So if K is quasi-alg.closed, then $cd(G(K_s/K))\le 1$ and $H^i(G(K_s/K),K_s^*)=0$ for $i\ge 1$.

Prop. (13.2.2.11) [Ax-Kochen]. For any d, there is a N_d that if $p>N_d$, then any homogenous polynomial $f(X_1,\ldots,X_n)$ of degree d with coefficient in $\mathbb{Q}_p$ that $d^k<n$ has a non-zero solution in $\mathbb{Q}_p^n$.

Proof: The proof uses Model theory.**?** □

3 Heights

Def. (13.2.3.1) [Equivalent Height function]. Let X be a projective scheme, two height functions $X(\overline{K}) \to \mathbb{R}$ are called equivalent iff they differ by a bounded function.

Prop. (13.2.3.2). There is a way of constructing the Weil heights as a special case of the global heights, which are sum of local heights, Cf.[Diophantine Geometry, Chap2].

Heights on Projective Spaces

Def. (13.2.3.3) [Canonical Heights on Projective Spaces]. For $K \in$ `LField` with base field K_0, let $x = (x_0, \ldots, x_n) \in K^{n+1} \setminus \{0\}$, then for a normalized place u on $\overline{K}$ and a normalized place v of K that $u|v$, suppose $\log(0) = -\infty$ and define

$$h_u((x_0, \ldots, x_n)) = \max_i(\log |x_i|_u), \quad H_u((x_0, \ldots, x_n)) = \exp(h_u((x_0, \ldots, x_n)))$$

$$h_v((x_0, \ldots, x_n)) = [K_v : (K_0)_{v_0}]h_u((x_0, \ldots, x_n)), \quad H_v((x_0, \ldots, x_n)) = \exp(h_v((x_0, \ldots, x_n))).$$

And if $F \in$ `GField` over base field F_0, for $x \in \mathbb{P}^n(F)$, define

$$h(x) = \frac{1}{[F : F_0]} \sum_{v \in \Sigma_F} h_v((x_0, \ldots, x_n)), \quad H(x) = \exp(h(x))$$

- $h_u((x_0, \ldots, x_n))$ is invariant under finite extensions of fields K'/K, thus this local height is defined on all $\overline{K}^{n+1}$.
- $h(x)$ is well-defined.
- $h(x) \geq 0$.
- $h(x)$ is invariant under finite extensions of fields F'/F, thus the height is defined on all $\mathbb{P}^n(\overline{F})$.
- For $\sigma \in \mathrm{Gal}(\overline{F}/F)$, $h(\sigma(x)) = h(x)$.

These are called **canonical heights** and **multiplicative canonical heights** on $\mathbb{P}^n$.

Proof: 1 is a consequence of the product formula(12.4.5.16). 2 follows from 1 because we can divide a constant to make a coordinate unit in K^*, thus clearly $h(x) \geq 0$. 3 follows from the fundamental identity. □

Prop. (13.2.3.4). If $P_1, \ldots, P_r \in \overline{K}^n$, then

$$h_u(P_1 + \ldots + P_r) \leq h_u(P_1) + \ldots + h_u(P_r) + \varepsilon_u \log |r|_u,$$

where $\varepsilon_u = 0$ if u is non-Archimedean and 1 otherwise.

Def. (13.2.3.5) [Height on Affine Spaces]. For $F \in$ `NField` and $\underline{x} = (x_1, \ldots, x_n) \in F^n$, the **affine height** is defined to be:

$$h^+(\underline{x}) = h([1, \underline{x}] \in \mathbb{P}^n(F)).$$

and similarly we define $H^+(\underline{x})$.

In particular, if α is an algebraic number, then the height of α is

$$h^+(\alpha) = \sum_{v \in \Sigma_F} \max(0, \log |\alpha|_v).$$

Lemma (13.2.3.6). For $\alpha \in \overline{\mathbb{Q}}$ and $\lambda \in \mathbb{Q}$, we have $h(\alpha^\lambda) = |\lambda| h(\alpha)$.

Proof: For $\lambda > 0$, this is easy. So it suffices to consider $\lambda = -1$. Notice

$$\log|\alpha|_v = \max\{0, \log|\alpha|_v\} - \max\{0, \log|1/\alpha|_v\},$$

summing over all places v and use the product formula, we get the desired results. □

Lemma (13.2.3.7) [Northcott]. Let $F \in$ `GField` and $C > 0, d > 0$, then $\{x \in \mathbb{P}^n(\overline{F}) | h(x) \le C, \deg(x) \le d\}$ is finite.

Proof: We first reduce to the case $k(x) = \mathbb{Q}$ or $\mathbb{F}_p(t)$: for a point x with $[k(x):\mathbb{Q}] \le d$, consider the point $(X_0, \ldots, X_m)$ in the projective space $\mathbb{P}^m$ of forms of degree $\deg(x)$ in $n+1$ variables corresponding to $\mathrm{Nm}(\sum x_i T_i)$. Notice the inverse image of any closed point in $\mathbb{P}^m$ is a finite set in $\mathbb{P}^n(\overline{K})$, and the height of $h((X_0, \ldots, X_m)) \le d!(n+1)h(x)$, so it suffices to prove for $\mathbb{P}^m(\mathbb{Q})$. In this case, we normalize a point to a unique point with integral coordinates with no common divisors, then $\max_i \log|x_i|_p = 0$ for any p, thus $h(x) = h_\infty(x)$, and clearly only f.m. points has bounded heights. □

Prop. (13.2.3.8) [Change of Coordinates]. Let h_1, h_2 be heights of $\mathbb{P}(\overline{K})$ defined w.r.t. two coordinates systems, then $h_1 \sim h_2$. Thus we can consider heights in any particular coordinates that is convenient.

Proof: The proof is straightforward. □

Heights of Polynomials

Def. (13.2.3.9) [Heights and Mahler Heights]. The height of a polynomial $f(T) = x_0 + x_1 T + \ldots + x_d T^d$ is defined to be $h^+(f) = h^+((x_0, \ldots, x_d))$, and similarly for $H^+(f)$.

The **Mahler height** of f is defined to be?

Lemma (13.2.3.10) [Gelfond].

Prop. (13.2.3.11). Let $f_1, \ldots, f_m \in \overline{\mathbb{Q}}[X_1, \ldots, X_n]$ of degree d, then

$$-d\log 2 + \sum_{j=1}^m h(f_j) \le h(f) \le d\log 2 + \sum_{j=1}^m h(f_j).$$

Proof: Cf.[Bombieri, P28].? □

Cor. (13.2.3.12). Let $d \in \mathbb{Z}_+$, then there exists constants $C_1, C_2 \in \mathbb{R}_+$ depending on d s.t. for any $\alpha \in \overline{\mathbb{Q}}$ with $\deg(\alpha) = d$, if $f_\alpha \in \mathbb{Z}[T]$ be a minimal polynomial of α with coprime coefficients, then

$$dh^+(\alpha) - C_1 \le h(f_\alpha) \le dh^+(\alpha) + C_2.$$

Arakelov Heights

Def. (13.2.3.13)[Arakelov Heights]. For a local field K with base field K_0, let $x = (x_0, \ldots, x_n) \in K^n$, then for a normalized place u on $\overline{K}$ and a normalized place v of K that $u|v$, define

$$h_u^{Ar}((x_0, \ldots, x_n)) = \begin{cases} \log\max_i(|x_i|_u) & , K \in \texttt{p-Field} \\ \log\sqrt{\sum_{j=0}^n |x_j|_u^2} & , K = \mathbb{R} \text{ or } \mathbb{C} \end{cases}, \quad H_u^{Ar}((x_0, \ldots, x_n)) = \exp(h_u^{Ar}((x_0, \ldots, x_n)))$$

$$h_v^{Ar}((x_0,\ldots,x_n)) = [K_v:(K_0)_{v_0}]h_u((x_0,\ldots,x_n)),\quad H_v^{Ar}((x_0,\ldots,x_n)) = \exp(h_v^{Ar}((x_0,\ldots,x_n))).$$

And if F is a global field over base field F_0, for $x\in\mathbb{P}^n(F)$, define

$$h^{Ar}(x) = \frac{1}{[F:F_0]}\sum_{v\in\Sigma_F} h_v(x),\quad H^{Ar}(x) = \exp(h^{Ar}(x)).$$

Then $h^{Ar}(x), H^{Ar}(x)$ are well-defined, positive, and invariant under finite extensions of fields for the same reason as(13.2.3.3). Then they extends to the algebraic closure, called the **Arakelov heights** and **multiplicative Arakelov heights** on $\mathbb{P}^n$.

Cor. (13.2.3.14). The Arakelov height is the height associated to the locally bounded metrized line bundle on $\mathcal{O}_{\mathbb{P}^n}(1)$ with Fubini-Study metrics in the Archimedean places and standard metric in the non-Archimedean places, so it is equivalent to the canonical height.

Def. (13.2.3.15) [Arakelov Heights on Matrices]. The Arakelov heights induces a height function on the Grassmannians by the canonical embedding, and for any matrix $A\in M_{n\times m}(\overline{F})$ of rank m, let the Arakelov heights of A be defined as the height of the point in the Grassmannian $\mathrm{Gr}_m(\overline{F})$ associated to the space spanned by the columns of A. And if $A\in M_{m\times n}(F)$ of rank m, then its Arakelov height is defined to be $H^{Ar}(A) = H^{Ar}(A^t)$.

Equivalently, it is the height of the point in $\mathbb{P}^{\binom{n}{m}-1}(F)$ represented by the $m\times m$-minors of A. And we can also define the local heights of A in this form.

Prop. (13.2.3.16). Let $K=\mathbb{R}$ or $\mathbb{C}$ and $A\in M_{n\times m}(\overline{K})$ has rank m, then $H_u(A) = \det(A^*A)^{1/2}$, by Binet's formula(2.3.10.11).

Prop. (13.2.3.17). Let K be a local field and $A=[B,C]\in M_{n\times m}(\overline{K})$ has rank m, then

$$H_u^{Ar}(A)\le H_u^{Ar}(B)H_u^{Ar}(C).$$

Prop. (13.2.3.18). Let $F\in$ `GField` and W be a subspace of F^n and $W^\perp\in(F^n)^*\cong F^n$ be the annihilator of W, then $h^{Ar}([W]) = h^{Ar}([W^\perp])$.

Proof: Cf.[B-G06]P68. □

Prop. (13.2.3.19). Let K be a local field and V,W be subspaces of $\overline{K}^n$, then

$$h_u^{Ar}([V+W]) + h_u^{Ar}([V\cap W])\le h_u^{Ar}([V]) + h_u^{Ar}([W]).$$

Proof: Cf.[B-G06]P69. □

Prop. (13.2.3.20) [Metric on Projective Space]. Let K be a local field, for a normalized place u on $\overline{K}$ and a normalized place v of K that $u|v$, for $x,y\in(\overline{K})^n\backslash\{0\}$, define

$$\delta_u(x,y) = \frac{H_u^{Ar}(x\wedge y)}{H_u^{Ar}(x)H_u^{Ar}(y)},\quad \delta_v(x,y) = \delta_u(x,y)^{[K_v:(K_0)_{v_0}]},$$

then $\delta(x,y)\in[0,1]$ by(13.2.3.19), and defines a metric on $\mathbb{P}^n(\overline{K})$, called the **projective metric on** $\mathbb{P}^n$. In the complex case, it is just the Fubini-Study metric.

And if F is a global field over base field F_0, for $x,y\in\mathbb{P}^n(\overline{F})$, define

$$\delta(x) = \prod_v \delta_v(x,y)^{\frac{1}{[F:F_0]}}.$$

Proof: Cf.[B-G06]P70. □

Prop. (13.2.3.21). Let F be a global field and $x, y \in \mathbb{P}^1(\overline{F})$, then

- If $O = [0, 1]$, then $H^{Ar}(x) = \frac{1}{\delta(x,O)}$.
- If $x = [1, \alpha], y = [1, \beta]$, then $\delta(x, y) = \frac{1}{H^{Ar}(\alpha)H^{Ar}(\beta)}$.

Heights on Abelian Varieties(Weil)

Prop. (13.2.3.22). Let X be a complete variety over K and $\varphi : X \to \mathbb{P}^k, \psi : X \to \mathbb{P}^l$ are two K-morphisms. If $\varphi^*(\mathcal{O}_{\mathbb{P}^k}(1)) \cong \psi^*(\mathcal{O}_{\mathbb{P}^l}(1))$, then the induced height function $h_\varphi - h_\psi$ is bounded on $X(\overline{K})$.

Proof: Let $\varphi^*(\mathcal{O}_{\mathbb{P}^k}(1)) \cong \psi^*(\mathcal{O}_{\mathbb{P}^l}(1)) \cong L$, then L is very ample. Consider a basis $\{s_0, \ldots, s_n\}$ of $\Gamma(X, L)$, then it induces a closed embedding $\chi : X \to \mathbb{P}^n : x \mapsto [s_0(x), \ldots, s_n(x)]$ and $\chi^*(\mathcal{O}_{\mathbb{P}^n}(1)) \cong L$. Then it suffices by symmetry to prove $h_\varphi \sim h_\chi$.

We may assume $\varphi(X)$ is not contained in any proper linear subspace of X, so we can choose a basis $T_0, \ldots, T_k$ of $\varphi^*(\Gamma(\mathbb{P}^k, \mathcal{O}_{\mathbb{P}^k}(1)))$, and let $s_0, \ldots, s_k = T_0, \ldots, T_k$. Let $x \in X(\overline{K})$, let $(x_0, \ldots, x_n)$ be the coordinate of $\chi(x)$ and $(x_0, \ldots, x_k)$ the coordinates of $\varphi(x)$. Then by the formula(13.2.3.3) clearly $h_\varphi \leq h_\chi$.

For the converse, let I be the homogenous ideal corresponding to $X \subset \mathbb{P}^n$, then X has coordinate ring $R = K[T_0, \ldots, T_n]/I$. The $T_0, \ldots, T_k$ generates a radical ideal equal to $(T_0, \ldots, T_n)$, because they have no common zero on X. Now there is an integer q and homogenous ideals F_{ij} that

$$T_{k+i}^q - \sum_{j=0}^{k} F_{ij}(T_0, \ldots, T_n)T_j \in I$$

so

$$q \log |x_{k+i}|_v \leq (q-1) \max_{j \leq n} \log |x_j|_v + \max_{j \leq k} \log |x_j|_v + C_v$$

where $C_v = 0$ unless v is Archimedean. Hence

$$\max_{j \leq n} \log |x_j|_v \leq \max_{j \leq k} \log |x_j|_v + C_v \Rightarrow \quad h_\chi \leq h_\varphi + C.$$

□

Prop. (13.2.3.23)[Weil Heights]. Let X be a projective variety over a number field K, then for each element $\mathcal{L} \in \mathrm{Pic}(X)$, we can assign a unique **Weil height** $h_\mathcal{L}$, determined up to equivalence, that

- $h_{L_1 \otimes L_2} \sim h_{L_1} + h_{L_2}$.
- If $X = \mathbb{P}^n$, then $h_{\mathcal{O}(1)}$ is the height defined in(13.2.3.3).
- For any K-morphism $\varphi : X \to Y$ and $L \in \mathrm{Pic}(Y)$, $h_{\varphi^*(L)} \sim h_L \circ \varphi$.

Proof: The uniqueness follows from the fact that $\mathrm{Pic}(X)$ is generated by very ample line bundles because X is projective. For the existence, we may take item3 as definition, extend it to all $\mathrm{Pic}(X)$, and it is essential to verify item1.

Let $L_1 = \varphi^*(\mathcal{O}(1)), L_2 = \psi^*(\mathcal{O}(1))$, where $\varphi : X \to \mathbb{P}^k, \psi : X \to \mathbb{P}^l$. Denote $\sigma : \mathbb{P}^k \times \mathbb{P}^l \to \mathbb{P}^{kl+k+l}$ the Segre embedding, then $L_1 \otimes L_2 \cong \chi^*(\mathcal{O}_{\mathbb{P}^{kl+k+l}}(1))$ where $\chi : X \xrightarrow{(\varphi,\psi)} \mathbb{P}^k \times \mathbb{P}^l \xrightarrow{\sigma} \mathbb{P}^{kl+k+l}$. And we check $h_\chi \sim h_\varphi + h_\psi$. □

Thm. (13.2.3.24) [Northcott]. Let X be a projective variety over a global field F and let h_c be a height function associated to an ample class $\mathcal{L}\in\mathrm{Pic}(X)$, then the set

$$\{P\in X(\overline{K})|h_{\mathcal{L}}(P)\leq C,[K(P):K]\leq d\}$$

is finite for any constant C,d.

Proof: There is a $m>0$ that mc is very ample. Because $mh_{\mathcal{L}}$ is the height function associated to $m\mathcal{L}$, we can assume that $\mathcal{L}$ is very ample, thus reducing to $X=\mathbb{P}^n$ and $\mathcal{L}=\mathcal{O}(1)$ by(13.2.3.23). This follows from(13.2.3.7). □

Prop. (13.2.3.25). Let X be a projective smooth variety over F and $c\in\mathrm{Pic}(X)$ an ample line bundle, $c'\in\mathrm{Pic}^0(X)$, then

$$h_{c'}=O(|h_c|^{1/2}+1).$$

Proof: By base change of fields, we may assume X has a rational point P_0. Consider the double Picard map $\varphi:X\to\widehat{\underline{\mathrm{Pic}}^0(X)}=\widehat{A}$. Viewing c' as a rational point of A, consider $c''=(p_A)_{c'}\in\mathrm{Pic}(\widehat{A})$, then $\varphi^*(c'')=(\mathrm{id}\times\varphi)^*(p_A)|_{c'}=(p_X)_{c'}=c'$. Thus $h_{c'}\sim h_{c''}$.

Let $\widehat{c}$ be an even ample line bundle on $\widehat{A}$(13.5.1.27), then for for some n large, $nc-\varphi^*(\widehat{c})$ is base-point-free, thus by(13.2.3.23), $h_{\widehat{c}}\circ\varphi=O(|h_c|+1)$. Thus it suffices to prove for c',c changed to $c'',\widehat{c}$, which is true by(13.5.12.11). □

Prop. (13.2.3.26) [Weil Heights in Intersection Theory]. Cf.[B-G06]P44?

Bounded Sets

Def. (13.2.3.27) [Bounded Sets]. Let K be a field and $|\cdot|$ a valuation on its alg.closure $\overline{K}$, X be a variety over K. Then:

- If X is an affine variety, then a subset $E\subset X(\overline{K})$ is called **bounded** if for any $f\in K[X]$, $|f|$ is bounded on E.
- If X is arbitrary, then a subset $E\subset X(\overline{K})$ is called **bounded** if there is a finite open affine covering U_i of X and sets $E_i\subset U_i(\overline{K})$ that E_i is bounded in U_i and $E=\cup E_i$.

Prop. (13.2.3.28) [Properties of Bounded Sets].

- For a bounded set E in X and any finite open affine covering U_i of X, there is a division of E:

$$E=\cup E_i,\quad E_i\subset U_i(\overline{K})$$

  and E_i being bounded in U_i.
- If E is bounded in X and Y is a closed subscheme of X, then $E\cap Y(\overline{K})$ is bounded in Y.
- The image of a bounded set under a morphism is also bounded.
- $\mathbb{P}^n(\overline{K})$ is bounded in $\mathbb{P}^n$.
- The inverse image of bounded set under a proper morphism is bounded. In particular, if X is a complete variety over a field K, then $X(\overline{K})$ is bounded in X.

Proof: 1: Because X is separated, it suffices to prove for X affine. And we can also take a refinement of the covering, thus assuming $U_i=X_{h_i}$. Suppose $\sum g_ih_i=1$, and let $E_i=\{P\in$

$E||h_i(P)| = \max_k |h_k(P)|\}$, then $E_i \subset U_i(\overline{K})$. To show E_i is bounded in U_i, it suffices to show $|1/h_i|$ is bounded in E_i. But this is clear, because $|g_i|$ is bounded on E.

2: Use local coordinates.

4: Use the affine open covering $X_i = \{x_i \neq 0\}$, and let $E_i = \{|x_i| = \max_{j=0,\ldots,n} |x_j|\}$, then clearly E_i is bounded in X_i.

5: Cf.[Diophantine Geometry, P55], may use Chow's lemma**?**. □

Prop. (13.2.3.29) [M-Bounded]. We can define the notion of M-boundedness similar to that of(13.2.3.27), where M is a set of places on K that for any $\alpha \neq 0 \in K$, only f.m. of M have nontrivial valuation. Then (E^u) is said to be **M-bounded** in an affine variety X if for any $f \in K[X]$,

$$C_v(f) = \sup_{u \in M, u|v} \sup_{P \in E^u} |f(P)|_u$$

is finite for any $v \in M_K$ and $C_v(f) > 1$ for only f.m. v.

Then similar properties as in(13.2.3.28) hold for M-bounded sets.

Def. (13.2.3.30). A real function f on $X(\overline{K})$ is called **locally bounded** if $f(E)$ is bounded for every bounded set E in X.

Distance Functions

Def. (13.2.3.31) [Distance Function on Curves]. Let C be a curve over a valued field K, let for $P, Q \in C(K)$, the **v-adic distance** function $d_v(P;Q)$ be defined to be $d_v(P;Q) = \min(|t_Q(P)|_v^{1/e}, 1)$, where t_Q is a function with only one zero of order e at Q.

To understand this definition, it is just same as the pullback of the local height via t_Q. It is a special case of local heights.

Prop. (13.2.3.32). Let C be a curve over a valued field K and $F \in K(C)$, then

$$\varinjlim_{P \in C(K), d_v(P,Q) \to 0} \frac{\log |F(P)|_v}{\log d_v(P,Q)} = \mathrm{ord}_Q(F).$$

Proof: In taking limit, scaling t_Q by a constant doesn't matter, so If we change $h_{\mathcal{O}(-Q)}$ to $h_{\mathcal{O}(-kQ)}^{1/k}$, the limit won't change, so we will do so and assume k is large enough s.t. there is a function that has only zeros at P of order k, so $f^*\mathcal{O}(1) = O(-kP)$, and thus we may change $O(kP)$ to $f^*\mathcal{O}(1)$ and then we see $f^{\mathrm{ord}_Q(F)}/F^k$ is regular and non-vanishing at Q, thus we can easily get the desired result. □

Prop. (13.2.3.33). If $\varphi : C_1 \to C_2$ is a non-constant map of curves over a valued field K, then for $Q \in C_1$,

$$\varinjlim_{P \in C(K), d_v(P,Q) \to 0} \frac{\log d_v(\varphi(P), \varphi(Q))}{\log d_v(P,Q)} = e_Q(\varphi).$$

Proof: Similar as that of(13.2.3.32). In fact(13.2.3.32) can be derived from this one. □

Metricized Line Bundles

Chevalley-Weil Theorem

Prop. (13.2.3.34)[Local Chevalley-Weil]. Let K be a non-Archimedean valued field. Let $\varphi : Y \to X$ be a finite unramified morphism of K-varieties and E a bounded set in $X(\overline{K})$. Then there is an $\alpha \neq 0 \in \mathcal{O}_K$ that $\alpha \in \widehat{\delta}_{P/Q}$ whenever $P \in Y(\overline{K})$ and $Q = \varphi(P) \in E$.

Proof: An unramified map is locally of the form a closed embedding of a standard étale morphism**?**, thus there are f.m. U_i, V_i covering X, Y respectively that $V_i \to U_i$ is closed embedding $V_i \to W_i$ of a standard étale morphism $W_i \to U_i$. Because φ is finite hence proper, $\varphi^{-1}(E)$ is bounded by(13.2.3.28), thus there is a decomposition of $\varphi^{-1}(E)$ into bounded sets $E'_i \subset V_i$. Then it suffices to prove for standard étale morphisms, because we can then multiply them.

The image of E_i in W_i is also bounded. Let $W_i \to U_i : \mathrm{Spec}(A[t]/f) \to \mathrm{Spec}\, A$, where

$$f = t^d + a_1 t^{d-1} + \ldots + a_d, \quad a_i \in A.$$

By boundedness, there is an $a \neq 0 \in R$ that

$$\max_{i=1,\ldots,d} \sup_{P\in E'} |a_i(\varphi(P))| \leq |a|^{-1}.$$

Then $\xi = a t_P$ is a root of the polynomial

$$g_Q(t) = t^d + a a_1(Q) t^{d-1} + \ldots + a^d a_d(Q),$$

and it is easily verified that $|\xi| \leq 1$ thus $\xi \in R_P$. Now let g_ξ be the minimal polynomial of ξ over $\widehat{K(Q)}$, then $g_Q = g_\xi h$, $h \in \widehat{K(Q)}[t]$. By Gauss lemma in fact $g_\xi, h \in \widehat{R}_Q[t]$.

Now the elements $1, \xi, \ldots, \xi^{\widehat{d}-1}$ form a basis of $\widehat{K(P)}/\widehat{K(Q)}$, so the discriminant $D_{g_\xi} \in \delta_{\widehat{K(P)}/\widehat{K(Q)}}$. By**??** and(4.2.7.37), $|D_{g_\xi}| = |N_{\widehat{K(P)}/\widehat{K(Q)}}(g'_\xi(\xi))| = |g'_\xi(\xi)|^{\widehat{d}}$. But

$$g'_\xi(\xi) h(\xi) = g'_Q(\xi) = a^{d-1} f'_Q(\xi) = a^{d-1} f'_Q(t_P) = a^{d-1} f'(P).$$

Because f' is unit, we have $|D^{-1}_{g_\xi}|$ is bounded on E'. So there is an $\alpha \neq 0 \in R$ that $|D_{g_\xi}| \geq |\alpha|$, independent of P. Then we are done, as $D_{g_\xi} \in \delta_{\widehat{K_P}/\widehat{K_Q}}$. □

Lemma (13.2.3.35) [Global Chevalley-Weil]. Let Σ be a set of discrete valuations of a field F that any element α has only f.m. nonzero valuations, $\varphi : Y \to X$ be an unramified finite F-morphism of complete K-varieties, and $(E^u)_{u\in\Sigma}$ is an Σ-bounded family in X(13.2.3.29), then for every $v \in \Sigma$ there is a nonzero $\alpha_v \in \mathcal{O}_{F,v}$ that $\alpha_v \in \widehat{\delta}^u_{P/Q}$ whenever $u|v$ and $P \in Y(\overline{K})$ with $\varphi(P) = Q \in E^u$. Moreover, $\alpha_v = 1$ for a.e. $v \in \Sigma$.

Proof: The proof is exactly the same as that of(13.2.3.34), noticing that a, α depend only on v but not $u|v$, and also $a = \alpha = 1$ for a.e. v.(13.2.3.29). □

Lemma (13.2.3.36) [Global Chevalley-Weil Theorem for Discrete Valuations]. Let Σ_K be a set of discrete valuations of a field K that any element $\alpha \in K^*$ has only f.m. nonzero valuations, $\varphi : Y \to X$ be an unramified finite K-morphism of complete K-varieties, then there are a finite set $S \subset M_K$ and for any $v \in S$ a nonzero element $\alpha_v \in \mathfrak{m}_v$ s.t. for any $P \in Y(\overline{F}), Q = \varphi(P)$ and any place $w_0|v$ of $K(Q)$, $K(P)/K(Q)$ is unramified outside S and if $v \in S$, $\alpha_v \in \delta^{w_0}_{P/Q}$.

Proof: We may assume φ is surjective because it is closed(finite is proper). Notice $X(\overline{K})$ is M-bounded in X(13.2.3.28), where M is the set of valuations of $\overline{K}$ extending that of M_K. Then we can use global Chevalley-Weil theorem(13.2.3.35) to find elements α_v for $v\in M_K$. Now notice

$$\delta^{w_0}_{P/Q}=\prod_{w|w_0}(\widehat{\delta}^{w}_{P/Q}\cap\mathcal{O}_{Q,v})$$

by(4.2.7.40), and the number of $w\in M_{K(P)}, w|w_0$ is bounded by $[K(P):K(Q)]$, which is further bounded by $\deg(f)$ as in(13.2.3.34). Hence we can take $\alpha_v=\alpha_v^{\deg(f)}$ to finish the proof. □

Prop. (13.2.3.37). Let F be a global field or the function field of a non-singular curve over a field k, and let $\varphi:Y\to X$ be a finite unramified morphism of F-varieties. If X is complete, then there is an $\alpha\neq 0\in\mathcal{O}_F$ that for any $P\in X(\overline{F})$ that $Q=\varphi(P)$, the discriminant $\delta_{P/Q}$ contains α.

Proof: By(5.11.1.14), we can use the above lemma(13.2.3.36) to $\Sigma=\Sigma_F$. Notice because $\delta_{P/Q}=\prod_{w_0\in\Sigma^0_{k(Q)}}(\delta^{w_0}_{P/Q}\cap\mathcal{O}_{X,Q})$, we can assume $\alpha_v\in\mathcal{O}_{X,Q}$, then take $\alpha=\prod_{v\in S}\alpha_v$. □

Thm. (13.2.3.38) [Chevalley-Weil]. Let F be a global field or the function field of a non-singular curve over a field k, $\varphi:Y\to X$ be a finite unramified morphisms of F-varieties. If X is complete, then there is a finite extension L/K that $P\in Y(L)$ for any $P\in Y(\overline{K})$ that $\varphi(P)\in X(K)$.

Proof: By Chevalley-Weil theorem(13.2.3.37), there is an $\alpha\in\mathcal{O}_F$ that $\alpha\in\delta_{P/Q}$ for any $P\in Y(F^s)$ that $\varphi(P)\in X(K)$, thus $K(P)/K(Q)$ is unramified outside $S(\alpha)$. But then(12.4.2.27) shows there are only f.m. possibilities of $k(P)$. Thus we are done. □

4 Small Points on $\mathbb{G}_m^n$

References are [Sch96] and [B-G06].

5 Approximations of Algebraic Numbers

Subspace Theorem

References are [B-G06], [Sch70], [E-S02], [Eve96] and [F-W94].

Lemma (13.2.5.1).

Thm. (13.2.5.2)[Subspace Theorem, Schmidt/Vojta]. For $F\in\texttt{NField}$ and $S\subset\Sigma_F$ a finite subset of places, $n\in\mathbb{N},\varepsilon\in\mathbb{R}_+$. For $v\in S$, let $\{L_{v0},\ldots,L_{vm_v}\}$ be a set of linear forms in $\overline{K_v}[X_0,\ldots,X_n]$ in general position. Then

- If $\Sigma_F^\infty\subset S$, then there are f.m. rational linear hyperspaces $T_1,\ldots,T_h$ of $\mathbb{A}^{n+1}_F$ s.t.

$$\Big\{\underline{x}\in\mathcal{O}^{n+1}_{F,S}\setminus\{0\}\Big|\prod_{v\in S}\prod_{i=0}^{m_v}|L_{vi}(\underline{x})|_v<H([\underline{x}])^{-\varepsilon}\Big\}\subset T_1\cup\ldots\cup T_h.$$

- There exists f.m. rational hyperplanes $T_1,\ldots,T_h$ of $\mathbb{P}^n_F$ s.t.

$$\Big\{[\underline{x}]\in\mathbb{P}^n(F)\Big|\prod_{v\in S}\prod_{i=0}^{m_v}\frac{|L_{vi}(\underline{x})|_v}{H_v(\underline{x})}<H([\underline{x}])^{-n-1-\varepsilon}\Big\}\subset T_1\cup\ldots\cup T_h.$$

Proof: 2: Firstly, it suffices to prove for $m_v = n$ for any v: We may assume $m_v \geq n$ by adding coordinate functions. And after partitioning into f.m. cases and reordering, we may assume that

$$|L_{v0}(\underline{x})|_v \leq |L_{v1}(\underline{x})|_v \leq \ldots \leq |L_{vm_v}(\underline{x})|_v.$$

As $L_{v0}, \ldots, L_{vn}$ are linearly independent, they form a basis for $\mathcal{O}_{\mathbb{P}^n}(1)$, so there are constants C_v s.t.

$$H_v(\underline{x}) \leq C_v \max_{0\leq i\leq n} |L_{vi}(\underline{x})|_v = C_v|L_{vn}(\underline{x})|_v \leq C_v|L_{vk}(\underline{x})|_v, \forall k > n.$$

Thus

$$\prod_{v\in S}\prod_{i=0}^{n} \frac{|L_{vi}(\underline{x})|_v}{H_v(\underline{x})} \leq C \prod_{v\in S}\prod_{i=0}^{m_v} \frac{|L_{vi}(\underline{x})|_v}{H_v(\underline{x})},$$

and the assertion follows from the case $m_v = n$, as the constant C can be eliminated by applying Northcott's theorem(13.2.3.24).

Secondly, item2 implies item1: For $\underline{x} \in \mathcal{O}_{F,S}^{n+1}$,

$$H([\underline{x}]) = \prod_{v\in\Sigma_F} H_v(\underline{x}) \leq \prod_{v\in S} H_v(\underline{x}),$$

so $[\underline{x}]$ is in the set considered in item2. And any two $\underline{x}, \underline{x}'$ with $[\underline{x}] = [\underline{x}']$ are contained in the same hyperplane.

Conversely, item1 implies item2: We may assume that S is sufficiently large that $\Sigma_F^\infty \subset S$ and $\mathrm{cl}(\mathcal{O}_{F,S}) < \infty$, because if we add a place v and take $L_{vi}(\underline{x}) = x_i$, then $|L_{vi}(\underline{x})|_v \leq H_v(\underline{x})$ for each i. Then for any $[\underline{x}]$ satisfying the inequality of item2, take the fractional ideal

$$\mathfrak{X} = \sum x_i\mathcal{O}_{F,S},$$

then $\mathfrak{X} = (\delta)$ for some $\delta \in K^\times$. And If $v \notin S$, we can see that $|\delta|_v = \max_i |x_i|_v = H_v(\underline{x})$. So we may change $\underline{x}$ to $\underline{x}' = \delta^{-1}\underline{x}$, in which case, $\underline{x}' \in \mathcal{O}_{F,S}^{n+1} \setminus \{0\}$, and $H_v(\underline{x}') = 1$ for $v \notin S$. So $\prod_{v\in S} H_v(\underline{x}') = H([\underline{x}']) = H([\underline{x}])$, and the inequality in item2 implies $\underline{x}'$ is in the subset in item1. Thus we are done.

Thus it suffices to prove item1: For this, Cf.[B-G06]P197.**?** □

Cor. (13.2.5.3) [Schmidt]. Let $\alpha_0, \ldots, \alpha_n \in \overline{\mathbb{Q}}$, then for any $\varepsilon \in \mathbb{R}_+$, there are only f.m. $\underline{x} \in \mathbb{Z}^{n+1}$ s.t.

$$0 < |\alpha_0x_0 + \ldots + \alpha_nx_n| \leq H(\underline{x})^{-n-\varepsilon}.$$

Proof: Use induction on n. For $n = 0$, this is trivial. For $n \geq 1$, the subspace theorem(13.2.5.2) with

$$F = \mathbb{Q}, S = \{\infty\}, L_{v0} = \alpha_0X_0 + \ldots + \alpha_nX_n, \quad L_{vi} = X_i, 1 \leq i \leq n$$

implies that the desired set is contained in f.m. rational linear subspaces of $\mathbb{A}_{\mathbb{Q}}^{n+1}$. Thus we can assume that the desired set all satisfy a linear relation of the form $\sum_j A_jX_j = 0$, with $A_n \neq 0$. Then with $\beta_n = \alpha_i - \alpha_nA_i/A_n$,

$$0 < |\alpha_0x_0 + \ldots + \alpha_nx_n| = |\beta_0x_0 + \ldots + \beta_{n-1}x_{n-1}| \leq H(x)^{-n-\varepsilon} \leq H(x)^{-n+1-\varepsilon}.$$

Thus the assertion follows from induction hypothesis. □

Cor. (13.2.5.4) [Schmidt]. Let $\alpha \in \overline{\mathbb{Q}}$ and $d \in \mathbb{Z}_+, \varepsilon \in \mathbb{R}_+$, then there exists only f.m. $\xi \in \overline{\mathbb{Q}}$ with $\deg(\xi) = d$ and

$$|\alpha - \xi| \leq H^+(\xi)^{-d(d+1)-\varepsilon},$$

Proof: For any such ξ, $|\xi - \alpha| \leq 1$, and we may assume that ξ is not conjugate to α, so $f_\xi(\alpha) \neq 0$. Suppose $f_\xi = x_0 + x_1 T + \ldots + x_d T^d \in \mathbb{Z}[T]$ with coprime coefficients, then $H(f_\xi) = \Theta(H^+(\xi)^d)$ by(13.2.3.12). Thus by mean-value theorem,

$$0 < |f_\xi(\alpha)| = |x_0 + x_1\alpha + \ldots + x_d\alpha^d| \leq C_\alpha|\alpha - \xi|H(f_\xi) \leq H(f_\xi)^{-d-\frac{\varepsilon}{d}} = H(\underline{x})^{-d-\frac{\varepsilon}{d}}.$$

So the assertion follows from(13.2.5.3). □

Prop. (13.2.5.5) [Absolute Subspace Theorem, Evertse-Schlickewei]. [B-G06]P228.?

Roth's Theorem

Lemma (13.2.5.6) [Roth's Lemma].

Thm. (13.2.5.7) [Roth]. Let $F \in$ `NField` and $\Sigma_F^\infty \subset S \subset \Sigma_F$ be finite, and for each $v \in S$ a number $\alpha_v \in \overline{F_v}$. Then for any $\varepsilon > 0$, there are only f.m. $\beta \in F$ that

$$\prod_{v\in S} H_v(\beta - \alpha_v) = \prod_{v\in S} \min(1, |\beta - \alpha_v|_v) \leq H^+(\beta)^{-2-\varepsilon}(13.2.3.5).$$

Moreover, α_v can be ∞ as well, in the sense that $|\beta - \alpha_v|_v = |\beta|_v^{-1}$.

Proof: It is clear that it suffices to show that there are only f.m. $\beta \in F$ s.t.

$$\prod_{v\in S} |\beta - \alpha_v|_v \leq H^+(\beta)^{-2-\varepsilon}, \quad |\beta - \alpha_v|_v < 1.$$

Let $x = [1, \beta] \in \mathbb{P}^1(K)$ and let $L_{v0} = X_1 - \alpha_v X_0$(If $\alpha_v = \infty$, take $L_{v0} = X_0$), then for any such β,

$$\prod_{v\in S} \frac{|L_{v0}(x)|_v}{H_v(\underline{x})} = \prod_{v\in S} |\beta - \alpha_v|_v \max(1, |\beta|_v)^{-1} \leq H^+(\beta)^{-2-\varepsilon}.$$

Thus the assertion follows from the subspace theorem(13.2.5.2).

□

Remark (13.2.5.8). The exponent in Roth's theorem is the best possible, by(13.2.5.22).

This theorem is ineffective in the sense it doesn't give a maximal bound on $H(\beta)$ for a solution β, but it is effective in the sense it gives a bound for the number of solutions.

Remark (13.2.5.9). This is not true for function fields, as if we choose F to be the splitting field of the separable polynomial $x^q - x + t$ over $\mathbb{F}_p(t)$, then there is a valuation w over the valuation v corresponding to (t) s.t. $F_w = \mathbb{F}_p((t))$, and $\alpha = t + t^q + t^{q^2} + \ldots$. Take $\beta_k = t + t^q + \ldots + t^{q^k}$, then $|\beta_k - \alpha|_v = c^{-q^{k+1}}$ with $H(\beta_k) = c^{q^k} = H(\beta)^{-q}$, thus cannot have a Roth's theorem.

Proof: □

Cor. (13.2.5.10) [Classical Roth's Theorem]. For any $\alpha \in \overline{\mathbb{Q}}$ and $\varepsilon > 0$, there are only f.m. $p/q \in \mathbb{Q}$ s.t. $|p/q - \alpha| \leq |q|^{-2-\varepsilon}$.

Proof: Take $F=\mathbb{Q}, S=\{\infty\}$ and $\alpha_\infty=\alpha$, then use Roth's theorem(13.2.5.7). □

Cor. (13.2.5.11). For an element $\alpha\in\mathbb{Q}_p$ and $\varepsilon>0$, there are only f.m. $n\in\mathbb{Z}$ s.t. $|n-\alpha|_p\le|n|^{-1+\varepsilon}$.

Proof: Take $F=\mathbb{Q}, S=\{\infty,p\}$ and $\alpha_\infty=\infty,\alpha_p=\alpha$, then use Roth's theorem(13.2.5.7). □

Cor. (13.2.5.12)[Another Interpretation]. Let $F\in$ `GField` and v a valuation of $\overline{F}$, C be a complete curve over F and $Q\in C(\overline{F})$, then for $f\in K(C)^*$,

$$\varliminf_{P\in C(F),d_v(P,Q)\to 0}\frac{\log d_v(P;Q)}{\log H_F(f(P))}\ge -2.$$

Proof: Replacing f by $1/f$ if necessary, we can assume $f(Q)\neq\infty$. Let $f-f(Q)$ has order e at Q, then by(13.2.3.32),

$$\varinjlim_{P\in C(F),d_v(P,Q)\to 0}\frac{\log|f(P)-f(Q)|_v}{\log d_v(P,Q)}=e.$$

And Roth's theorem implies

$$H_K(f(P))^{2+\varepsilon}|f(P)-f(Q)|_v\ge 1$$

for a.e. P. Thus by taking limit and varying ε, the conclusion follows. □

Cor. (13.2.5.13) [Thue's Equation]. Let $F(x,y)\in\mathbb{Z}[x,y]$ be a homogenous polynomial that has at least three different linear factors in $\mathbb{C}[x,y]$, then for any $m\in\mathbb{Z}^\times$, there are only f.m. solutions of $F(x,y)=m$ in $\mathbb{Z}^2$.

Proof: Let $F_1,\ldots,F_r$ be non-isomorphic irreducible polynomials in $\mathbb{Z}[x,y]$ dividing F, suppose there are i.m. solutions to $F(x,y)=m$, then there are inf.m. rational points x_n/y_n converging but not equal to a root of F_i for each i. Thus $r=1$, and $\deg F_1\ge 3$ by hypothesis. And it is clear that for some root α of F_1 and some constant $C>0$, there are i.m. rational points n s.t. $|x_n/y_n-\alpha|\le C|y_n|^{-3}$, contradicting Roth's theorem(13.2.5.10). □

Prop. (13.2.5.14) [Quantitative Bounds for Roth's Theorem]. Cf.[B-G06]Chap6.5.

Prop. (13.2.5.15) [Liouville]. Let $\alpha\in\overline{\mathbb{Q}},\deg(\alpha)\le 2$, then there is a constant $C>0$ s.t. for all $p/q\in\mathbb{Q}$, $|p/q-\alpha|\ge C/q^d$. Notice only the $d=2$ case is not covered by Roth's theorem(13.2.5.10).

Proof: We can assume $\alpha\in\mathbb{R}$, because otherwise $C=\operatorname{Im}\alpha$ works. Let $f(T)\in\mathbb{Z}[T]$ be a minimal polynomial of α over $\mathbb{Q}$, then f has no roots in $\mathbb{Q}$. Suppose C_1 is the maximum of $|f'(t)|$ for $t\in[\alpha-1,\alpha+1]$. Suppose $|p/q-\alpha|\le 1$, then $|f(p/q)|=|f(p/q)-f(\alpha)|\le C_1|p/q-\alpha|$, and also $q^df(p/q)\in\mathbb{Z}$ thus $|q^df(p/q)|\ge 1$. Thus we get $|p/q-\alpha|\ge 1/C_1q^d$. Thus for general p/q, $C=\min(C_1^{-1},1)$ works. □

Warning's Problem

Def. (13.2.5.16) [Warning's Problem]. For $k\ge 1$, let $g(k)\in\mathbb{Z}_+$ be the smallest number s.t. every positive integer is a sum of at most $g(k)$ positive k-th powers.

Prop. (13.2.5.17). Situation as in(13.2.5.16), $g(k)\ge\lfloor 2^k\rfloor+\lfloor(\frac{3}{2})^k\rfloor-2$.

Proof: This is because the number $\lfloor(\frac{3}{2})^k\rfloor 2^k-1$ requires $\lfloor(\frac{3}{2})^k\rfloor-1$ powers 2^k and 2^k-1 powers 1^k. □

Prop. (13.2.5.18) [Dickson-Niven-Pillai-Rubugunday]. Situation as in(13.2.5.16),

$$g(k)=\begin{cases}2^k+\lfloor(\frac{3}{2})^k\rfloor-2, & \lceil(\frac{3}{2})^k\rceil-(\frac{3}{2})^k\geq(\frac{3}{4})^k\\ ?, & \text{otherwise}\end{cases}.$$

In particular, $g(1)=1, g(2)=4, g(3)=9, g(4)=19$.

Proof: □

Cor. (13.2.5.19) [Mahler]. Situation as in(13.2.5.16), $g(k)=2^k+\lfloor(\frac{3}{2})^k\rfloor-2$ a.e. k.

Proof: Apply Roth's theorem(13.2.5.7) with $K=\mathbb{Q}, S=\{\infty,2,3\}$ with $\alpha_\infty=1,\alpha_2=\infty,\alpha_3=0$, and $\beta_k=3^k/n2^k$ with $n=\lceil(\frac{3}{2})^k\rceil$. Then $|\beta-\alpha_2|_2\leq 2^{-k}, |\beta-\alpha_3|_3\leq 3^{-k}|n|_3^{-1}$, and $H(\beta_k)=3^k|n|_3$. Thus Roth's theorem says for any $\varepsilon>0$,

$$|1-3^k/n2^k|_\infty\leq 2^k3^k|n|_3(3^k|n|_3)^{-2-\varepsilon}$$

holds for only f.m. k. Which implies that $\lceil(\frac{3}{2})^k\rceil-(\frac{3}{2})^k\geq 3^{-\varepsilon k}$ holds for a.e. k. Thus we can apply(13.2.5.18). □

Remark (13.2.5.20). Notice it is not known for how large k this is true, due to the ineffectiveness of the proof of Roth's theorem(13.2.5.7).

Diophantine Approximation on Abelian Varieties

Prop. (13.2.5.21) [Product Theorem, Faltings]. Suppose $k\in\texttt{Field}^0, k=\overline{k}$, $m,n_1,\ldots,n_m\in\mathbb{Z}_+$, $P=\mathbb{P}_k^{n_1}\times\ldots\times\mathbb{P}_k^{n_m}$, for any $f\in\Gamma(P,\mathcal{O}_P(d_1,\ldots,d_m))\setminus\{0\}$ where $d_1>d_2\ldots>d_m$ are positive integers, denote

$$Z_\sigma(f)=\{x\in P(K):\frac{\partial}{\partial\alpha}f=0,\quad\forall\alpha,\alpha/\underline{d}<\sigma\},\sigma\in\mathbb{R}_+.$$

Then for any $\varepsilon\in\mathbb{R}_+$, there exists $C>0$ satisfying the following: If $d_h/d_{h+1}\geq C$ for $h=1,2,\ldots,m-1$, then for any $\sigma\in\mathbb{R}_+$, any irreducible component Z of $Z_\sigma\cap Z_{\sigma+\varepsilon}$ is of the form $Z=Z_1\times\ldots Z_m$, where Z_i are closed subvarieties of $\mathbb{P}_K^{n_i}$ with $\deg(Z_i)$ bounded in terms of ε and $n_1+\ldots+n_m$ only.

Proof: ? □

Approximations by Algebraic Numbers

Prop. (13.2.5.22) [Dirichlet-Hurewitz]. Let $\alpha\in\mathbb{R}\setminus\mathbb{Q}$, then there are infinitely many $\frac{p}{q}\in\mathbb{Q}$ s.t. $|\frac{p}{q}-\alpha|\leq\frac{1}{\sqrt{5}q^2}$.

Proof: Cf. [G. H. Hardy and E. M. Wright. An introduction to the theory of numbers]Thm194?. We prove here for a weaker result:

For $N>0$, consider the sets $\{\{q\alpha\}|q=0,\ldots,N\}$, where $\{\beta\}$ are the fractional part of β. Then by pigeonhole principle gives two $0\leq q_1<q_2\leq N$ s.t. $|(q_1-q_2)\alpha-p|\leq 1/N\leq(q_2-q_1)$. Let $q=q_2-q_1$, then $|p/q-\alpha|\leq 1/q^2$. □

Prop. (13.2.5.23) [Dirichlet-Hurewitz/Davenport-Schmidt]. For $d\in\mathbb{Z}_+$, let $k_d\in[-1,\infty]$ be the supremum of numbers $w\in\mathbb{R}_+$ s.t. for any $\alpha\in\mathbb{R}$ not an algebraic number of degree$\leq d$ and any $\varepsilon\in\mathbb{R}_+$, there exists a constant $C=C(\alpha,\varepsilon)$ s.t. there are inf.m. real algebraic number ξ of degree d satisfying

$$|\alpha-\xi|\leq CH^+(\xi)^{-dk_d+\varepsilon}.$$

Then

- $k_1=2$ by(13.2.5.22).
- $k_2=3$.
- $k_d\leq d+1$.

Proof: 2: One direction is by(13.2.5.4), the other by [Davenport-Schmidt, Approximation to real number by quadratic irrationals]**?**.

3 follows from(13.2.5.4). □

Prop. (13.2.5.24) [Dirichlet-Hurewitz/Davenport-Schmidt/Roy]. For $d\in\mathbb{Z}_+$, let $k_d\in[-1,\infty]$ be the supremum of numbers $w\in\mathbb{R}_+$ s.t. for any $\alpha\in\mathbb{R}$ not an algebraic integer of degree$\leq d$ and any $\varepsilon\in\mathbb{R}_+$, there exists a constant $C=C(\alpha,\varepsilon)$ s.t. there are inf.m. real algebraic number ξ of degree d satisfying

$$|\alpha-\xi|\leq CH^+(\xi)^{-dk_d+\varepsilon}.$$

Then

- $k_1=-1$ trivially.
- $k_2=3$.
- $k_3=\frac{3+\sqrt{5}}{2}$.
- $\lfloor\frac{d+1}{2}\rfloor\leq k_d\leq d+1$.

Proof: 2: One direction is Roth's theorem, the other is [Davenport-Schmidt, Approximation to real number by algebraic integers].

3: [Davenport-Schmidt, Approximation to real number by algebraic integers] and [Approximation by cubic algebraic integers, Roy].

4: (13.2.5.4) and [Davenport-Schmidt, Approximation to real number by algebraic integers] and [Approximation by cubic algebraic integers, Roy]. □

6 Rational Points

Prop. (13.2.6.1) [Esnault]. Let $p\in\mathbf{P},q\in p^{\mathbb{Z}},X\in\mathcal{S}\mathrm{m}\mathcal{P}\mathrm{roj}\mathcal{V}\mathrm{ar}/\mathbb{F}_q$ s.t. $\mathrm{CH}_0(X_{\overline{R(X)}})=\mathbb{Z}$, then $\#X(\mathbb{F}_q)\equiv 1(\mathrm{mod}\ q)$. In particular, X has a rational point.

Proof: Cf.[Weil 1 Proof]. □

Cor. (13.2.6.2). Any rationally chain connected varieties over a finite field $k=\mathbb{F}_q$ s.t. $\mathrm{CH}_0(X_{\overline{R(X)}})=\mathbb{Z}$, then $X(K)\equiv 1 \mod q$. In particular, X has a rational point.

Cor. (13.2.6.3) [Manin-Lang]. If $X/\mathbb{F}_q$ is a smooth projective Fano variety, then $X(K)\equiv 1 \mod q$.

Proof: This is because by(5.10.4.4), any Fano variety is rationally chain connected. □

Lang's Conjecture

Conj. (13.2.6.4) [Lang]. Let $F \in \texttt{NField}$ and X is a variety over F of general type?, then there are f.m. subvarieties $X_i \subset X$ of lower dimensions s.t. $X(F) = \cup_i X_i(F)$.

Proof: □

Thm. (13.2.6.5) [Mordell Conjeture, Faltings]. By(13.14.4.4), for $F \in \texttt{NField}$ and C/F be a complete non-singular curve of genus $g \geq 2$, then $\#C(F) < \infty$.

7 Integral Points

Diophantine Sequences

Def. (13.2.7.1) [Diophantine Sequences]. For $m \in \mathbb{Z}_+$, a sequence of positive integers $a_1 \leq a_2 \leq \ldots \leq a_n$ is called a **Diophantine sequence** of length m if for any $1 \leq i < j \leq n$,

$$a_i a_j + 1 \in (\mathbb{Z})^2.$$

Prop. (13.2.7.2) [Baker-Davenport]. $(1, 3, 8, x)$ is a Diophantine sequence iff $x = 120$.

Proof: Cf.[A. Baker and H. Davenport, The equations $3x^2 2 = y^2$ and $8x^2 7 = z^2$. Quart. J. Math. Oxford Ser. (2) 20 (1969), 129–137.].? □

Thm. (13.2.7.3) [Bo-Alain-Volker]. There are no Diophantine sequences of length 5.

Proof: Cf.[There is no Diophantine quintuple. (English summary) Trans. Amer. Math. Soc. 371 (2019), no. 9, 6665–6709.] □

Siegel's Theorem

References are [C-Z02] and [Sie35].

Thm. (13.2.7.4) [Siegel]. If $F \in \texttt{NField}$ and $C/F \subset \mathbb{A}^n_F$ is an affine curve with normalization C_{sm}, and let $\overline{C}$ be the completion of C_{sm}. Suppose $g(\overline{C}) > 0$ or $\#\widetilde{C} \setminus C_{\text{sm}} \geq 3$, then for any finite set of places $\Sigma^\infty_F \subset S$, $\#C(\mathcal{O}_{F,S}) < \infty$.

Proof: Firstly, it suffices to prove for C smooth: As the normalization is finite and birational(5.4.2.7), by omitting f.m. points, we may assume that all rational points of C lift to rational points of C. Moreover, if $\Gamma(C_{\text{sm}}) = \Gamma(C)[f_1, \ldots, f_r]$, where f_i are integral over C_{sm}. We can enlarge S s.t. C has an integral model over $\mathcal{O}_{F,S}$, and each f_i is integral over $\Gamma(C/\mathcal{O}_{F,S})$. Then each $\mathcal{O}_{F,S}$-points of C lifts to C_{sm}, and the assertion reduces to C_{sm}.

For $g(\overline{C}) \geq 2$, this is a special case of Faltings' Theorem(13.2.6.5).

For $g = 1$, the assertion follows from(13.9.8.2).

For $g = 0$, then $\#\widetilde{C} \setminus C_{\text{sm}} \geq 3$(in fact, any other cases can be reduced to the case $\#\widetilde{C} \setminus C_{\text{sm}} \geq 3$, Cf.[B-G06]P184.) Then

□

abc-Conjecture

Conj. (13.2.7.5) [Strong abc-Conjecture, Masser-Oesterlé1985]. Given $F \in \texttt{NField}$, for any $\varepsilon > 0$, there is a constant C_ε that for any $a, b, c \in \mathcal{O}_F$ that $a + b = c$,

$$H_F([a,b,c]) \leq C_\varepsilon |\operatorname{Nm}_{K/\mathbb{Q}}(\prod_{\mathfrak{p}|abc} \mathfrak{p})|^{1+\varepsilon}.$$

Proof: □

Hilbert's 10-th Problem

Conj. (13.2.7.6) [Hilbert's 10-th Problem]. Let K be a global number field, X be a projective scheme over $\mathcal{O}_K$, it there an algorithm to determine in a finite number of operations whether this curve has a K-rational point.

Proof: □

Remark (13.2.7.7)[Mazur-Rubin]. If the BSD conjecture holds for all elliptic curves over any number fields, then Hilbert's 10-th problem has a negative answer for any number field.

Proof:

□

Others

Prop. (13.2.7.8) [Fermat's Equation in Function Case]. If $n \geq 2$, then any non-trivial solutions to the equation in $\mathbb{C}[T]$ of

$$X^n + Y^n = Z^n$$

are of the form $n = 2, X = (a^2 - b^2)/2, Y = ab, Z = (a^2 + b^2)/2$, where $a, b, c \in \mathbb{C}[T]$.

Proof: The $n = 2$ case is easy. If $n > 2$, we show there are no non-trivial solutions: Differentiate it to get:

$$X^{n-1}X' + Y^{n-1}Y' = Z^{n-1}Z',$$

And cancelling X^{n-1}, we get

$$Y^{n-1}(X'Y - Y'X) = Z^{n-1}(X'Z - Z'X).$$

Now $X'Z - Z'X \neq 0$ because X, Z are not linearly equivalent, and Y, Z is coprime, so $Y^{n-1}|X'Z - Z'X$. But then if we assume $\dim Y \geq \dim X$, then $(n-1)\dim Y \leq 2\dim Y - 1$, which implies $n \leq 2$, contradiction. □

13.3 Arithmetic of Algebraic Groups

Main references are [Algebraic Groups and Number Theory], [Mil17b].

Notation (13.3.0.1).
- Use notations from Group Schemes I: Structure Theory.
- Use notations from p-adic Analysis.

1 over p-adic Number Fields

Notation (13.3.1.1).
- Let $(K, \mathcal{O}_K, k) \in p\text{-}\mathtt{NField}$.

Prop. (13.3.1.2). If $G \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}}/\mathcal{O}_F$, then $G(\mathcal{O}_F)$ is compact.

Prop. (13.3.1.3). If G is a reductive group over K, then $\mathcal{G}(\mathcal{O}_K)$ is a maximal compact subgroup of $G(K)$.

Proof:

Prop. (13.3.1.4) [Reductive Groups are Unimodular]. If G/K is a reductive group, then $G(K)$ is unimodular.

Proof: □

□

Cor. (13.3.1.5). $GL(n, \mathcal{O}_F)$ is a maximal compact subgroup of $GL(n, F)$, and any compact subgroup of $GL(n, F)$ is conjugate to $GL(n, \mathcal{O}_F)$.

Proof: $GL(n, \mathcal{O}_F)$ is compact by(13.3.1.2).

For maximality, for any compact subgroup Γ, consider the standard representation of $\mathrm{GL}(n)$, it suffices to find an $\mathcal{O}_L$-lattice that is stable under Γ-action. Notice $\rho(\Gamma) \cap GL(n, \mathcal{O}_{L'})$ is open in $\rho(\Gamma)$, thus is of finite index, so $\Gamma(\mathcal{O}_L^n)$ is a lattice that is stable under Γ(12.2.3.32). □

Prop. (13.3.1.6). $SL(n, \mathbb{Q}_p)$ has two maximal subgroups

$$SL(n, \mathbb{Z}_p), \quad \begin{bmatrix} p & \\ & 1 \end{bmatrix}^{-1} SL(n, \mathbb{Z}_p) \begin{bmatrix} p & \\ & 1 \end{bmatrix}$$

up to conjugacy.

Proof: □

2 over Global Fields

Def. (13.3.2.1) [Groups of Non-Compact Types]. Let $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}/\mathbb{Q}$ be semisimple, then G is said to be a **group of compact type** if $G(\mathbb{R})$ is compact, and said to be a group of non-compact type if it doesn't contain a non-trivial normal subgroup of compact type.

Prop. (13.3.2.2) [Real Approximation]. If $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}/\mathbb{Q}$ satisfies each connected components of G contains a rational point, then $G(\mathbb{Q})$ is dense in $G(\mathbb{R})$.

Proof: Cf.[Mil17]P54. □

Congruence Subgroups

Def. (13.3.2.3) [Congruence Subgroups]. Let $G \in \mathcal{A}lg\mathcal{G}rp/\mathbb{Q}$ with an embedding $G \to \mathrm{GL}(n)_{\mathbb{Q}}$, for $N \in \mathbb{Z}_+$, define $\Gamma(N) = G(\mathbb{Q}) \cap \{g \in \mathrm{GL}(n;\mathbb{Z}) | g \equiv \mathbb{1}(\mathrm{mod}\ \ GL(n;N))\}$, and a **congruence subgroup** of $G(\mathbb{Q})$ is any subgroup of $G(\mathbb{Q})$ that contains some $\Gamma(N)$ as a finite index subgroup.

The notion is compatible with that defined in(13.3.3.13). In particular, the set of congruence subgroups of G doesn't depend on the embedding**?**.

Prop. (13.3.2.4) [Congruence Subgroup Problem]. Let G be a reductive group over $\mathbb{Q}$,

- If G is split simply connected other than $\mathrm{SL}(2)$, then every arithmetic subgroup of G is a congruence subgroup.
- If $G = \mathrm{SL}(2)$ or non-simply connected, there are many arithmetic subgroups of G that is not congruence subgroups.

Proof: Cf.[MATSUMOTO 1969. Sur les sous-groupes arithmétiques des groupes semi-simples de ´ploye´s. Ann. Sci. Ecole Norm. Sup. (4) 2:1 – 62.].[SURY, B. 2003. The congruence subgroup problem, volume 24 of Texts and Readings in Mathematics. Hindustan Book Agency, New Delhi.] □

Prop. (13.3.2.5). The image of a congruence subgroup may not be a congruence subgroup.

Proof:

□

Prop. (13.3.2.6) [Minkowski]. The congruence subgroup $1 + pGL(n;\mathbb{Z})$ is torsion-free for $p \in \mathbf{P} \setminus \{2\}$.

Proof: Cf.[**?**]P232. □

3 over Adeles

Notation (13.3.3.1).

- In this subsection, let $F \in$ `GField` and $G \in \mathcal{A}lg\mathcal{G}rp/F$.

Def. (13.3.3.2) [Adele Groups]. Let $G \subset \mathrm{GL}(V) \in \mathcal{A}lg\mathcal{G}rp/F$, where $V \in \mathcal{V}ect_F$, $G(\mathbf{A}_F)$ is called the **group of Adele points of** G. Let Λ be a $\mathcal{O}_F$-lattice of V, for any place $v \in \Sigma_F^{\mathrm{fin}}$, let K_v be the stabilizer of $\Lambda_v = \Lambda \otimes_{\mathcal{O}_F} \mathcal{O}_v$ in $G(F_v)$, then $\mathcal{K}_v$ are compact open subgroups of $G(F_v)$. Define the **adelic group of** G

$$G(A_F) = \prod_v{}' (G(F_v), \mathcal{K}_v),$$

which is a locally compact topological group. These K_v are called **hyperspecial compact subgroups**, and they are maximal subgroups of $G(\mathcal{K}_v)$ for a.e. v if G is reductive(13.3.1.3). We can modify the remaining v s.t. $\mathcal{K}_v$ are special maximal compact subgroups**?**, and denote

$$\mathcal{K} = \mathcal{K}^f \mathcal{K}_\infty, \quad \mathcal{K}^f = \prod_{v \in \Sigma_F^{\mathrm{fin}}} \mathcal{K}_v, \quad \mathcal{K}_\infty = \prod_{v \in \Sigma_F^{\infty}} \mathcal{K}_v.$$

Proof: To show $G(\mathbf{A}_F)$ is independent of Λ, notice $|G(\mathbf{A}_F)|$ is clearly invariant, and if Λ' is another lattice, then $d^{-1}\Lambda \subset \lambda' \subset d\Lambda$ for some $d \in \mathbb{Z}_+$, so $\mathcal{K}_v$ are the same for $v \nmid d$.

$\mathcal{K}_v$ are compact open subgroups of $G(F_v)$ because they are the intersection of $GL(\Lambda_v) \cong GL(n, \mathcal{O}_v)$ with $G(F_v)$. To show they are maximal, for any other compact subgroup $\mathcal{K}'$ of $G(F_v)$, as $\mathcal{K}_v \cap \mathcal{K}$ is open, $\mathcal{K}'/K' \cap \mathcal{K}_v$ is a finite set, thus **?** □

Cor. (13.3.3.3). $G(\mathbf{A}_F) = G(\mathbf{A}_{F,S}) \times G(\mathbf{A}_F^S)$.

Prop. (13.3.3.4). For a closed embedding of algebraic groups $G \subset G' \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}/F$, the inclusion $G(\mathbf{A}_F) \subset G'(\mathbf{A}_F)$ is a closed embedding. But for open immersions, the induced inclusion may not be immersions. For example, the embedding $\mathbb{G}_m \subset \mathbb{A}^1$ doesn't induce immersion $\mathbf{I}_F \subset \mathbf{A}_F$.

Proof: ? □

Example (13.3.3.5) [GL(n)]. Fix the following compact subgroup of $GL(n, A)$:

$$\mathcal{K} = \prod \mathcal{K}_v, \quad \mathcal{K}_v = \begin{cases} O(n) & v \text{ real} \\ U(n) & v \text{ complex} \\ GL(n, \mathcal{O}_v) & v \text{ non-Archimedean} \end{cases}.$$

then $\mathcal{K}$ is the maximal compact subgroup of $GL(n, \mathbf{A}_F)$ in the sense that any compact subgroup can conjugate into K.

$\mathfrak{gl}_{n,\infty} = \prod_{v \in S_\infty} \mathfrak{gl}(n, F_v)$, then we can define $(\mathfrak{gl}_{n,\infty}, \mathcal{K}_\infty)$-modules.

Prop. (13.3.3.6). $GL(F)$ is discrete in $GL(A_F)$.

Proof: □

Prop. (13.3.3.7) [Fundamental Domain]. $GL(F)\backslash GL(\mathbf{A}_F)$ has a fundamental domain which can be covered by a sufficiently large **Siegel sets** $\mathfrak{S}_{c,d}$.

Proof: □

Prop. (13.3.3.8). $GL(F)\backslash GL(A_F)$ has finite volume if G is semisimple, and it is compact if G is anisotropic.

Proof: □

Def. (13.3.3.9) [Strong Approximation Property]. Let S be a finite set of places containing Σ_F^∞, a group G is said to satisfy the **strong approximation** for S if it satisfies the following equivalent conditions:

- The image of $G(F)$ is dense in $G(\mathbf{A}^S)$,
- $G(F)G(\mathbf{A}_S)$ is dense in $G(\mathbf{A})$.
- For any compact open subgroup $U^S \subset G(\mathbf{A}^S)$, $G(A) = G(F)G(A_S)U^S$.

In particular,

$$\Gamma\backslash G(\mathbf{A}_S) \cong G(F)\backslash G(\mathbf{A})/U^S.$$

where Γ is the image of $G(F) \cap (G(\mathbf{A}_S) \times U^S)$ in $G(\mathbf{A}_S)$.

Thm. (13.3.3.10) [Strong Approximation]. Assume G is a simply-connected semisimple group(8.3.2.1) and $G(A_S)$ is non-compact for some finite subset $\Sigma_F^\infty \subset S \subset \Sigma_F$, then G satisfies strong approximation for S.

Proof: Cf.[Algebraic Groups and Number Theory, P427]. □

Remark (13.3.3.11). This is not true for non-semisimple or non-simply connected: for $\mathbb{G}_m$, $\mathbb{Q}^\times$ is not dense in $\mathbb{A}_{\mathbb{Q},f}^\times$.

For PGL(2), the determinant of $PGL(2, \mathbb{Q})$ is $\mathbb{Q}^\times/(\mathbb{Q}^\times)^2$ and the determinant of $PGL(2, \mathbb{A}_{\mathbb{Q},f})$ is $\mathbb{A}_{\mathbb{Q},f}^\times/(\mathbb{A}_{\mathbb{Q},f}^\times)^2$, which is not dense.

Cor. (13.3.3.12) [Strong Approximation for $\mathrm{SL}(n)$**].** Let $F \in$ `NField`, then

- $\mathrm{SL}(n)_F$ satisfies strong approximation for Σ_F^∞.
- Let K_0 be an open compact subgroup of $GL(n, \mathbf{A}^f)$, then

$$GL(n,F)GL(n,A_\infty)K_0T_1(A) = GL(n,A).$$

- Let K_0 be an open compact subgroup of $GL(n, \mathbf{A}^f)$ that the image of K_0 under the determinant map is $\prod_{v\in\Sigma_F^{\mathrm{fin}}} \mathcal{O}_v^*$, then

$$\det : GL(n,F)GL(n,\mathbf{A}_\infty)\backslash GL(n,\mathbf{A}_F)/K_0 \to F^\times\,\mathbf{I}_{F,\infty}\backslash I_F/\prod_{v\in\Sigma_F^{\mathrm{fin}}}\mathcal{O}_v^* = \mathrm{Cl}_1(F)$$

is an isomorphism.

Proof: 1 is a direct consequence of(13.3.3.10).

2 is a direct consequence of 1.

3: det is clearly surjective. To show it is injective, if $\det(a) = \det(b) \in \mathrm{Cl}_1(F)$, then $\det(a) = \det(g_1g_\infty bk_0)$ where $g_1 \in GL(n,F), g_\infty \in GL(n,A_{F,\infty}), k_0 \in GL(n,A_F^f)$ by hypothesis. Then $g_1g_\infty bk_0a^{-1} \in SL(n,\mathbf{A}_F)$, and by item1 it is of the form $h_1h_\infty k_0$ where $h_1 \in SL(n,F), h_\infty \in SL(n,A_{F,\infty}), k_1 \in a(K_0\cap SL(n,\mathbf{A}_F^f))a^{-1}$. Then the assertion follows. □

Prop. (13.3.3.13) [Passage From Archimedean to Adele via Congruence Subgroups]. If $F \in$ `GField`, $U_\Gamma \subset G(\mathbf{A}_F^f)$ a compact open subgroup and Γ the image of $G(F)\cap(G(A_\infty)\times U_\Gamma)$ in $G(A_\infty)$, called a **congruence subgroup** of G. If G satisfies strong approximation for $S = \Sigma_F^\infty$(13.3.3.9), then

$$\Gamma\backslash G(A_\infty) \cong G(F)\backslash G(A)/U_\Gamma.$$

In general, for any open compact subgroup $U \subset G(A_f)$,

$$\#G(F)\backslash G(A)/G(A_\infty)U < \infty.$$

Thus if $\{g_i\} \subset G(A_f)$ is a set of double coset representatives,

$$G(F)\backslash G(A)/U = \coprod_i \Gamma_i\backslash G(A_\infty)$$

where Γ_i is the image of $(g_iUg_i^{-1}\times G(A_\infty))\cap G(F)$ in $G(A_\infty)$. Thus the passage from Archimedean to adele is not seriously affected by the lack of strong approximation.

Proof: The double coset is finite because for any $(g_v) \in G(A_F^f)$, by strong approximation for $\mathbb{G}_a$, we can choose a $g \in G(F)$ s.t. $g^{-1}g_v \in K_v$ for any $v \in \Sigma_F^{\mathrm{fin}}$, then the image is finite as U is compact open and $\prod_v K_v$ is compact. □

4 Integral Models

Groups over $\mathbb{Z}$

References are [Groups over $\mathbb{Z}$, Gross].

13.4 Arithmetic Subgroups

Main references are [Mor15] and [V. Platonov and A. Rapinchuk: Algebraic Groups and Number Theory.]

1 Arithmetic Subgroups

Def. (13.4.1.1) [Arithmetic Subgroups]. For $G \in \mathcal{L}\text{in}\mathcal{A}\text{lg}\mathcal{G}\text{rp}/\mathbb{Q}$, an **arithmetic subgroup** $\Gamma \leq G(\mathbb{Q})$ is a subgroup that is commensurable with $G(\mathbb{Q}) \cap GL(n, \mathbb{Z})$ for some embedding $G \hookrightarrow \mathrm{GL}(n)_{\mathbb{Q}}$. This notion is independent of the embedding chosen.

If $G \subset \mathrm{GL}(V)$ and $L \subset V$ be a lattice, then the arithmetic subgroup $G(\mathbb{Q}) \cap GL(n, \mathbb{Z})$ is also denoted by $G(\mathbb{Z}; L)$, called the **group of units of** G. If no confusion is make, it is also denoted by $G(\mathbb{Z})$.

Proof: Cf.[P-R94]P171. □

Lemma (13.4.1.2) [Invariance of Arithmetic Subgroups]. For $\varphi : G \to G' \in \mathcal{L}\text{in}\mathcal{A}\text{lg}\mathcal{G}\text{rp}/\mathbb{Q}$, the kernel of an arithmetic subgroup is an arithmetic subgroup.

Proof: □

Cor. (13.4.1.3). If $G = H \ltimes N \subset \mathrm{GL}(V) \in \mathcal{L}\text{in}\mathcal{A}\text{lg}\mathcal{G}\text{rp}/\mathbb{Q}$, then $H(\mathbb{Z}) \ltimes N(\mathbb{Z}) \subset G(\mathbb{Z})$ has finite index.

Proof: Let $\mathrm{pr} : G \to H$ be the projection, then $H(\mathbb{Z}) \ltimes N(\mathbb{Z}) = \mathrm{pr}^{-1}(H(\mathbb{Z}))$. □

Prop. (13.4.1.4). If $\varphi : G \to G' \in \mathcal{L}\text{in}\mathcal{A}\text{lg}\mathcal{G}\text{rp}/\mathbb{Q}$ is surjective, then φ maps an arithmetic subgroup to an arithmetic subgroup.

Proof: ? □

Prop. (13.4.1.5). There exists arithmetic subgroups not of the form $G(\mathbb{Z}; L)$.

Proof: ? By the proof of(13.4.1.2), any $G^L_{\mathbb{Z}}$ must contain some congruence subgroup $G_{\mathbb{Z}}(d)$, but there are examples of subgroups of finite index of $SL(2, \mathbb{Z})$ not of this form, Cf.[P-R94]Chap9.5. □

Prop. (13.4.1.6). Let $G \in \mathcal{L}\text{in}\mathcal{A}\text{lg}\mathcal{G}\text{rp}/\mathbb{Q}$ and Γ be an arithmetic subgroup, then for any f.d. representation $\rho \in \mathrm{Rep}^{\mathrm{fd}}_{\mathbb{Q}}(G)$, there exists a Γ-invariant lattice.

Proof: Cf.[P-R94]P173. □

Reduction Theory

Prop. (13.4.1.7). Let $G \in \mathcal{L}\text{in}\mathcal{A}\text{lg}\mathcal{G}\text{rp}/\mathbb{Q}$ and Γ be an arithmetic subgroup, then Γ is finitely presented.

Proof: ? □

Prop. (13.4.1.8). Let $G \in \mathcal{L}\text{in}\mathcal{A}\text{lg}\mathcal{G}\text{rp}/\mathbb{Q}$, then there exists only f.m. conjugacy classes of finite subgroups of $G_{\mathbb{Z}}$.

Proof: ? □

Thm. (13.4.1.9) [Borel Density Theorem]. Let $G \in \mathcal{L}\text{in}\mathcal{A}\text{lg}\mathcal{G}\text{rp}/\mathbb{Q}$ be semisimple of non-compact type, then any arithmetic subgroup Γ is Zariski-dense in G.

Proof: Cf.[P-R94]P205.? □

Compactness of $G(\mathbb{R})/G(\mathbb{Z})$

Prop. (13.4.1.10). Let $S \in \mathcal{L}in\mathcal{A}lg\mathcal{G}rp/\mathbb{Q}$ be a torus, then the following are equivalent:

- S is $\mathbb{Q}$-anisotropic.
- $S(\mathbb{R})/S(\mathbb{Z})$ is compact.

Proof: Cf.[P-R94]P205.? □

Prop. (13.4.1.11). Let $G \in \mathcal{L}in\mathcal{A}lg\mathcal{G}rp/\mathbb{Q}$, then the following conditions are equivalent:

- $G(\mathbb{R})/G(\mathbb{Z})$ is compact.
- The reductive part of G^0 is anisotropic over $\mathbb{Q}$.

Proof: Cf.[P-R94]P210.? □

Prop. (13.4.1.12) [Mahler's Criterion]. A subset $\Omega \subset GL(n;\mathbb{R})$ is compact modulo $GL(n;\mathbb{Z})$ iff it satisfies:

- $\{\det(g) | g \in \Omega\}$ is bounded.
- $[\Omega.(\mathbb{Z}^n \setminus \{0\})] \cap U = \varnothing$ for some nbhd U of $0 \in \mathbb{R}^n$.

Proof: Cf.[P-R94]P211.? □

Finiteness of the Volume of $G(\mathbb{R})/G(\mathbb{Z})$

Prop. (13.4.1.13). For $G \in \mathcal{L}in\mathcal{A}lg\mathcal{G}rp/\mathbb{Q}$, $G(\mathbb{R})/G(\mathbb{Z})$ has finite volume iff G^0 doesn't have non-trivial characters defined over $\mathbb{Q}$.

Proof: Cf.[P-R94]P213. □

Prop. (13.4.1.14). If $G \in \mathcal{L}in\mathcal{A}lg\mathcal{G}rp/\mathbb{Q}$ is semisimple, and Γ is an arithmetic subgroup, then $G(\mathbb{R})/\Gamma$ has finite volume.

Proof: Cf.[P-R94]P220. □

Finite Arithmetic Groups

Conj. (13.4.1.15). If $G \subset \mathrm{GL}(n)_{\mathbb{Q}} \in \mathcal{A}lg\mathcal{G}rp/\mathbb{Q}$ is of compact-type, then for any totally real extension $F/\mathbb{Q}$, $G(\mathcal{O}_F) = G(\mathbb{Z})$.

Proof: □

Remark (13.4.1.16). By(13.4.1.17), it suffices to prove this conjecture for $\mathrm{O}(V)$ for any inner space $V/\mathbb{Q}$.

Prop. (13.4.1.17). If $G \subset \mathrm{GL}(n) \in \mathcal{A}lg\mathcal{G}rp/\mathbb{Q}$ satisfies $G(\mathbb{R})$ is compact and Zariski dense in G, then G preserves a quadratic definite quadratic form f.

Proof: Cf.[P-R94]P230. □

Prop. (13.4.1.18) [Bartels-Kitaoka]. Let $F/\mathbb{Q}$ be a totally real nilpotent Galois extension, and $\Gamma \leq \mathrm{GL}(n;\mathcal{O})$ is a finite $\mathrm{Gal}(F/\mathbb{Q})$-invariant subgroup, then $\Gamma \subset \mathrm{GL}(n;\mathbb{Z})$.

Proof: Cf.[P-R94]P234. □

Prop. (13.4.1.19). Let $V/\mathbb{Q}$ be an inner space and $A = (a_{ij}) \in GL(n;\mathbb{Z})$ be an integral Gram matrix for V. If $a_{ii} \leq 4\lambda$ for any i, where λ is the smallest eigenvalue of A, then for any totally real extension $F/\mathbb{Q}$, $\mathrm{O}(V;\mathcal{O}_F) = \mathrm{O}(V;\mathbb{Z})$.

Proof: Cf.[P-R94]P236. □

2 Arithmetic Subgroup of Lie Groups

Def. (13.4.2.1) [Arithmetic Subgroups]. Let H be a connected real Lie group, then an **arithmetic subgroup** $\Gamma \subset H$ is a subgroup s.t. there exists an algebraic group $G \in \mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}/\mathbb{Q}$, a surjective homomorphism $G(\mathbb{R})^0 \to H$ with compact kernel, and $\Gamma_0 \subset G(\mathbb{Q})$ an arithmetic subgroup(13.4.1.1) s.t. $\Gamma_0 \cap G(\mathbb{R})^0$ is mapped to Γ.

Prop. (13.4.2.2). Let H be a semisimple real Lie group that admits a faithful f.d. representation, then every arithmetic subgroup of H is discrete of finite covolume, and contains a torsion-free subgroup of finite index.

Proof: Cf.[Mil17b]P34. □

Prop. (13.4.2.3). In any connected real Lie group there are only countably many arithmetic subgroups up to conjugacy.

Proof: Cf.[Mor15]5.1.20. □

Thm. (13.4.2.4) [Margulis]. Every discrete subgroup of finite volume in a non-compact simple real Lie group H is arithmetic unless H is isogenous to $SO(1,n)$ or $SU(1,n)$.

Note that $SL(2,\mathbb{R})$ is isogenous to $SO(1,2)$, so the theorem doesn't apply to it.

Proof: Cf.[Mor15]5.2.? □

13.5 Arithmetic of Abelian Varieties

Main references are [Sta], [Abelian Varieties notes Conrad], [Mil08], [B-G06], [Abelian Variety van der Geer], [BLR90]. See [Bhatt's notes] for everything done in the relative setting. A history of Abelian varieties can be found in [Mil08]P125.

1 Basics

Def. (13.5.1.1) [Abelian Schemes]. An **Abelian variety** A over a field k is a group variety over k that is a complete variety over k.

For $S \in \mathcal{S}\mathrm{ch}$, an **Abelian scheme** over S is a proper smooth group scheme $A \in \mathcal{S}\mathrm{ch}/S$ s.t. all the fibers A_s are Abelian varieties over the resp. residue field $\kappa(s)$. Denote $\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/S$ the subcategory of $\mathcal{A}\mathrm{lg}\mathcal{G}\mathrm{rp}/S$ consisting of Abelian schemes over S.

Being an Abelian scheme is stable under base change of fields, by(5.10.1.3).

Prop. (13.5.1.2). If X is an Abelian variety, any global tangent vector on a group variety is left invariant.

Proof: Because $\Gamma(X, \mathcal{O}_X) = k$(5.10.1.12), so by(8.1.4.35), $\Gamma(X, \mathcal{O}_X \otimes T_{X,e}) = T_{X,e}$ are all generated by left invariant vectors(left and right translation commutes). □

Prop. (13.5.1.3) [Abelian Varieties are Projective, Weil]. Abelian varieties are projective, by(8.1.4.8) and(5.4.5.3).

Prop. (13.5.1.4) [Rigidity Theorem]. Let $f : X \to Y$ be a morphism of an Abelian varieties to a group variety, then it is a group homomorphism followed by a translation $t_{f(e_X)}$.

Proof: Set $y = i_Y(f(e_X))$ and consider $h = t_y \circ f$, then $h(e_X) = e_Y$, and consider the morphism:

$$g : X \times X \to Y : (x, x') \mapsto h(xx')(h(x)h(x'))^{-1}.$$

then $g(e_X, X) = g(X, e_X) = e_Y$, so the rigidity lemma(5.10.1.20) shows g is constant with value e_Y. Thus $h \circ m_X = m_Y \circ (h \times h)$, thus a group homomorphism. □

Cor. (13.5.1.5) [Abelian Varieties are Commutative].

- Let X be a variety over k, then there is at most one one structure of Abelian variety on X.
- The group law of an Abelian variety is commutative, justifying the name.

Remark (13.5.1.6). The completeness of X is essential for the proof. In fact, there are many non-commutative group varieties, like $\mathrm{GL}(n)$.

From now, use the additive notation for Abelian varieties.

Proof: 1: If there are two structure $(m, i), (n, j)$, then consider $X \times X \to X \to X : (x, y) \mapsto m(x, y)(n(x, y)^{-1})$, then it is constant on $e_X \times X$ and $X \times e_X$, thus it is constant, so $m = n$. And $i = j$ is also clear by the associativity.

2: The inverse i is a group homomorphism by(13.5.1.4), thus it is Commutative. □

Prop. (13.5.1.7) [Rigidity of Morphism from Smooth Varieties]. If X is an Abelian variety over a field K, then any rational map from a smooth K-variety Y extends to a morphism $Y \to X$.

Proof: By(8.1.4.34), V is regular, thus by(5.4.5.15), a rational map is defined on a set whose complement has codimension ≥ 2, but then(8.1.1.20) shows it must be defined on all of X. □

Cor. (13.5.1.8) [Quotient by Finite Subgroups]. Quotients of an Abelian variety A are also an Abelian varieties.

Proof: It is a group variety of dimension 1 with a rational point by(8.1.5.29). And it is complete by(5.4.5.3). □

Remark (13.5.1.9). WARNING: it is not true that the quotient of an Abelian variety by any finite group of automorphisms is an Abelian variety, as the quotient by the hyperelliptic involution(i.e. -1) is just $\mathbb{P}^1$.

Cor. (13.5.1.10) [Even Functions]. Let E be an elliptic curve, then $f \in K(E)$ is even iff $f \in K(x)$.

Proof: Write $f(x,y) = g(x) + h(x)y$, then the condition says $(2y + a_1x + a_3)h(x) = 0$ for any $(x,y) \in E(\overline{K})$. Thus $h(x) = 0$, otherwise E is degenerate, which is not possible. □

Pseudo-Abelian Varieties

Def. (13.5.1.11) [Pseudo-Abelian varieties]. A **pseudo-Abelian variety** is a group variety with no non-trivial affine normal group subvarieties.

Prop. (13.5.1.12). Abelian varieties are pseudo-Abelian varieties.

Proof: Every normal group subvariety is closed thus complete, hence if it is affine, it equals e. □

Prop. (13.5.1.13). Being a pseudo-Abelian variety is stable under separable base change of fields.

Proof: Cf.[Mil17]P149. □

Prop. (13.5.1.14). Let G be a group variety over k, then there exists a unique affine normal group subvariety N s.t. G/N is a pseudo-Abelian variety. And this N is stable under base change.

Proof: This follows from(8.1.4.34) and(8.1.5.30)(8.1.5.29). □

Prop. (13.5.1.15) [Barsotti-Chevalley]. Let k be perfect, then any pseudo-Abelian variety over k is complete hence is an Abelian variety.

Proof: Cf.[Mil17]P154. □

Cor. (13.5.1.16). If G is a group variety over a perfect field k, then unique affine normal group subvariety N s.t. G/N is an Abelian variety, by(13.5.1.14).

Prop. (13.5.1.17)[Algebraic Groups are Extensions of Abelian Varieties]. Let G be a connected algebraic group over a field k, then there is a connected affine normal algebraic subgroup N(not necessarily smooth) s.t. G/N is is an Abelian variety.

Proof: Cf.[Mil17]P155. □

Cor. (13.5.1.18). Every pseudo-Abelian variety G is commutative.

Proof: As G is smooth and connected, so is $[G,G]$(8.1.4.27), so it is a group variety(8.1.4.34). Let N be given by(13.5.1.17), then because G/N is an Abelian variety, $[G,G] \subset N$. Thus $[G,G]$ is affine, which implies $[G,G] = e$. □

Prop. (13.5.1.19) [Totaro(2013)]. Any pseudo-Abelian variety is an extension of a connected unipotent group variety U by an Abelian variety A in a unique way.

Proof:

□

Line Bundles

Remark (13.5.1.20). As Abelian varieties are regular, $\mathrm{Cl}(X)\cong \mathrm{Pic}(X)$, by(5.5.3.15).

Prop. (13.5.1.21) [Theorem of the Cube]. If X is an Abelian variety, and L is a line bundle over X, then

$$\Theta(L)=\mathrm{pr}_{123}^*(L)\otimes \mathrm{pr}_{12}^*(L^{-1})\otimes \mathrm{pr}_{13}^*(L^{-1})\otimes \mathrm{pr}_{23}^*(L^{-1})\otimes \mathrm{pr}_{1}^*(L)\otimes \mathrm{pr}_{2}^*(L)\otimes \mathrm{pr}_{3}^*(L)$$

is trivial.

Proof: This is trivial on $0\times X\times X, X\times 0\times X, X\times X\times 0$, so it is trivial, by(5.10.1.23). □

Cor. (13.5.1.22). There is a form of morphisms from a scheme to X, just by considering $(f,g,h): Y\times Y\times Y\to X\times X\times X$, i.e.

$$(f+g+h)^*L\otimes (f+g)^*L^{-1}\otimes (f+h)^*L^{-1}\otimes (g+h)^*L^{-1}\otimes f^*L\otimes g^*L\otimes h^*L$$

is trivial.

Cor. (13.5.1.23) [Theorem of the Square]. Let A be an Abelian variety that $\mathcal{L}$ is a line bundle, then for any $x,y\in A$,

$$t_{x+y}^*L\otimes L\cong t_x^*L\otimes t_y^*L\in \mathrm{Pic}(A_{k(x)k(y)}).$$

Notice this isomorphism is defined under the field generated by the residue fields of x and y.

Proof: Apply the theorem of the cube(13.5.1.22) for $f=\mathrm{id}_X$ and g,h the function with constant value x,y. □

Cor. (13.5.1.24). For a line bundle L on an Abelian variety X, then the map $\varphi_L: X\to \mathrm{Pic}(X): x\mapsto [t_x^*L\otimes L^{-1}]$ is a homomorphism.

Cor. (13.5.1.25). For any line bundle L,

$$[n]^*L\cong L^{n(n+1)/2}\otimes [-1]^*L^{n(n-1)/2}.$$

Proof: Use(13.5.1.22) in case $f=[n],g=[1],h=[-1]$, then we have:

$$n^*L^2\otimes (n+1)^*L^{-1}\otimes (n-1)^*L^{-1}\cong (L\otimes [-1]^*L)^{-1}.$$

So we can use induction. □

Def. (13.5.1.26) [Even Line Bundle]. Consider the involution $[-1]$ of X and its action on the line bundles, then a **even/odd line bundle** is defined to be a line bundle L that $[-1]^*\mathcal{L}\cong L$(resp. $\mathcal{L}^{-1}$).

Prop. (13.5.1.27). On an Abelian Variety, there is an even very ample line bundle.

Proof: Abelian variety is projective by(13.5.1.3), thus there is a very ample line bundle L, and $[-1]^*L$ is also very ample, so $L\otimes[-1]^*L$ is even and very ample, by(5.5.4.21). □

Prop. (13.5.1.28). For an Abelian variety over a number field K and any line bundle $c\in \mathrm{Pic}(X)$, there are an odd line bundle c^- and an even line bundle c^+ that $c=c_-+c_+$.

Proof: Consider $2c = (c + [-1]^*(c)) + (c - [-1]^*(c))$. $c - [-1]^*(c)$ is odd thus is in $\mathrm{Pic}^0(X)$ by(13.5.4.8), thus by(13.5.6.14), there is a $c^* \in \mathrm{Pic}^0(X)$ that $2c^* = c - [-1]^*(c)$. Then $c = (c - c^*) + c^*$ satisfies the requirement. □

Lemma (13.5.1.29). Let A be an Abelian variety over K and $\mathrm{pr}_i : A \times A \to A$ be the projections and m be the multiplication, then the following are equivalent:

- $m^*(c) \cong \mathrm{pr}_1^*(c) + \mathrm{pr}_2^*(c)$.
- $\tau_a^*(c) \cong c$ for $a \in A$.

And if these are satisfied, c is even.

Proof: The equivalence is a consequence of the formula $(m^*(c) - \mathrm{pr}_1^*(c) - \mathrm{pr}_2^*(c))|_{A\times\{a\}} = \tau_a^*(c) - c$ and the see-saw principle(5.10.1.22). the last assertion is a consequence of the first equation pulled back via the morphism

$$A \to A \times A : a \mapsto (a, -a).$$

□

Prop. (13.5.1.30) [Projective Embeddings]. No Abelian varieties of dimension g can be embedded into $\mathbb{P}^{2g-1}$. No Abelian variety except for elliptic curves and Abelian surfaces of degree 10 in $\mathbb{P}^4$ can be embedded into $\mathbb{P}^{2g}$.

Proof: Cf.[Van de Geer P26], where algebraic topologies are used. □

2 Formal Groups

Def. (13.5.2.1) [Formal Group Law of Abelian Varieties]. Given an Abelian variety A over a field K, the group structure on A induces a homomorphism $\mathcal{O}_{A,e} \to (\mathcal{O}_{A,e} \times \mathcal{O}_{A,e})_{e\times e}$, whose completion is a formal group law of dimension n.

3 over Alg.Closed Fields

All Abelian variety X in this subsection is over an alg.closed field k.

Prop. (13.5.3.1). There is a closed pt 0 in X that corresponds to 0 in the group $X(k)$, if we denote Ω_0 the cotangent space at 0, it is the stalk of the differential $\Omega_{X/k}$ at 0(5.5.5.6).

Def. (13.5.3.2) [Fields of Moduli]. Let k be a field, the **field of moduli** of an Abelian variety A over $\overline{k}$ is the fixed field of $\{\sigma \in \mathrm{Gal}(\overline{k}/k) | A^\sigma \cong A\}$.

Def. (13.5.3.3) [Fields of Definition]. Let k be a field, the **field of moduli** of an Abelian variety A over $\overline{k}$ is the minimal field $\overline{k} \supset k' \supset k$ s.t. A is defined over k'.

Remark (13.5.3.4). Generally, the field of definition is bigger than the field of moduli.

Prop. (13.5.3.5). For any Abelian variety A over a field $k = \overline{k}$ of dimension g, $\dim_k H^1(A, \mathcal{O}_A) \leq g$. In fact, equality holds by(13.5.4.12).

Proof: This follows from Borel's classification of Hopf-algebras(2.9.1.15). Cf.[Van de Geer P94] or [Conrad Notes, P45].**?** □

p**-Divisible Groups**

Prop. (13.5.3.6). For $k \in \texttt{Field}$, $\mathrm{char}\, k = p$, $A \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/k$, $A(k^{\mathrm{sep}})$ is an Abelian group and its l^n torsion is isomorphic to $(\mathbb{Z}/(l^n))^{2g}$ and its p^n torsion is isomorphic to $(\mathbb{Z}/(p^n))^r$ for some $r \geq 1$.

Prop. (13.5.3.7). There is an isomorphism

$$H_t^m(\Lambda_{K^{\mathrm{sep}}}, \mathbb{Q}_l) \cong \bigwedge_{\mathbb{Q}_l}^m (V_l(A))^*.$$

Cf.[Grothendieck Monodromy theorem].

4 Dual Abelian Varieties

Def. (13.5.4.1)[Dual Abelian Variety]. For an Abelian variety A, the **dual Abelian variety** $\widehat{A}$ is defined to be its Picard variety $\underline{\mathrm{Pic}}^0_{A/k}$, which represents $\widetilde{\underline{\mathrm{Pic}}}^0_{A/k}$ and is a projective scheme by(8.7.3.33). We will see it is an Abelian variety in(13.5.4.12).

Prop. (13.5.4.2)[$A \to \widehat{A}$ Induced by a Line Bundle]. If A is an Abelian variety over k, for any line bundle c, there is a line bundle on $A \times A$ given by the **Mumford line bundle**

$$\Lambda(c) = m^* c - \mathrm{pr}_1^* c - \mathrm{pr}_2^* c,$$

where $m : A \times A \to A$ is the product. It is in $\mathrm{Pic}^0(A)$ because $\Lambda(c)|_{e\times A} = 0$ and $\Lambda(c)|_{A\times a} = \tau_a^* c - c$. Then by definition, this line bundle corresponds to a morphism $\varphi_c : A \to \widehat{A}$ over k, and by(8.7.3.34) $\varphi_c(a) = \tau_a^* c - c \in \widehat{A}(k(a))$. This is also a homomorphism of Abelian variety, by(13.5.1.4), as $\varphi_c(e) = e$.

Cor. (13.5.4.3) [φ-Construction]. It is clear from the definition above that $\mathcal{L} \mapsto \varphi_{\mathcal{L}}$ is a group homomorphism $\mathrm{Pic}(A) \mapsto \mathrm{Hom}(A, \widehat{A})$.

Cor. (13.5.4.4). For $x \in A(k)$, $\varphi_{\tau_x^* \mathcal{L}} = \varphi_{\mathcal{L}}$.

Proof: This follows from see-saw lemma, by observing that stalks of the line bundles in(13.5.4.2) are $\tau_{a+x}^* \mathcal{L} - \tau_x^* \mathcal{L}$ and $\tau_a^* \mathcal{L} - \mathcal{L}$ resp.. □

Cor. (13.5.4.5). $(1, \varphi_{\mathcal{L}})^* p_A = \mathcal{L} \otimes [-1]^* \mathcal{L}$.

Proof:

$$(1, \varphi_{\mathcal{L}})^* p_A = (x \mapsto (x, -x))^* (1, -\varphi_{\mathcal{L}})^* p_A = (x \mapsto (x, -x))(-m^* \mathcal{L} + \mathrm{pr}_1^* \mathcal{L} + \mathrm{pr}_2^* \mathcal{L}) = \mathcal{L} \otimes [-1]^* \mathcal{L}.$$

□

Prop. (13.5.4.6)[Poincaré Class is Even]. Let $p \in \mathrm{Pic}(A \times \widehat{A})$ be the Poincaré class of A, then p is even in $\mathrm{Pic}(A \times \widehat{A})$.

Proof: Let $b \in \widehat{A}$, then

$$([-1]^*(p))|_{A\times\{b\}} = [-1]^*(p|_{A\times\{-b\}}) = [-1]^*(-b) = b.$$

and

$$([-1]^*(p))|_{\{0\}\times\widehat{A}} = [-1]^*(p|_{\{0\}\times\widehat{A}}) = 0.$$

Thus $[-1]^* p \cong p$ by(8.7.3.34) and the see-saw principle(5.10.1.22). □

Lemma (13.5.4.7). If $b \in \mathrm{Pic}(A)$ that $\varphi_b = 0$, then for any ample $c \in \mathrm{Pic}(A)$, there is some $a \in A(K)$ that $b = \tau_a^*(c) - c$.

Proof: [Mumford, P77]. □

Prop. (13.5.4.8) [Characterizing $\widehat{A}$]. For $c \in \mathrm{Pic}(A)$, $[-1]^*(c) - c \in \mathrm{Pic}^0(A)$, the following are equivalent:

1. $b \in \mathrm{Pic}^0(A)$.
2. $\ker(\varphi_b) = A$.
3. For every ample line bundle c, there is an $a \in A$ that $b \cong \tau_a^*(c) - c$.
4. There is an ample line bundle c and an $a \in A$ that $b \cong \tau_a^*(c) - c$.
5. c is odd.
6. For any scheme X, the map $\mathrm{Mor}(X, A) \to \mathrm{Pic}(X) : \varphi \mapsto \varphi^*(c)$ is linear.

Proof: $2 \to 3$ is by the lemma(13.5.4.7). $4 \to 1$ is by(13.5.4.2).

$1 \to 2$: By(8.7.3.22), It suffices to prove for K alg.closed. Firstly we shows there is a morphism underlying the map

$$\varphi : A \times \underline{\mathrm{Pic}}^0(A) \to \underline{\mathrm{Pic}}^0(A) : (a, b) \mapsto \tau_a^*(b).$$

For $T = A \times Pic^0(A)$, consider the line bundle $c = (m \times \mathrm{id}_{\underline{\mathrm{Pic}}^0(A)})^*(p)$ on $A \times T$. Notice the restriction of $m \times \mathrm{id}_{\underline{\mathrm{Pic}}^0(A)}$ on $A \times \{a\} \times \{b\}$ is given by τ_a,

$$c|_{A \times \{a\} \times \{b\}} = \tau_a^*(b),$$

and also $c|_{\{0\} \times T} = p$, so the family $c - \mathrm{pr}_2^*(p)$ of $\mathrm{Pic}^0(A)$ parametrized by T gives an morphism $T \to \underline{\mathrm{Pic}}^0(A)$ extending φ.

Next, because $\varphi(A \times \{0\}) = 0$, by rigidity lemma(5.10.1.20) we have $\tau_a^*(b) \cong b$ for any line bundle b.

$6 \to 5$ is trivial, and 6 is clearly equivalent to the assertion when $X = A$, and it is equivalent to 2 by(13.5.1.29).

We next prove $[-1]^*(c) - c \in \mathrm{Pic}^0(A)$: because $[-1]\tau_a = \tau_{-a}[-1]$, we have

$$\tau_a^*([-1]^*(c)) - [-1]^*(c) = [-1](\tau_{-a}^*(c) - c).$$

since $\tau_{-a}^*(c) - c \in \mathrm{Pic}^0(X)$ by(13.5.4.2), the equation is equal to $c - \tau_{-a}^*(c)$ by implication$1 \to 2 \to 6$. and this further equals $\tau_a^*(c) - c$ by the theorem of square(13.5.1.23). Then

$$\tau_a^*([-1]^*(c) - c) - ([-1]^*(c) - c) = 0.$$

Hence $[-1]^*(c) - c \in \mathrm{Pic}^0(A)$ by the implication $2 \to 3 \to 4 \to 1$.

$5 \to 1$: Let c be an odd element, then $-2c = [-1]^*(c) - c \in \mathrm{Pic}^0(A)$ by what just proved, we have $c \in \mathrm{Pic}^0(A)$, then φ_c has image in the kernel of $[2]$ on $\widehat{A}$, by the implication $1 \to 2$, thus it has trivial image, by(13.5.6.14). □

Cor. (13.5.4.9). $\mathcal{L} \mapsto \varphi_{\mathcal{L}}$ induces an injective map

$$\mathrm{NS}(A_{\overline{k}}) = \mathrm{Pic}(A_{\overline{k}}) / \mathrm{Pic}^0(A_{\overline{k}}) \hookrightarrow \mathrm{Hom}_{\overline{k}}(A_{\overline{k}}, \widehat{A}_{\overline{k}}).$$

Cor. (13.5.4.10) [Abelian Varieties are Finite Torsion-Free]. For an Abelian variety A, $\mathrm{NS}(A_{\overline{k}})$ is a finite free $\mathbb{Z}$-module. (Although this is true for any complete variety).

Proof: This follows from(13.5.4.9) and(13.5.6.9). □

Prop. (13.5.4.11)[Ample Implies Non-Degenerate]. A class $\mathcal{L}\in\mathrm{Pic}(A)$ is ample iff $\ker\varphi_{\mathcal{L}}$ is finite and $H^0(A,nc)\neq 0$ for some $n>0$.

In particular, an effective line bundle on A is ample iff $\ker\varphi_{\mathcal{L}}$ is finite.

Proof: Cf.[Diophantine Geometry, P253] or [Conrad notes].**?** □

Cor. (13.5.4.12) [Dual Abelian Variety]. Let $k\in\texttt{Field}$ and $A\in\mathcal{A}b\mathcal{V}ar/k$, then

$$A^\vee=\underline{\mathrm{Pic}}^0_{X/S}=\underline{\mathrm{Pic}}^0_{X/S,\mathrm{red}}=\underline{\mathrm{Pic}}^\tau_{X/S}$$

is also an Abelian variety, and $\dim A=\dim\widehat{A}=\dim_k H^1(A,\mathcal{O}_A)$.

Proof: Take an ample line bundle $\mathcal{L}$ on A, then $\varphi_L:A\to\widehat{A}$ has finite kernel, thus $\dim\widehat{A}\geq\dim A$, but by(13.5.3.5) and(8.7.3.24), $\dim_k H^1(A,\mathcal{O}_A)=T_e(\widehat{A})\leq\dim A$, thus it is regular by(4.3.5.17).

$\underline{\mathrm{Pic}}^\tau_{X/S}=\underline{\mathrm{Pic}}^0_{X/S}$ as we can pass to the $k=\overline{k}$, and use the fact Abelian varieties are torsion-free(13.5.4.10). □

Def. (13.5.4.13)[Non-degenerate Line Bundles]. A **non-degenerate line bundle** on an Abelian variety is a line bundle $\mathcal{L}$ s.t. $K(\mathcal{L})=\ker\varphi_{\mathcal{L}}$ is a finite group scheme, i.e. $\varphi_{\mathcal{L}}$ is an isogeny.

Prop. (13.5.4.14)[Ample Line Bundles induce Isogenies]. For any ample line bundle c on A, the morphism $\varphi_c:A\to\widehat{A}$ is an isogeny, because it is surjective by(8.1.5.14).

Lemma (13.5.4.15). For $k\in\texttt{Field}$ and $A\in\mathcal{A}b\mathcal{V}ar/k$, $\mathcal{L}\in\mathrm{Pic}(A)$, consider the double Picard map(8.7.3.37) $\kappa_A:A\to\widehat{\widehat{A}}$, then $\varphi_{\mathcal{L}}=\widehat{\varphi}_{\mathcal{L}}\circ\kappa_A:A\to\widehat{A}$.

Proof: Cf.[van Der Geer, P100]. □

Prop. (13.5.4.16)[Double Duality Theorem]. For $k\in\texttt{Field}$ and $A\in\mathcal{A}b\mathcal{V}ar/k$, the double Picard map(8.7.3.37) $A\to\widehat{\widehat{A}}$ is an isomorphism.

Proof: Cf.[van Der Geer, P101].**?** □

5 Cohomology of Line Bundles

Prop. (13.5.5.1). $H^n(A\times A^\vee,p_A)=\delta_{n,g}$.

Proof: Cf.[Conrad, P62]. □

Prop. (13.5.5.2)[Riemann-Roch]. Let A be an Abelian variety of dimension g, and $\mathcal{L}\in\mathrm{Pic}(A)$, then $\chi(\mathcal{L})=c_1(\mathcal{L})^g/g!$ and $\chi(\mathcal{L})^2=\deg(\varphi_{\mathcal{L}})$.

Proof: Cf.[Van de Geer, P131]. □

Cor. (13.5.5.3). Let $f:X\to Y$ be an isogeny of Abelian varieties, then $\chi(f^*\mathcal{L})=\deg(f)\chi(\mathcal{L})$.

Proof: □

Prop. (13.5.5.4) [Index]. If $\mathcal{L}$ is a non-degenerate line bundle on an Abelian variety A over a field k, then there is a unique integer $0 \le i \le g$ s.t. $H^i(X, \mathcal{L}) \neq 0$. Such an i is called the **index of $\mathcal{L}$**. Notice index0 just means it is effective.

Proof: □

Thm. (13.5.5.5) [Kempf-Mumford-Ramanujam]. Let $\mathcal{L}$ be a line bundle on an Abelian variety A, and fix an ample line bundle H on A, let Φ be the Hilbert polynomial of $\mathcal{L}$ w.r.t. H, then

- The multiplicity of 0 in Φ equals $\dim K(\mathcal{L})$.
- If $\mathcal{L}$ is non-degenerate, then all roots of Φ in $\mathbb{C}$ are real, and the number of positive roots equals $i(\mathcal{L})$.

Proof: Cf.[Van de Geer, P139,140]. □

Cor. (13.5.5.6). Let $\mathcal{L}$ be a non-degenerate line bundle on A and $f : B \to A$ is an isogeny of Abelian varieties, then $i(\mathcal{L}) = i(f^*\mathcal{L})$.

Proof: This follows from the relation of Hilbert polynomial resulted from(13.5.5.3) and the above theorem(13.5.5.5). □

6 Isogenies and Tate Modules

Isogenies

Prop. (13.5.6.1) [Isogenies of Abelian Varieties]. Let $k \in \mathtt{Field}$ and $f : X \to Y \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/k$, the following are equivalent:

- f is an isogeny.
- f is surjective and $\dim X = \dim Y$.
- $\ker f$ is a finite group scheme and $\dim X = \dim Y$.
- f is finite.

The set of isogenies from X to Y is denoted by $\mathrm{Isog}(X, Y)$. $\mathrm{Isog}(X, X) \cup \{0\}$ is denoted by $\mathrm{Isog}(X)$.

Proof: This follows from the theory of algebraic groups. □

Def. (13.5.6.2) [Isogenous Abelian Varieties]. For $k \in \mathtt{Field}$ and $A, B \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/k$, write $A \sim B$ to mean that A, B is isogenous. This is an equivalence relation.

Prop. (13.5.6.3) [Separable Isogenies]. Let $f : X \to Y$ be an isogeny of Abelian varieties over k, then

- For any $Q \in Y(\overline{k})$, $\#f^{-1}(Q)(\overline{k}) = \deg_s(f)$, and for any $P \in X$, $e_P(f) = \deg_i(f)$.
- The map: $X[f] \to \mathrm{Gal}(K(X_{\overline{k}})/\varphi^*(K(Y_{\overline{k}}))) : P \mapsto \tau_P^*$ is an isomorphism of groups.
- f is unramified iff it is étale iff it is separable, and in this case, $K(X_{\overline{k}})/K(Y_{\overline{k}})$ is an Abelian Galois extension of degree $\deg(f)$.

Proof: 1: By(5.10.3.4), this holds for Q in a dense open subset of Y, thus by homogeneity, it holds for all Q. The second assertion follows from the fact after shrining f is finite locally free of rank $\deg(f)$ by using homogeneity on X.

2: This is clearly a group homomorphism. By Galois theory, it suffices to show it is injective, which is clear.

3: This follows from(13.5.6.1) and generic unramifiedness(5.6.5.9). □

Prop. (13.5.6.4) [Isogenous is an Equivalence Relation]. If $k \in \texttt{Field}, X, Y \in \mathcal{A}b\mathcal{V}ar/k$ and $f \in \mathrm{Isog}(X, Y)$, $d = \deg(f)$, then there exists $g \in \mathrm{Isog}(Y, X)$ s.t. $g \circ f = [d]_X, f \circ g = [d]_Y$.

Proof: As $\ker(f)$ is a finite group scheme of rank d, $[d]\ker(f) = 0$, so $[d]$ factors through f via $g : Y \to X$, so $g \circ f = [d]_X$. Then also $[d]_Y \circ f = f \circ [d]_X = f \circ (g \circ f) = (f \circ g) \circ f$, thus $[d]_Y = f \circ g$ as f is a quotient map. □

Prop. (13.5.6.5) [Dual Isogenies]. Let $A, A' \in \mathcal{A}b\mathcal{V}ar/k$ and $\varphi \in \mathrm{Hom}(A, A')$, then we get a dual homomorphism $\widehat{\varphi} \in \mathrm{Hom}(\widehat{A'}, \widehat{A})$. Then:

- $\widehat{\widehat{\varphi}} = \varphi$.
- $\deg(\widehat{\varphi}) = \deg(\varphi)$.
- $\widehat{\varphi + \psi} = \widehat{\varphi} + \widehat{\psi}$.
- $\widehat{[m]_E} = [m]_{\widehat{E}}$.

Proof: 1: This is formal.
2: [Conrad, P66].?
3: This is clear from the modular description of $\widehat{A}$.
4: This follows from 3. □

<u>$\mathrm{Hom}(X, Y)$</u>

Def. (13.5.6.6) [Simple Abelian Varieties]. A **simple Abelian variety** is an Abelian variety that has no non-trivial Abelian subvarieties.

Prop. (13.5.6.7) [Poincaré's Complete Reducibility Theorem]. Let B be an Abelian subvariety of A, then there exists an Abelian subvariety C of A that the addition gives an isogeny

$$B \times C \to A.$$

Proof: Choose an ample line bundle c on A, let $\iota : B \to A$ be the inclusion and $\widehat{\iota} : \widehat{A} \to \widehat{B}$ the dual map, then

$$(\widehat{\iota} \circ \varphi_c)|_B = \varphi_{\iota^*(c)}.$$

Since $\iota^*(c)$ is also ample, $\varphi_{\iota^*(c)}$ is an isogeny, thus has finite kernel. Let $C = \ker(\iota \circ \varphi_c)$, then we have $C \cap B$ is finite, whence $B \times C \to A$ has finite kernel. The dimension theorem(8.1.4.36) applied to $\iota \circ \varphi_c$ shows

$$\dim C + \dim \widehat{B} = \dim \widehat{A}.$$

and this together with(13.5.4.12) shows $B \times C \to A$ is a surjection, because A is irreducible. Thus it is an isogeny. □

Cor. (13.5.6.8). For $k \in \texttt{Field}, A \in \mathcal{A}b\mathcal{V}ar/k$, there are simple Abelian subvarieties $B_1, \ldots, B_n$ of A that the inclusions give an isogeny

$$B_1 \times \ldots \times B_n \to A.$$

Prop. (13.5.6.9) [$\mathrm{Hom}(A, A')$ is Torsion-Free and F.g.]. Let k be a field and $A, A' \in \mathcal{A}b\mathcal{V}ar/k$, then $\mathrm{Hom}(A_1, A_2)$ w.r.t. the addition is a f.g. torsion-free Abelian group of rank at most $4g^2$.

Proof: Assume $[m] \circ \varphi = 0$, then $\varphi \circ [m] = 0$, and use the fact $[m]$ is surjective(13.5.6.14). The last assertion follows from(13.14.1.1). □

Def. (13.5.6.10) [Quasi-Isogenies]. For $A, A' \in \mathcal{A}b\mathcal{V}ar/k$, $\mathrm{Hom}_{\mathbb{Q}}(A, A') = \mathrm{Hom}(A, A') \otimes \mathbb{Q}$ is called the set of **quasi-isogenies** from A to A'.

Define the category Isog/k to be the category consisting of Abelian varieties over k with morphisms $\mathrm{Mor}(A, A') = \mathrm{Hom}(A, A') \otimes \mathbb{Q}$. Notice $f : A \to A' \in \mathcal{A}b\mathcal{V}ar/k$ is an isogeny iff f is an isomorphism in Isog/k, by(5.4.4.20).

Thus by(13.5.6.8), Isog/k is a semisimple $\mathbb{Q}$-linear Abelian category.

Prop. (13.5.6.11). For $A, A' \in \mathcal{A}b\mathcal{V}ar/k$, if $A \sim A'$, then $\mathrm{End}_{\mathbb{Q}}(A) = \mathrm{End}_{\mathbb{Q}}(A')$. Moreover, $\mathrm{End}_{\mathbb{Q}}(A)$ is a semisimple $\mathbb{Q}$-algebra, and it is simple iff A is simple.

Proof: These follow from(13.5.6.8). □

Tate Modules

Prop. (13.5.6.12). Let $S \in \mathcal{S}ch$ be locally Noetherian, and $A \in \mathcal{A}b\mathcal{V}ar^g/S, n \in \mathbb{Z}_+$, then $A[n]$ is a finite locally free S-group scheme of order n^{2g}.

Proof: ? □

Cor. (13.5.6.13). For an Abelian variety X and any $n > 0$, the group of geometric points of order n in X is finite.

Prop. (13.5.6.14) [Multiplication Map, Weil]. Let $k \in \texttt{Field}^p, A \in \mathcal{A}b\mathcal{V}ar/k$, and $n \in \mathbb{Z} \cap k^\times$, then $[n] : A \to A$ is finite faithfully flat of degree $n^{2\dim A}$. In particular it is an isogeny(13.5.6.1), and

- If $n \in \mathbb{Z} \cap k^*$, then $[n]$ is finite étale and $A[n] \cong (\mathbb{Z}/n\mathbb{Z})^{2\dim A}$.
- If $n = 0 \in k$, then $[n]$ is not separable.
- If $p > 0$, then $\ker([p]) \cong (\mathbb{Z}/p\mathbb{Z})^r \times \alpha_p^{2g-2r} \times \mu_p^r$ for some $0 \le r \le g$. In particular, $A[p^e] = (\mathbb{Z}/(p^e))^r$ for any $e \ge 0$. This r is called the p**-rank** of A. It is invariant under isogenies.

Proof: 1, 2: Let $Z = \ker([n])$, then it is proper. By(13.5.1.25), choose an ample line bundle $\mathcal{L} = \mathcal{L}(D) \in \mathrm{Pic}(A)$, then $\mathcal{O}_Z = \mathcal{L}_Z^{n(n+1)/2} \otimes [-1]^*\mathcal{L}_Z^{n(n-1)/2}$. As $\mathcal{L}_Z$ and $[-1]^*\mathcal{L}_Z$ are both ample, $\mathcal{O}_Z$ is ample. Now(5.4.4.20) shows Z is finite. Thus by dimension equation, $[n]$ is finite and faithfully flat.

The action of $[n]$ on the tangent space at the origin is given by multiplying by n by(8.2.2.1), thus it is unramified at the origin iff $n \in \mathbb{Z} \cap k^*$ by(5.6.5.12), and also on any other closed points by homogeneity. Thus if $n \in \mathbb{Z} \cap k^*$, $[n]$ is finite étale, and otherwise $[n]$ is not separable, by(5.6.5.12), as it is not generically unramified.

To calculate $A[n]$ in the étale case, notice $[n]^*D = n^2 D$, and the intersection number formula

$$n^{2g}(D \cdot D \cdot \ldots \cdot D) = ([n]^*D \cdot [n]^*D \cdot \ldots \cdot [n]^*D) = \deg([n])(D \cdot D \cdot \ldots \cdot D)$$

where the intersection is g-fold, thus $(D \cdot D \cdot \ldots \cdot D)$ equals the degree of the projection embedding of X via $\mathcal{L}(D)$ thus positive, so we get $\deg([n]) = n^{2g} = \#A[n]$ as $[n]$ is finite étale. To see the structure of $A[n]$, notice this is true for any $m|n$.

3: ?Cf.[Conrad]. The last assertion follows from the fact the fact $[p]$ is surjective and the structure theory of Abelian groups. □

Def. (13.5.6.15) [Tate Modules]. Let $k \in \texttt{Field}$, $A \in \mathcal{A}b\mathcal{V}ar/k$. For $\ell \in \mathbf{P}\backslash \operatorname{char} k$, define $T_\ell(A) = \varprojlim_{n\geq 0} A[\ell^n]$, called the **Tate module** of A. Then it is naturally a $\mathbb{Z}_\ell$-module and isomorphic to $\mathbb{Z}_\ell^{2g}$ by(13.5.6.14).

Thus we can define $V_\ell(A) = T_\ell(A) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$. There are Gal_k actions on them, as $[\ell^n]$ is étale and Gal_k preserves $A[\ell^n]$ because O is Gal_k-invariant.

For $\ell = \operatorname{char} k = p > 0$, we can also define $T_p(A)$, which is isomorphic to $\mathbb{Z}_p^r$ for some $0 \leq r \leq g$ by(13.5.6.14), but there is not Galois action on it.

Def. (13.5.6.16) [Adelic Tate Modules]. Situation as in(13.5.6.15), if $\operatorname{char} k = 0$, define the **Adelic Tate module** to be

$$T_f(A) = \prod_{\ell\in\mathbf{P}} T_\ell(A), \quad V_f(A) = \prod_{\ell\in\mathbf{P}}{}' (V_\ell(A), T_\ell(A)).$$

Prop. (13.5.6.17) [Étale Cohomology and Tate Modules]. Let $k = k^s$ and $A \in \mathcal{A}b\mathcal{V}ar/k$, and $\ell \in \mathbf{P}\backslash \operatorname{char} k$, then

- There is a canonical isomorphism $H^1_{\text{ét}}(A, \mathbb{Z}_\ell) \cong \mathrm{Hom}_{\mathbb{Z}_\ell}(T_\ell(A), \mathbb{Z}_\ell)$. Thus $H^1_{\text{ét}}(A, \mathbb{Z}_\ell) \cong \mathbb{Z}_\ell^{2g}$ by(13.5.6.14).
- The cup product define isomorphisms $\wedge^r H^1_{\text{ét}}(A, \mathbb{Z}_\ell) \cong H^r(A, \mathbb{Z}_\ell)$ for any $r > 0$.

Proof: Cf.[Mil08]P55.**?** □

Cor. (13.5.6.18). There is a natural Gal_k-invariant pairing $\wedge^r T_\ell(A) \times \mathrm{H}^r_{\text{ét}}(A, \mathbb{Z}_\ell) \to \mathbb{Z}_\ell$.

Prop. (13.5.6.19) [Semisimplicity]. Let $F \in \texttt{GField}$, $\ell \in \mathbf{P}\backslash \operatorname{char} F$, $A \in \mathcal{A}b\mathcal{V}ar/F$, then the action of Gal_F on $V_\ell(A)$ is semisimple.

Proof:

□

7 Polarizations and Weil Pairings

Polarizations and Rosati Involutions

Def. (13.5.7.1) [Polarizations]. Let $k \in \texttt{Field}$, a **polarization** of an Abelian variety $A \in \mathcal{A}b\mathcal{V}ar/k$ is an isogeny $\lambda : A \to \widehat{A}$ that $\lambda_{\overline{k}} = \varphi_{\mathcal{L}}$ for some ample invertible sheaf $\mathcal{L} \in \mathrm{Pic}(A_{\overline{k}})$. A **principal polarization** of an Abelian variety is a polarization of degree1.

The category of Abelian varieties over k of dimension g together with a polarization of degree d is denoted by $\mathcal{A}b\mathcal{V}ar^{\dim=g,\mathrm{polar}=d}/k$.

Prop. (13.5.7.2) [Zariski's Trick]. For any $k \in \texttt{Field}$ and $A \in \mathcal{A}b\mathcal{V}ar/k$, $(A \times A^\vee)^4$ is canonically principally polarized.

Proof: Cf.[Mil08]P60. □

Prop. (13.5.7.3) [Finitely Many Polarizations]. Let $k \in \texttt{Field}$ and $A \in \mathcal{A}b\mathcal{V}ar/k$, then for any $d \in \mathbb{Z}_+$, there are only f.m. isomorphism classes of polarizations on A of degree d.

Proof: Cf.[Mil08]P63. □

Def. (13.5.7.4) [Rosati Involution].

Prop. (13.5.7.5). Let $k \in \texttt{Field}$ and $(A, \lambda) \in \mathcal{A}b\mathcal{V}ar/k$, then

- $\#\,\mathrm{Aut}((A, \lambda)) < \infty$.
- for any $n \geq 3$, any automorphism of (A, λ) acting trivially on $A[n]$ is the identity.

Weil Pairings

Prop. (13.5.7.6) [Weil Pairing for Elliptic Curves]. Let $E \in \mathcal{E}\mathrm{ll}/k$, then for any $m \in \mathbb{Z} \cap k^*$, there is a non-degenerate pairing

$$e_m : E[m] \times E[m] \to \mu_m$$

that is alternating, non-degenerate and Gal_k-invariant.

Moreover, $e_{mm'}(S, T) = e_m([m']S, T)$ for $S \in E[mm']$ and $S \in T[m]$. In particular, for $\ell \in \mathbf{P} \backslash \operatorname{char} k$, we can define a Weil pairing on the Tate module

$$e : T_\ell(E) \times T_\ell(E) \to \mu_{\ell^\infty}.$$

Proof: Let $T \in E[m]$, then by(13.9.1.21), there exists some $f \in \overline{K}(E)^*$ s.t. $\mathrm{div}(f) = m[E] - m[O]$. Let $T' \in E[m^2]$ s.t. $mT' = T$, then there exists a function $g \in \overline{K}(E)^*$ s.t.

$$\mathrm{div}(g) = [m]^*(T) - [m]^*(O) = \sum_{R \in E[m]} ([T' + R] - [R]).$$

Notice $f \circ [m]$ and g^m have the same divisor, so we may assume $f \circ [m] = g^m$. Then for any $S \in E[m]$ and $X \in E$, $g(S + X)^m = f(mX) = g(X)^m$, so $E \to \mathbb{P}^1 : g(X + S)/g(X)$ is constant and has value in μ_m, denote it by $e(T, S)$.

For bilinearity, Cf.[Sil16]P94**?**.

For alternating, Cf.[Sil16]P94**?**.

For non-degeneracy, if $e_m(S, T) = 1$ for any $T \in E[m]$, then g is $E[m]$-invariant, which implies $g = h \circ [m]$ for some $h \in \overline{K}(E)^*$ by(13.5.6.3) and the fact $[m]$ is separable. Then $(h \circ [m])^m = f \circ [m]$, so $f = h^m$, and $\mathrm{div}(h) = [T] - [O]$, so $T = O$.

Galois invariance is clear.

The last assertion follows by taking $g' = g \circ [m']$ and $f' = f^{m'}$. □

Cor. (13.5.7.7) [Primitive Pairing]. Let $E \in \mathcal{E}\mathrm{ll}/k$, then for any $m \in \mathbb{Z} \cap k^*$, $\mu_m \subset K(E[m])$, and there exists some $S, T \in E[m]$ s.t. $e_m(S, T)$ is a primitive m-th roots of unity.

Proof: If the subgroup generated by all $e_m(S, T)$ is μ_d, then $e_m([d]S, T) = 1$ for any $S, T \in E[m]$, so $[d]S = 0$ by non-degeneracy, so $d = m$ because $\#E[m] = (\mathbb{Z}/(m))^2$. Then the Gal_k-invariance of e shows $\mu_m \subset K(E[m])$. □

Prop. (13.5.7.8) [Duality with Isogenies]. Let $\varphi : E_1 \to E_2$ be an isogeny between elliptic curves over a field k, $m \in \mathbb{Z} \in k^*$, then for $S \in E_1[m], T \in E_2[m]$,

$$e_m(S, \widehat{\varphi}(T)) = e_m(\varphi(S), T).$$

In particular, for $S \in T_\ell(E_1)$ and $T \in T_\ell(E_2)$, $e(S, \widehat{\varphi}(T)) = e(\varphi(S), T)$.

Proof: Cf.[Sil16]P97**?**. □

Prop. (13.5.7.9). Let $E \in \mathcal{E}\mathrm{ll}/k$ and $\varphi \in \mathrm{End}(E), \varphi \in \mathrm{End}(E)$, $\ell \in \mathbf{P} \backslash \operatorname{char} k$, then $\det(\varphi_\ell) = \deg(\varphi), \mathrm{tr}(\varphi_\ell) = 1 + \deg(\varphi) - \deg(1 - \varphi)$.

Proof: For any $v, v' \in T_\ell(E)$, use the Weil pairing:

$$e(v, v')^{\deg(\varphi)} = e([\deg(\varphi)]v, v') = e(\varphi_\ell v, \varphi_\ell v') = e(v, v')^{\det(\varphi_\ell)},$$

thus $\deg(\varphi) = \det(\varphi_\ell)$. The latter equality follows from the identity $\mathrm{tr}(A) = 1 + \det(A) - \det(1 - A)$ for any $A \in M_2(R)$. □

8 Over Archimedean Local Fields

Prop. (13.5.8.1) [Complex Abelian Varieties and Complex Tori]. By(11.9.5.9) and GAGA(11.8.7.17), the category of Abelian varieties over $\mathbb{C}$ is the same as the category of complex tori V/Λ with a Riemann form ω.

Such a complex tori V/Λ with a Riemann form ω is called a **polarizable integral Hodge structure**.

Prop. (13.5.8.2) [Rosati Involutions are Positive]. Let $X = V/\Lambda \in \mathcal{A}b\mathcal{V}ar/\mathbb{C}$, then for any $\alpha \in \mathrm{End}_{\mathbb{Q}}(X)$, there exists $\alpha' \in \mathrm{End}_{\mathbb{Q}}(X)$ s.t.

$$\omega(\alpha x, y) = \omega(x, \alpha' y).$$

And this determines an involution on $\mathrm{End}_{\mathbb{Q}}(X)$, called the **Rosati involution**. Notice this is compatible with that defined in(13.5.7.4), by using(11.9.5.10).

Then this is a positive involution on $\mathrm{End}_{\mathbb{Q}}(X)$.

Proof: Notice the form $\omega_J : (x, y) \mapsto \omega(x, Jy)$ is symmetric and positive, and

$$\omega_J(\alpha x, y) = \omega(\alpha x, Jy) = \omega(x, \alpha' Jy) = \omega(x, J\alpha' y) = \omega_J(x, \alpha' y).$$

So this involution is positive by(13.6.2.19). □

Thm. (13.5.8.3) [Frobenius-Lefschetz-Poincaré-Riemann-Weierstrass]. The functor $A \mapsto H_1(A, \mathbb{Z})$ defines an equivalence from $\mathcal{A}b\mathcal{V}ar/\mathbb{C}$ to the category of polarizable integral Hodge structures of type $\{(-1, 0), (0, -1)\}$.

Proof: ? □

Elliptic Curve Case

Prop. (13.5.8.4) [Complex Tori as Elliptic Curves]. Let Λ be a complete real lattice of $\mathbb{C}$, then we can make $\mathbb{C}/\Lambda$ into a Riemannian surface as the quotient space of $\mathbb{C}$. Then it is positive by**??**t is a smooth curve of genus 1 with the origin as the rational point, which means it is an elliptic curve.

Prop. (13.5.8.5) [Elliptic Curve as Complex Tori]. For an elliptic curve $\mathbb{C}/\Lambda$ over $\mathbb{C}$, by(10.6.4.7), the Weierstrass functions(10.6.4.5) $\mathfrak{P}, \mathfrak{P}'$ are just the rational functions in(13.9.1.6), so the map

$$z \mapsto [\mathfrak{P}(z), \mathfrak{P}'(z), 1]$$

is biholomorphic from $\mathbb{C}/\Lambda$ to the elliptic curve defined by the Weierstrass equation $y^2 = 4x^3 - g_2(\Lambda)x - g_3(\Lambda)$ that $g_2^3 - 27g_3^2 \neq 0$. And it also preserves the group structure.

Proof: To show that the homomorphism preserves group structure, notice that if z_1, z_2, z_3 maps to three points that is colinear, then they satisfy a equation

$$f(z) = a\mathfrak{P}(z) + b\mathfrak{P}'(z) + c.$$

If $b \neq 0$, then this is a meromorphic function with three poles, thus three zeros, which is exactly z_1, z_2, z_3, so by(10.6.4.2), $z_1 + z_2 + z_3 \equiv 0 \mod \Lambda$. If $b = 0$, then $z_3 = 0$, which corresponds to the point $(1, 0, 0) \in \mathbb{P}^2$, then the same argument shows $z_1 + z_2 + 0 \equiv 0 \mod \Lambda$. □

Lemma (13.5.8.6) [Isogenies and Homogeneities]. If E_1, E_2 are elliptic curves in $\mathbb{P}^2$ corresponding to Λ_1, Λ_2 via(13.5.8.5) resp., then the natural map

$$\{\text{isogenies } E_1 \to E_2\} \to \{\text{non-constant holomorphic maps } \varphi : \mathbb{C}/\Lambda_1 \to \mathbb{C}/\Lambda_2, \varphi(0) = 0\}$$

is a bijection.

Proof: By(11.9.5.2), it suffices to show for any lattices Λ_1, Λ_2 and $\alpha \in \mathbb{C}^*$ that $\alpha\Lambda_1 \subset \Lambda_2$, the map

$$[\mathfrak{P}(z, \Lambda_1), \mathfrak{P}'(z, \Lambda_1), 1] \to [\mathfrak{P}(\alpha z, \Lambda_2), \mathfrak{P}'(\alpha z, \Lambda_2), 1]$$

is a morphism. For this, notice $\mathfrak{P}(\alpha z, \Lambda_2)$ is an elliptic function for Λ_1, thus by(10.6.4.7), it is a rational function of $\mathfrak{P}(z, \Lambda_1)$ and $\mathfrak{P}'(z, \Lambda_1)$. □

Lemma (13.5.8.7). Let $E/\mathbb{C}$ be an elliptic curve in $\mathbb{P}^2$ defined by a Weierstrass equation, then there exists a lattice $\Lambda \subset \mathbb{C}$, unique up to homothety, that the embedding given in(13.5.8.5) induces an isomorphism $\mathbb{C}/\Lambda \cong E(\mathbb{C})$.

Proof: This is a consequence of(10.6.4.8) and(13.9.1.13). □

Prop. (13.5.8.8) [Elliptic Curves and Complex Tori]. The following categories are equivalent:

- Category of elliptic curves over $\mathbb{C}$ with morphisms given by isogenies.
- Category of complex tori with morphisms homomorphisms preserving 0.
- Category of lattices in $\mathbb{C}$ with homotheties as morphisms.

Proof: This is a consequence of(13.5.8.5)(13.5.8.6) and(11.9.5.2). □

Prop. (13.5.8.9) [Complex Multiplication]. Let $E/\mathbb{C}$ be an elliptic curve, and let ω_1, ω_2 be a generator of the lattice Λ corresponding to E(13.5.8.8), then one of the following is true:

- $\mathrm{End}(E) \cong \mathbb{Z}$.
- $\mathbb{Q}(\omega_2/\omega_1)$ is an imaginary quadratic extension of $\mathbb{Q}$ and $\mathrm{End}(E)$ is isomorphic to an order of $\mathbb{Q}(\omega_2/\omega_1)$.

Proof: Cf.[Sil16]P176.? □

Prop. (13.5.8.10). Let $E/\mathbb{C}$ be an elliptic curve and Λ a lattice in $\mathbb{C}$ that $E(\mathbb{C}) \cong \mathbb{C}/\Lambda$, then

- there is a natural isomorphism $H_1(E(\mathbb{C}), \mathbb{Z}) \cong \Lambda : \gamma \mapsto \int_\gamma dz$.
- There is a natural isomorphism $H_1(E(\mathbb{C}), \mathbb{Z}/(m)) \cong E[m]$.

Proof: Cf.[Sil16]P176. □

Over $\mathbb{R}$

Prop. (13.5.8.11). Let $E \in \mathcal{E}\mathrm{ll}/\mathbb{R}$, then there exists a unique τ in the set

$$\mathcal{C} = \{\mathrm{i}\, t | t \geq 1\} \cup \{e^{\mathrm{i}\,\theta} | \pi/3 \leq \pi/2\} \cup \{1/2 + \mathrm{i}\, t | t \geq \sqrt{3}/2\}.$$

s.t. $j(\tau) = j(E)$. And by(13.9.6.3), each $\tau \in \mathcal{C}$ corresponds to exactly two isomorphism classes of elliptic curves over $\mathbb{R}$.

Proof: Firstly these τ satisfies $j(\tau)\in\mathbb{R}$ because by the power expansions of $j(\tau)$(16.2.5.10), for $\tau = it$ or $1/2+it$, $q\in\mathbb{R}$, thus $j(\tau)\in\mathbb{R}$. For $\tau = e^{i\theta}$, $\overline{j(e^{i\theta})} = j(-e^{-i\theta}) = j(e^{i\theta})$ as $j\in M_0(\Gamma(1))$.

Next it can be proven $j(i\infty)=+\infty$ and $j(1/2+i\infty)=-\infty$, and j is injective on $\mathcal{C}$ by(16.2.5.10). Thus the assertion follows by continuity. □

Remark (13.5.8.12). Notice by action of $\alpha = \begin{bmatrix}0 & -1\\ 1 & -1\end{bmatrix}\in \mathrm{SL}(2,\mathbb{Z})$ on $\{e^{i\theta}|\pi/3\le\pi/2\}$, we can also replace $\mathcal{C}$ by

$$\mathcal{C}' = \{\mathrm{i}\,t|t\ge 1\}\cup\{1/2+\mathrm{i}\,t|t>1/2\}.$$

9 char $k>0$ Case

Prop. (13.5.9.1). If $k\in\texttt{Field}, \#k<\infty$, then for any $g,d>0, \#\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}^{\mathrm{dim}=g,\mathrm{polar}=d^2}/k<\infty$.

Proof: Cf.[Mil08]P54. □

Prop. (13.5.9.2). Let $p\in\mathbf{P}, q\in p^{\mathbb{Z}}$, and $(A,\lambda)\in\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}^{\mathrm{polar}}/\mathbb{F}_q$ with Rosati involution $\dagger\in\mathrm{End}(A)_{\mathbb{Q}}$, then

$$\mathrm{Frob}_{q,A}^{\dagger}\circ\mathrm{Frob}_{q,A}=[q].$$

Proof: Cf.[Mil08]P76.**?** □

Honda-Tate Theory

References are [Tat66] and [Hon68].

Prop. (13.5.9.3)[Weil Conjecture for Abelian Varieties]. For $p\in\mathbf{P}, r\in\mathbb{Z}_+, q=p^r, \ell\in\mathbf{P}\backslash\ell$, and $A\in\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}^g/\mathbb{F}_q$, let $\varphi_A=\varphi^r$ be the Frobenius of A, and let $P_\varphi(X)$ be the characteristic polynomial of the action of φ_A on $T_\ell(A)$, then

- $P_{A,\ell}(X)\in\mathbb{Z}[X]$, and is invariant of ℓ chosen. Thus we omit ℓ from now on.
- $P_A(X)=\prod_{i=1}^{2g}(X-\alpha_i)$, where $\alpha_i\in\mathbb{C}$ and $|\alpha_i|=q^{1/2}$.
- $\#A(\mathbb{F}_{q^m})=\prod_{i=1}^{2g}(1-\alpha_i^m)$.

In particular,

$$|\#A(\mathbb{F}_{q^m})-q^{mg}|\le 2gq^{m-\frac{1}{2}}+(4^g-2g-1)q^{m(g-1)}.$$

Proof: These follow from(13.5.6.17) and Weil conjecture(13.12.2.6)(19.1.4.4). □

Thm. (13.5.9.4)[Honda-Tate]. For $p\in\mathbf{P}, q\in p^{\mathbb{Z}_+}$ and $A\in\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}^g/\mathbb{F}_q$ simple, by(13.5.9.3), for any embedding $\mathbb{Q}(\varphi_A)\hookrightarrow\mathbb{C}$, $\iota(\alpha)$ is a Weil q-number(12.4.2.13), and we get a map of sets

$$A\mapsto[\varphi_A]:\{\text{simple Abelian varieties}/\mathbb{F}_q\}/(\sim\text{isogenies})\to\mathrm{Weil}(q^{1/2})/(\sim\text{conjugations}).$$

Then this is a bijection.

Proof: The injectivity follows from(13.14.1.3) and the irreducibility of the action of φ_A on $V_\ell(A)$**?**, and the surjectivity is proven by Honda**??****?**(or [Chai-Oort]). □

Thm. (13.5.9.5)[Description of $\mathrm{End}(A)_{\mathbb{Q}}$ in terms of φ_A]. For $p\in\mathbf{P}, q\in p^{\mathbb{Z}_+}$ and $A\in\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}^g/\mathbb{F}_q$ be simple, let $D=\mathrm{End}(A)_{\mathbb{Q}}, \varpi=\varphi_A\in D$, then

- D is a central division ring over $\mathbb{Q}(\varpi)$.
- For any $v \in \Sigma_{\mathbb{Q}(\varpi)}$, $\mathrm{inv}_v(D) = \frac{\mathrm{ord}_v(\varpi)}{\mathrm{ord}_v(q)}[\mathbb{Q}(\varpi)_v : \mathbb{Q}_p] \in \mathbb{Q}/\mathbb{Z}$. In particular, for $v \notin \Sigma^{p\infty}_{\mathbb{Q}(\varpi)}$, $\in_v (D) = 0$.
- $[D : \mathbb{Q}]_{\mathrm{red}} = 2 \dim A$.

Proof: Cf.[Tat66] or [Waterhouse and Milne, 1971].**?** □

10 Reductions

over DVRs

Prop. (13.5.10.1) [Good Reductions]. Let (R, K, k) be a DVR and $A \in \mathcal{A}b\mathcal{V}ar/K$, then A has good reduction over R(13.8.1.2) iff there exists $\mathcal{A} \in \mathcal{A}b\mathcal{V}ar/R$ with generic fiber A. In this case, $A(K) \cong \mathcal{A}(R) \to \widetilde{A}(k)$ is a surjective map of Abelian groups.

It will be shown in(13.5.15.7) that a good reduction is unique if it exists.

Def. (13.5.10.2)[Conductor]. Let E be an elliptic curve over F, then the **conductor of** E is defined in [Sil99]P380.**?**

If $F = \mathbb{Q}$, then the conductor $N_E = \prod_{p\in\mathbf{P}} p^{f_p}$, where

$$f_p = \begin{cases} 0, & E \text{ has good reduction at } p \\ 1, & E \text{ has multiplicative reduction at } p \\ 2, & E \text{ has additive reduction at } p \ \& \ p \neq 2,3 \\ 2+\delta_p, & E \text{ has additive reduction at } p \ \& \ p = 2,3 \end{cases}$$

where $0 \leq \delta_2 \leq 6, 0 \leq \delta_2 \leq 3$.

Proof: □

Prop. (13.5.10.3)[Semistable Reduction Theorem].

- If K'/K is a finite extension, and E has stable or semistable reduction, then the reduction type of $E_{K'}$ is the same as that of E.
- If K'/K is a finite unramified extension, then the reduction type of $E_{K'}$ is the same as that of E.
- There exists a finite extension K'/K s.t. $E_{K'}$ is of stable or split semistable reduction type.

Proof: 1: For these two cases, c_4 and Δ cannot be reduced anymore to another minimal Weierstrass equation by(13.9.4.4).

2: It suffices to consider the additive reduction case: **?** The short Weierstrass equation case is clear, for the general case, use Tate's algorithm.

3: Use the Legendre or Deuring form(13.9.1.16)(13.9.1.17) to analyze Δ and c_4. □

Thm. (13.5.10.4)[Néron-Ogg-Shafarevich Criterion]. Let (R, K, k) be a DVR and $A \in \mathcal{A}b\mathcal{V}ar/K$, $\ell \in \mathbf{P}\setminus \mathrm{char}\, k$, then the following are equivalent:

- A has good reduction.
- The module $|A[m]|$ is unramified as a Gal_K-module, for all $m \in \mathbb{Z}\setminus \mathrm{char}\, k$.

- The Tate module $T_\ell(A)$ is unramified for all(some) primes $\ell \in \mathbf{P}\backslash \operatorname{char} k$.
- The module $A[m]$ is unramified for infinitely many $m \in \mathbb{Z}\backslash \operatorname{char} k$.

Proof: 2 → 3 → 4 are obvious.

For the rest, Cf.http://virtualmath1.stanford.edu/~conrad/mordellsem/Notes/L11.pdfP20 or [Mil08]P141.**?**

1 → 2: Let K' be the finite extension of K generated by $E[m]$, then (13.5.10.3) implies $E_{K'}$ has the same reduction type as E. Then by(13.9.4.20), $E[m] \to \widetilde{E}_{K'}(k')$ is an injection. So clearly I_v acts trivially on $E[m]$.

4 → 1: Let $m \in \mathbb{Z}\backslash \operatorname{char} k$ s.t. $E[m]$ is unramified and $m > \#E(K^{\mathrm{ur}})/E_0(K^{\mathrm{ur}})$, where $\#E(K^{\mathrm{ur}})/E_0(K^{\mathrm{ur}}) < \infty$ by(13.9.4.16). Then because $E[m] \cong (\mathbb{Z}/(m))^2 \subset E(K^{\mathrm{ur}})$, $E_0(K^{\mathrm{ur}})$ contains some subgroup isomorphic to $(\mathbb{Z}/(\ell))^2$ for some $\ell \in \mathbf{P}\backslash \operatorname{char} k$, thus by(13.9.4.20), $\widetilde{E}_{\mathrm{sm}}(\overline{k})$ contains some subgroup isomorphic to $(\mathbb{Z}/(\ell))^2$. But by(13.9.1.15), this is possible only when $\widetilde{E}_{\mathrm{sm}} = \widetilde{E}$. Thus $E_{K^{\mathrm{ur}}}$ has good reduction, so E also has good reduction by(13.5.10.3). □

Cor. (13.5.10.5). If $0 \to A' \to A \to A'' \to 0$ are exact sequences of Abelian varieties over K and A has good reduction, then A', A'' also have good reductions.

Cor. (13.5.10.6)[Isogeny and Good Reductions]. Let (R, K, k) be a DVR and $A \to A' \in \mathcal{A}b\mathcal{V}ar/K$ is an isogeny, then A has good reduction iff A' does.

Proof: Use(13.5.10.4) and the fact if $\ell \in \mathbf{P}$ is prime to $\operatorname{char} k$ and $\deg \varphi$, then $\varphi_\ell : T_\ell(A) \to T_\ell(A')$ is an isomorphism of Gal_K-modules. □

Prop. (13.5.10.7). If $K \in p$-`LField`, $\ell \in \mathbf{P}\backslash p$ and $A \in \mathcal{A}b\mathcal{V}ar/K$ satisfies $\rho_{\ell,A}(\mathrm{Gal}_K)$ has finite image, then A has potential good reduction.

Proof: It follows from class field theory that the image of I_K is a quotient of $\mathcal{O}_K^*$, which contains a pro-p-group of finite index, and $\mathrm{End}(T_\ell(A))$ contains a pro-ℓ-group of finite index, so the image is finite. Then A has potential good reduction by(13.5.10.4). □

Thm. (13.5.10.8) [Néron-Ogg-Shafarevich Criterion for Elliptic Curves]. Let K be a CDVR, $\ell \in \mathbf{P}\backslash \operatorname{char} k$ and $A \in \mathcal{A}b\mathcal{V}ar/K$, then

- A has good reduction iff $T_\ell(A)$ is an unramified Gal_K-module.
- A has good or semistable reduction iff I_K acts unipotently on $T_\ell(A)$.
- A has potential good reduction iff $T_\ell(E)$ is potentially unramified, i.e. $\rho_{\ell,A}(I_K)$ is finite.

Proof: 1 follows from(13.5.10.4).

2: We only prove for $\dim A = 1$ case**?**: As I_K acts trivially on $\det(T_\ell(E))$ by(15.3.4.3), it acts unipotently on $T_\ell(E)$ iff it has a fixed vector. If it has a fixed vector, then $\widetilde{E}_{\mathrm{sm}}(\overline{k})$ contains a subgroup isomorphic to $\mathbb{Z}/(\ell)$, which is possible only if E has semistable or good reduction, by(13.9.1.15) and(13.5.10.3). The converse is proved the same way as that of(13.5.10.4).

3 follows from(2.2.5.11). □

Cor. (13.5.10.9). If K is a CDVR with residue characteristic p and $\varphi : E \to E'$ is an isogeny of degree p of elliptic curves over K, then E has good reduction of ordinary type/supersingular type iff E' does.

Proof: By(13.5.10.6) we can assume both E, E' have good reductions, then their minimal Weierstrass equations are their Néron models, thus by definition φ extends to a map $\widetilde{\varphi}: \widetilde{E} \to \widetilde{E}'$. Let $\psi = \widehat{\varphi}$, then we also have $\widetilde{\psi}: \widetilde{E}' \to \widetilde{E}$ s.t. $\widetilde{\psi} \circ \widetilde{\varphi} = [p]_{\widetilde{E}}$, and $\widetilde{\varphi} \circ \widetilde{\psi} = [p]_{\widetilde{E}'}$. Thus $[p]_{\widetilde{E}'} \circ \widetilde{\varphi} = \widetilde{\varphi} \circ [p]_{\widetilde{E}}$, which implies $\deg_s([p]_{\widetilde{E}}) = \deg_s([p]_{\widetilde{E}'})$, thus we are done by(13.9.3.5). □

Prop. (13.5.10.10) [Isogeny and Semistability]. If $A, B \in \mathcal{A}b\mathcal{V}ar/k$ are isogenous, then A is semistable iff B is semistable.

Proof: **?** □

over Dedekind Domains

Def. (13.5.10.11) [Conductor]. For an elliptic curve E over a $F \in$ `GField`, the **conductor of** E is defined to be the integral ideal of F given by

$$N_{E/F} = \prod_{v \in \Sigma_F^0} \mathfrak{p}_v^{f_v}$$

where f_v is the local conductors(13.5.10.2).

Conj. (13.5.10.12) [Szpiro]. For any $\varepsilon > 0$, there exists $C_\varepsilon > 0$ s.t.

$$|N_{K/\mathbb{Q}}(\Delta_E)| \leq C_\varepsilon |N_{K/\mathbb{Q}}(N_E)|^{6+\varepsilon}$$

for any $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$, where N_E is the conductor of E.

Proof: □

Prop. (13.5.10.13) [No Everywhere Good Reduction over $\mathbb{Q}$]. There are no elliptic curve E over $\mathbb{Q}$ with everywhere good reductions. There are 24 elliptic curves over $\mathbb{Q}$ with good reductions away form 2, and 784 elliptic curves over $\mathbb{Q}$ with good reduction away from $2, 3$.

Proof: Let $E: y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6$ be an elliptic curve over $\mathbb{Q}$ with $a_i \in \mathbb{Z}$ and $\Delta = \pm 1$, then a_1 must be odd, otherwise $\Delta \equiv 5b_6^2 \equiv \pm 1 \mod 8$ is impossible. Thus $c_4 = b_2^2 - 24b_4 \equiv 1 \mod 8$. And $c_4^3 - c_6^2 = (\pm 12)^3$ shows that $c_4 \pm 12$ is a square or 3 times a square, which are both impossible by modulo 8.

For good reduction away from $2, 3$ **?** □

Prop. (13.5.10.14). Let F be a number field and $A, B \in \mathcal{A}b\mathcal{V}ar/F$, and $S \subset \Sigma_F$ is a finite set of places of F containing Σ_F^∞ and all places s.t. A or B has bad reduction, then for any $\ell \in \mathbf{P}$ s.t. $S(\ell) \cap S = \varnothing$, there exists a finite set $T = T(S, \ell, g) \in \Sigma_\infty^0$ s.t. $T \cap (S \cup S(\ell)) = \varnothing$, and

$$P_\ell(\widetilde{A}_v, t) = P_\ell(\widetilde{B}_v, t) \Rightarrow A \sim B$$

Proof: Cf.[Mil08]P142. □

Prop. (13.5.10.15) [Reduction Theorem]. For any number field F and $A \in \mathcal{A}b\mathcal{V}ar/F$, there exists a finite extension L/F s.t. A_L is semistable.

Proof: **?** □

11 Galois Cohomologies

Prop. (13.5.11.1) [Fundamental Exact Sequence]. Let $\varphi : X \to X'$ be an étale isogeny between Abelian varieties over a field k, then there is an exact sequence

$$0 \to \ker(\varphi)(k^s) \to X(k^s) \to X'(k^s) \to 0$$

by(8.1.5.5), thus taking Galois cohomology, there is an exact sequence

$$0 \to X'(k)/\varphi(X(k)) \xrightarrow{\delta} H^1(G_k, X[\varphi]) \to H^1(G_k, X)[\varphi] \to 0.$$

Cor. (13.5.11.2). By(13.5.6.14), if $n \in \mathbb{Z} \cap K^\times$, then there is an exact sequence

$$0 \to X(k^s)/nX(k^s) \xrightarrow{\delta} H^1(G_k, X[n]) \to H^1(G_k, X)[n] \to 0.$$

And the first map is described as follows: for $P \in X(k^s)$, let $[n]Q = P$ where $Q \in K(k^s)$, then P is mapped to the 1-cocycle $f(\sigma) = \sigma(Q) - Q$.

Prop. (13.5.11.3). Let F be a global field or the function field of a non-singular smooth curve over an alg.closed field k, $\varphi : X \to X' \in \mathcal{A}b\mathcal{V}ar/F$ an étale isogeny, then by restriction(10.1.1.10), there is an exact sequence

$$\begin{array}{ccccccccc} 0 & \longrightarrow & X'(F)/\varphi(X(F)) & \longrightarrow & H^1(\mathrm{Gal}_F, X[\varphi]) & \longrightarrow & H^1(\mathrm{Gal}_F, X)[\varphi] & \longrightarrow & 0 \\ & & \downarrow & & \downarrow \mathrm{res} & & \downarrow \mathrm{res} & & \\ 0 & \longrightarrow & \prod_{v\in\Sigma_F^{\mathrm{fin}}} X'(F_v)/\varphi(X(F_v)) & \longrightarrow & \prod_{v\in\Sigma_F^{\mathrm{fin}}} H^1(\mathrm{Gal}_{F_v}, X[\varphi]) & \longrightarrow & \prod_{v\in\Sigma_F^{\mathrm{fin}}} H^1(\mathrm{Gal}_{F_v}, X)[\varphi] & \longrightarrow & 0 \end{array}.$$

Where v are extended to K^s arbitrarily.

Def. (13.5.11.4) [(Classical)Selmer Groups]. Let F be a global field or the function field of a non-singular smooth curve over an alg.closed field k, $\varphi : A \to A' \in \mathcal{A}b\mathcal{V}ar/F$ an étale isogeny, the φ-Selmer group of A/F is a subgroup of $H^1(\mathrm{Gal}_F, A[\varphi])$ defined by

$$\mathrm{Sel}^\varphi(A/F) = \ker\Big(H^1(\mathrm{Gal}_F, A[\varphi]) \to \prod_{v\in\Sigma_F} H^1(\mathrm{Gal}_{F_v}, A)[\varphi]\Big).$$

Notice the kernel is independent of the extension of v to F^s, because any two such extensions induce conjugate groups Gal_{F_v} in Gal_F and use(10.1.1.12).

Def. (13.5.11.5) [Shafarevich-Tate Group]. The **Shafarevich-Tate group** of $A \in \mathcal{A}b\mathcal{V}ar/F$ is the subgroup of $H^1(\mathrm{Gal}_F, A[\varphi])$ defined by

$$Ш(A/F) = \ker\Big(H^1(\mathrm{Gal}_F, A) \to \prod_{v\in\Sigma_F^0} H^1(\mathrm{Gal}_{F_v}, A)\Big).$$

Notice the kernel is independent of the extension of v to F^s, because any two such extensions induces conjugate groups Gal_{F_v} in Gal_F and use(10.1.1.12).

For $f : A \to B \in \mathcal{A}b\mathcal{V}ar/F$, there is a natural map $f_* : Ш(A/F) \to Ш(B/F)$.

Prop. (13.5.11.6) [Selmer Groups and Shafarevich-Tate Groups]. Let C be a proper Dedekind scheme or a non-singular curve over a field k with fraction field F, $\varphi : A \to A'$ an étale isogeny of Abelian varieties over F, then there is an exact sequence

$$0 \to A'(K)/\varphi(A(K)) \to \mathrm{Sel}^{\varphi}(A/K) \to Ш(A/K)[\varphi] \to 0.$$

Proof: This exact sequence is a consequence of(13.5.11.3) and(13.5.11.4)(13.5.11.5). □

Remark (13.5.11.7) [Computability]. It is difficult to characterize $A'(K)/\varphi(A(K)) \subset \mathrm{Sel}^{\varphi}(A/K)$.

Prop. (13.5.11.8) [$\mathrm{Sel}^{\varphi}(A)$ **is Finite].** Let F be a global field or the function field of a non-singular smooth curve over an alg.closed field k, $\varphi : A \to A'$ an étale isogeny of Abelian varieties over F, then if S is a finite set of places of F containing all the places dividing $\deg(\varphi)$, and the places that A has bad reductions, then any element in $\mathrm{Sel}^{\varphi}(A/F)$ is unramified at all finite places outside S. In particular, $\mathrm{Sel}^{\varphi}(A/F)$ is finite, by(10.1.3.11).

Proof: By definition of Sel^{φ} and(13.5.11.3), if $\xi \in \mathrm{Sel}^{\varphi}(A/F)$, then for any $v \in \Sigma_F^0$, there is some $P \in A(F_v^s)$ s.t. $\xi_\sigma = \sigma(P) - P \in A[\varphi]$ for any $\sigma \in G_v$. But if A has good reduction at v and $\sigma \in I_v$, then $\sigma(P) - P$ mapsto $\widetilde{O} \in \widetilde{A}_v$. But notice $A[\varphi] \subset A[m]$ which maps injectively into $\widetilde{A}_v(k_v)$ by(13.9.4.20) if v is not dividing $\deg(\varphi)$. Thus in this case, $\xi_\sigma = 0$ for any $\sigma \in I_v$. □

Cor. (13.5.11.9) [ℓ^∞**-Selmer Groups].** If $\ell \in \mathbf{P} \backslash \operatorname{char} F$, then the ℓ-primary part $Ш(A/F)[\ell^\infty] = \varinjlim_{n\geq 1} Ш(A/F)[\ell^n]$ is isomorphic to $(\mathbb{Q}_\ell/\mathbb{Z}_\ell)^{\delta_\ell} \times T_\ell$ for some $\delta_\ell \in \mathbb{N}$ and $T_\ell \in \mathcal{A}\mathrm{b}^{\mathrm{fin}}$. And define

$$\mathrm{Sel}^{\ell^\infty}(A/F) = \varinjlim_{n\geq 1} \mathrm{Sel}^{\ell^n}(A/F),$$

called the ℓ^∞**-Selmer group**. Then by taking limits of the exact sequence in(13.5.11.6), there is an exact sequence

$$0 \to A(F) \otimes \mathbb{Q}_\ell/\mathbb{Z}_\ell \to \mathrm{Sel}^{\ell^\infty}(A/F) \to Ш(A/F)[\ell^\infty] \to 0.$$

If we define the ℓ^∞**-Selmer rank** $\mathrm{rank}_\ell(A/F) = \mathrm{rank}(A/F) + \delta_\ell$, then

$$\mathrm{Sel}^{\ell^\infty}(A/F) = (\mathbb{Q}_\ell/\mathbb{Z}_\ell)^{\mathrm{rank}_\ell(A/F)} \cdot \widetilde{Ш}(A/F)[\ell^\infty],$$

where $\#\widetilde{Ш}(A/F)[\ell^\infty] < \infty$. Notice $\mathrm{rank}_\ell(A/F)$ is a cohomological number.

Conj. (13.5.11.10) [Tate-Shafarevich]. For $A \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/F$, $\#Ш(A/F) < \infty$.

Proof: □

Prop. (13.5.11.11) [Cassels-Tate Pairing]. Let $A \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/F$ and $\widehat{A}$ its dual, then there is a bilinear **Cassels-Tate pairing** $Ш(A/K) \times Ш(\widehat{A}/K) \to \mathbb{Q}/\mathbb{Z}$ and the kernel on both sides are the set of divisible elements.

Proof: Cf.[Birch and Swinnerton-Dyer Conjecture, P10].? □

Cor. (13.5.11.12) [Principally Polarized Case]. If $K \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/F$ has a principal polarization λ that comes from a rational divisor D, then the pullback pairing $Ш(A/K) \times Ш(A/K) \to \mathbb{Q}/\mathbb{Z}$ is alternating. In particular, if $\#Ш(A/F) < \infty$, then it is a perfect square, by(2.1.4.17).

In particular, if $E \in \mathcal{E}\mathrm{ll}/F$ and $\#Ш(E/F) < \infty$, then it is a perfect square.

Proof: □

Remark (13.5.11.13). This is not right for general Abelian varieties.

The discussion of Selmer groups and ranks are continued in BSD Conjecture19.5.

12 Néron-Tate Heights

Prop. (13.5.12.1) [Néron-Tate Heights]. Let X be an Abelian variety over a global field K, $\mathcal{L} \in \mathrm{Pic}(X)$, then there are uniquely defined bilinear form $b_{\mathcal{L}}$, additive homomorphism $l_{\mathcal{L}}$ on $X(\overline{K})$ s.t.

$$\widehat{h}_{\mathcal{L}}(x) = \frac{1}{2} b_{\mathcal{L}}(x,x) + l_{\mathcal{L}}(x) \sim h_{\mathcal{L}}(x),$$

called the **Néron-Tate height** of $\mathcal{L}$.

Proof: We want to use(2.1.4.13) for the Weil height(13.2.3.23) $h_{\mathcal{L}}$ on $X(\overline{K})$: apply the theorem of the cube(13.5.1.21) to the projections $\pi_i : X \times X \times X \to X$ and pullback to X via the diagonal map, then taking the Weil heights, we will get the desired relation

$$h_{\mathcal{L}}(\sum_{i=1}^{3} x_i) - \sum_{1 \le i < j \le 3} h_{\mathcal{L}}(x_i + x_j) + \sum_{i=1}^{3} h_{\mathcal{L}}(x_i) \sim 0.$$

□

Cor. (13.5.12.2). The Néron-Tate height is a refinement of Weil heights(13.2.3.23) made for Abelian varieties:

- The map $\widehat{h} : \mathrm{Pic}(X) \mapsto \mathbb{R}^{X(\overline{K})} : \mathcal{L} \mapsto \widehat{h}_{\mathcal{L}}$ is an additive homomorphism.
- (Symmetry)If $\varphi : A \to B$ is a homomorphisms of Abelian varieties, then $\widehat{h}_{\varphi^*(\mathcal{L})} = \widehat{h}_{\mathcal{L}} \circ \varphi$.
- (Positivity)Let $\mathcal{L} \in \mathrm{Pic}(X)$ be even. If $\mathcal{L}$ is base-free or ample, then $\widehat{h}_{\mathcal{L}} \ge 0$.
- (Boundedness)Let $\mathcal{L} \in \mathrm{Pic}(X)$ be even and ample(such an $\mathcal{L}$ exists by(13.5.1.27)), then $\widehat{h}_{\mathcal{L}}$ induces a symmetric bilinear form on $X(K)$ satisfying $\{x \in X(\overline{K}) | \deg(x) \le d, (x,x) < C\}$ is finite for all $C > 0$

Proof: $1, 2$ follow from the corresponding property of Weil heights(13.2.3.23) and the uniqueness in(2.1.4.13).

3: Notice that the fact $\mathcal{L}$ is even implies $\widehat{h}_{\mathcal{L}} = \frac{1}{2} b(x,x)$. The ample case reduces to the base-free case, because there is a multiple $m\mathcal{L}$ that is very ample, and then $\widehat{h}_{m\mathcal{L}} = m\widehat{h}_{\mathcal{L}}$. For the base-free case, c is the pullback of $\mathcal{O}(1)$ for some morphism $X \to \mathbb{P}^n$, thus $h_{\mathcal{L}}$ is non-negative by(13.2.3.3), and $h_{\mathcal{L}} \sim \widehat{h}_{\mathcal{L}}$, thus $\widehat{h}_{\mathcal{L}}$ must also be non-negative.

4 follows from Northcott's theorem(13.2.3.24). □

Cor. (13.5.12.3)[Positive Definiteness]. For any ample line bundle $\mathcal{L} \in \mathrm{Pic}(A)$, $b_{\mathcal{L}}$ induces a positive definite symmetric bilinear form on $A(\overline{K}) \otimes_{\mathbb{Z}} \mathbb{R}$

Proof: We want to use(2.1.4.14). Notice $b_{\mathcal{L}}$ is just $2\widehat{h}_{\mathcal{L} \otimes [-1]^* \mathcal{L}}$, thus satisfies the conditions by(13.5.12.2). □

Prop. (13.5.12.4) [Tate's Limiting argument].

Proof: Cf.[Diophantine Geometry, P285].? □

Cor. (13.5.12.5). Tate's limiting argument gives another way of constructing Néron-Tate heights. More generally, for any projective variety X over a global field K, if $\varphi : X \to X$ a morphism over K, $\mathcal{L}$ a line bundle on X and $k, l \in \mathbb{Z}, |k| > |l|$ that

$$l\varphi^*(\mathcal{L}) = k\mathcal{L},$$

then there is a unique function $\widehat{h}_{\varphi,\mathcal{L}}$ in the equivalent class of $h_\mathcal{L}$ that

$$l\widehat{h}_{\varphi,\mathcal{L}}(\varphi(x)) = k\widehat{h}_{\varphi,\mathcal{L}}(x).$$

In particular, the Néron-Tate heights on an Abelian variety for an even or odd line bundle is obtained by taking $\varphi = [m]$ for some $m \geq 2$.

Proof: Assume $l \neq 0$, consider the subgroup $\mathcal{N} = \{\lambda^r | r \in \mathbb{N}\}$, where $\lambda = k/l$, and $\mathcal{N}$ acts on $X(\overline{K})$ by $\lambda^r \cdot x = \varphi^r(x)$, then $h_\mathcal{L}$ is quasi-homogenous of degree 1, so Tate's limiting argument(13.5.12.4) shows

$$\widehat{h}_{\varphi,\mathcal{L}}(x) = \lim_{r\to\infty} \lambda^{-r} h_\mathcal{L}(\varphi^r(x))$$

satisfies the requirement. And similarly, it is non-negative if c is ample or base-free. □

Prop. (13.5.12.6) [Zero of Heights and Torsion]. If F is a global field, $A \in \mathcal{A}b\mathcal{V}ar/F$ and $\mathcal{L}$ is ample, then $\widehat{h}_{\varphi,\mathcal{L}}(x) = 0$ iff x is preperiodic, i.e. the sequence $\{x, \varphi(x), \varphi^2(x), \ldots\}$ is finite.

In particular, $\widehat{h}_\mathcal{L}(x) = 0$ iff x is torsion.

Proof: Assume $l \neq 0$. If x is preperiodic, then clearly $\widehat{h}_{\varphi,\mathcal{L}}(x) = \lim_{r\to\infty} \lambda^{-r} h_\mathcal{L}(\varphi^r(x)) = 0$. Conversely, if $\widehat{h}_{\varphi,\mathcal{L}}(x) = 0$, then $\widehat{h}_{\varphi,\mathcal{L}}(\varphi^r(x)) = 0$ for any r, then $|h_\mathcal{L}(\varphi^r(x))| \leq |\widehat{h}_{\varphi,\mathcal{L}}(\varphi(x))| + C(\varphi,\mathcal{L}) = C(\varphi,\mathcal{L})$ is bounded and also $\varphi^r(x) \in X(k(x))$, thus has bounded degree. So by Northcott's theorem(13.2.3.24), there are only f.m. such points. □

Cor. (13.5.12.7) [Kronecker]. The height(13.2.3.5) of a $\zeta \in \overline{\mathbb{Q}}$ equals 0 iff it is a root of unity.

Proof: This is a special case of(13.5.12.6), where $\varphi : \mathbb{P}^1 \to \mathbb{P}^1 : [x,y] \mapsto [x^n, y^n]$ and $\mathcal{L} = \mathcal{O}(1)$, thus the preperiodic points are just $0, \infty$ and all the roots of unity. □

Prop. (13.5.12.8) [Néron-Tate Pairings]. Let K be a number field and $A \in \mathcal{A}b\mathcal{V}ar/K$, then $A \times \widehat{A}$ is also an Abelian variety with the even Poincaré class p(13.5.4.6), thus generating a function:

$$\widehat{h}_{A\times\widehat{A},p} : A(\overline{K}) \times \widehat{A}(\overline{K}) \to \mathbb{R}.$$

Then in fact this pairing is bilinear, called the **Néron-Tate pairing** $\langle\cdot,\cdot\rangle_{A,K}$.

The Weil-Tate pairing satisfies the functoriality property: If $f : A \to B$ is a homomorphism of Abelian varieties, then $\langle f(a), b\rangle_{B,K} = \langle a, \widehat{f}(b)\rangle_{A,K}$.

Proof: Use functoriality of heights for $A \to A \times \widehat{A}$, then $\widehat{h}_{A\times\widehat{A},p}((a,0)) = \widehat{h}_{A,0}(a) = 0$. Similarly, $\langle 0, a\rangle_{A,K} = 0$. Thus $\widehat{h}_{A\times\widehat{A},p}$ is bilinear by(2.1.4.8).

The last assertion follows from(8.7.3.36). □

Prop. (13.5.12.9). Let $\mathcal{L} \in \mathrm{Pic}(A)$ and $\varphi_\mathcal{L} : A \to \widehat{A}$ the associated homomorphism(13.5.4.2), then for any $a, a' \in A(\overline{K})$,

- $\widehat{h}_{\tau^*_{a'}\mathcal{L}}(a) = \widehat{h}_\mathcal{L}(a) + b(a,a')$.
- $\widehat{h}_\mathcal{L}(a) = \langle a, \mathcal{L}\rangle_{A,K}$.
- $b_\mathcal{L}(a,a') = \langle a, \varphi_\mathcal{L}(a')\rangle_{A,K} = \widehat{h}_{\varphi_\mathcal{L}(a')}(a)$.

Proof: 1: $b_{\mathcal{L}}(a,a')=\widehat{h}_{\mathcal{L}}(a+a')-\widehat{h}_{\mathcal{L}}(a)-\widehat{h}_{\mathcal{L}}(a')=\widehat{h}_{\mathcal{L}}(\tau_{a'}a)-\widehat{h}_{\mathcal{L}}(a)-\widehat{h}_{\mathcal{L}}(a')$. Then $b(\cdot,a')+\widehat{h}_{\mathcal{L}}$ is a representative in the class $h_{\tau_{a'}^*(\mathcal{L})}$ by functoriality. And it is a quadratic function, thus by uniqueness, we are done.

2: Because the pullback of p to $A\times\{\mathcal{L}\}$ is $\mathcal{L}$ by(8.7.3.34), and thus this follows from functoriality and(13.5.12.8).

3: By(13.5.4.2) and item1, $b(a,a')=\widehat{h}_{\varphi_{\mathcal{L}}(a')}(a)$. Thus we are done by item2. □

Cor. (13.5.12.10) [Regulator]. The Néron-Tate pairing induces a non-degenerate pairing $A(K)/A(K)_{\mathrm{tor}}\times\widehat{A}(K)/\widehat{A}(K)_{\mathrm{tor}}\to\mathbb{R}$. The discriminant of this pairing is called the **regulator** of A, denoted by $R(A/K)$.

Proof: Let $\mathcal{L}\in\mathrm{Pic}(A)$ be ample, then $\varphi_{\mathcal{L}}:A\to\widehat{A}$ is an isogeny, thus $\varphi_{\mathcal{L}}:A(K)/A(K)_{\mathrm{tor}}\to\widehat{A}(K)/\widehat{A}(K)_{\mathrm{tor}}$ is injective, and by(13.13.1.7), the image is a subgroup of $\widehat{A}(K)/\widehat{A}(K)_{\mathrm{tor}}$ of the same rank, thus we are done by(13.5.12.9) item3 and(13.5.12.3). □

Cor. (13.5.12.11). Let A be an Abelian variety, $c\in\mathrm{Pic}(A)$ an even ample class, $c'\in\mathrm{Pic}(A)$, then $\widehat{h}_{c'}=O(\widehat{h}_c^{1/2})$.

Proof: By(13.5.4.14), φ_c is isogeny thus surjective, thus we can assume $c'=\varphi_c(a')$ for some $a'\in A(K)$. Then by(13.5.12.9), $\widehat{h}_{c'}(a)=b_c(a,a')$. Because b_c is positive semi-definite by(13.5.12.2), by Cauchy-Schwartz(2.1.4.7), $|\widehat{h}_{c'}(a)|^2\leq b(a,a)b(a',a')=4\widehat{h}_c(a)\widehat{h}_c(a')$. □

Hilbert's Irreducibility Theorem

Prop. (13.5.12.12) [Runge's Theorem].

Prop. (13.5.12.13) [Hilbert's Irreducibility Theorem]. Let C be a smooth irreducible projective curve over a number field K and let $f:C\to\mathbb{P}^1$ be a surjective rational function on C over K, then for all $n\in\mathbb{N}$ except for a set of natural density 0, the divisor $f^*[n]$ is a prime divisor over K.

Proof: Cf.[Diophantine Geometry, P319]. □

Local Height Pairings

Cf.[Sil99]Chap6 or [Local Heights on Curves, Gross, in Arithmetic Geometry] and [B-G06] or [Introduction to Diophantine Geometry, Lang].

13 Jacobians of Curves

Prop. (13.5.13.1) [Picard Schemes of Curves]. Let C be a smooth complete precurve over a field k of genus g with a rational point, then

- $\underline{\mathrm{Pic}}_{C/k}$ is representable by a disjoint union of smooth complete varieties $\underline{\mathrm{Pic}}^d_{C/k}, d\in\mathbb{Z}$ where $\underline{\mathrm{Pic}}^d_{C/k}$ corresponds to relative line bundles of degree d.
- $\underline{\mathrm{Pic}}^0_{C/k}$ is an Abelian variety over k.
- for $d\geq 0$, the Abel map $\mathrm{Div}^d_{C/k}\to\underline{\mathrm{Pic}}^d_{C/k}$ is surjective for $d\geq g$ and smooth for $d\geq 2g-1$.
- The morphism $\mathrm{Div}^g_{C/k}\to\underline{\mathrm{Pic}}^g_{C/k}$ is birational.

Proof: Cf.[Sta]0BA0 or [Neron Models] or(13.5.13.2)**?**. item1 follows from(7.1.12.5) □

Prop. (13.5.13.2)[Picard Scheme of Relative Curves]. If X/S is locally projective, flat with fibers all curves, $m \in \mathbb{Z}$, let $\underline{\mathrm{Pic}}^m_{X/S}$ denote the subfunctor of $\underline{\mathrm{Pic}}_{X/S}$ representing invertible sheaves $\mathcal{L}$ with $\deg(\mathcal{L}) = m$, then

- $\underline{\mathrm{Pic}}^m_{X/S}$ are clopen subschemes of $\underline{\mathrm{Pic}}_{X/S}$ of f.t. and form a disjoint cover of it, and forming it commutes with base change.
- $\underline{\mathrm{Pic}}^{(0)}_{X/S} = \underline{\mathrm{Pic}}^0_{X/S} = \underline{\mathrm{Pic}}^\tau_{X/S}$, and each $\underline{\mathrm{Pic}}^m_{X/S}$ is a fppf-torsor under $\underline{\mathrm{Pic}}^0_{X/S}$.
- If X/S is projective and S is Noetherian, then each $\underline{\mathrm{Pic}}^m_{X/S}$ is quasi-projective over S.

Proof: Cf.[Kle05]P60.? □

Def. (13.5.13.3)[Jacobians of Curves]. For a smooth complete precurve over a field k, its **Jacobian variety** $\mathrm{Jac}(C)$ is just its Picard variety $\underline{\mathrm{Pic}}^0_{C/k}$(13.5.13.1).

Cor. (13.5.13.4). For a smooth complete precurve C over a field with a rational point, $x \in \mathrm{Pic}_{C/k}$ is in $\mathrm{Jac}(C)$ iff the corresponding line bundle x on $C_{k(x)}$ has degree 0, by(13.5.13.1).

Prop. (13.5.13.5). If C is a smooth complete curve of dimension g, then $\mathrm{Jac}(C)$ has dimension g, by(8.7.3.24) and(8.7.3.22).

Def. (13.5.13.6)[Symmetric Product]. Let C be a smooth curve, then the symmetric product $C^{(r)} = C^r/S_r$ is a smooth variety of dimension r by considering the symmetric functions.

Prop. (13.5.13.7)[Generic Riemann-Roch].

Prop. (13.5.13.8)[Polarization of Jacobians].

Prop. (13.5.13.9)[Push and Pull]. For a non-constant morphism $\varphi : C_1 \to C_2$ of pointed smooth curves over k, the push and pull induce maps

$$\varphi_* : \mathrm{Jac}(C_1) \to \mathrm{Jac}(C_2), \quad \varphi^* : \mathrm{Jac}(C_2) \to \mathrm{Jac}(C_1).$$

s.t. $\varphi_* \circ \varphi^* = [\deg(\varphi)]$.

Proof: □

Prop. (13.5.13.10)[Abel-Jacobi]. Let X be a smooth curve over $\mathbb{C}$ with a rational point x_0, then $\mathrm{Jac}(C)$ is isomorphic to $\Omega^1_{\mathrm{hol}}(X)^\vee/H_1(X,\mathbb{Z})$ as complex manifolds via

$$\mathcal{L}(\sum_x n_x x) \mapsto \sum_x n_x \int_{x_0}^x .$$

Proof: □

Prop. (13.5.13.11). Let $k \in \mathtt{Field}, C$ be a smooth complete curve over k, $P \in C(k)$, then for any $\ell \in \mathbf{P}$, the map $f_P : C \to \mathrm{Jac}(C)$ induce isomorphisms

$$H^1(\mathrm{Jac}(C), \mathcal{O}_{\mathrm{Jac}(C)}) \cong H^1(C, \mathcal{O}_C), \quad H^1(\mathrm{Jac}(C), \mathbb{Z}_\ell) \cong H^1(C, \mathbb{Z}_\ell).$$

Proof: Cf.[Mil08]P114. □

Prop. (13.5.13.12) [Surjection by Jacobians]. Let $k \in \texttt{Field}$ and $A \in \mathcal{A}b\mathcal{V}ar/k$, there exists a smooth complete curve C over k and a surjection $\mathrm{Jac}(C) \to A$.

Proof: We only prove for $\#k = \infty$. For k finite, Cf.[Gabber, On space filling curves and Albanese varieties], [Poonen, Bjorn, Bertini theorems over finite fields. Ann. of Math].?

Since elliptic curves are their own Jacobians, we can assume that $\dim A > 1$. Choose a projective embedding $A \to \mathbb{P}^n_k$, then by Bertini and the fact $\#k = \infty$, there is a hyperplane cut $A \cap H$ that is also a smooth complete k-variety. By repeating $\dim A - 1$ dimes, we get a k-curve C on A. This curve gives a map $\mathrm{Jac}(C) \to A$ by(13.5.13.8) and double duality(13.5.4.16). The image is an Abelian subvariety of A. If it is not the whole of A, then by Poincaré 's reducibility theorem(13.5.6.7), there exists another Abelian subvariety $A_2 \subset A$ s.t. $\mathrm{Jac}(C) \times A_2 \to A$ is an isogeny. In particular, $\mathrm{Jac}(C) \cap A_2$ is finite.

Using the embedding $C \subset \mathrm{Jac}(C)$, C is regarded as a subscheme of $\mathrm{Jac}(C)$. Take $n \in \mathbb{Z} \cap k^*$ large, the composition $\mathrm{Jac}(C) \times A_2 \xrightarrow{(1,n)} \mathrm{Jac}(C) \times A_2 \to A$ is finite, and the inverse image of C projects to $[n]^{-1}(A_1 \cap A_2) \subset A_2$, which is finite and disconnected. So the inverse image of C is not connected, which contradicts the fact it is an ample divisor by(5.5.4.12) and(5.8.6.25). □

Conj. (13.5.13.13) [Resolution Conjecture]. Let $k \in \texttt{Field}, k = \overline{k}$, and $A \in \mathcal{A}b\mathcal{V}ar/k$, we can find a surjective homomorphism $J_1 \to A$ where J_1 is a Jacobian of a curve by(13.5.13.12). Then the identity component of the kernel is also an Abelian variety. Then we can do the same process again.

is it possible to choose the Jacobians s.t. the process terminate after finite steps?

Proof: □

Thm. (13.5.13.14) [Tonelli]. Let $k \in \texttt{Field}$ and $k = \overline{k}$, and $(C, P), (C', P')$ be pointed complete smooth curves over k. Let $f : C \to \mathrm{Jac}(C)$ and $f' : C' \to \mathrm{Jac}(C')$ be the maps corresponding to P, P'. Then if $\beta : (\mathrm{Jac}(C), \lambda) \cong (\mathrm{Jac}(C'), \lambda')$ is an isomorphism of polarized Jacobians, then

- There exists an isomorphism $\alpha : C \to C'$ s.t. $f' \circ \alpha = \pm\beta \circ f + c$ for some $c \in \mathrm{Jac}(C')(k)$.
- If $g(C) \geq 2$ and C is non-hyperelliptic, then $\alpha, \pm 1, c$ are determined by β, P, P'. And if $g(C) \geq 2$, then ± 1 can be arbitrary, and α, c is determined by $\beta, \pm 1, P, P'$.

Proof: Cf.[Mil08]P120. □

Cor. (13.5.13.15).

- If $k \in \texttt{Field}, C, C'$ are complete smooth curves over k with rational points s.t. their polarized Jacobians are isomorphic, then C, C' are isomorphic over k.
- If $k \in \texttt{Field}$ is perfect, C, C' are complete smooth curves of genus≥ 2 over k, then if their polarized Jacobians are isomorphic, then C, C' are also isomorphic over k.

Proof: Let $\beta : (\mathrm{Jac}(C), \lambda) \cong (\mathrm{Jac}(C'), \lambda')$ is an isomorphism, for any $P \in C(\overline{k}), P' \in C'(\overline{k})$, there is a unique isomorphism $\alpha : C_{\overline{k}} \cong C'_{\overline{k}}$ s.t. $f^{P'} \circ \alpha = \pm\beta \circ f^P + c$, and if C is hyperelliptic, take $\pm = +$. Then if Q, Q' are different points, $f^P = f^Q + d$, $f^{Q'} = f^{P'} + e$ for some $d \in \mathrm{Jac}(C)(\overline{k}), e \in \mathrm{Jac}(C')(\overline{k})$. So α is invariant of the points P, P' chosen. In particular,

$$f^{\sigma(P')} \circ \alpha = \sigma(f^{P'}) \circ \alpha = \pm\beta \circ \sigma(f^P) + \sigma(c) = \pm\beta f^{\sigma(P)} + \sigma(c).$$

for any $\sigma \in \mathrm{Gal}_k$. So α is invariant under Gal_k, which means C, C' are isomorphic over k. □

Arithmetics

Prop. (13.5.13.16). If F is a global field and C is a complete smooth curve over F with good reduction at a place P of F, then $\mathrm{Jac}(C)$ has good reduction at P.

Proof: The hypothesis implies C extends to a smooth proper curve $\mathcal{C}$ over $\operatorname{Spec} R_P$. Then the Picard scheme $\mathcal{J}$ of $\mathcal{C}/\operatorname{Spec} R_P$(13.5.13.2) has generic fiber $\mathrm{Jac}(C)$, which implies $\mathrm{Jac}(C)$ has good reduction at P. □

14 Abelian Schemes

Prop. (13.5.14.1) [Rigidity Lemma].

Proof: □

Cor. (13.5.14.2). Any morphism of Abelian schemes in $\mathcal{A}b\mathcal{V}ar/S$ preserving the zero section is a homomorphism. Thus the group structure is determined by the zero section, and any Abelian scheme is commutative.

Prop. (13.5.14.3) [Dual Abelian Schemes]. If X/S is a projective Abelian scheme, then

- $\underline{\mathrm{Pic}}^0_{X/S} = \mathrm{Pic}^\tau_{X/S}$ is a projective Abelian scheme over S, called the **dual Abelian scheme** of X/S.
- the double Picard map(8.7.3.37) $A \to A^{\vee\vee}$ is an isomorphism.

Proof: By reducing to the fiber, these reduces to the case that S is a field, and this case follows from(13.5.4.12) and(13.5.4.12). □

15 Néron Models

Main references are [Serre/Tate, Good Reduction of Abelian Varieties], [BLR90] and http://virtualmath1.stanford.edu/~conrad/mordellsem/Notes/L11.pdf.

Def. (13.5.15.1) [Néron Models]. Let (R,K) be a DVR and $X \in \mathcal{S}\mathrm{ch}^{\mathrm{sm,sep,ft}}/K$, then a **Néron model** for X/K is a scheme $\mathcal{X} \in \mathcal{S}\mathrm{ch}^{\mathrm{sm,sep,ft}}/R$ satisfying the following universal property: For any smooth scheme $\mathcal{Y}$ over R and any morphism $f : \mathcal{Y}_K \to X$, there exists a unique morphism $\mathcal{Y} \to \mathcal{X}$ extending f.

In particular, the natural map $\mathcal{X}(R) \to X(K)$ is a bijection.

Prop. (13.5.15.2) [Étale Valuation Criterion for Group Schemes]. Let (R,K) be a DVR and $X \in \mathcal{S}\mathrm{ch}^{\mathrm{sm,sep,ft}}/K$, then if $\mathcal{X}/R$ is a Néron model for X, then $\mathcal{X}$ satisfies valuation criterion for any R' that is the integral closure of R in an unramified field extension K'/K.

Conversely, if X is a group scheme over K, then the converse is also true: If $\mathcal{G}$ is a smooth R-group scheme of f.t., then $\mathcal{G}$ is a Néron model of its generic fiber iff the natural map $\mathcal{G}(R^{\mathrm{sH}}) \to \mathcal{G}(K^{\mathrm{sH}})$ is an isomorphism.

Proof: Cf.[BLR90]Prop. 7.1.1. □

Prop. (13.5.15.3) [Unramified Base Change]. Let (R,K) be a DVR and $X \in \mathcal{S}\mathrm{ch}^{\mathrm{sm,sep,ft}}/K$, K'/K an unramified field extension, R' the integral closure of R in K', then if $\mathcal{X}$ is a Néron model for X, then $\mathcal{X}_{R'}$ is a Néron-model for $X_{K'}$.

Proof: Because R'/R is smooth(by(5.6.4.6) and the definition of unramifiedness(12.2.2.4)), for any $\mathcal{Y}'/R'$ smooth,

$$\mathrm{Mor}_{R'}(\mathcal{Y}', \mathcal{X}_{R'}) = \mathrm{Mor}_R(\mathcal{Y}', \mathcal{X}) = \mathrm{Mor}_K(\mathcal{Y}'_K, X) = \mathrm{Mor}_{K'}(\mathcal{Y}'_{K'}, X_{K'}).$$

□

Prop. (13.5.15.4) [Étale Descent]. Let $(R, K) \subset (R', K') \subset (R^{\mathrm{sH}}, K^{\mathrm{sH}})$ be DVRs. If G is a smooth K-group scheme of f.t. over K s.t. $G_{K'}$ has a Néron model $\mathcal{G}'/R'$, then $\mathcal{G}'$ descends to a Néron model $\mathcal{G}/R$ of G.

Proof: Cf.[BLR90]Prop. 6.5.4. □

Cor. (13.5.15.5). Let $(R, K) \subset (R', K')$ be an unramified extension of DVRs, and G is a smooth K-group scheme of f.t. over K, then G has a Néron model iff $G_{K'}$ has a Néron model.

Proof: Cf.[BLR90]Prop. 6.5.4. □

Prop. (13.5.15.6)[Néron Model of Abelian Varieties]. Let (R, K, k) be a DVR and $A \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/K$ with Néron model $\mathcal{A}/R$, then $\mathcal{A}$ is an R-group scheme by universal property. The **relative identity component** $\mathcal{A}_0$ of $\mathcal{A}$ is defined to be the open subgroup of $\mathcal{A}$ deleting all non-identity components of $\mathcal{A}_k$.

Prop. (13.5.15.7) [Good Reduction of Abelian Varieties]. Let (R, K) be a DVR, $A \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/K$ and $\mathcal{A} \in \mathcal{S}\mathrm{ch}/R$ is proper smooth with generic fiber A, then the group structure extends to $\mathcal{A}$, making it the Néron model of A.

In particular, the good reduction of A is unique if it exists.

Proof: Cf.[BLR90]Prop. 7.2.1 of [Milne, CM, P49].

To show the group structure extends, Cf.[Koizumi, On specializations of the Albanese and Picard Varieties] or might be somewhere in [BLR90]. □

Cor. (13.5.15.8). Let (R, K, k) be a DVR, $A \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/K$ with Néron model $\mathcal{A}/R$, then the following are equivalent:

- $\mathcal{A}$ is an Abelian scheme.
- A has good reduction over R.
- The identity component $\mathcal{A}^0_k$ of $\mathcal{A}_k$ is proper hence an Abelian variety over k.

Proof: $1 \to 2, 1 \to 3$ is clear. $2 \to 1$ follows from the proposition. $3 \to 1$: By(5.10.5.3) $\mathcal{A}_0$ is an Abelian scheme, so $\mathcal{A}_0 = \mathcal{A}$ is the Néron model by the proposition. □

Prop. (13.5.15.9)[Exactness]. Let (R, K) be a DVR with mixed characteristic $(0, p)$ and ramification index $e < p - 1$. If $0 \to A' \to A \to A'' \to 0$ is an exact sequence in $\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/K$, and A has good reduction, then so does A' and A'' by(13.5.10.4). Then the Néron models

$$0 \to \mathcal{A}' \to \mathcal{A} \to \mathcal{A}'' \to 0$$

for an exact sequence.

Proof: Cf.[BLR90]Prop7.5.4.. □

Prop. (13.5.15.10) [Extending Polarizations]. Let (R, K) be a DVR and $A \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/K$ has good reduction over R, then any polarization $\lambda : \mathcal{A} \to \mathcal{A}^\vee$ extends to a polarization on $\mathcal{A}$.

Proof: See [Artin 1986, 4.4 in Arithmetic Geometry], and [Chai and Faltings 1990].? □

Existence of Néron Models

Prop. (13.5.15.11)[Néron Model for Abelian Varieties]. Let X be an Abelian variety over K and A be any ring of integers in the field K, then there exists an open subset $Y = \operatorname{Spec} A_S \subset \operatorname{Spec} A$, and a scheme $\widetilde{X}$ projective over Y, and morphisms $\widetilde{m} : \widetilde{X} \times \widetilde{X} \to \widetilde{X}$ over Y and $\widetilde{e} : Y \to X$ that:

- The fiber of $\widetilde{X}$ over a generic point of Y with the morphisms $\widetilde{m}, \widetilde{e}$ are Abelian varieties isomorphic to X.
- $\widetilde{X}$ is a group scheme over Y, and its fiber over any closed point of Y with the morphisms $\widetilde{m}, \widetilde{e}$ are Abelian varieties.
- The mapping in item1 induces an isomorphism of groups $\widetilde{X}(Y) \cong X(K)$.

Proof: 1: Consider for any qc scheme over a field K, it is glued together from f.m. affine schemes, and these glueing involves f.m. polynomials and rational transition functions, and the coefficients of them are contained in a subring $A_S \subset K$ of f.t. over A. Thus this variety can be seen as a variety over A_S with the same equations, satisfying item1. The situation is similar for morphisms between qc schemes, in particular $\widetilde{m}$ and $\widetilde{e}$, thus constructing $\widetilde{X}$.

2: Cf.[Mumford, P265].?

3: Cf.[Mumford, P265].? □

Cor. (13.5.15.12). Let $x \in \widetilde{X}(Y)$, consider x as a closed subscheme of $\widetilde{X}$ and denote $n^{-1}(x)$ the closed subscheme in $\widetilde{X}$ the inverse image of x under the morphism $[n]_Y$. Then the natural projection $n^{-1}(x) \to Y$ is étale over all points $y \in Y$ that $\operatorname{char} k(y) \nmid n$.

Proof: [Mumford, P265].? □

Thm. (13.5.15.13) [Existence of Néron Models]. Let (R, K) be a DVR and $A \in \mathcal{A}b\mathcal{V}ar/K$, then A admits a Néron model $\mathcal{A}/R$.

Proof: □

Def. (13.5.15.14) [Tamagawa Numbers]. Let (R, K, k) be a DVR and $A \in \mathcal{A}b\mathcal{V}ar/K$ with Néron model $\mathcal{A}/R$, define the **component group of** A to be $\pi_0(\mathcal{A}_k)$, denoted by $\Phi(A)$. And $\#\Phi(A) < \infty$ is called the **Tamagawa number** of A.

Then $c(A)$ equals the number of geo.connected components of $\mathcal{A}_k$. And if k is finite, it also equals the connected components of $\mathcal{A}_k$ with a rational point.

Proof: Cf.[Liu Qing, 10.2.21(a)]. □

13.6 Complex Multiplication Theory

Main references are [Mil20b], [Lang, Complex Multiplication], [Abelian varieties with complex multiplication and modular functions, Shimura(1998)] and [The Fundamental Theorem of Complex Multiplication, Milne, 2007].

Notation (13.6.0.1).
- Use notations defined in Arithmetic of Abelian Varieties.

1 Introduction

Abelian varieties with complex multiplication correspond to special points on the moduli variety of abelian varieties, and their arithmetic is intimately related to that of the values of modular functions and modular forms at those points.

2 CM-Algebras and CM-Types

Def. (13.6.2.1) [CM-Fields]. A **CM-field** is a number field that is a totally imaginary quadratic extension of a totally real field.

Prop. (13.6.2.2) [Characterizing CM-Fields]. For $E \in \mathtt{NField}$, then E is a CM-field or totally real iff there exists exactly one $\mathfrak{c}_E \in \mathrm{Aut}(E)$ s.t. for any $\rho \in \mathrm{Hom}(E,\mathbb{C}), \rho \circ \mathfrak{c}_E = \mathfrak{c} \circ \rho$. And it is CM iff $\mathfrak{c}_E \neq \mathrm{id}_E$.

Proof: If $\rho \circ \mathfrak{c}_E = \mathfrak{c} \circ \rho$ for any $\rho \in \mathrm{Hom}(E,\mathbb{C})$, then $\rho \circ \mathfrak{c}_E^2 = \rho$, so $\mathfrak{c}_E^2 = \mathrm{id}$. if F is the fixed field of $\mathfrak{c}_E$, then $[E:F] = 2$, and clearly F is totally real. Conversely, if E is a CM-field or totally real, then clearly there exists a unique such $\mathfrak{c}_E$, which is the identity if E is totally real and the unique involution fixing the totally real subfield F.

In this case, if $\mathfrak{c}_E \neq \mathrm{id}_E$, then $\rho(E) \subsetneq \mathbb{R}$ for any $\rho \in \mathrm{Hom}(E,\mathbb{C})$, thus E is totally imaginary. And if $\mathfrak{c}_E = \mathrm{id}_E$, then E is also totally real. □

Cor. (13.6.2.3). A finite composite of CM-fields is a CM-field. In particular, the Galois closure of a CM-field is a CM-field.

And the composite of all CM-fields in $\mathbb{C}$ are the field $\mathbb{Q}^{\mathrm{cm}} \subset \overline{\mathbb{Q}}$ corresponding to the subgroup of $\mathrm{Gal}_{\mathbb{Q}}$ generated by all the elements $\{[\sigma,\mathfrak{c}] | \sigma \in \mathrm{Gal}_{\mathbb{Q}}\}$, which is a normal subgroup.

Proof: The complex involutions on these CM-fields is compatible on their intersections, thus defines a complex involution on their composite. □

Cor. (13.6.2.4). Any CM-field E is of the form $E = F(\alpha)$, where F is totally real, $\alpha^2 \in F$, and $\rho(\alpha^2) \in \mathbb{R}_-$ for any homomorphism $\rho : F \to \mathbb{C}$.

Proof: If F is the totally real field contained in E and $\alpha \in E$ generates E over F, then by completing the square, we can assume $\alpha^2 \in F$. Then $\rho(\alpha^2) \in \mathbb{R}_-$ for any $\rho : F \to \mathbb{C}$, otherwise E is not totally imaginary. □

Def. (13.6.2.5) [CM-Algebras]. A **CM-algbera** is a finite product of CM-fields.

Def. (13.6.2.6) [CM-Types]. A **CM-type** for a CM-algebra E is a subset $\Phi \subset \mathrm{Hom}(E,\mathbb{C})$ s.t. $\mathrm{Hom}(E,\mathbb{C}) = \Phi \coprod \Phi^{\mathfrak{c}_E}$.

A pair (E,Φ) where E is a CM-algebra and Φ is a CM-type on E is called a **CM-pair**.

More generally, if E is an étale algebra over $\mathbb{Q}$, then a **CM-type** on E is a subset $\Phi \subset \mathrm{Hom}(E,\mathbb{C})$ s.t. $\mathrm{Hom}(E,\mathbb{C}) = \sigma\Phi \coprod \mathfrak{c} \circ \sigma\Phi$ for any $\sigma \in \mathrm{Gal}_{\mathbb{Q}}$.

Prop. (13.6.2.7). Let E be an étale algebra over $\mathbb{Q}$ and F the product of the largest totally real subfields of the factors of E, then choosing a CM-type is equivalent to choosing an extension ρ' to E of any homomorphism $\rho : F \to \mathbb{R}$. Thus a CM-pair (E, Φ) defines an isomorphism

$$E \otimes_{\mathbb{Q}} \mathbb{R} \xrightarrow[\cong]{\Phi} \prod_{\rho:F\to\mathbb{R}} \mathbb{C} \cong \mathbb{C}^{\Phi} : a \otimes r \mapsto (\rho'(a)r)_{\rho}, \quad \Phi = \{\rho' | \rho : F \to \mathbb{R}\}$$

Def. (13.6.2.8) [Primitive CM-Fields]. If E_0 is a CM-field and E/E_0 is a finite extension, then a CM-type Φ_0 on E_0 extends to a CM-type on E(13.6.2.6) by defining

$$\Phi = \{\varphi \in \mathrm{Hom}(E, \mathbb{C}) | \varphi|_{E_0} \in \Phi_0\}.$$

A **primitive CM-field** is a CM-pair(13.6.2.6) (E, Φ) where $E \in$ `Field` and there doesn't exist a proper subfield $E_0 \subset E$ s.t. Φ is the extension of a CM-type on E_0.

Prop. (13.6.2.9). Every CM-pair (E, Φ) where E is a field is an extension of a unique primitive CM-pair (E_0, Φ_0) s.t. $E_0 \subset E$. Moreover, for any Galois CM-field E_1 containing E, E is the fixed field of E defined by the subgroup

$$H = \{\sigma \in \mathrm{Gal}(E_1/\mathbb{Q}) : \Phi_1^{\sigma} = \Phi_1\},$$

where Φ_1 is the extension of Φ to E_1.

Proof: If E is Galois over $\mathbb{Q}$, and E_0 is defined as above, then $\Phi\, \mathfrak{c}_E = \mathfrak{c}\, \Phi \neq \Phi$, so $\mathfrak{c}_E \notin H$, thus $\mathfrak{c}_E$ acts non-trivially on E_0. And $\mathfrak{c}_E$ preserves E_0: We need to show that $\sigma\, \mathfrak{c}_E\, a = \mathfrak{c}_E\, a$ for any $a \in E_0$. For which it suffices to show that $\mathfrak{c}_E\, \sigma\, \mathfrak{c}_E \in H$. For this, notice

$$\Phi\, \mathfrak{c}_E\, \sigma\, \mathfrak{c}_E = \mathfrak{c}\, \Phi \sigma\, \mathfrak{c}_E = \mathfrak{c}\, \Phi\, \mathfrak{c}_E = \Phi.$$

Thus E_0 is CM-subfield of E. And $\Phi_0 = \Phi|_{E_0}$ is a CM-type on E_0, because if $\varphi'|_{E_0} = \mathfrak{c}\, \varphi|_{E_0}$ for different $\varphi, \varphi' \in \Phi$, then $\mathfrak{c}\, \varphi \in \varphi' H \subset \Phi$, contradiction.

And if E_0 is extended from another CM-subfield E', then any $\sigma \in \mathrm{Gal}(E/\mathbb{Q})$ fixing E' will fix Φ and lies in H. This shows $E_0 \subset E'$. So (E_0, Φ_0) is primitive.

For the general case, it suffices to notice that this E_0 is contained in E because any $\sigma \in \mathrm{Gal}(E_1/\mathbb{Q})$ fixing E will fix Φ_1 thus fixes E_0 by definition. And Φ clearly extends Φ_0. □

Cor. (13.6.2.10). A CM-pair (E, Φ) where E is a field is primitive iff there exists a Galois CM-field E_1 containing E s.t. E is the fixed field of E defined by the subgroup

$$H = \{\sigma \in \mathrm{Gal}(E_1/\mathbb{Q}) : \Phi_1^{\sigma} = \Phi_1\},$$

where Φ_1 is the extension of Φ to E_1.

Prop. (13.6.2.11) [Shimura-Taniyama]. Let E be a CM-field, $F = E^{\mathfrak{c}_E}$(13.6.2.2) and $E = F(\alpha)$ where $\alpha^2 \in F$ is totally negative. Then

$$\Phi = \{\varphi \in \mathrm{Hom}(E, \mathbb{C}) : \mathrm{Im}(\varphi(\alpha)) > 0\}$$

is a CM-type on E. And (E, Φ) is a primitive CM-pair iff

- $E = \mathbb{Q}(\alpha)$.
- $\sigma(\alpha)/\alpha$ is not totally positive for any $\sigma \in \mathrm{Gal}(E/\mathbb{Q})$.

Proof: Φ is a CM-type on E because for any $\varphi\in\Phi$, $\varphi\,\mathfrak{c}_E\notin\Phi$ because $\mathrm{Im}(\varphi\,\mathfrak{c}_E(\alpha))=-\mathrm{Im}(\varphi(\alpha))<0$.

Let F_1 be the Galois closure of F and $E_1=F_1(\alpha)$, and Φ_1 is the extension of Φ to E_1, then

$$\Phi_1=\{\varphi\in\mathrm{Hom}(E_1,\mathbb{C}):\mathrm{Im}(\varphi(\alpha))>0\}.$$

and if

$$H=\{\sigma\in\mathrm{Gal}(E_1/\mathbb{Q}):\Phi_1^\sigma=\Phi_1\},$$

then H is exactly the group of $\sigma\in\mathrm{Gal}(E_1/\mathbb{Q})$ s.t. $\sigma(\alpha)/\alpha\in\mathbb{R}_+$. Then the assertion follows from(13.6.2.10). □

Reflex Fields

Def. (13.6.2.12) [Reflex Fields of CM Pairs]. Let (E,Φ) be a CM-pair, then the **reflex field** E^* of (E,Φ) is the subfield of $\overline{\mathbb{Q}}$ generated by the elements $\{\sum_{\varphi\in\Phi}\varphi(a)|a\in E\}$.

Prop. (13.6.2.13). Let (E,Φ) be a CM-pair with reflex field E^*, then

- E^* is the fixed field of the group $\{\sigma\in\mathrm{Gal}_{\mathbb{Q}}|\sigma(\Phi)=\Phi\}$.
- E^* is a CM-field.
- If (E_1,Φ_1) is an extension of (E,Φ)(13.6.2.8), then the reflex field of (E_1,Φ_1) is just E^*.

Proof: 1: This group is clearly in the fixed group of E^*, and if σ is in the fixed group of E^*, then

$$\sum_{\varphi\in\Phi}\varphi(a)=\sum_{\varphi\in\Phi}\sigma\varphi(a),$$

so $\sigma(\Phi)=\Phi$ by the linear independence of characters.

2: For $\sigma\in\mathrm{Gal}_{\mathbb{Q}}$ and $a\in E$,

$$\mathfrak{c}\,\sigma(\sum_{\varphi\in\Phi}\varphi(a))=\mathfrak{c}\sum_{\varphi\in\Phi}\sigma\varphi(a)=\sum_{\varphi\in\Phi}\sigma\varphi(\mathfrak{c}_E(a))=\sigma\sum_{\varphi\in\Phi}\varphi(\mathfrak{c}_E(a))=\sigma\,\mathfrak{c}(\sum_{\varphi\in\Phi}\varphi(a)).$$

Thus E is a CM-field or totally real by(13.6.2.2). The latter case is not possible because of the linear independence of characters and the fact $\mathfrak{c}(\Phi)\neq\Phi$.

3 is trivial. □

Def. (13.6.2.14)[Reflex CM-Pairs]. Let (E,Φ) be a CM-pair that E is contained in $\mathbb{Q}$, let E_1 be the Galois closure of E, and Φ_1 the extension of Φ to E_1. Then (E_1,Φ^{-1}) is also a CM-pair. Then the primitive subfield (E^*,Φ^*) satisfies E^* is the reflex field of (E,Φ).

(E^*,Φ^*) is called the **reflex CM-pair** of (E,Φ).

Classification of Primitive CM-Pairs

Prop. (13.6.2.15). Milne, Prop1.30.?

Cor. (13.6.2.16). Milne, Prop1.31.?

Positive Involutions

Def. (13.6.2.17) [Positive Involutions]. Let B be a f.d. $\mathbb{Q}$-algebra, and $\mathrm{tr}: B \to \mathbb{Q}$ is a $\mathbb{Q}$-linear functional, then a **positive involution** w.r.t. tr is an involution ι on B s.t.

$$\mathrm{tr}(x) = \mathrm{tr}(\iota(x)), \quad \mathrm{tr}(x \cdot \iota(x)) > 0$$

for any nonzero $x \in B$.

Prop. (13.6.2.18) [Positive Involutions are Semisimple]. If B is a f.d. $\mathbb{Q}$-algebra with a positive involution ι, then B is semisimple. And if Z is the center of B, then $Z = \prod_i K_i$ where $K_i \in \mathtt{NField}$, and each K_i are stable under ι.

Proof: By(2.4.2.8), it suffices to show that B is Jacobson semisimple: If $\mathfrak{a}$ is a nonzero nilpotent two-sided ideal of B, $a \neq 0 \in \mathfrak{a}$ is nilpotent, then $b = a\iota(a) \neq 0$ because $\mathrm{tr}(a\iota(a)) > 0$. Thus $b \neq 0 \in \mathfrak{a}$, and $\iota(b) = b$. So by the same reason $b^2 \neq 0$, and so on, so b is not nilpotent, contradicting(2.4.2.6).

The center is clearly invariant under the isomorphism given, so it is also semisimple, which is then a product of fields. To show each factor is stable under ι, notice that if $1 = \sum_i e_i$ is a decomposition w.r.t. this product, then $1 = \sum_i \iota(e_i)$, so $\{\iota(e_i)\} = \{e_i\}$. Moreover, $\iota(e_i) = e_i$ for each i, because otherwise $e_i\iota(e_i) = 0$, and $\mathrm{tr}(e_i\iota(e_i)) = 0$. □

Prop. (13.6.2.19). Let B be a f.d. $\mathbb{Q}$-algebra an ι an involution on B, then the following are equivalent:

- There is a faithful B-module V with a positive definite symmetric $\mathbb{Q}$-bilinear form $(-,-): V \times V \to \mathbb{Q}$ s.t.
$$(bu, v) = (u, \iota(b)v), \quad b \in B, u, v \in V.$$
- For any f.d. B-module V, there exists a positive definite symmetric $\mathbb{Q}$-bilinear form $(-,-): V \times V \to \mathbb{Q}$ s.t.
$$(bu, v) = (u, \iota(b)v), \quad b \in B, u, v \in V.$$
- There exists a $\mathbb{Q}$-linear functional tr on B s.t. ι is positive w.r.t. tr.

Proof: $1 \to 2$: As B is semisimple, any f.d. B-module is a direct summand of a direct sum of the faithful module V.

$2 \to 3$: Apply item2 to the B-module B itself, then we find a positive definite symmetric $\mathbb{Q}$-bilinear form $(-,-)$ on B, and an orthonormal basis $(e_1, \ldots, e_n)$ of B. Then we define

$$\mathrm{tr}: B \to \mathbb{Q}: \mathrm{tr}(b) = \sum_i (bb_i, b_i)$$

then $\mathrm{tr}(b) = \mathrm{tr}(\iota(b))$, and

$$\mathrm{tr}(b\iota(b)) = \sum_i (b\iota(b)b_i, b_i) = \sum_i (\iota(b)b_i, \iota(b)b_i) > 0.$$

$3 \to 1$: B is semisimple by(13.6.2.18), and then we can take $V = B$, and the positive definite symmetric $\mathbb{Q}$-bilinear form

$$(x, y) \mapsto \mathrm{tr}(\iota(y)x).$$

then $(bx, y) = \mathrm{tr}(\iota(y)bx) = \mathrm{tr}(\iota(\iota(b)y)x) = (x, \iota(b)y)$. □

Prop. (13.6.2.20) [Commutative Positive Involutions]. Every f.d. commutative $\mathbb{Q}$-algebra with a positive involution ι is a product of the following two:

- F is a totally real field and $\iota = \mathrm{id}_F$.
- E is a CM-field and $\iota = \mathfrak{c}_E$.

Proof: Firstly, any product of these two are positive involutions. Conversely, if (B, tr) is a f.d. $\mathbb{Q}$-algebra with a positive involution, then by(13.6.2.18), B is semisimple, thus a finite product of number fields. Then by(13.6.2.18), each factor is fixed by the involution, so it suffices to consider the case $B \in$ `NField`. Let F be the fixed field of ι. Because the trace form $\mathrm{tr}_{B/\mathbb{Q}}$ is non-degenerate, we can assume $\mathrm{tr}(x) = \mathrm{tr}(\alpha x)$ for some $\alpha \in B^\times$.

If $F = B$, then F is totally real: if there exists a non-real embedding $\sigma : F \to \mathbb{C}$, then we can use weak approximation to find $x \in F^\times$ s.t. $\sigma(\alpha x^2)$ is near -1 and $\varphi(\alpha x^2)$ is near 0 for any other embedding $\varphi : F \to \mathbb{C}$. Then clearly $\mathrm{tr}(\alpha x^2) < 0$, contradiction.

If $F \neq B$, then $[B : F] = 2$, and $\mathrm{tr}_{B/\mathbb{Q}}(\alpha x \iota(x)) > 0$ for any $x \in B^\times$. Take $x = 1$, we see $\mathrm{tr}_{B/\mathbb{Q}}(\alpha) > 0$. In particular, $\alpha + \iota(\alpha) \neq 0 \in F$. Then in particular, $\mathrm{tr}_{B/\mathbb{Q}}(\alpha x \iota(x)) = \mathrm{tr}_{F/\mathbb{Q}}((\alpha + \iota(\alpha)) x \iota(x)) > 0$. So by the argument above, F is totally real. And B is totally imaginary: If there exists a real embedding $\sigma : B \to \mathbb{C}$, then σ and $\sigma \circ \iota$ corresponds to different places, and by weak approximation, we can find $x \in B$ s.t. $\sigma((\alpha + \iota(\alpha))x)$ is near -1 and $\sigma(\iota(x))$ is near 1, and $\varphi(x)$ is near 0 for any other $\varphi : B \to \mathbb{C}$. Then $\mathrm{tr}_{F/\mathbb{Q}}((\alpha + \iota(\alpha)) x \iota(x)) < 0$, contradiction. So in this case B is a CM-field, and $\iota = \mathfrak{c}_B$. □

Cor. (13.6.2.21). There exists uniquely a positive involution on any CM-algebra, which is $\mathfrak{c}_E$.

Weil q-Integers

Prop. (13.6.2.22) [Weil q-Integers and CM Fields]. If $p \in \mathbf{P}, q \in p^{\mathbb{Z}}$ and $\varpi \in \mathrm{Weil}(q^{1/2})$, then $\mathbb{Q}(\varpi)$ is either isomorphic to $\mathbb{Q}$ or $\mathbb{Q}(\sqrt{q})$ or a CM-field.

Proof: For any embedding $\rho : \mathbb{Q}(\pi) \to \mathbb{C}$,

$$\rho(\pi)\overline{\rho(\pi)} = q = \rho(\pi)\rho(q/\pi),$$

so $\bar{}(\rho(\pi)) = \rho(q/\pi)$, and $E = \mathbb{Q}(\pi)$ is a CM-field with the endomorphism $\mathfrak{c}_E : \pi \mapsto q/\pi$. □

Prop. (13.6.2.23). Let $p \in \mathbf{P}, q \in p^{\mathbb{Z}}$, $F \in$ `NField` and $\pi, \pi' \in F \cap \mathrm{Weil}(q^{1/2})$. If $\mathrm{ord}_v(\pi) = \mathrm{ord}_v(\pi')$ for any $v \in \Sigma_F^p$, then π/π' is a roots of unity in E.

Proof: This is because there is an endomorphism of F(the conjugation) taking π to q/π, so for any $v \notin \Sigma_F^p$, $\mathrm{ord}_v(\pi) = 0$. Since the same is true for π', and $\mathrm{ord}_v(\pi) = \mathrm{ord}_v(\pi')$ for $v \in \Sigma_F^\infty$ too, by the definition of Weil q-integers. Thus $|\pi/\pi'|_v = 1$ for any $v \in \Sigma_F$, and the assertion follows from(12.4.5.30). □

3 CM Abelian Varieties

Def. (13.6.3.1) [Complex Multiplications]. For $k \in$ `Field` and $A \in \mathcal{A}b\mathcal{V}ar/k$,

$$[\mathrm{End}_{\mathbb{Q}}(A) : \mathbb{Q}]_{\mathrm{red}} \leq 2 \dim A.$$

And A is called an Abelian variety with **complex multiplication** or a CM Abelian variety if the equality holds.

Proof: Take $\ell \in \mathbf{P} \setminus \{\mathrm{char}\, k\}$, then $\mathrm{End}_{\mathbb{Q}}(A)$ acts faithfully on $T_\ell(A, \mathbb{Q}_\ell)$ by(13.14.1.1), which has dimension $2 \dim A$(13.5.6.15), so we finish by(13.5.6.11) and(2.4.3.24). □

Prop. (13.6.3.2). For $k \in \texttt{Field}$ and $A \in \mathcal{A}b\mathcal{V}\mathrm{ar}/k$, the following are equivalent:

- A is CM.
- $\mathrm{End}_{\mathbb{Q}}(A)$ contains an étale subalgebra of rank $2\dim A$ over $\mathbb{Q}$.
- For any Weil cohomology $\mathscr{H}^*$ with coefficients in $\Omega \in \texttt{Field}^0$, the centralizer of $\mathrm{End}_{\mathbb{Q}}(A)$ in $\mathrm{End}_{\Omega}(H^1(A))$ is commutative (and equals $Z(\mathrm{End}_{\mathbb{Q}}(A)) \otimes \Omega$).

Proof: $1 \iff 2$ follows from the fact the maximal étale subalgebra of $\mathrm{End}_{\mathbb{Q}}(A)$ has degree $[\mathrm{End}_{\mathbb{Q}}(A) : \mathbb{Q}]_{\mathrm{red}}$(2.4.3.23).

$2 \iff 3$ follows by noticing $\dim_{\Omega}(\mathscr{H}^1(A)) = 2\dim A$, and $\mathrm{End}_{\Omega}(A)$ acts faithfully on it**?**. Then use(2.4.3.24). □

Lemma (13.6.3.3). Let $A \in \mathcal{A}b\mathcal{V}\mathrm{ar}/\mathbb{C}$ and $F \subset \mathrm{End}_{\mathbb{Q}}(A)$. If F has a real place, then $[F : \mathbb{Q}] | \dim A$.

Proof: **?** □

Prop. (13.6.3.4). For $k \in \texttt{Field}$ and $A \in \mathcal{A}b\mathcal{V}\mathrm{ar}/k$,

- if A is simple, then A is CM iff $\mathrm{End}_{\mathbb{Q}}(A)$ is a CM-field of degree $2\dim A$ over $\mathbb{Q}$.
- If A is isotopic, then A is CM if $\mathrm{End}_{\mathbb{Q}}(A)$ contains a CM-field of degree $2\dim A$ over $\mathbb{Q}$, which is invariant under some Rosati involution.
- A is CM iff $\mathrm{End}_{\mathbb{Q}}(A)$ contains an étale CM-algebra of degree $2\dim A$ over $\mathbb{Q}$, which is invariant under some Rosati involution. And in this case, for $\ell \in \mathbf{P} \setminus \{\mathrm{char}\, k\}$, $T_\ell(A)$ is free of rank 1 over this algebra.

Proof: We use(13.6.3.2).

1: It suffices to show that if $\mathrm{End}_{\mathbb{Q}}(A)$ is a field of degree $2\dim A$, then it is CM.**?**

2: **?**

3 follows from 2. □

Prop. (13.6.3.5) [Tate1966]. Every Abelian variety over a finite field has CM.

Proof: **?** □

Complex CM Abelian Varieties

Prop. (13.6.3.6) [CM-Types of Complex Abelian Varieties]. Let E be a CM-algebra of degree $2g$, $A \in \mathcal{A}b\mathcal{V}\mathrm{ar}^g/\mathbb{C}$ and $E \subset \mathrm{End}_{\mathbb{Q}}(A)$, then the action of E on $\mathrm{Tgt}_0(A)$ is faithful, so

$$\mathrm{Tgt}_0(A) \cong \oplus_{\varphi \in \Phi} \mathbb{C}_{\varphi}$$

where Φ is a set of homomorphisms from E to $\mathbb{C}$. Then from the decomposition

$$H_1(A, \mathbb{R}) \cong \mathrm{Tgt}_0(A) \oplus \overline{\mathrm{Tgt}_0(A)}$$

and the fact $H_1(A, \mathbb{Q})$ is a free E-module of rank 1(13.6.3.4), we see $\Phi \coprod \mathfrak{c}\Phi = \mathrm{Hom}(E, \mathbb{C})$. So Φ is a CM-type on E.

Thus A is said to have **CM-type** (E, Φ) if Φ is a CM-type on E and

$$\mathrm{Tgt}_0(A) \cong \mathbb{C}^{\Phi}$$

as E-algebras.

Def. (13.6.3.7) [Reflex Field of a CM Abelian Variety]. Let $A \in \mathcal{A}b\mathcal{V}ar/\mathbb{C}$ be CM, then if E_0 is the center of $\mathrm{End}_{\mathbb{Q}}(A)$, by(13.6.3.4) and(13.6.3.6), E_0 is a CM-algebra, and there exists a CM-type Φ_0 on E_0 s.t. for any CM-pair E s.t. A is of CM-type (E,Φ), there Φ is the extension of Φ_0 to E.

Then the reflex field of (E_0,Φ) equals that of (E,Φ) for any (E,Φ), called the **reflex field** of A.

?

Prop. (13.6.3.8) [Abelian Varieties attached to CM-Pairs]. Let (E,Φ) be a CM-pair and Λ is a $\mathbb{Z}$-lattice in E, then

$$\Lambda\otimes_{\mathbb{Z}}\mathbb{R}\cong E\otimes_{\mathbb{Q}}\mathbb{R}\xrightarrow[\cong]{\Phi}\mathbb{C}^{\Phi}(13.6.2.7).$$

Thus $\Lambda\otimes_{\mathbb{Z}}\mathbb{R}$ has a complex structure and we get a Riemann pair (Λ, J_Φ), which corresponds to a complex torus A_Φ.

Then $R=\{x\in E|a\Lambda\subset\Lambda\}\subset\mathrm{End}(A_\Phi)$ is an order in E(12.4.2.36), and then $E\subset\mathrm{End}_{\mathbb{Q}}(A_\Phi)$.

Then there is a Riemann form on (Λ, J_Φ) whose associated positive Rosati involution(13.5.8.2) stabilizes E(and thus equals $\mathfrak{c}_E$ on E by(13.6.2.21)). In particular, A_Φ is a complex Abelian variety(13.5.8.1).

Proof: To give such a Riemann form, by(11.9.5.9), it suffices to give a non-degenerate bilinear form $\psi: E\times E\to\mathbb{Q}$ that satisfies

1. $\psi(ax,y)=\psi(x,\overline{a}y)$ for $a,x,y\in E$.
2. $\psi(x,y)=-\psi(y,x)$ for $x,y\in E$.
3. $\psi(J_\Phi x, J_\Phi y)=\psi(x,y)$ for $x,y\in E\otimes_{\mathbb{Q}}\mathbb{R}$.
4. $\psi(x,J_\Phi x)>0$ for any non-zero $x\in E\otimes_{\mathbb{Q}}\mathbb{R}$.

Now because the trace form $\mathrm{tr}: E\times E\to\mathbb{Q}$ is non-degenerate, non-degenerate $\mathbb{Q}$-bilinear forms of E are exactly of the form

$$\psi(x,y)=\mathrm{tr}_{E/\mathbb{Q}}(\overline{y}\alpha x),\alpha\in E^\times.$$

And the conditions (1) is automatic, and (3) is automatic because in the isomophism

$$E\otimes_{\mathbb{Q}}\mathbb{R}\xrightarrow[\cong]{\Phi}\prod_{\rho:F\to\mathbb{R}}\mathbb{C}\cong\mathbb{C}^{\Phi}: a\otimes r\mapsto(\rho'(a)r)_\rho,\quad \Phi=\{\rho'|\rho:F\to\mathbb{R}\}, (13.6.2.7)$$

$\psi_{\mathbb{R}}$ corresponds to

$$\psi'((x_\varphi),(y_\varphi))=\sum_{\varphi\in\Phi}\mathrm{tr}_{\mathbb{C}/\mathbb{R}}(\varphi(a)\overline{y_\varphi}x_\varphi)$$

and J_Φ corresponds to the isomorphism

$$(x_\varphi)_{\varphi\in\Phi}\mapsto(\mathrm{i}\,x_\varphi)_{\varphi\in\Phi}.$$

Thus it suffices to choose α s.t. $\varphi(\alpha)\in\mathrm{i}\,\mathbb{R}_+$ for any $\varphi\in\Phi$.

By(13.6.2.4), there exists $\alpha\in E^\times$ s.t. $E=F(\alpha)$ s.t. $\varphi(\alpha)\in\mathrm{i}\,\mathbb{R}$ for any $\varphi\in\Phi$, and we can then use weak approximation on F to modify α s.t. $\varphi(\alpha)\in\mathrm{i}\,\mathbb{R}_+$ for any $\varphi\in\Phi$. So this α clearly exists. Moreover, any other element α' is α times some element $a\in F$ that is totally positive. □

Prop. (13.6.3.9) [Classifying Complex CM Abelian Varieties up to Isogeny]. The map $(A,i)\to(E,\Phi)$ defines a bijection between the set of isogeny classes of CM Abelian varieties $A/\mathbb{C}$ with an embedding $i:E\to\mathrm{End}_{\mathbb{Q}}(A)$ and the set of isomorphism classes of CM-pairs (E,Φ), with inverse $(E,\Phi)\mapsto(A_\Phi,i_\Phi)$ which is the Abelian variety corresponding to the lattice $\Lambda=\mathcal{O}_E$(13.6.3.8), called the **principally-CM Abelian variety** of type (E,Φ).

Proof: Notice in(13.6.3.8), any two choice of the lattice $\mathfrak{a}$ give isogenous Abelian varieties, and because $H_1(A,\mathbb{Q})$ is free of rank 1 over E, let $e\in H_1(A,\mathbb{Q})$ be a basis vector, then $\mathfrak{a}e=H_1(A,\mathbb{Z})$ for some lattice $\mathfrak{a}\subset E$. Then this e defines an isomorphism

$$Ee\cong H_1(A,\mathbb{Z})\otimes\mathbb{Q}=H_1(A,\mathbb{Q})$$

thus the isomorphism

$$A\cong H_1(A,\mathbb{C})/H_1(A,\mathbb{Z})\xrightarrow[\cong]{e^{-1}}E\otimes_{\mathbb{Q}}\mathbb{C}/\mathfrak{a}\xrightarrow[\cong]{\Phi}\mathbb{C}^{\Phi}/\Phi(\mathfrak{a})\sim\mathbb{C}^{\Phi}/\Phi(\mathcal{O}_E).$$

This is clearly a bijection. □

Prop. (13.6.3.10) [Classifying Simple Complex CM Abelian Varieties]. Let A be a simple complex Abelian variety over $\mathbb{C}$ with CM and $E=\mathrm{End}_{\mathbb{Q}}(A)$, then E is a CM-field, and the map $A\mapsto(E,\Phi_A)$ defines a bijection between the set of isomorphism classes of simple complex Abelian varieties with CM and the set of isomorphism classes of primitive CM-paris.

Proof: $E\in\mathtt{Field}$ by(13.6.3.4), and if it is not primitive, then (E,Φ) is extended from a primitive CM-field (E_0,Φ_0), and a choice of E_0-basis of E defines an embedding $E\subset\mathrm{Mat}([E:E_0],E_0)\subset\mathrm{End}_0(A_{\Phi_0}^{[E:E_0]})$, and

$$E\otimes_{\mathbb{Q}}\mathbb{R}=E\otimes_{E_0}(E_0\otimes_{\mathbb{Q}}\mathbb{R})\cong E\otimes_{E_0}(\mathbb{C}^{\Phi_0})\cong\mathbb{C}^{\Phi}$$

shows $A_{\Phi_0}^{[E:E_0]}$ is also of type (E,Φ). Thus $A\sim A_{\Phi_0}^{[E:E_0]}$ by(13.6.3.9), contradicting the fact A is simple. □

Cor. (13.6.3.11). The simple Abelian varieties with complex multiplications are classified up to conjugacy by the $\mathrm{Gal}_{\mathbb{Q}}$-orbits of CM-types on $\mathbb{Q}^{\mathrm{cm}}$, by(13.6.2.16).

Good Reductions

Prop. (13.6.3.12) [Potential Good Reduction of CM-Abelian Varieties]. Let $E\in\mathtt{NField}$, $A\in\mathcal{A}b\mathcal{V}ar/\mathbb{C}$ has complex multiplication by E, then A is defined over some number field F. And F can be chosen s.t. A_F has good reduction.

Proof: Cf.[Milne, Abelian Varieties, P55].? □

4 Mumford-Tate Groups

5 Fundamental Theorem

Thm. (13.6.5.1) [Fundamental Theorem of Complex Multiplication, Shimura-Taniyama]. Let $A\in\mathcal{A}b\mathcal{V}ar/\mathbb{F}_q$ be the reduction from an complex Abelian variety of CM-type (E,Φ), then the Weil-q-integers of A can be constructed as follows:

Proof: Cf.[Milne, Abelian Varieties, P83].? □

6 Elliptic Curves

References are [Deu58] and [Ser67].

Prop. (13.6.6.1). By(13.9.1.27), if $E \in \mathcal{E}\mathrm{ll}/\mathbb{C}$ has CM(13.6.3.1), then $\mathrm{End}(E)$ is an $\mathbb{Z}$-order in an imaginary quadratic field $\mathcal{K}/\mathbb{Q}$, which must be of the form $\mathcal{O}_{\mathcal{K},f} = \mathbb{Z} + f\mathcal{O}_K$ for some $f \in \mathbb{Z}_+$**?**.

Proof: □

Thm. (13.6.6.2). Given any imaginary quadratic field $\mathcal{K}$ and an $\mathbb{Z}$-order $\mathcal{O}_{\mathcal{K},f} \subset \mathcal{K}$, the isomorphism classes of elliptic curves over $\mathbb{C}$ with maximal CM by $\mathcal{O}_{\mathcal{K},f}$ is in bijection with $\mathrm{Pic}(\mathcal{O}_{\mathcal{K},f})$, denoted by $\mathcal{E}\mathrm{ll}_{\mathbb{C}}(\mathcal{O}_{\mathcal{K},f})$.

In particular, $\#\,\mathcal{E}\mathrm{ll}_{\mathbb{C}}(\mathcal{O}_{\mathcal{K},f}) < \infty$. The j-values of elliptic curves with maximal CM by $\mathcal{O}_{\mathcal{K},f}$ are called **associated to** $\mathcal{O}_{\mathcal{K},f}$.

Proof: If $E \cong \mathbb{C}/\Lambda$, then Λ is a projective $\mathcal{O}_{\mathcal{K},f}$-module of rank 1**?**. □

Thm. (13.6.6.3) [Weber-Fueter]. Let $\mathcal{E}\mathrm{ll} \in \mathcal{E}\mathrm{ll}/\mathbb{C}$ with maximal CM by $\mathcal{O}_{\mathcal{K},f}$, then

- $j(E) \in \mathcal{O}_{\overline{\mathbb{Q}}}$, and $\mathcal{K}(j(E))$ is the ray class field $\mathcal{K}_f$ of $\mathcal{K}$.
- $\mathrm{Gal}(\mathcal{K}_f/\mathcal{K})$ acts transitively on the j-values associated to $\mathcal{O}_{\mathcal{K},f}$(13.6.6.2).

Proof: Cf.[Serre] or [Sutherland]L21. □

Cor. (13.6.6.4). There are 13 elliptic curves $E \in \mathcal{E}\mathrm{ll}/\mathbb{C}$ with complex multiplication and $j(E) \in \mathbb{Q}$, namely they are associated to $\mathcal{O}_{\mathcal{K},f}$ with

- $f = 1, \mathcal{K} = \mathbb{Q}(\sqrt{-d})$ with $d \in \{1, 2, 3, 7, 11, 19, 43, 67, 163\}$, with corresponding j-invariances
$$j = 2^6{\cdot}3^3,\quad 2^6{\cdot}5^3,\quad 0,\quad -3^3{\cdot}5^3,\quad -2^{15},\quad -2^{15}{\cdot}3^3,\quad -2^{18}{\cdot}3^3{\cdot}5^3,\quad -2^{15}{\cdot}3^3{\cdot}5^3{\cdot}11^3,\quad -2^{18}{\cdot}3^3{\cdot}5^3{\cdot}23^3{\cdot}29^3.$$
- $f = 2, \mathcal{K} = \mathbb{Q}(\sqrt{-d})$ with $d \in \{1, 3, 7\}$, with corresponding j-invariances
$$j = 2^3 \cdot 3^3 \cdot 11^3,\quad 2^4 \cdot 3^3 \cdot 5^3,\quad 3^3 \cdot 5^3 \cdot 17^3.$$
- $f = 3, \mathcal{K} = \mathbb{Q}(\sqrt{-3})$ with corresponding j-invariances $j = 2^{15} \cdot 3 \cdot 5^3$.

Proof: □

Thm. (13.6.6.5) [Hasse]. For $[\Lambda] \in \mathrm{Pic}(\mathcal{O}_{\mathcal{K},f})$, denoted $j(\Lambda) = j(\mathbb{C}/\Lambda)$, then if $\mathfrak{p}$ is a prime ideal of $\mathcal{O}_{\mathcal{K}}$ prime to the conductor and $\mathfrak{p}_f = \mathfrak{p} \cap \mathcal{O}_{K,f}$, then
$$\mathrm{Frob}_{\mathfrak{p}}(j(\Lambda)) = j(\Lambda{\cdot}\mathfrak{p}_f).$$

Proof: **?** □

Prop. (13.6.6.6) [CM j-Invariants are Integral]. For $K \in p$-`LField` and $E \in \mathcal{E}\mathrm{ll}/K$ with CM, $j(E) \in \mathcal{O}_K$.

Proof: □

Prop. (13.6.6.7) [CM j-Invariants are Integral]. If $F \in$ `NField` and $E \in \mathcal{E}\mathrm{ll}/F$ has CM, then $j(E) \in \mathcal{O}_F$.

Proof: Cf.[Sil99]P447. □

Prop. (13.6.6.8). If $k \in \texttt{Field}^p$, and $E \in \mathcal{E}\mathrm{ll}/k$ has CM, then $j(E) \in \overline{\mathbb{F}}_q \cap k$, by(13.9.3.5).

Thm. (13.6.6.9) [Kronecker's Jugendtraum]. Let $\mathcal{K}$ be an imaginary quadratic field and $E \in \mathcal{E}\mathrm{ll}(\mathcal{O}_\mathcal{K})$, then

$$\mathcal{K}^{\mathrm{ab}} = \mathcal{K}(j(E), \{x_{\mathrm{tor}}(E)\}),$$

where $\{x_{\mathrm{tor}}(E)\}$ is the set of x-coordinates of torsion points of E.

Proof: ? □

CM-Lifting

Thm. (13.6.6.10) [Honda/Chai-Conrad-Oort2014]. For any $A \in \mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/\mathbb{F}_q$, there exists an isogeny $A \sim B_0$ s.t. B_0 admits a CM lift to characteristic 0.

Proof: □

Thm. (13.6.6.11)[Deuring CM-Lifting Lemma]. Let $p \in \mathbf{P}$ and $E \in \mathcal{E}\mathrm{ll}/\overline{\mathbb{F}}_p$, and $\alpha_0 \in \mathrm{End}(E_0) \setminus \mathbb{Z}$, then there exists $F \in \texttt{NField}$, $\mathcal{E} \in \mathcal{E}\mathrm{ll}/\mathcal{O}_F$ and $\alpha \in \mathrm{End}(\mathcal{E})$, $\mathfrak{p} \in \Sigma_F^p$ s.t.

$$\mathcal{E}_{\overline{\kappa(\mathfrak{p})}} \cong E_0$$

s.t. $\alpha_{\overline{\kappa(\mathfrak{p})}}$ corresponds to α_0.

Proof: Cf.[Suw19]P5? □

Hilbert Class Polynomials

Def. (13.6.6.12) [Hilbert Class Polynomials]. Let $\mathcal{O}$ be a order in an imaginary quadratic field $\mathcal{K}$, the **Hilbert class polynomial** associated to $\mathcal{O}$ is defined to be

$$H_\mathcal{O}(X) = \prod_{E \in \mathcal{E}\mathrm{ll}_\mathbb{C}(\mathcal{O})} (X - j(E)).$$

For $D \in \mathbb{Z}, D \equiv 0, 1 (\mathrm{mod}\ 4)$, the **Hilbert class polynomial** of discriminant D is the class equation for the order $\mathcal{O}_D$.

Lemma (13.6.6.13). For $\ell \equiv -1 (\mathrm{mod}\ 4) \in \mathbf{P} \setminus \{3\}$ and $D = -\ell$ or -4ℓ, $H_D(1728) \equiv 0 (\mathrm{mod}\ \ell)$.

Proof: Consider the curve $E : y^2 = x^3 - x$, it is supersingular by(13.9.3.12) or(13.6.6.19), and has j-invariant 1728. Thus $\varphi_E^2 = -\ell$ by (13.9.3.9)(13.9.3.3). Notice $E[2] = \{\infty, (0, 0), (\pm 1, 0)\}$, which are all defined over $\mathbb{F}_p$, so $2 | (1 + F)$, and $\mathbb{Z}[\frac{1+\varphi_E}{2}] \cong \mathcal{O}_\ell$. Thus by Deuring CM-lifting lemma(13.6.6.11), there is an elliptic curve over some $\mathcal{O}_F$ with maximal CM by $\mathcal{O}_{-\ell}$ whose j-invariant is mapped to $1728 (\mathrm{mod}\ \ell)$, so $H_{-\ell}(1728) \equiv 0 (\mathrm{mod}\ \ell)$.

Similarly, E has endomorphism $I : (x, y) \mapsto (-x, \mathrm{i}\, y)$, $I^2 = -1, IF = -FI$, so we can lift IF to get an elliptic curve over some $\mathcal{O}_F$ with CM by $\mathcal{O}_{-4\ell}$. And it is maximal CM, because $\frac{1+IF}{2} \notin \mathrm{End}(E)$, as $(1 + IF)(P = (1, 0)) = (1, 0) + (-1, 0) \neq O$. □

Lemma (13.6.6.14). For $\ell \equiv -1 (\mathrm{mod}\ 4) \in \mathbf{P} \setminus \{3\}$ and $D = -\ell$ or -4ℓ, let $\mathcal{K}_D$ be the ray class field of $\mathcal{O}_D$, then for any root x_0 of $H_D(X)$ s.t. $x_0 \equiv 1728 (\mathrm{mod}\ \ell)$, there exists a unique $\mathfrak{l} \in \Sigma_{\mathcal{K}_D}^\ell$ s.t. $x_0 - 1728 \in \mathfrak{l}$. The j-invariant of this elliptic curve is mapped to $1728 (\mathrm{mod}\ \ell)$, so $H_{-\ell}(1728) \equiv 0 (\mathrm{mod}\ \ell)$.

Proof: The existence follows from(13.6.6.13), and if there are two primes $\mathfrak{l}, \mathfrak{l}'$ that divides $x - 1728$, then there exists $\sigma \neq \mathrm{id}$ s.t. $x_1 = \sigma(x_1) \equiv 1728 (\mathrm{mod}\ \ell)$. Then there are two elliptic curves $E_1, E_2/\overline{\mathbb{Q}}$ with j-invariants x_0, x_1 that reduces to the elliptic $E/\mathbb{F}_\ell : y^2 = x^3 - x$. Then we get a degree-preserving injection $\mathrm{Hom}(E_1, E_2) \hookrightarrow \mathrm{End}(E_{\overline{\mathbb{F}}_\ell}) = A$.

For the rest, see[Suw19]P8**?** □

Prop. (13.6.6.15). For $\ell \equiv -1 (\mathrm{mod}\ 4) \in \mathbf{P} \setminus \{3\}$, there exists $R, S \in \mathbb{Z}[X]$ s.t.

$$H_{-\ell}(X) = (X - 1728)R(X)^2, \quad H_{-4\ell}(X) = (X - 1728)S(X)^2.$$

Proof: Notation as in(13.6.6.14), there exists an involution τ of $\mathcal{K}_D$ s.t. $\sigma(x_0) = x_0$. Thus by the lemma, $\tau(\mathfrak{l}) = \mathfrak{l}$, and $f(\mathfrak{l}/\ell)$ is odd because $\mathrm{Gal}(\mathcal{K}_D/\mathcal{K})$ does(12.4.4.3). So σ acts trivially on $\kappa(\mathfrak{l})$. But τ doesn't fix any roots x of $H_D(X)$ other than x_0(because x_i corresponds to ideal classes of $\mathcal{O}_D$ where x_0 corresponds to the trivial class, and τ acts by $[I] \mapsto [I]^{-1}$), so the other roots come in pairs, and the assertion follows. □

Prop. (13.6.6.16). For $\ell \equiv -1 (\mathrm{mod}\ 4) \in \mathbf{P} \setminus \{3\}$, the only real roots of $H_\ell(X)$ and $H_{4\ell}(X)$ are $j(\frac{1}{2}(1 + \sqrt{-\ell}))$ and $j(\sqrt{-\ell})$ resp..

Proof: For $D = \ell$ or -4ℓ, since the complex conjugation is compatible with the correspondence in(13.6.6.2), and because $I\overline{I} = \mathrm{Nm}(I)\mathcal{O}_D$, so the fixed points of $\mathfrak{c}$ are just 2-torsions in $\mathrm{Pic}(\mathcal{O}_D)$. But $\mathrm{Pic}(\mathcal{O}_D)$ is odd by(12.4.4.3), thus the only real j-value corresponds to the trivial class. □

Cor. (13.6.6.17). For any $j \in \mathbb{R}$, for $\ell \equiv -1 (\mathrm{mod}\ 4) \in \mathbf{P} \setminus \{3\}$ sufficiently large, $H_{-\ell}(j) > 0$ and $H_{-4\ell}(j) < 0$.

Proof: This is because $j(\frac{1}{2}(1 + \sqrt{-\ell})) \to -\infty$ and $j(\sqrt{-\ell}) \to \infty$ as $\ell \to \infty$, by the power expansion(16.2.5.10). □

Supersingular Primes

References are [Elk87] and [Suw19].

Lemma (13.6.6.18). Let $k \in \mathtt{Field}^p$ and $E \in \mathcal{E}\mathrm{ll}/k$, E is supersingular iff there exists an order $\mathcal{O}$ of an imaginary quadratic field $\mathcal{K}$ s.t. $\mathcal{O} \subset \mathrm{End}(E)$ and p doesn't split in $\mathcal{K}$.

Proof: By(13.9.3.6), if it is ordinary, then $\mathrm{End}(\mathcal{O})$ is a $\mathbb{Z}$-order in an imaginary quadratic field $\mathcal{K}$. Then consider the p-adic representation

$$\mathcal{K} \otimes \mathbb{Q}_p = \mathrm{End}(E) \otimes \mathbb{Q}_p \to \mathrm{End}_{\mathbb{Q}_p}(V_p(E)) \cong \mathbb{Q}_p.$$

Then this map has a kernel, so $\mathcal{K} \otimes \mathbb{Q}_p$ is not a field, and p splits in $\mathcal{K}$. □

Thm. (13.6.6.19) [Supersingular Criterion for CM Elliptic Curves, Deuring]. Let $F \in \mathtt{NField}$ and $E \in \mathcal{E}\mathrm{ll}/F$ with CM by an imaginary quadratic field $\mathcal{K}$. If $\mathfrak{p} \in \Sigma_F^p$ is a good reduction for E, then $\widetilde{E}/\kappa(\mathfrak{p})$ is ordinary/supersingular iff p is split/non-split in $\mathcal{K}$.

Proof: Cf.[Lang, Elliptic Functions, Thm13.12].**?** □

Cor. (13.6.6.20) [Supersingular Reductions for CM Elliptic Curves]. For $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$ with CM by $\mathcal{K}$, then

$$\#\{p \in \mathbf{P}, p \leq X | \widetilde{E}/\mathbb{F}_p \text{ is supersingular elliptic}\} = \frac{X}{2\log X} + O(\frac{X}{\log X}).$$

Proof: This follows from the effective Chebotarev density theorem(12.6.5.4). □

Prop. (13.6.6.21) [Elkies]. For any $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$, there are infinitely many $p \in \mathbf{P}$ s.t. $\widetilde{E}/\mathbb{F}_p$ is supersingular elliptic. (This is also true if $\mathbb{Q}$ is replaced by a real field, Cf.[Elkies, 1989]).

Proof: By Deuring's CM-lifting lemma(13.6.6.11), for $D = -\ell$ or -4ℓ, $\widetilde{E}/\mathbb{F}_p$ has CM by $\mathcal{O}_D$ iff $H_D(j(E)) = 0 \in \mathbb{F}_p$. So by(13.6.6.18), p is a supersingular prime for E if

- $H_{-\ell}(j(E)) \in p\mathbb{Z}_p$ or $H_{-4\ell}(j(E)) \in p\mathbb{Z}_p$, and
- $\mathrm{ord}_p(\ell)$ is odd or $-\ell$ is a quadratic non-residue modulo p.

Suppose that there is a finite set S containing all the supersingular primes of E, assume $2 \in S$. By Dirichlet's theorem, there exists $\ell \in \mathbf{P}$ sufficiently large s.t.

$$\ell \equiv 3 (\mathrm{mod}\ 4), \quad \left(\frac{p}{\ell}\right) = 1, \quad p \in S.$$

Then by quadratic reciprocity, if $p \in \mathbf{P}$ and $H_{-\ell}(j(E)) \in p\mathbb{Z}_p$ or $H_{-4\ell}(j(E)) \in p\mathbb{Z}_p$, then $p \neq \ell$ and $\left(\frac{p}{\ell}\right) = 1$, otherwise there would be a new supersingular prime for E that is not in S.

As $H_{-\ell}, H_{-4\ell} \in \mathbb{Z}[X]$, for any $p \in \mathbf{P}$,

$$H_{-\ell}(j(E))^{-1} \in p\mathbb{Z}_p \iff j(E)^{-1} \in p\mathbb{Z}_p \iff H_{-4\ell}(j(E))^{-1} \in p\mathbb{Z}_p,$$

and if $j(E)^{-1} \in p$, then

$$\mathrm{ord}_p(H_{-\ell}(j(E))^{-1}) + \mathrm{ord}_p(H_{-4\ell}(j(E))^{-1}) = \mathrm{ord}_p(j(E)^{-1}) \cdot (\deg(H_{-\ell}) + \deg(H_{-4\ell}))$$

which is even by(13.6.6.15). And $H_{-\ell}(j(E))H_{-4\ell}(j(E)) < 0$ by(13.6.6.17). So $H_{-\ell}(j(E))H_{-4\ell}(j(E))$ would be a quadratic non-residue modulo ℓ by our hypothesis. But this contradicts(13.6.6.15). □

Without CM case

Thm. (13.6.6.22) [Serre]. For $F \in$ `NField` and $E \in \mathcal{E}\mathrm{ll}/F$ without CM, $\rho_E(\mathrm{Gal}_F) \subset \mathrm{GL}(2; \mathbf{A}^f)$ has finite index.

Proof: Cf.[Abelian l-adic representations and elliptic curves, Serre]. or [Bounds for Serre's open image theorem for elliptic curves over number fields]. □

Conj. (13.6.6.23) [Lang-Trotter]. For $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$ without CM,

$$\#\{p \in \mathbf{P}, p \leq X | \widetilde{E}/\mathbb{F}_p \text{ is supersingular elliptic}\} \sim \frac{\sqrt{X}}{\log X}.$$

Proof: □

Prop. (13.6.6.24) [Serre-Elkies]. For $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$ without CM,

$$\#\{p \in \mathbf{P}, p \leq X | \widetilde{E}/\mathbb{F}_p \text{ is supersingular elliptic}\} \leq X^{3/4+\varepsilon}.$$

In particular, supersingular primes have density 0.

Proof: [N. D. Elkies. Distribution of supersingular primes. Asterisque, (198-200):127–132 (1992), 1991. Journe´es Arithme´tiques, 1989]. □

Conj. (13.6.6.25) [Sato-Tate]. Let $F \in \texttt{NField}$ and $E \in \mathcal{E}\mathrm{ll}/F$ without CM, then for any place v, define $a_v = q_v + 1 - \#\widetilde{E}_v(\kappa_v)$, then by Weil conjecture, $|a_v| \leq 2\sqrt{q_v}$, Let $a_v/2\sqrt{q_v} = \cos\theta_v, 0 \leq \theta \leq \pi$, then $\{\theta_v\}$ for places v leveled by q_v has distribution density $\frac{2}{\pi}\sin^2\theta$.

Remark (13.6.6.26) [Clozel-Harris-Shepherd-Barron-Taylor]. If $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$ with $j(E) \notin \mathbb{Z}$, then the Sate-Tate conjecture(13.6.6.25) is true.

Proof: [Clozel-Harris-Taylor, Automorphy for some ℓ-adic lifts of automorphic mod ℓ representations], [A family of Calabi-Yau varieties and potential automorphy]. □

Cor. (13.6.6.27) [Birch]. Given $p \in \mathbf{P}$, for any $E \in \mathcal{E}\mathrm{ll}/\mathbb{F}_p$, define $a_v(E) = p + 1 - \#\widetilde{E}_v(\mathbb{F}_p)$ and $a_v(E)/2\sqrt{p} = \cos\theta_p(E), 0 \leq \theta \leq \pi$, then the distribution density of $\{\theta_p(E)\}$ for $E \in \mathcal{E}\mathrm{ll}/\mathbb{F}_p$ tends to $\frac{2}{\pi}\sin^2\theta$ for $p \to \infty$ when $p \to \infty$.

Proof: **?** □

13.7 Surfaces and Arithmetic Surfaces

Main references are [Sil99], [Liu Qing].

Notation (13.7.0.1).

- In this section, let $S \in \mathcal{S}ch$ be a Dedekind scheme with generic point η or a spectrum of a field, and $\eta = S$.

1 Over Fields

Main references are [Liu Qing, Algebraic Geometry and Arithmetic Curves].

Prop. (13.7.1.1) [27-Lines]. Any smooth cubic surface in $\mathbb{P}^3_k$ contains exactly 27 lines.

Proof: □

Prop. (13.7.1.2). Any birational transformation of non-singular surfaces will be factorized into f.m blowing-ups and blowing-downs of points.

Proof: □

Prop. (13.7.1.3). Any smooth surface over a field k is projective.

Proof: Cf.[Badescu, Algebraic Surfaces]Thm1.28. □

Prop. (13.7.1.4) [Non-Projective Smooth Proper Threefold]. Cf.[Vak17]P671.

Proof:

□

Resolution of Surfaces

Cf.[Sta]Chap51.

Regular Surfaces

2 Fibered presurfaces

Def. (13.7.2.1) [fibered presurfaces]. Let $S \in \mathcal{S}ch$ be Dedekind, a **fibered presurface** over S is proper? flat S-scheme integral of dimension 2.

Prop. (13.7.2.2). Let $S \in \mathcal{S}ch$ be Dedekind, X a fibered presurface over S, then X_s has dimension 1 for any $s \in S$, and X_η is a precurve.

Proof: Cf.[Qing Liu]P348. □

Example (13.7.2.3). Let $q \in \mathbb{Z}_+$ be a square-free integer, then $\mathcal{C} = \mathbf{Proj}(\mathbb{Z}[X, Y, Z]/(X^q + Y^q + Z^q))$ is a normal fibered presurface over Spec Z.

Proof: Cf.[Qing Liu]P455. □

Prop. (13.7.2.4) [Horizontal and Vertical Divisors]. Let $S \in \mathcal{S}ch$ be Dedekind, X a fibered presurface over S, then

- If x is a closed point of X_η, then $\overline{\{x\}}$ is an integral closed subscheme of X that is finite surjective over S, called a **horizontal divisor**.
- If $D \subset X$ is a prime Weil divisor, then D is either a horizontal divisor, or an integral component of a special fiber, called a **vertical divisor**.
- If $x_0 \in X$ is closed, then $\dim \mathcal{O}_{X,x_0} = 2$.

Moreover, call a Weil divisor D on X horizontal or vertical if it consists of horizontal or vertical prime divisors.

Proof: Cf.[Qing Liu]P349. □

Prop. (13.7.2.5) [Generically Smoothness]. Let $S \in \mathcal{S}\mathrm{ch}$ be Dedekind and $\pi : X \to S$ be a fibered presurface s.t. X_η is smooth, then there is a dense open subscheme $V \subset S$ s.t. $\pi^{-1}(V) \to V$ is smooth.

Proof: Cf.[Qing Liu]P352. □

Regular Fibered Presurfaces

Prop. (13.7.2.6) [Regular Fibered Presurfaces are Projective]. Let S be affine and X/S be a flat morphism with fibers of dimension 1, then X/S is projective. In particular, a regular fibered presurface is projective.

Proof: Cf.[Qing Liu]P353. □

Prop. (13.7.2.7) [Sections are Regular]. Let $\pi : \mathcal{C} \to S$ be a regular fibered presurface and $s \in S$, then

- If $s \in S$ is closed and $x \in \mathcal{C}_s$ is closed, then $\mathcal{C}_s$ is regular at x iff $\pi^\sharp(\mathfrak{p}_s) \not\subseteq \mathfrak{m}_x^2$.
- If $P : U \to \mathcal{C}$ is a rational section, then $\mathcal{C}_p$ is smooth at $P(s)$ for $s \in U$.

Proof: 1: This is because $\mathcal{O}_{\mathcal{C}_s,x} = \mathcal{O}_{\mathcal{C},x}/\pi^\sharp(\mathfrak{p}_s)$, $\mathfrak{m}_{\mathcal{C}_s,x} = \mathfrak{m}_{\mathcal{C},x}/\pi^\sharp(\mathfrak{p}_s)$ and use the definition of regularity.

2: We show that $\pi^\sharp(\mathfrak{p}_s) \not\subseteq \mathfrak{m}_x^2$: Suppose otherwise, then

$$\mathfrak{p}_s = (\pi \circ P)^\sharp(\mathfrak{p}_s) \subset \pi^\sharp(\mathfrak{m}_x^2) = \mathfrak{p}^2,$$

which is impossible. □

Cor. (13.7.2.8). Let $\mathcal{C}/S$ be a regular fibered presurface, then $\mathcal{C}(S) = \mathcal{C}_{\mathrm{sm}}(S)$. If moreover $\mathcal{C}/S$ is proper, then $\mathcal{C}(S) = \mathcal{C}_{\mathrm{sm}}(S) = \mathcal{C}_\eta(K)$.

Example (13.7.2.9).

- $\mathcal{C} \subset \mathbb{P}^2_{\mathbb{Z}}$ defined by the equation $y^2 = x^3 + 2x^2 + 6$ is a regular fibered presurface over $\mathbb{Z}$ with 3 singular points.
- $\mathcal{C} \subset \mathbb{P}^2_{\mathbb{Z}}$ defined by the equation $y^2 = x^3 + 2x^2 + 6$ is not regular at $(x, y, 2)$.

Proof: 1: The determinant $\Delta = -2^6 \cdot 3 \cdot 97$, so it is has three singular fibers $\mathcal{C}_2, \mathcal{C}_3, \mathcal{C}_{97}$:

$$\mathcal{C}_2 : y^2 = x^3, \quad \mathcal{C}_3 : y^2 = x^2(x + 2), \quad \mathcal{C}_{97} : y^2 = (x + 66)^2(x + 64).$$

By(13.9.1.15), they are singular at a single point, and we check these points are regular in $\mathcal{C}$:

For $\mathcal{C}_2$, the singular point is defined by $(x, y, 2)$, and has residue field $\mathbb{F}_2$. To show it is regular, it suffices to show that $(x, y, 2)/(x, y, 2)^2$ is generated by 2 elements x, y: $2 = 3^{-1}(y^2 - x^3 - 3x^2)$. The $\mathcal{C}_3, \mathcal{C}_{97}$ cases are similar. □

3 Arithmetic Surfaces

Def. (13.7.3.1)[Arithmetic Surfaces]. An **arithmetic surface** is a flat of f.t. over S that is integral normal and excellent, such that its generic fiber is a non-singular projective curve, and its special fibers are unions of curves.

Prop. (13.7.3.2). Any arithmetic surface is regular in codimension 1.

Prop. (13.7.3.3)[Mordell-Weil for Function Fields]. Let $\mathcal{E}\to C$ be an elliptic surface defined over a field k. Let $E/K(C)$ be the generic fiber. If k is a number field or $\mathcal{E}/C$ is not split, then $E(K(C))$ is a f.g. Abelian group.

Proof: Cf.[Sil99]P230. □

4 Intersection Theory

Def. (13.7.4.1)[Canonical Divisors]. $K_{X/S}$, Cf.[Qing Liu]P389.

Def. (13.7.4.2)[Vertically Nef]. Let X/S be a regular fibered presurface, then $D\in \mathrm{Cl}(X)$ is called **vertically nef** if $D\cdot C\geq 0$ for any vertical divisor C.

Prop. (13.7.4.3)[Factorization Theorem]. Any birational morphism of regular fibered presurfaces over S is a finite composition of blowing-up along a single closed point.

Proof: Cf.[Qing Liu]P395. □

Arithmetic Surfaces

Prop. (13.7.4.4)[Intersection between Vertical Divisors]. Let X/S be an arithmetic surface and $s\in S$ a closed point, then for any $\Gamma\in \mathrm{Div}_s(X)$, $\Gamma\cdot X_s=0$. In particular, if $\Gamma_1,\ldots,\Gamma_r$ are irreducible components of X_s of multiplicities $d_1,\ldots,d_r$, then

$$\Gamma_i^2=-\frac{d_j}{d_i}\sum_{j\neq i}\Gamma_i\cdot\Gamma_j\leq 0.$$

5 Minimal Arithmetic Surfaces

Def. (13.7.5.1) [Exceptional Divisors]. Let X/S be a regular fibered presurface, then an **exceptional divisor** or (-1)**-curve** $E\subset X$ is a prime divisor s.t. there is a morphism of regular fibered presurfaces $f:X\to Y$ s.t. $f(E)$ is a closed point. Notice an exceptional divisor must be a vertical divisor.

Prop. (13.7.5.2) [Castelnuovo's criterion, Lichtenbaum/Shafarevich]. Let X/S be a regular fibered presurface, $E\subset X_s$ a vertical prime divisor. Let $k'=H^0(E,\mathcal{O}_E)$, then E is an exceptional divisor iff $E\cong\mathbb{P}^1_{k'}$. And this is the case if $E^2=-[k':k(s)]$.

Proof: Cf.[Qing Liu]P416. □

Prop. (13.7.5.3)[Characterizing Exceptional Divisors]. Let X/S be a regular fibered presurface, then for a vertical prime divisor E on X,

- E is exceptional iff $K_{X/S}\cdot E<0$(13.7.4.1) and $E^2<0$. And in this case, $K_{X/S}\cdot E=E^2$.

- If $\dim S = 0$ and $H^0(X, [\omega_{X/S}]^q) \neq 0$ for some $q \geq 1$ or $\dim S = 1$ and $p_a(X_\eta) > 0$, then E is exceptional iff $K_{X/S} \cdot E < 0$.

Proof: Cf.[Qing Liu]P417. □

Def. (13.7.5.4) [Minimal Surfaces]. A **relatively minimal surface** over S is a regular fibered presurface $\mathcal{C}/S$ s.t. for any other such regular fibered presurface $\mathcal{C}'$ and any birational morphism $\mathcal{C} \to \mathcal{C}'$ is an isomorphism. Equivalently, $\mathcal{C}$ is a regular proper model that doesn't contain an exceptional curve of the first kind, i.e. cannot be blown down by(13.7.4.3). Cf.[Sta]0C21.

A **minimal surface** over S is a regular fibered presurface $\mathcal{C}/S$ s.t. for any other such regular fibered presurface $\mathcal{C}'$ and any birational map $\mathcal{C}' \to \mathcal{C}$ is a birational morphism. In particular, a minimal surface $\mathcal{C}/S$ is relatively minimal, and $\mathrm{Aut}_S(\mathcal{C}) \cong \mathrm{Aut}_K(\mathcal{C}_\eta)$ is an isomorphism.

Cor. (13.7.5.5). If a relatively minimal arithmetic surface over S is birational to a minimal surface over S, then they are isomorphic over S.

Prop. (13.7.5.6) [Étale Descent]. Let X/S be an arithmetic surface with $p_a(X_\eta) > 0$, and $S' \to S$ is an étale covering or $S = \operatorname{Spec} R$ where R is a DVR and $S' = \operatorname{Spec} \widehat{R}$, then X/S is minimal iff $X \times_S S'/S'$ is minimal.

Proof: Cf.[Qing Liu]P423. □

Cor. (13.7.5.7). Let X/S be an arithmetic surface with $p_a(X_\eta) > 0$ and $T \to S$ is a smooth morphism, then for any $\xi \in T$ of codimension 1, $X \times_S \mathcal{O}_{T,\xi}$ is a minimal regular surface over $\mathcal{O}_{T,\xi}$.

Proof: Cf.[Qing Liu]P424. □

Minimal Models

Prop. (13.7.5.8) [Minimal Models]. Let $\mathcal{C}/S$ be a normal fibered presurface, then a **regular model** for $\mathcal{C}/S$ is a regular fibered presurface $\mathcal{C}'/S$ with a birational map $\mathcal{C}' \to \mathcal{C}$ over S. Notice $\mathcal{C}'_\eta \to \mathcal{C}_\eta$ is a birational map of regular projective precurve, thus an isomorphism.

A (relatively)**minimal model** for $\mathcal{C}/S$ is a regular model for $\mathcal{C}/S$ that is (relatively) minimal. Notice if a minimal model exists, it is unique up to a unique isomorphism.

Lemma (13.7.5.9). If X/S is an arithmetic surface, then there exists only f.m. fibers X_s containing an exceptional divisor.

Proof: Cf.[Qing Liu]P420. □

Prop. (13.7.5.10) [Blowing Down to Relatively Minimal Surfaces]. If X/S is an arithmetic surface, then X is a finite blowing-up of relatively minimal arithmetic surface over S.

Proof: The number of exceptional divisors decreases along contractions**?** □

Prop. (13.7.5.11) [Lichtenbaum/Shafarevich]. Let X/S be an arithmetic surface with $p_a(X_\eta) \geq 1$, then X admits a unique minimal model over S.

Proof: Cf.[Qing Liu]P422. □

Remark (13.7.5.12). This is not true for $p_a(X_\eta) = 0$, Cf.[Qing Liu]P422.

Cor. (13.7.5.13)[Minimal and Relatively Minimal Surfaces]. If X/S is an arithmetic surface s.t. $p_a(X_\eta) > 1$, then X is minimal iff it is relatively minimal iff $K_{X/S}$ is vertically nef, by(13.7.5.5) and(13.7.5.4)(13.7.5.3). **?** In the field case, why the hypothesis is satisfied?

Cor. (13.7.5.14). If X/S is a smooth arithmetic surface, then X/S is relatively minimal by(13.7.4.4) as in this case X_s is a disjoint union of irreducible curves. And if $p(X_\eta) > 0$, then X is minimal.

13.8 Reductions

1 Semistable Reductions

Def. (13.8.1.1) [Models]. Let S be a Dedekind domain with function field K and X an algebraic K-scheme, a **model over** S for X is a proper flat f.t. S-scheme $\mathcal{X}$ s.t $\mathcal{X} \times_S K \cong X$.

Def. (13.8.1.2) [Good Reduction]. Let (R, K, k) be a DVR and $X \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}}/K$, X is said to have **good reduction** over R if there is a smooth model $\mathcal{X}$ for X. If this is the case, then $\widetilde{X} = \mathcal{X}_k$ is a smooth scheme over k, called the **reduction of** X.

In this case, the reduction map $X(\overline{K}) \cong \mathcal{X}(\mathcal{O}_{\overline{K}}) \to \widetilde{X}(\overline{k})$ is surjective, by valuation criterion and formal smoothness criterion.

2 Reduction of Curves

Main references are [Sta]Chap55 and [Qing Liu].

Def. (13.8.2.1)[Semistable and Stable Unions of Curves]. Let $k \in \texttt{Field}$, k, C an algebraic union of curves over k, then C is called a **semistable union of curves** iff $C_{\overline{k}}$ is reduced and the singular points of $C_{\overline{k}}$ are all ordinary double points. C is called a **stable union of curves** if moreover it satisfies:

- $C_{\overline{k}}$ is connected and projective, with $p_a(C) \geq 2$.
- Let Γ be an integral component of C that is isomorphic to $\mathbb{P}^1_k$, then it meets other integral components at at least 3 points.

Minimal Models

Def. (13.8.2.2) [Minimal Models]. Let R be a DVR with fraction field K. Let C be a smooth projective curve over K, then a **minimal model for** C is a regular proper model $\mathcal{C}$ for C s.t. for any other such model $\mathcal{C}'$, any birational map of models $\mathcal{C} \to \mathcal{C}'$ is an isomorphism.

Equivalently, $\mathcal{C}$ is a regular proper model that doesn't contain an exceptional curve of the first kind, i.e. cannot be blown down**?** Cf.[Sta]0C21.

Prop. (13.8.2.3) [Resolution of Singularities for Arithmetic Surfaces]. Let (R, K) be a DVR, C a smooth projective curve over K of genus g. Then there exists a proper regular model for C.

Proof: Cf.[**?**] □

Prop. (13.8.2.4) [Minimal Model Theorem]. Let (R, K) be a Dedekind domain and C a smooth projective precurve over K, then of genus≥ 1, then there exists a minimal model for C.

Proof: Cf.[**?**] □

Prop. (13.8.2.5) [Semistable Reductions]. Let (R, K) be a DVR, for a smooth complete curve C over K, the following are equivalent:

- There exists a proper model of C that is at-most-nodel of relative dimension 1 over R.
- There exists a minimal model of C that is at-most-nodel of relative dimension 1 over R.
- Any minimal model of C that is at-most-nodel of relative dimension 1 over R.

If this is the case, then C is said to have **semistable reduction**.

Proof: Cf.[Sta]0CDG. □

Prop. (13.8.2.6) [Good Reductions]. Let R be a DVR with fraction field K, for a smooth projective curve C over K, the following are equivalent:

- C has good reduction over R.
- There exists a minimal model of C that is smooth over R.
- Any minimal model of C is smooth over R.

Proof: Cf.[Sta]0CDI. □

Good Reduction for Curves

Prop. (13.8.2.7) [Reduction of Morphisms]. For any morphism $\varphi : C \to C'$ of smooth projective curves over $\mathbb{Q}$ with good reduction at p and $g(C') > 0$, there exists a unique reduction morphism $\widetilde{\varphi} : \widetilde{C} \to \widetilde{C}'$ that commutes with the reduction map(13.8.1.2). This defines a functor from the category of smooth projective curves of positive genus with good reduction to the category of smooth curves over $\mathbb{F}_p$.

Moreover, $\deg(\varphi) = \deg(\widetilde{\varphi})$, and by(13.8.1.2), if φ is surjective, $\widetilde{\varphi}$ is also surjective. And φ is an isomorphism iff $\widetilde{\varphi}$ is an isomorphism.

Proof: Cf.[BLR90]Prop 9.5.1**?** □

Cor. (13.8.2.8). If $\varphi : E \to E'$ is an isogeny of elliptic curves over $\mathbb{Q}$ with good reduction at p, then the reduction morphism $\widetilde{\varphi} : \widetilde{E} \to \widetilde{E}'$ is also an isogeny.

Proof: Because it maps $\widetilde{O}_E$ to $\widetilde{O}_{E'}$ and is surjective, this follows from(13.5.1.4). □

Prop. (13.8.2.9) [Pushforward of Divisors]. Let C be a smooth projective curve over $\mathbb{Q}$ with good reduction at p, then the reduction map $X(\overline{K}) \to \widetilde{X}(\overline{F}_p)$ induces a map

$$\mathrm{Div}^0(X) \to \mathrm{Div}^0(\widetilde{X})$$

that maps principal divisors to principal divisors, so inducing a map $\varphi_* : \mathrm{Pic}^0(C) \to \mathrm{Pic}^0(C')$, which is compatible with pushforward of divisors along morphisms of curves: if $h : C \to C'$ is a morphism of smooth projective curves over $\mathbb{Q}$ with good reductions at p, then the following digram is commutative:

$$\begin{array}{ccc} \mathrm{Pic}^0(C) & \xrightarrow{h_*} & \mathrm{Pic}^0(C') \\ \downarrow & & \downarrow \\ \mathrm{Pic}^0(\widetilde{C}) & \xrightarrow{\widetilde{h}_*} & \mathrm{Pic}^0(\widetilde{C}') \end{array}$$

Proof: Cf.[BLR90]Prop 9.5.1**?** □

Classification of Special Fibers of the Minimal Regular Models of Curves of Genus 2

Cf.[Y. Namikawa, K. Ueno, The complete classification of fibers in pencils of curves of genus two, Manuscripta Math. 9 (1973), 143–186.] and [A. P. Ogg, On pencils of curves of genus two, Topology 5 (1966), 355–362.].

13.9 Arithmetic of Elliptic Curves

Main References are [Sil16] and [Sil99], [Sil11]. Should add Sutherland's noteshttps://math.mit.edu/classes/18.783/2017/lectures.htmlL2-11, 13-14, 17-24. and Snowden's noteshttp://www-personal.umich.edu/~asnowden/teaching/2013/679/index.htmlL5,6,7,9,11, 14, 15, 17-23.

Notation (13.9.0.1).

- Use notations defined in Arithmetic of Abelian Varieties.
- Use notations defined in Global Fields.

1 Basics

Def. (13.9.1.1) [Elliptic Curves]. An **elliptic curve** E is a complete non-singular curve of genus 1 over a field k, together with a specified rational pt O. In(13.9.1.9), we will see an elliptic curve is smooth.

Let $S\in\mathcal{S}\mathrm{ch}$, then an **elliptic scheme** over S is a proper smooth scheme over S with a section $e:S\to E$ s.t. all the fibers are elliptic curves over the resp. residue field $k(s)$ with the origin given by e. The category of elliptic schemes over S is denoted by $\mathcal{E}\mathrm{ll}/S$.

Remark (13.9.1.2). Elliptic curves are Abelian varieties by(13.9.1.9). Thus the theory of Abelian varieties apply to elliptic curves.

Weierstrass Theory

Def. (13.9.1.3) [Weierstrass Equations]. A **Weierstrass equations** is an equation of the form

$$y^2+a_1xy+a_3y=x^3+a_2x^2+a_4x+a_6.$$

Def. (13.9.1.4) [Important Identities]. Let $k\in\texttt{Field}$, $E\in\mathcal{E}\mathrm{ll}/k$, given any Weierstrass equation as in(13.9.1.3), we can define

- $b_2=a_1^2+4a_2,\quad b_4=a_1a_3+2a_4,\quad b_6=a_3^2+4a_6,\quad b_8=a_1^2a_6-a_1a_3a_4+a_2a_3^2+4a_2a_6-a_4^2.$
- $\Delta=-b_2^2b_8-8b_4^3-27b_6^2+9b_2b_4b_6$ the **discriminant of** E, to determine whether E is singular.
- the quantity $c_4=b_2^2-24b_4$, used in the singular case to determine iff it has a node or cusp.
- the quantity $c_6=-b_2^3+36b_2b_4-216b_6$, used to determine twisted elliptic curves.
- the j**-invariant** $j=c_4^3/\Delta$, which is used to in the non-singular case to characterize E.

They satisfy the equations:

$$4b_8=b_2b_6-b_4^2,\quad 1728\Delta=c_4^3-c_6^2.$$

Prop. (13.9.1.5) [Reduced Weierstrass Equations]. Let $k\in\texttt{Field}$, $E\in\mathcal{E}\mathrm{ll}/k$, given any Weierstrass equation as in(13.9.1.3),

- If $\operatorname{char}k\neq 2$, we can replace (x,y) by $(x,y-(a_1x+a_3)/2)$ to eliminate a_1,a_3 to transform the original Weierstrass equation to

$$y^2=x^3+\frac{b_2x^2+2b_4x+b_6}{4}.$$

- If $\operatorname{char} k \neq 2,3$, then we can further replace (x,y) to $((x-3b_2)/36, y/216)$ to eliminate b_2 to transform the Weierstrass equation to
$$y^2 = x^3 - 27c_4x - 54c_6.$$
In particular, E has a Weierstrass equation of the form
$$y^2 = x^3 + a_4x + a_6, \quad \Delta = -16(4a_4^3 + 27a_6^2), \quad j = 1728\frac{4a_4^3}{4a_4^3 + 27a_6^2}$$
- If $\operatorname{char} k = 3$, then E has a Weierstrass equation of the form
$$y^2 = x^3 + a_2x^2 + a_6, \quad \Delta = -a_2^3a_6, \quad j = -a_2^3/a_6, \text{or} \quad y^2 = x^3 + a_4x + a_6, \quad \Delta = -a_4^3, \quad j = 0$$
- If $\operatorname{char} k = 2$, then E has a Weierstrass equation of the form
$$y^2 + xy = x^3 + a_2x^2 + a_6, \quad \Delta = a_6, \quad j = 1/a_6, \text{or} \quad y^2 + a_3y = x^3 + a_4x + a_6, \quad \Delta = a_3^4, \quad j = 0.$$

Prop. (13.9.1.6) [Explicit Embedding of Elliptic Curves]. Any $E \in \mathcal{E}\mathrm{ll}/k$ is isomorphic to the plane curve in $\mathbb{P}^2_k$ defined by an affine Weierstrass equation in $k[x,y]$.

And any isomorphism between elliptic curves defined by affine Weierstrass equations over k and fixes $[0,1,0]$ are linear maps of the form
$$(X,Y) \mapsto (u^2X + r, u^3Y + su^2X + t), \quad u \in k^*, s, r \in k.$$

Proof: If E is an elliptic curve over k, consider a rational point $O \in E(k)$, Riemann-Roch(5.11.2.9) tells $l(nP) = \deg(nP) = n$ for $n \geq 1$. Now $L(kP) = k$ by Riemann-Roch(5.11.2.9). So we choose a basis $1, x$ for $\mathcal{O}_X(2O)$, and extend it to a basis $1, x, y$ of $L(3P)$. Since $L(6O) = 6$, there is a linear relation between the seven elements $1, x, x^2, xy, y^2, x^3$. And y^2, x^3 must occur by observing the pole order at P. Thus by rescaling, we can write the relation as
$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6.$$

So x, y defines a rational map of E to $\mathbb{P}^2 : a \mapsto (x(a), y(a), 1)$. This map extends to an embedding of E into $\mathbb{P}^2$, by(5.11.1.15). Moreover, by the above proof, if E' is another Weierstrass form, then $1, x'$ are basis for $\mathcal{O}_X(2O)$ and $1, x', y'$ are basis for $\mathcal{O}_X(3O)$. Thus we have the linear relation between (X,Y) and (X',Y').

To define an Abelian structure on E, first notice that
$$E(k) \to \mathrm{Cl}^0(E) : Q \mapsto [Q] - [P]$$
is an isomorphism. Using Riemann-Roch, it is injective because $l(Q) = 1$ for $Q \in E(k)$, and for any divisor A of degree 0, $L(A + P) > 0$, so there exists an effective divisor that is equivalent to $A + P$, but this must be a rational point $Q \in E(k)$. Thus we can endow $E(k)$ with a group structure inherited from $\mathrm{Cl}^0(E)$. By(13.9.1.8), there is a group variety structure prolonging this construction, so E is a group scheme. □

Remark (13.9.1.7). There is a more advanced way to prove that this is a group action, in [Qing Liu]P492.?

Lemma (13.9.1.8) [Explicit Group Structure]. Let E be an elliptic curve given by a Weierstrass equation

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6,$$

then the group addition on $E\backslash O$ is given by

- $-(x_0, y_0) = (x_0, -y_0 - a_1x - a_3)$.
- $(x_1, y_1) + (x_2, y_2) = O$ iff $x_1 = x_2$ and $y_1 + y_2 + a_1x_2 + a_3 = 0$. Otherwise

$$(x_1, y_1) + (x_2, y_2) = (\lambda^2 + a_1\lambda - a_2 - x_1 - x_2, -(\lambda + a_1)x_3 - \nu - a_3)$$

where

$$\lambda = \begin{cases} \frac{y_1-y_2}{x_1-x_2} & x_1 \neq x_2 \\ \frac{3x^2+2a_2x_1+a_4-a_1y_1}{2y_1+a_1x_1+a_3} & x_1 = x_2 \end{cases}, \quad \nu = \begin{cases} \frac{y_2x_1-y_1x_2}{x_1-x_2} & x_1 \neq x_2 \\ \frac{-x_1^3+a_4x_1+2a_6-a_3y_1}{2y_1+a_1x_1+a_3} & x_1 = x_2 \end{cases}$$

- (Doubling Formula) $x([2]P) = \frac{x^4-b_4x^2-2b_6x-b_8}{4x^3+b_2x^2+2b_4x+b_6}$.

Thus the group actions defined in(13.9.1.6) are all morphisms. In particular, E is a group variety.

Proof: Cf.[Sil16]P53. □

Cor. (13.9.1.9) [Elliptic Curves and Abelian Varieties]. If X is an Abelian variety of dimension 1, then X is an elliptic curve. The converse is also true, by(13.9.1.6). In particular, the theory of Abelian varieties13.5 applies to elliptic curves. And we will use notations for Abelian varieties.

Proof: By(8.1.4.35)(8.1.4.34), the tangent space $T_{X/k}$ is trivial of rank 1, thus it is a curve of genus 1 by(5.11.1.24). it is also regular, by(5.6.4.16). □

Prop. (13.9.1.10) [Normalized Invariant Differential Form]. Let $k \in$ `Field`, $E \in \mathcal{E}\mathrm{ll}/k$ defined by a Weierstrass equation $W : y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6$. Then the differential form given by

$$\omega = \frac{dx}{2y + a_1x + a_3} = \frac{dy}{3x^2 + 2a_2x + a_4 - a_1y}$$

is a non-zero section of $\mathcal{K}_E$. It is normalized s.t. at the origin, with the uniformizer $z = -x/y$, it has value 1.

Moreover, it is invariant under translation. It is called the **normalized invariant differential form** on E w.r.t W.

Proof: Firstly we show $\mathrm{div}(\omega) = 0$: consider a finite point $P_0 = (x_0, y_0)$, then it cannot have pole, otherwise P_0 is singular. Because $x - x_0 \in L(2O)$, $\mathrm{ord}_{P_0}(x - x_0) \leq 2$, and if $\mathrm{ord}_{P_0}(x - x_0) = 2$, $\mathrm{ord}_{P_0}(y - y_0) \geq 2$ also by inspecting the Weierstrass equation. Thus $\mathrm{ord}_P(\omega) = 0$. Also consider the situation at ∞, $\mathrm{ord}_O(x) = -2, \mathrm{ord}_O(y) = -3$, thus $\mathrm{ord}_O(\frac{dx}{2y+a_1x+a_3}) = 0$ except possibly char $K = 2$. But the same calculation shows $\mathrm{ord}_O(\frac{dy}{3x^2+2a_2x+a_4-a_1y}) = 0$ except possibly char $K = 3$. Thus we are done.

Now any translation action induces a map $\tau_x^*\omega = a(x)\omega$, where $a \in K(C)^\times$. But $a(x)$ has no pole and zeros, thus $a(x) \in k^\times$. But then $a(x)$ is rational function with no zero and poles, thus $a(x) = a(O) = 1$. □

Cor. (13.9.1.11). $[m]_E^*\omega = \mathrm{pr}_1^*\omega + \mathrm{pr}_2^*\omega$.

Proof: It follows from this and the see-saw principal that $m_E^*\mathcal{K}_E \cong \mathrm{pr}_1^*\mathcal{K}_E \otimes \mathrm{pr}_2^*\mathcal{K}_E$. □

Prop. (13.9.1.12) [Change of Variables]. A change of variables of the form (x, y) replaced by $(u^2x + a, u^3y + bx + c)$ changes c_4 to $u^{-4}c_4$, c_6 to $u^{-6}c_6$, Δ to $u^{-12}\Delta$, and preserves j.

Proof: This is just a equation of identities, so it suffices to prove for k of characteristic 0, then in this case, by(13.9.1.5), c_4, c_6 is just the coefficients of the Weierstrass equation transformed into the reduced form(times a constant). So it suffices to prove for transformation between reduced Weierstrass equations. In this case, $a = b = c = 0$, and the assertion is clear. □

Prop. (13.9.1.13) [Characterizing Singularities]. Let $k \in \texttt{Field}$, then

- The plane cubic E over k defined by a Weierstrass formula f is never singular at $O = [0, 1, 0]$, and it is a curve.
- - E is smooth iff its determinant $\Delta \neq 0$. And in this case it is an elliptic curve by genus formula.
  - E has a node iff $\Delta = 0$ and $c_4 \neq 0$.
  - E has a cusp iff $\Delta = c_4 = 0$.
- For $E, E' \in \mathcal{E}\mathrm{ll}/k$, $E_{\overline{k}} \cong E'_{\overline{k}}$ iff $j(E) = j(E')$. In fact, they are isomorphic over a separable field extension k'/k of degree 24, and if $j \neq 0, 1728$, then they are isomorphic over a separable field extension k'/k of degree 2.

Proof: 1: Firstly, E is never singular at $[0, 1, 0]$: On $U(z)$, the curve is given by $z + a_1xz + a_3z^2 = x^3 + a_2x^2z + a_4xz^2 + a_6z^3$, which is not singular at $(0, 0)$. Secondly, E has genus 1. Finally it is a curve by(2.2.3.13) and checking f doesn't has a root $y \in \overline{k}(x)$: This is true by degree reasons using reduced Weierstrass equations(13.9.1.5).

2: (1): By(13.9.1.9), non-singular is equivalent to smoothness. So we may base change to $\overline{k}$. If P is non-singular, linearly transform it to $(0, 0)$, then by Jacobian criterion, $\frac{\partial}{\partial x} f = \frac{\partial}{\partial y} f = 0$, so $a_3 = a_4 = a_6 = 0$, and it can be verified that $\Delta = 0$. Conversely, if $\Delta = 0$, then use the reduced Weierstrass equations and argue case by case, we can find a singular point.

(2), (3): In this case, assume $a_3 = a_4 = a_6 = 0$, then $c_4 = (a_1^2 + 4a_2)^2$, and $E : y^2 + a_1xy - a_2x^2 - x^3 = 0$, so the assertion is clear.

2: We use the reduced Weierstrass equations, derive an equation between their coefficients, and take a suitable change of variables. Details are omitted. □

Prop. (13.9.1.14) [Fields of Moduli]. For any element $j_0 \in \overline{k}$, there exists an elliptic curve over $k(j_0)$ with j-invariant j. In particular, any elliptic curve over k is defined over $k(j(E))$, by(13.9.1.13).

Proof: If $j_0 \neq 0, 1728$, then we can take the curve

$$E : y^2 + xy = x^3 - \frac{36}{j_0 - 1728}x - \frac{1}{j_0 - 1728}$$

with $\Delta(E) = \frac{j_0^3}{(j_0 - 1728)^3}, j(E) = j_0$.

If $j = 0$ or 1728, we can take one of the curves

$$E : y^2 + y = x^3, \quad \Delta = -27, \quad j = 0$$

$$E : y^2 = x^3 + x, \quad \Delta = -64, \quad j = 1728.$$

Notice for $\operatorname{char} k = 2$ or 3, $0 = 1728$, and at least one of these are elliptic curves. □

Prop. (13.9.1.15) [Singular Weierstrass]. If $k \in$ `Field` is perfect or $\mathrm{char}\, k \neq 2, 3$, $E \in \mathbb{P}^2_k$ is a plane cubic given by a Weierstrass equation W is singular, then

- E has a unique singular point, and it is a rational point.
- E is birational to $\mathbb{P}^1_k$, i.e. its non-singular projective model is $\mathbb{P}^1$(5.11.1.18).
- E_{sm} is a commutative k-group under the group action given in(13.9.1.8) with origin $O = [0, 1, 0]$, and $E_{\mathrm{sm}} \cong \mathbb{G}_m$ if E has a split node, and $E_{\mathrm{sm}} \cong \mathbb{G}_a$ if E has a cusp.

Proof: 1: By(13.9.1.13), the singular points must be a finite point, and $\Delta = 0$. Over $\overline{k}$, the singular points of E is characterized by the equations $W = \frac{\partial}{\partial x} W = \frac{\partial}{\partial y} W = 0$. Then we can use the reduced Weierstrass equations(13.9.1.5): If $\mathrm{char}\, k \neq 2, 3$, then clearly $(x_0, y_0) \in k^2$. The perfect case is similar.

2: Because the curve is never singular at O by(13.9.1.13), by a linear change, we can assume that one of the singular point is $(0, 0)$. Then by Jacobian criterion, it must be of the form

$$y^2 + a_1 xy = x^3 + a_2 x^2.$$

Then the projection along $(0, 0)$ is an isomorphism**?** this is wrong!

$$E \backslash \{0, \infty\} \to \mathbb{P}^1_k \backslash \{[0:1]\} : (x, y) \mapsto [x : y]$$

with inverse

$$[1, t] \mapsto (t^2 + a_1 t - a_2, t^3 + a_1 t^2 - a_2 t).$$

E_{sm} is a group scheme because we can verify on closed points, and the fact any line through $(0, 0)$ has multiplicity more than 1. To determine the group structure, Cf.[Sil16]P56**?**. □

Prop. (13.9.1.16) [Legendre Forms]. Let $\mathrm{char}\, K \neq 2$, then

- every elliptic curve over $\overline{K}$ is isomorphic to an elliptic curve in **Legendre form**

$$E_\lambda : y^2 = x(x-1)(x-\lambda), \quad \lambda \neq 0, 1 \in \overline{K}.$$

- $\Delta(E_\lambda) = 16\lambda^2(\lambda-1)^2, j(E_\lambda) = 2^8 \frac{(\lambda^2-\lambda+1)^3}{\lambda^2(\lambda-1)^2}, c_4 = 16(1 - \lambda(1-\lambda))$.
- If K is a valued field, we may take $v(\lambda) \geq 0$ as $j(E_\lambda) = j(E_{\lambda^{-1}})$.
- The map $\overline{K} \to \overline{K} : \lambda \mapsto j(E_\lambda)$ is 6 to 1 except above the points 0 and 1728, where for $\mathrm{char} K \neq 2, 3$, $\# j^{-1}(0) = 2$, $\# j^{-1}(1728) = 3$, and for $\mathrm{char} K = 3$, $j^{-1}(0 = 1728) = 1$.

Proof: 1: put the Weierstrass equation of E in the reduced form(13.9.1.5), then it is of the form

$$y^2 = (x - e_1)(x - e_2)(x - e_3)$$

in $\overline{K}[x, y]$, and because $\Delta = 16(e_1 - e_2)^2(e_2 - e_3)^2(e_3 - e_1)^2 \neq 0$, so e_1, e_2, e_3 are pairwise distinct. Thus the linear transform

$$x \mapsto (e_2 - e_1)x' + e_1$$

makes the Weierstrass equation in the Legendre form with $\lambda = \frac{e_3 - e_1}{e_2 - e_1}$.

2: Direct calculation.

3: Directly calculating the differential of j.**?** □

Prop. (13.9.1.17) [Duering Normal Form]. Every elliptic curve over $\overline{K}$, except possibly char $K = 3$ and $j(E) = 0$, is isomorphic to an elliptic curve in **Deuring normal form**

$$E_\alpha : y^2+\alpha xy+y = x^3, \quad \alpha \in \overline{K}, \quad \Delta(E_\alpha) = \alpha^3-27 \neq 0, \quad j(E_\alpha) = \frac{\alpha^3(\alpha^3-24)^3}{\alpha^3-27}, \quad c_4 = \alpha(\alpha^3-24).$$

And if K is a valued field, we can take $v(\alpha) > 0$.

Proof: Use(13.9.1.13), it suffices to show that $j(\alpha)$ can take any value $j \in \overline{K}$.

The last assertion is because if $v(\alpha) < 0$, then the product of roots of $\frac{x(x-24)^3}{x-27} = \frac{\alpha^3(\alpha^3-24)^3}{\alpha^3-27}$ other than α is $-72^3/(\alpha-27)$ has positive valuations. □

Prop. (13.9.1.18) [Automorphism Group]. Let E be an elliptic curve over a field k, then the the automorphic group of E is

$$\mathrm{Aut}(E) \cong \begin{cases} \mu_2(k) & j(E) \neq 0, 1728 \\ \mu_4(k) & j(E) = 1728, \mathrm{char}\, k \neq 2,3 \\ \mu_6(k) & j(E) = 0, \mathrm{char}\, k \neq 2,3 \\ D_{12} & j(E) = 0 = 1728, \mathrm{char}\, k = 3, k = \overline{k} \\ C_3 \ltimes Q_8 & j(E) = 0 = 1728, \mathrm{char}\, k = 2, k = \overline{k} \end{cases}$$

Proof: Any automorphism of E is defined by a linear maps of the form

$$(X,Y) \mapsto (u^2X + r, u^3Y + su^2X + t), \quad u \in k^\times, s, r \in K.$$

If char $k \neq 2,3$, use the reduced Weierstrass form $E : y^2 = x^3 + Ax + B$, so it is of the form $(X,Y) \mapsto (u^2X, u^3Y)$, which is possible iff $u^{-4}A = A, u^{-6}B = B$. Thus by arguing case by case, we are done.

The char $k = 2,3$ cases are similar, use reduced Weierstrass forms(13.9.1.5) and argue case by case. □

Prop. (13.9.1.19) [Dual Elliptic Curves]. An elliptic curve E is canonically isomorphic to its dual $\widehat{E}$, by the mapping $P \mapsto \mathcal{L}(P-O)$.

Proof: This morphism is induced by the ample line bundle $\mathcal{L}(O)$(13.5.4.2), and it is an isomorphism because it has degree 1, by Riemann-Roch(13.5.5.2). □

Cor. (13.9.1.20). For any $\mathcal{L} \in \mathrm{Pic}(E)$ of degree d, $\varphi_{\mathcal{L}} = [d] : E \to E$ via the canonical duality, because $\mathrm{Pic}^0(E)$ induces trivial maps by(13.5.4.8) and(7.1.12.5).

Cor. (13.9.1.21) [Characterizing Principal Divisors]. Let $E \in \mathcal{E}\mathrm{ll}/k$ and $D = \sum n_i[P_i] \in \mathrm{Div}(E)$, where P_i are rational points, then D is a principal divisor iff $\sum n_i = 0$ and $\sum [n_i]P_i = O$.

Proof: Of course $\sum n_i = 0$. In this case, $\sum [n_i]P_i$ is mapped to the line bundle corresponding to $[D] \in \widehat{E}$ via $E \to \widehat{E}$, so $[D] = 0$ iff $\sum [n_i]P_i = O$. □

Isogenies

Prop. (13.9.1.22). Let $\varphi, \varphi' : E' \to E$ be isogenies of elliptic curves over k, and let ω be an invariant differential on E, then by(13.9.1.11),

$$(\varphi + \varphi')^*\omega = \varphi^*\omega + (\varphi')^*\omega.$$

Cor. (13.9.1.23). $[m]^*\omega = m\omega$.

Cor. (13.9.1.24)[End(E) is Commutative in Characteristic 0]. Let $E \in \mathcal{E}\mathrm{ll}/k$ with the normalized invariant differential form ω, then there is a ring homomorphism

$$\mathrm{End}(E_{\overline{k}}) \to \overline{k} : \varphi \mapsto a_\varphi, \text{where } \varphi^*\omega = a_\varphi\omega.$$

And the kernel is the set of inseparable endomorphisms of $E_{\overline{k}}$. In particular, if $\mathrm{char}\, k = 0$, then $\mathrm{End}(E_{\overline{k}})$ is commutative.

Proof: Cf.[Sil16]P79.? □

Prop. (13.9.1.25) [Dual Isogenies]. Let $k \in \mathtt{Field}, E, E' \in \mathcal{E}\mathrm{ll}/k$ and $\varphi \in \mathrm{Hom}(E, E')$, then under the canonical isomorphism(13.9.1.19), the dual map $\widehat{\varphi}$ can be regarded as a map $\widehat{\varphi} : E' \to E$. Then

$$\widehat{\varphi} \circ \varphi = [\deg(\varphi)]_E, \varphi \circ \widehat{\varphi} = [\deg(\varphi)]_{E'}.$$

$\mathrm{End}(E) \to \mathrm{End}(E) : \varphi \mapsto \widehat{\varphi}$ is additive, and defines an involution on $\mathrm{End}(E)$.

Proof: Let $d = \deg(\varphi)$. By unwinding definition, $\widehat{\varphi} \circ \varphi : E \to E' \to \widehat{E}' \to \widehat{E}$ is just $\varphi_{\varphi^*\mathcal{L}(O)}$. But for elliptic curves, $\varphi_{\mathcal{L}}$ only depends on $\deg(\mathcal{L})$, thus $\varphi_{\varphi^*\mathcal{L}(O)} = \varphi_{\mathcal{L}(dO)} = [d]\varphi_{\mathcal{L}(O)}$. The second assertion follows by noticing $\varphi = \widehat{\widehat{\varphi}}$ and $\deg(\varphi) = \deg(\widehat{\varphi})$(13.5.6.5). □

Cor. (13.9.1.26)[End(E)]. Let k be a field and $E \in \mathcal{E}\mathrm{ll}/k$, then $\mathrm{End}(E) \otimes \mathbb{Q}$ is a division ring.

Prop. (13.9.1.27)[Classification of End(E)]. Let $k \in \mathtt{Field}, E \in \mathcal{E}\mathrm{ll}/k$, then $\mathrm{End}(E)$ has the following three possibilities:

- $\mathbb{Z}$.
- an $\mathbb{Z}$-order in an imaginary quadratic extension over $\mathbb{Q}$.
- an $\mathbb{Z}$-order in a definite quaternion algebra over $\mathbb{Q}$.

And the third case won't happen in characteristic0, by(13.9.1.24).

Proof: This follows from(2.4.5.1) and(13.14.1.1). □

2 Formal Groups of Elliptic Curves

In this subsection, the formal group structure of an elliptic is studied.

In this subsection, E is an elliptic curve over a field K given by Weierstrass equation $y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6$.

Prop. (13.9.2.1) [Calculation of Formal Group Law]. Make a change of variable $z = -x/y, w = -1/y$ to the Weierstrass equation of E, the equation becomes

$$w = z^3 + (a_1z + a_2z^2)w + (a_3 + a_4z)w^2 + a_6w^3 = f(z, w).$$

Then

- $\widehat{\mathcal{O}}_{E,O} \cong K[[z]]$.
- There is a unique power series $w(z) \in \mathbb{Z}[a_1, \ldots, a_6][[z]]$ satisfying $w(0) = 0$ and $w(z) = f(z, w(z))$.
- $w(z) = z^3(1 + A_1 z + A_2 z^2 + \ldots)$, where A_n is a homogenous polynomial in $a_1, \ldots, a_6$, where a_i has weight i.
- $$x(z) = z/w(z) = z^{-2} - a_1 z^{-1} - a_2 - a_3 z - (a_4 + a_1 a_3) z^2 + \ldots \in \mathbb{Z}[a_1, \ldots, a_6][[z]]$$
  $$y(z) = -1/w(z) = -z^{-3} + a_1 z^{-2} + a_2 z^{-1} + a_3 + (a_4 + a_1 a_3) z + \ldots \in \mathbb{Z}[a_1, \ldots, a_6][[z]]$$
- The formal group law of E(13.5.2.1) is given by
  $$\begin{aligned} F(z_1, z_2) = {} & z_1 + z_2 - a_1 z_1 z_2 - a_2(z_1^2 z_2 + z_1 z_2^2) \\ & + (-2a_3 z_1^3 z_2 + (a_1 a_2 - 3a_3) z_1^2 z_2^2 - 2a_3 z_1 z_2^3) + \ldots \in \mathbb{Z}[a_1, \ldots, a_6][[z_1, z_2]]. \end{aligned}$$
- The normalized invariant differential form(13.9.1.10)
  $$\begin{aligned} \omega(z) = \frac{dx(z)}{2y(z) + a_1 x(z) + a_3} = {} & [1 + a_1 z + (a_1^2 + a_2) z^2 + (a_1^3 + 2a_1 a_2 + 2a_3) z^3 \\ & + (a_1^4 + 3a_1^2 a_2 + 6a_1 a_3 + a_2^2 + 2a_4) z^4 + \ldots] dz \in \mathbb{Z}[a_1, \ldots, a_6][[z]] dz \end{aligned}$$
- $$i(z) = \frac{x(z)}{y(z) + a_1 x(z) + a_3} = \frac{z^{-2} - a_1 z^{-1} + \ldots}{-z^{-3} + 2a_1 z^{-2} + \ldots} \in \mathbb{Z}[a_1, \ldots, a_6][[z]].$$

In particular, this formal group law is defined over $\mathbb{Z}[a_1, \ldots, a_6]$.

Proof: $\omega(z) \in \mathbb{Z}[a_1, \ldots, a_6][[z]]dz$ by(8.5.3.16).
For $F(z_1, z_2)$: **?** □

Prop. (13.9.2.2) [Inseparable Degree and Heights]. Let K be a field of characteristic $p > 0$ and $E_1/K, E_2/K$ be two elliptic curves, and $\varphi : E_1 \to E_2$ a non-zero isogeny of elliptic curves over K, and let $\widehat{\varphi} : \widehat{E}_1 \to \widehat{E}_2$ be the homomorphism of formal group schemes, then

$$\deg_i(\varphi) = p^{\mathrm{ht}(\widehat{\varphi})}.$$

Proof: Cf.[Sil16]P134.**?** □

Cor. (13.9.2.3). Let K be a field of characteristic $p > 0$, then $\mathrm{ht}(\widehat{E}) = 1$ or 2, because $\deg([p]_E) = p^2$(13.5.6.14).

3 char $k > 0$ case

Notation (13.9.3.1).

- Let $k \in \mathtt{Field}^p$,
- Let $E \in \mathcal{E}\mathrm{ll}/k$ be given by a Weierstrass equation $y^2 + a_1 xy + a_3 y = x^3 + a_2 x^2 + a_4 x + a_6$.

Prop. (13.9.3.2). Let $k = \mathbb{F}_q$, $\#E(k) \equiv 0 \mod 4$.

Proof: There are two involutions on E: $(x,y,z)\mapsto(x,-y,z)$, $(x,y,z)\mapsto(z,y/x,x)$. The fixed points of these elements contain

$$(0,1,0),\quad (0,0,1),\quad (\varepsilon_1,\varepsilon_2\sqrt{2\varepsilon_1},0),\quad (\varepsilon_3\sqrt{-1},0,1).$$

Considering either cases s.t. $-1\in\mathbb{F}_q^2$ or $2\in\mathbb{F}_q^2$, the number of these points are divisible by 4, thus we are done. □

Prop. (13.9.3.3) [Hasse-Weil]. Let $p\in\mathbf{P}, q=p^r$, $k=\mathbb{F}_q$ and $E\in\mathcal{E}\mathrm{ll}/k$, then

- If $a=1+q-\#E(\mathbb{F}_q)$, α,β be the two roots of $T^2-aT+q=0$, then $\#E(\mathbb{F}_{q^n})=1+q^n-\alpha^n-\beta^n$.
- $|\#E(\mathbb{F}_q)-1-q|\leq 2\sqrt{q}$.
- The Frobenius map $\varphi_E:E\to E$ satisfies $\varphi^2-a\varphi+[q]=0$.
- $a=1+q-\deg(1-\varphi)$, and $[a]=\varphi+\widehat{\varphi}$.

Proof: $1,2$ are special cases of(13.5.9.3). $3,4$ follow from(13.5.7.9) and(13.5.6.17). □

Cor. (13.9.3.4). Let $k=\mathbb{F}_q$, $p\neq 2$ and E is given by $y^2=x^3+a_2x^2+a_4x+a_6$, then

$$|\sum_{x\in\mathbb{F}_q}(\frac{x^3+a_2x^2+a_4x+a_6}{\mathbb{F}_q})|\leq 2\sqrt{q}.$$

Proof: This is because $\#E(\mathbb{F}_q)=\sum_{x\in\mathbb{F}_q}(1+(\frac{x^3+a_2x^2+a_4x+a_6}{\mathbb{F}_q}))$. □

Supersingular Elliptic Curves

Main references are [Igu58].

Def. (13.9.3.5) [Supersingular Elliptic Curve]. Let $k\in\texttt{Field}$, $\operatorname{char}k=p>0$, $F_{E/k,r}:E\to E^{(p^r)}$ the relative Frobenius(5.2.10.1), and $\widehat{F}_{E/k}$ be its dual. Then the following are equivalent:

- $E[p^r]=1$ for all $r\geq 1$.
- $E[p^r]\ncong\mathbb{Z}/p^r\mathbb{Z}$ for some $r\geq 1$.
- $\widehat{F}_{E/k,r}$ is purely inseparable for one(thus all) r.
- $[p]:E\to E$ is purely inseparable, and $j(E)\in\mathbb{F}_{p^2}$.
- $\mathrm{End}(E)$ is an order in a quaternion algebra.
- The formal group $\widehat{E}/K$ associated to E has height $2(\neq 1)$.

Such curves are called **supersingular elliptic curves**, otherwise E is called an **ordinary elliptic curve**.

Being supersingular is stable and reflective under base change.

Proof: Cf.[Silverman P144].**?** □

Prop. (13.9.3.6) [Ordinary Elliptic Curves]. Let $k\in\texttt{Field}$, $\operatorname{char}k=p>0$, $E\in\mathcal{E}\mathrm{ll}/k$ be an ordinary elliptic curve, then

- If $j(E)\in\overline{\mathbb{F}}_p$, then $\mathrm{End}(E)$ is an order in an imaginary quadratic field. In particular, this is the case when k is a finite field.
- If $j(E)\notin\overline{\mathbb{F}}_p$, then $\mathrm{End}(E)\cong\mathbb{Z}$.

Proof: 1: If $j(E)\in\overline{\mathbb{F}}_p$, then E is defined over some $\mathbb{F}_q$. Let φ be the Frobenius, then if $\varphi^r\in\mathbb{Z}$, $\varphi^r=[\pm q^r]$, so $\#E[\varphi^r]=\deg_s(\varphi^r)=1$ by(13.5.6.3), contradicting the fact E is ordinary. Thus the assertion follows from(13.9.1.27).

2: **?** □

Cor. (13.9.3.7). For $E\in\mathcal{E}\mathrm{ll}/\overline{\mathbb{F}_p}$, E is ordinary iff $\mathrm{End}(E)$ is an order in an imaginary quadratic field, and E is supersingular iff $\mathrm{End}(E)$ is an order in a quaternion algebra.

Def. (13.9.3.8) [Hasse Invariant]. The **Hasse invariant** for E is a number which is 0 if E is supersingular and 1 if E is ordinary. The definition of it is in [Katz, p-adic Modular Forms].**?**

Prop. (13.9.3.9) [Supersingular and Trace]. Let $E\in\mathcal{E}\mathrm{ll}/\mathbb{F}_q$ and φ_E be the Frobenius of $E/\mathbb{F}_q$, then

- E is supersingular iff $\#E(\mathbb{F}_q)\equiv 1 \mod p$, iff $a_p=\alpha+\beta\equiv 0 \mod p$ in(13.9.3.3).
- If $q=p\geq 5$ is a prime, then E is supersingular iff $\#E(\mathbb{F}_p)=p+1$. This is false for $p=2$ or $p=3$.

Proof: 1: By(13.9.3.3), let $a=1+q-\#E(\mathbb{F}_q)$, then $\widehat{\varphi}_E=[a]-\varphi$ is separable iff $a=0\in\mathbb{F}_q$ by**??**. Thus the assertion follows from(13.9.3.5).

2: Because $|\alpha+\beta|\leq 2\sqrt{p}<p$ in this case. □

Cor. (13.9.3.10). Let $p\geq 5$ and $E\in\mathcal{E}\mathrm{ll}/\mathbb{F}_p$ be supersingular, then

$$\#E(\mathbb{F}_{p^n})=\begin{cases}p^n+1 & n=2k+1\\ (p^{n/2}-(-1)^{n/2})^2 & n=2k\end{cases}$$

Proof: This is because $\alpha=-\beta=\sqrt{p}i$. □

Prop. (13.9.3.11) [Supersingular in Characteristic2]. Let k be a field of characteristic2, then E/k is supersingular iff $j(E)=0$. In particular, $y^2+y=x^3$ is the only supersingular elliptic curve over $\overline{k}$.

Proof: We use the condition $\#E(\mathbb{F}_2)=2$. We use the reduced Weierstrass equations in(13.9.1.4). By doubling formula(13.9.1.8), this is equivalent to the non-existence of a point $(x,y)\in E(\overline{k})\backslash O$ s.t. $a_1x+a_3=0$. And it can be checked this is true iff $j(E)=0$. □

Prop. (13.9.3.12) [Supersingulars over Finite Fields, Igusa]. Let $p\in\mathbf{P}$ and $E\in\mathcal{E}\mathrm{ll}/\overline{\mathbb{F}}_p$.

1. If $p=2$, the only supersingular elliptic curve over $\overline{\mathbb{F}}_2$ is isomorphic to $y^2+y=x^3$.
2. If $p\geq 3$ and E is given by a Weierstrass form $y^2=f(x)$, then E is supersingular iff $\mathrm{Coef}(\frac{f(x)^{(p-1)/2}}{x^{p-1}})=0\in\overline{\mathbb{F}}_p$.
3. If $p\geq 3$ and E is given by a Legendre form $y^2=x(x-1)(x-\lambda)$, then E is supersingular iff
$$H_p(\lambda)=\sum_{i=1}^{(p-1)/2}\binom{\frac{(p-1)}{2}}{i}^2\lambda^i=0.$$
4. If $p\geq 3$, the polynomial H_p has distinct roots in $\overline{\mathbb{F}}_p$, and the number of isomorphism classes of supersingular elliptic curves over $\overline{\mathbb{F}}_p$ is
$$\begin{cases}1 & ,p=3\\ [\frac{p}{12}] & ,p\equiv 1 \mod 12\\ [\frac{p}{12}]+1 & ,p\equiv 5,7 \mod 12\\ [\frac{p}{12}]+2 & ,p\equiv 11 \mod 12\end{cases}$$

5. (Mass Formula)

$$\sum_{E/\overline{\mathbb{F}}_p \text{ supersingular}} \frac{1}{\mathrm{Aut}(E)} = \frac{p-1}{24}.$$

Remark (13.9.3.13). This has relations to the class number of normal quaternion algebras over $\mathbb{Q}$ ramified at p, Cf.[Igu58].

Proof: 1: This follows from(13.9.3.11).

2: Let $E \in \mathcal{E}\mathrm{ll}/\mathbb{F}_q$, denote $A_q = \mathrm{Coef}(\frac{f(x)^{(q-1)/2}}{x^{q-1}})$, then

$$\#E(\mathbb{F}_q) \equiv \sum_{x\in\mathbb{F}_q} (1 + (\frac{x^3 + a_2x^2 + a_4x + a_6}{\mathbb{F}_q})) \equiv 1 - A_q \mod p.$$

Then $A_q \equiv a_E \mod p$, and the assertion follows from(13.9.3.9).

Finally, it can be seen from the equation $f(x)^{(p^{r+1}-1)/2} = f(x)^{(p^r-1)/2}[f(x)^{(p-1)/2}]^{p^r}$ that $A_{p^{r+1}} = A_{p^r}A_p^{p^r}$. So by an induction argument, $A_q = 0$ iff $A_p = 0$.

3:

$$\mathrm{Coef}(\frac{(x(x-1)(x-\lambda))^{(p-1)/2}}{x^{p-1}}) = \mathrm{Coef}(\frac{(x-1)^{(p-1)/2}(x-\lambda)^{(p-1)/2}}{x^{(p-1)/2}}) = \sum_{i=1}^{(p-1)/2} \binom{\frac{(p-1)}{2}}{i}^2 \lambda^i = H_p(\lambda)$$

4: Consider the **Picard-Fuchs differential operator**

$$D = 4t(t-1)\frac{\partial^2}{\partial t^2} + 4(1-2t)\frac{\partial}{\partial t} - 1,$$

then direct calculation shows

$$DH_p(t) = p\sum_{i=1}^{(p-1)/2} (p-2-4i)\binom{\frac{(p-1)}{2}}{i}^2 t^i = 0.$$

Thus possible multiple roots of H can only be 1 or 0. But $H_p(0) = 1$, and $H_p(1) = \binom{p-1}{\frac{p-1}{2}} = (-1)^{\frac{p-1}{2}}$, thus $H_p(t)$ has no multiple roots.

Let $\varepsilon_p(j) = 1$ if the elliptic curve E with the indicated j-invariant is supersingular, and $\varepsilon_p(j) = 0$ otherwise. Notice for $p \geq 5$, $j : \lambda \to j(E_\lambda)$ is 6 to 1 except $\#j^{-1}(0) = 2$ and $\#j^{-1}(1728) = 3$, thus by counting the number of zeros of $H_p(\lambda)$, the number of supersingular elliptic curves is

$$\frac{1}{6}(\frac{p-1}{2} - 2\varepsilon_p(0) - 3\varepsilon_p(1728)) + \varepsilon_p(0) + \varepsilon_p(1728) = \frac{p-1}{12} + \frac{2}{3}\varepsilon_p(0) + \frac{1}{2}\varepsilon_p(1728).$$

Thus the assertion follows from determining elliptic curves of j-invariants 0 and 1728 are supersingular or not, which is done by(13.9.3.14).

5: It follows from the proof of item4 that this number is 1/2 of number of roots of $H_p(\lambda) = \frac{p-1}{24}$. □

Lemma (13.9.3.14) [Examples of Supersingular Elliptic Curves].

- For $p \geq 5$, the elliptic curve $E : y^2 = x^3 + 1$ with j-invariant 0 is supersingular iff $p \equiv 2 \mod 3$.
- For $p \geq 3$, the elliptic curve $E : y^2 = x^3 + x$ with j-invariant 1728 is supersingular iff $p \equiv 3 \mod 4$.

Proof: These follows form calculating the x^{p-1}-term of $(x^3 + 1)^{(p-1)/2}$ or $(x^3 + x)^{(p-1)/2}$ and(13.9.3.12) item2. □

4 Reduction of Elliptic Curves

Main references are [Liu02].

In this subsection, let S be a Dedekind scheme with generic point η and function field K.

Prop. (13.9.4.1) [Minimal Models of Elliptic Curves]. Let $E \in \mathcal{E}\mathrm{ll}/K$ and $\mathcal{E}/S$ be a minimal model for E, then

- $\mathcal{E}_{\mathrm{sm}}(S) = \mathcal{E}(S) = E(K)$.
- The automorphism $(m, \mathrm{pr}_2) : E \times_K E \to E \times_K E$ extends to an automorphism $t : \mathcal{E} \times_S \mathcal{E}_{\mathrm{sm}} \to \mathcal{E} \times_S \mathcal{E}_{\mathrm{sm}}$.
- t induces an automorphism $\mathcal{E}_{\mathrm{sm}} \times_S \mathcal{E}_{\mathrm{sm}} \to \mathcal{E}_{\mathrm{sm}} \times_S \mathcal{E}_{\mathrm{sm}}$, and $\mathrm{pr}_1 \circ E$ makes $\mathcal{E}_{\mathrm{sm}}$ a smooth group scheme over S extending that of E.

Proof: Cf.[Liu02]P492. □

Prop. (13.9.4.2) [$\mathcal{N} = \mathcal{E}_{\mathrm{sm}}$]. Let (R, K) be a DVR, $E \in \mathcal{E}\mathrm{ll}/K$ with minimal model $\mathcal{E}$(13.8.2.4), then $\mathcal{E}_{\mathrm{sm}}$ is a Néron model for E.

Proof: To show universal property, let X/S be smooth, and $f : X_\eta \to E$ be a morphism considered as a rational morphism $X \to \mathcal{E}_{\mathrm{sm}}$. Let $\xi \in X$ be a point of codimension 1, and $T = \operatorname{Spec} \mathcal{O}_{X,\xi}$, then by(13.7.5.7) and the proof of(13.9.4.1), $\mathcal{E} \times_S T \to T$ is an arithmetic surface with smooth locus $\mathcal{N} \times_S T$**?**, so by(13.7.2.8), $\mathcal{N}(T) = \mathcal{N}_T(T) = E(K)$, which means f can be extended to ξ. Then in fact f is a morphism by(8.1.1.20). □

over DVRs

In this subsubsection, let $(R, K, \mathfrak{m}, k)$ be a DVR, $S = \operatorname{Spec} R$.

Def. (13.9.4.3) [Minimal Weierstrass Equation]. Let $E \in \mathcal{E}\mathrm{ll}/K$, then a **minimal Weierstrass equation** for E is an Weierstrass equation for E in $R[X, Y]$ with determinant Δ with minimal valuation.

Prop. (13.9.4.4) [Uniqueness of Minimal Weierstrass Equations]. Let $E \in \mathcal{E}\mathrm{ll}/K$, then E has a minimal Weierstrass equation, and it is unique up to change of variables of the form

$$(X, Y) \mapsto (u^2 X + r, u^3 Y + su^2 X + t), \quad u \in R^*, r, s, t \in R.$$

Moreover, given any Weierstrass equation, then any change of coordinates that is used to produce a minimal Weierstrass equation is of the form

$$(X, Y) \mapsto (u^2 X + r, u^3 Y + su^2 X + t), \quad u, r, s, t \in R.$$

Proof: Cf.[Sil16]P186.**?** □

Cor. (13.9.4.5) [Weierstrass Models]. Let $E \in \mathcal{E}\mathrm{ll}/K$, a minimal Weierstrass of E defines a model $\mathcal{W}/R$ of E, and it is invariant of the Weierstrass equation chosen, called the **Weierstrass model** of E. Denote $\widetilde{E} = \mathcal{W}_k$.

Cor. (13.9.4.6) [Néron Differentials]. Let $E \in \mathcal{E}\mathrm{ll}/K$, a minimal Weierstrass equation of E defines an invariant differential on $\mathcal{W}/R$ by(13.9.1.10), called the **Néron differential** of E.

Prop. (13.9.4.7) [Weierstrass Model of Elliptic Curves]. Let (R, K) be a DVR, if $E \in \mathcal{E}\mathrm{ll}/K$, then a Weierstrass equation with $a_i \in R$ defines a scheme $\mathcal{W} \in \mathbb{P}^2_R$. Then

- Both $\mathcal{W}_{\mathrm{sm}}$ and $\mathcal{W}$ has generic fiber E. If E has good reduction and W is a minimal Weierstrass equation, then $\mathcal{W} = \mathcal{W}_{\mathrm{sm}}$ is smooth.
- The natural map $\mathcal{W}(R) \to E(K)$ is a bijection. If $\mathcal{W}$ is regular, then $\mathcal{W}_{\mathrm{sm}}(R) \to \mathcal{W}(R)$ is also a bijection.
- The group structure on E/K extends to a group structure on $\mathcal{W}_{\mathrm{sm}}/R$, and the addition further extends to a group action of $\mathcal{W}_{\mathrm{sm}}/R$ on $\mathcal{W}/R$.

Proof: Cf.[**?**]P321. □

Prop. (13.9.4.8) [Weierstrass Model and Minimal Models]. Let (R, K) be a DVR, if $E \in \mathcal{E}\mathrm{ll}/K$ with minimal model $\mathcal{E}$, then any minimal Weierstrass model $\mathcal{W}$ can be obtained by blowing down the finitely many components of $\mathcal{E}_k$ which are disjoint from the closure in $\mathcal{E}$ of O_E. In particular, by(13.9.4.2), $\mathcal{W}_{\mathrm{sm}}$ is isomorphic to the relative identity component $\mathcal{N}_0$ of the Néron model of E.

Proof: Cf.[Liu Qing, Thm. 9.4.35] □

Def. (13.9.4.9) [Reduction Types]. Let (R, K, k) be a DVR with k perfect or $\mathrm{char}\, k \neq 2, 3$, and $E \in \mathcal{E}\mathrm{ll}/K$ with minimal Weierstrass model $\mathcal{W}$, then by(13.9.1.15), $\widetilde{E}$ is a geo.irreducible cubic in $\mathbb{P}^2$ with at most one rational singular point, and E is called

- a **good reduction** or **stable reduction** if $\widetilde{E} \in \mathcal{E}\mathrm{ll}/k$.
- a **multiplicative reduction** or **semistable reduction** if $\widetilde{E}$ has a node. And it is called a **split multiplicative reduction** if the node is split, otherwise it is called a **non-split multiplicative reduction**.
- a **additive reduction** or **unstable reduction** if $\widetilde{E}$ has a cusp.

By(13.9.1.15), exactly one of the above is true.

Moreover, E is called a **potentially good reduction** if $\widetilde{E_{K'}} \in \mathcal{E}\mathrm{ll}/K'$ for some finite extension K'/K.

Cf.`http://virtualmath1.stanford.edu/~conrad/mordellsem/Notes/L11.pdf` P19.**?**

Def. (13.9.4.10) [Redution Modulo]. Let E be an elliptic curve over a CDVR K, let W be a minimal Weierstrass equation for E, then W defines a projective scheme $\mathcal{W}$ in $\mathbb{P}^2_R$. By valuation criterion of properness, the natural map $\mathcal{W}(R) \to E(K)$ is an isomorphism. Let $\widetilde{E} = \mathcal{W} \otimes_R k$, called the **reduction modulo of** E. Then there is a natural map $E(K) \to \widetilde{E}(k)$, let

$$E_0(K) = \{P \in E(K), \widetilde{P} \in \widetilde{E}_{\mathrm{sm}}(k)\}, \quad E_1(K) = \{P \in E(K), \widetilde{P} = \widetilde{O}\},$$

then by(13.9.1.15), $E_0(K)$ and $E_1(K)$ are Abelian groups, and $E_0(K) \to \widetilde{E}_{\mathrm{sm}}(k)$ is a group homomorphism. $E_1(K)$ is called the **kernel of the reduction**.

Proof: To see $\widetilde{E}$ is well-defined, use(13.9.4.4). □

Prop. (13.9.4.11). There is an exact sequences of Abelian groups

$$0 \to E_1(K) \to E_0(K) \to \widetilde{E}_{\mathrm{sm}}(k) \to 0.$$

Proof: Only the right surjectivity needs to be proved: Let $\widetilde{P}\in\widetilde{E}_{ns}(k)$. If $\widetilde{P}=\widetilde{O}$, then it is in the image, so we assume $\widetilde{P}$ is a finite point $(\overline{x}_0,\overline{y}_0)$. Then the minimal Weierstrass equation $f(x,y)$ of E satisfies $\frac{\partial f}{\partial x_0}\not\equiv 0 \mod \mathfrak{m}$ or $\frac{\partial f}{\partial y_0}\not\equiv 0 \mod \mathfrak{m}$. We may assume the first case occurs. Let x_0 be a lift of x_0, then the equation $f(x_0,y)\in K[y]$ has a simple root $\overline{y}_0$ in R, then by Hensel's lemma(4.3.10.6), it has a root y_0 in R lifting $\overline{y}_0$. Then $P=(x_0,y_0)\in E(K)$ is a lift of $\widetilde{P}$. □

Prop. (13.9.4.12) [Formal Group is the Kernel]. Let E be given a minimal Weierstrass equation, then with notations as in(13.9.2.1),

$$\widehat{E}(\mathfrak{m})\to E_1(K): z\mapsto [z,-1,w(z)]$$

is an isomorphism of groups.

Proof: By(13.9.2.1), $\omega(z)\in z^3R[[z]]$, and by the definition of $w(z)$, $[z,-1,w(z)]\in E_1(K)$, and it is a group homomorphism by the definition of formal group law associated to E. It remains to prove that this map is surjective:

Clearly O is in the image, suppose $(x_0,y_0)\in E_1(K)$, then $v(x_0)<0, v(y_0)<0$, thus by inspecting the Weierstrass equation, $v(x_0)=-2r, v(y_0)=-3r$ for some $r>0\in\mathbb{Z}$. Then $z_0=x_0/y_0\in\mathfrak{m}$, and (x_0,y_0) is the image of z_0. □

Prop. (13.9.4.13) [Characterizing Reductions]. Let E/K be an elliptic curve over K given by a Weierstrass equation $E: y^2+a_1xy+a_3y=x^3+a_2x^2+a_4x+a_6$, then by(13.9.1.13),

- $\widetilde{E}$ is a good reduction iff $\Delta\in R^*$.
- $\widetilde{E}$ is a multiplicative reduction iff $\Delta\in\mathfrak{m}$ and $c_4\in R^*$.
- $\widetilde{E}$ is an additive reduction iff $\Delta, c_4\in\mathfrak{m}$.

Prop. (13.9.4.14) [Characterizing Potentially Good Reduction]. E has potentially good reduction iff $j(E)\in R$.

In particular, an elliptic curve with complex multiplication over K has potentially good reduction.

Proof: If $E_{\overline{k}}$ has good reduction, then $j(E)=(c_4')^3/\Delta'\in R'$. Conversely, if $j(E)\in R$, use Legendre form or Deuring form(13.9.1.16)(13.9.1.17), the equation

$$j=2^8\frac{(\lambda^2-\lambda+1)^3}{\lambda^2(\lambda-1)^2}\text{ or } j=\frac{\alpha^3(\alpha^3-24)^3}{\alpha^3-27}$$

implies $\lambda\in R^*, \lambda(\lambda-1)\in R^*$(or $\alpha\in R^*, \alpha^3-27\in R^*$), so $E_{\overline{k}}$ has good reduction. □

Prop. (13.9.4.15) [Tamagawa Numbers]. Let (R,K,k) be a DVR and $E\in\mathcal{E}\mathrm{ll}/K$ with minimal model $\mathcal{E}/R$, then $c(E)$ equals the number of geo.integral components occuring with multiplicity 1 in $\mathcal{E}_k$.

Proof: Cf.[Liu Qing, 10.2.24]. □

Prop. (13.9.4.16) [Tamagawa Numbers]. Let $E\in\mathcal{E}\mathrm{ll}/K$. If E has split multiplicative reduction over K, then $E(K)/E_0(K)$ is a cyclic group of order $v(\Delta)=-v(j)$. And in other cases, the group is finite and has order at most 4.

Proof:

□

Cor. (13.9.4.17). If $K \in$ p-`Field` and $E \in \mathcal{E}\mathrm{ll}/K$, then $E(K)$ contains a subgroup of finite index that is isomorphic to $\mathcal{O}_K$.

Proof: Because $E(K)/E_0(K)$ and $E_0(K)/E_1(K) \cong \widetilde{E}_{ns}(k)$ are all finite by(13.9.4.16), it suffices to prove that $E_1(K) \cong \widehat{E}(\mathfrak{m})$ has a subgroup of finite index that is isomorphic to $\mathcal{O}_K$. But this follows from the fact $\widehat{E}(\mathfrak{m}^r) \cong \mathfrak{m}^r$ for r large(8.5.4.7). □

Tate Algorithm

Prop. (13.9.4.18)[Kodaira-Néron]. Let $(R, \mathfrak{m})$ be a DVR with fraction field K and alg.closed residue field k. Let E/K be an elliptic curve, and $\mathcal{C}/R$ a minimal proper regular model for E over R, then the special fiber of $\mathcal{C}$ has one of the following Forms:

- (Type I_0) An elliptic curve.
- (Type I_1) A rational curve with a node.
- (Type $\mathrm{I}_n, n \geq 2$) n smooth rational curves intersecting transversally at a single point one-by-one in the shape of a n-gon.
- (Type II) A rational curve with a cusp.
- (Type III) Two non-singular rational curves which intersects tangentially at a single point.
- (Type I_0^*) A non-singular rational curve of multiplicity 2 with 4 non-singular rational curves of multiplicity1 attached.
- (Type I_n^*) A chain of $n+1$ non-singular rational curves of multiplicity2, with two non-singular curves of multiplicity1 attached at each end.
- (Type IV^*) ?
- (Type III^*) ?
- (Type II^*) ?

Proof: Cf.[?]P354. □

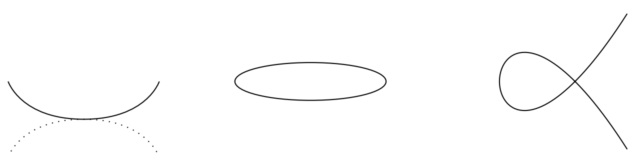

Figure (13.9.4.1): Kodaira Types

Prop. (13.9.4.19)[Tate Algorithm]. There is an algorithm that determines if a Weierstrass equation for E is minimal.?

Torsion Points

Prop. (13.9.4.20)[Controlling Torsion Points]. Let $m \in \mathbb{Z} \cap k^\times$, then

- $E_1(K)[m] = O$
- The reduction map $E_0(K)[m] \to \widetilde{E}_{\mathrm{sm}}(k)[m]$ is injective.

- If E has good reduction and $K = K^{\text{sep}}$, then it is also an isomorphism.

Proof: 1: By(13.9.4.12), $E_1(K)[m] \cong \widehat{E}(\mathfrak{m})[m]$, which has only one element because $[m]_{\widehat{E}}$ is an isomorphism(8.5.3.5).

2 follows from 1 and the exact sequence in(13.9.4.11).

3 follows as they have the same cardinality. □

Prop. (13.9.4.21) [Controlling Torsion Points]. Let $\operatorname{char} K = 0$ and $\operatorname{char} k = p > 0$, let E be given by a Weierstrass equation

$$E : y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6 \in R[X, Y].$$

Let $P = (x_0, y_0) \in E(K)$ be a torsion point of exact order m, then

- If m is not a p-power, then $x_0, y_0 \in R$.
- If $m = p^n$, then $v(x) \geq -2\lfloor \frac{v(p)}{p^n - p^{n-1}} \rfloor$, $v(y) \geq -3\lfloor \frac{v(p)}{p^n - p^{n-1}} \rfloor$.

Proof: Change the Weierstrass equation to a minimal Weierstrass equation, then by(13.9.4.3), the coordinates in the new equation satisfies $v(x') \leq v(x_0), v(y') \leq v(y_0)$, thus it suffices to prove for minimal Weierstrass equations.

If $v(x_0) \geq 0$, then $v(y_0) \geq 0$. Suppose $v(x_0) < 0$, then $v(y_0) < 0$, and $v(x_0) = -2r, v(y_0) = -3r$ for some $r > 0$. thus $P \in E_1(K)$ and thus corresponds to $z \in \widehat{E}(\mathfrak{m})$(13.9.4.12). Then the theorem follows from(8.5.4.6). □

Over Dedekind Domains

Def. (13.9.4.22) [Canonical Heights]. For a number field F and $E \in \mathcal{E}\mathrm{ll}/F$, by(13.5.13.4) and(13.5.4.8), $\widehat{h}_{\mathcal{L}}$ only depends on $\deg(\mathcal{L})$. And by(5.11.2.20), any degree 1 line bundle is ample, and the Néron-Tate bilinear form $\langle \cdot, \cdot \rangle_{\text{N-T}}$ given by this line bundle is called the **canonical height pairing** of E. It is a positive-definite quadratic form on $E(\overline{K}) \otimes \mathbb{R}$ by(13.5.12.3). And for $P \in E(\overline{K})$, $\langle P, P \rangle_{\text{N-T}}$ is called the **canonical height** of P.

In particular we can take the line bundle $\mathcal{O}(O)$, then $\langle O, O \rangle_{\text{N-T}} = 0$, and for any $P \neq 0 \in \mathcal{L}(O)$,

$$\langle P, P \rangle_{\text{N-T}} = \lim_{n \to \infty} h(x([2^n]P))/4^N.$$

Proof: For the final assertion, apply(13.2.3.23) to the morphism $\varphi : E \to \mathbb{P}^1$ associated to the rational function x:

$$\langle P, P \rangle_{\text{N-T}} = \lim_{n \to \infty} \widehat{h}_{\mathcal{O}(2O)}([2^n]P)/4^N = \lim_{n \to \infty} h_{\mathcal{O}_{\mathbb{P}^1}(1)}(\varphi([2^n]P))/4^N = \lim_{n \to \infty} h(x([2^n]P))/4^N.$$

□

Prop. (13.9.4.23) [Elliptic Regulator]. Let F be a number field and $E \in \mathcal{E}\mathrm{ll}/F$, then the **elliptic regulator** is the volume of a fundamental domain of $E(K)/E(K)_{\text{tor}}$ computed using the canonical height. In particular, it is the discriminant of $(\langle X_i, X_j \rangle_{E,F})_{i,j}$ where $\{X_i\}$ is a basis for $E(K)/E(K)_{\text{tor}}$.

Def. (13.9.4.24) [Minimal Discriminant]. For an elliptic curve E over a global field F, define the **minimal discriminant** $\Delta^{\min}_{E/F}$ to be $\Delta^{\min}_{E/F} = \prod_v \mathfrak{p}_v^{\operatorname{ord}(\Delta_v)}$, where Δ_v is the discriminant of a minimal Weierstrass equation for E_v.

Then for any Weierstrass equation W for E, by(13.9.1.12), $\mathfrak{D}_{E/F} = \Delta^{\min}_{E/F}(\mathfrak{a}_W)^{12}$ for some ideal $\mathfrak{a}$ of F, and the ideal class of $\mathfrak{a}_\Delta$ is stable under change of Weierstrass equations, called the **Weierstrass class** of E, denoted by $\overline{\mathfrak{a}}_{E/F}$.

Prop. (13.9.4.25) [A Curve Related to Fermat's Last Theorem]. Let $a, b, c \in \mathbb{Z}^\times$ satisfy $(a, b, c) = 1$, let E be the elliptic curve defined by the Weierstrass equation

$$E : y^2 = x(x + a)(x - b),$$

then

- the minimal discriminant(13.9.4.24) $\Delta_{E/K}^{\min}$ of E is either $2^4|abc|^2$ or $2^{-8}|abc|^2$.
- E has semistable reduction for any odd prime.

Proof: By calculation

$$\mathfrak{D}_W = 2^4(abc)^2, \quad c_4 = 2^4(a^2 + ab + b^2), \quad c_6 = -2^5(2a^3 + 3a^2b + 3ab^2 + 2b^3),$$

$$(22a^2 - 8ab - 8b^2)c_4 + (a + 2b)c_6 = 288a^2, \quad -(8a^2 + 8ab - 22b^2)c_4 - (2a + b)c_6 = 288b^2.$$

1: Any change of variable of E to the minimal Weierstrass equation satisfies $u^4|c_4, u^6|c_6$, so

$$u^4|(288a^2, 288b^2)$$

so $u = 1$ or 2, and $\Delta_E^{\min} = u^{-12}\mathfrak{D}_W = 2^4|abc|^2$ or $2^{-8}|abc|^2$.

2: If $p \in \mathbf{P}\backslash\{2\}$ and $p|\Delta_E^{\min}$, then p divides a or b or c. In each case, $p \nmid c$, so E has multiplicative reduction at these p(13.9.4.13). □

Prop. (13.9.4.26) [Global Minimal Weierstrass Equation]. For a global field F and $E \in \mathcal{E}\mathrm{ll}/F$, E has a global minimal Weierstrass equation if its Weierstrass class is trivial.

In particular, if $\mathrm{Cl}(F) = 1$, e.g. $F = \mathbb{Q}$, then any $E \in \mathcal{E}\mathrm{ll}/F$ has a global minimal Weierstrass equation.

Proof: Choose any Weierstrass equation for E over K, let

$$x = u_v^2x + r_v, \quad y = u_v^3y + s_vu_v^2x + t_v, \quad u_v, r_v, s_v, t_v \in \mathcal{O}_{K,v}$$

be the local change of variable to get the minimal Weierstrass equation at place v, then by hypothesis, $(u_v)_v$ is principal, which means there is some $u \in K$ s.t. $v(u) = v(u_v)$ for any v. Then choose by Chinese remainder theorem $r, s, t \in \mathcal{O}_K$ that is closed to r_v, s_v, t_v for each relevant v, then the change of variables

$$x = u^2x + r, \quad y = u^3y + su^2x + t$$

changes the coordinates to a minimal Weierstrass equation. □

Cor. (13.9.4.27). Let F be a global field with class number prime to 6 and E/K is an elliptic curve over F with everywhere good reduction, then E has a minimal model.

Proof: Because in this case the Weierstrass class $\mathfrak{a}_\Delta$ is a 12-torsion in $\mathrm{Cl}(F)$, which implies it is trivial. □

Cor. (13.9.4.28). If $F \in \mathtt{NField}$ and S is a finite set of places of K s.t. $\mathrm{Cl}(\mathcal{O}_{F,S}) = 1$, then any elliptic curve over F has a minimal Weierstrass equation of the form $W : y^2 = x^3 + Ax + B$ with $A, B \in \mathcal{O}_{K,S}$ satisfying $\mathfrak{D}_W\mathcal{O}_{F,S} = \Delta_{E/F}^{\min}\mathcal{O}_{F,S}$.

Proof: The proof is easier than that(13.9.4.26). □

Prop. (13.9.4.29). If $F \in \texttt{NField}$ with $\mathrm{Cl}(F) \neq 1$, there exists an elliptic curve over F with no global minimal Weierstrass equations.

Proof: Cf.[Weierstrass equations and the minimal discriminant of an elliptic curve", Mathematika 31 (1984), no. 2, 245–251]. □

Prop. (13.9.4.30) [Density of Global Minimal Models].

Proof: Cf.[The density of elliptic curves having a global minimal Weierstrass equation", J. Number Theory 109 (2004), no. 1, 41–58.]. □

5 Tate Curves

Def. (13.9.5.1) [Formal Power Series]. Define power series

$$s_k(q) = \sum_{n\geq 1} \sigma_k(n) q^n = \sum_{n\geq 1} \frac{n^k q^n}{1-q^n} \in \mathbb{Z}[[q]],$$

$$a_4(q) = -5 s_3(q), \quad a_6(q) = -\frac{5s_3(q) + 7s_5(q)}{12} \in \mathbb{Z}[[q]],$$

$$X(u,q) = \sum_{n\in\mathbb{Z}} \frac{q^n u}{(1-q^n u)^2} - 2s_1(q), \quad Y(u,q) = \sum_{n\in\mathbb{Z}} \frac{(q^n u)^2}{(1-q^n u)^3} + s_1(q) \in \mathbb{Z}[u][[q]].$$

Prop. (13.9.5.2).

$$s_1(q) = \sum_{n\geq 1} \frac{q^n}{(1-q^n)^2} \in \mathbb{Z}[[q]],$$

$$X(u,q) = \frac{u}{(1-u)^2} + \sum_{n\geq 1} [\frac{q^n u}{(1-q^n u)^2} + \frac{q^n u^{-1}}{(1-q^n u^{-1})^2} - \frac{2q^n}{(1-q^n)^2}] \in \mathbb{Z}[u][[q]],$$

$$Y(u,q) = \frac{u^2}{(1-u)^3} + \sum_{n\geq 1} [\frac{(q^n u)^2}{(1-q^n u)^3} + \frac{q^n u^{-1}}{(1-q^n u^{-1})^3} + \frac{q^n}{(1-q^n)^2}] \in \mathbb{Z}[u][[q]],$$

Thus

$$X(qu,q) = X(u,q) = X(u^{-1},q), \quad Y(qu,q) = Y(u,q) \in \mathbb{Z}[u,u^{-1}][[q]].$$

Proof: The first one follows from(8.5.2.2). □

Prop. (13.9.5.3)[Relation to Weierstrass $\mathfrak{P}$-Functions]. Let $\wp(z;\tau)$ be the Weierstrass $\mathfrak{P}$-function associated to the lattice $\Lambda_z = \mathrm{span}\{1,\tau\}$(10.6.4.5), then $X(e^{2\pi i z}, q(\tau)), Y(e^{2\pi i z}, q(\tau))$ converges and uniformly and absolutely on $\mathbb{C}\backslash\Lambda_z$ in $\mathbb{C}$ to holomorphic functions, and

$$\frac{1}{(2\pi\,\mathrm{i})^2}\mathfrak{P}(z;\tau) = X(e^{2\pi i z}, q(\tau)) + \frac{1}{12}, \quad \frac{1}{(2\pi i)^3}\wp(z;\tau)' = X(e^{2\pi i z}, q(\tau)) + 2Y(e^{2\pi i z}, q(\tau)).$$

Proof: The convergence of X, Y is clear. By(13.9.5.1), $X(e^{2\pi i z}, q(\tau))$ is $\{1,\tau\}$-doubly periodic, and clearly it has a double pole at the origin. Also the Laurent part of $X(e^{2\pi i z}, q(\tau))$ at $z = 0$ is the Laurent part of $\frac{e^{2\pi i z}}{(1-e^{2\pi i z})^2}$, which is $\frac{1}{(2\pi i)^2 z^2} - \frac{1}{12}$. Then by comparison with that of $\mathfrak{P}(z;\tau)$(10.6.4.6) and use Liouville's theorem.

The second identity follows from applying $\frac{\partial}{\partial z}$. □

Prop. (13.9.5.4) [Tate Curve over $\mathbb{C}$]. Notation as in(13.9.5.1), then for $q \in \mathbb{C}, 0 < |q| < 1$,

- $E_q : y^2 + xy = x^3 + a_4(q)x + a_6(q)$ is an elliptic curve over $\mathbb{C}$, and
$$\varphi : \mathbb{C}^*/q^{\mathbb{Z}} \to E_q^{an} : u \mapsto [X(u,q), Y(u,q), 1]$$
is a complex analytic isomorphism.
- The discriminant of E_q is given by
$$\Delta(E_q) = \Delta(q) : q\prod_{n\geq 1}(1-q^n)^{24}(16.2.5.8), \quad j(E_q) = j(q)(16.2.5.10)$$
- For any elliptic curve $E/\mathbb{C}$, there exists a $q \in \mathbb{C}^*, |q| < 1$ s.t. E is isomorphic to E_q.

Proof: Cf.[Sil99]P410.? □

Prop. (13.9.5.5) [Formal Identities]. There are identities

1. $$-a_6(q) + a_4^2(q) + 72a_4a_6 - 64a_4^3 - 432a_6^3 = \Delta(q) \in \mathbb{Z}[[q]].$$
2. $$Y(u^{-1}, q) = -Y(u,q) - X(u,q) \in \mathbb{Z}[u, u^{-1}][[q]].$$
3. $$Y(u,q)^2 + X(u,q)Y(u,q) = X(u,q)^3 + a_4(q)X(u,q) + a_6(q) \in \mathbb{Z}[u][[q]].$$
4. $$\begin{aligned}(X(u_2,q) - X(u_1,q))^2X(u_1u_2,q) = (Y(u_2,q) - Y(u_1,q))^2 + (Y(u_2,q) - Y(u_1,q))(X(u_2,q) - X(u_1,q))\\ - (X(u_2,q) - X(u_1,q))^2(X(u_2,q) + X(u_1,q))\end{aligned}$$
$$\begin{aligned}(X(u_2,q) - X(u_1,q))Y(u_1u_2,q) = -[(Y(u_2,q) - Y(u_1,q)) + (X(u_2,q) - X(u_1,q))]X(u_1u_2,q)\\ - (Y(u_1,q)X(u_2,q) - Y(u_2,q)X(u_1,q))\end{aligned}$$

Proof: Verify these in the complex analytic case.?
3: By(10.6.4.7) and(13.9.5.3)(16.2.5.5),
$$\mathfrak{P}'(z)^2 = 4\mathfrak{P}(z)^3 - g_2\mathfrak{P}(z)^2 - g_3\mathfrak{P}(z)$$
implies the desired equation.

□

Cor. (13.9.5.6) [Tate Curve]. $E_q : y^2 + xy = x^3 + a_4(q)x + a_6(q)$ is an elliptic scheme over $\mathbb{Z}[[q]]$, called the **Tate curve**. The discriminant of E_q is given by
$$\Delta(E_q) = \Delta(q) : q\prod_{n\geq 1}(1-q^n)^{24}(16.2.5.8), \quad j(E_q) = j(q)(16.2.5.10).$$

Prop. (13.9.5.7) [Tate Curve over $\mathbb{R}$]. Let $E/\mathbb{R}$ be an elliptic curve, then there exists a unique $q \in \mathbb{R}, 0 < |q| < 1$ s.t.

- E is isomorphic to $E_q : y^2 + xy = x^3 + a_4(q)x + a_6(q)$ over $\mathbb{R}$.

- the isomorphism composed with

$$\varphi : \mathbb{C}^*/q^{\mathbb{Z}} \cong E_q^{an} : u \mapsto (X(u,q), Y(u,q))$$

as in(13.9.5.9) induces an isomorphism of complex Lie groups $\psi : \mathbb{C}^*/q^{\mathbb{Z}} \to E_{\mathbb{C}}^{an}$ that commutes with complex conjugation. In particular, ψ induces an isomorphism of real Lie groups

$$\psi : \mathbb{R}^*/q^{\mathbb{Z}} \cong E^{\mathbb{R}-an}.$$

Proof: 1: By(13.5.8.11) and(13.5.8.12), there are exactly on $\tau \in \mathcal{C}' = \{it|t \geq 1\} \cup \{1/2+it|t > 1/2\}$ s.t. $j(\tau) = j(E) \in \mathbb{R}$, and

$$\mathcal{J} = \{it|t > 0\} \cup \{1/2 + it|t > 0\}.$$

corresponds to $q \in \mathbb{R}, 0 < |q| < 1$ via $\tau \mapsto q = e^{2\pi i\tau}$. Also there are identifications

$$\begin{bmatrix} & -1 \\ 1 & \end{bmatrix} \{it|t > 1\} = \{it|t < 1\}, \quad \begin{bmatrix} 1 & -1 \\ 2 & -1 \end{bmatrix} \{1/2+it|t > 1/2\} = \{1/2+it|t < 1/2\}, \quad \begin{bmatrix} & -1 \\ 1 & -1 \end{bmatrix} (i) = \frac{1}{2}+\frac{i}{2},$$

thus it suffices to show that for any two $q, q' \in \mathcal{J}$ with $q \neq q'$, $E_q \ncong E_{q'}$. It suffices to show for the twists, where we can use(13.9.6.3) to show that their c_4, c_6 changed sign, so they are not isomorphic over $\mathbb{R}$.

2: This follows from(13.9.5.9). □

Cor. (13.9.5.8) [Connected Components]. Let $E \in \mathcal{E}\mathrm{ll}/\mathbb{R}$, then

$$E(\mathbb{R}) \cong \begin{cases} \mathbb{R}/\mathbb{Z} & \Delta(E) < 0 \\ \mathbb{R}/\mathbb{Z} \times \mathbb{Z}/(2) & \Delta(E) > 0 \end{cases}$$

as real Lie groups.

Proof: Notice $\mathrm{sgn}(\Delta) = \mathrm{sgn}(q)$ by(13.9.5.9). The $q > 0$ case is clear. For $q < 0$, notice there is an isogeny $E_{q^2} \to E_q$ with kernel q, so $E^{\mathbb{R}-an} \cong [\mathbb{R}/\mathbb{Z} \times \mathbb{Z}/(2)]/(1/2, -1) \cong \mathbb{R}/\mathbb{Z}$. □

Prop. (13.9.5.9) [over Complete Valued Fields]. Notation as in(13.9.5.1), let K be a complete non-Archimedean valued field, then for $q \in K, 0 < |q| < 1$,

- $E_q : y^2 + xy = x^3 + a_4(q)x + a_6(q) \in \mathcal{E}\mathrm{ll}/K$. The discriminant of E_q is given by

$$\Delta(E_q) = \Delta(q) : q \prod_{n \geq 1} (1 - q^n)^{24} (16.2.5.8), \quad j(E_q) = j(q) (16.2.5.10)$$

- $$\varphi : \overline{K}^{\times} \to E_q(\overline{K}) : u \mapsto [X(u,q), Y(u,q), 1]$$

is a continuous surjective homomorphism with kernel $q^{\mathbb{Z}}$, and it is Gal_K-invariant, thus for any $K \subset L \subset \overline{K}$ inducing a continuous surjective homomorphism

$$\varphi : L^{\times} \to E_q(L)$$

with kernel $q^{\mathbb{Z}}$.

Proof: 1: This follows from(13.9.5.6) by base change.

2: Clearly $X(u,q), Y(u,q)$ converges for any $u \in K^\times/q^{\mathbb{Z}}$, and by(13.9.5.1) it suffices to consider the case $|q| < |u| < |q|^{-1}$. In this case, the formal power series for $X(u,q), Y(u,q)$ are convergent in the complete field $K(u)$, and it follows from(13.9.5.5) that $\varphi(\overline{K}^*) \in E$. It is clearly continuous for $u \neq 1$, and if u converges to 1, $X(u,q)/Y(u,q) \to 0$ by the expansion in(13.9.5.5), so $\varphi(1) = O$.

To show φ is a homomorphism, it suffices to verify for $1 < |u_1| < |q|^{-1}, |q| < |u_2| < 1$ that $\varphi(u_1) + \varphi(u_2) = \varphi(u_1 u_2)$. Notice by the argument above, $\varphi(u) = O$ iff $u = 1$. If $u_1 = 1$ or $u_2 = 1$, then $\varphi(u_1) + \varphi(u_2) = \varphi(u_1 u_2)$ is clear, and if $u_1 u_2 = 1$, then $\varphi(u_1) + \varphi(u_2) = O$ by the identities in(13.9.5.5) and(13.9.1.8). When $u_1 \neq 1, u_2 \neq 1,_1 u_2 \neq 1$, $\varphi(u_1) \neq \varphi(u_2)$, $\varphi(u_1) + \varphi(u_2)$ are determined by polynomial equations with coordinates of $\varphi(u_1), \varphi(u_2)$, and we can show this equation holds for $\varphi(u_1 u_2)$ because it holds in the complex case(13.9.5.9). For the case $\varphi(u_1) = \varphi(u_2)$, notice that $\mathrm{Im}(\varphi)$ is infinite, as for $|t| < 1$, $|X(1+t)| = |t|^{-2}$ by the formula in(13.9.5.5). Now this case follows from(2.1.3.14).

Next, we show $\varphi : L^\times \to E_q(L)$ is surjective. As K is arbitrary, we may assume $L = K$. For this, Cf.[Tate, a review of non-Archimedean Elliptic Functions]**?**. □

Lemma (13.9.5.10). Let $\alpha \in K$ with $|\alpha| > 1$, then there exists a unique $q \in K$ s.t. $|q| < 1$ s.t. $j(q) = \alpha$. Moreover, $q \in \mathbb{Z}[[\frac{1}{\alpha}]]$.

Proof: Let $f(q) = j(q)^{-1} \in q + q^2\mathbb{Z}[[q]]$, thus by(8.5.1.3) there exists a $g \in q\mathbb{Z}[[q]]$ s.t. $f(g(q)) = q = g(f(q))$. So if $f(q) = \frac{1}{\alpha}$, then $q = f(\frac{1}{\alpha})$. And this q do satisfies $j(q) = \alpha$. □

Thm. (13.9.5.11) [p-Adic Uniformization, Tate]. Let K be a complete valued field, $E \in \mathcal{E}\mathrm{ll}/K$ with $|j(E)| > 1$, then

- There exists a unique $q \in K$ s.t. $E_{\overline{K}} \cong (E_q)_{\overline{K}}$.
- For this q, the following are equivalent:
  - $E \cong E_q$.
  - $\gamma(E) = 1$(13.9.6.3).
  - E has split multiplicative reduction.

Proof: 1 follows from(13.9.5.10) and(13.9.1.13).

2: Firstly $\gamma(E_q) = 1$, because

$$c_4(E_q) = 1 - 48a_4(q) = 1 + 240s_3(q), \quad -c_6(E_q) = 1 - 72a_4(q) - 864a_6(q) = 1 - 504s_5(q)$$

are all of the form $1 + 4\alpha, |\alpha| < 1$, thus they are both squares in $K^\times$, as $1 + 4\alpha = [(1+4\alpha)^{1/2}]^2$**??**

Next, $|a_4(q)|, |a_6(q)| \leq 1$, so $\widetilde{E}_q : y^2 + xy = x^3$ has split multiplicative reduction. Then $1 \iff 2$ by(13.9.6.3), and to show $1 \iff 3$, it suffices to show that if E has split multiplicative reduction, then $\gamma(E) = 1$: Let the valuation ring of K be R with maximal ideal $\mathfrak{m}$ and residue field k. Let $y^2 + a_1xy + a_3 = x^3 + a_2x^2 + a_4x + a_6$ be a minimal polynomial. We may assume the singular point is $(0,0) \in \widetilde{E}(k)$, then $a_3 \equiv a_4 \equiv a_6 \equiv 0 \mod \mathfrak{m}$, thus $b_4 = a_1a_3 + 2a_4 \equiv 0 \mod \mathfrak{m}$, and $c_4 = b_2^2 - 2b_4 \equiv b_2^2 \mod m$. Thus $b_2 \in R^*$, and

$$\gamma(E) = -\frac{c_4}{c_6} = \frac{1}{b_2}\frac{1 - 24b_4/b_2^{-2}}{1 - 36b_4/b_2^2 + 216b_6/b_2^3} \mod (K^\times)^2.$$

So by**??**gain, $\gamma(E) \cong b_2 \mod (K^\times)^2$.

Because E has multiplicative split reduction, $y^2 + \bar{a}_1xy - \bar{a}_2x^2 = (y - \overline{\alpha}x)(y - \overline{\beta}x) \in k$, $\overline{\alpha} \neq \overline{\beta}$. Thus by Henselian lifting, $y^2 + a_1xy - a_2x^2 = (y - \alpha x)(y - \beta x) \in K$ for some α, β, and $b_2 = a_1^2 + 4a_2 = (\alpha - \beta)^2 \in (K^\times)^2$. □

Cor. (13.9.5.12). If $\gamma(E)\neq 1$, let $L=K(\sqrt{\gamma(E)})$, then $E_L\cong (E_q)_L$, and

$$E(K)\cong\{u\in L^*/q^{\mathbb{Z}}|N_{L/K}(u)\in{}^{\mathbb{Z}}\}.$$

Proof: Cf.[Sil99]P444. □

6 Galois Cohomology

Prop. (13.9.6.1) [Twists of Elliptic Curves]. Because the category of smooth curves with a fixed point is an algebraic stack, thus the set $\mathrm{Twist}(E/k)$ of twisted curves of an elliptic curve over k is in bijection with $H^1(G_k,\mathrm{Isom}(E_{\overline{k}}))$ by(5.1.5.2).

Also the category of elliptic curves over k with the origin fixed is an algebraic stack, thus the set $\mathrm{Twist}((E,O)/k)$ of twisted elliptic curves of an elliptic curve over k is in bijection with $H^1(G_k,\mathrm{Aut}(E_{\overline{k}}))$.

Remark (13.9.6.2). [?]P318,342 has a direct proof, and can find the twist corresponding to a cocycle explicitly.?

Prop. (13.9.6.3) [$\mathrm{Twist}((E,O)/k)$]**.** Let k be a field s.t. $\mathrm{char}\,k\neq 2,3$, $E\in\mathcal{E}\mathrm{ll}/k$. Denote $n=\#\mathrm{Aut}(E_{\overline{k}})$, then

- $\mathrm{Twist}((E,O)/k)$ is canonically isomorphic to $K^\times/(K^\times)^n$.
- For E/k with Weierstrass equation $y^2=x^3+Ax+B$, the twisted elliptic curve of E corresponding to $D\mod (K^\times)^n$ has the Weierstrass equation

$$E_D:\begin{cases}y^2=x^3+D^2Ax+D^3B, & j(E)\neq 0,1728\\ y^2=x^3+DAx, & j(E)=1728\\ y^2=x^3+DB, & j(E)=0\end{cases}.$$

- In case $j(E)\neq 0,1728$, $n=2$, define $\gamma(E)=-c_4/c_6\in\mathbb{K}^\times/(K^\times)^2$, which equals A/B in the short form, then for $E,E'\in\mathcal{E}\mathrm{ll}/k$ with $j(E),j(E')\neq 0,1728$,

$$E\cong E'\iff j(E)=j(E')\ \&\ \gamma(E)=\gamma(E').$$

Proof: This is because the Kummer sequence and(13.9.1.18) implies $H^1(G_k,\mathrm{Aut}(E_{\overline{k}}))\cong H^1(G_k,\mu_n(\overline{k}))=K^\times/(K^\times)^n$. For the corresponding elliptic curve, Cf.[Sil16]P343.? □

Def. (13.9.6.4)[Weil-Châtelet Groups]. Define the **Weil-Châtelet Group** $\mathrm{WC}(X/k)$ of an elliptic curve X/k to be the isomorphism classes of X-torsors on $\mathcal{S}\mathrm{ch}_{\text{ét}}/\operatorname{Spec}k$.

Prop. (13.9.6.5)[Torsors for E]. For any E-torsor X, choose a geometric point(exists by definition), then we see that X is a smooth curve of genus 1, and is a twist of A.

In fact, there is an isomorphism of pointed set $\mathrm{WC}(E/k)\cong H^1(k,E)$, by[Sil16]P325.?

Proof: □

Prop. (13.9.6.6). If C is an étale torsor for E/k, then $\mathrm{Jac}(C)\cong E$.

Proof: Because C is a smooth curve, let $p \in C$ be a geometric point, and take the line bundle $\mu^*\mathcal{L}(p) - \mathrm{pr}_2^*\mathcal{L}(p) - \mathrm{pr}_1^*\mathcal{L}(O)$, where $\mu : E \times C \to C$ is the action. Then after a base change to $k(p)$, this map corresponds to the canonical isomorphism $E \cong \widehat{E}$(13.9.1.19), thus it is also an isomorphism because $\mathcal{S}\mathrm{ch}_X$ is a prestack over $\mathcal{S}\mathrm{ch}_{\mathrm{fpqc}}$. □

Prop. (13.9.6.7). Let $E \in \mathcal{E}\mathrm{ll}/\mathbb{R}$, then

$$\mathrm{WC}(E/\mathbb{R}) \cong \begin{cases} 0 & \Delta(E) > 0 \\ \mathbb{Z}/(2) & \Delta(E) < 0 \end{cases}.$$

Proof: By(13.9.6.5) and(13.9.5.7), the Galois cohomology of the exact sequence $1 \to q^{\mathbb{Z}} \to \mathbb{C}^\times \to E(\mathbb{C}) \to 1$ says

$$0 \to \mathrm{WC}(E/\mathbb{R}) \to H^2(\mathrm{Gal}(\mathbb{C}/\mathbb{R}), q^{\mathbb{Z}}) \to H^2(\mathrm{Gal}(\mathbb{C}/\mathbb{R}), \mathbb{C}^\times),$$

and $\mathbb{H}^2(\mathrm{Gal}(\mathbb{C}/\mathbb{R}), q^{\mathbb{Z}}) \cong q^{\mathbb{Z}}/q^{2\mathbb{Z}}, H^2(\mathrm{Gal}(\mathbb{C}/\mathbb{R}), \mathbb{C}^\times) \cong \mathbb{R}^\times/(\mathbb{R}^\times)^2$ by(10.1.3.5)(10.1.1.20). So we are done by observing $\mathrm{sgn}(\Delta) = \mathrm{sgn}(q)$ by(13.9.5.9). □

Conj. (13.9.6.8). The Shafarevich-Tate group is finite.

Proof: □

Remark (13.9.6.9). There are still no elliptic curve E over $\mathbb{Q}$ with $\mathrm{rank}_{\mathrm{an}}(E/\mathbb{Q}) \geq 2$ s.t. $Ш(E/\mathbb{Q})$ can be shown to be finite.

Prop. (13.9.6.10). For $F \in \texttt{NField}, E \in \mathcal{E}\mathrm{ll}/F, p \in \mathbf{P}$, and E has good ordinary reduction over all primes lying over p. Assume $F_\infty = \cup_n F_n$ is a $\mathbb{Z}_p$-extension of F, then the natural map

$$\mathrm{Sel}(E/F_n)_p \to \mathrm{Sel}(E/F_\infty)_p^{\mathrm{Gal}(F_\infty/F_n)}$$

has finite kernels and cokernels of bounded orders as $n \to \infty$.

Proof: Cf.[Mazur's Control Theorem for Elliptic Curves]. □

7 Rational Points

Ranks

Conj. (13.9.7.1) [Unboundedness Conjecture]. For $F \in \texttt{GField}$, the rank of elliptic curves over F can take arbitrary large values.

Proof: □

Remark (13.9.7.2). For function fields, this is proven by Tate-Shafarevich.

Prop. (13.9.7.3)[Lang Conjecture]. For any $\varepsilon > 0$, there exists a constant $C_\varepsilon > 0$ s.t. for any elliptic curve E over $\mathbb{Q}$, there exists a basis $\{P_1, \ldots, P_r\}$ of the free part of $E(\mathbb{Q})$ satisfying

$$\max_{i \leq i \leq r} \widehat{h}(P_i) \leq C_\varepsilon^{r^2} |D_{E/\mathbb{Q}}|^{\frac{1}{12}+\varepsilon}.$$

where $D_{E/\mathbb{Q}}$ is the minimal discriminant of $E/\mathbb{Q}$ and $\widehat{h}$ is the canonical height.

Conj. (13.9.7.4)[Rank Distribution]. The distribution of elliptic curves ordered by height(13.9.4.22) satisfies

$$\mathrm{P}_{\mathrm{rank}}(r) = \begin{cases} 50\% & r = 0 \\ 50\% & r = 1 \\ 0 & r \geq 2 \end{cases}.$$

In particular, $\mathbb{E}(r) = 0.5$

Prop. (13.9.7.5) [Bhargava-Shankar]. $\mathbb{E}(r) \leq 0.99$, if it exists.

Proof: □

8 Integral Points

Thm. (13.9.8.1) [Siegel]. Let E/K be an elliptic curve with $\#E(K) = \infty$. Let v be an absolute valuation of $\overline{K}$, $Q \in E(\overline{K})$ and $f \in R(E)^\times$ which corresponds to a morphism $\varphi : E \to \mathbb{P}^1 : P \mapsto [1, f(P)]$, then

$$\varinjlim_{P \in E(K), h(\varphi(P)) \to \infty} \frac{\log d_v(P; Q)}{h(\varphi(P))} = 0.(13.2.3.31)$$

Proof: Cf.[Sil16]P276. □

Cor. (13.9.8.2) [Finiteness of Integral Points]. If C/K is a complete smooth curve of genus 1 and $f \in R(C)^\times$, $S \subset \Sigma_K$ a finite set, then $\{P \in C(K) | f(P) \in \mathcal{O}_{K,S}\}$ is a finite set.

Proof: By a finite base change of fields, we may assume $\varphi^{-1}(\infty)$ contains a rational point O, and this point makes C into an elliptic curve. Let $\varphi : E \to \mathbb{P}^1 : P \mapsto [1, f(P)]$. It follows from the definition that there is some $v \in S$ s.t.

$$h(\varphi(P)) \leq \#S \log |f(P)|_v$$

for any $P \in C(K)$ s.t. $f(P) \in \mathcal{O}_{K,S}$. Then if $\#\{P \in C(K) | f(P) \in \mathcal{O}_{K,S}\} = \{P_1, \ldots, P_n, \ldots\}$ is infinite, it follows from Northcott's theorem(13.2.3.7) that $h(\varphi(P_i)) \to \infty$, and $|f(P_i)|_v \to \infty$ for a specific $v \in S$. Suppose $e_O(\varphi) = e$, then **?** □

13.12 ℓ-adic Étale Cohomologies over Finite Fields

Basic References are [Conrad Seminar note in Stanford], [Seminar on Gross-Zagier over Function Fields, Lei Fu], [Seminar notes on Weil 2 Bhatt], [Weil conjectures Perverse Sheaves and l-adic Fourier Transform Kiehl/Weissauer], [Etale Cohomology and Weil Conjecture], [A course on Weil Conjectures, Szamuely], [Deligne's proof of the Weil Conjecture, Jannsen].

Notation (13.12.0.1).

- $p \in \mathbf{P}, r \in \mathbb{Z}_+, q = p^r$, $k \cong \mathbb{F}_q$. Denote k_n the unique extension of k of degree n in $\overline{k}$.
- $\ell \in \mathbf{P} \backslash p$.
- $X_0 \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}}/k$, $X = X_0 \otimes_k \overline{k}$ is its base change.
- If $\mathcal{F}_0$ is a sheaf on X_0, then $\mathcal{F} = \mathcal{F}_0 \otimes_k \overline{k}$.
- If $x_0 \in X_0(\overline{k})$, $x = x_0 \otimes_{\kappa(x)} \overline{k}$, and $\overline{x} \in x$ is a point over x_0.
- Fix a CDVR $(\Lambda, K, \mathfrak{m}, k)$ of characteristic $(0, \ell)$.
- For a Noetherian ring A with a distinguished ideal $I \subset A$, let $A_n = A/I^n$.

1 Weil Sheaves

Weil Sheaves

Def. (13.12.1.1) [Weil Groups]. Cf.[Conrad, L19].?

Def. (13.12.1.2) [Weil Sheaves]. By Galois descent, the pullback induces an equivalence of categories between the category of constructible $\overline{\mathbb{Q}}_\ell$-sheaves on X_0 to the category of constructible $\overline{\mathbb{Q}}_\ell$-sheaves on X with an specified $G(X/X_0) = G(\overline{k}/k) \cong \widehat{\mathbb{Z}}$-actions. In practice, sometimes it is hard to verify the action of $\mathbb{Z} \subset \widehat{\mathbb{Z}}$ is continuous, which leads to the following definition:

The category $\mathrm{W}\mathcal{S}\mathrm{h}_\ell(X_0)$ of **Weil-sheaves** on X_0 consists of pairs $\mathcal{G}_0 = (\mathcal{G}, F_\mathcal{G})$ where $\mathcal{G}_0$ on an algebraic scheme X_0 over k consists of a constructible $\overline{\mathbb{Q}}_\ell$-sheaf $\mathcal{G}$ on X and an isomorphism $F_\mathcal{G} : F_X^*\mathcal{G} \to \mathcal{G}$(5.2.10.1). Notice F_X^* is not $\overline{k}$-linear! There are natural definition of morphisms of Weil-sheaves. A **lisse Weil-sheaf** is a Weil-sheaf that $\mathcal{G}$ is lisse.

Prop. (13.12.1.3) [Constructible $\overline{\mathbb{Q}}_\ell$-Sheaves as Weil Sheaves]. For any constructible $\overline{\mathbb{Q}}_\ell$-sheaf $\mathcal{F}_0$ on X_0, the canonical $F_X^* \mathrm{pr}^* \mathcal{F}_0 \cong (\mathrm{pr} \circ F_X)^*\mathcal{F}_0 = \mathrm{pr}^* \mathcal{F}_0$ makes $\mathcal{F}$ into a Weil-sheaf.

Prop. (13.12.1.4).

- $\mathrm{W}\mathcal{S}\mathrm{h}_\ell(X_0)$ is an Abelian category, and contains the category of lisse $\overline{\mathbb{Q}}_\ell$-sheaves form as an Abelian subcategory.
- The constructions like $R^if_*, R^if_!, f^*$ is functorial thus is definable on $\mathrm{W}\mathcal{S}\mathrm{h}_\ell(X)$ by(7.4.2.19).
- The specified isomorphism $F_{\mathcal{G}_0} : F_X^*\mathcal{G} \to \mathcal{G}$ gives us an action F_X^* of F_X on $H^i_{\text{ét},c}(X, \mathcal{G})$, just like in(7.4.2.28).
- (Stalkwise Description)Let $x_0 \in X_0(\overline{k}), x = x_0 \otimes_{\kappa(x)} \overline{k}, \overline{x} \in x$, there is an action $F_{x_0}^*$ of F_X on $\mathcal{G}_x$, by pulling back $\mathcal{G}_0$ to a Weil-sheaf on x_0, and given as follows: $F_x^*\mathcal{G}_x \cong \mathcal{G}_x$ gives an isomorphism $\mathcal{G}_{F^{i+1}(\overline{x})} \cong \mathcal{G}_{F^i(\overline{x})}$, whose composition $\mathcal{G}_{\overline{x}} \cong \mathcal{G}_{F^{\deg(x_0)-1}(\overline{x})} \cong \ldots \cong G_{F(\overline{x})} \cong \mathcal{G}_{\overline{x}}$. For different choice of $\overline{x}$, the actions are conjugate.

  In the case $\mathcal{G}_0$ is a constructible sheaf on X_0, this map is just the inverse of (the base change of)$\varphi_{\kappa(x_0)}$ on $(\mathcal{G}_0)_{x_0}$, by(7.4.2.29), as .

Prop. (13.12.1.5) [Weil Sheaves and Representation]. When X_0 is geo.connected, there is an equivalence of categories

$$\mathrm{W}\mathcal{S}\mathrm{h}_\ell(X_0) \cong \mathrm{Rep}_\ell(W(X_0, \overline{x})) : \mathcal{G}_0 \mapsto (\mathcal{G}_0)_{\overline{x}},$$

and the correspondence defined in(7.4.7.27) is a sub-correspondence of this.

Thus the notion of **geometric irreducible/semisimple** is definable for Weil-sheaves.

Proof: Because by the correspondence(7.4.7.27), $\mathcal{G}$ corresponds to a representation of $\pi_1(X, \overline{x})$, and $\pi_1(X, \overline{x})$ acts trivially on the Galois cover X/X_0. Now a representation of $W(X_0, \overline{x})$ is equivalent to an automorphism $\rho(\sigma)$(where $\sigma \in W(X_0, \overline{x})$ satisfies $\deg(\sigma)$ corresponds to the geometric Frobenius) that $\rho(\sigma)\rho(\pi_1(X, \overline{x}))\rho(\sigma^{-1}) = \rho(\sigma\pi_1(X, \overline{x})\sigma^{-1})$, which is equivalent to an isomorphism $F_X^*\mathcal{G} \to \mathcal{G}$. □

Prop. (13.12.1.6) [Weil Sheaves and Eigenvalues]. If X_0 is geo.connected, a lisse Weil-sheaf $\mathcal{G}_0$ on X_0 is a usual $\overline{\mathbb{Q}}_\ell$-sheaf iff some deg1 element σ in $W(X, \overline{x})$ acts on $\mathcal{G}_{0\overline{x}}$ with eigenvalues which are ℓ-adic units.

Proof: This is purely a Galois representation problem, concerning whether the representation of $W(X_0, \overline{x})$ can be extended to a representation of $\pi_1(X_0, \overline{x})$, and it is a continuity problem.

Firstly the representation of $\pi_1(X, \overline{x})$ stabilizes a lattice O_E^n for some $E/\mathbb{Q}_\ell$ finite, and then extends E to contain coefficients of $\rho(\sigma)$ and even its rational form. Then notice $\pi_1(X_0, \overline{x})$ is the profinite completion of $W(X_0, \overline{x})$, thus it suffices to see if the image $\rho(W(X_0, \overline{x}))$ is compact, and this is equivalent to eigenvalues of $\rho(\sigma)$ are units. □

Prop. (13.12.1.7) [Determinential Criterion]. If X_0 is a normal variety, then a irreducible lisse Weil-sheaf on X_0 is an actual $\overline{\mathbb{Q}}_\ell$-sheaf iff its determinant bundle is.

Proof: Use geometric monodromy group. Cf.[Conrad L19 P7].

First assume that $\mathcal{G}_0$ is geometrically irreducible, then(13.12.4.4) shows that there is a nonzero power $\sigma^m = gz$ where $g \in G_{geo}(\overline{\mathbb{Q}}_\ell)$ and $z \in Z(G(\overline{\mathbb{Q}}_\ell))$. Now G_{geo} is a semisimple algebraic group(13.12.4.4), so the determinential character maps $G_{geo}(G(\overline{\mathbb{Q}}_\ell))$ to a finite group, because connected semisimple algebraic group has no nontrivial character as $[G, G] = G$**?**. So the determinant of g is an l-unit, and $\det(\sigma^m) = \det(z)$ is a unit. But z is a scalar by Schur's lemma, thus z is an l-adic unit. Now it suffices to show the eigenvalue of g are all l-units.

Now consider $\rho(\pi_1(X, \overline{x}))$ is a compact group in $\mathrm{End}(V)$, thus it generates a finite $\mathcal{O}_E$-submodule A , which is full-rank lattice in $\mathrm{End}(V)$ by Jacobson density theorem**?** and the fact ρ is absolutely irreducible. g normalized A, because σ and z both normalizes $\rho(\pi_1(X, \overline{x}))$, so the eigenvalue of the conjugate action of g are all l-units, but its eigenvalue are of the form $\lambda_i\lambda_j^{-1}$ where λ_k are eigenvalues of g, so this together with the fact $\det(g)$ is l-units shows that all λ_i are l-units.

For the general case, Cf.[Conrad L19 P7].**?** □

Cor. (13.12.1.8) [Filtration of Weil Sheaf]. If X_0 is a normal variety, then for any irreducible lisse Weil-sheaf $\mathcal{G}_0$, there is some $b \in \overline{\mathbb{Q}}_\ell^\times$ and a lisse Weil-sheaf $\mathcal{F}_0$ that $\mathcal{G}_0 \cong \mathcal{F}_0 \otimes \mathcal{L}_b$, where $\mathcal{L}_b$ is the Weil-sheaf corresponding to the character $W(X_0, \overline{x}) \to \overline{\mathbb{Q}}_\ell^\times : x \mapsto b^{\deg(x)}$, which is a pull back from $\mathrm{Spec}\,\mathbb{F}_q$.

More generally, for any lisse Weil-sheaf, there is a filtration that each quotient is of the form $\mathcal{F}_0^{(i)} \otimes \mathcal{L}_{b_i}$ for some $b_i \in \overline{\mathbb{Q}}_\ell^\times$ and $\mathcal{F}_0^{(i)}$ lisse $\overline{\mathbb{Q}}_\ell$-sheaves.

Proof: Just choose $b = \chi_{\det}(\sigma)^{1/n}$, where $\deg(\sigma) = 1$, then

$$\wedge(\mathcal{G}_0 \otimes \mathcal{L}_{b^{-1}}) \cong \wedge(\mathcal{G}_0) \otimes \mathcal{L}_{\chi_{\det}(\sigma)}^{-1}$$

which has unit eigenvalues thus is a lisse $\overline{\mathbb{Q}}_\ell$-sheaf. □

2 Trace Formulae

Def. (13.12.2.1)[Zeta-Functions]. For $\mathcal{F}\in \mathrm{W}\mathcal{S}\mathrm{h}(X_0)$, the **Zeta-function** associated to $\mathcal{F}_0$ is defined to be

$$Z(X_0,\mathcal{F}_0;T)=\prod_{x_0\in|X_0|_0}\det(1-F_{x_0}^*T^{\deg(x)}|\mathcal{F}_{\overline{x}})^{-1}\in 1+T\Lambda[[T]],$$

where $F_{x_0}^*$ is defined in(13.12.1.4). Notice if $\mathcal{F}_0\in \mathcal{S}\mathrm{h}((X_0)_{\text{ét}})$, then $F_{x_0}^*=\varphi_{\kappa(x_0)}^{-1}$ by(13.12.1.4).

Prop. (13.12.2.2). Situation as in(13.12.2.1),

$$Z(X_0,\mathcal{F}_0;T)=\exp(\sum_{n\geq 1}\sum_{x\in X_0(k_n)}\mathrm{tr}(F_x^*|\mathcal{F}_{\overline{x}})\frac{T^n}{n})$$

Proof: By(2.3.10.22),

$$\begin{aligned}Z(X_0,\mathcal{F}_0;T)&=\prod_{x_0\in X(\overline{k})}\exp(\sum_{n\geq 1}\mathrm{tr}((F_{x_0}^*)^n|\mathcal{F}_{\overline{x}})\frac{T^{n\deg(x)}}{n})\\&=\exp(\sum_{n\geq 1}\sum_{x_0\in X_0(\overline{k})}\deg(x)\,\mathrm{tr}((F_{x_0}^*)^n|\mathcal{F}_{\overline{x}})\frac{T^n}{n})\\&=\exp(\sum_{n\geq 1}\sum_{x_0\in X_0(k_n)}\mathrm{tr}(F_{x_0}^*|\mathcal{F}_{\overline{x}})\frac{T^n}{n})\end{aligned}$$

where in the last equality, notice there are exactly $\deg(x_0)$ many points in $X_0(\overline{k})$ over $x_0\in X_0(k_n)$. □

Cor. (13.12.2.3). If $\mathcal{F}=\mathbb{Q}_\ell$, then

$$Z(X_0,\mathbb{Q}_\ell;T)=\prod_{x_0\in|X_0|_0}\frac{1}{1-T^{\deg(x_0)}}$$

is just the Z-function defined in(19.1.4.1).

Lemma (13.12.2.4)[Weil Trace Formula]. Let $X_0\in \mathcal{S}\mathrm{ch}^{\mathrm{sep,ft}}/k$, A be a Noetherian $\mathbb{Z}/(\ell^n)$-algebra, $\mathcal{F}_0\in D^b_{ctf}(X_0,A)$, then

$$\sum_{x_0\in X_0(k)}\mathrm{tr}(F_{x_0}^*|\mathcal{F}_{\overline{x}})=\mathrm{tr}(F_X^*|[R\Gamma_c(X,\mathcal{F})])$$

Proof: Cf.[Fu11]P596?. □

Prop. (13.12.2.5) [General Trace Formula for Frobenius]. Let $X_0\in \mathcal{S}\mathrm{ch}^{\mathrm{sep,ft}}/k,\mathcal{F}_0\in D^b_{\mathrm{const}}(X_0,\overline{\mathbb{Q}}_\ell)$, then

$$\sum_{x_0\in X_0(k)}\mathrm{tr}(\varphi_{\kappa(x)}^{-1}|(\mathcal{F})_{\overline{x}})=\mathrm{tr}(F_X^*|[R\Gamma_c(X,\mathcal{F})]).$$

Proof: Cf.[Fu11]P596?. □

Prop. (13.12.2.6) [Grothendieck-Lefschetz Trace Formula for Weil Sheaves]. For $S_0 \in \mathcal{S}\mathrm{ch}^{\mathrm{ft}}/k$, $f_0 : X_0 \to S_0 \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,ft}}/S$, $\mathcal{F}_0 = (\mathcal{F}, F_{\mathcal{F}}) \in \mathrm{W}\mathcal{S}\mathrm{h}(X_0)$(13.12.1.2),

$$Z(X_0, \mathcal{F}_0; T) = \prod_{n=0}^{2\dim X_0} Z(S_0, R^n f_{0!}\mathcal{F}_0; T)^{(-1)^n}.$$

In particular, for $S = \operatorname{Spec} k$, $X_0 \in \mathcal{S}\mathrm{ch}^{\mathrm{sep,ft}}/k$, by base change and(13.12.1.4),

$$Z(X_0, \mathcal{F}_0; T) = \prod_{n=0}^{2\dim X_0} \det(1 - F_X^* T | H^n_{\text{ét},c}(X, \mathcal{F}))^{(-1)^{n+1}}$$

Notice by(7.4.5.7), the higher proper pushforwards just vanish.

Proof: Use the filtration in(13.12.1.8), notice that the trace is additive for a filtration, so we can reduce to the case $\mathcal{G}_0 = \mathcal{F}_0 \otimes \mathcal{L}_b$ and $\mathcal{G}_{\overline{x}} = \mathcal{F}_{\overline{x}} \otimes \mathcal{L}_{b,\overline{x}}$, then the Euler factors are

$$\det(1 - b^{\deg(x)} \varphi^{-1}_{\kappa(x)} T^{\deg(x)} | \mathcal{F}_{\overline{x}})$$

and the cohomology factor is

$$\det(1 - F_X^* T | H^i_{\text{ét},c}(X, \mathcal{F} \otimes \mathcal{L}_b)) = \det(1 - bF_X^* T | H^i_{\text{ét},c}(X, \mathcal{F}))$$

where the projection formula(7.4.5.8) is used, noticing the $\mathcal{L}_b$ is pulled back from $\operatorname{Spec} \mathbb{F}_q$. Then the assertion is clear from(13.12.2.5) and(13.12.2.2)(13.12.1.4). □

Cor. (13.12.2.7). $Z(X_0, \mathcal{F}_0; T)$ is a rational function in T.

3 Weights and Purity

Determinantial Weights

Prop. (13.12.3.1)[Structure of Weil Group of Curves]. If X_0 is a smooth curve over $\mathbb{F}_q$, then the image of $\pi_1(X, \overline{x})$ in $W(X_0, \overline{x})^{ab}$ is a product of a finite group and a pro-p group.

Proof: Let K be the function field of X_0, $\overline{X_0}$ be the regular completion of X_0, with $S_0 = \overline{X_0} - X_0$, then we have an isomorphism $\pi_1(\overline{X_0}, \overline{x}) \cong G_K$ Cf.[Étale Cohomology Lei Fu P136]?. So we can use global class field theory:

$$\begin{array}{ccccccccc}
 & & \pi_1(\overline{X}, \overline{x})^{ab} & \longrightarrow & \pi_1(\overline{X_0}, \overline{x})^{ab} & \longrightarrow & G_k \cong \widehat{\mathbb{Z}} & \longrightarrow & 0 \\
 & & \downarrow & \searrow & \uparrow & & \uparrow & & \\
0 & \longrightarrow & I_K & \longrightarrow & W(\overline{X_0}, \overline{x})^{ab} \cong W(K,k) & \longrightarrow & W(k) \cong \mathbb{Z} & \longrightarrow & 0 \\
 & & \downarrow\cong & & \downarrow\cong & & \downarrow\cong & & \\
0 & \longrightarrow & K^*\backslash (A_K^*)^1/\prod_v \mathcal{O}_v^* & \longrightarrow & K^*\backslash A_K^*/\prod_v \mathcal{O}_v^* & \longrightarrow & q^{\mathbb{Z}} & \longrightarrow & 0
\end{array}$$

So the image of $\pi_1(\overline{X}, \overline{x})$ factors through $\pi_1(\overline{X}, \overline{x}) \to \pi_1(\overline{X}, \overline{x})^{ab} \to K^*\backslash A_K^*/\prod_v \mathcal{O}_v^*$ which is the class number of K, is finite.

In this diagram, $W(X_0, \overline{x})$ corresponds to $K^*\backslash A_K^*/\prod_{v \notin S_0} \mathcal{O}_v^*$, so

$$0 \to \ker(W(X_0, \overline{x}) \to W(\overline{X_0}, \overline{x})) \to \operatorname{Im}(\pi_1(X_0, \overline{x})) \to \operatorname{Im}(\pi_1(\overline{X_0}, \overline{x})) \to 0$$

But the kernel is a quotient of $\prod_{v \in S_0} \mathcal{O}_v^*$, which is a pro$-p$ group times a finite group, so finally $\operatorname{Im}(\pi_1(X_0, \overline{x}))$ is a product of a pro-p-group times a finite group. □

Lemma (13.12.3.2) [Curve Rank 1 case]. If X_0/k is a smooth curve and $\chi : W(X_0,\overline{x}) \to \overline{\mathbb{Q}}_\ell^\times$ be a continuous character, then there exists a $c \in \overline{\mathbb{Q}}_\ell^\times$ that χ is a product of a character of finite order and the character $\sigma \mapsto c^{\deg(\sigma)}$.

In particular, the Weil-sheaf corresponding to χ is punctually ι-pure of weight $2\log_q|\iota(c)|$.

Proof: By(15.3.1.3), the image of χ is in $\mathcal{O}_E^*$ for some $E \in \ell\text{-}\mathtt{LField}$, so by(13.12.3.1), it has an open subgroup which is pro-p and pro-ℓ so trivial, thus $\pi_1(X_0,\overline{x})$ is mapped to a finite group.

In particular there is an n that $\chi^n = \mathrm{id}$ on $\pi_1(X_0,\overline{x})$, so there is some b that $\chi^n = b^{\deg(\sigma)}$, hence if c is an n-th roots of b and we let $\chi' = \chi/c^{\deg(\sigma)}$, then $(\chi')^n = 1$. □

Cor. (13.12.3.3) [Rank 1 Lisse Sheaf is Pure]. If X_0/k is a smooth curve, then any lisse Weil-sheaf of rank 1 is pure.

Def. (13.12.3.4) [Determinential Weight]. Let $\mathcal{F}_0$ be a lisse Weil-sheaf on a geometrically connected smooth scheme X_0, and $0 = \mathcal{F}_n \subset \mathcal{F}_{n-1} \subset \ldots \subset \mathcal{F}_0$ be a filtration of lisse sheaves that the quotients are irreducible, we define the **determinential ι-weights** of $\mathcal{F}_0$ to be that of the ι-weights of the top wedge products of the successive quotients divided by their ranks, which exists by(13.12.3.3).

Notice that the determinential ι-weights are unchanged when $\mathcal{F}_0$ is replaced by its semisimplification $\mathcal{F}_0^s = \oplus_{i\geq 0}(\mathcal{F}_i/\mathcal{F}_{i-1})$.

Purity

Def. (13.12.3.5) [Purity]. For an embedding $\iota : \overline{\mathbb{Q}}_\ell \to \mathbb{C}$, $\mathcal{F}_0 \in \mathrm{W}\mathcal{S}\mathrm{h}(X_0)$ is called **ι-pure** of weight w if for any closed point $x \in X$, the $\overline{\mathbb{Q}}_\ell$-eigenvalues of $F_{\mathcal{G}}$ on the stalks $\mathcal{F}_x$ are algebraic and satisfy $|\iota(\alpha_i)| = (q^{\deg(x)})^{w/2}$.

It is called **pure of weight** w iff for any closed point $x \in X$, the $\overline{\mathbb{Q}}_\ell$-eigenvalues are $q^{\deg(x)}$-Weil numbers of weight w(12.4.2.13), i.e. ι-pure for any embedding $\iota : \overline{\mathbb{Q}}_\ell \to \mathbb{C}$.

It is said to be **(ι-)mixed** with weights $w_1,\ldots,w_n$ if it has a filtration of constructible $\overline{\mathbb{Q}}_\ell$-sheaves that each quotient is pure of weight w_i respectively.

Example (13.12.3.6). $\mathbb{Q}_\ell(r)$ is pure of weight $-2r$.

Proof: This is because the geometric Frobenius $\varphi_{\kappa(x)}^{-1}$ acts by $1/q^{d_x}$-th power, which is additively multiplying by $(q^{d_x})^{-2/2}$. □

Prop. (13.12.3.7) [Permanence Properties].

- $f_0 : X_0 \to Y_0$ is a morphism, and $\mathcal{G}_0$ is a Weil-sheaf on Y_0, then if $\mathcal{G}_0$ is ι-pure, then $f_0^*\mathcal{G}_0$ is also ι-pure, and the converse is also true if f is surjective.
- If $f_0 : X_0 \to Y_0$ is finite, and $\mathcal{G}_0$ is a Weil-sheaf on X_0, then if $j_0^*(\mathcal{G}_0)$ is ι-pure, then $\mathcal{G}_0$ is ι-pure.
- Let k'/k be a finite field extension, then a Weil-sheaf $\mathcal{G}_0$ on X_0 is pure of weight β iff $(\mathcal{G}_0)_{k'}$ is on $(X_0)_{k'}$.

Proof: 1 is because the stalk corresponds.

2: This is because the stalks can be calculated, by?.

3: ? □

Semicontinuity of Weights

Def. (13.12.3.8) [Maximal Weight]. For a general Weil-sheaf $\mathcal{G}_0$ on X_0, we can also define the **maximal ι-weight** of $\mathcal{G}_0$ as

$$w(\mathcal{G}_0) = \sup_{x\in|X_0|} \sup_{\alpha_i} 2\log_{N(x)}(|\iota(\alpha_i)|).$$

Lemma (13.12.3.9). $|X_0(k_n)| = O(q^{n\dim X})$

Proof: We can pass to the reduced structure of X_0, then we can use excision to pass to the integral case. Then choose an open affine dense subset U_0 of X_0, then by Noetherian normalization, it factors through a finite map $f: U_0 \to \mathbb{A}^{\dim X_0}_{k_n}$, so

$$|U(k_n)| \leq (\deg f) q^{n\dim X_0}$$

Then we can use induction on dimension, because $\dim(X_0 - U_0) < \dim X_0$. □

Lemma (13.12.3.10). Let $\mathcal{G}_0$ be a Weil-sheaf on X_0 and β be a real number that $\beta \geq w(\mathcal{G}_0)$, then the L-function

$$\iota(L(X_0,\mathcal{G}_0,t)) = \prod_{x\in|X_0|} \iota(\det(1-t^{d_x}F_x,\mathcal{G}_{0,\overline{x}})^{-1})$$

converges for $|t| < q^{-\beta/2-\dim X_0}$ and has no zero or pole there.

Proof: We can show that it has no zero or pole using the fact that the logarithmic derivative has no poles(when it is convergent). We suppress the isomorphism $\iota: \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ and calculate:

$$\frac{d\log}{dt} L(X_0,\mathcal{G}_0,t) = \sum_{x\in|X_0|}\sum_{n\geq 1} d_x(\mathrm{tr}(F_x^n))t^{d_x n-1}\mathbf{??} = \sum_{n\geq 1}\sum_{x\in|X_0|,d_x|n} d_x(\mathrm{tr}(F_x^{n/d_x}))t^{n-1}$$

Notice by assumption on β, $|\mathrm{tr}(F_x^{n/d_x})| \leq rq^{n\beta/2}$, where $r = \max_{x\in|X_0|}\dim_{\overline{\mathbb{Q}}_\ell}\mathcal{G}_{0,x}$ is finite because it has a stratification by(7.4.7.15), so

$$|\frac{d\log}{dt} L(X_0,\mathcal{G}_0,t)| \leq \sum_{n\geq 1}\sum_{x\in|X_0|,d_x|n} d_x r q^{n\beta/2}t^{n-1} = \sum_{n\geq 1}|X_0(k_n)| r q^{n\beta/2}t^{n-1}$$

converges for $|t| < q^{-\beta/2-\dim X_0}$ by(13.12.3.9). □

Lemma (13.12.3.11) [Semicontinuity of Weights for Curves]. If X_0/k be a smooth curve and $U_0 \xrightarrow{j_0} X_0$ be a nonempty open with $S_0 = X_0 - U_0$. Let $\mathcal{G}_0$ be a Weil-sheaf on X_0 s.t. the restriction $j_0^*\mathcal{G}_0$ is lisse and $H^0_S(X,\mathcal{G}) = 0$, then $w(j_0^*(\mathcal{G}_0)) \leq \beta$ implies $w(\mathcal{G}_0) \leq \beta$.

Proof: For any point x, consider an affine open subset of X_0, then reduce to the affine case, and because $H^0_S(X,\mathcal{G}) = 0$ and the excision sequence(7.4.5.5), we have $\mathcal{G} \hookrightarrow j_*j^*\mathcal{G}$, so the weights of $\mathcal{G}_0$ are no more than that of $j_*j^*\mathcal{G}$, and replacing $\mathcal{G}_0$ with $j_{0*}j_0^*\mathcal{G}_0$, we can assume $\mathcal{G}_0 = j_{0*}j_0^*\mathcal{G}_0$. Then

$$H^0_c(X,\mathcal{G}) = H^0_c(X,j_*j^*\mathcal{G}) = H^0_c(U,j^*\mathcal{G}) = 0$$

by Poincare duality and the fact j_* is exact because it is finite.

Now by Grothendieck-Lefschetz trace formula,

$$L(X_0,\mathcal{G}_0,t)=L(U_0,j_0^*(\mathcal{G}_0),t)\cdot\prod_{s\in|S_0|}\det(1-t^{d_s}F_s,\mathcal{G}_{\overline{s}})^{-1}=\frac{\det(1-F_Xt|H^1_{\text{ét},c}(X,\mathcal{G}))}{\det(1-F_Xt|H^2_c(X,\mathcal{G}))}$$

Denote $\mathcal{F}_0=j_0^*\mathcal{G}_0$, then

$$H^2_c(X,\mathcal{G})=H^2_c(U,\mathcal{F})=(\mathcal{F}_{\overline{x}})_{\pi_1(U,\overline{x})}(-1)$$

So the weights of eigenvalues of F_X on $H^2_c(X,\mathcal{G})\le$ weights of $\mathcal{F}+2$, hence the L-function converges for $|t|<q^{-\beta/2-1}$. Now the LHS has $L(U_0,j_0^*(\mathcal{G}_0),t)$ converges for $|t|<q^{-\beta/2-1}$ because $w(\mathcal{F}_0)\le\beta$, and so for the points in S_0, we also have $\det(1-t^{d_s}F_s,\mathcal{G}_{\overline{s}})$ has no zero there, which means they have weights$\le\beta+1$. Now consider replacing $\mathcal{G}_0$ with $\mathcal{G}_0^{\otimes k}$ and let $k\to\infty$, then their weights$\le\beta$. □

Prop. (13.12.3.12) [Semicontinuity of Weights]. Let X_0 be geo.normal, $\mathcal{G}_0$ be a lisse sheaf on X_0 and $j_0:U_0\to X_0$ be an open dense subscheme, then

- $w(\mathcal{G}_0)=w(j_0^*\mathcal{G}_0)$.
- If $j_0^*(\mathcal{G}_0)$ is ι-pure of weights β, then $\mathcal{G}_0$ is also ι-pure of weights β.
- Let X_0 be irreducible and normal, and $\mathcal{G}_0$ is irreducible, then if $j_0^*\mathcal{G}_0$ is ι-mixed, then $\mathcal{G}_0$ is ι-pure.

Proof: 1: The weights is local so we may assume X_0 is irreducible, and then for any closed point x, we can connect it with U_0 with a curve(choose an affine open and use Noetherian Normalization to choose an irreducible component of an arbitrary curve in $\mathbb{A}^n$). Notice $H^0_S(X,\mathcal{G})=0$ because it is lisse thus $H^0(X,\mathcal{G})$ is determined by stalk thus $H^0(X,\mathcal{G})\to H^0(U,\mathcal{G}|_U)$ is injective. So we finish by the curve case(13.12.3.11).

2: Apply item1 to $\mathcal{G}_0$ and $\mathcal{G}_0^\vee$.

3: It is ι-mixed so it has ι-pure Weil-sheaf constituents. Now by(7.4.7.15) we can find an open dense U_0 that restriction to U_0 has constituents ι-pure lisse sheaves. But it is also irreducible because $\pi_1(U_0,\overline{a})\to\pi_1(X_0,\overline{a})$ is surjective**?**, so it is ι-pure and item2 shows $\mathcal{G}_0$ is ι-pure. □

L^2-Norms and Maximal Weights

Def. (13.12.3.13). As in(13.12.8.1), for any $\mathcal{G}_0\in D^b_{cons}(X_0,\overline{\mathbb{Q}}_\ell)$, we have a a function

$$f^{\mathcal{G}_0}:X_0(\mathbb{F}_{q^n})\to\overline{\mathbb{Q}}_\ell:x\mapsto\sum_i(-1)^i\operatorname{tr}(F_x^{n/d_x}|(H^i(\mathcal{G}_0))_{\overline{x}}),$$

Fix an arbitrary isomorphism $\overline{\mathbb{Q}}_\ell\cong\mathbb{C}$, we can consider the usual L^2-norm for functions on $X_0(k_n)$, denoted by $(f,g)_n$.

Def. (13.12.3.14). Notice the equation form(13.12.3.10) can be rewritten as

$$\frac{d\log}{dt}L(X_0,\mathcal{G}_0,t)=\sum_{n\ge1}\sum_{x\in|X_0|,d_x|n}d_x(\operatorname{tr}(F_x^{n/d_x}))t^{n-1}=\sum_n(f^{\mathcal{G}_0},1)_nt^{n-1}.$$

Now we define another closed related function

$$\varphi^{\mathcal{G}_0}(t)=\sum_n||f^{\mathcal{G}_0}||_n^2t^{n-1},$$

which works better with Fourier transform we are about to define later.

Lemma (13.12.3.15). There is a constant C that $||f^{\mathcal{G}_0}(x)||^2 \leq Cq^{n(w(\mathcal{G}_0)+\dim X_0)}$, so $\varphi^{\mathcal{G}_0}(t)$ converges for $|t| \leq q^{-w(\mathcal{G}_0)-\dim X_0}$.

Proof: The proof is similar to that of(13.12.3.10) thus omitted. □

Def. (13.12.3.16) [Norm of a Weil Sheaf]. Define the Norm of a Weil-sheaf as

$$||\mathcal{G}_0|| = \sup\{\rho| \limsup_n \frac{||f^{\mathcal{G}_0}||_n^2}{q^{n(\rho+\dim X_0)}} > 0\}$$

Then $q^{-||\mathcal{G}_0||-\dim X_0}$ is just the radius of convergence of the function $\varphi^{\mathcal{G}_0}(t)$, and $||\mathcal{G}_0|| \leq w(\mathcal{G}_0)$ by lemma(13.12.3.15) above.

Prop. (13.12.3.17) [Radius of Convergence]. Let $\mathcal{G}_0$ be a ι-mixed sheaf on a smooth curve X_0 over k, and $H^0_{\text{ét},c}(X, \mathcal{G}) = 0$, then $||\mathcal{G}_0|| = w(\mathcal{G}_0) = \beta$.

Proof: It suffices to show $w(\mathcal{G}_0) \leq ||\mathcal{G}_0||$. First notice we can assume X_0 is reduced because the nilpotents corredsponds to zero Frobenius eigenvalues, and also it is connected, because the function $f^{\mathcal{G}_0}$ is additive in X. Now we study by cases:

1: If $\mathcal{G}_0$ is a lisse ι-pure sheaf on a smooth affine curve X_0, we may assume $\mathcal{G}_0 \neq 0$, then $\mathcal{G}_0 \otimes \overline{\mathcal{G}_0}$(13.12.5.2) is ι-real of weight 2β and $(f^{\mathcal{G}_0\otimes\overline{\mathcal{G}_0}}, 1)_n = ||f^{\mathcal{G}_0}||_n^2$, so $\varphi^{\mathcal{G}_0}(t)$ is just the logarithmic derivative of the L-function $L(X_0, \mathcal{G}_0 \otimes \overline{\mathcal{G}_0}, t)$, thus(13.12.3.10) shows its convergence radius$\geq q^{-\beta-1}$. And notice the H^0_c terms vanish so the poles can only appear as the zeros of H^2_c term, so(13.12.5.3) shows the poles of the $L(X_0, \mathcal{G}_0 \otimes \overline{\mathcal{G}_0}, t)$ has weight $2\beta + 2$, thus the poles can only appear on $|t| = q^{-\beta-1}$.

Now consider each local Euler factor $\det(1 - F_x t^{d_x} |(\mathcal{G}_0 \otimes \overline{\mathcal{G}_0})_x)^{-1}$ has non-negative coefficients, they have poles because $\mathcal{G}_0 \neq 0$, and their poles have weight β because of purity, thus their product also has (real)poles, by previous argument, the pole has weight $\beta + 1$, thus it has convergence radius at most $q^{-\beta-1}$, so we are done.

2: If $\mathcal{G}_0$ is a ι-mixed, consider its semisimplification $\mathcal{G}_0^{ss} = \mathcal{F}_0 \oplus \mathcal{H}_0$, where $\mathcal{F}_0$ is ι-pure of weight $w(\mathcal{G}_0)$, and $w(\mathcal{H}_0) \leq w(\mathcal{F}_0)$.

Then $f^{\mathcal{G}_0} = f^{\mathcal{F}_0} + f^{\mathcal{H}_0}$, and

$$\varphi^{\mathcal{G}_0}(t) = \varphi^{\mathcal{F}_0}(t) + \sum_{n\geq 1} 2\operatorname{Re}(f^{\mathcal{F}_0}, f^{\mathcal{H}_0})_n t^{n-1} + \varphi^{\mathcal{H}_0}(t)$$

then by item1 $\varphi^{\mathcal{F}_0}(t)$ has convergence radius $q^{-w(\mathcal{G}_0)-1}$, and by(13.12.3.15) $\varphi^{\mathcal{H}_0}(t)$ has radius at least $q^{-w(\mathcal{H}_0)-1} > q^{-w(\mathcal{G}_0)-1}$, and by Cauchy inequality the middle term satisfies

$$|2\operatorname{Re}(f^{\mathcal{F}_0}, f^{\mathcal{H}_0})_n| \leq 2||f^{\mathcal{F}_0}||_n ||f^{\mathcal{H}_0}||_n \leq Cq^{n(w(\mathcal{F}_0)+w(\mathcal{H}_0)/2+1)}$$

So the middle term has convergence radius$>$ $q^{-w(\mathcal{G}_0)-1}$, so their sum has convergence radius $q^{-w(\mathcal{G}_0)-1}$. □

4 Geometric Monodromy

Def. (13.12.4.1) [Notations]. Let X_0 be a geometrically connected normal scheme over $k = \mathbb{F}_q$ in this subsection.

Def. (13.12.4.2) [Geometric Monodromy Group]. Let $\mathcal{G}_0$ be a Weil-sheaf associated to a representation $(V,\rho) = GL(\mathcal{G}_{\overline{x}})$ of $W(X_0,\overline{x})$, the **geometric monodromy group** G_{geo} associated to $\mathcal{G}_0$ is the Zariski Closure of $\rho(\pi_1(X,\overline{x})) \subset GL(V)$.

Every element in $\rho(W(X_0,\overline{x}))$ normalizes G_{geo} by continuity, so choosing an arbitrary generator $\sigma \in W(\overline{k}/k)$, we have an action of $W(\overline{k}/k)$ on G_{geo}. Define $G = W(\overline{k}/k) \ltimes G_{geo}$ the **arithmetic monodromy group** of $\mathcal{G}_0$.

Lemma (13.12.4.3). If G_{geo} is connected, then there is a positive integer N that the semidirect sequence

$$1 \to G_{geo} \to \deg^{-1}(N\mathbb{Z}) \xrightarrow{\deg} N\mathbb{Z} \to 1$$

is direct, i.e. $\deg^{-1}(N\mathbb{Z}) \cong G_{geo} \times \mathbb{Z}$.

Proof: Choose a $\deg(g) = 1$. The representation G_{geo} splits as a characters of $Z(G)$, and then some g^n stablizes these characters, hence stablizes $Z(G)$, which then it descends to an action on G_{adj}, whose automorphism is the automorphism of the Dynkin diagram**?**, so finite, so some g^m fixes G_{adj} after changing a semidirect product, thus induces a map $\mathrm{Hom}(G_{adj}, Z(G))$, but G_{adj} is semisimple(8.3.3.19), so the connected component is mapped to 1 in $Z(G)$(8.3.3.17), so there are only f.m. such homomorphism, showing g^k is 1, so the product is exact for $N = k$. □

Prop. (13.12.4.4) [Geometric Monodromy Group is Semisimple]. Let $\mathcal{G}_0$ be a geometrically semisimple lisse Weil-sheaf(13.12.1.5), then

- G_{geo} and G_{geo}^0 are semisimple algebraic group.
- Let $Z = Z(G(\overline{\mathbb{Q}}_\ell))$, then the map $\psi : Z \to W(\overline{k}/k)$ has finite kernel and cokernel. In particular, Z contains an element of finite degree, and it is surjective after a finite base change of fields.

And notice in fact if $\mathcal{G}_0$ is semisimple, then it is automatically geometrically semisimple by(15.1.2.10).

Proof: 1: L G_{geo} is semisimple iff G_{geo}^0 is semisimple. Pass to a finite étale covering, we may assume $G_{geo} = G_{geo}^0$. Let $R(G_{geo}^0)$ be the radical and $R_u(G_{geo}^0)$ be the unipotent radical, then R is normal in G^0 and G^0 is normal in G, so by(15.1.2.10) $V = GL(\mathcal{G}_{\overline{x}})$ is irreducible $R(G_{geo}^0)$ representation, but it is solvable, so V is a direct sum of 1-dimensional representations, and $R_u(G_{geo}^0)$ is trivial, in particular G_{geo}^0 is reductive. So it is semisimple if the maximal Abelian quotient G_{geo}^{ab} is finite(8.3.3.17).

let T_1 be the maximal central torus of G_{geo}^0, then lemma(13.12.4.3) shows after a finite base change of fields, we may assume $G = G_{geo} \times \mathbb{Z}$, consider the composite $W(X_0,\overline{x}) \to G_{geo} \times \mathbb{Z} \to G_{geo} \to G_{geo}^{ab}$, then $\pi_1(X,\overline{x})$ is Zariski dense in G_{geo}^{ab}, and (13.12.3.3) shows clearly G_{geo}^{ab} has no maximal torus thus finite.

2: $\ker\psi \subset Z(G_{geo}(\overline{\mathbb{Q}}_\ell))$ is finite since G_{geo} is semisimple. To find an element in $Z(G)$ of positive degree, we may use the same method as before to find an element ζ that commutes with G_{geo}^0, and pass to a power, we may assume it acts trivially on G_{geo}/G_{geo}^0.

For any $g \in G_{geo}$, consider $vp_g(n) = g\zeta^n g^{-1}\zeta^{-n} \in G_{geo}^0$, so $\varphi_g(m+n) = \varphi_g(n)\zeta^n\varphi_g(m)\zeta^{-n} = \varphi_g(n)\varphi_g(m)$, thus it is a homomorphism, and if $g' \in G_{geo}^0$, then

$$\varphi_g = \varphi_{g(g^{-1}g'g)} = \varphi_{g'g} = g'\varphi_g(g')^{-1}$$

so φ_g has image in $Z(G_{geo}^0)$, which is finite, so $\varphi_g(n) = 1$ for some n, then ζ^n commutes with G_{geo} so $\zeta^n \in Z(G)$. □

Cor. (13.12.4.5) [Weights and Center Element Actions]. Let $\mathcal{G}_0$ be a semisimple lisse Weil-sheaf on X_0, if $z \in Z(G(\overline{\mathbb{Q}}_\ell))$ satisfies $\deg(z) = n \neq 0$, which exists by(13.12.4.4), then if z acts on V with eigenvalues α_i, then $\frac{2}{n}\log_q(|\iota(\alpha_i)|)$ is just the determinential ι-weights of $\mathcal{G}_0$.

Proof: z is in the center, thus by Shur's lemma, it acts on each irreducible part of $\mathcal{G}_0$ by a constant. Thus the determinential weights are clear, by definition. □

Cor. (13.12.4.6) [Properties of Determinential Weights]. Let X_0/k be a smooth curve, $\mathcal{F}_0, \mathcal{G}_0$ be lisse Weil-sheaves on X_0, then

- If α_i are the determinential ι-weights of $\mathcal{F}_0$ and β_j be that of $\mathcal{G}_0$, then $\alpha_i + \beta_j$ are those of $\mathcal{F}_0 \otimes \mathcal{G}_0$ with multiplicity.
- For $\gamma \in \mathbb{R}$, let $r(\gamma)$ be the sum of ranks of all irreducible constituents of $\mathcal{F}_0$ which have determinential weight γ w.r.t ι, then the determinential weights of $\wedge^r \mathcal{F}_0$ are the numbers $\sum_\gamma n(\gamma)\gamma$ with $\sum n(\gamma) = r$ and $0 \leq n(\gamma) \leq r(\gamma)$, $n(\gamma) \in \mathbb{Z}$ with multiplicity.

Proof: Firstly notice the determinential weight is unchanged when we change $\mathcal{F}_0, \mathcal{G}_0$ to their semisimplification $\mathcal{F}_0^{ss}, \mathcal{G}_0^{ss}$(13.12.3.4). And notice $(\mathcal{F}_0 \otimes \mathcal{G}_0)^{ss} = ((\mathcal{F}_0)^{ss} \otimes (\mathcal{G}_0)^{ss})^{ss}$, thus the determinential weights of $\mathcal{F}_0 \otimes \mathcal{G}_0$ are also unchanged. Similarly for the wedge product.

2: We may assume $\mathcal{F}_0, \mathcal{G}_0$ are irreducible, and let $\mathcal{H}_0 = (\mathcal{F}_0 \otimes \mathcal{G}_0)^{ss}$, $G_{geo}^{\oplus}, G_{geo}^{ss}$ be the geometric monodromy group of $\pi_1(X, \overline{x})$ in $GL(\mathcal{F}_{\overline{x}} \oplus \mathcal{G}_{\overline{x}})$ and $GL(\mathcal{H}_{\overline{x}})$ correspondingly, then $G_{geo}^{\oplus} \to G_{geo}^{ss}$ is surjective because they are both the geometric monodromy group of $\mathcal{H}_{\overline{x}}$. So also $G^{\oplus} \to G^{ss}$ is surjective. So if g be an element in the center of $G^{\oplus}$ that has nonzero degree, then it maps to the center of G^{ss} of nonzero degree. And the action of g on each factor $\mathcal{F}_x, \mathcal{G}_x$ is a constant, so action on H_x is also a constant, so we are done.

3: Easy from2. □

5 Real Sheaves

Def. (13.12.5.1) [ι-Real Sheaf]. Let $\mathcal{F}_0$ be a Weil-sheaf on X_0, then $\mathcal{F}_0$ is called **ι-real** if for any $x \in |X_0|$, the characteristic polynomial $\iota(\det(1 - F_x t; \mathcal{F}_{\overline{x}}))$ of F_x real coefficients.

Prop. (13.12.5.2). Any ι-pure Weil-sheaf of weight w is a direct sum of a ι-real ι-pure Weil-sheaf. In fact, $\mathcal{F}_0 \oplus \mathcal{F}_0^\vee(-w) = \mathcal{F}_0 \oplus \overline{\mathcal{F}_0}$ is ι-real.

Lemma (13.12.5.3) [Eigenvalue of Cohomology and Stalk in Curve case]. Let X_0/k be a smooth curve, $\mathcal{F}_0 \in \mathrm{W}\mathcal{S}\mathrm{h}(X_0)$ is lisse, then the eigenvalues of F_X on $H^0(X, \mathcal{F})$ or $H^2_{\text{ét},c}(X, \mathcal{F})$ is related to the determinential weights of $\mathcal{F}_0$ and the eigenvalue of F_x on $\mathcal{F}_{\overline{x}}$.

Proof: Let $V = \mathcal{F}_{\overline{x}}$, then

$$H^0(X, \mathcal{F}) = V^{\pi_1(X, \overline{x})}, \quad H^2_c(X, \mathcal{F}) = V_{\pi_1(X, \overline{x})}(-1).$$

Then the base change sheaf of the sheaf $V^{\pi_1(X,\overline{x})}$ or $V_{\pi_1(X,\overline{x})}(-1)$ on $\operatorname{Spec} k$ is the maximal subsheaf/quotient lisse sheaf of $\mathcal{F}_0$ that is constant on X. Then it has determinential weights just the action of F_X on the stalk by(13.12.4.5), which are also determinential weights of $\mathcal{F}_0$ by(13.12.4.6). □

Lemma (13.12.5.4) [Rankin-Selberg Method]. Let X_0/k be a smooth curve, $\mathcal{F}_0 \in \mathrm{W}\mathcal{S}\mathrm{h}(X_0)$ is lisse, and w be the largest determinential weight of $\mathcal{F}_0$, then for any $x \in |X_0|$, $w_{N(x)}(\alpha) \leq w$.

Proof: By the arbitraryness of x, we can replace X_0 by an affine open nbhd of x. Then $H^0_c(X,\mathcal{G})=0$ by Artin vanishing(7.4.2.12). By Grothendieck trace formula,

$$\prod_{x\in|X_0|}\iota\det(1-t^{d_x}F_x|\otimes^{2k}\mathcal{F}_{\overline{x}})^{-1}=\frac{\iota\det(1-tF_X^*|H^1_c(X,\otimes^{2k}\mathcal{F}))}{\iota\det(1-tF_X^*|H^2_c(X,\otimes^{2k}\mathcal{F}))}$$

Now the weight of root t_0 of $\det(1-tF_X^*|H^2_c(X,\otimes^{2k}\mathcal{F}))$ has weight$\leq$(determinential weight of $\mathcal{G}_0^{\otimes 2k}$)$+2$(13.12.5.3) $\leq 2kw+1$(13.12.4.6), so $|t_0|\geq q^{-k\beta-1}$.

Now by the formula**??** and noticing $\mathrm{tr}(F_x^n,\otimes^{2k}\mathcal{F}_{\overline{x}})=(\mathrm{tr}(F_x,\mathcal{F}_{\overline{x}}))^{2k}$, so $(1-t^{d_x}F_x|\otimes^{2k}\mathcal{F}_{\overline{x}})^{-1}$ has non-negative coefficients, which means their convergence radius are no less than $q^{-k\beta-1}$, equivalently, $(1-t^{d_x}F_x|\otimes^{2k}\mathcal{F}_{\overline{x}})$ has no zeros with eigenvalue$< q^{-k\beta-1}$.

So for any eigenvalue α of F_x acting on $\mathcal{F}_{\overline{x}}$, $|\iota(\alpha^{-2k/d_x})|\leq q^{-k\beta-1}$, or equivalently,

$$|\iota(\alpha)|^2\leq N(x)^{\beta+1/k}.$$

Now let $k\to\infty$, we are done. □

Lemma (13.12.5.5) [Real Sheaf Mixed Curve case]. Let X_0/k be smooth curve and $\mathcal{F}_0\in\mathrm{W}\mathcal{S}\mathrm{h}(X_0)$ is ι-lisse, then all irreducible constituents of $\mathcal{F}_0$ is ι-pure, and their ι-weights coincides with their determinential weights.

Proof: For $\beta\in\mathbb{R}$, let $\mathcal{F}_0(\beta)$ be the sum of constituents of $\mathcal{F}_0$ of determinential weight β, and let $n(\beta)=\mathrm{rank}(\mathcal{F}_0(\beta))$, then we need to show that $w_{N(x)}(\alpha_i(\beta))=\beta$ for any eigenvalue of $\mathcal{F}_x$ on $\mathcal{F}(\beta)_{\overline{x}}$.

By definition of determinential weight, for each γ, we have $\sum w_{N(x)}(\alpha_j(\gamma))=n(\gamma)\gamma$. Now let $N=\sum_{\gamma>\beta}n(\gamma)$, then any determinential weight of $\wedge^{N+1}\mathcal{F}_0$ has weight$\leq\beta+\sum_{\gamma>\beta}n(\gamma)\gamma$: This is clear by(13.12.4.6) as the determinential weights of $\wedge^{N+1}\mathcal{F}_0$ is of the form $\sum_\gamma a(\gamma)\gamma$ that $0\leq a(\gamma)\leq\gamma$ and $\sum_\gamma a(\gamma)=N+1$.

But now $\alpha_i(\beta)\prod_{\gamma>\beta}\prod_{i=1}^{n(\gamma)}\alpha_j(\gamma)$ is an eigenvalue of $(\wedge^{N+1}\mathcal{F}_0)_{\overline{x}}$, but by lemma(13.12.5.4), $w_{N(x)}(\alpha_i(t))\leq t$. Thus we must have equality $w_{N(x)}(\alpha_i(\beta))=\beta$. □

Prop. (13.12.5.6) [Real Sheaf is Mixed]. Let X_0 be an algebraic scheme over $\mathbb{F}_q$, then

- Any ι-real Weil-sheaf on X_0 is ι-mixed.
- If X_0 is irreducible and normal, any irreducible constituent of a lisse of an ι-real sheaf is ι-pure.

Proof: Cf.[Bhatt P28], [KW, P36].

We have the following devissages:

- Choose an open subset $j_0:U_0\hookrightarrow X_0, S_0=X_0-U_0$ and consider the fundamental excision sequence(7.4.5.4), we can reduce to an open affine subscheme $U_0\subset X_0$.
- We may base change to a finite field extension.**?**
- So we may reduce to the case X_0 is smooth, irreducible affine, and $\mathcal{G}_0$ is lisse, with all the irreducible constituents geometrically irreducible(by base change, because they are geometrically semisimple(13.12.4.4)). And we may assume $\dim X_0>1$ because the curve case is proven.
- Change k to the alg.closure of k in the function field of X_0, we can assume X_0 is geometrically irreducible by(5.4.3.16).

Embed X_0 in some projective space $\mathbb{P}^N_0$, then by a suitable Bertini theorem, the linear subspaces of codimension $\dim X-1$ that intersects X with a non-empty smooth irreducible curve C_L is dense in the Grassmannian. Now the closed points in any C_L is a pure-point for the any irreducible component $\mathcal{F}_0$ of $\mathcal{G}_0$ of the same weights. Now let L vary, then there is a dense subset of a finite extension of X_0 that $\mathcal{F}_0$ is pure. So we are done. □

6 Deligne's Purity Theorem

Thm. (13.12.6.1)[Deligne's Purity Theorem]. If $f : X_0 \to Y_0$ is a separated morphism of algebraic scheme over k, and $\mathcal{F}_0$ is a lisse $\overline{\mathbb{Q}}_\ell$-sheaf on X that is mixed weights$\geq n$, then for any integer $i \geq 0$, the sheaf $R^i f_! \mathcal{F}$ is also ι-mixed of weights$\leq n + i$.

Moreover, each ι-weight of of $R^i f_! \mathcal{F}$ is equivalent modulo $\mathbb{Z}$ to an ι-weight of $\mathcal{F}$. In particular, if all ι-weights of $\mathcal{F}$ is integral, then so is $R^i f_! \mathcal{F}$.

Proof: This follows from(13.12.6.6). □

Cor. (13.12.6.2). If X_0 is a smooth separated algebraic scheme over k, $\mathcal{F}_0$ is mixed of weight $\geq n$, then $\mathrm{H}^i_{\text{ét}}(X, \mathcal{F})$ is mixed of weights $\geq n + i$.

Proof: By Poincaré duality(7.4.8.11), $H^{2d-n}_{\text{ét},c}(X, \mathcal{F}^\vee(d)) = (\mathrm{H}^n_{\text{ét}}(X, \mathcal{F}))^\vee$ as Galois representation, and $\mathcal{F}^\vee(d)$ is still a lisse sheaf pure of weight $-w-2d$, thus Deligne's purity theorem(13.12.6.1) shows that $H^{2d-n}_{\text{ét},c}(X_{\overline{k}}, \mathcal{F}^\vee(d))$ has weight $\leq (-w - 2d) + (2d - n) = -w - n$, thus we are done. □

Cor. (13.12.6.3)[Weil's Conjecture]. Let X_0 be a smooth separated algebraic k-scheme, and $\mathcal{F}_0$ is a lisse $\overline{\mathbb{Q}}_\ell$-sheaf which is pure of weight w, then the image of $H^n_{\text{ét},c}(X, \mathcal{F})$ in $\mathrm{H}^n_{\text{ét}}(X, \mathcal{F})$ is pure of weight $w + n$.

Proof: The morphism $H^n_{\text{ét},c}(X, \mathcal{F}) \to \mathrm{H}^n_{\text{ét}}(X, \mathcal{F})$ defined in(7.4.5.6) is compatible with Frobenius, so from(13.12.6.2) we know the image has weights$\geq w + n$, so combined with Deligne's purity theorem(13.12.6.1), we know it is pure of weight $w + n$. □

Cor. (13.12.6.4). If $f_0 : X_0 \to Y_0$ is a smooth proper map of algebraic schemes and $\mathcal{F}_0$ is ι-pure of weight β, then $R^i f_{0,*} \mathcal{F}_0$ is ι-pure of weight $\beta + i$.

Proof: Use proper base change of(7.4.5.5) to reduce to the case of(13.12.6.3). Notice in the proper case, $Rf_* = Rf_!$. □

Cor. (13.12.6.5) [Riemann Hypothesis]. If $X_0 \in \mathcal{S}m\mathcal{P}rpr/k$, then $\mathrm{H}^n_{\text{ét}}(X; \mathbb{Q}_\ell)$ as a Weil-sheaf over $\operatorname{Spec} k$, is pure of weight n.

Reduction to Curve case

Prop. (13.12.6.6). Deligne's purity theorem(13.12.6.1) can be reduced to case that X_0 is a smooth geometrically connected affine curve$\subset \mathbb{A}^1_{\mathbb{F}_q}$ and $\mathcal{F}_0$ a lisse $\overline{\mathbb{Q}}_\ell$-sheaf.

Proof: We have the following dévissages:

- It is trivial in case f_0 is quasi-finite. This is because of(7.4.5.7), as the fiber has dimension 0.
- We can replace X_0 by an affine open $U_0 \subset X_0$ by Noetherian induction and excision sequence(7.4.5.5), which commutes with Frobenius action.
- If the conclusion is true for g_0, h_0, then it is true for $f_0 = g_0 \circ h_0$, this follows from the Leray spectral sequence(7.4.5.5), which is Frobenius equivariant by(7.4.2.27).
- We can replace Y_0 with an affine open $U_0 \subset Y_0$: If the image f_0 is not dense, then trivial, if it is dense, then choose any affine open U_0, then it suffices to prove for $f_0 : f_0^{-1}(U_0) \to Y_0$ by item2, then then by item3 it suffice to prove for $f_0 : f_0^{-1}(U_0) \to U_0$, because $U_0 \hookrightarrow Y_0$ is quasi-finite and use item1.

Now we claim we can reduce to the case of $f_0 : X_0 \to Y_0$ surjective affine smooth with the fibers being geometrically irreducible curves: By devissage2 and 4, we may assume X_0, Y_0 is affine, thus f_0 is affine. Take a generic point η of Y_0, then $(X_0)_\eta \to \operatorname{Spec} k(\eta)$ is affine hence by Noetherian normalization(4.2.4.22) there is a finite map $X_\eta \to \mathbb{A}^n_{k(\eta)}$, and this spread out to a finite morphism $f_0^{-1}(U_0) \to U_0$ for some affine open $U_0 \subset Y_0$ because f_0 is of f.t.. Then by Devissage1 and 3 we are reduced to the case $A^1_{Y_0} \to Y_0$. Now by(7.4.7.15), there is an affine open $U_0 \subset A^1_{Y_0}$ that $\mathcal{F}_0|_{U_0}$ is lisse, so by Devissage2 we may change X_0 to U_0.

That is we reduced to the case that $\mathcal{F}_0$ is lisse and X_0 is open in $A^1_{Y_0}$ so f_0 is smooth affine, in particular open(5.6.4.4), so we can replace Y_0 by $f(X_0)$ and assume f_0 is surjective. Then the fiber are all geometrically irreducible curves.

Then the assertion about weights are clear from proper base change(7.4.5.5) and the curve case.

For the ι-mixedness, we may use(13.12.5.2) and(13.12.5.6) to reduce to showing that $R^i f_!$ maps ι-real sheaves to ι-real sheaves.

for a geometric point $\overline{x} \to x \to X_0$, let $C \to C_0$ be the fiber, which is affine irreducible, so $H^0_c(X, \mathcal{F}) = 0$ by Poincaré duality(7.4.8.11) and Artin vanishing theorem(7.4.2.12), so

$$\iota L(C_0, \mathcal{G}_0, t) = \frac{\iota \det(1 - tF_X^* | H^1_c(C, \mathcal{G}|_C))}{\iota \det(1 - tF_X^* | H^2_c(C, \mathcal{G}|_C))}$$

by Grothendieck-Lefschetz formula(13.12.2.6). Now we can use Poincare duality and the definition that $\mathcal{G}_0$ is pure of weight β, we know $H^2_c(C, \mathcal{G}|_C)$ is pure of weight $\beta+2$, by(13.12.5.3). And $H^2_c(C, \mathcal{G}|_C)$ has weights smaller than $\beta + 1$ by the curve case, so the two polynomial is coprime, and both has constant coefficient 1, which shows they are both real. And then by proper base change(7.4.5.5), this just says $R^i f_{0!}\mathcal{G}_0$ is ι-real. □

Third Reduction

Prop. (13.12.6.7). If X_0 is a smooth affine curve$\subset \mathbb{A}^1_{\mathbb{F}_q}$ and $\mathcal{F}_0$ a lisse $\overline{\mathbb{Q}}_\ell$-sheaf, the Deligne's purity theorem is true.

Proof: We have the following devissages:

- We only need to check for $H^1_c(X, \mathcal{F})$, because H^0_c vanish by Poincaré duality(7.4.8.11) and Artin vanishing theorem(7.4.2.12) and , $H^2_c(X, \mathcal{F})$ is dealt with in(13.12.5.3).
- We are free to pass to finite base change.
- We may assume $\mathcal{F}_0$ is geometrically irreducible: By(13.12.4.4), all the irreducible constituents of $\mathcal{F}_0$ are geometrically semisimple, so pass to a finite base change, we may assume that its irreducible filtration is just the geometric irreducible filtration, then because $H^0_c = 0$, H^1_c is left exact.
- We can assume that $\mathcal{F}_0$ can be extended to a lisse sheaf on ∞. This is because we can choose a closed point and move it to ∞ by using Möbius transform, after a finite base change.
- We can assume $\mathcal{F}_0$ is not geometrically constant: if $\mathcal{F}_0 \cong \underline{\overline{\mathbb{Q}}_\ell}$, then let $i : U_0 \to P^1_{\mathbb{F}_q}$ and $Z_0 = P^1_{\mathbb{F}_q} - U_0$, then there is a short exact sequence

$$0 \to j_{0!}(\underline{\overline{\mathbb{Q}}_\ell}) \to j_*(\underline{\overline{\mathbb{Q}}_\ell}) \to \mathcal{Q} \to 0$$

where $\mathcal{Q}$ is supported at S, so its higher compact cohomology vanish, and weights of $H^0(\mathcal{Q}) = \prod_{s \in S}(j_{0*}(\mathcal{F}_0))_{\overline{s}}$ is no more than the maximal weight of $\underline{\overline{\mathbb{Q}}_\ell}$ on X_0, which is 0, by semicontinuity of weights for curves(13.12.3.11). And $j_*(\overline{\mathbb{Q}}_\ell)$ is also geometrically constant, thus its cohomology is $\mathrm{Pic}(\mathbb{P}^1)[n]=0$ by(7.4.8.2), so $H^1(P^1,\overline{j_{0!}}(X_0))$ has weights zero.

The actual proof will use the following lemma(13.12.6.8). After that, notice by(13.12.8.8)

$$(T_\psi(G_0))|_{\{0\}} = R\Gamma_c(\mathbb{A}^1,\mathcal{G})[1] = R\Gamma_c(U,\mathcal{F})[1] = H^1_c(U,\mathcal{F})$$

Then to understand the Frobenius eigenvalues of $H^1_c(U,\mathcal{F})$, it suffices to understand the weights of $T_\psi(\mathcal{G}_0)$, i.e.

$$w(T_\psi(\mathcal{G}_0)) \le w+1$$

Then we use(13.12.3.17), notice the condition is satisfied by lemma(13.12.6.8), so $w(T_\psi(\mathcal{G}_0)) = ||T_\psi(\mathcal{G}_0)||$, and also $w(G_0)=||G_0||$ for the same reason as $H^0_c(\mathbb{A}^1,\mathcal{G}) = H^0_c(U,\mathcal{F})=0$ by Poincare duality. Now(13.12.8.12) gives the result.

□

Lemma (13.12.6.8) [Key Assertions of Weil Proof]. If $\mathcal{G}_0 = j_{0!}(\mathcal{F}_0)$ where $j_0 : U_0 \hookrightarrow A^1_{\mathbb{F}_q}$, $\psi : \mathbb{F}_q \to \overline{\mathbb{Q}}_\ell$ is a fixed non-trivial additive character, then

- $T_\psi(\mathcal{G}_0)$ is a sheaf placed at degree 0.
- $H^0_c(\mathbb{A}^1, T_\psi(\mathcal{G}_0)) = 0$.
- $T_\psi(\mathcal{G}_0)$ is ι-mixed.

Proof: 1: By(13.12.8.8), we need to show $H^i(\mathbb{A}^1,\mathcal{G}_0\otimes\mathcal{L}(\psi_a))=0$ for $i\neq 1$, and this is equivalent to

$$H^i(\mathbb{A}^1, j_!\mathcal{F}\otimes\mathcal{L}(\psi_a)) = H^i(U, F\otimes\mathcal{L}(\psi_a)) = 0.$$

Notice by vanishing resultproper-pushforward-to-direct-image-sheanomqsk, only need to show $i=0, i=2$, $i=0$ case is done by Poincare duality(7.4.8.11) and Artin vanishing(7.4.2.12) because it is smooth and $\mathcal{F}$ is lisse.

$H^2_c(\mathcal{G}_0\otimes\mathcal{L}(\psi_a)) = V_{\rho\otimes\chi_a}|_{\pi_1(U,\overline{x})}(-1)$ by(13.12.5.3), and $\rho\otimes\chi_a$ irreducible as ρ does, so if $V_{\rho\otimes\chi_a}|_{\pi_1(U,\overline{x})}\neq 0$, then $\rho\otimes\psi_a$ is trivial representation. Then $\mathcal{G}\cong\mathcal{L}_{\psi_{-a}}$ on $\mathbb{P}^1_{\overline{k}}$ as an étale sheaf on $\mathbb{A}^1\cup\{\infty\}=\mathbb{P}^1$ by our reduction, so we have the character ψ_{-a} factors through $\pi_1(\mathbb{P}^1,\overline{x})$, i.e.

$$\begin{array}{ccccc} \pi_1(\mathbb{A}^1,\overline{x}) & \longrightarrow & \pi_1(\mathbb{P}^1,\overline{x}) = 0 & & \\ \downarrow & & \downarrow & & \\ \pi_1(\mathbb{A}^1_0,\overline{x}) & \longrightarrow & \pi_1(\mathbb{P}^1_0,\overline{x}) & \xrightarrow{\psi_{-a}} & \overline{\mathbb{Q}}_\ell \end{array}.$$

But this is in contradiction with the fact the Artin-Schreier cover is geometrically irreducible?.

2: Denote $T_\psi(\mathcal{G}_0)=\mathcal{K}_0$, then by(13.12.8.7) and Fourier inversion(13.12.8.10):

$$H^0_c(\mathbb{A}^1,\mathcal{K}) = \mathcal{H}^{-1}((T_{\psi^{-1}}(\mathcal{K}_0))_0) = \mathcal{H}^{-1}(T_{\psi^{-1}}\circ T_\psi(j_{0!}(\mathcal{F}_0))_0) = \mathcal{H}^{-1}(j_{0!}(\mathcal{F}_0)(-1))_0 = 0$$

because $\mathcal{F}_0$ is placed at degree 0.

3: To show ι-mixed, the only thing we can do it show it is embedded in a ι-real sheaf: Consider the ι-real sheaf

$$\mathcal{H}_0 = \mathrm{pr}_2^*(j_{0!}\mathcal{F}_0)\otimes m^*(\mathcal{L}(\psi)) \oplus \mathrm{pr}_2^*(j_{0!}\mathcal{F}_0^\vee)\otimes m^*(\mathcal{L}(\psi^{-1}))(-w)$$

Then

$$(R^i\pi_!^1(\mathcal{H}_0))_{\overline{x}} = H^i(\{\overline{x}\}\times\mathbb{A}^1,\mathcal{H}_0) = H^i(j_{0!}\mathcal{F}_0\otimes\mathcal{L}(\psi_x))\oplus H^i(j_{0!}\mathcal{F}_0^\vee\otimes\mathcal{L}(\psi_{x^{-1}}^{-1}))(-w)$$

which we proved to vanish for $i\neq 1$. So using Poincare duality on $\{\overline{x}\}\times\mathbb{A}^1$,

$$\det(1-tF_x^{d_x}|(R^1\pi_!^1(\mathcal{H}_0)_{\overline{x}})) = \det(1-tF_X|H_c^1(\{\overline{x}\}\times\mathbb{A}^1,H_0|_{\{\overline{x}\}\times\mathbb{A}^1})) = \prod_{y\in\mathbb{F}_{q^n}}\det(1-tF_y^{d_y}|(\mathcal{H}_0)_{\overline{(x,y)}})^{-1}$$

which is real, so by(13.12.5.5), the direct summand $T_\psi(\mathcal{G}_0)$ is ι-mixed. □

Remark (13.12.6.9). If we use the machinery of perverse sheaf and show that Fourier transform preserves perversity, then item1, 2 will be a direct consequence, Cf.[Bhatt notes, P39]. In fact, this is just the bigger picture, given in [Weil conjectures Perverse Sheaves and l-adic Fourier Transform Kiehl/Weissauer].

7 Semisimplicity and Hard Lefschetz

Prop. (13.12.7.1) [Semisimplicity Theorem]. If X_0 is smooth and $\mathcal{F}_0$ is a lisse and ι-pure $\overline{\mathbb{Q}}_\ell$-sheaf, then $\mathcal{F}_0$ is semisimple, thus geometrically semisimple by(13.12.4.4) .

Proof: Let $\mathcal{F}'$ be the sum of irreducible lisse subsheaves of $\mathcal{F}$, then it is the largest semisimple subsheaf of $\mathcal{F}$. It is stable under $G(\overline{\mathbb{F}_q}/\mathbb{F}_q)$, thus can be descended to a lisse subsheaf $\mathcal{F}_0'$ of $\mathcal{F}_0$, and let $\mathcal{F}''=\mathcal{F}_0/\mathcal{F}_0'$, we want to show the exact sequence

$$0\to\mathcal{F}_0'\to\mathcal{F}_0\to\mathcal{F}_0''\to 0$$

splits geometrically. Notice this exact sequence defines an element in $\mathrm{Ext}^1_X(\mathcal{F}'',\mathcal{F}') = H^1(X,(\mathcal{F}'')^\vee\otimes\mathcal{F}')$?. $\mathcal{F}_0$ is pure, hence so does $(\mathcal{F}_0'')^\vee\otimes\mathcal{F}_0'$, thus $H^1(X,(\mathcal{F}'')^\vee\otimes\mathcal{F}')$ is ι-mixed of weights≥ 1. But the exact sequence is compatible with Frobenius action, it defines a Frobenius fixed element, which then must vanish. □

Cor. (13.12.7.2). If $f:X\to Y$ is proper between smooth algebraic schemes, then the sheaves $R^if_*\underline{\mathbb{Q}_\ell}$ are semisimple.

Hard Lefschetz

Def. (13.12.7.3). The setup is k is a finite field, $F\in\mathtt{Field}^0$ and $\mathscr{H}$ is a cohomology theory $\mathcal{S}m\mathcal{P}\mathrm{roj}/k\to\mathcal{CR}\mathrm{ing}^{\mathrm{gr}}/F$ which satisfies

- (Poincaré duality)$\mathscr{H}^i(X)\otimes_F\mathscr{H}^{2n-i}(X)\to\mathscr{H}^{2n}(X)$ is a perfect pairing, and the Frobenius $F_X^*=q^n$ on $\mathscr{H}^{2n}(X)$.
- (Weak Lefschetz)If $\mathcal{L}$ is an ample line bundle on X and $H\subset X$ is a smooth divisor in $|\mathcal{L}|$, then

  $$f^*:\mathscr{H}^i(X)\to\mathscr{H}^i(Y)$$

  is an isomorphism for $i=n-2$ and injective for $i=n-1$.
- (Zeta Function)Let $\mathscr{P}^i(X;T)=\det(1-F_X^*T|\mathscr{H}^i(X))$, then the Hasse-Weil zeta function

  $$Z(X;T)=\prod_{i=0}^{2n}\mathscr{P}(X;T)^{(-1)^{i+1}}.$$

Prop. (13.12.7.4). Crystalline and ℓ-adic cohomologies satisfy the hypothesis(13.12.7.3).

Proof: □

Prop. (13.12.7.5). Situation as in(13.12.7.3), then $\mathscr{P}^i(X;T) = P^i_{\text{ét}}(X;T)$.

Proof: **?** □

Cor. (13.12.7.6).

- The characteristic polynomial $P_{\text{ét}}(X;T)$ is independent of ℓ chosen.
- $\dim_F \mathscr{H}^i(X) = \dim_{\mathbb{Q}_\ell} \mathrm{H}^i_{\text{ét}}(X)$.
- (Hard Lefschetz)If $\mathcal{L}$ is an ample line bundle on X, then

  $$\mathscr{H}^{n-i}(X) \xrightarrow{c_1(\mathcal{L})^i} \mathscr{H}^{n+i}(X)$$

  is an isomorphism.

Cor. (13.12.7.7).

$$b_d \geq b_{d-2} \geq \ldots, \quad b_{d-1} \geq b_{d-3} \geq \ldots$$

Prop. (13.12.7.8) [Hard-Lefschetz]. Cf.[Bhatt P42].

8 Fourier Transformation

Sheaf to Functions Correspondence

Def. (13.12.8.1) [Sheaf to Functions Correspondence]. For a complex $K_0 \in D^b_{cons}(X_0, \overline{\mathbb{Q}}_\ell)$, we can associate a function

$$f^{K_0} : X_0(\mathbb{F}_{q^n}) \to \overline{\mathbb{Q}}_\ell : x \mapsto \sum_i (-1)^i \operatorname{tr}(F_x^{n/d_x} | (\mathcal{H}^i(K_0))_{\overline{x}})$$

Prop. (13.12.8.2). We can use Grothendieck formula for a constructible sheaf(13.12.2.6) to relate the function f^{K_0} to the compact cohomologies of $\mathcal{H}^i K_0$, and we can translate many know theorems:

- $f^{f^* K_0} = f^{K_0} \circ f$.
- $$f^{K_0} \cdot f^{T_0} = f^{K_0 \otimes^L T_0} \textbf{?}$$
- (Base Change)(7.4.5.5) asserts that given a Cartesian diagram

  $$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{f'} & & \downarrow{f} \\ Y' & \xrightarrow{g} & Y \end{array}$$

  then it says in case Y' is a closed point of Y,

  $$f^{Rf_! K_0}(y) = \sum_{x \in X_y(\mathbb{F}_{q^n})} f^{K_0}(x)$$

  where $y \in Y(\mathbb{F}_{q^n})$, and more generally

  $$\sum_{x' \in X'_{y'}} f^{K_0}(g'(x')) = \sum_{x \in X_{g(y')}} f^{K_0}(x)$$

- The projection formula(7.4.5.8) turns out to say something trivial:

$$\sum_{x\in X_y}(f^{K_0}(f(x))\cdot f^{T_0}(x)) = f^{K_0}(y)\cdot(\sum_{x\in X_y} f^{T_0}(x))$$

Artin-Schreier Sheaves

Prop. (13.12.8.3) [Characters]. Any character $\psi:\mathbb{F}_q\to\overline{\mathbb{Q}}_\ell^\times$ can be extended to $\mathbb{F}_{q^n}$ by

$$\mathbb{F}_{q^n}\xrightarrow{\mathrm{tr}} F_q\xrightarrow{\psi}\overline{\mathbb{Q}}_\ell^\times,$$

also denoted by ψ.

Prop. (13.12.8.4) [Artin-Schreier Sheaf]. Let $y^{q^n}-y-x\in\mathbb{A}_0^2$ be the finite Galois cover of $\mathbb{A}_0^1$ via x coordinates, with the Galois group isomorphic to $\mathbb{F}_q$ with $1\mapsto(x\mapsto x+1)$. Then we get a surjection $\pi_1(\mathbb{A}_0^1,\overline{x})\to\mathbb{F}_q$, when composed with ψ, we get a rank1 étale sheaf $\mathcal{L}_0(\psi)$ called the **Artin-Schreier sheaf** on $\mathbb{A}_0^1$.

Prop. (13.12.8.5). $f^{\mathcal{L}_0(\psi)}(x)=\psi(-x)$.

Proof: If $k(x)=\mathbb{F}_{q^n}$, then consider the arithmetic Frobenius $\sigma:(x,y)\mapsto(x^{q^n},y^{q^n})$, then if $y^{q^n}-y=x$, then we have

$$y^q=y+x,\quad y^{q^2}=y^q+x^q=y+x^q+x,\ldots,\quad y^{q^n}=y+x+x^q+\ldots+x^{q^{n-1}}=y+\mathrm{tr}_{\mathbb{F}_{q^n}/\mathbb{F}_q}(x)$$

So in the correspondence(13.12.8.4), we know $F_{\overline{x}}$ acts on $\mathcal{L}_\psi$ by multiplication by $\psi(\mathrm{tr}_{\mathbb{F}_{q^n}/\mathbb{F}_q}(x))=\psi(x)$, so the geometric Frobenius acts by $\psi(-x)$. □

Def. (13.12.8.6) [Deligne-Fourier Transform]. Consider the multiplication map $\mathbb{A}_0\times\mathbb{A}_0'\to\mathbb{A}_0$, let the sheaf $\mathcal{L}(\psi)$ be placed at A_0, and $K_0\in D_c^b(\mathbb{A}_0',\overline{\mathbb{Q}}_\ell)$ be placed at $\mathbb{A}_0'$, then define the **Deligne-Fourier transform**

$$T_\psi: D_c^b(\mathbb{A}_0',\overline{\mathbb{Q}}_\ell)\to D_c^b(\mathbb{A}_0,\overline{\mathbb{Q}}_\ell): K_0\mapsto R\pi_!^1(\mathrm{pr}_2^*K_0\otimes^L m^*\mathcal{L}_0(\psi))[1]$$

Lemma (13.12.8.7). We have $f^{T_\psi K_0}(x)=-\sum_{y\in\mathbb{F}_{q^n}}f^{K_0}(y)\psi(-xy)$ for any $x\in F_{q^n}$.

Proof: Use(13.12.8.2), we have

$$\begin{aligned}f^{T_\psi K_0}(x)&=\sum_{y\in\mathbb{F}_{q^n}}f^{(\mathrm{pr}_2^*K_0\otimes^L m^*\mathcal{L}_0(\psi))[1]}((x,y))\\&=-\sum_{y\in\mathbb{F}_{q^n}}f^{\mathrm{pr}_2^*K_0}((x,y))\cdot f^{m^*\mathcal{L}_0(\psi)}((x,y))\\&=-\sum_{y\in\mathbb{F}_{q^n}}f^{K_0}(y)\psi(-xy).\end{aligned}$$

□

Prop. (13.12.8.8). Let a be a geometric point of $\mathbb{A}_0^1$, then

$$(T_\psi(K_0))_a=R\Gamma_c(K\otimes^L\mathcal{L}(\psi_a))[1]$$

where $\psi_a:\mathbb{F}_{q^n}\to\overline{\mathbb{Q}}_\ell^\times$ maps $x\mapsto\psi(ax)$. In particular, $\mathcal{H}^i((T_\psi(K_0))_0)=H^i_{\text{ét},c}(\mathbb{A}^1,K)$, so we placed the complex into a family of deformations.

Proof: By base change(7.4.5.5),

$$(T_\psi(K_0))_a = R\Gamma_c((\mathrm{pr}_2^* K_0 \otimes^L m^*\mathcal{L}_0(\psi)|_{\{a\}\times\mathbb{A}^1})[1] = R\Gamma_c(K \otimes^L \mathcal{L}(\psi_a))[1].$$

□

Lemma (13.12.8.9). If $\delta_0 = i_{0*}\overline{\mathbb{Q}}_\ell$ be the skyscraper sheaf, where $i_0 : \{0\} \hookrightarrow \mathbb{A}^1$, then

$$T_\psi(\overline{\mathbb{Q}}_\ell[1]) = \delta_0(-1).$$

Proof: For the Artin-Schreier cover $P : x \mapsto x^q - x$, we have

$$P_*\overline{\mathbb{Q}}_\ell \cong \oplus_{x\in\mathbb{F}_q}\mathcal{L}(\psi_x)\text{?}$$

and P is finite thus proper and P_* is exact(7.4.1.18), so using the Leray spectral sequence(7.4.5.5), we can calculate

$$H^1_c(\mathbb{A}^1, \mathcal{L}(\psi_x)) = 0 = H^1_c(\mathbb{A}^1, \overline{\mathbb{Q}}_\ell), \quad H^2_c(\mathbb{A}^1, \mathcal{L}(\psi_x)) = 0(7.4.5.7), \quad H^2_c(\mathbb{A}^1, \mathcal{L}(\psi_x)) = \delta_0(x)\overline{\mathbb{Q}}_\ell(-1)(13.12.5.3)$$

So

$$(R\pi^1_!(m^*\mathcal{L}_0(\psi)[1])[1])_x = R\Gamma_c(\mathcal{L}(\psi_x))[2] = \delta_0(-1).$$

□

Prop. (13.12.8.10) [Fourier Inversion]. $T_{\psi^{-1}}T_\psi K_0 = K_0(-1)$.

Proof: Consider

$$\begin{array}{ccccc}
\mathbb{A}^1_0 \times \mathbb{A}^1_0 \times \mathbb{A}^1_0 & \xrightarrow{\mathrm{pr}_{23}} & \mathbb{A}^1_0 \times \mathbb{A}^1_0 & \xrightarrow{\mathrm{pr}_2} & \mathbb{A}^1_0 \\
\downarrow{\scriptstyle \mathrm{pr}_{12}} & & \downarrow{\scriptstyle \mathrm{pr}_1} & & \\
\mathbb{A}^1_0 \times \mathbb{A}^1_0 & \xrightarrow{\mathrm{pr}_2} & \mathbb{A}^1_0 & & \\
\downarrow{\scriptstyle \mathrm{pr}_1} & & & & \\
\mathbb{A}^1_0 & & & &
\end{array}$$

And we will use the following Cartesian diagrams:

$$\begin{array}{ccc}
\mathbb{A}^3_0 & \xrightarrow{\alpha:(x,y,z)\mapsto(y,z-x)} & \mathbb{A}^2_0 \\
\downarrow{\scriptstyle \pi^{13}} & & \downarrow{\scriptstyle \mathrm{pr}_2} \\
A^2_0 & \xrightarrow{\beta:(x,z)\mapsto z-x} & A^1_0
\end{array}, \qquad
\begin{array}{ccc}
A^1_0 & \longrightarrow & * \\
\downarrow{\scriptstyle \Delta} & & \downarrow{\scriptstyle i_0} \\
A^2_0 & \xrightarrow{\beta} & A^1_0
\end{array}$$

Then

$T_{\psi^{-1}}T_\psi K_0$ $\qquad\qquad (T_{\psi^{-1}}T_\psi f)(x)$

$= R\pi^1_!(\mathrm{pr}_2^* R\pi^1_!(\mathrm{pr}_2^* K_0 \otimes m^*\mathcal{L}_0(\psi)) \otimes m^*\mathcal{L}_0(\psi^{-1}))[2]$ $\qquad\qquad = \sum_y(\sum_z f(z)\psi(-yz))\psi(xy)$

By base change(7.4.5.5) :

$= R\pi^1_!(R\pi^{12}_! \mathrm{pr}_{23}^*(\mathrm{pr}_2^* K_0 \otimes m^*\mathcal{L}_0(\psi)) \otimes m^*\mathcal{L}_0(\psi^{-1}))[2]$

By projection formula(7.4.5.5) :

$= R\pi^1_! R\pi^{12}_! (\mathrm{pr}^*_{23}(\mathrm{pr}^*_2 K_0 \otimes m^*\mathcal{L}_0(\psi) \otimes \mathrm{pr}^*_{12} m^*\mathcal{L}_0(\psi^{-1})))[2]$ $\qquad = \sum_y \sum_z f(z)\psi(-yz)\psi(xy)$

Combine the character:

$= R\pi^1_! R\pi^{12}_! (\mathrm{pr}^*_{23}\, \mathrm{pr}^*_2 K_0 \otimes \alpha^* m^*\mathcal{L}_0(\psi))[2]$ $\qquad = \sum_y \sum_z f(z)\psi(-y(z-x))$

Change order of summation:

$= R\pi^1_! R\pi^{13}_! (\pi^{13*}\, \mathrm{pr}^*_2 K_0 \otimes \alpha^* m^*\mathcal{L}_0(\psi))[2]$ $\qquad = \sum_z \sum_y f(z)\psi(-y(z-x))$

By projection formula:

$= R\pi^1_! (\mathrm{pr}^*_2 K_0 \otimes R\pi^{13}_1 \alpha^* m^*\mathcal{L}_0(\psi))[2]$ $\qquad = \sum_z f(z) \sum_y \psi(-y(z-x))$

By base change:

$= R\pi^1_! (\mathrm{pr}^*_2 K_0 \otimes \beta^* R\pi^2_! (m^*\mathcal{L}_0(\psi))[2] = R\pi^1_! (\mathrm{pr}^*_2 K_0 \otimes \beta^* T_\psi \overline{\mathbb{Q}}_\ell[-1])[2]$

By(13.12.8.9) :

$= R\pi^1_! (\mathrm{pr}^*_2 K_0 \otimes \beta^* \delta_0[-2])[2] = R\pi^1_! (\mathrm{pr}^*_2 K_0 \otimes \beta^* \delta_0(-1))$ $\qquad = \sum_z f(z) q^n \delta_0(z-x)$

Use base change and noticing$i_0$is finite thus proper and exact:

$= R\pi^1_! (\mathrm{pr}^*_2 K_0 \otimes R\Delta_! \overline{\mathbb{Q}}_\ell(-1))$ $\qquad = \sum_z \sum_{x=z} q^n$

By projection formula:

$= R\pi^1_! R\Delta_! (\Delta^* \mathrm{pr}^*_2 K_0 \otimes \overline{\mathbb{Q}_\ell})(-1)$ $\qquad = q^n \sum_{\{z|z=x\}} f(z)$

$= K_0(-1)$ $\qquad = q^n f(x)$

□

Prop. (13.12.8.11) [Plancherel Formula].

$$||f^{T_\psi(K_0)}||_n = q^{n/2} ||f^{K_0}||_n.$$

Proof: By definition and using(13.12.8.7),

$$\begin{aligned} ||f^{T_\psi(K_0)}||^2_n &= \sum_{x \in \mathbb{F}_{q^n}} f^{T_\psi(K_0)}(x) \overline{f^{T_\psi(K_0)}(x)} \\ &= \sum_{x,y,z} f^{K_0}(y) \overline{f^{K_0}(z)} \psi(-xy)\psi(xz) \\ &= q^n \sum_{z=y} f^{K_0}(y) \overline{f^{K_0}(z)} \\ &= q^n (f,f)_n \end{aligned}$$

□

Cor. (13.12.8.12). Notice by the definition of norm of a Weil-sheaf $\mathcal{G}_0$, we have

$$||T_\psi(K_0)|| \leq ||K_0|| + 1$$

9 Integrality Problems

Def. (13.12.9.1) [Integral Sheaves]. Let X_0 be a separated algebraic scheme over k and $\mathcal{F}_0$ a lisse constructible sheaf on X_0, then $\mathcal{F}_0$ is called an **integral lisse sheaf** if for all $x_0 \in X_0$, all the eigenvalues of F_x^* acting on $\mathcal{F}_{\overline{x}}$ are algebraic integers.

Prop. (13.12.9.2) [Deligne]. If $\mathcal{F}_0$ is an integral lisse sheaf(13.12.9.1) on X_0, then all coefficients of $H^i_{\text{ét},c}(X, \mathcal{F})$ are integral.

Proof: Cf.[Weil 1 Proof, P21]. □

Cor. (13.12.9.3). All eigenvalues of $H^i_{\text{ét},c}(X, \mathcal{F})$ are algebraic integers.

13.13 Rational Points on Abelian Varieties

Main references are [Sta], [Abelian Varieties notes Conrad], [Mil08], [B-G06], [Abelian Variety van der Geer], [BLR90], [Sil16] and [Sil99], [Sil11], http://www-personal.umich.edu/~asnowden/teaching/2013/679/index.html.

1 Mordell-Weil Theorem

Prop. (13.13.1.1) [Local Chevalley-Weil Theorem for Abelian Varieties]. Let S be a Dedekind scheme with function field F, Let A be an Abelian variety over F and $m \in \mathbb{Z} \cap F^*$. Let $s \in S$ be a closed point s,t. A has good reduction over $\mathcal{O}_{S,s}$ and $m \neq 0 \in \kappa(s)$, then for any $P \in A(\overline{F})$, the extension $\kappa(P)/\kappa([m]P)$ is unramified at all places over v.

Proof: By base change, we may assume $Q = [m]P$ is a rational point. Let w be a place of $\kappa(P)$ that $w|v_s$ with valuation ring R_w. As A has good reduction in v, A extends to an Abelian scheme $\overline{A}$ over $\mathcal{O}_{S,s}$, then the valuation criterion of properness shows P extends to a R_w-valued point of $\overline{A}$. Now the theorem follows from(13.5.6.14) and(5.6.5.16). □

Cor. (13.13.1.2). Let F be a global field, $X \in \mathcal{A}b\mathcal{V}ar/F$ and $n \in \mathbb{Z} \cap F^*$, $L = K(X[n](\overline{F}))$, i.e. the composite of all fields in $\overline{F}$ obtained by adjoining $[n]^{-1}x, x \in X(F)$, then L is a finite field extension of F.

Proof: This follows from the proposition and(12.4.2.27). □

Lemma (13.13.1.3) [Weak Mordell-Weil Theorem]. Let F be a global field and X be an Abelian variety over K, then for $n \in \mathbb{Z} \cap F^*$, $X(F)/nX(F)$ is finite.

Proof: This follows from the finiteness of the Selmer group(13.5.11.8) and(13.5.11.6). □

Prop. (13.13.1.4) [Mordell-Weil Theorem]. Let F be a global field, then the group $X(F)$ of rational points of an Abelian variety X is f.g.

Proof: Because of(13.13.1.3) and(13.5.12.2), this follows from(2.1.4.15) applied to $M = X(K')$ and the symmetric bilinear form on $X(K')$ given by(13.5.12.2). □

Remark (13.13.1.5) [Computability]. The difficulty of computing $X(F)$ lies entirely at computing $X(F)/nX(F)$ for some n, for which, see(13.5.11.7).

Cor. (13.13.1.6) [Rank]. $X(F) \cong \mathbb{Z}^r \oplus X(F)_{\mathrm{tor}}$, where $X(F)_{\mathrm{tor}}$ is a finite group, and r is called the **rank of X**.

Cor. (13.13.1.7) [Isogenous Varieties have the same Rank]. Let F be a global field and $X, X' \in \mathcal{A}b\mathcal{V}ar/F$ are isogenous, then $\mathrm{rank}(X) = \mathrm{rank}(X')$. In particular, $\mathrm{rank}(X) = \mathrm{rank}(\widehat{X})$.

Proof: The isogeny implies $X(F)/X(F)_{\mathrm{tor}} \to \widehat{X}(F)/\widehat{X}(F)_{\mathrm{tor}}$ is injective. Thus $\mathrm{rank}(X) \leq \mathrm{rank}(\widehat{X})$. The converse follows from(13.5.6.4). □

2 Lang-Néron Theorem

Main references are[Con06].

Def. (13.13.2.1) [Regular Extensions]. A field extension K/k is called **primary** if k is separably closed in K. It is called **regular** if it is separable and primary.

Prop. (13.13.2.2). Let K/k be a primary extension, then

- If $A \in \mathcal{A}b\mathcal{V}ar/k$, then any Abelian subvariety of A_K is defined over k.
- If $A, B \in \mathcal{A}b\mathcal{V}ar/k$, then any homomorphism $A_K \to B_K$ is defined over k.

Proof: □

Prop. (13.13.2.3) [K/k-Images and K/k-Traces]. For a field extension K/k, the K/k**-image** is a functor $\mathrm{Im}_{K/k} : \mathcal{A}b\mathcal{V}ar/K \to \mathcal{A}b\mathcal{V}ar/k$ left adjoint to the base change functor, and K/k**-trace** is a functor $\mathrm{tr}_{K/k} : \mathcal{A}b\mathcal{V}ar/K \to \mathcal{A}b\mathcal{V}ar/k$ right adjoint to the base change functor.

Then for K/k primary, $\mathrm{Im}_{K/k}$ and $\mathrm{tr}_{K/k}$ exist, and are resp. left and right inverses to the base change functor. Also there is a natural isomorphism

$$\widehat{\mathrm{Im}_{K/k}(A)} \cong \mathrm{tr}_{K/k}(\widehat{A}).$$

The adjunction maps are denoted by

$$\tau_{A,K/k} : \mathrm{tr}_{K/k} A \to A, \quad \lambda_{A,K/k} A \to \mathrm{Im}_{K/k} A.$$

Proof: It suffices to prove for $\mathrm{Im}_{K/k}$, and $\mathrm{tr}_{K/k}$ follows by double duality theorem(13.5.4.16). For this, Cf.[Con06]P16**?**. □

Prop. (13.13.2.4). Let K/k be a primary extension and $A \in \mathcal{A}b\mathcal{V}ar/K$, the unique map $\mathrm{tr}_{K/k} A \to \mathrm{Im}_{K/k} A$ descending $\lambda_{A,K/k} \circ \tau_{A,K/k}$ is an isogeny.

Proof: Cf.[Con06]P22**?**. □

Prop. (13.13.2.5). Let K/k be a regular extension, then for any $A \in \mathcal{A}b\mathcal{V}ar/K$, the finite group $\ker(\tau_{A,K/k})$ is connected and coconnected. In particular, $\tau_{A,K/k}(K) : \mathrm{tr}_{K/k}(A)(K) \to A(K)$ is injective.

Prop. (13.13.2.6) [Lang-Néron]. Let K/k be a f.g. regular extension, then $A(K)/\mathrm{tr}_{K/k}(A)(k)$ is a f.g. Abelian group.

Proof: Cf.[Con06]P23**?**. □

Prop. (13.13.2.7) [Grothendieck]. Let K be an alg.closed field with prime field k, then any Abelian variety of CM-type over K is isogenous to an Abelian variety defined over a finite extension of k.

Proof: Cf.[Oort, The isogeny class of a CM-type abelian variety is defined over a finite extension of the prime field]. □

3 Elliptic Curve Case

Prop. (13.13.3.1) [Controlling Torsion Points]. Let K be a number field, let E be given by a Weierstrass equation

$$E : y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6 \in \mathcal{O}_K[X, Y].$$

Let $P = (x_0, y_0) \in E(K)$ be a torsion point of exact order m, then

- If m is not a p-power, then $x_0, y_0 \in \mathcal{O}_K$.
- If $m = p^n$, then for any place v of K, $v(x) \geq -2\lfloor \frac{v(p)}{p^n - p^{n-1}} \rfloor$, $v(y) \geq -3\lfloor \frac{v(p)}{p^n - p^{n-1}} \rfloor$.

Proof: This follows by base change E to each $\mathcal{O}_{K,v}$ and use(13.9.4.21). □

Cor. (13.13.3.2) [Integrality of Torsion Points in $\mathbb{Q}$]. Let $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$ and $P = (x_0, y_0) \in E(\mathbb{Q})$ a torsion point of exact order m. then if m is not a p-power, $x_0, y_0 \in \mathbb{Z}$. If $m = p^n$, then $\lfloor \frac{v(p)}{p^n - p^{n-1}} \rfloor = 0$ unless $p = 2$ and $n = 1$. Thus $x_0 \in \frac{1}{4}\mathbb{Z}, x_0 \in \frac{1}{8}\mathbb{Z}$, and if $m \geq 3$, $x_0, y_0 \in \mathbb{Z}$.

The former case can occur, for example

$$E : y^2 + xy = x^3 + 4x + 1, \quad (-\frac{1}{4}, \frac{1}{8}) \in E(\mathbb{Q})[2].$$

Prop. (13.13.3.3) [Nagell–Lutz]. Let F be a number field and $E \in \mathcal{E}\mathrm{ll}/F$ be given by a Weierstrass equation

$$E : y^2 = x^3 + Ax + B \in \mathbb{Z}[x, y],$$

Let $P = (x_0, y_0) \in E(\mathbb{Q})_{\mathrm{tor}}$, then

- $x_0, y_0 \in \mathbb{Z}$.
- Either $y_0 = 0$, i.e. $[2](P) = O$ or y_0^2 divides $4A^3 + 27B^2$.

Proof: 1: Let P has exact order m. If $m = 2$, then $y_0 = 0$, and then $x_0 \in \mathbb{Z}$ as it is integral over $\mathbb{Z}$. If $m \geq 2$, the results follows from(13.13.3.1).

2: Suppose $[2](P) = (x_1, y_1) \neq O$, then $y_0 \neq 0$, and $x_0, y_0, x_1 \in \mathbb{Z}$. Now(13.9.1.8) shows $x_1 = \varphi(x_0)/4\psi(x_0)$ where

$$\varphi(X) = X^4 - 4AX^2 - 8BX + A^2, \quad \psi(X) = X^3 + AX + B.$$

And they satisfy a polynomial equation

$$f(X)\varphi(X) - g(X)\psi(X) = 4A^2 + 27B^2$$

where $f(X) = 3X^2 + 4A$, $g(X) = 3X^3 - 5AX - 27B$. Then because $y_0^2 = x_0^3 + Ax_0 + B$, we get

$$y_0^2(4f(x_0)x_1 - g(x_0)) = 4A^2 + 27B^2.$$

□

Prop. (13.13.3.4). If $p \in \mathbf{P}$ and $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$ has a rational torsion point of order p, then E is isogenous to $E'/\mathbb{Q}$ with a rational point of order p and $\mathbb{Q}(E'[p])$ is a ramified extension of $\mathbb{Q}(\mu_p)$.

Proof: Cf.[Elliptic Curves, Group Schemes and Mazur's Theorem, P26]?. □

Prop. (13.13.3.5). If $p > 13 \in \mathbf{P}$ and $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$ has a rational torsion point of order p, then $\mathbb{Q}(E[p])$ is an unramified extension of $\mathbb{Q}(\mu_p)$.

Proof: Cf.[Elliptic Curves, Group Schemes and Mazur's Theorem, P29]?. □

Lemma (13.13.3.6) [Mazur-Tate]. For $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$ and $p > 7 \in \mathbf{P}$ and $p \neq 13$, E doesn't contain a rational torsion point of order p.

Proof: Cf.http://www-personal.umich.edu/~asnowden/teaching/2013/679/index.html. □

Lemma (13.13.3.7). For $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$, E doesn't contain a rational torsion point of order 13.

Proof: Cf.http://www-personal.umich.edu/~asnowden/teaching/2013/679/index.html. □

Lemma (13.13.3.8) [Kubert]. If $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$, then

- E doesn't contain a rational torsion point of exact order N where $N \in \{14, 15, 16, 18, 20, 21, 24, 25, 27, 35, 49\}$.
- $E(\mathbb{Q})_{\mathrm{tor}}$ doesn't contain a subgroup isomorphic to $\mathbb{Z}/(2) \times \mathbb{Z}/(10)$ or $\mathbb{Z}/(2) \times \mathbb{Z}/(12)$.

Proof: Cf.[Kubert. Universal bounds on the torsion of elliptic curves.]?

Firstly, notice for $N \in \{11, 14, 15, 17, 19, 20, 21, 24, 27, 32, 36, 49\}$, $X_0(N)$ has genus 1(16.2.4.19). And by taking the cusp as the origin, $X_0(N)$ is an elliptic curve. Then Kubert finds that $\mathrm{rank}(X_0(N)) = 0$, and can find all the rational points. Only for $N = 21$ or $N = 27$ there are non-cusp rational points. So it suffices to show that for $X_0(21)$ and $X_0(27)$, the quadratic twists of the elliptic curves corresponding to the rational non-cusp points of $X_0(N)$ don't have rational 21 torsion-points.

For $N = 21$, the non-cusp rational points of $X_0(N)$ are given by quadratic twists of

$$y^2 = x^3 + 45x - 18$$

$$y^2 = x^3 - 75x - 262$$
$$y^2 = x^3 - 1515x - 46106$$
$$y^2 = x^3 - 17235x - 870894.$$

For $N = 27$, the non-cuspidal rational points of $X_0(N)$ are given by quadratic twists of

$$y^2 + y = x^3 - 30x - 5.$$

For the second case, let P be a generator of $\mathbb{Z}/(2)$ and Q a generator of $\mathbb{Z}/(10)$ or $\mathbb{Z}/(12)$, then the dual map $E/P \to E \to E/Q$ is a cyclic isogeny, thus corresponds to a rational point on $Y_0(20)$ or $Y_0(24)$, which in fact has no rational point.

For $N = 16$, ?

For $N = 18$, ?

For $N = 25$, ?

For $N = 35$, let $E = X_0(35)/w_5$, where w_5 is the Atkin-Lehner involution. Then E is an elliptic curve, and $E(\mathbb{Q}) \cong \mathbb{Z}/(3)$. Then Kubert computed that the preimages of these points are cusps. □

Thm. (13.13.3.9) [Mazur]. For $E \in \mathcal{E}\mathrm{ll}/\mathbb{Q}$, $E(\mathbb{Q})_{\mathrm{tor}}$ can only be isomorphic to one of the following 15 groups:

- $\mathbb{Z}/(n)$ for $n \leq 10$ or $n = 12$,
- $\mathbb{Z}/(2) \oplus \mathbb{Z}/(2n)$ for $n \leq 4$.

Moreover, each of these groups occur, by(13.13.3.11).

Proof: This follows from(13.13.3.6)(13.13.3.7) and(13.13.3.8). Notice the existence of elliptic curves with these torsion groups can also be shown using modular curves, as they parametrize elliptic curves with torsion points.? □

Thm. (13.13.3.10) [Uniform Bound of Torsion Groups, Merel]. For any $d \in \mathbb{Z}_+$ there is a constant $N(d)$ s.t. for any number field $F/\mathbb{Q}$ of degree d and all elliptic curves E over K,

$$\#E(F)_{\text{tor}} \leq N(d).$$

Proof: □

Prop. (13.13.3.11) [Bounding Torsion Points]. The proposition(13.9.4.20) is useful in controlling torsion points of E, for example: If $E/\mathbb{Q}$ is an elliptic curve with Weierstrass equation

- $E : y^2 + y = x^3 - x + 1$, then $\Delta = -13 \cdot 47$, so E has good reduction modulo 2. But it can be calculated that $\widetilde{E}(\mathbb{F}_2) = \widetilde{O}, E(\mathbb{Q})[2] = O$, thus $E(\mathbb{Q})_{\text{tor}} = O$.
- $E : y^2 = x^3 + 3$, then $\Delta = -2^4 \cdot 3^5$, so E has good reduction modulo p for $p \geq 5$. But it can be calculated that $\#\widetilde{E}(\mathbb{F}_5) = 6, \#\widetilde{E}(\mathbb{F}_7) = 13$, so $E(\mathbb{Q})[p] = O$ for any prime p, and $E(\mathbb{Q})_{\text{tor}} = O$. In particular, $(1, 2) \in E(\mathbb{Q})$ has infinite order.
- $E : y^2 = x^3 + x$, then $\Delta = -2^6$, so E has good reduction modulo p for $p \geq 3$. But it can be calculated that $\widetilde{E}(\mathbb{F}_3) \cong \mathbb{Z}/(4)$, $\widetilde{E}(\mathbb{F}_5) \cong \mathbb{Z}/(2) \times \mathbb{Z}/(2)$, thus $E(\mathbb{Q})_{\text{tor}} \cong 0$ or $\mathbb{Z}/(2)$. The latter case is right, as $(0, 0) \in E(\mathbb{Q})$.
- $E : y^2 = x^3 + 2$.
- $E : y^2 = x^3 + 8$.
- $E : y^2 = x^3 + 4$.
- $E : y^2 = x^3 + 4x$.
- $E : y^2 - y = x^3 - x^2$.
- $E : y^2 = x^3 + 1$.
- $E : y^2 = x^3 - 43x + 166$. then $\Delta = -2^{19} \cdot 13$, thus E has good reduction modulo $3, 5$. But it can be calculated that $\#\widetilde{E}(\mathbb{F}_3) = 7 = \#\widetilde{E}(\mathbb{F}_3)$, thus $E(\mathbb{Q})_{\text{tor}} \cong 0$ or $\mathbb{Z}/(7)$. By(13.13.3.3), for any torsion point (x, y), $y|2^7$, thus we can find rational points

  $$\{(3, \pm 8), \quad (-5, \pm 16), \quad (11, \pm 32)\}.$$

  And using doubling formula(13.9.1.8) for $P = (3, 8)$,

  $$x([2](P)) = -5, \quad x([4](P)) = 11, \quad x([8](P)) = 3.$$

  Thus P must have order 7, and $E(\mathbb{Q})_{\text{tor}} \cong \mathbb{Z}/(7)$.
- $E : y^2 + 7xy = x^3 + 16x$.
- $E : y^2 + xy + y = x^3 - x^2 - 14x + 29$.

- $E : y^2 + xy = x^3 - 45x + 81.$
- $E : y^2 + 43xy - 210y = x^3 - 210x^2.$
- $E : y^2 = x^3 - 4x.$
- $E : y^2 = x^3 + 2x^2 - 3x.$
- $E : y^2 + 5xy - 6y = x^3 - 3x^2.$
- $E : y^2 + 17xy - 120y = x^3 - 60x^2.$

13.14 Mordell-Lang Conjecture(Faltings Theorem)

References are [Mordell Seminar notes, Bhatt], http://virtualmath1.stanford.edu/~conrad/mordellsem/, [Fal86] and [Mil08].

1 Tate's Hom Conjecture

References are [Fal86] and [Tat66].

Lemma (13.14.1.1). Let k be a field, $A_1, A_2 \in \mathcal{A}b\mathcal{V}ar/k$, and $\ell \in \mathbf{P} \setminus \operatorname{char} k$, then the natural map

$$\operatorname{Hom}(A_1, A_2) \otimes \mathbb{Z}_\ell \to \operatorname{Hom}_{\mathbb{Z}_\ell}(T_\ell(A_1), T_\ell(A_2))$$

is injective.

Proof: Same as the proof of the Elliptic case? Cf.[Silverman]. □

Thm. (13.14.1.2) [Tate's Hom Conjecture, Tate/Faltings]. Let $k \in \texttt{Field}^{\text{fin}}$ or $k \in \texttt{GField}$, $\ell \in \mathbf{P} \setminus \{\operatorname{char} k\}$, $A_1, A_2 \in \mathcal{A}b\mathcal{V}ar/k$, then

$$\operatorname{Hom}(A_1, A_2) \otimes \mathbb{Z}_\ell \to \operatorname{Hom}_{\operatorname{Gal}_k}(T_\ell(A_1), T_\ell(A_2))$$

is an isomorphism.

Proof: Firstly notice that

$$\operatorname{Hom}(A_1, A_2)_{\mathbb{Q}_\ell} \to \operatorname{Hom}_{\operatorname{Gal}_k}(V_\ell(A_1), V_\ell(A_2))$$

is injective, and it suffices to show this is surjective: This follows from(13.14.1.1) and the fact $\mathbb{Q}_\ell$ is flat over $\mathbb{Z}_\ell$ and

$$\operatorname{Coker}\Big(\operatorname{Hom}(A_1, A_2) \otimes \mathbb{Z}_\ell \to \operatorname{Hom}_{\operatorname{Gal}_k}(T_\ell(A_1), T_\ell(A_2))\Big)$$

is torsion-free, because if $[f] \in \operatorname{Hom}_{\operatorname{Gal}_k}(T_\ell(A_1), T_\ell(A_2))$ satisfies $n[f] = [g]$ for $g \in \operatorname{Hom}(A_1, A_2) \otimes \mathbb{Z}_\ell$, then we may assume $n \in \ell^{\mathbb{Z}_+}$, and then g vanishes on $A_1[n]$, then $g = nf$ for some $f \in \operatorname{Hom}(A_1, A_2)$. ? □

Cor. (13.14.1.3). Let $k \in \texttt{Field}^{\text{fin}}$ or $k \in \texttt{GField}$, $\ell \in \mathbf{P} \setminus \{\operatorname{char} k\}$, $A_1, A_2 \in \mathcal{A}b\mathcal{V}ar/k$, then A_1, A_2 are isogenous iff $T_\ell(A_1) \cong T_\ell(A_2)$ as Gal_k-modules.

2 Heights of Abelian Varieties

Def. (13.14.2.1) [Faltings Heights]. Let F be a number field and $A \in \mathcal{A}b\mathcal{V}ar/F$, take the Néron model $\mathcal{A}/\mathcal{O}_F$, then $\mathcal{K}_{\mathcal{A}/\mathcal{O}_F}$ is an invertible sheaf, and thus $Ms^{-1}\mathcal{K}_{\mathcal{A}/\mathcal{O}_F}$ is an invertible $\mathcal{O}_F$-sheaf, represented by a fractional ideal $M \subset F$, and $M \otimes_R F = \Gamma(A, \mathcal{K}_{A/F})$ by(8.1.1.14).

We define a norm on $M \otimes_F F_v = \Gamma(A_v, \mathcal{K}_{A_v/F_v})$ for each $v \in \Sigma_F^\infty$:

$$||\omega||_v = \Big((\frac{i}{2})^g \int_{A(\overline{F}_v)} \omega \wedge \overline{\omega}\Big)^{1/2}.$$

This make $\widetilde{M}$ a metrized line bundle on $\mathcal{O}_F$(18.2.1.1).

Then we define the **Faltings height** of A:

$$H(A)=H((\widetilde{M},|\cdot|))(18.2.1.2),\quad h(A)=\frac{1}{[F:\mathbb{Q}]}\log H(A).$$

More explicitly, take a non-zero holomorphic g-form ω on A, and for $v\in\Sigma_F^0$, let ω_v be a Néron differential ω_v on A_v(i.e. corresponding to an element in K_v of valuation 1), then

$$H(A)=\frac{1}{\prod_{v\in\Sigma_F^0}|\omega/\omega_v|_v\cdot\prod_{v\in\Sigma_F^\infty}\left((\frac{i}{2})^g\int_{A(\overline{F}_v)}\omega\wedge\overline{\omega}\right)^{[K_v:\mathbb{Q}_v]/2}}$$

Def. (13.14.2.2) [Stable Faltings Height]. Let F be a number field and $A\in\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/F$, then by(13.5.10.15) there exists a finite extension L/F s.t. A_L is semistable. Then the Néron model of A_L are stable under base change**?**. Then we can define the **stable Faltings height** $h_s(A)=h(A_L)$, which is invariant of L chosen.

Prop. (13.14.2.3). Let F be a number field and $A\in\mathcal{A}\mathrm{b}\mathcal{V}\mathrm{ar}/F$, then $h(A)=h(A^\vee)$.

Proof: Cf.[Szpiro, La Conjecture de Mordell, Séminaire Bourbaki, 1983/84]. □

Thm. (13.14.2.4).

Modular Heights
