# Outline

- 1 Introduction to Local Langlands
  - Local Langlands for  $GL_n$
  - Beyond  $GL_n$
  - DeBacker-Reeder
- 2 Local Langlands for Tamely Ramified Unitary Groups
  - The Torus
  - The Character
  - Embeddings and Induction
- 3 Character Sheaves
  - A Different Induction Process
  - Greenberg of Néron
  - Character Sheaves

# What is the Langlands Correspondence?

- A generalization of class field theory to non-abelian extensions.
- A tool for studying L-functions.
- A correspondence between representations of Galois groups and representations of algebraic groups.

# Local Class Field Theory

Irreducible 1-dimensional representations of  $\mathcal{W}_{\mathbb{Q}_p}$

Irreducible representations of  $GL_1(\mathbb{Q}_p)$

The 1-dimensional case of local Langlands is local class field theory.

# Conjecture

Irreducible  $n$ -dimensional representations of  $\mathcal{W}_{\mathbb{Q}_p}$

Irreducible representations of  $GL_n(\mathbb{Q}_p)$

In order to make this conjecture precise, we need to modify both sides a bit.

# Smooth Representations

For  $n > 1$ , the representations of  $GL_n(\mathbb{Q}_p)$  that appear are usually infinite dimensional.

## Definition

A *smooth  $\mathbb{C}$ -representation* of  $GL_n(\mathbb{Q}_p)$  is a pair  $(\pi, V)$ , where

- $V$  is a  $\mathbb{C}$ -vector space (possibly infinite dimensional),
- $\pi: GL_n(\mathbb{Q}_p) \rightarrow GL(V)$  is a homomorphism,
- The stabilizer of each  $v \in V$  is open in  $GL_n(\mathbb{Q}_p)$ .

The only finite-dimensional irreducible smooth  $\pi$  are

$$g \mapsto \chi(\det(g))$$

for some character  $\chi: \mathbb{Q}_p^\times \rightarrow \mathbb{C}^\times$ .

# Langlands Parameters

We also need to clarify what kinds of representations of  $\mathcal{W}_{\mathbb{Q}_p}$  to focus on.

## Definition

A *Langlands parameter* is a pair  $(\varphi, V)$  with

$$\varphi: \mathcal{W}_{\mathbb{Q}_p} \rightarrow \mathrm{GL}(V) \quad \dim_{\mathbb{C}} V = n$$

such that  $\varphi$  is continuous and semisimple.

# Parabolic Subgroups

Given a number of Langlands parameters  $\varphi_i: \mathbf{W}_{\mathbb{Q}_p} \rightarrow GL(V_i)$ , one can form their direct sum. There should be a corresponding operation on the  $GL_n(\mathbb{Q}_p)$  side.

## Definition

A *parabolic subgroup* of  $GL_n$  is a subgroup  $P$  conjugate to one consisting of block triangular matrices of a given pattern. For example:

$$\begin{pmatrix} * & * & * & * & * \\ 0 & * & * & * & * \\ 0 & * & * & * & * \\ 0 & 0 & 0 & * & * \\ 0 & 0 & 0 & * & * \end{pmatrix}$$

Such a subgroup has a Levi decomposition  $P = M \ltimes N$ , where  $M$  is conjugate to the corresponding subgroup of block diagonal matrices, and  $N$  consists of the subgroup of  $P$  with identity blocks on the diagonal.

# Parabolic Induction

Since each Levi subgroup  $M$  is just a direct product of  $GL_{n_i}$ , a collection of representations  $\pi_i: GL_{n_i}(\mathbb{Q}_p) \rightarrow GL(V_i)$  yields a representation  $\boxtimes_i \pi_i$  of  $M$ . We can pull this back to  $P$  and then induce to obtain

$$\pi = \text{Ind}_P^{GL_n(\mathbb{Q}_p)} \boxtimes_i \pi_i.$$

## Definition

We say that  $\pi$  is the *parabolic induction* of the  $\pi_i$ . We say that  $\pi$  is *supercuspidal* if  $\pi$  is not parabolically induced from any proper parabolic subgroup of  $GL_n(\mathbb{Q}_p)$ .

# The Weil-Deligne Group

There is a natural bijection

Supercuspidal  
representations of  $GL_n(\mathbb{Q}_p)$

$\leftrightarrow$

$n$ -dimensional irreducible  
representations of  $\mathcal{W}_{\mathbb{Q}_p}$ .

But the parabolic induction of irreducible representations does not always remain irreducible. To extend this bijection from supercuspidal representations of  $GL_n(\mathbb{Q}_p)$  to all smooth irreducible representations of  $GL_n(\mathbb{Q}_p)$ , one enlarges the right hand side using the following group:

$$WD_{\mathbb{Q}_p} := \mathcal{W}_{\mathbb{Q}_p} \times SL_2(\mathbb{C}).$$

Theorem (Local Langlands for  $GL_n$ : Harris-Taylor, Henniart)

*There is a unique system of bijections*

*Irreducible representations  
of  $GL_n(\mathbb{Q}_p)$*

$\xrightarrow{\text{rec}_n}$

*$n$ -dimensional  
irreducible  
representations of  $WD_{\mathbb{Q}_p}$*

- $\text{rec}_1$  is induced by the Artin map of local class field theory.
- $\text{rec}_n$  is compatible with 1-dimensional characters:  
 $\text{rec}_n(\pi \otimes \chi \circ \det) = \text{rec}_n(\pi) \otimes \text{rec}_1(\chi)$ .
- The central character  $\omega_\pi$  of  $\pi$  corresponds to  $\det \circ \text{rec}_n$ :  
 $\text{rec}_1(\omega_\pi) = \det(\text{rec}_n(\pi))$ .
- $\text{rec}_n(\pi^\vee) = \text{rec}_n(\pi)^\vee$
- $\text{rec}_n$  respects natural invariants associated to each side, namely  $L$ -factors and  $\epsilon$ -factors of pairs.

# A First Guess

Now suppose  $\mathbf{G}$  is some other connected reductive group defined over  $\mathbb{Q}_p$ , such as  $SO_n$ ,  $Sp_n$  or  $U_n$ . We'd like to use a Langlands correspondence to understand representations of  $\mathbf{G}(\mathbb{Q}_p)$  in terms of Galois representations. Something like

Homomorphisms  
 $\varphi: \mathrm{WD}_{\mathbb{Q}_p} \rightarrow \mathbf{G}(\mathbb{C})$

$\leftrightarrow$

Irreducible representations  
of  $\mathbf{G}(\mathbb{Q}_p)$ .

We need to modify this guess in two ways:

- change  $\mathbf{G}(\mathbb{C})$  to a related group,  ${}^L\mathbf{G}(\mathbb{C})$ ,
- and account for the fact that our correspondence is no longer a bijection.

# Root Data

Reductive groups over algebraically closed fields are classified by root data

$$(X^*(\mathbf{S}), \Phi(\mathbf{G}, \mathbf{S}), X_*(\mathbf{S}), \Phi^\vee(\mathbf{G}, \mathbf{S})),$$

where

- $\mathbf{S} \subset \mathbf{G}$  is a maximal torus,
- $X^*(\mathbf{S})$  is the lattice of characters  $\chi: \mathbf{S} \rightarrow \mathbb{G}_m$ ,
- $X_*(\mathbf{S})$  is the lattice of cocharacters  $\lambda: \mathbb{G}_m \rightarrow \mathbf{S}$ ,
- $\Phi(\mathbf{G}, \mathbf{S})$  is the set of roots (eigenvalues of the adjoint action of  $\mathbf{S}$  on  $\mathfrak{g}$ ),
- $\Phi^\vee(\mathbf{G}, \mathbf{S})$  is the set of coroots ( $\langle \alpha, \alpha^\vee \rangle = 2$ ).

# Connected Langlands Dual

Given  $\mathbf{G} \supset \mathbf{S}$ , the connected Langlands dual group  $\hat{\mathbf{G}}$  is defined to be the algebraic group over  $\mathbb{C}$  with root datum

$$(X_*(\mathbf{S}), \Phi^\vee(\mathbf{G}, \mathbf{S}), X^*(\mathbf{S}), \Phi(\mathbf{G}, \mathbf{S})).$$

For semisimple groups, this has the effect of exchanging the long and short roots (as well as interchanging the simply connected and adjoint forms).

$\mathbf{G}$	$GL_n$	$SL_n$	$PGL_n$	$Sp_{2n}$	$SO_{2n}$	$U_n$
$\hat{\mathbf{G}}$	$GL_n$	$PGL_n$	$SL_n$	$SO_{2n+1}$	$SO_{2n}$	$GL_n$

# Langlands Dual Group

For non-split  $\mathbf{G}$ , such as  $U_n$ , we need to work a little harder. Suppose that  $\mathbf{G}$  is quasi-split with Borel  $\mathbf{B} \supset \mathbf{S}$ , splitting over a finite extension  $E/\mathbb{Q}_p$ . The fact that  $\mathbf{B}$  is defined over  $\mathbb{Q}_p$  implies that  $\text{Gal}(E/\mathbb{Q}_p)$  acts on the root datum. The connected dual group  $\hat{\mathbf{G}}$  comes equipped with maximal torus  $\hat{\mathbf{S}}$  canonically dual to  $\mathbf{S}$ . By choosing basis vectors for each (1-dimensional) root space in the Lie algebra of  $\hat{\mathbf{G}}$ , we can extend the action of  $\text{Gal}(E/\mathbb{Q}_p)$  from the root datum to an action on  $\hat{\mathbf{G}}$ .

Define

$${}^L\mathbf{G} := \hat{\mathbf{G}} \rtimes \text{Gal}(E/\mathbb{Q}_p),$$

the L-group of  $\mathbf{G}$ .

# Unitary Groups

A unitary group over  $\mathbb{Q}_p$  is specified by the following data:

- $E/\mathbb{Q}_p$  a quadratic extension (so for  $p \neq 2$  there are three possibilities),
- set  $\tau \in \text{Gal}(E/\mathbb{Q}_p)$  the nontrivial element,
- $V$  an  $n$ -dimensional  $E$ -vector space,
- Non-degenerate Hermitian form  $\langle, \rangle$  (so  $\langle x, y \rangle = \tau \langle y, x \rangle$ ).

Then  $U(V)$  is the group of automorphisms of  $V$  preserving  $\langle, \rangle$ . Over  $\bar{\mathbb{Q}}_p$ ,  $U$  becomes isomorphic to  $GL_n$ , so  $\hat{U}_n$  is  $GL_n$ , but  ${}^L\mathbf{G}$  is non-connected:  $\tau$  acts on  $GL_n(\mathbb{C})$  by the outer automorphism

$$g \mapsto (g^{-1})^T.$$

# Langlands Parameters

A Langlands parameter is now an equivalence class of homomorphisms

$$\varphi: \mathrm{WD}_{\mathbb{Q}_p} \rightarrow {}^L\mathbf{G}.$$

- We require that the composition of  $\varphi$  with the projection  ${}^L\mathbf{G} \rightarrow \mathrm{Gal}(E/\mathbb{Q}_p)$  agrees with the standard projection  $\mathcal{W}_{\mathbb{Q}_p} \rightarrow \mathrm{Gal}(E/\mathbb{Q}_p)$ .
- We consider two parameters to be equivalent if they are conjugate by an element of  $\hat{\mathbf{G}}$ . This definition of equivalence is chosen to match up with the notion of isomorphic representations on the  $\mathbf{G}(\mathbb{Q}_p)$  side.

# A Map

## Conjecture

There is a natural map

Irreducible  
representations of  $\mathbf{G}$

$\rightarrow$

Langlands parameters

$$\varphi: \mathrm{WD}_{\mathbb{Q}_p} \rightarrow {}^L\mathbf{G}$$

It is surjective and finite-to-one; the fibers are called *L-packets*.

# L-packets

Moreover, we can naturally parameterize these fibers. Given a Langlands parameter  $\varphi$ , let  $Z_{\hat{\mathbf{G}}}(\varphi)$  be the centralizer in  $\hat{\mathbf{G}}$  of  $\varphi$ , and let  ${}^L Z$  be the center of  ${}^L \mathbf{G}$ . Define

$$A_\varphi = \pi_0(Z_{\hat{\mathbf{G}}}(\varphi)/{}^L Z).$$

The fibers should be in bijection with

$$A_\varphi^\vee = \{\text{irreducible representations of } A_\varphi\}.$$

So we get a natural bijection

Irreducible representations  
of  $\mathbf{G}$

$\leftrightarrow$

$(\varphi, \rho)$  with  $\varphi: \text{WD}_{\mathbb{Q}_p} \rightarrow {}^L \mathbf{G}$   
and  $\rho \in A_\varphi^\vee$

# Approaches to Local Langlands

- One approach to proving the local Langlands correspondence for general  $\mathbf{G}$  is to try to reduce to the  $GL_n$  case: the recent book of Jim Arthur for example.
- Another approach is that of Stephen DeBacker and Mark Reeder, outlined below.

# Assumptions

- Let  $\mathbf{G}$  be a connected reductive group defined over  $\mathbb{Q}_p$ , and assume that  $\mathbf{G}$  splits over an unramified extension  $E/\mathbb{Q}_p$ .
- Let  $\varphi$  be a Langlands parameter vanishing on  $SL_2(\mathbb{C})$ .
- Assume that  $\varphi$  is *tame*: it vanishes on wild inertia.
- Assume that  $\varphi$  is *discrete*: the centralizer of  $\varphi$  in  $\hat{\mathbf{G}}$  is finite modulo the center of  ${}^L\mathbf{G}$ .
- Assume that  $\varphi$  is *regular*: the image of inertia is generated by a semisimple element of  $\hat{\mathbf{G}}$  whose centralizer is a maximal torus  $\hat{\mathbf{S}}$ .

DeBacker-Reeder produce an L-packet that satisfies many of the properties expected of the local Langlands correspondence.

# DeBacker and Reeder's approach

For each  $\lambda \in X^*(\hat{\mathbf{S}})$  they construct

- $F_\lambda$ , a twisted action of Frobenius on  $\mathbf{G}(\bar{\mathbb{Q}}_p)$ , and
- $\pi_\lambda$ , a representation of  $\mathbf{G}(\bar{\mathbb{Q}}_p)^{F_\lambda}$ .

They define an equivalence relation on such pairs, and prove that the equivalence class of  $(\pi_\lambda, F_\lambda)$  depends only on the class of  $\lambda$  in

$$X^*(\hat{\mathbf{S}})/(1 - w\theta)X^*(\hat{\mathbf{S}}) \cong A_\varphi^\vee$$

where  $w\theta$  is the automorphism of  $X^*(\hat{\mathbf{S}})$  induced by  $\varphi(\mathbf{F}) \in N_{L\mathbf{G}}(\hat{\mathbf{S}})$ . The  $\lambda$  with image in  $A_\varphi^\vee$  are those with  $\mathbf{G}(\bar{\mathbb{Q}}_p)^{F_\lambda} \cong \mathbf{G}(\mathbb{Q}_p)$ , and the corresponding equivalence classes of  $\pi_\lambda$  form the L-packet associated to  $\varphi$ .

# The Construction of $\pi_\lambda$

- Using the Bruhat-Tits building they construct an anisotropic torus  $\mathbf{T}_\lambda$  in  $\mathbf{G}$ ,
- apply a canonical modification to  $\varphi$  so that the image lies in a group isomorphic to  ${}^L\mathbf{T}_\lambda$ ,
- obtain a character of  $\mathbf{T}_\lambda(\mathbb{F}_p)$  using the (depth-preserving) local Langlands correspondence for tori,
- use Deligne-Lusztig theory to produce an irreducible representation of the parahoric subgroup  $\mathbf{G}_\lambda$ , and
- compactly induce to  $\mathbf{G}(\bar{\mathbb{Q}}_p)^{F_\lambda}$ , yielding a depth zero supercuspidal representation  $\pi_\lambda$ .

# L-packets

They then prove that  $\mathbf{G}(\mathbb{Q}_p)$  acts on the pairs  $(F_\lambda, \pi_\lambda)$ , and the orbit of a given pair is independent of all choices. Moreover, two such pairs are equivalent if and only if the two  $\lambda$ s are equivalent modulo  $(1 - w\theta)X^*(\hat{\mathbf{S}})$ . Much of their paper is then devoted to proving that this construction yields L-packets with desirable properties:

- The ratio of formal degrees  $\deg(\pi_\lambda) / \deg(\text{St}_\lambda)$  is independent of  $\lambda$ .
- Generic representations in the L-packet correspond to hyperspecial vertices in the building.
- Their L-packet yields a stable class function on the set of strongly regular semisimple elements of  $\mathbf{G}(\mathbb{Q}_p)$ .

# Restrictions on $\varphi$

From now on we fix a totally ramified quadratic extension  $E/\mathbb{Q}_p$  and set  $\mathbf{G} = \mathbf{U}(V)$  for  $V$  a quasi-split Hermitian space over  $E$ .

We say that a Langlands parameter  $\varphi$  is

- *discrete* if  $Z_{\hat{\mathbf{G}}}(\varphi)$  is finite,
- *tame* if  $\varphi$  factors through the maximal tame quotient (and thus  $p \neq 2$ ).
- *regular* if  $Z_{\hat{\mathbf{G}}}(\varphi(\tilde{\tau}))$  is connected and minimum dimensional (here  $\tilde{\tau}$  is a procyclic generator of tame inertia).

We will construct an L-packet of supercuspidal representations of  $\mathbf{G}(\mathbb{Q}_p)$  given a tame, discrete regular parameter.

# Filtrations

$\mathbf{G}(\mathbb{Q}_p)$  acts on the Bruhat-Tits building  $\mathcal{B}(\mathbf{G})$ , and we can classify the compact subgroups of  $\mathbf{G}(\mathbb{Q}_p)$  as stabilizers of convex subsets of  $\mathcal{B}(\mathbf{G})$

- Any compact subgroup can be written as  $\mathbf{H}(\mathbb{Z}_p)$  for some  $\mathbb{Z}_p$ -scheme  $\mathbf{H}$ .
- There is a decreasing filtration on each compact subgroup.
- $\mathbf{H}^0$  is the schematic closure of the identity component on the special fiber and is of finite index in  $\mathbf{H}$ .
- $\mathbf{H}(\mathbb{F}_p)$  is given by  $\mathbf{H}/\mathbf{H}^{0+}$ .
- The filtration on  $\mathbf{T}$  is the one given by Moy and Prasad, coming from the filtration on  $\mathbb{Q}_p^\times$ .

We can thus obtain representations of compact subgroups of  $\mathbf{G}$  by pulling back representations of reductive groups over finite fields.

# Outline

Our plan for constructing an L-packet from  $\varphi$  is as follows. We construct:

- A maximal unramified anisotropic torus  $\mathbf{T}$ , which embeds into  $\mathbf{G}$  in various ways,
- A character  $\chi_\varphi$  on  $\mathbf{T}^0$  that vanishes on  $\mathbf{T}^{0+}$ ,
- For each  $\rho \in A_\varphi^\vee$ , an embedding of  $\mathbf{T}$  into a maximal compact subgroup  $\mathbf{H} \subset \mathbf{G}$ .
- We get a Deligne-Lusztig representation of  $\mathbf{H}^0(\mathbb{F}_\rho) = \mathbf{H}^0/\mathbf{H}^{0+}$  associated to the torus  $\mathbf{T}^0(\mathbb{F}_\rho) = \mathbf{T}^0/\mathbf{T}^{0+}$  and the character  $\chi_\varphi$ .
- We induce this representation up to a representation of  $\mathbf{G}$ .

# Structure of a Tame Parameter

The tame Weil group is topologically generated by two elements: an (arithmetic) Frobenius  $F$  and a generator  $\tilde{\tau}$  of the procyclic group

$$\mathcal{I}_{\mathbb{Q}_p} = \text{Gal}(\varinjlim \tilde{K}(p^{1/m})/\tilde{K}) \cong \prod_{\ell \neq p} \mathbb{Z}_{\ell}.$$

- The assumption that  $E/\mathbb{Q}_p$  is totally ramified implies that  $\varphi(F) \in \hat{\mathbf{G}}$ , while  $\varphi(\tilde{\tau}) \in {}^L\mathbf{G}$  projects to  $\tau \in \text{Gal}(E/\mathbb{Q}_p)$ .
- Recall that we have a specified maximal torus  $\hat{\mathbf{S}}$  in  ${}^L\mathbf{G}$ . As Langlands parameters are defined only up to conjugacy, we may conjugate so that  $\varphi(\tilde{\tau}) \in \hat{\mathbf{S}}^{\tau} \times \text{Gal}(E/\mathbb{Q}_p)$ .

# A Twisted Torus

- The equality

$$F \tilde{\tau} F = \tilde{\tau}^p$$

implies that  $\varphi(F)$  lies in the normalizer of  $\varphi(\tilde{\tau})$ , and thus in the normalizer of  $\hat{\mathbf{S}}$ .

- Composing with the projection onto the Weyl group, we get a cocycle in

$$H^1(\langle F \rangle, W^{\mathcal{I}}) \hookrightarrow H^1(\mathbb{Q}_p, W).$$

- Such a cocycle is precisely the data needed to define a torus over  $\mathbb{Q}_p$  as a twist of  $\mathbf{S}$ : here we've identified the Weyl groups of  $\mathbf{S}$  and  $\hat{\mathbf{S}}$ . Write  $\mathbf{T}$  for this torus.

# Unramified and Anisotropic

- $\mathbf{T}$  cannot literally be unramified, since no torus in  $\mathbf{G}$  splits over an unramified extension. But it does become isomorphic to the canonical torus  $\mathbf{S}$  after an unramified extension: we will call such tori in  $\mathbf{G}$  *unramified*.
- A torus  $\mathbf{T}$  is called *anisotropic* if  $X_*(\mathbf{T})^{\text{Gal}(\bar{\mathbb{Q}}_p/\mathbb{Q}_p)} = 0$ , or equivalently if  $\mathbf{T}(\mathbb{Q}_p)$  is compact. The action of inertia on  $\mathbf{T}$  is the same as on  $\hat{\mathbf{S}}$ , so any invariants in  $X_*(\mathbf{T})$  would yield invariants in  $X_*(\mathbf{S}^\tau)$  under the action of  $\varphi(F)$ . But any such invariants would contradict our assumption that  $\varphi$  is discrete, since

$$(\hat{\mathfrak{g}}^{\mathcal{I}})^F = 0.$$

Thus  $\mathbf{T}$  is anisotropic.

# Image of a Parameter

- Since the tame Weil group is topologically generated by  $F$  and  $\tilde{\tau}$ , the image of  $\varphi$  is contained in  $N_{\hat{\mathbf{G}}}(\hat{\mathbf{S}}) \times \text{Gal}(E/\mathbb{Q}_p)$ . In fact, it is contained in the subgroup  $D$  of  ${}^L\mathbf{G}$  generated by  $\hat{\mathbf{S}} \times \text{Gal}(E/\mathbb{Q}_p)$  and  $\varphi(F)$ .
- The minimal splitting field  $M = \mathbb{Q}_p^s \cdot E$  of  $\mathbf{T}$  has Galois group

$$\text{Gal}(M/\mathbb{Q}_p) \cong \text{Gal}(E/\mathbb{Q}_p) \times \langle w \rangle,$$

where  $w \in \mathbf{W}^I$  is the image of  $\varphi(F)$ . Thus  $D$  fits into an exact sequence

$$1 \rightarrow \hat{\mathbf{S}} \rightarrow D \rightarrow \text{Gal}(M/\mathbb{Q}_p) \rightarrow 1.$$

# A Character

- Suppose that this sequence split and  $D \cong \hat{\mathbf{T}} \rtimes \text{Gal}(M/\mathbb{Q}_p)$ . Then  $\varphi$  would yield an element of  $H^1(\mathbb{Q}_p, \hat{\mathbf{T}})$ , and the local Langlands correspondence for tori would give us a character of  $\mathbf{T}(\mathbb{Q}_p)$ :

$$H^1(\mathbb{Q}_p, \hat{\mathbf{T}}) \cong \text{Hom}(\mathbf{T}(\mathbb{Q}_p), \mathbb{C}^\times).$$

- In general the sequence for  $D$  does not split. So our next task is to modify the Langlands correspondence for tori to obtain a character in the non-split case. We will get a character  $\chi_\varphi$  of  $\mathbf{T}^0(\mathbb{Q}_p)$ .

Constructing  $\chi_\varphi$ 

- Let  $D_S$  be the subgroup of  $D$  generated by  $\hat{\mathbf{T}}$  and  $(1, \tau)$ ; the splitting  $\text{Gal}(E/\mathbb{Q}_p) \rightarrow {}^L\mathbf{G}$  implies  $D_S \cong \hat{\mathbf{T}} \rtimes \text{Gal}(M/\mathbb{Q}_{p^s}) \cong {}^L\mathbf{T}$ . Since  $\varphi(\text{Gal}(\bar{\mathbb{Q}}_p/\mathbb{Q}_{p^s})) \subset D_S$ , the local Langlands correspondence for tori gives a character  $\chi$  of  $T(\mathbb{Q}_{p^s})$ .
- Let  $\Gamma = \text{Gal}(\mathbb{Q}_{p^s}/\mathbb{Q}_p)$ . Since  $\chi$  was determined by the restriction of a parameter on all of  $\text{Gal}(\bar{\mathbb{Q}}_p/\mathbb{Q}_p)$ , it factors through the coinvariants  $T(\mathbb{Q}_{p^s})_{\text{Gal}(\mathbb{Q}_{p^s}/\mathbb{Q}_p)}$ .
- From Tate cohomology we have

$$1 \rightarrow \hat{H}^{-1}(\Gamma, \mathbf{T}) \rightarrow \mathbf{T}(\mathbb{Q}_{p^s})_\Gamma \rightarrow \mathbf{T}(\mathbb{Q}_p) \rightarrow \hat{H}^0(\Gamma, \mathbf{T}) \rightarrow 1$$

When  $\mathbf{T}^0(\mathbb{Q}_p) \neq \mathbf{T}(\mathbb{Q}_p)$ , the outer groups can be nontrivial.

# Depth of Character

- Using Lang's theorem on the cohomology of connected algebraic groups over finite fields, the corresponding outer terms for  $\mathbf{T}^0$  vanish. We define  $\chi_\varphi$  as the restriction of  $\chi$  to  $\mathbf{T}^0(\mathbb{Q}_{p^s})_\Gamma \cong \mathbf{T}^0(\mathbb{Q}_p)$ .
- Since  $\varphi$  vanished on wild inertia, the depth-preservation properties of the local Langlands correspondence for tori imply that  $\chi_\varphi$  vanishes on  $\mathbf{T}^{0+}(\mathbb{Q}_p)$ , and thus induces a character of  $\mathbf{T}^0(\mathbb{F}_p)$ .
- The regularity of  $\varphi$  implies that  $\chi_\varphi$  is not fixed by any element of  $\mathbf{W}^{\mathcal{I}}$ : it is in “general position.”

# Summary

From a Langlands parameter  $\varphi$  we've produced:

- An anisotropic unramified torus  $\mathbf{T}$ . Note that  $\mathbf{T}$  is not yet provided with an embedding into  $\mathbf{G}$ .
- A character  $\chi_\varphi$  of  $\mathbf{T}^0(\mathbb{F}_p)$ .

In order to produce representations of  $\mathbf{G}(\mathbb{Q}_p)$  we need to understand the embeddings of  $\mathbf{T}$  into  $\mathbf{G}$ .

# Basic Tori

We classify unramified anisotropic twists of the “quasi-split” torus  $\mathbf{S}$ . For each  $s = 2r$ , define  $\mathbf{T}_s = \{x \in E_s : \text{Nm}_{E_s/L_r} x = 1\}$ ,

Every anisotropic unramified torus in  $\mathbf{G}$  is a product of such basic tori, together with at most one copy of  $\mathbf{U}_1$ .

# Embeddings of Basic Tori

In order to get Deligne-Lusztig representations, we need to embed  $\mathbf{T}$  into maximal compact of  $\mathbf{G}$ . We do so by building a Hermitian space around each basic torus in the product decomposition of  $\mathbf{T}$ .

For each  $\kappa \in L_r^\times$ , we define a Hermitian product on  $E_S$

$$\phi_\kappa(x, y) = \mathrm{Tr}_{E_S/E} \left( \frac{\kappa}{\pi_L} x \cdot \eta_S(y) \right).$$

This Hermitian space is quasi-split if and only if  $v_L(\kappa)$  is even. By the definition of  $\mathbf{T}_S$  we have an embedding of  $\mathbf{T}_S$  into  $\mathrm{U}(E_S, \phi_\kappa)$ .

# Embeddings of General Tori

In general, we choose a  $\kappa_j$  for each basic torus in the decomposition of  $\mathbf{T}$ . This choice corresponds to a choice of  $\rho \in A_\varphi^\vee$  as long as the sum of the valuations of the  $\kappa_j$  is even.

We prove  $\mathbf{T}$  fixes a unique point on the building  $\mathcal{B}(\mathbf{G})$  and thus embeds in a unique maximal compact  $\mathbf{H} \subset \mathbf{G}$ .

The reduction of  $\mathbf{H}$  is

$$\mathrm{O}(m) \times \mathrm{Sp}(m'),$$

where  $m$  is the sum of the dimensions of basic tori whose  $\kappa_j$  has even valuation and  $m'$  is the sum of those with  $v(\kappa_j)$  odd.

# Constructing a representation of $\mathbf{G}(\mathbb{Q}_p)$

Modulo  $p$ , we have a maximal torus  $\mathbf{T}^0(\mathbb{F}_p)$  sitting in a connected reductive group  $\mathbf{H}^0(\mathbb{F}_p)$  and a character  $\chi_\varphi$  of  $\mathbf{T}^0(\mathbb{F}_p)$ . This situation was studied by Deligne and Lusztig, and they produce a representation of  $\mathbf{H}^0(\mathbb{F}_p)$  using étale cohomology. The irreducibility of this representation follows from the regularity condition on  $\varphi$ .

We pull back to  $\mathbf{H}^0$  and the only wrinkle in the induction process occurs between  $\mathbf{H}^0$  and  $\mathbf{H}$ . Once we have a representation of  $\mathbf{H}$ , we define a representation on all of  $\mathbf{G}(\mathbb{Q}_p)$  by compact induction.

# A Finite Induction

There are three cases for the induction from  $\mathbf{H}^0$  to  $\mathbf{H}$ .

- $n$  even,  $\mathbf{H}(\mathbb{F}_p) = \mathrm{Sp}(n)$ . Here  $\mathbf{H} = \mathbf{H}^0$  and there is no induction.
- $n$  even, otherwise. The fact that the normalizer of  $\mathbf{T}^0(\mathbb{F}_p)$  in  $\mathbf{H}(\mathbb{F}_p)$  contains the normalizer in  $\mathbf{H}^0(\mathbb{F}_p)$  with index 2 implies that the induction remains irreducible.
- $n$  odd. Now the induction from  $\mathbf{H}^0$  to  $\mathbf{H}$  splits into two irreducible components. We can pick one using a recipe for the central character, together with the fact that in the case that  $n$  is odd the center of  $\mathrm{O}(m)$  is not contained in  $\mathrm{SO}(m)$ .

# Two Paths

# Current work

The remainder of this talk is

- joint with Clifton Cunningham
- a summary of work in progress.

The right hand side of the diagram outlines an alternate construction of a distribution on  $\mathbf{G}(\mathbb{Q}_p)$  from a depth zero character on  $\mathbf{T}^0(\mathbb{Q}_p)$  and an embedding  $\mathbf{T} \hookrightarrow \mathbf{G}$ .

**Warning: no step on the right side is complete**

For the remainder of this talk I will discuss the first arrow: the passage from a depth zero character of  $\mathbf{T}$  to a character sheaf on a related scheme  $\mathfrak{T}$ .

# The Néron model of $\mathbb{G}_m$

Now let  $\mathbf{T} = \mathbb{G}_m$ . The Néron model of  $\mathbf{T}$  is a separated, smooth commutative group scheme  $\mathbf{T}_{\mathbb{Z}_p}$  locally of finite type over  $\mathbb{Z}_p$  with the Néron mapping property. In particular,

$$\mathbf{T}_{\mathbb{Z}_p}(\mathbb{Z}_p) = \mathbf{T}(\mathbb{Q}_p) = \mathbb{Q}_p^\times.$$

The earlier  $\mathbf{T}^0$  is just the identity component of the Néron model, and in the  $\mathbb{G}_m$  case the Néron model is a union of copies of  $\mathbb{G}_m/\mathbb{Z}_p$ , glued along the generic fiber. Set  $\mathbf{T}_d = \mathbf{T}_{\mathbb{Z}_p} \times_{\mathbb{Z}_p} (\mathbb{Z}/p^{d+1}\mathbb{Z})$ .

# The Greenberg functor

The Greenberg functor  $\text{Gr}$  takes an affine group scheme over an Artinian local ring  $A$  and produces an affine group scheme over the residue field  $k$  whose  $k$  points are canonically identified with the  $A$ -points of the original scheme. We set

$$\mathfrak{T}_d = \text{Gr}(\mathbf{T}_d)$$

and

$$\mathfrak{T} = \varprojlim \mathfrak{T}_d.$$

$\mathfrak{T}$  is a commutative group scheme over  $\mathbb{F}_p$  with  $\mathfrak{T}(\mathbb{F}_p) = \mathbb{Q}_p^\times$ , but it is neither connected nor locally of finite type.

# Character Sheaves

- An  $\ell$ -adic Weil local system on a scheme  $X$  over  $K$  is a pair  $(\bar{\mathcal{L}}, \phi_{\mathcal{L}})$ , where  $\bar{\mathcal{L}}$  is an  $\ell$ -adic local system on the étale site of  $X_{\bar{K}}$  and  $\phi_{\mathcal{L}}$  is an action of  $\text{Gal}(\bar{K}/K)$  on  $\bar{\mathcal{L}}$  compatible with the action on  $X_{\bar{K}}$ .
- An  $\ell$ -adic Weil character sheaf on a group scheme  $G$  is an  $\ell$ -adic Weil local system  $\mathcal{L}$  on  $G$  satisfying

$$m^*(\bar{\mathcal{L}}) \cong \bar{\mathcal{L}} \boxtimes \bar{\mathcal{L}}$$

as well as some compatibility conditions.

- An  $\ell$ -adic Weil character sheaf on  $\mathfrak{T}$  is *smooth of depth  $d$*  if it arises as the pullback from  $\mathfrak{T}_d$  of an  $\ell$ -adic Weil character sheaf (with  $d$  minimal).

# Characters and Character Sheaves

## Theorem

*There is a canonical, depth preserving isomorphism between smooth characters of  $\mathbf{T}(\mathbb{Q}_p) = \mathbb{Q}_p^\times$  and smooth  $\ell$ -adic Weil character sheaves on  $\mathfrak{T}$ .*
